TABLE OF CONTENTS

Dear friends and colleagues:

On behalf of the Organizing Committee I would like to welcome you to the European Polymer Congress EPF 2011 and XII GEP, in this special year of Chemistry and in the worldwide recognized city of Granada, meeting point of legendary cultures and world heritage site with a long history in the contributions to Science and Culture of different civilizations.

The European Polymer Congress is the main activity of the European Polymer Federation and has become a world reference in the field of Polymer Science and Technology with increasing interest of the Scientific Community. This edition has been carefully organized to present the most relevant and advanced vision of the Chemistry, Physics, Technology and Applications of the broad field of Polymers and composites. Thanks to the enormous interest of the most relevant researchers in the field, we have prepared an exciting program with 12 plenary leader speakers, six parallel sessions, 58 selected invited speakers, 432 podium presentations and more than 600 posters presentations that will be exhibited permanently during the five days of the congress.

The great attendance of excellent professionals in all of the Polymer Science and Technology fields will offer the best scenario to find colleagues and common interest with specialists all over the world. In addition, the legendary city of Granada will provide the complementary and excellent scenario for the success of an unforgettable meeting.

This congress could not have been organized without the work and contribution of individuals, groups and referential schools. Therefore, I would like to acknowledge to all the speakers, exhibitors, committee members, chairpersons, reviewers and all the people that have been involved in the organization and presentation of relevant results and perspectives.

Enjoy the EPF 2011 congress and breathe the special atmosphere of Granada and the “Alhambra Palace”.

Julio San Roman

Chair of the EPF2011 Congress

Dutch Polymer Institute will grant DPI Invention Award

The Dutch Polymer Institute (DPI) will grant the DPI Invention Award for the third time at the European Polymer Congress 2011 in Granada, Spain. The award will be granted to a researcher who has significantly contributed to the development of polymer research and technology in Europe and who has enabled scientific knowledge to be quickly converted into industrial applications.

The winner of the 2011 edition of the DPI Invention Award is Prof. Cor E. Koning of the Eindhoven University of Technology in The Netherlands. The organization of the European Polymer Congress and DPI have created a special session dedicated to this award on Wednesday 29 June from 14.30 – 16.15 hrs. The session features three lectures from academics working in the same field as the award winner. There will also be a lecture by Prof. Koning.

The research performed by Prof. Koning's group at Eindhoven University of Technology within the DPI programme has resulted in several inventions that were filed for patent because the inventions attracted the interest from industrial partners of DPI. In many cases this resulted in follow-up projects and/or transfers to parties who are now further developing the technologies.

Prof. Koning's work in the fields of bio-based as well as biocompatible/biodegradable polymers and conductive polymer nanocomposites (such as carbon nanotubes and graphene) fits perfectly with the societal and environmental responsibilities that are taking shape in DPI's research programme.

Dutch Polymer Institute

DPI was established in 1997 as a public-private partnership to perform pre-competitive research into polymers and their application, linking scientific knowledge to the industrial need for innovation. This results in added value for universities in the form of scientific publications and for companies in intellectual property rights and the possibilities to execute new activities. Some 200 researchers (PhDs and Post-Docs) are involved in DPI projects at known institutes throughout the world. DPI connects more than 30 national and international companies and almost 50 highly ranked knowledge institutes.

OFFICIAL LANGUAGE

The official language at the congress is English. No simultaneous translations will be provided.

REGISTRATION AND INFORMATION DESK

The registration desk for the European Polymer Congress 2011 will be located in the *Palace of Congress and Exhibitions of Granada Main Hall* and will be open from Sunday to Friday:

Sunday, June 26, 2011	14:00 – 19:00
Monday, June 27, 2011	8:00 – 19:00
Tuesday, June 28, 2011	8:00 – 19:00
Wednesday, June 29, 2011	8:00 – 19:00
Thursday, June 30, 2011	8:00 – 19:00
Friday, July 1, 2011	8:00 – 11:00

CONFERENCE IDENTIFICATION BADGE

A conference identification badge will be included in the conference material provided upon registration. Conference participants are required to wear their named badges in order to gain entry to the scientific sessions and social activities.

INTERNET CONNECTION

Free Wi-Fi will be available in the *Palace of Congress* during the five days of the meeting.

COFFEE BREAKS

During the session breaks, coffee, tea and refreshments will be served free of charge to participants wearing conference identification badges in the *Poster and Sponsor Area*.

LUNCHES

Informal lunches are included in the registration fee and will be served in the *Poster and Sponsor Area.*

INSTRUCTIONS FOR ORAL PRESENTATIONS

- Each lecture hall will be equipped with a computer and an overhead projector.
- The duration of the presentations is limited to:
  - 45 min for plenary lectures.
  - 30 min for invited lectures including discussion.
  - 15 min for oral presentations including discussion.
- File type: Microsoft Power Point. Please do not use fonts smaller than 16 pt.
- Please upload your file to the appropriate computer and check the presentation one day before your presentation. Please contact the support staff for assistance.
- It is strictly necessary that all podium speakers keep to their presentation times given. Chairpersons will have to control the timeframe in order to assure timely running parallel sessions.

INSTRUCTIONS FOR POSTER PRESENTATIONS

Poster session will take place during the coffee breaks over the five days of the congress.

The poster board will be marked with the poster number. Please refer to the Final Program for the poster number assigned to you.

Posters boards are 95 cm wide and 110 cm high. The preferred poster form is 90 cm wide and 100 cm high. Alternatively presenters may present their material on several smaller sheets, however please observe the maximum poster board size.

The title and author's names as stated in the submitted abstract should appear at the top of the poster. The text, illustrations, etc. should be of an appropriate size to be read from a distance of 1.5 meter (4.5 feet).

Tacks and technical equipment for hanging the poster will be available in the *Poster and Sponsor Area*.

The presenting authors are kindly requested to stay at their posters for discussion during the poster session.

Posters will be displayed during the entire congress in the *Poster and Sponsor Area*. The poster session and all breaks will provide excellent opportunities for in-depth discussions. All delegates are encouraged to visit and discuss the posters.

SOCIAL EVENTS

Sunday, June 26, 2011

20:00

Welcome reception at the TERRACE of the Palace of Congress with beautiful views of the Granada city and surrounding mountains at sunset.

Tuesday, June 28, 2011

21:00

Special dinner for chairpersons and invited speakers in an exclusive restaurant "La Chumbera" in the area of "Sacromonte" with beautiful views of the Alhambra Palace at night.

Transport by bus will be organized with departure from the Palace of Congress at 20:30.

Thursday, June 30, 2011

21:00

Gala dinner in the Restaurant "La Mamunia" near to Granada, with a nice decoration inspired in Nazari Period.

Transport by bus will be organized with departure from the Palace of Congress at 20:30.

12:00-12:15	

	FEDERICO GARCIA LORCA
12:15	CLOSING SESSION

ORAL CONTRIBUTIONS

OPENING CONFERENCES

OC – 1	**Life without polymers.** *Cristopher K. Ober*
OC – 2	**Smart polymer applications in drug delivery and diagnostics.** *A. S. Hoffman; P. S. Stayton; P. Yager; A. Convertine; J. Lai; M. Nash; C. Duvall; D. Benoit*

SPECIAL LECTURES

SL – 1	**Plant oils: the perfect renewable resource for polymer science?!** *M. Meier*
SL – 2	**Carbohydrate-based polycondensation polymers.** *S. Muñóz-Guerra*
SL – 3	**On the importance of carbon allotrope network organisation in nanocomposites.** *J. Loos*

PLENARY LECTURES

PL – 1	**Macromolecular engineering for nanostructured materials via ATRP.** *K. Matyjaszewski*
PL – 2	**A holistic view on the biodegradable macromolecular design.** *A. Albertsson*
PL – 3	**Layered polymeric systems - lessons from biology.** *E. Baer*
PL – 4	**Ordered supramolecular polymers and their hybrids with covalent chains.** *S. Stupp*
PL – 5	**Radical polymers for an organic-based rechargeable battery and photovoltaic cell.** *H. Nishide*
PL – 6	**Sustainable coatings, plastics and fibers from novel biomass-based polymers.** *C. E. Koning; B. Noordover; L. Jasinska; J. Wu; D. Tang; I. van der Meulen; M. de Geus; A. Heise; D. van Es; J.van Haveren; M. Villani; S. Rastogi*
PL – 7	**Design of intelligent surfaces for cell sheet tissue engineering.** *T. Okano*
PL – 8	**Trainer project: Research on self- and inteligent healing materials.** *P. Martí*
PL – 9	**Self-assembling processes of organic-inorganic nanobuilding blocks and supromolecular units as new routes for nanostructured polymer network.** *J.F. Gerard; J. Duchet; J. Galy; J. Bernard; L. Dai; F. Lortie*

INVITED LECTURES

TOPIC 1: Synthetic Routes: Monomers and Polymers from Bioresources and Advanced Methodologies

T1 - IL1	**Cyclic and multiblock polystyrene-b-polyisoprene copolymers by combining anionic polymerization and azid/alkyne "click" chemistry.** *A. Touris; N. Hadjichristidis*
T1 - IL2	**Vegetable oils as platform chemicals for polymer synthesis.** *J.C. Ronda; G. Lligadas; M. Galià; V. Cádiz*
T1 - IL3	**Hybrid nanoparticles for biotechnological applications.** *J. Ramos; J. Forcada*
T1 - IL4	**Synthesis of multicompartment nanoparticles.** *A. Van Herk; S. Imran Ali; H. Heuts*
T1 - IL5	**Synthesis and characterization of multivalent dendritic glycopolymers.** *B. Voit; D. Appelhans*
T1 - IL6	**Polyester synthesis using enzymatic catalysis by Yarrowia lipolytica Lipase.** *A. Martinez-Richa; K. Barrera-Rivera; A. Marcos-Fernandez*
T1 - IL7	**RAFT polymerization and various click reactions to develop a micellar drug delivery system for albendazole.** *M. Stenzel; Y. Kim; Y. Zhao; F.M. Yhaya*
T1 - IL8	**Hybrid brushes nanoparticles: synthesis and properties.** *J. Paez; A. Cappelletti; M. Strumia*
T1 - IL9	**Organocatalysis of polymerizations: the contribution of N-heterocyclic carbenes.** *J. Raynaud; J. Pinaud; M. Fèvre; J. Vignolle; D. Taton; Y. Gnanou*
T1 - IL10	**Self-assembly of nanocomposite polymer latex and structural color films.** *L. Wu; Z. Shen; L. Duan; B. You*

TOPIC 2: New Analytical and Characterization Tools

T2 - IL1	**New opportunities with spectroscopic imaging.** *S. Kazarian*
T2 - IL2	**Elucidation of macromolecular structure using the MHS plot.** *B. Sabagh; S. Olivier; P.G.Clarke*
T2 - IL3	**The use of analytical techniques in the study and development of structural adhesives: ambient cure.** *S. Paz; A. Moreno-Cid; P. Prendes; R. Meizoso*
T2 - IL4	**Solid state NMR methods for studying functional macromolecular and supramolecular systems.** *H. W. Spiess*
T2 - IL5	**Effect of (3,1) chain-walking defects compared with other regio and constitutional defects in the crystallization and melting of isotactic poly(propylene).** *R. Alamo; C. Ruiz-Orta1; J. Fernandez-Blazquez; A. Anderson; G. Coates*
T2 - IL6	**Towards complex and integrated platforms in nanotechnology employing responsive polymer-metal-semiconductor hybrid materials.** *G. J. Vancso*
T2 - IL7	**Broad band dielectric relaxation for identification of gene mutation in plant model.** *A. Léonard ; J.F. Capsal; F. Roig; J. Dandurand; E. Dantras; P. Demont; C. Lacabanne*
T2 - IL8	**Two photon fluorescence microscopy and small angle X ray and neutron scattering: tools for the structural characterization of complex polymer architectures.** *I. Morfin*
T2 - IL9	**Combined mechanical and electrical characterization of polymers by atomic force microscopy.** *A. Mednick; C. Li; S. Lesko*
T2 - IL10	**Transient rheology: improving measurements at very short time.** *A. Diogo*

TOPIC 3: Advanced Processing and Recycling Technologies

T3 - IL1	**Inducing supramolecular structures in polymers by the combined effects of nanoparticles and flow.** *G. Marom*
T3 - IL2	**Processing of thermosetting matrix nanocomposites: modelling and characterization of the electrical behaviour.** *J. Kenny; L.Torre; M. Monti; M. Natali*
T3 - IL3	**Polymers processing using supercritical fluid technology.** *C. Domingo; C.A. García-González; A. López-Periago*
T3 - IL4	**How to use block copolymers for processing of thermosets and composites?!** *J. Pascault; F. Lortie; D. Portinha; J. Gérard*
T3 - IL5	**Functional polymers with capability to remove pollutant ions.** *B. Rivas*
T3 - IL6	**Preparation of advanced soft tissue engineering scaffolds by stereolithography.** *S. Schüller-Ravoo; S.M. da Silva Texeira; J. Feijen; D. Grijpma*
T3 - IL7	**Electrospinning of biopolymers: biomedical, pharmaceutical and food related application.** *J. M. Lagaron*
T3 - IL8	**Recombinamer-based, coomplex and highly functional systems attained by mild, clean and biocompatible processing technology.** *J.C. Rodríguez Cabello*
T3 - IL9	**Influence of polymer microstructure and post-treatment on the performance of latex-based pressure sensitive adhesives.** *M. Dubé; L. Qie*

TOPIC 4: Polymers for Advanced Applications Including Energy, Transport, Packaging and Environmentally Friendly Activities

T4 - IL1	**Polymer membranes for water purification.** *B. Freeman; D. R. Paul; J. E. McGrath; H. B. Park; A. J. Hill; B. McCloskey; W. Xie; J. Cook; D. Miller; G. Geise; S. Kasemset; A. Lee*
T4 - IL2	**Bioinspired reversible adhesives.** *A. Del Campo*
T4 - IL3	**Macroporous cryopolymer and hybrid hydrogels: biomedical and environmental applications.** *S. Mikhalovsky; S. James; L. James; R. Shevchenko; I. Allan; I. Savina; R. Whitby; A. Cundy*
T4 - IL4	**Polymer electrolyte membranes based on poly(phenylene ether)s with pendant perfluoroalkyl sulfonic acids.** *M. Ueda; K. Nakabayashi; T. Hiagshihara*
T4 - IL5	**Biobased/biodegradable/compostable polymers/blends/nanocomposites for packaging and agro-based uses.** *E. Piskin; F.Y. Ekinci*
T4 - IL6	**Thermally rearranged polymer membranes with tuned microcavities for CO_2 capture.** *Y. M. Lee*
T4 - IL7	**RAFT polymerization and various click reactions to develop.** *F. Stelzer; R. Saf; C. Slugovc; G. Trimmel; F. Wiesbrock*
T4 - IL8	**Porous polycyanurates: new film materials derived from old polymers.** *D. Grande; O. Grigoryeva; A. Fainleib*
T4 - IL9	**Epoxy polymers and composites for advanced applications.** *R. Williams*
T4 - IL10	**Ageing and long-term durability of polymer-based solar cells.** *J. Gardette; A. Rivaton; S. Thérias*

TOPIC 5: Chemistry and Physics of Nanomaterials and Nanotechnologies

T5 - IL1	**A direct way to fabricate polymer and polymer-based composite nanostructures.** *C. Mijangos; J. Martin; I. Blaszczyk-Lezak; Y. Maíz; J. Sacristán*
T5 - IL2	**Polymer films with nano-to micro-structured surfaces for marine biofouling-release coatings.** *G. Galli*
T5 - IL3	**Mimicking nature using copolymers.** *G. J. Bataglia*
T5 - IL4	**Synthesis and functionalization of "nanosponges" to enhance the efficacy of a broad range of therapeutics.** *D. M. Stevens; G. Hariri; J. N. Dobish; E. Harth*
T5 - IL5	**Microphase separation for diblock-copolymers: Novel aspects of an old problem.** *A. Khokhlov*
T5 - IL6	**Morphology, nucleation and crystallization kinetics of biodegradable double crystalline PLLA-b-PCL diblock copolymers.** *A. J. Müller; R. V. Castillo; J. M. Raquez;P. Dubois*
T5 - IL7	**Polymer conjugates as single agents or in combination therapy: Versatile platform technology for tissue repair and cancer therapy.** *M. Vincent*
T5 - IL8	**Nanomaterials based on poly(ε-caprolactone) - a versatile and intriguing biomedical building block.** *S. Hvilsted; I. Javakhishvili*
T5 - IL9	**Homo- and block copolymers of poly(β-benzyl-l-aspartate)s and poly(γ-benzyl-l-glutamate)s of different architectures.** *B. Brulc; E. Zagar; M. Gadzinowski; S. Somkowski; M. Zigon*
T5 - IL10	**Light-responsive block copolymers based on azobenzene.** *J. Barrio; E. Blasco; P. Forcén; C. Berges; R.M. Tejedor; J.L. Serrano; M. Piñol; C. Sánchez; R. Alcalá; L. Oriol*

TOPIC 6: Bioinspired Polymers, Bioengineering and Biotechnology

T6 - IL1	**Material considerations for annulus fibrosus and nucleus pulposus composite structures.** *S. Deb*
T6 - IL2	**Scaffold functionalisation strategies for modulation of inflammation.** *A. Pandit*
T6 - IL3	**Recent progress on the use of natural origin polymers and stem cells in tissue engineering strategies.** *R. L. Reis*
T6 - IL4	**Polyethylene glycol hydrogels for therapeutic vascularization.** *E. A. Phelps; A. J. Garcia*
T6 - IL5	**Polymer-silica nanocomposites: Structure, properties, bioactivity and biological performance of their scaffolds.** *M. Monleón Pradas*
T6 - IL6	**Rational design and synthesis of amphilphilic biodegradable polymers for alveolar bone regeneration.** *F. Rasoul; D. Wang; D. Hill; A. Symons; S. Varanasi; A. Whittaker*
T6 - IL7	**Polymeric endograft for the treatment of abdominal aortic aneyrysms.** *D. Cohn; R. Abbas; I. Pelled; R. Malal*
T6 - IL8	**Additive manufacturing of wet-spun scaffolds for bone tissue engineering.** *E. Chiellini; D. Puppi*
T6 - IL9	**Nano- and microparticles with controlled surface properties; synthesis, properties, selected medical applications.** *S. Slomkowski; M. Gosecki; M. Gadzinowski; M. Gosecka; T. Basinska; P. Wozniak*

ORAL PRESENTATIONS

TOPIC 1: Synthetic Routes: Monomers and Polymers from Bioresources and Advanced Methodologies

T1 - OP1	**Ferrocenyl-containing compounds as modifying additives for radical polymerization of vinyl monomers.** *R.M. Islamova, O.I. Golovochesova, S.V. Nazarova, Y.B. Monakov*
T1 - OP2	**New biobased epoxy resins.** *S. Caillol; B. Boutevin; H. Fulcrand; H. Nouailhas*
T1 - OP3	**Effective catalytic systems for atom transfer radical polymerization based on the carborane complexes of ruthenium.** *I. Grishin; E. Turmina; I. Chizhevsky; D. Grishin*
T1 - OP4	**Polylactic acid and Polyamide11 with controlled macromolecular architecture** *G. Di Silvestro, M. Ortenzi, H. Farina, C.M. Yuan, L. Basilissi, E. Zini, L. Martino; M. Scandola*
T1 - OP5	**Ring-opening co- and terpolymerization of an alicyclic oxirane with carboxylic acid anhydrides and CO_2 in the presence of chromium porphyrin and salen or zinc aryloxide catalysts.** *E. Hosseini Nejad; R. Duchateau; C. Koning*
T1 - OP6	**Polyurethane elastomers from castor oil and chemically modified yucca starch: synthesis and physical-chemical, physical-mechanical and thermical properties.** *M. F. Valero Valdivieso*
T1 - OP7	**New degradable aminovalerolactone-based copolyesters for biomedical applications: synthesis, characterization and biocompatibility.** *S. Blanquer; M. Patterer; V. Darcos; D. Domurado; X. Garric; B. Nottelet; J. Coudane*
T1 - OP8	**Renewable hybrid materials through living radical polymerization.** *U. Edlund; J. Voepel; A.C. Albertsson*
T1 - OP9	**Synthetic route effect on macromolecular architecture: from block to gradient copolymers based on acryloyl galactose monomer using RAFT polymerization.** *P. Escalé; S. R. Ting; A. Khoukh; L. Rubatat; M. Save; M. H. Stenzel; L. Billon*
T1 - OP10	**Bio-inspired cationic polymerization of isoprene initiated by allylic alcohols/b$(C_6F_5)_3$.** *S. Ouardad; F. Peruch; A. Deffieux*
T1 - OP11	**Synthesis and characterization of antibacterial polyurethanes coatings from novel quaternary ammonium functionalized soybean oil based polyol.** *H. Bakhshi; H. Yeganeh; M.A. Shokrgozar; A. Yari*
T1 - OP12	**Dextran-poly(deoxycholate) block copolymers as new biodegradable materials.** *M. Nichifor; M.C. Stanciu*
T1 - OP13	**Π-conjugated polymers with functional endgroups through modified nickel initiators.** *A. Smeets; K. Van Den Bergh; P. Willot; J. De Winter; P. Gerbaux; T. Verbiest; G. Koeckelberghs*
T1 - OP14	**Step growth polymerization of starch-derived dianhydrohexitol stereoisomers: versatile platform for the design of linear polymers and polymer networks with original properties.** *C. Besset; E. Fleury; J.P. Pascault; J. Bernard; E. Drockenmuller*
T1 - OP15	**New functional materials from polysaccharides modified by copper catalyzed azide-alkyne cycloaddition.** *M. Bertoldo; G. Zampano; S. Nazzi; F. La Terra; F. Ciardelli*
T1 - OP16	**Production of polyether polyols with phosphorous initiators.** *M. M. Velencoso; M. J. Ramos; J.C. García-Martínez; A. de Lucas; J. F. Rodriguez*
T1 - OP17	**Towards ring opening metathesis polymerisation: special initiators for special applications.** *A. Leitgeb; E. Pump; A. Szadkowska; K. Grela; C. Slugovc*
T1 - OP18	**New polyurethanes from natural and synthetic rubbers.** *N. Kébir; I. Campistron; A. Laguerre; J.F. Pilard; C. Bunel*
T1 - OP19	**Chitosan-graft-polyaniline-based hydrogels: eloboration and properties.** *P. Marcasuzaa; S. Reynaud; J. Desbrières*

T1 - OP20	**BODIPY-conjugated thermo-sensitive fluorescent polymers based on 2-(2-methoxyethoxy)ethyl methacrylate.** *M. Liras; I. Quijada; O. García; R. Paris*
T1 - OP21	**Malic acid as key building block for the synthesis of OH-functional polyesters.** *C. Hahn; H. Keul; M. Möller*
T1 - OP22	**Synthesis of biobased polyols by thiol-ene 'click chemistry' from vegetable oils.** *M. Desroches; S. Caillol; R. Auvergne; B. Boutevin*
T1 - OP23	**Crosslinking of epoxidized natural rubber by dicarboxylic acids: monitoring crosslinking density, polar interactions and kinetics rate.** *M. Pire; S. Norvez; I. Iliopoulos; B. Le Rossignol; L. Leibler*
T1 - OP24	**Synthesis of terpolymers based acrylamides by RAFT polymerization and their application in the synthesis of goldnanoparticles.** *V. J. Gonzalez Coronel; J. A. Corcino Campos; E. R. Rodriguez; N. Tepale Ochoa*
T1 - OP25	**Preparation of furfuryl functionalised polystyrenes by atom transfer radical polymerization and their use in the surface chemical modifications of multi-wall carbon nanotubes by "grafting to".** *R. Paris, M. M. Bernal, M. Liras, R. Verdejo, I. Quijada-Garrido, M. A. López-Manchado.*
T1 - OP26	**Cationic polymerization of isobutylene using $AlCl_3OBu_2$ as a co-initiator: synthesis of highly reactive polyisobutylene.** *S. Kostjuk; I. Vasilenko; A. Frolov*
T1 - OP27	**Functionalisation of unsaturated polyesters from enzymatic ring-opening polymerisation of macrolactones by thiol–ene click chemistry.** *Z. Ates; I. van der Maulen; P. D. Thornton; A. Heise*
T1 - OP28	**Structure of polyamides made from aldaric acids.** *S. Leon; C. E. Fernández; A. Díaz; M. Bermúdez; M. G. García-Martín; M. Mancera; J. A. Galbis; S. Muñoz-Guerra*
T1 - OP29	**One-pot multistep reactions based on thiolactones: extending the realm of thiol-ene chemistry in polymer synthesis.** *P. Espeel; F. Goethals, F. Du Prez*
T1 - OP30	**Polymeric platforms based on thiolactone monomers for post-polymerization functionalization.** *P. Espeel; L. Petton; M. Stamenovi; F. Goethals; F. Du Prez*
T1 - OP31	**"Click" synthesis of fatty acid derivatives as polyanhydride precursors.** *C. Lluch; G. Lligadas; J. C. Ronda; M. Galià; V. Cádiz*
T1 - OP33	**Controlled synthesis of reactive polyethers: application to free-isocyanate polyurethane.** *A. Brocas; G. Cendejas; A. Deffieux; S. Carlotti*
T1 - OP34	**Sol-gel transition and gelatinization kinetics of wheat starch.** *F. Teyssandier; P. Cassagnau; J. Gérard; N. Mignard*
T1 - OP35	**Aliphatic polyesters from the carbohydrate-based bicyclic monomer methyl di-o-methylene-galactarat.** *C. Lavilla; A. Alla; A. Martínez de Ilarduya; E. Benito; M. G. García-Martín; J. A. Galbis; S. Muñoz-Guerra*
T1 - OP36	**Controlled release of polyphenols from cellulose-based hydrogels.** *D. Ciolacu; A. Oprea; G. Cazacu; M. Cazacu*
T1 - OP37	**Microwave-assisted nitroxide-mediated radical polymerization of acrylamide in aqueous solution.** *J. Rigolini; B. Grassl; L. Billon; S. Reynaud; O.Donard*
T1 - OP38	**Unique fully aliphatic or aliphatic/aromatic copolyesters containing biobased w-hydroxy fatty acids: Molecular structures and properties.** *A. Celli; P. Marchese; S. Sullalti; C. Berti; R. A. Gross*
T1 - OP39	**Pyridinium and picolinium ionic liquids as a media for biphasic ethylene polymerizaton.** *K. Dziubek, W. Ochędzan-Siodłak, K. Czaja*

T1 - OP40	**Novel poly(carboxybetaine methacrylamides) synthesized via Living/controlled aqueous RAFT polymerization.** *C. Rodriguez-Emmenegger; B. Schmidt; Z. Sedláková; V. Šubr; E. Brynda; A. Bologna Alles; C. Barner-Kowollik*
T1 - OP41	**Zinc powder-alkyl halide: a novel initiation system for living radical polymerization of vinyl monomers.** *G. Cankaya; N. Bicak*
T1 - OP42	**Microwave-assisted synthesis of PAMAM type dendrimers & their analytical applications.** *C. Dizman; T. Parali; A. S. Ertürk; M. Tulu*
T1 - OP43	**Ring-opening polymerization of D,L-lactide using Zinc(II) octoate as catalyst.** *R. Mazarro; G. Storti; M. Morbidelli*
T1 - OP44	**Emulsion polymerization of oleic acid-based monomers.** *M. Moreno; M. Goikoetxea; M. J. Barandiaran*
T1 - OP45	**Synthesis of functionalised hyperbranched polymers via catalytic chain transfer polymerisation and thiol-ene click chemistry.** *J. Menzel; D. Haddleton; E. Khoshdel*
T1 - OP46	**Reaction and mass-transfer in polycondensation process of PA-MXD6.** *Z. Xi; Y. Zhao; L. Zhao*

TOPIC 2: New Analytical and Characterization Tools

T2 - OP1	**IR and raman two dimensional correlation vibrational spectroscopy and QM modeling applied to the study of fluorinated polymers.** *S. Radice*
T2 - OP2	**High temperature asymmetrical flow field-flow fractionation (HT-AF4) - New possibilities for characterizing polyolefins.** *T. Otte; T. Klein; E. Moldenhauer*
T2 - OP3	**Characterization and applications of aromatic-aromatic interactions between water-soluble polymers and low molecular-weight molecules.** *I. Moreno-Villoslada; J. P. Fuenzalida-Werner; R. Araya-Hermosilla; E. Araya-Hermosilla; C. Torres-Gallegos; J. Gómez-Manosalba; D. Muñoz; V. Barrueto; M. Flores; N. Sano; W. Tomita; F. Oyarzun-Ampuero; H. Nishide*
T2 - OP4	**Raman structural analysis of olefin – based materials.** *Y.V. Zavgorodnev; K. Prokhorov; G. Nikolaeva; E. Sagitova; P. Pashinin*
T2 - OP6	**Semiflexible macromolecules in nanoslit confinement.** *P. Cifra*
T2 - OP7	**Behaviour of water during temperature-induced phase transition in poly(vinyl methyl ether) aqueous solutions. NMR and optical microscopy study.** *J. Spevacek; L. Hanykova; J. Labuta*
T2 - OP8	**Co-crystallization process of syndiotactic polystyrene/naphthalene revealed by the measurements of angular distributions of polarized fluorescence intensities.** *T. Sago; H. Itagaki*
T2 - OP9	**Tandem mass spectrometry of poly(2-oxazoline)s by electrospray ionization (ESI), matrix assisted laser desorption/ionization (MALDI), and atmospheric pressure chemical ionization (APCI).** *E. Altuntas; K. Kempe; A. Crecelius; U. S. Schubert*
T2 - OP10	**Characterisation of viscoelasticity and dynamics in polymers and proteins using DLS microrheology.** *C. Rega; S. Amin; H. Jankevics*
T2 - OP11	**Relating performance and structure of nanocomposites by new methods in time-resolved X-ray scattering.** *N. Stribeck; A. Zeinolebadi; M. Ganjaee Sari*
T2 - OP12	***In situ* SAXS investigation of transient nanostructure of thermoplastic polyurethane elastomers during thermal treatments.** *N. Stribeck, A. Zeinolebadi, M. Ganjaee Sari*
T2 - OP13	**Determination of the macromolecular dimensions of hydrophobically modified polymers by micellar size exclusion chromatography coupled with multiangle light scattering.** *G. Dupuis; J. Rigolini; G. Clisson; D. Rousseau; R. Tabary; B. Grassl*
T2 - OP15	**Characterization of nanogels by a combination of light and small-angle x-ray scattering.** *G. Roshan Deen; T. Alsted; W. Richtering; J. S. Pedersen*
T2 - OP16	**Mechanism of degradation of acrylic-melamine thermoset. Relating material properties to structure evolutions.** *J.F. Larché; P.O. Bussiere; P. Wong-Wah-Chung; J.L. Gardette*
T2 - OP17	**Keeping track of water in complex multilayered films with NMR imaging.** *H.P. Huinink; V. Baukh; S.J.F. Erich; O.C.G. Adan; L.G.J. van der Ven*
T2 - OP18	**NMR for determining the structure of new polysulphones.** *M. Gorbunova; A. Vorob'eva; R. Muslukhov*
T2 - OP19	**The glass transition of thin polystyrene films - heterogeneity studies by single molecule fluorescence spectroscopy.** *D. Wöll; B. Flier; M. Baier; S. Mecking; K. Müllen; A. Zumbusch*
T2 - OP20	**TD-NMR investigation of nanoconfined soft phase in SEBS.** *M. Mauri; L. Mauri; R. Simonutti*

T2 - OP21	**Kinetics and modeling of aqueous-phase N-vinylformamide free radical polymerization studied by reaction calorimetry.** *J. Zataray; J. C. De la Cal; J. R. Leiza*
T2 - OP22	**Characterization of polyfurfuryl alcohol resin - a new biomass-based resin for advanced composite materials.** *J. C. Domínguez; B. Madsen*
T2 - OP23	**Effect of architecture and molecular weight of PEO based electrolytes on the ionic conductivity and viscosity.** *D. Devaux; D. Glé; T. Phan; R. Denoyel; D. Bertin; D. Gigmes; R. Bouchet*
T2 - OP24	**Investigation of the morphology of elastomeric blends.** *M. Merlin; J. Majesté; C. Carrot; V. Pelissier; M. Eloy; I. Anselme-Bertrand*
T2 - OP25	**Non-linear rheological parameters for characterization of molecular structural properties in polyolefins.** *K. Klimke; S. Filipe; A.T. Tran*
T2 - OP26	**Rheology behavior and study of payne effect in natural rubber/regenerated cellulose/ montmorillonite clay nanocomposites.** *R.M. Mariano; R.C.R. Nunes; L.L.Y. Visconte*
T2 - OP27	**Two-dimensional liquid chromatography of complex polymers: PDMS-PS block copolymers.** *M.I. Malik; P. Sinha; G.W. Harding; H. Pasch*
T2 - OP28	**Imaging polymer nanostructures with scanning transmission X-ray spectro-microscopy.** *B. Watts; C.R. McNeill; J. Raabe*
T2 - OP29	**Comprehensive molecular characterization of complex polymer systems with liquid chromatography.** *D. Berek*
T2 - OP30	**Uptake of water and ions in nylon 6 as studied by MRI imaging.** *N.J.W. Reuvers; H.P. Huinink; H.R. Fischer; O.C.G. Adan*
T2 - OP32	**Recent progress of polymer investigation using SAXS and WAXS laboratory setups.** *P. Panine; S. Rodrigues*
T2 - OP33	**Phosphorus dendrimers functionalized with TEMPO radicals. Synthesis and study by electron paramagnetic resonance spectroscopy.** E. Badetti; V. Lloveras; R.M. Sebastián; A.M. Caminade; J.P. Majoral; J. Veciana; J. Vidal-Gancedo
T2 - OP34	**A new generation dual controlled-stress/rate extensional rheometer for polymer melts.** *R.J. Andrade; P. Harris; J.M. Maia*
T2 - OP35	**Evaluation of polyethylene films photodegradation by analitycal fractionation techniques.** *M.T. Exposito; C. Dominguez; J. Codina; R.A. García;*
T2 - OP36	**Microstructure characterization of polyolefins by high temperature HPLC.** *B. Monrabal*
T2 - OP37	**Photochromic reaction of fluorescent rhodamine 6G-polyelectrolyte complexes and the sensitivity of the complexes to Mercury in solution.** *R. Araya-Hermosilla; C. Alarcón; E. Araya-Hermosilla; M. Flores; I. Moreno-Villoslada*
T2 - OP38	**Local thermomechanical analysis of polymers on the sub-µm scale using heated SFM-probes.** *T. Fischinger; S. Hild*
T2 - OP39	**Dielectric properties of poly(vinyl alcohol) hydrogels prepared by freezing/thawing technique.** *M.E. Londoño López; J.M. Jaramillo Ocampo; R. Sabater i Serra; J.M. Vélez Restrepo*
T2 - OP40	**The creep behavior of linear low density polyethylene.** *Y. Unigovski; A. Bobovitch; E. Gutman*
T2 - OP41	**The advantages of TOPEM in studying the cure of a trifunctional epoxy resin (TGAP).** *J. Hutchinson; F. Shiravand; Y. Calventus; I. Fraga*
T2 - OP42	**Real-time raman spectroscopy measurements to study the uniaxial tension of isotactic polypropylene.** *P. Bourson; J. Martin; S. Chaudemanche; M. ponçot; J. Hiver; A. Dahoun*
T2 - OP43	**Investigation of the dispersion process of different PP/nanoclay composites at different processing conditions during extrusion by on-line near infrared and ultrasonic spectroscopy.** *D. Fischer; S. Kummer; J. Müeller; B. Kretzschmar*

T2 - OP44	**Monitoring atom transfer radical polymerisation (ATRP) and the resulting polymers using ^{14}C radio-labeled initiators.** *M. Long; S. Rogers; D. Thornthwaite; F. Livens; S. Rannard*
T2 - OP46	**Molecular structure and local dynamic in impact polypropylene studied by preparative TREF and subsequent 2D solid-state NMR spectroscopy.** *R.A. García; A. Fernández; M.T. Expósito; B. Peña; B. Coto; I. Suarez; J. Shu; R. Graf; H.W. Spiess*
T2 - OP47	**Mass spectrometry reveals the degradation product patterns of biodegradable polyesters.** *A. Höglund; M. Hakkarainen; A.C. Albertsson*
T2 - OP48	**Carbon dioxide plasticized polymer melts – An interpretation of the plasticizing effect by means of the free volume concept.** *B. Duscher; A. Schausberger; W. Stadlbauer*
T2 - OP49	**Development of a thermoplastic starch to be used in the co-injection process.** *E. Benavent; B. Galindo; O. Menes; A. Pascual; F. Marti*
T2 - OP50	**Monitoring of the epoxy curing with different methods.** *G. Teteris; W. Stark*
T2 - OP51	**Modeling of phase separation of polymer blends using spectrum method.** *M. A. Parsa; M. Ghiass*
T2 - OP52	**Evolution of elastomers network structures during the vulcanization process as investigated by ^{1}H low-field multiple-quantum NMR.** *J. L. Valentín; I. Mora-Barrantes; M. A. Malmierca; P. Posadas Bernal; A. Fernandez-Torres; Á. Marcos-Fernández; A. Rodríguez; L. Ibarra*

TOPIC 3: Advanced Processing and Recycling Technologies

T3 - OP1	**Photoelectrochemical properties of doped polyaniline: application to hydrogen production upon visible light upon visible light.** *Z. Benabdelghani; G. Rekhila; M. Trari; A. Etxeberria*
T3 - OP2	**T.T.T & C.C.T diagrams for PP/SGFR PA 66 reinforced blends: Effect of PP-g-MAH as a compatibilizer.** *Z. Safidine; A. Belhadj; S. Fellahi; D. Benachour; H. J. Radusch*
T3 - OP3	**Ternary blends: morphology and properties.** *L. Gonzalez-Gomez; M. Alvarez-Lainez*
T3 - OP4	**Formation of self-assembled buffer layer from fullerene end-capped poly(ethylene glycol) for high performnace of P3HT/PCBM heterojuction solar cells.** *J. W. Jung; W. H. Jo*
T3 - OP5	**Cryostructured polymer/clay aerogel materials.** *D.A. Schiraldi; M.D. Gawryla; Y. Wang; J.R. Johnson*
T3 - OP6	**Preparation of polyether-block-amide copolymer/organoclay composite via freeze-drying.** *Y. Wang; S.M. Alhassan; D.A. Schiraldi*
T3 - OP8	**Controlled chain-cleavages of polydienes by oxidation and by metathesis: Application to the waste tire recycling.** *F. Sadaka; I. Campistron; A. Laguerre; J.F. Pilard*
T3 - OP9	**Anomalous mechanical anisotropy of extruded polypropylene sheet with beta-form crystallites.** *P. Phulkerd; Y. Uchiyama; M. Yamaguchi*
T3 - OP10	**New methodology to produce a polyetherimide (PEI) via chloro-displacement by SABIC innovative plastic.** *P. Forcén*
T3 - OP11	**Polypropylene functionalization using acid, anhydride and alcohol monomers by reactive extrusion.** *T. Sadik; F. Becquart; M. Taha; V. Massardier*
T3 - OP12	**Polymeric surface modification of capillaries for the separation of DNA by capillary electrophoresis.** *K. Allan; C. Lenehan; H. Kobus; A. Ellis*
T3 - OP13	**Radiation induced vulcanization of SBR blends containing pristine silica and silica modified by polybutadiene grafting: reaction mechanisms and physicochemical properties of the vulcanizates.** *D. Dondi; A. Lostritto; L. Conzatti; M. Castellano; A. Turturro;, S. Bracco; M. Galimberti; A. Buttafava; A. Faucitano*
T3 - OP14	**Preparation of polystyrene nanocomposite nanofibers by electrospinning.** *N. Reshad; M. Najafi; H. Roughani-Mamaqani; M. Salami-Kalajahi; V. Haddadi-Asl*
T3 - OP15	**The effect of partially crosslinking of high density polyethylene on its structure and rheology.** *K. Montaser Asadi; J. Morshedian; Y. Jahani; A. Pakdaman*
T3 - OP16	**Precision design of novel copolymers and nanohybrids by cobalt-mediated radical polymerization (CMRP).** *C. Detrembleur; M. Hurtgen; Y. Piette; J.M. Thomassin; C. Jérôme; A. Debuigne*
T3 - OP17	**Synthesis and characterization of poly(fatty alkyloylethylacrylate-*co*-methylmethacrylate) as solid solid phase change materials for thermal energy storage.** *T.G. Ertuğral; O.F. Ensari; C. Alkan*
T3 - OP18	**New recycling polymer-immobilizing catalysts for the controlled/living radical polymerization.** *E. Geraskina; M. Lazarev; D. Grishin*
T3 - OP19	**Effet of coupling agent on the mechanical properties of cellulose fiber/polystyrene composites II. Dependent on the fiber content** *C.D. Zanrosso; M. Poletto; A. Zettera; M. Zeni*
T3 - OP20	**Mechanical recycling of polymers from real WEEE deposits: morphology, blend composition, impact strength.** *S. Ausset; M. Barthès; O. Mantaux; M. Pedros; M. Dumon*

T3 - OP21	**Polymers with hydrogen bonding moieties via ROMP.** *S. Kurzhals; W.H. Binder*
T3 - OP22	**Large-scale nacre-mimetic hybrid films and paper via rapid self-assembly.** *A. Walther; L. Berglund; O. Ikkala*
T3 - OP23	**Recycling of polyurethane-based shape memory polymers.** *M. Ahmad; J.K. Luo; H. Purnawali; W.M. Huang; M. Miraftab*
T3 - OP25	**Advances in small scale processing equipment for polymers and additives.** *B. Jakob*
T3 - OP26	**Role of rheology on quality of polymeric articles.** *F. Aghazadeh; H. Hosseini*
T3 - OP27	**Re-use and recycling of PLA and its mechanical properties.** *R. Forstner; J. Pleiner*
T3 - OP28	**Characterization of iron oxide nanoparticles created in a polymer brush matrix.** *S. Neuhaus; C. Padeste; N. D. Spencer*
T3 - OP29	**Chain architecture modifications of poly(lactic acid) by reactive extrusion.** *O.O. Santana; J. Callioux; E. Franco-Urquiza; J. Bou; F. Carrasco; J. Gámez-Pérez; M. Ll. Maspoch*
T3 - OP30	**Electromechanical characterization of styrene-butadiene-styrene / carbon nanotube composites for deformation sensors.** *P. Costa; J.C. Viana; S. Lanceros Mendez*
T3 - OP31	**High velocity compaction: a fast process insensitive to viscosity.** *N. Doucet; O. Lame; G. Vigier; F. Doré*
T3 - OP32	**Microphase separation in asymmetric coil-coil and coil-amphiphilic comb block copolymers in strong segregation limit.** *M. Asad Ayoubi; K. Zhu; B. Nyström; U. Olsson; K. Almdal; A. Khokhlov; L. Piculell*
T3 - OP33	**Influence of polymer and process characteristics on microstructure and physical properties of SLS parts.** *S. Dupin; O. Lame; C. Barres; J.Y. Charmeau*
T3 - OP34	**Key issues in re-processing aged polyamide-12 powders by selective laser sintering: influence of polymer features evolution upon part properties.** *C. Barrès; S. Dupin; A. Msakni; O. Lame; J.Y. Charmeau*
T3 - OP35	**Poly(D,L-lactide)-b-poly(2-hydroxyethyl acrylate) block copolymers as potential biomaterials for peripheral nerve repair.** *T. Trimaille; B. Clément; F. Féron; P. Decherchi; D. Bertin; K. Mabrouk; D. Gigmes; T. Marqueste*
T3 - OP36	**A new building block concept for polymers based on multifunctional coupling agents.** *F. Böhme; L. Jakisch*
T3 - OP37	**Amorphous silica obtained from rice husk: Study of the enhanced surface area for use as reinforcement of rubber.** *D. Mosca; C. Mantero; P. Raimonda*
T3 - OP38	**Recycling of Poly(ethylene terephthalate) bottle waste with modified styrene butadiene rubber through reactive mixing.** *O. Moini Jazani; A. Ghaemi; A. Ebrahimi Jahromi*
T3 - OP39	**Grafting of a biodegradable pH-sensitive copolymer based on poly(ethylene glycol) methyl ether and poly(ethyl glyoxylate) onto maghemite nanoparticles.** *C.H. Brachais; L. Hu; F. Xu; A. Percheron; D. Chaumont; G. Boni; J.P. Couvercelle*
T3 - OP40	**Epoxy/amine: simulation of reactive rotational molding.** *E. Mounif; S. Khelladi; F. Bakir; A. Tcharkhtchi*
T3 - OP41	**Biodegradation in compost of recycled low density polyethylene/polycaprolactone blends.** *J. J. Bou; L.M. Marroyo; A. Alla; L. Ollé, A. Bacardit; O.O. Santana; M. L. Maspoch*
T3 - OP42	**Thermoplastic elastomer/organoclay nanocomposites: morphology, thermal and mechanical properties.** *A. Szymczyk; S. Paszkiewicz; Z. Roslaniec*

T3 - OP43	**A comparison in dispersion of carbon nanotubes in aqueous media.** *V. Ghamgosar khorshidi; G.R. Bakhshandeh; A. Salimi; G. Naderi*
T3 - OP44	**X-ray investigation of iPP and propene/ethylene random copolymers solidification during ultra fast cooling.** *G. Portale; D. Cavallo; L. Balzano; G. Alfonso*
T3 - OP45	**The behaviour of the inorganic nano-filler in polypropylene composite fibres.** *E. Borsig; A. Augustinova; A. Ujhelyiova; A. Marcincin*
T3 - OP46	**Synthesis and characterization of natural oil based alkyd–acrylic copolymers.** *P. Rämänen; S.L. Maunu*

TOPIC 4: Polymers for Advanced Applications Including Energy, Transport, Packaging and Environmentally Friendly Activities

T4 - OP1	**Multiarm star poly(glycidol)-block-poly(ε-caprolactone) of different arms lengths and their use as modifiers of diglycidylether of bisphenol A thermosets.** *M. Morell; A. Lederer; X. Ramis; B. Voit; A. Serra*
T4 - OP2	**Dynamics of uniaxially oriented natural rubber using dielectric spectroscopy.** *M. Hernández; T. Ezquerra; M. López-Manchado*
T4 - OP3	**Adhesion properties of polycaprolactones and polycaprolactone based polyurethane prepolymers.** *M. García Ruiz; J. L. Valentin; A. Marcos-Fernandez*
T4 - OP4	**Polyvinyl butyral furfural: molecular structure and thermomechanical properties.** *A.G. Rodionov; N.K. Kobyakova; Y.A. Kursky; I.V. Blagodatskikh; E.A. Litmanovich; V.M. Aleksashin*
T4 - OP5	**Transmissive to black electrochromic aramids based on electroactive tetraphenylbenzidine units.** *H.J. Yen; K.Y. Lin; G.S. Liou*
T4 - OP6	**Charge-transporting polymers and molecular glasses for optoelectronic applications.** *J.V. Grazulevicius*
T4 - OP7	**Model poly(dimethylsiloxane-*b*-ε-caprolactone) obtained by anionic ring opening polymerization.** *A.J. Satti; F.G. Nador; E.M. Vallés; M.A. Villar; A.E. Ciolino*
T4 - OP8	**Synergistic effect of H-bond and chain mobility in enhancing proton transfer: a study case in urocanic acid system.** *C. Jarumaneeroj; S. Chriachanchai*
T4 - OP9	**New crystalline-crystalline diblock copolymers of poly(3-hexylthiophene-*b*-steryl acrylate) for field effect transistors.** *J.C. Lin; C.C. Kuo; W.Y. Lee; J.C. Hsu; W.C. Chen*
T4 - OP10	**Nanocomposite functional membranes for biomedical applications.** *A.M. Popa; F. Teixeira; S. Zuber; R. Rossi*
T4 - OP11	**Foamed nanocomposites: a system in which nanofillers play a multifunctional role.** *M.A. Rodríguez-Pérez; C. Saiz-Arroyo; J.A. de Saja*
T4 - OP12	**Poly(meth)acrylates obtained by cascade reaction.** *H. Keul; D. Popescu; E. Hrsic; M. Möller*
T4 - OP13	**High speed polymer semiconductors for applications on printed integrated circuits.** *K.J. Baeg; Y.Y. Noh; D.Y. Kim; A. Facchetti; S.W. Jung; J.B. Koo; I.K. You*
T4 - OP14	**Electrically bistable memory devices based on poly(3-hexylthiophene)-*block*-poly(3-phenoxylthiophene) and Its PCBM composite films** *Y.C. Lai; K. Ohshimizu; W.Y. Lee; T. Higashihara; M. Ueda; W.C. Chen*
T4 - OP15	**Effect of composition on the properties of sulfonated poly(indene)/poly(vinyl alcohol) membranes.** *N. Löser; B. Santos; R. Cavalheiro, M. M. Camargo Forte*
T4 - OP16	**Unimolecular polymeric nanoparticles: from conventional to highly efficient 'click'chemistry routes.** *J. A. Pomposo; L. Buruaga; J. Colmenero*
T4 - OP17	**Thermally rearranged (TR) poly(ether-benzoxazole) membranes for gas separation.** *M. Calle; Y. M. Lee*
T4 - OP18	**One single composite for chemical sensor or heating purposes.** *M. Bouhadid; J. Desbrières; C. Pillon; N. Redon; S. Reynaud*
T4 - OP19	**Synthesis and applications of copoly(*p*-phenylene)s containing bipolar triphenylamine and 1,2,4-triazole groups.** *C. Wu; Y. Chen*
T4 - OP20	**Synthesis of new two-dimensional thiophene-based conjugated copolymers and their applications to thin film transistors and photovoltaic cells.** *H.W. Lin; J.H. Tsai; C.J. Lin; H.C. Wu; C. Lu; Y.W. Lin; Y.C. Lai; W.C. Chen*

T4 - OP21	**Physicochemical study of the gelation kinetics and mechanism of polyacrylamide-based copolymers and polyethyleneimine hydrogels.** *R.V. Castillo; B. Grassl; S. Dagreou; N. Blin; G. Dupuis; A. Karam*
T4 - OP22	**Viscoelastic and generalized newtonian fluid flows simulation in single screw extruder using computational flow dynamics.** *A. Ahmadian; Y. Tamsilian; A. Ramazani S. A.*
T4 - OP23	**Ion exchange and electron exchange properties of polycalixresorcinarene.** *H.N. Altshuler; E.V. Ostapova*
T4 - OP24	**Working with water insoluble organic molecules in aqueous media: piperazinedione derivative-containing polymers as sensory materials for the fluorogenic sensing of biomolecules.** *S. Vallejos; P. Estévez; H. El Kaoutit; M. Trigo; F. Serna; F. García; J. L. Peña; J. M. García*
T4 - OP25	**Electrospun aligned nanofibers of two-dimensional conjugated P4TDPP for high performance field effect transistors.** *C.J. Lin; J.C. Hsu; J.H. Tsai; C.C. Kuo; W.C. Chen*
T4 - OP26	**Preparation of open submicron cell structure by $scCO_2$ foaming of highly oriented isotactic polypropylene.** *J.B. Bao; T. Liu; L. Zhao; G.H. Hu*
T4 - OP27	**Design rules for fuel cell membranes.** *G. Maier; M. Groß; T. Fuller; S. MacKinnon; C. Gittleman; C. Mittelsteadt*
T4 - OP28	**Dextran based micro-/nano-gels as injectable device for controlled release system.** *S.V. Ghugare; E. Chiessi; M. Telling; G. Paradossi*
T4 - OP29	**Structure and supramolecular formations of star-shaped fullerene-containing polymers in solution.** *V.T. Lebedev; G. Torok; L.V. Vinogradova*
T4 - OP30	**Phase segregation and thermal degradation of polycarbonatediol-based polyurethanes. Effect of hard segment content and soft segment length.** *A. Nohales; V. Costa; J. Latorre; C. Guillem; P. Félix; C. M. Gómez*
T4 - OP31	**Characterization of a microbial fucose-containing polysaccharide produced from glycerol byproduct.** *C. A. Torres; F. Freitas; M. A. Reis; I. de Sousa; V. D. Alves*
T4 - OP32	**Block copolymers containing photocleavable side groups : Formation and disruption of micelles by light.** *O. Bertrand; J.M. Schumers; C.A. Fustin; J.F. Gohy*
T4 – OP33	**Carbon atom volume as indicator for biodegradation susceptibility in highly oxidized species.** *A. Kržan; J. Mavri*
T4 - OP35	**Design of complex polymersomes structures and "one pot" loading of hydrophilic model drug using simple co-flow microfluidic chip.** *A. Perro; C. Nicolet; J. Angly; A. Colin; S. Lecommandoux; J.F. Le Meins*
T4 - OP36	**Click chemistry to fluorescent hyperbranched polymeric sensors: synthesis and characterization.** *S. Medel; V. Abenza; P. Ramírez-López; M. C. De La Torre; C. Peinado; P. Bosch*
T4 - OP37	**Solid state properties of fluorinated polyimides containing perylene and oxadiazole moieties.** *M.D. Damaceanu; R.D. Rusu; M. Bruma*
T4 - OP38	**Characterization, melting and crystalline properties of isotactic (4,2)-enchained poly(1-butene).** *C. Ruiz-Orta; R.G. Alamo*
T4 - OP39	**SU8 - carbon nanotubes composites: preparation, characterisation and patterning.** *M. Mionic; R. Gaal; L. Forro; S. Jiguet; M. Judelewicz; A. Magrez*
T4 - OP40	**Synthesis of highly soluble polymer-coated magnetic nanoparticles using a combination of diazonium salt chemistry and the iniferter method.** *N. Griffete; A. Lamouri; F. Herbst; S. Ammar; C. Mangeney*
T4 - OP41	**Monitoring the swelling/deswelling of stimuli-responsive hydrogels with magneto-resistive methods.** *K. Arndt; I. Moench; C. Kaiser; R. Koseva*
T4 - OP42	**Synthesis of microcapsules via reactive surfactants.** *F. Gayet; A. Limer; N. Jagielski; A. Heming; I. Shirley; D. M. Haddleton*

T4 - OP43	**Nanocomposites based on polyamidoimides with hydrosilicate nanotubes for membrane technology.** *G. Gubanova; S. Kononova; M. Vilegzhanina; T. Sukhanova; E. Korytkova; D. Timpu; M. Cristea; V. Harabagiu*
T4 - OP44	**Study of diffusion of jeffamines into reactive "surface-attached" polymer networks.** *R. Navarro; M. Pérez Perrino; O. Prucker; J. Rühe*
T4 - OP45	**Fabrication of low density foam shells using TMPTMA aerogel by UV polymerization.** *C. Lattaud; L. Guillot; C.H. Brachais; B. Reneaume; E. Fleury; O. Legaie; J.P. Couvercelle*
T4 - OP46	**Self-assembling of polyelectrolyte multilayers.** *E. Guzmán; R. Chulia; J. Cavallo; F. Ortega; R. Rubio; M. Strumia; C. Gómez*
T4 - OP47	**Aggregation and chain dynamics in supramolecular polymers by dynamic rheology: cluster formation and self-aggregation.** *F. Herbst; K. Schröter; I. Gunkel; S. Gröger; T. Thurn-Albrecht; J. Balbach; W.H. Binder*
T4 - OP48	**Functionalized nanoporous materials from photocleavable block copolymers.** *J.M. Schumers; A. Vald; C.A. Fustin; J.F. Gohy*
T4 - OP49	**Photostable polymer/clay nanocomposite encapsulant for organic solar cells.** *J. Gaume; S. Therias; A. Rivaton; S. Cros; S. Guillerez; J.L. Gardette*
T4 - OP50	**Advanced organic-soluble polymers for optical and electronic application: new colorless, transparent and thermally stable polynorbornenes via ROMP.** *W.R. Lian; K.L. Wang; J.C. Jiang; D.J. Liaw, K.R. Lee; J.Y. Lai*
T4 - OP51	**Solvent induced morphology in polymer-based systems for organic photovoltaics.** *M. A. Ruderer; S. Guo; R. Meier; H.Y. Chiang; V. Körstgens; J. Perlich; S. V. Roth; P. Muller-Buschbaum*
T4 - OP52	**Convenient method for functional biocompatible hyperbranched polymers.** *T. Loontjens; F. Xiang; L. Asri; J. Yin; S. Roest*
T4 - OP53	**Fabrication of clickable thin-film composite membranes for reduced biofouling.** *M. Haeussler; S. Harrisson; G. Li; J. Habsuda; E. Rizzardo; M. Jasieniak; H. Grieser; C. Barner-Kowollik; M. Le Hellaye; V. Chen; J. Mansouri, I. Dagley*
T4 - OP54	**Applying post polymerisation hypercrosslinking on polyHIPE material.** *I. Pulko; P. Krajnc*
T4 - OP55	**Composites of semiconductive polyelectrolytes for optoelectronic applications.** *J. Pfleger; S. Kazim; V. Sluneckova; D. Bondarev; J. Vohlidal*
T4 - OP56	**Supramolecular poly(3-hexylthiophene)s for solar cells: synthesis and electronic properties.** *C. Enders; A. Shaigan Nia; W.H. Binder*
T4 - OP57	**Fluorene based core-polymers for efficient white oled: correlation between molecular structure and photophysical properties.** *S. Destri; U. Giovanella; F. Samperi; S. Battiato*
T4 - OP58	**Obtention of modified polypropylene using the trifunctional cyclic initiator DEKTP as the radical initiator in the presence of different crosslinking co-agentes.** *G. Morales; L. García-Salazar; F. Avalos*
T4 - OP59	**Aggregates of constant size in dilute solutions of associating polyelectrolyte.** *E. Korchagina; O. Philippova*
T4 - OP60	**Magnetic, molecular imprinted polymeric nanoparticles for developing optical sensors.** *A. Medina-Castillo; G. Mistlberger; J. Fernández-Sánchez; I. Klimant; A. Fernández-Gutiérrez*
T4 - OP61	**Effect of masterbatch dilution on the structure and mechanical properties of carbon-based nanocomposites.** *E.V. Kuvardina; S.S. Abramchuk; V.G. Krasheninnikov; S.M. Lomakin*
T4 - OP62	**3D optical waveguides produced by two photon photopolymerisation of a flexible silanol terminated polysiloxane containing acrylate functional groups.** *R. Woods; S. Feldbacher; G. Langer; D. Zidar Satzinger; W. Kern*
T4 - OP63	**Bioinspired polymeric foam-lattice composite combining stochastic and periodic systems at two different length scales: Lightweight materials for absorption applications.** *R. Rinaldi; C. Hammetter; J. Bernal-Ostos; A.J. Jacobsen; F.Z. Zok*

T4 - OP64	**Polymeric sensors based on polymer phase transition and thiazole dyes.** *C. Pietsch; R. Menzel; R. Hoogenboom; R. Beckert; U.S. Schubert*
T4 - OP65	**Cancer drug targeting by a magnetic polymer – *in vivo* proof of concept.** *J. L. Arias; L. H. Reddy; P. Couvreur*
T4 - OP66	**Synthesis, characterization and application of amphiphilic elastomeric polyurethane networks in drug delivery.** *C. S. Pita; P. C. Caracciolo; G. A. Abraham; J. Gironès; J. A. Méndez; M. A. Pèlach*
T4 - OP67	**Double hydrophilic copolymer poly(ethylene oxide)-*block*-poly(2-ethyl oxazoline) as a carrier of cobalt bis(dicarbollide) conjugates designed as HIV protease inhibitors.** *P. Matejicek; V. Dordovic; M. Uchman; K. Prochazka; B. Gruner; A. Nykanen; J. Ruokolainen; M. Gradzielski*
T4 - OP68	**Polyesters and polyesterimides containing phosphaphenanthrene bulky groups for high performance applications.** *D. Serbezeanu; T. Vlad-Bubulac; C. Hamciuc; M. Aflori*
T4 - OP69	**From polymers to well-patterned membranes by mimicking the nature.** *A. Gugliuzza*
T4 - OP70	**Preserving cytokines' stability and activity: a novel controlled release polymeric drug delivery approach.** *H. Younes; M. Shaker*
T4 - OP71	**Phase-morphology and structure of model fullerene - polymer materials.** *D. Bucknall; G. Bernardo; M. Shofner; N. Deb; D. Raghavan; B. Sumpter; S. Sides; A. Karim*
T4 - OP72	**Liquid crystal homo and alternating (co)polymers based on π-conjugated backbone for organic Electronics.** *F. Mathevet; I. Tahar-Djebbar; D. Zeng; B. Heinrich; B. Donnio; D. Guillon; D. Kreher; A. Attias*
T4 - OP73	**Light microstructuring of thiol-yne photopolymers: cell adhesion on surface relief patterns.** *M. Lomba; L. Oriol; C. Sánchez; R. Alcalá; J. L. Serrano; M. Moros; J. Martínes de la Fuente; V. Grazú*
T4 - OP74	**PHEMA based polymer dielectrics for gravure-printed OTFTs** *J. Farmer; B. Muir; N. Vaklev; A. Campbell; J. Steinke*
T4 - OP75	**Modified epoxy resin as electrolytes for structural supercapacitors.** *A. Bismarck; S. Carreyette; Q. P. Fontana; E. S. Greenhalgh; G. Kalinka; A.Kucernack; M. Shaffer; N. Shirshova; J. H. Steinke; M. Wienrich*
T4 - OP76	**Kinetics of thermo-stimulated volume phase transition in poly(2-(2-methoxyethoxy)ethyl methacrylate) hydrogels; Raman and dielectric spectroscopy studies.** *M. Pastorczak; Y. A. Yoon; M. Kozanecki; L. Okrasa; S. Kadlubowski; R. Kisiel; T. Kowalewski; K. Matyjaszewski; J. Ulanski*
T4 - OP77	**Electro - responsive MWNT-PMAA hydrogel composites for controlled drug delivery.** *A. Servant; K.T. Al-Jamal; C. Bussy; K. Kostarelos*
T4 - OP78	**Exploiting adsorption to taylor the behavior of polymers at the nanoscale.** *S. Napolitano; C. Rotella; M. Wübbenhorst*
T4 - OP79	**New insights in the synthesis of rod-like polyamides. Dependence of molecular weight on the synthetic method.** *G. Hernández; C. Álvarez; J. G. de la Campa; J. de Abajo; A. E. Lozano*
T4 - OP80	**Heterocomplementary H-Bonding RAFT agents: new tools for the preparation of tailor-made supramolecular block copolymers.** *S. Chen; A. Bertrand; P. Alcouffe; C. Ladaviere; J.F. Gérard; F. Lortie; J. Bernard*
T4 - OP81	**Copolymers of trimethylene carbonate and glycolide: synthesis and relationship between microstructure and properties.** *E. Díaz-Celorio; L. Franco; A. Rodríguez-Galán; J. Puiggalí*
T4 - OP82	**Innovative polyelectrolytes for advanced applications.** *D. Mecerreyes; A. Pascual; A. Abouzadheh*
T4 - OP83	**Improving thermal energy storage in rpu foams by incorporating microcapsules containing PCMs.** *A. M. Borreguero; J. L. Valverde; J. F. Rodríguez; M. Carmona*

T4 - OP84	**Design of high inorganic content organic-inorganic hybrids based on a fluorinated polymer via combination of sol-gel chemistry and reactive extrusion.** *F. Niepceron; V. Bounor-Legaré; J. Gérard; P. Buvat; H. Galiano*
T4 - OP85	**Synthesis of phenylphosphine oxide containing urethane acrylates and their applications.** *B. Türel Erbay; I. E. Serhatli*
T4 - OP86	**Hybrid macroporous hydrogels with iron oxide nanoparticles.** *I.N. Savina; C. J. English; R. L.D. Whitby; S. V. Mikhalovsky; A. B. Cundy*
T4 - OP87	**Design of functional S/DVB microspheres: from hydrophilic particles to superhydrophobic surfaces.** *J. Rodríguez-Hernández; A. Muñoz-Bonilla; C. Labrugere; E. Ibarboure; E. Papon*
T4 - OP88	**Novel functional chromatographic supports: from preparation to application.** *A. Lamprou; A. F.M. Gavriilidou ; G. Storti; M. Morbidelli*
T4 - OP89	**New developments on hybrid coloidal materials for applications in magnetic hyperthermia.** *R. Hernández; C. Echeverria ; V. Zamora; C. Mijangos*
T4 - OP90	**Multi-shape memory effect of thermo-responsive semi-crystalline polymeric blends.** *J.M. Cuevas; L. German; R. Rubio; J.M. Laza; F. Mijangos; J.L. Vilas; L.M. León*
T4 - OP91	**Multi-armed, biodegradable polyphosphazenes and their use as macromolecular anti-cancer drug carriers.** *S. Wilfert; I. Teasdale; I. Nischang; O. Brüeggemann*
T4 - OP92	**Effects of parameters on emittance of thermal control coatings based on polyurethane and titanium dioxide.** *M. Taheran; A. H. Navarchian; R. Shoja Razavi*
T4 - OP93	**Functional particles obtained by emulsion polymerization using glycopolymer surfactants.** *A. Muñoz-Bonilla; V. Bordegé; O. León; R. Cuervo-Rodríguez; M. Sánchez-Chaves; M. Fernández-García*
T4 - OP94	**Fundamentals aspects of crosslinking control of PDMS rubber at high temperatures for development of new thermoplastic silicone vulcanizate (super-TPV).** *S. Mani; P. Cassagnau; M. Bousmina; P. Chaumont*
T4 - OP95	**Thermodegradable polyaldehydes: from amiphiphilic block-copolymers to advanced materials patterning.** *S. Köstler; D. Wachter; B. Zechner; H. Pichler; A. Rudorfer; S. Spirk; H. Fasl; B. Trathnigg; V. Ribitsch*
T4 - OP96	**Poly(2-oxazoline)-based non-cytotoxic hydrogels with tailor-made swelling degrees for drug delivery.** *F. Wiesbrock; A. M. Kelly; A. Hecke; B. Wirnsberger*
T4 - OP97	**Magnetic properties of neutral substituted poly(thiophenes)s.** *S. Vandeleene; A. Stesmans; M. Van Bael; T. Verbiest; G. Koeckelberghs*
T4 - OP98	**Optimization of multilayer heat sealing.** *E. Planes; L. Flandin*
T4 - OP99	**Characterization of soluble and precipitated chitosan adsorption onto cellulose viscose fibres.** *T. Ristic; L. Fras Zemljic*
T4 - OP100	**Modification of surface properties of organically modified clay particles for preparation of nanocomposite hydrogels.** *M. Kurecic; S. Hribernik; M. Tomsic; A. Jamnik; K. Stana Kleinschek; M. Sfiligoj-Smole*
T4 - OP101	**An elegant and facile single-step UV-curing approach to self-assembled metallopolymer capacitors.** *J. R. Nair; C. Gerbaldi; V. s. Ijeri; R. Bongiovanni; N. Penazzi*
T4 - OP102	**Synthesis and characterization of photoactive and extrudable polymers in view of developing a new solvent-free process for production of organic solar cells.** *L. Perrin; A. Nourdine; E. Planes; L. Flandin; N. D. Alberola*
T4 - OP103	**Multiscale gold and silver plasmonic plastics by melt compounding.** *N. García; P. Tiemblo; E. Benito; A. Esteban; R. Pina; C. Pecharromán;*
T4 - OP104	**Block copolymer coated magnetic nanoparticles as hybrid systems for imaging and therapeutic Applications.** *C. Schatz; S. Louguet; S. Lecommandoux; R. Epherre; E. Duguet; S. Mornet; C. Boiziau; A. Vekris; K. Petry;*

T4 - OP105	**Effect of polymer structure of acrylic pressure-sensitive adhesives on light leakage phenomenon in TFT-LCD panel.** *I. Nam; K. Ha; K. Lee; L. J. Kim; C. Lee; M. Kim; T. Chang*
T4 - OP106	**Nanofiber networks of aromatic polybenzimidazole.** *J. Gong; T. Uchida; S. Yamazaki; K. Kimura*
T4 - OP107	**Self-assembling of tapered dendrons of various nature and functionality.** *M. Shcherbina; A. Bakirov; V. Percec; U. Beginn; M. Moller; S. Chvalun*
T4 - OP108	**Towards chromogenic and fluorogenic sensing materials via molecular imprinting.** *R. Wagner; I. Lazraq; J. Fernández Sánchez; J. L. Urraca-Ruiz; M. Biyikal; K. Rurack; E. Benito-Peña; M. Moreno-Bondi; G. Orellana; B. Sellergren*
T4 - OP109	**Conformational behavior of conjugated polymers with oligo(phenylenevinylene) side chains.** *H. Peeters; W. Vanormelingen; T. Verbiest; G. Koeckelberghs*
T4 - OP110	**Nanocomposites: dispersion quality and percolation threshold.** *N. Watzeels; H. E. Miltner; C. Block; G. Van Assche; B. Van Mele; H. Rahier*
T4 - OP111	**Poly(ethylene oxide) based block copolymers : synthesis, characterization and applications.** *T. N.T. Phan; D. Bertin; D. Gigmes; E. Bloch; V. Hornebecq; P. Llewellyn; G. Bonniol; D. Quémener; A. Deratani*
T4 - OP112	**Synthesis and characterization of biodegradable polyurethane sealants containing rosin resin.** *P. Carbonell-Blasco; J.M. Martín-Martínez*

TOPIC 5: Chemistry and Physics of Nanomaterials and Nanotechnologies

T5 - OP1	**Development of light responsive membranes for controlled drug release.** *L. Baumann; E. Aslan-Gürel; D. de Courten; M. Wolf; R. M. Rossi; L. J. Scherer*
T5 - OP2	**Polyesterification catalyzed by hydrotalcite modiefied nanoparticles.** *Z. Boncza-Tomaszewski; M. Kedzierski*
T5 - OP3	**Epitaxial growth from the crystalline cores of cylindrical polyferrocenylsilane (PFS) block copolymer micelles.** *S. F. Mohd Yusoff; J. B. Gilroy; I. Manners*
T5 - OP4	**From heterogeneous to homogeneous nucleation of isotactic poly(propylene) confined in nanoporous alumina.** *H. Duran; M. Steinhart; H. Butt; G. Floudas*
T5 - OP5	**Polyethylene/graphene nanocomposites obtained by *in situ* polymerization.** *F.C. Fim; N.R.S. Basso; D.S. Azambuja; G. Barrera Galland;*
T5 - OP6	**Impact of synergy between carbon nanotubes and carbon black on the rheological and electrical properties of an EPDM rubber.** *M. Charman; F. Leonardi; C. Bissuel; C. Derail*
T5 - OP7	**Ordered lithium-ion-conducting polymer electrolytes.** *D. Golodnitsky; K. Shvartsman; E. Peled; L. Adler-Abramovich; E. Gazit; A. Greenbaum; S. Greenbaum*
T5 - OP8	**Atmospheric pressure plasma jet deposition of gas and vapour barrier coatings onto polymer films for packaging applications.** *R. Sulcis; P. Scopece; M. Muzio; I. Kulyk; A. Patelli*
T5 - OP9	**Preparation, surface properties and applications of nanometric cellulose model films.** *R. Kargl; T. Mohan; S. Köstler; M. Reischl; A. Doliška; K. Stana-Kleinschek; V. Ribitsch*
T5 - OP10	**Formulation and optical study of ordered phases of copolymers and nanoparticles.** *V. Ponsinet; B. Maxit; C. Tallet; D. Bendejacq*
T5 - OP11	**Nanostructures from tunable self-assembly of a simple diblock copolymer.** *A. Bianchi; M. Mauri; R. Simonutti*
T5 - OP12	**The melting and non-isothermal crystallization behaviors of polypropylene/montmorillonite (MMT)nanocomposites under high pressure CO_2.** *C. Jie; L. Tao; Z. Ling; Y. Wei-Kang*
T5 - OP13	**Mechanical properties of PA66/PA6/multi-walled carbon nanotube ternary nanocomposite prepared by melt mixing method** *M. Hadizade ; A. Shojaei; R. Bagheri*
T5 - OP14	**Nanocomposites based on carbonaceous nanoestructures oxidized by solar energy.** *M. López; M. Blanco; E. Aranzabe; A. Marcaide*
T5 - OP15	**Tailored designed cellulosic nanoparticles for possible pharmaceutical and biotechnological applications.** *M.R. Kulterer; V.E. Reichel; M. Reischl; R. Kargl; J. Schaller; K. Stana-Kleinschek; V. Ribitsch*
T5 - OP16	**Preparation and characterization of nitrile butadiene rubber-nanoclay composites with maleic acid anhydride as compatibilizer- Part I: Rheometric and swelling characteristics.** *E. Sadek; D. El-Nashar*
T5 - OP18	**Transition behavior of block copolymer films on controlled interaction.** *D. Y. Ryu; E. Kim; H. Ahn; J. Gong*
T5 - OP19	**Morphology evolution driven by transreactions in a polyurethane / α, ω-aminopropyl polydimethylsiloxane blend.** *F. Fenouillot; F. Méchin; F. Boisson; P. Alcouffe; T. Pokropski; T. Kallel; M. Mnif*
T5 - OP20	**Effect of clay/polymeric modifier combination on structure and properties of epoxy nanocomposite.** *I. Kelnar; J. Rotrekl; L. Kaprálková*

T5 - OP21	**Structural changes in liquid crystal polymer vesicles induced by temperature variation and magnetic field.** *A. Brulet; S. Hocine; L. Jia; J. Yang; A. Di Cicco; L. Bouteiller; M.H. Li*
T5 - OP22	**Preparation of fluoroalkyl end-capped oligomers possessing nonflammable and flammable characteristics in silica gel matrices.** *H. Sawada*
T5 - OP23	**Synthesis, micelle formation, and gelation of (PEG – P(MA-POSS)) amphiphilic hybrid block copolymers.** *H. Hussain; B. Tan; C. He*
T5 - OP24	**Thermoset nanosphere formation: a model case from SEBS and benzoxazine molecular assembly system.** *S. Chirachanchai; W. Rungswang*
T5 - OP25	**Effect of carbon nanotubes on thermo-mechanical properties of polyimide-carbon nanotube nanocomposites.** *R. Misiego; B. Pipes*
T5 - OP26	**Antimicrobial activity of nanocomposites based on polycaprolactone/MMT-(PCL-*b*-DEAEMA).** *I. Larraza; C. Abrusci; J. Pablos; M. Luzón; F. Catalina; C. Peinado; T. Corrales*
T5 - OP27	**Phase diagrams of the mobility of charge carriers in conducting polymers.** *L. F. Roncaratti; P. H. Neto; W. F. Cunha; R. Gargano; J. F. Teixeira; G. M. E Silva*
T5 - OP28	**Non conventional methods to prepare conducting polymer nanocomposite.** *W.M. de Azevedo; R.A. de Barros; J.F. Felix; E.F. da Silva Jr*
T5 - OP29	**Concentration and temperature influenceon the rheological behavior of a filled polymer.** *A.I. Gómez-Merino; M.H. Spillman; F.J. Rubio-Hernández*
T5 - OP30	**Properties of thin films of amphiphilic block copolymers based on *N*-vinylpyrrolidone and 2,2,3,3-tetrafluorpropylmethacrylate.** *I.V. Deniskina; O.G. Zamyshlyayeva; M.A. Batenkin; G.A. Shandryuk*
T5 - OP31	**Hierarchically structured polymeric films used as a model substrate for the investigation of adhesion and wettability.** *P. Escalé; M. Save; C. Derail; L. Billon; L. Rubatat*
T5 - OP32	**Complex architectures of hybrid nanoparticles controlled by amphiphilic copolymers.** *C. Geidel; K. Schmidtke; M. Klapper; K. Muellen*
T5 - OP33	**Theory and self-consistent field modeling of dendritic polymer brushes.** *T. Birshtein; A. Polotsky; O. Borisov*
T5 - OP34	**Solutions of amphiphilic polyelectrolytes: effect of electrostatic interactions on self-organization.** *S. Venev; I. Potemkin*
T5 - OP35	**Mesoscale simulation of network formation and structure,combining molecular dynamics and kinetic monte carlo approaches.** *A. V. Berezkin; P. U. Biedermann; A. A. Auer*
T5 - OP36	**Surface modifications of polymeric materials with functional Ag nano-particles; a comparative study of different immobilization techniques.** *D. Breitwieser; S. Lenz; R. Kargl; M. Wu; H. Fasl; K. Stana-Kleinschek; V. Ribitsch*
T5 - OP38	**Network formation by thiol-ene 'click' chemistry / by controlled radical polymerization: a 'single-molecule' view.** *K. Goossens; W. Van Camp; H. Uji-i; D. Wöll; K. Müllen; F. Du Prez; J. Hofkens*
T5 - OP39	**The sharp thermal transition of the diblock copolymers methoxy-poly(ethylene glycol)-*block*-poly(*N*-isopropylacrylamide) (PNIPAAM-*b*-MPEG).A combined analytical-ultracentrifugation and dynamic-light-scattering study.** *A. Ortega; R. Pamies; J. García de la Torre*
T5 - OP40	**Ionic liquids: structuration agents in a fluorinated matrix.** *S. Livi; J.F. Gérard; J. Duchet-Rumeau*

T5 - OP41	**Dynamic dielectric spectroscopy and thermo stimulated current for identification of gene mutation in a model plant.** *F. Roig; E. Dantras; J. Grima-Pettenati; C. Lacabanne*
T5 - OP42	**"Amphiphilic" ionic liquid in a mixte of nonionic liquids: theoretical study.** *A.A. Aerov; A.R. Khokhlov; I.I. Potemkin*
T5 - OP43	**Thermal and electronic conduction in conjugated polymers.** *L. Roncaratti; P. H. de Oliveira Neto; W. F. da Cunha; R. Gargano; G. Magela e Silva*
T5 - OP44	**Quantum dots functionalised with polymers via RAFT polymerisation for the fluorescent detection of latent fingerprints.** *J. Dilag; H. Kobus; A. Ellis*
T5 - OP45	**Polyacrylate core-shell stars – synthesis and application.** *A. Kowalczuk; N. Koseva; S. Rangelov; B. Trzebicka; A. Dworak*
T5 - OP46	**Water-soluble polymer-*grafted* platinum nanoparticles for the subsequent binding of enzyme: synthesis and SANS study.** *G. Carrot; F. Gal; H. Perez*
T5 - OP47	**Full exfoliation of clay and nanocomposite preparation.** *Y. Seo; K. Oh; Y. Seo; S. M. Hong*
T5 - OP48	**Synthesis and study of random amphiphilic polymers for molecular encapsulation of pyrene and clofazimine.** *M. Schott; C. Barbaud; J. Coudane; D. Domurado*
T5 - OP49	**Modification of the electrical properties of TPU by modified expanded graphites.** *J. Pionteck; F. Piana*
T5 - OP50	**Processing and properties of carbon nanotube-polymer composite fibers.** *C. Mercader, A. Lucas, P. Miaudet, A. Derré, M. Maugey, P. Poulin, C. Zakri*
T5 - OP51	**Phase behavior and structure formation under fast cooling of syndiotactic poly(propylene) nucleated with 1,3:2,4-bis(3,4-dimethylbenzylidene)sorbitol.** *A.M.J.T. Meijer-Vissers; J.G.P. Goossens*
T5 - OP52	**Study of the effect of carbon nanofillers on the foaming evolution of polyurethane foams.** *M. M. Bernal; A. Mortamet; M. A. López-Manchado; A. J. Ryan; R. Verdejo*
T5 - OP53	**Crystallinity and chain conformations in polymer / layered silicate nanohybrids.** *K. Chrissopoulou; K. Andrikopoulos; S. Bollas; S. Fotiadou; G. Voyiatzis; S. H. Anastasiadis*
T5 - OP54	**New hybrid core-shell star-like architectures made of poly(*n*-butylacrylate): synthesis and properties.** *S. Pensec; F. Périneau; G. Hu; L. Rozes; F. Ribot; C. Sanchez; C. Creton; L. Bouteiller*
T5 - OP55	**Crystallization in co-continuous nanostructured blends and composites.** *S. Tencé-Girault; L. Gani; T. Périé; L. Leibler*
T5 - OP56	**Electrical conductivity of carbon nanotube/polymer composite fibers in extensional shear.** *F. Grillard; C. Zakri; P. Poulin; A. Korzhenko; P. Gaillard*
T5 - OP57	**Maleinized polybutadienes as clay modifiers for sbr-based rubber nanocomposites.** *G. Colucci; R. Bongiovanni; A. Priola; M. Alessi; L. Conzatti; P. Stagnaro*
T5 - OP58	**Directing self assembly of RAFT polymers using end group functionalization.** *H. Willcock; R. O'Reilly*
T5 - OP59	**Effect of acrylic acid hairy layer length on film formation and properties.** *E. González; A. Chuvilin; M. Paulis; M. J. Barandiaran*
T5 - OP60	**Evolution of the electrical conductivity of MWCNT/PUR nanocomposites from non-quiescent molten state to solid state.** *M. Fernández; M. Landa; M. E. Muñoz; A. Santamaría*
T5 - OP61	**Semi-interpenetrating networks based on poly(*N*-isopropylacrylamide) reinforced with nano-clays and linear hydrophilic polymers.** *J. Djonlagic; D. Zugic; A. Lancuski; M. Nikolic; Z. Petrovic*

T5 - OP62	**Generation of metal polymer nanohybrids in the irradiated polyelectrolyte metal complexes of different architecture.** *A. Zezin; V. Feldman; S. Abramchuk; E. Zezina; A. Danchenko*
T5 - OP63	**Step-and repeat assembly of molecularly controlled ultrathin polyaramide layers.** *M. Perez; N. Lomadze; H. Reinecke; O. Prucker; J. Rühe*
T5 - OP64	**Synthesis of core-branched ABC block copolymer nanoparticles having incompatible functional moieties.** *E. Hasan; J. V. Weaver; D. J. Adams*
T5 - OP65	**Polyesteramide nanofibers – preparation and properties.** *J. Brožek; L. Malinová; V. Benešová; D. Lubasová; L. Martinová; J. Roda*
T5 - OP66	**Polyurethane functionalized with hydroxyapatite nanostructures by a non-conventional route. Thermal behavior as a function of pressure.** *L. Popescu; R. M. Piticescu; T. Buruiana; E. Vasile; R. Trusca*
T5 - OP67	**Nanostructured polymer composites based on carbon nanotubes.** *M. Galimberti; M. Coombs; I. Tritto; A. Ravasio; T. Riccò; S. Passera; L. Conzatti; C. D'Arrigo; S. Senatore*
T5 - OP68	**Preparation and characterization of sol-gel functionalized polysaccharides.** *H. M. Ehmann; S. Spirk; K. Stana-Kleinschek; V. Ribitsch*
T5 - OP69	**Nano-hybrid PDMA/silica hydrogels: from structure to mechanical properties.** *S. Rose; A. Marcellan; T. Narita; D. Hourdet*
T5 - OP70	**Structure/highly electrical conductivity relationships of gold nanowires/P(VDF-TrFE) nanocomposites.** *A. Lonjon; L. Lafffont; P. Demont; E. Dantras; C. Lacabanne*
T5 - OP71	**Design of "all-supramolecular" nanocapsules made of low-molecular weight bis-ureas through interfacial reaction in miniemulsion.** *E. Groison; S. Adjili; A. F. Ferrand; F. Lortie; N. Sintes-Zydowicz; D. Portinha*
T5 - OP72	**Synthesis and characterization of PCL-*b*-PLA di-block copolymers.** *L. Peponi; L. Casaban; A. Marcos-Fernández; J. M. Kenny*
T5 - OP73	**Foaming in CO_2 *sc* medium as an efficient way to produce electromagnetic interference shielding materials.** *L. Monnereau; J. Thomassin; N. Quiévy; P. Bollen; S. Eggermont; T. Pardoen; C. Bailly; I. Huynen; C. Jérôme; C. Detrembleur*
T5 - OP74	**Ag(PbS)/Poly-*p*-xylylene nanocomposites by VDP-method.** *S. Ozerin; A. Gusev; K. Mailyan; A. Pebalk; I. Ryzhikov; S. Zavyalov; S. Chvalun*
T5 - OP75	**Relaxation dynamics in ultrathin polymer films investigated at the nanoscale.** *K. H. Nguyen; D. Prevosto; M. Labardi; S. Capaccioli; M. Lucchesi; P. Rolla*
T5 - OP76	**Tuning thermomechanical properties of polystyrene/polybutadiene-based thermoplastic elastomers by grafting.** *J. Prévost; M. N. Nguyen; I. Iliopoulos; L. Leibler*
T5 - OP77	**Dielectric properties of poly(ethylene-*co*-butylene) modified MWCNT/polypropylene composites.** *A.E. Daugaard; K. Jankova; J. Bøgelund; J.M.R. Marín; S. Hvilsted*
T5 - OP78	**Electrosynthesis study of poly(*N*-methyl aniline)/Ag nanocomposite.** *S. M. Seyed Mohaghegh; F. Ansari; B. Najafzadeh*
T5 - OP79	**New approaches to development of equipment for nanoscale investigations in aqueous solutions of polymers.** *D. Shaltykova; V. Bublik; D. Bobrovnokov; N. Semenyakin; E.E. Kopishev; I.K. Nam; A. Timofeyev*
T5 - OP80	**Interpolyelectrolyte complexes based on star-like polyionic species.** *D.V. Pergushov; I.A. Babin; A. Wolf; H. Schmalz; A.B. Zezin; A.H. Mueller*
T5 - OP81	**Hybrid carbonaceous and plasmonic nanostructures as efficient elements in energy conversion devices.** *D.H. Kim; Y.H. Jang; Y.J. Jang*
T5 - OP82	**Voltage-induced swelling and de-swelling of weak polybase brushes.** *M.P. Weir; S.Y. Heriot; S.J. Martin; A.J. Parnell; S.A. Holt; J.R.P. Webster; R.A.L. Jones*
T5 - OP83	**Fabrication and ordering of noble metal nanoparticles through functional polymers.** *A. Ledo-Suárez; M.A. López-Quintela; M. Lazzari*

T5 - OP84	**PVC modified with well dispersed nano silica spheres.** *M. Conradi; M. Zorko; I. Jerman; B. Orel*
T5 - OP85	**Viscoelastic behavior of magnetic elastomers depending on composition and magnetic field.** *E.Y. Kramarenko; G.V. Stepanov; N.S. Perov; A.V. Chertovich; A.R. Khokhlov*
T5 - OP86	**Polyelectrolyte-clay multilayers for surface modification of biopolymers: preparation and possible applications.** *G. Findenig; S. Nowitsch; R. Kargl; M. Reischl; A. Doliska; T. Heinze; K. Stana-Kleinschek; V. Ribitsch*
T5 - OP87	**Block-gradient copolymers of styrene and acrylic acid synthesized by nitroxide-mediated radical polymerization.** *O. Borisova; L. Billon; M. Zaremski; B. Grassl; Z. Bakaeva; A. Lapp; P. Stepanek; O. Borisov*
T5 - OP88	**Self-organization of amphiphilic macromolecules in semidiluted and concentrated solutions.** *V.V. Vasilevskaya; A.A. Glagoleva; M.K. Glagolev*
T5 - OP89	**Local structure around nano-clay agglomerates in PP composites – a scanning X-ray diffraction study with sub micron resolution.** *M. Feuchter; G. Maier; M. Burghammer; M. Kracalik; S. Laske; J. Keckes; G. Pinter*
T5 - OP90	**Poly(ethylene oxide)/sepiolite and poly(ethylene oxide)/sepiolite/Li salt nanocomposites: Confinement effects and preliminary results on their performance as solid electrolytes.** *A. Mejía; J. Guzmán; N. García; P. Tiemblo*
T5 - OP91	**Nanocomposites prepared with montmorillonite modified by quaternary polyesters.** *M. Huskic; M. Žigon*
T5 - OP92	**Polymeric micelles using pseudo-amphiphilic block copolymers and their cellular uptake.** *M. Benaglia; E. Spisni; A. Alberti; A. Papi; E. Treossi; V. Palermo*
T5 - OP93	**Patterning polymer brush microstructures by colloidal lithography.** *T. Chen; R. Jordan; S. Zauscher*
T5 - OP94	**Penetrants interacting with matrix of polymeric membrane. Problems and perspective.** *I.V. Vorotyntsev; N.A. Petukhova*
T5 - OP95	**From bulk to attograms of matter: dynamics and phase transitions of polymeric materials.** *A. Serghei; T.P. Russell*
T5 - OP96	**Effect of organoclay surface treatment on the property profile of recycled PET nanocomposites.** *M. Kracalik; A. Witschnigg; S. Laske; C. Holzer*
T5 - OP97	**Effect of two different surfactants on the properties of PET nanocomposites.** *I.F. Leite; A.P.S. Soares; O.L. Malta; S.M. de Lima Silva*
T5 - OP98	**Optical writing in self-assembled azobenzene block copolymers and their blends with PMMA.** *S. Menghetti; M. Alderighi; F. Tantussi; F. Fuso; M. Allegrini; R. Solaro; G. Galli*
T5 - OP99	**Generating hierarchical nanostructures in polymer surfaces.** *J.P. Fernández-Blázquez; A. del Campo*
T5 - OP100	**Electric conductivity of aqueous solutions of partially neutralized poly(thiophene-3-ylacetic acid) as predicted by different polyelectrolyte theories – comparison with experiment.** *J. Cerar; D. Bondarev; J. Vohlidal; V. Vlachy*
T5 - OP101	**Characterization of the morphology of co-extruded, thermoplastic/rubber multi-layer tapes.** *J.G.P. Goossens; R.M.A. l'Abee; A.M.J.T. Meijer-Vissers; A.B. Spoelstra; M. van Duin*
T5 - OP102	**Cationized nanofibrillated cellulose by aqueous free radical polymerization: synthesis, structure, and antibacterial properties.** *K. Littunen; U. Hippi; J. Seppälä*
T5 - OP104	**A new approach to peptides encapsulation.** *B. Trzebicka; A. Dworak; B. Robak; P. Weda; J. Silberring*

TOPIC 6: Bioinspired Polymers, Bioengineering and Biotechnology

T6 - OP1	**Some novel applications of biodegradable elastomers.** *S. Venkatraman; V. Lipik; K.J. Fong; H. Yingying; N. V; F. Boey*
T6 - OP2	**Amyloid peptides and peptide copolymers: from self-assembly, towards therapeutics.** *I.W. Hamley; V. Castelletto*
T6 - OP3	**New smart heparin-based bioconjugates synthesized by ATRP and click chemistry.** *F. Reyes; G. Rodriguez; M.R. Aguilar; J. San Román; W. Li; S. Averick; K. Matyjaszewski*
T6 - OP4	**Synthesis of PLA-*b*-PHEA block copolymers as precursors of tubular guides for peripheral nerve repair.** *B. Clement; T. Trimaille; K. Mabrouk; D. Bertin; D. Gigmes*
T6 - OP6	**Polymer hydrogels with a 'memory' effect to drugs.** *S.S. Ivanchev; V.F. Danilichev; V.N. Pavlyuchenko; O.N. Primachenko; S.Y. Khaikin*
T6 - OP7	**Synthesis and characterization by lipase-catalyzed ring-opening polymerization of poly(ε-caprolactone) with different reaction mediums.** *E. Özsağıroğlu; B. İyisan, Y. Avcıbaşı Güvenilir*
T6 - OP8	**Polyesters from natural macrolactones for biomedical applications.** *I. Van der Meulen; C.E. Koning; A. Heise; R. Deumens*
T6 - OP9	**Developing and evaluating mucoadhesive polymers and mucosa-mimetic materials.** *V. Khutoryanskiy*
T6 - OP10	**Macromolecular nanoparticles with cholesterol for solid tumour targeting: how do they look like from inside. The origin of functionality.** *S.K. Filippov; P. Chytil; P.V. Konarev; D.I. Svergun; J. Plestil; A. Jugunov; T. Etrych; K. Ulbrich; P. Stepanek*
T6 - OP11	**Photo cross-linked and pH sensitive polymersomes as bionanoreactors.** *J. Gaitzsch; D. Appelhans; D. Gräfe; P. Schwille; B. Voit*
T6 - OP12	**Enzyme sensitive dendrimers with defined chirality via 'click' coupling of enantio-pure building blocks.** *B. Yeniad; H. Naik; R. Amir; C. Koning; C. Hawker; A. Heise*
T6 - OP13	**Design of bioinspired asymmetric diblock copolypeptides for DNA-template self assembled coating.** *A. Hernández-García; M. Werten; F. de Wolf; R. de Vries*
T6 - OP14	**Modification of polymers materials to achieve antibacterial properties.** *J. Casimiro; P. Roger; B. Lepoittevin; C. Boisse Laporte*
T6 - OP15	**Core-shell type nanofibrous scaffolds using coaxial electrospinning for bioapplication.** *H. Park; H. Yoo; T. Hwang; T. Park; I. W. Cheong; J. H. Kim*
T6 - OP16	**Vinyl sulfonate terminated polyglycidol for biomedical applications.** *D. Haamann; H. Yoshida; H. Keul; M. Akashi; D. Klee; M. Möller*
T6 - OP17	**Biosynthesis – structure – property relations for branched polysaccharides as revealed by two-dimensional macromolecular size/branch chain-length distributions** *F. Vilaplana; M.A. Sullivan; J. Hasjim; R.G. Gilbert*
T6 - OP18	**Compositionally-tunable surface nanostructuration of microspheres obtained from a self-stabilizing copolymerization of methylmethacrylate and vinylpyrrolidone.** *I. Aranaz; H. Reinecke; C. Elvira; A. Gallardo*
T6 - OP19	**Matrix protein dynamics on polymer surfaces** *C. González-García, P. Rico, M. Cantini, J. Ballester-Beltrán, V. Llopis-Hernández, M. Salmerón-Sánchez*
T6 - OP20	**Thermo-responsive self assembled nanoparticles from elastin-like recombinamers.** *L. Martín; C. García-Arévalo; F.J. Arias; M. Alonso; J.C. Rodríguez-Cabello*
T6 - OP21	**Lysine dendrimers and their conjugates and complexes with amyloid-like peptides.** *I. Neelov*
T6 - OP22	**Poly(ester amide)s based on α-amino acids and α-hydroxy acids oligomers: Synthesis, characterization and biodegradation studies** *A.C. Fonseca; P.N. Simões; M.H. Gil;*

T6 - OP23	**Nanoengineered polymeric capsules for drug delivery.** *G. Such; C.J. Ochs; Y.Y. Yan; F. Caruso*
T6 - OP24	**A water-based antibacterial nanohybrid solution for coating stainless steel.** *C. Falentin-Daudré; E. Faure; C. Jérôme; C. Van de Weerdt; J. Martial; C. Archambeau; A.S. Duwez; C. Detrembleur*
T6 - OP25	**Bioinspired protein imprinted poly(dopamine)-silica composite as separation materials in high-pressure liquid chromatography.** *A. Nematollahzadeh; B. Selleregren; A. Shojaei; M.J. Abdekhoadie*
T6 - OP26	**Development and characterization of antimicrobial PCL fibres for surgical suture applications.** *L. Botta; R. Scaffaro; M. Sanfilippo; G. Gallo; A.M. Puglia*
T6 - OP27	**Enzymatically cross-linked proteins: hierarchical biopolymers.** *Y. Saricay; P. Wierenga; R. de Vries*
T6 - OP28	**Polymer-cooperative blocking the viruses - strategy, synthesis, and effectiveness.** *A.V. Serbin; E.N. Karaseva; O.L. Alikhanova; V.B. Tsvetkov*
T6 - OP29	**Non-linear viscoelastic models for random coil polysaccharide solution rheology over a broad range of concentrations.** *W.M.H. Verbeeten*
T6 - OP30	**Porous protein based scaffolds produced using a freeze-thawing technique.** *H. Kirsebom; L. Elowsson; M. Durbeej; B. Mattiasson*
T6 - OP31	**Galactomannan in imidazolium-based ionic liquids.** *E. Sultan; A. Bussard; E. Fleury; A. Charlot*
T6 - OP32	**Hierarchically self-organized PS-*b*-P4VP Honeycomb films with reversible pH-responsive wettability.** *P. Escale, M. Save, C. Derail, L. Rubatat; L. Billon*
T6 - OP33	**Lipase catalyzed synthesis of biopolyester and related clay-based nanohybrids.** *H. Öztürk Düşkünkorur; E. Pollet; P. Debeire; V. Phalip; L. Avérous*
T6 - OP34	**Intelligence polymers behavior and its application idea in treatment of some diseases of centeral nervous system.** *M. Abolhassani; A. Yavari; P. Abolhassani; S. Shouli*
T6 - OP35	**Hydrogels based on poly(vinyl alcohol)/phosphoester and poly(ethylene glycol)/phosphoester for biomedical applications.** *T. Vlad-Bubulac; A. Oprea; D. Serbezeanu; C. Hamciuc*
T6 - OP36	**The missing lactam – thermoresponsive poly(*N*-vinylpiperidone).** *C. Ieong; R.K. O'Reilly*
T6 - OP37	**Polysaccharide capsules with engineered hydrophobic drug-loaded multilayers.** *J. Jing; D. Cui, I. Pignot-Paintrand; B. De Geest; C. Picart; R. Auzély-Velty*
T6 - OP38	**Non-monotonic variation of polymer size with increasing confinement.** *D. Chaudhuri; B. Mulder*
T6 - OP39	**Poloxamines for injectable scaffolds with osteogenic activity.** *C. Alvárez-Lorenzo; A. Rey-Rico; M. Silva; J. Couceiro; A. Concheiro*
T6 - OP40	**The key factors driving *in vivo* immobilization of proteins to PHA.** *N. Dinjaski; J.L. García; M.A. Prieto*
T6 - OP41	**Polymeric bio-functionalisation to generate enzyme-responsive biomaterials.** *P.D. Thornton; A. Heise*
T6 - OP42	**Nanohybrides and composites as perspective biomedical materials.** *V.P. Zubov; D.V. Kapustin; A.N. Generalova; I.V. Bakeeva*
T6 - OP43	**Sol-Gel coatings for metal implants.** *M. Hernández-Escolano; M.J. Juan-Díaz; M. Martínez; M.D. Gurruchaga; M.I. Goñi; J.J. Suay*
T6 - OP44	**Spray dried hydroxyapatite-chitosan biocomposites.** *T. Başargan; G. Nasün-Saygılı*
T6 - OP45	**Antiheparin activity of cationic dextran derivatives in rats *in vivo*.** *K. Kaminski; K. Szczubialka; M. Nowakowska; B. Kalaska; W. Buczko*

T6 - OP46	**Trimethyl chitosan-based complexes as nanocarriers for pH-triggered lysosomal delivery of therapeutic proteins.** *M. I. Giannotti; O. Esteban; M. F. García-Parajo; F. Sanz*
T6 - OP47	**Modeling of nanotubes penetration through a phospholipid bilayer.** *S. Pogodin; N.K.H. Slater; V.A. Baulin*
T6 - OP48	**Zinc oxide protects etch&rinse adhesive resin-dentin hybrid layers from MMPs degradation.** *M. Toledano; M. Yamauti; P. Suarez; M. Quintana; E. Osorio; R. Osorio*
T6 - OP49	**Preparation and characterisation of glycopolymers by CCTP and click chemistry.** *Y. Gou; D.M. Haddleton*
T6 - OP50	**Recognition and release of biological catechols in NIPAM-based copolymers bearing phenylboronic acid receptors.** *N. Martin; S. Norvez; I. Iliopoulos*
T6 - OP51	**Chitin-immobilized lipase catalyst for ring opening polymerization of ε-caprolactone.** *B. Iyisan; E. Özsağıroğlu; N. Deveci Aksoy; Y. Avcıbaşı Güvenilir*
T6 - OP52	**Novel bioimaging probes combining well-defined multifunctional polymers and two-photon absorption chromophores.** *C. Cepraga; S. Adjili; S. Marotte; T. Gallavardin; J. Massin; J.C. Mulatier; C. Monnereau; O. Maury; Y. Bretonnière; A. Favier; Y. Leverrier; J. Marvel; P.L. Baldeck; C. Andraud; M.T. Charreyre*
T6 - OP53	**Blends and composites of biodegradable polyesters with cellulosic fibers. Effect of chemical modification on the morphological, thermal and mechanical properties.** *M. Pracella; M.U. Haque; M. Errico; G. Gentile; V. Alvarez*
T6 - OP54	**Synthesis and (bio)conjugation of polypeptides from *N*-carboxyanhydride (NCA) polymerization.** *J. Huang; G. Habraken; A. Heise*
T6 - OP55	**Study on biodgradability of xenobiotic polymers based on numerical simulation and experimental outcomes.** *M. Watanabe; F. Kawai*
T6 - OP56	**Presence of nano precursors in lignin of hevea brasiliensis (rubber wood): a sem, ftir study.** *S. Tabassum; O. Sulaiman; R. Hashim*
T6 - OP57	**Cellulose nanostructure in natural fibers from position resolved SAXS and WAXS measurements.** *C.J. Garvey; M.P. Weir; K.J. Jarrett; C.E. Buckley*
T6 - OP58	**Polymeric lipidic membrane permeabilizers displaying densely packed arrays of crown ether lateral substituents.** *M Liu; N.Illy; B.Brissault; K.Ondrias; J.Penelle; V.Barbier*
T6 - OP59	**Synthesis of monodisperse linear poly(oxazolines) with minimised structural defects as model compounds for elucidating cell membrane properties.** *B. Monnery; S. Shaunak; M. Thanou; J. Steinke*
T6 - OP60	**Proteins as mechanophores in damage self-reporting polymeric materials.** *N. Bruns; S. Lörcher; T. Winkler*
T6 - OP61	**Synthesis and characterization of redox and pH-sensitive poly(aspartic acid) hydrogels.** *B.S. Gyarmati, Á. Némethy, T. Gyenes, A. Szilágyi*
T6 - OP62	**Copoly(2-oxazoline)s exhibiting side chains for thiol-ene reactions – synthesis of glycopolymers and their potential for biological applications.** *K. Kempe; C. Biskup; M. Gottschaldt; U. S. Schubert*
T6 - OP63	**Engineering Alg-PEG hybrid microspheres for biomedical applications.** *R. Mahou; C. Gonelle; G. Parnnaud; F. Schmitt; G. Kollárikova; L. Jullierat; I. Laçik; C. Wandrey*
T6 - OP64	**Degradation of polyglycidol in aqueous solution by UV light.** *A. Utrata-Wesolek; R. Trzcinska; B. Trzebicka; A. Dworak*
T6 - OP65	**DNA complexes with charged compounds, that are useful for nanotechnology.** *N. Kasyanenko; B. Dribinsky; A. Puchkova; P. Sokolov*

T6 - OP66	**Viscoelastic and thermal behavior of polyurethane films prepared as shape memory polymer.** *C. Citak; I. Yavuz; M. Bonfil; F. S. Guner*
T6 - OP67	**Wavelength-responsive polymer materials.** *V. San Miguel; A. Del Campo*
T6 - OP68	**Photoresponsive polymer brushes.** *J. Cui; A. Del Campo*
T6 - OP69	**Properties of cyanoacrylate adhesives with different alkyl chain length.** *R. Torregrosa-Coque; A.M. Villarreal-Gómez; J. M. Martín-Martínez*
T6 - OP70	**Multi-block copolymers of polyamide 6 and diepoxy propylene adipate obtained by solid state polymerization.** *S. Cakir; C. Koning; M. Eriksson; M. Martinelle*
T6 - OP71	**Dynamics of hydrogen bonds and protein in hydrated elestin.** *V. Samouillan; D. Tintar; F. Delaunay; J. Dandurand; C. Lacabanne*
T6 - OP72	**The effect of degradation on PLLA/PCL scaffolds prepared by freeze extraction.** *L. A. Gaona Corral; J. L. Gómez; J.E. Perilla; M. Lebourg*

POSTER CONTRIBUTIONS

TOPIC 1: Synthetic Routes: Monomers and Polymers from Bioresources and Advanced Methodologies

T1-001	**Low temperature photoinitated RAFT of vinyl acetate.** *M. K. Ham; S. H. Shim; Y. Jeong; Y. K. Kwon; Y. J. Kwark*
T1-002	**Towards sustainable polymerization of stimuli-responsive polyglycerol hydrogels.** *S. Salehpour; M. A. Dube*
T1-003	**Biocomposites based on elastomeric polyurethane and cellulose nanocrystals.** *L. Rueda; B. Fernández d'Arla[1]; M.L. González; A. Valea; I. Mondragon; M.A. Corcuera; A. Eceiza*
T1-004	**Polyurethanes derived from renewable resources: effect of polyol structure.** *A. Saralegui; L. Rueda; B. Fernández d'Arlas; M. D. Martín; I. Mondragon; A. Eceiza; M. A. Corcuera*
T1-005	**Synthesis of polyesters from castor oil and their use as polymer matrix for magnetic nanocomposites.** *P. A. Ziani Suarez; F. Machado Silva; E. U. Xavier Péres; F. Gomes de Souza Jr*
T1-006	**Thermosensitive copolymers based on alginate and poly(N-isopropylacrylamide) obtained by gamma-radiation.** *M. S. Lencina; N. A. Andreucetti; M. A. Villar*
T1-007	**Study of incorporation of vegetable waste as filler in flexible polyurethane foam.** *F. J. Melero Muñoz; M. V. Navarro Bañon; J. R. Vega Baudrit; M. R. Sibaja*
T1-008	**Lyocell fibers reinforced with anisotropic nanofiller.** *A. J. Uddin; A. Yamamoto; Y. Gotoh*
T1-009	**Castor oil based poly(urethane-co-pyrrole)s as novel electroactive anticorrosive coatings for steel.** *R. Gharibi; M. Yousefi; H. Yeganeh*
T1-010	**Synthesis of isotactic poly(hydroxy acrylic acid) by radical polymerization of methylene dioxolanone prepared from lactic acid.** *H. Tanaka; Y. Matsubara; K. Okuda; M. Niwa*
T1-011	**Investigation of the type of the bridge on the activity of supported metallocene catalyst in ethylene polymerization.** *A. Talaei*
T1-012	**Biopolymers from natural oils.** *A. Remeikyte; J. Ostrauskaite; J. Vidas Grazulevicius*
T1-014	**Synthesis of polystyrene waterborne nanoparticles by miniemulsion polymerization.** *L. Ronco; R. J. Minari; J. R. Vega; L. M. Gugliotta*
T1-015	**Lithium naphthalenide initiators for controlled anionic polymerization.** *V. A. González; A. J. Satti; M. D. Ninago; E.M. Vallés; M. A. Villar; A. E. Ciolino*
T1-016	**A new method for synthesis of photocurable low molecular weight chitosan.** *L. Solhi; M. Atai; A. Nodehi; M. Imani*
T1-017	**Study of rare earth metal triflates as new catalyst for the formation of oxazolidone-isocyanurate-ether networks from DGEBA and 4-toluene-2,4-diisocyanate.** *M. Flores; X. Fernández-Francos; J. M. Salla; A. Mantecón; A. Serra; E. Jimenez-Piqué; X. Ramis*
T1-018	**Binuclear carbonyl complexes of transition metals of VI Group in homo- and copolymerization of methyl methacrylate and styrene.** *M. V. Pavlovskaya; A. A. Zolotukhin; D. F. Grishin*
T1-019	**Amphiphilic copolymers based on sucrose methacrylate and acrylic monomers.** *H. F. N. de Oliveira; M. I. Felisberti*
T1-020	**Non isocyanate polyurethane obtained from different vegetable oils.** *P. Mazo; L. Rios*

T1-021	**Kinetic study of 2-acrylamido-2-methylpropanesulfonic acid in free-radical polymerization method by differential scanning calorimetry.** *E. Nadim; H. Bouhendi; F. Ziaee, R. Bazhrang*
T1-022	**Synthesis and characterization of novel bio-based polyesters based on curcumin as a natural diol monomer and commercially available aromatic dicarboxylic acids.** *A. Shockravi; A. Javadi; S. Hajavi*
T1-023	**The oxypropylation of olive stone and the use of the ensuing polyols for the synthesis of novel polyesters and polyurethanes based on renewable resources.** *M. Matos; F. Barreiro; A. Gandini*
T1-024	**Microwave synthesis: an alternative approach to synthesize conducting end-capped polymers.** *P. Marcasuzaa; S. Reynaud; B. Grassl; J. Desbrières; O. F. Donard*
T1-025	**Synthesis and characterization of new sensitive copolymer of poly-2,7-fluorene-1,4-(2,3-diamine)naphthalene for aqueous media.** *R. Vázquez-Guilló; A. Calero; A. Salinas-Castillo; C.R. Mateo; R. Mallavia*
T1-026	**Copolymers from poly(lactic acid) (PLA) and chain extenders or branching agents.** *A. Hitos-Rodríguez; A. Bacardit; L. Olle; O. O. Santana; M. L. Maspoch; J. J. Bou*
T1-028	**Synthesis of photocleavable block copolymers based on p-methoxyphenacyl groups.** *O. Bertrand; C .A. Fustin; J. F. Gohy*
T1-029	**Semi-IPNs based on poly(n-vinylpyrrolidone) and poly(L-lactide): synthesis and characterization.** *A. P. R. Camilo; M. I. Felisberti; V. Mano*
T1-030	**Evaluation of yam agriculture wastes to obtain fructans.** *M. Esquivel; A. Aguilar; R. Sibaja; J. Vega-Baudrit; S. Madrigal-Carballo*
T1-031	**Synthesis of low formaldehyde emission urea-formaldehyde resins and their application to the manufacturing of particleboards.** *P. Estévez; S. Vallejos; H. El Kaoutit; M. Trigo-López; F. Serna; F. García; J. L. de la Peña: J. M. Pérez*
T1-032	**Controlled free-radical copolymerization of 4-vinyl pyridine and tert-butyl acrylate via reversible addition-fragmentation chain transfer (RAFT) technique: kinetics and mechanism.** *E. Sivtsov; A. Gostev; E. Chernikova*
T1-033	**Conventional and RAFT copolymerization of N-vinyl succinimide and 4-vinyl pyridine.** *A. Gostev; E. Sivtsov*
T1-034	**Aromatic copolyesters containing cyclic diacetalized D-glucitol.** *C. Japu; A. Martínez de Ilarduya; A. Alla; E. Benito; M. G. García-Martín; J. A. Galbis; S. Muñoz-Guerra*
T1-035	**Eco-friendly aliphatic polyesters containing 1,4-cyclohexane dicarboxylate units: effect of diol chain length on thermo-mechanical properties.** *A. Celli; P. Marchese; S. Sullalti; J. Boyenval; S. Commereuc*
T1-036	**Synthesis and modification of biopolymers with unsatured terminal groups.** *C. Berti; A. Celli; L. Cruciani; P. Marchese; L. Sisti; M. Vannini*
T1-037	**Synthesis and characterization of lactide-graft-poly(vinyl alcohol) and miscibility study with poly(ethylene oxide).** *A. Lejardi; A. Etxeberria; E. Meaurio; J. Fernandez; J. R.Sarasu*[1]
T1-038	**Oleic and undecylenic acids-based diols and derived polyurethanes via thiol-ene coupling.** *R. J. González-Paz; G. Lligadas; J. C. Ronda; M. Galià; V. Cádiz*
T1-039	**Synthesis and microbiologic assays of new polymers based on antibacterial biomolecules.** *B. Lepoittevin; J. Casimiro; C. Rinfray; J. M. Herry; M. N. Bellon-Fontaine; P. Roger*

T1-040	**Carbohydrate-based polyurethanes: a comparative study of polymers made from isosorbide and 1,4-butanediol.** *R. Marín; A. Alla; A. Martínez de Ilarduya; S. Muñoz-Guerra*
T1-041	**Thermal and hydrolytic degradability of polyesters containing cyclic acetalized carbohydrate units.** *C. Lavilla; C. Japu; M. G. García-Martín; J. A. Galbis; S. Muñoz-Guerra*
T1-042	**Polyhydroxybutyrate nanocomposite microcapsules with brazilian smectitic clays.** *M. G. da Silva Valenzuela; W. H. Shu; H. Wiebeck; F. R. Valenzuela Diaz*
T1-043	**Structural features of copolymers of styrene and macromers of a vegetable oil.** *S. Gómez Robles; M. I. Felisberti*
T1-044	**Synthesis and characterization of poly(L-lactide-co-ε-caprolactone) random copolymers.** *J. Fernández; A. Etxeberria; E. Zuza; E. Meaurio; S. Petisco; J. R. Sarasua*
T1-045	**Thermosets from methyldiphenolic acid-based benzoxazine and diphenolic acid mixtures.** *C. Zuñiga; G. Lligadas; J. C. Ronda; M. Galià; V. Cádiz*
T1-046	**Polybenzoxazine foams from renewable diphenolic acid.** *C. Zúñiga; G. Lligadas; J. C Ronda; M. Galià; V. Cádiz*
T1-047	**Aminoalkylphosphonic acids and glycylaminoalkylphosphonic acids as antibacterial additives in textile chemistry.** *M. H. Kudzin; Z. H. Kudzin; J. Drabowicz*
T1-048	**Amphiphilic poly(4-vinylpyrine) (P4VP) block copolymer micelles for metal binding.** *N. Abdul Rahim; F. Audoin; J. G. Vos; A. Heise*
T1-049	**Sunflower oil-modified polyester synthesis by ring opening polymerization and its use in organic coatings.** *C. Tasdelen-Yucedag; A. Tuncer Erciyes*
T1-050	**Synthesis and optical, electrochemical and electroluminescence properties on new series of copoly-2,7-fluorene-1,4-(2/3-amino)benzene.** *A. Calero; R. Vazquez-Guilló; A. Salinas-Castillo; F. Montilla; C. Coya; A. L. Alvarez; C. R. Mateo; R. Mallavia*
T1-051	**Metathesis degradation of natural rubber in the presence of avocado and mandarin oils using ruthenium alkylidene catalysts.** *A. Martínez; M. A. Tlenkopatchev*
T1-052	**Thiol-yne coupling to undecylenic acid derivatives. Synthesis of polyurethanes.** *Z. Beyazkilic; R.J. González-Paz; G. Lligadas; J. C. Ronda; M. Galià; V. Cádiz*
T1-053	**Phosphorus-containing high oleic sunflower oil flame retardant thermosets.** *M. Moreno; G. Lligadas; J. C. Ronda; M. Galià; V. Cádiz*
T1-054	**Amphiphilic triblock copolymers of poly(ethylene glycol) and L-lactide: a possible mechanism of polymerization for coordination/insertion catalysts.** *R. Bergamo Trinca; H. F. Nunes de Oliveira; M. I. Felisberti*
T1-055	**Styrenated oil synthesis by "click" chemistry approach.** *P. Yazgan; A. Tuncer Erciyes; N. Alemdar; Y. Yagci*
T1-056	**Effect of organoclay preparation and the processing conditions on the extent of exfoliation in nylon 6/ modified clay nanocomposites.** *E. Erdmann; M. A. Toro; H. A. Destéfanis; M. Modesti*
T1-057	**Thermoplastic polyurethanes with undecylenic acid-based soft segments: synthesis and properties.** *C. Lluch; G. Lligadas; J. C. Ronda; M. Galià; V. Cádiz*
T1-058	**Polybenzoxazine prepolymers from renewable fatty acid derivatives.** *A. Tüzün; G. Lligadas; J. C. Ronda; M. Galià; V. Cádiz*
T1-059	**Molecularly imprinted nanoparticles prepared by non-aqueous emulsion polymerization.** *G. Dvorakova; R. Hashick; K. Chiad; M. Klapper; K. Müllen; J. Vohlidal; A. Biffis*

T1-060	**Synthesis of functionalized polyesters via ring-opening polymerization of ε-caprolactone initiated by Al-based catalysts.** *Y. A. Piskun; I. V. Vasilenko; S. V. Kostjuk; K. V. Zaitsev; S. S. Karlov*
T1-061	**Styrenated oil production by RAFT method.** *N. Caglar; A. Tuncer Erciyes; N. Alemdar; N. Bicak*
T1-062	**Starch containing polyurethanes: structure and biodegradability.** *T. Travinskaya; E. Mishchuk; Y. Savelyev*
T1-063	**Preparation of ordered Au/PEO-b-PFOMA hybrid films through phase transition of micellar thin films.** *E. J. Yoon; N. T. Hoai An; D. H. Kim; K. T. Lim*
T1-064	**In situ micelle formation and inter-block crosslinking of PAA-b-PS via RAFT polymerization.** *E. S. Lim; L. T. Bao Tran; K. T. Lim*
T1-065	**Ethylene/1-octene copolymerization with supported salen-type complexes. Effect of metal type.** *A. Pietruszka; M. Białek; K. Czaja*

TOPIC 2: New Analytical and Characterization Tools

T2-001	**Fractionation analysis techniques for the characterization of copolymers with bimodal chemical composition distribution.** *B. Paredes; A. Carrero; R. van Grieken; I. Suarez*
T2-002	**Novel method for the in-situ estimation of curing shrinkage using FTIR/ATR spectroscopy and refractive index measurements.** *X. Fernández-Francos; X. Ramis; À. Serra; M. Sangermano*
T2-003	**Raman evaluation of the structure of organic materials by analyzing the region of stretching vibrations of CH_2 and CH_3 groups – benefits and limitations.** *P. Donfack; K. Prokhorov; E. Sagitova; Y.V. Zavgorodnev; G. Nikolaeva; M. Guseva; V. Gerasin; A. Materny; E. Antipov; P. Pashinin*[2]
T2-004	**Polymer film analysis.** *R. M. Zacur; D. R. Ercoli; G. S. Goizueta*
T2-005	**Interplay between raman scattering and atomic force microscopy in characterization of polymer blends.** *P.Dorozhkin; A. Shelaev; S. Magonov*
T2-006	**Characterization of different polymer systems via asymmetric flow field-flow fractionation (AF4).** *E. Altuntas; N. Fritz; M. Hage; U. S. Schubert*[1]
T2-007	**Thermogravimetric analysis of an acrylic copolymer.** *T. G. Oberti; M. S. Cortizo; J. L. Alessandrini*
T2-008	**Structural analysis of synthetic polymer by high-energy CID using MALDI SpiralTOF-TOF.** *T. Satoh; A. Kubo; Y. Ito; M. Hashimoto; M. Ubukata; T. Sato; J. Tamura; A. Kusai*
T2-009	**Mechanical characterization of a linear polyethylene by means of depth sensing indentation (DSI) measurements.** *V. Lorenzo; M. Ulagares de la Orden; R. Claramunt; J. Martínez-Urreaga*
T2-010	**Characterization of different varieties of cassava flour by solid state NMR spectroscopy.** *G. C. V. Iulianelli; M. I. B. Tavares*
T2-011	**Kinetic investigation of thermal degradation for low molecular weight 1,2-polybutadiene.** *M. Ronagh Baghbani; F. Ziaee; H. Bouhendi; F. Ziaie*
T2-012	**Three-dimensional modeling of mold filling process in injection process using OpenFOAM.** *N. Jafari Esfad; B. Azinfar; A. Ramazani*
T2-013	**Derivatives of coumarin as fluorescent probes for monitoring photopolymerization processes by fluorescence probe technology.** *J. Ortyl; R. Popielarz*
T2-014	**Study of thermo-mechanical and thermo-oxidative degradation of polylactide by MALDI-TOF-MS. A statistical design of experiments to optimize the sample preparation procedures.** *J. D. Badía; E. Strömberg; A. Ribes-Greus; S. Karlsson*
T2-015	**Diffusion during radical bulk polymerization of styrene and methyl methacrylate.** *B. K. Stempfle; M. Dorfschmid; D. Wöll*
T2-016	**PVT analysis of chemical reactions: polymerization, transesterification, crosslinking.** *J. Pionteck*
T2-017	**In situ studies of phase structure and crystalline development of poly(L-lactide/ε-caprolactone)/poly(ethylene glycol) blends by atomic force microscopy.** *N. Hernández Montero; J. M. Ugartemendia; T. Suárez; J. R. Sarasua*
T2-018	**SEC-DAD as a powerful tool for characterization of conjugated polymers.** *O. Trhlíková; D. Bondarev; J. Sedlácèk; J. Vohlídal*
T2-019	**Heterogeneity during controlled radical polymerization – a single molecule fluorescence microscopy investigation.** *J. Martin Nölle; K. Goossens; W. van Camp; D. Wöll*
T2-020	**Continuous-flow off-line pyrolysis-GC/MS for detection of poly(vinylpyrrolidone).** *M. Antic; V. Antic; A. Kronimus; K. Oing; J. Schwarzbauer*

T2-021	**Investigation of the miscibility (solubility) of molten polypropylene-polyethylene blends by means of rheometry.** *M. Mihalic; A. Schausberger*
T2-022	**Comparative study of various grades of polyethylene by raman spectroscopy: microstructural attribution of bands.** *R. Jumeau; P. Bourson; M. Ferriol; F. Lahure*
T2-023	**Characterisation of morphology of uniaxial oriented PET – films and pressure-induced i-PP via confocal and polarised μ-RAMAN spectroscopy.** *K. Vincze-Minya; S. Hild; T. Keplinger; S. Jilg; W. Stadlbauer; M. Aigner; J. Miethlinger*
T2-024	**A thermoset-thermoplastic blend: spectroscopy characterization.** *F. A. Mesa Rueda; A. Cuellar Burgos; C. Vargas Hernandez; J. E. Perilla*
T2-025	**Characterization of the mechanical properties of EVA foams by TMA.** *M. I. Beltrán; A. Marcilla; I. Pelaez; A. Otero*
T2-026	**Molecular weight distribution changes in irradiated films of vinyl ketone copolymers.** *S. Sánchez-Ballester; J. D. Badia; A. Martinez-Felipe; A. Ribes-Greus; V. Soria*
T2-027	**Study of the thermal behavior of syndiotactic and atactic polystyrene by raman spectroscopy.** *N. Brun; P. Bourson; S. Margueron; M. Duc*
T2-028	**Study, by raman spectroscopy, of the microstructure evolution of isotactic polypropylene during tensile test and relaxation: measuring the chains orientation.** *S. Chaudemanche; M. Ponçot; J. Martin; J. M. Hiver; P. Bourson; A. Dahoun*
T2-029	**Chromatographic characterization of PS-block-PEO.** *M. Grabowsky; M. I. Malik; P. Sinha; H. Pasch*
T2-030	**Nanoparticle characterisation by field-flow fractionation.** *W. van Aswegen; I. Malik; T. Otte; H. Pasch*
T2-032	**Predicting the slow crack growth resistance of polyethylene resins using alternative short-time performance tests** *C. Dominguez; A. Adib; J. Rodríguez; C. Martín; R. A. García*

TOPIC 3: Advanced Processing and Recycling Technologies

T3-002	**Phase behaviour of blends of poly(4-vinylphenol-co-methyl methacrylate) / poly(styrene-co-4-vinylpyridine).** *Z. Benabdelghan; A. Etxeberria*
T3-003	**Chemical characterization of organic-inorganic coating for dental applications.** *M. J. Juan-Díaz; M. Martinez; M. Hernández-Escolano; J. Suay; M. Gurruchaga; I. Goñi*
T3-005	**Low-temperature polymerization of vinyl monomers controlled by metallocomplexes based on C2B8-carborane ligand.** *I. Grishin; A. Ohapkin; I. Chizhevsky; D. Grishin*
T3-006	**Morphological characterization of PP for different foam injection molding processes with chemical blowing agents.** *V. Contreras; N. Villarreal-Bastardo; J. C. Merino ; J. M. Pastor*
T3-007	**Development of glass reinforced PVC composite.** *D. Gomes de Araujo; E. Hage Jr.; L. H. Grizzo*
T3-008	**New copolymer of tautomerizable monomer.** *J. M. Giussi; P. E. Allegretti; M. S. Cortizo*
T3-009	**"Smart pellet" additives for reinforcement in polypropylene composite.** *Y. Wang; D. A. Schiraldi*
T3-010	**Carbon nanotube imprinting technique using brownian motion in polymer melt.** *M. Yamaguchi; H. W. Yoon*
T3-011	**Polymerisation of pyrrole with phenyliodine bis(trifluoroacetate).** *E. Ateş; N. Kızılcan*
T3-012	**Performance improvement of silicone rubber/carbon fiber composites.** *E. S. Kim; Y. H. Jeon; M. Y. Jo; J. S. Yoon*
T3-013	**Novel mechanochemistry reactor and its use for rubber degradation studies in presence of stabilizers under controlled reactive gas atmosphere.** *D. Dondi; A. Buttafava; M. Bianchi; A. Zeffiro; A. Faucitano*
T3-014	**Ion-imprinted silsesquioxane polymers: synthesis and structure.** *M. Barczak; K. Michalak; Y. L. Zub*
T3-015	**Free radical melt grafting of polyolefins by using nitroxide radicals.** *D. Bélékian; P. Chaumont; E. Beyou; P. Cassagnau; S. Quinebèche; J. J. Flat*
T3-016	**Polyvinylchloride: synthesis and modification of properties by copolymerization.** *E. Kotlova; M. Pavlovskaya; M. Filippova; D. Grishin*
T3-017	**Photodegradation and bacterial biodegradation of polyethylene-vinyl acetate (EVA) mulching films. Effect of calcium and iron stearates as pro-oxidant additives.** *J. L. Pablos; C. Abrusci; I. Marín; E. Espi; T. Corrales; F. Catalina*
T3-018	**Evaluation of photodegradation of polyethylene films with pro-degradant agents II. Morphological analysis.** *J. M. Klein; A. M. C. Grisa; R. N. Brandalise; M. Zeni*
T3-019	**Chemical modification of ethylene butyl acrylate copolymer with hindered amine light stabilizer HALS. Photostabilization study.** *L. López-Vilanova; E. Espí; A. I. Real; M. Calvo; A. Fontecha; J. L. G. Fierro; C. Peinado; F. Catalina*[1]
T3-020	**Synthesis of low formaldehyde emission urea-formaldehyde resins and their application to the manufacturing of particleboards.** *P. Estévez; S. Vallejos; H. El Kaoutit; M. Trigo-López; F. Serna; F. García; J. L. de la Peña; J. M. Pérez*
T3-021	**Modeling of butadiene polymerization using neodymium catalyst complex.** *A. M. Gumerov; I. M. Davletbaeva*
T3-022	**Effects of incorporating waste rigid polyurethane foam in polymer compounds based on polypropylene.** *S. Fontana Pereira; E. Hage Jr*
T3-023	**Parallel versus perpendicular lamellar-within-lamellar self-assembly of A-b-(B-b-A)$_n$-b-C and (B-b-A)$_n$-b-C ternary multiblock copolymer melts: SSL theory, DPD, SCFT investigation.** *V. A. Markov; Y. A. Kriksin; A. V. Subbotin; G. ten Brinke*

T3-024	**Aminoiminophosphoranate complexes of platinum and palladium in radical polymerization of vinyl monomers.** *E. V. Kolyakina; M. V. Pavlovskaya; N. A. Ustynyuk; D. F. Grishin*
T3-025	**Atom transfer radical polymerization of methyl methacrylate in the presence of four-coordinated cobalt complex with sterically hindered o-iminobenzoquinone ligand.** *E. V. Kolyakina; A. A. Poddel'sky; D. F. Grishin*
T3-026	**Nitroxide-mediated (Co) polymerization of vinyl monomers with high-molecular-weight alkoxyamines, derived from C-phenyl-N-tert-butylnitrone.** *A. Shchepalov; D. Grishin*
T3-027	**Synthesis and singlet-singlet energy transfer studies of copolymers involving fluorene-carbazole units as energy donor and porphyrin as pendant acceptor group.** *S. M. A. Pinto; M. J. F. Calvete; H. D. Burrows; M. M. Pereira; A. Salinas-Castillo; R. Mallavia*
T3-028	**Degradation kinetics of electron beam irradiated poly (propylene-co-ethylene) heterophasic copolymer.** *M. Koosha; N. Ebrahimi; Y. Jahani; S. A. Seyed Sajadi*
T3-029	**Effect of process conditions on the compatibilization of in-reactor alloys.** *H. Bagheri; M. Nekoomanesh; S. Hakim; Y. Jahani; Z. Q. Fan*
T3-030	**Investigation of expanded graphite nanoplatelet its properties and composites applied in EMI shielding.** *C. P. Chang; C. S. Tsai; J. W. Lu; C. Y. Huang*
T3-032	**Electrosedimentation thromboresistant polymeric coverings on purely iron electrode.** *S. H. Sargsyan; A. S. Sargsyan; K. S. Margaryan*
T3-033	**Temperature effects in the dynamics of bipolaron in polymer chains.** *J. F. Teixeira; W.F da Cunha; P.H.O. Neto; L. F. Roncaratti; R. Gargano; G. M. e Silva*
T3-034	**Excitons dissociation in semiconducting polymers PN junctions.** *W. F. da Cunha; P. H. O. Neto; L. F. Roncaratti; F. V. Moura; R. Gargano; G. M. e Silva*
T3-035	**Modification of linear low-density polyethylene in single-screw extruder.** *K. Ono; M. Yamaguchi*
T3-036	**PET modification using PLA and chitosan.** *D. Palma Ramírez, A. M. Torres Huerta, M. A. Domínguez Crespo, E. O. Bustamante*
T3-037	**Mechanical properties of postconsumer agave/polyethylene biocomposites.** *R. Jimenez Amezcua; I. Reyes Gonzalez; S. Garcia Enriquez; R. Gonzalez Nunez*
T3-038	**Study of conductivity of PANI compounds processed by extrusion and compression.** *J. Ruiz; B.Gonzalo; J. L.Vilas; J. M. Laza; L. M. León*
T3-039	**Rheological modeling of single-screw extruders.** *H. Hosseini; F. Aghazadeh*
T3-040	**Preparation of core-shell, organic-inorganic, hybrid latexes via a new single-step pickering emulsion polymerization method.** *A. Pakdel; H. Eslami; S. Pourmahdian*
T3-041	**Influence of crosslinker and stabilizer additives on the mechanical and the rheological properties of recycled plastic mixtures.** *J. Acosta García; C. Fonseca Valero; T. Aguinaco Castro; M. U. de la Orden; J. Martínez Urreaga; C. González Sánchez*
T3-042	**The effect of oil content on the grinding EPDM elastomers and on the structure of rubber powders** *D. V. Solomatin; O. P. Kuznetsova; E. V. Prut*
T3-043	**Characterization of induced thermo-mechanical degradation on poly (ethylene terephthalate).** *J. D. Badía; E. Strömberg; S. Karlsson; A. Ribes-Greus*
T3-044	**Influence of the multi-walled carbon nanotubes on morphology and material properties of PC/ABS nanocomposites obtained by extrusion.** *M. Wegrzyn; I. Buezas; E. Gimenez*

T3-045	**Effect of nano particles on mechanical properties of biodegradable LDPE/ starch/nanoclay composite.** *A. Oromiehie; P. Gusheh*
T3-046	**Antimicrobial gluten-gelatin films containing fatty-acids.** *F. Fakhouri; S .M. Martelli; A. Teixeira; F. Yamashita; L. H. Innocentini-Mei; F. P. Collares-Queiroz*
T3-047	**The development of a new co-polymer for immobilizing an optical Hg^{2+}-sensitive probe.** *F. J. Orriach-Fernández; A.L. Medina-Castillo; J.F. Fernández-Sánchez; A. Muñoz de la Peña; A. Fernández-Gutiérrez*
T3-048	**Study of structural features of fluorinated paraffins.** *V.M. Bouznik; Y. E. Vopilov; M. V. Doroshkevich; L. N. Ignatieva;M. D. Nivikova; M. A. Smirnov; V. P.Tarasov; A. N. Toropov; E .P. Kharitonova; A. V. Chernyak; G. Y. Yurko[1]*
T3-049	**Bioactive textile materials covered with polymers as continuous layers, microparticles or microcapsules.** *G. Mocanu; M. Nichifor; D. Mihai; L. C. Oproiu*
T3-050	**Rheology applied to the study of processing behaviour of PVC-PBA block copolymers.** *M. I. Calafel; B. Pascual; J. I. Conde; M. Boix; A. Santamaría; M. E. Muñoz*
T3-051	**Effects of reprocessing cycles on the structure and properties of polypropylene/cloisite 15A nanocomposites.** *S. Bruzaud; N. Touati; M. Kaci; Y. Grohens*
T3-052	**Obtaining porous polyimides with controlled pore size.** *E. Rangel-Rangel; E. M. Maya; J. de Abajo; A. E. Lozano; J. G. de la Campa*
T3-053	**Advanced polymeric composites for self-healing structural materials.** *M. Raimondo; R. Corvino; L. Guadagno; P. Longo; C. Naddeo; A. Mariconda*
T3-054	**Relationships between structures and physical properties of PVDF/MWNT composite.** *S. M. Hong; J. M. Koo*
T3-055	**Thermoplastic composites reinforced with keratin fibers.** *F. Giunco; L. Conzatti; P. Stagnaro; A. Aluigi; E. Marsano; M. Castellano; C. Marano*
T3-056	**Interfacial interactions in flax fibre/PLA biocomposite: from model surfaces to real fibres.** *E. Balnois; G. Raj; C. Baley; Y. Grohens*
T3-057	**Valorisation of maghnite-H^+ as a catalyst for the synthesis of various biodegradable polyesters and polyacetals.** *S. Bennabi; N. Sahli; M. Belbachir; C. H. Brachais; J. P. Couvercelle*
T3-059	**Thermal decomposition of PVC plastisol foams. Influence of the concentration of plasticizer.** *A. Marcilla; A. Zoller; M. I. Beltrán*
T3-060	**Waste recycling and public awareness "the case of plastic waste".** *A. R. Abay; M. Öksüz*
T3-061	**Thermal decomposition of PVC plastisol foams. Influence of the type of plasticizer.** *A. Marcilla; A. Zoller; M.I. Beltrán*
T3-062	**Monitoring of Recycled AAO Templates. An Exhaustive Characterization after Polymer Extraction.** *Iwona Blaszczyk-Lezak, Jon Maiz, Javier Sacristan, Carmen Mijangos*

TOPIC 4: Polymers for Advanced Applications Including Energy, Transport, Packaging and Environmentally Friendly Activities

T4-001	**Fluoropolymer dispersions: new environment-friendly products and technology.** *S. Musio; V. Kapeliouchko; T. Poggio*
T4-002	**Properties enhanced PU coating using (Desmodure Z 4470) as isocyanate and the different Desmophens as polyalcohols.** *A. Shokuhi Rad*
T4-003	**New epoxy thermosets obtained from DGEBA and hyperbranched polyesters having reactive/ unreactive chain ends using adipic dihydrazide as latent curing agent.** *Adrian Tomuta; Xavier Ramis; Francesc Ferrando; Àngels Serra*
T4-004	**Inhibition of the migration of low molecular weight moieties to rubber-polyurethane coating interface by incorporating filler.** *R. Torregrosa-Coque; J. M. Martin-Martinez;*
T4-005	**Epoxy polymers and composites for advanced applications.** *R. J. J. Williams*
T4-006	**Development of flexible temperature sensors - realization and characterization of multifilaments based on immiscible polymers loaded with carbon nanotubes.** *A. Cayla; C. Campagne; M. Rochery; E. Devaux*
T4-007	**New polytricyclnonenes and polytricyclononadienes: from monomer synthesis to polymer gas permeability.** *B. Bulgakov; M. V. Bermeshev; L. E. Starannikova; E. S. Finkelshtein*
T4-008	**Enhancement of epoxy thermosets by modification with commercially available hyperbrached poly(ethyleneimine)s (LUPASOLTM) as polymeric modifiers.** *X. Ramis; D. Santiago; X. Fernández-Francos; J. M. Salla; A. Cadenato; J. M. Morancho; À. Serra*
T4-009	**Preparation of L-arabinitol-based functional polyurethanes.** *C. Ferris; M. V. de Paz; F. Zamora; B. Begines; J. A. Galbis*
T4-010	**Thiol-ene coupling reactions: a new approach to functionalized polyurethanes.** *M. V. De Paz; C. Ferris; J. A. Galbis*
T4-011	**Biodegradable linear sulfur-containing polyurethanes derived from carbohydrates.** *B. Begines; F. Zamora; V. de Paz; C. Ferris; J. A. Galbis*
T4-012	**Sugar-based polyurethanes and polyureas.** *F. Zamora; B. Begines; I. Roffé; M. Mancera; J. A. Galbis*
T4-013	**Synthesis and properties of aromatic polyamides derived from isomeric biphenyldicarboxylic acids. theoretical study of the polycondensation reaction.** *G. Hernández; J. M. Pérez; F. García; Á. E. Lozano; J. G. de la Campa; J. de Abajo*
T4-014	**Silarylene –containing poly(amide)s based on 4-(4-((4-(4-aminophenoxy)phenyl)dimethylsilyl)phenoxy) benzenamine. Effect of dicarboxylic acid structure used.** *C. A. Terraza; L. H. Tagle; A. Tundidor; D. Coll*
T4-015	**Thermal rearrangement in poly(o-hydroxyimide)s. Isomeric effects on physical and gas separation properties.** *B. Comesaña; P. Cuadrado; C. Álvarez; A. Hernández; M. Calle; Y. M. Lee; J. G. de la Campa; J. de Abajo; A. E. Lozano*
T4-016	**Peculiarities of water emulsion copolymerization of tetrafluoroethylene with perfluoro(3,6-dioxa-4-methyl-7-octene)sulfonyl fluoride to obtain proton conducting copolymers.** *S. S. Ivanchev; V. S. Likhomanov; A. Y. Menshikova; O. N. Primachenko; S. Y. Khaikin*
T4-017	**Application of pulverized concrete cement powder as filler in PVC pipe.** *M. Natamai Subramanian; T. Arunachalam*
T4-018	**New copolymers of norbornene and vinyl monomers.** *D. S. Popov; V. I. Bykov; K. L. Makovetskii; M. V. Bermeshev; T. A. Butenko; E. S. Finkelshtein*

T4-019	**Macromolecular design of energetic tetrazole-containing olygomers and polymers.** *V. N. Kizhnyav; F. A. Pokatilov; L. I. Vereschagin; A. I. Smirnov*
T4-020	**The effect of fiber orientation on the thermal behavior of polypropylene fibers.** A. Parviz; F. Dadashian
T4-021	**Generation of conductivity through transfer charge properties in flourene and diphenylsilane-containing poly(ester)s and poly(amide)s.** *C. González-Herríquez; L. H. Tagle; C. A. Terraza; A. Barriga; A. Cabrera; U. Volkmann*
T4-023	**Barrier performance of gelatin coated pla films.** *M. Leobono; C. Frova; R. Zacur; D. Ercoli; G. Goizueta*
T4-024	**Polypropylene films of high oxygen and water vapor permeability for MAP applications.** *M. Acosta; D. Ercoli; G. Goizueta; J. Lozano; N. Capiati*
T4-025	**Studies on preparation and properties of novel photoluminescence hydrogels.** *W. F. Lee; H.H. Tsai*
T4-026	**Photovoltaic cell based on lead sulfide\conjugated polymer bilayer heterojunction.** *F. Mighri; J. Patel; A. Ajji*
T4-027	**Photoinduced electron transfer in an oligo-meta-phenylene ethynylene donor-bridge-acceptor complex.** *B. Bingöl; A. C. Durrell; A. J. Di Bilio; R. H. Grubbs; H. Gray*
T4-028	**Synthesis and photopolymerizations of new hydrolysis-stable dental monomers containing phosphonic acids.** *B. Akgün; D. Avci*
T4-029	**Nanocomposite membranes based on nafion and $TiSiO_4$ nanoparticle.** *Y. Devrim; N. Bac; I. Eroglu*
T4-030	**Effect of processing conditions on the performance of polymer-based materials for biomedical applications.** *J. S. Gonzalez; L. N. Ludueña; V. A. Alvarez*
T4-031	**Changing essential characteristics of poly(vinylalcohol) cryogels by thermal treatments.** *J. S. Gonzalez; V. A. Alvarez*
T4-032	**Highly-ordered nanoporous TiO_2 films with hierarchical order directed by self-assembly.** *W. Kim; S. Y. Choi; Y. C. Kim; S. H. Kim*
T4-033	**Synthesis of regioregular poly(3-hexylthiophene) with low polydispersity using zincate complex: toward a purification-free system.** *T. Higashihara; M. Ueda*
T4-034	**Improvement of mechanical properties of soy protein-based films.** *P. Guerrero; T. Garrido; S. Cabezudo; K. de la Caba*
T4-035	**Polyaniline–silver composites: oxidation of aniline with silver nitrate accelerated by p-phenylenediamine.** *P. Bober; M. Trchova; J. Stejskal*
T4-036	**Light triggered solutes release from covalent DNA gels.** *D. Costa; A. J. M. Valente; M. Miguel; B. Lindman*
T4-037	**Surface properties of cationic polyelectrolytes hydrophobically modified.** *H. E. Ríos; J. González; M. D. Urzúa*
T4-038	**Release of amoxicillin embedded in cellulose acetate-poly(vinyl pyrrolidone) fibers by coaxial electrospinning.** *M. M. Castillo-Ortega; A. L. Nájera-Luna; D. E. Rodriguez-Felix; F. Rodriguez-Felix; J. Romero-García; P. J.Herrera-Franco*
T4-039	**Effect of fatty acids on the functional properties of biofilms for packaging applications.** *P. Guerrero; I. Leceta; N. Gabilondo; K. de la Caba*
T4-040	**Block copolymers of polypyrrole with 4-vinylaniline modified cyclohexanone formaldehyde resin.** *E. Ates; N. Kızılcan*
T4-041	**Sustainable anaerobic adhesive technology development.** *D. Birkett*

T4-042	**Nanoporous membranes with controlled pore dimensions.** *Y. Gonzalez-Lemus; D. J. Broer*
T4-043	**Incorporation of bioactive molecules in polymer matrix for food packaging.** *C. Nguimjeu; M. Kurek; F Sadaka; L Tighzert; I Vroman; C-H Brachai;, J. P. Couvercelle*
T4-044	**Modeling migration of colored food compounds into thermoplastic polymers: application to food cooking in reusable polymer bags**. *S. Narses; N. Lautard; T. Fichu; F. Sadaka; C. H. Brachais; J. P. Couvercelle*
T4-045	**Poly lactic acid active packaging: migration of natural and synthetic antioxidants.** *M. Jamshidian; E. Arab-Tehrany; S. Desobry*
T4-047	**New polyester obtained from ethylketene.** *N. Hayki; N. Desilles; F. Burel*
T4-048	**Synthesis of cyclo-aliphatic polyamide precursors by polycondensation of diamines with ketene symetric dimers.** *N. Kébir; M. Ben Haddi; N. Hayki; F. Burel*
T4-049	**Self-assembling waves in nanocomposites on hydrophilic polymer base and their advanced applications.** *I. E. Suleimenov*
T4-050	**Effect of poly(amic acid)-treated $BaTiO_3$ on the dielectric and mechanical properties of $BaTiO_3$/polyimide composites.** *J. Kim*
T4-051	**New phenolic resins for advanced materials.** *G. Konishi*
T4-052	**Covalent attachment of cholesterol oxidase on transparent polyaniline film for cholesterol sensing.** *T. Del Castillo Castro; M. M. Castillo Ortega; A. Ortiz Rascón; E. F. Placencia Fontes*
T4-053	**Synthesis of new two-dimensional thiophene-based conjugated copolymers and their applications to thin film transistors and photovoltaic cells.** *H. W. Lin; J. H. Tsai; C. J. Lin; H. C. Wu; C. Lu; Y. W. Lin; Y. C. Lai; W. C. Chen*
T4-054	**Obtaining and stability of iodine-cationic starch complexes.** *R. Klimaviciute; J. Bendoraitiene; R. Rutkaite; A. Zemaitaitis*
T4-055	**Stabilization of liposomes by multilayer films of modified polysaccharides.** *A. Karewicz; D. Bielska; A. Socha; M. Nowakowska*
T4-056	**Polysaccharide coating of liposomes via layer-by-layer self-assembly as novel delivery system for proteins.** *S. Madrigal-Carballo; M. Esquivel; J. Vega-Baudrit; M. Sibaja; A. O. Vila*
T4-057	**Microparticles of the natural polymer chitosan in aqueous suspension: stability of particle size distribution.** *A. C. R. N. Barboza; F. B. T. Pessine*
T4-058	**Preparation and evaluation of novel absorptive and antibacterial polyurethane membranes for wound dressing application.** *A. Yari; H. Yeganeh; H. Bakhshi*
T4-059	**Swelling behavior of macroporous polymer networks.** *C. G. Gómez; G. Pastrana; D. Serrano; E. Zuzek; M. A. Villar; M. C. Strumia*
T4-060	**On the morphology of drawn UHMWPE gel films and PTFE extrudates.** *H. M. Shabana*
T4-062	**Nonvolatile memory transistors using ferroelectric p(VDF-TrFE) and printed semiconducting channel.** *S. W. Jung; K. J. Baek; S. M. Yoon; J. B. Koo; Y. S. Yang; K. D. Kim; I. K. You*
T4-063	**Drawing and tensile properties of polyamide 6 / calcium chloride composite fibers.** *J. T. Yeh; Y. C. Lai; H. P. Chen; L. Qiu; F. C. Tsai; C. Y. Yeh*
T4-064	**Drawing properties of modified polyamide 6 fibers.** *J. T. Yeh; F. C. Tsai; Z. W. Liu; D. R. Wu; Y. C. Lai; C. R. Yeh; K. H. Hsieh*

T4-065	**Ultradrawing properties of ultra-high molecular weight polyethylene/functionalized carbon nanotube fibers.** *J. T. Yeh; C. H. Tsou; Y. C. Lai; W. H. Wang; H. P. Zhou; C. Y. Yeh*
T4-066	**Investigation of argon plasma modification on peel strength of woven type ultra high molecular weight polyethylene.** *C. Y. Huang; J. T. Yeh; K. N. Chen; C. S. Tsai; S.K. Lin; K. Y. Tsao; J. Y. Wu; C. P. Chang*
T4-067	**Design and synthesis of low refractive index, organosoluble, and thermally stable fluorinated polyamides having *ortho*-linked aromatic units in the main chain.** *A. Javadi; A. Shockravi*
T4-068	**Multiple bicolor fluorescent micropattern formation on a single polymer film based on the polymeric photobase generator containing oxime-urethane and anthracene groups** *K. H. Chae; H. S. Kim*
T4-069	**Starburst triarylamine-containing electroactive aramids with ultra-stable near-infrared and multicolor electrochromism.** *G. S. Liou; H. J. Yen; H. Y. Lin*
T4-070	**Synthesis of copolymer based on polydimethylsiloxane and alkylamine.** *L. Leymarie; P. Chaumont; E. Fleury; N. Sintes*
T4-071	**Ion conducting solid electrolytes based on differents macromolecular architecture containing PEO.** *D. Glé; D. Devaux; T. Phan; R. Bouchet; M. Robinet; D. Bertin; D. Gigmes*
T4-072	**Block copolymers via macromercaptan initiated ring opening polymerization.** *D. Glé; C. Lefay; M. Rollet; D. Gigmes; D. Bertin; C. Schmid; C. Barner-Kowollik*
T4-073	**Batch anionic polymerization of octamethylcyclotetrasiloxane in emulsion using cationic and nonionic emulsifiers.** *I. Mohoriè; U. Šebenik;*
T4-074	**Kinetic study of aqueous free- radical polymerization of 2-acrylamido-2-methyl-1-propanesulfonic acid via on-line ^{1}H NMR technique.** *E. Nadim; H. Bouhendi; F. Ziaee; A. Nouri*
T4-075	**Continuous synthesis of polyesteramides via a reactive extrusion process.** *M. Gupta; F. Siegmund; X. Zhu; M. Möller; E. Haberstroh; M. Fijten*
T4-077	**Electromagnetic properties of polyaniline hybrid nanocomposite application to gas sensing and EMI shielding.** *N. El Kamchi; J. L. Wojkiewicz; N. Redon; T. Lasri*
T4-078	**Graft copolymers via ROMP and Diels–Alder click reaction strategy.** *N. Cerit; H. Durmaz; A. Dað; O. Sirkecioglu; G. Hizal; U. Tunca*
T4-079	**Branching polyethylenimine functionalized with methylbenzimidazole: an approach to enhance proton conductivity via multi-direction of heterocycles.** *A. Pangon; K. Tashiro; S. Chirachanchai*
T4-080	**Preparation and characterization of impregnated PVA/PSSA_MA/THS-PSA membranes into porous polyethylene membranes for fuel cell applications.** *C. J. Park; I. H. Kim; S. P. Kim; H. M. Lee; J. W. Rhim*
T4-081	**Dual 'stimuli' responsive hydrogel: effect of ionizable monomer on the swelling behavior.** *G. Roshan Deen; V. Chua; X. Jun Loh*
T4-082	**Copolymerization of 2,2-diallyl-1,1,3,3-tetraethylquanidiniumchloride with maleic and fumaric acides .** *M. Gorbunova*
T4-083	**Influence of microcrystalline cellulose on thermal properties of polypropylene composite nonwovens.** *K. Bujnicka; J. Kałużka*
T4-084	**Contact polymerization of the composition on the basis of acrylamide and formaldehyde on metal surfaces.** *L. Kolzunova; M. Karpenko*

T4-085	**Synthesis and characterization of poly(L-lactic acid) nanocomposites with vermiculite of different modification.** *I. Aranburu; M. D. Fernandez; M. J. Fernandez*
T4-086	**Upon the synthesis possibilities of 2 - hydroxyethyl methacrylate copolymer with a comonomer with spiroacetal moiety.** *A. P. Chiriac; L. E. Nita; M. T. Nistor*
T4-087	**The temperature influence upon the complexation process between poly(aspartic acid) and poly (ethylene glycol).** *L. E. Nita; A. P. Chiriac; M. Bercea; I. Neamtu*
T4-088	**Light-driven wettability changes on a photoresponsive electrospun mat.** *M. Chen; F. Besenbachor*
T4-089	**Polymeric nanocomposites produced from polypropylene and nanocellulose whiskers.** *H. A. Önen; N. Ucar; E. Bahar; M. Öksüz; Y. Wang; M. Ucar; O. Ayaz; A. Demir*
T4-090	**High molecular weight polymers for gas separation applications.** *L. Escorial; A. Tena; A. E. Lozano; J. de Abajo; A. Hernández; P. Prádanos; L. Palacio*
T4-091	**Synthesis of poly(o-acyloxyamide)s for gas separation applications.** *B. Díez; A. Marcos-Fernández; P. Cuadrado; A. Hernández; J. G. de la Campa; J. de Abajo; A. E. Lozano*
T4-092	**Design of experiment - versatile tool for structure-property relationship investigations.** *A. Buryak*
T4-093	**Synthesis and characterization of star-shaped conjugated systems with triphenylamine core for photovoltaic applications.** *N. Metri; X. Sallenave; C. Plesse; L. Beouch ; P.H. Aubert ; G. Sini ; F. Goubard ; C. Chevrot*
T4-094	**Functionalization of polystyrene surfaces.** *A. Del Prado Abellán; N. Briz; A. Gallardo; C. Elvira; H. Reinecke*
T4-096	**Enhancing the formation of the new trigonal polymorph in iPP-1-pentene copolymers.** *E. Perez; M. L. Cerrada; R. Benavente; J. M. Gomez-Elvira*
T4-097	**Persistence of order in liquid crystalline copolymers.** *V. Rodriguez-Amor; J. P. Fernandez-Blazquez; M. L. Cerrada; A. Bello; E. Perez*
T4-099	**Mineralization ability of HEMA-AMPSA copolymers incubated in simulated body fluid.** *P. Stanescu; C. Zaharia; C. Cincu; F. Miculescu*
T4-100	**Experimental investigation of crosslinkedpolymer formulation for drilling fluid approach to modified rheological properties in carbonate wells.** *T. Yousef; S. A Ahmad Ramazani*
T4-101	**Hybrid composites based on polypropylene (PP): mechanical properties of PP/talc composites reinforced with different calcium based inorganic fillers.** *M. Yazdani-Pedram; H. Aguilar; P. Toro; R. Quijada*
T4-102	**Hot melt poly-ε-caprolactone/poloxamine implantable blends that sustain the release of ciprofloxacin.** *A. M. Puga; C. Alvarez-Lorenzo; B. Magariños; A. Concheiro*
T4-103	**Monomers vs polymers of Cu(III) corroles on reduction of O_2.** *J. Velez; F. Isaac; M. J. Aguirre*
T4-105	**Electrical resistance behavior under strain of in situ polymerized polyaniline in swollen NBR.** *J. C. Encinas; M. M. Castillo Ortega; T. Del Castillo Castro; P. J. Herrera Franco*
T4-106	**Ultra-thin electronic nanocomposites of carbon nanotubes and self assembled block copolymers.** *C. Park; J. Sung; Y. S. Choi; S. H. Cho*
T4-107	**Polymer electrolyte membranes based on poly(phenylene ether)s with pendant perfluoroalkyl sulfonic acids.** *K. Nakabayashi; T. Hiagshihara; M. Ueda*
T4-108	**Study of the new functionalized dimethacrylate copolymers for biochemical applications.** *B. Podkoscielna; B. Gawdzik; A. Bartnicki*
T4-109	**Rheologhical properties of poly (acryl amide with 2-acrylamido-2-methy-1-propane sulphonic acid) microgel via precipitation polymerization..** *M. Fathollahi; H. Bouhendi; M. J. Zohurian-Mehr; K. Kabiri; S. Roostamizadeh*

T4-110	**A feasible route to disperse bacterial cellulose nanowhiskers in polymers by melt compounding of interest in packaging applications and physical characterization of the optimized nanocomposites.** *M. Martinez-Sanz; A. Lopez-Rubio; J. M. Lagaron*
T4-111	**Synthesis of novel oligoimides and their applications to non-volatile memory.** *T. Kurosawa; W. Y. Lee; T. Higashihara; M. Ueda; W. C. Cheng*
T4-112	**Click chemical modifications of PVC surfaces for antibacterial applications.** *J. Lafarge; N. Kebir; F. Burel*
T4-114	**Sensory coumarin-containing polymers.** *S. Vallejos; P. Estévez; H. El Kaoutit; M. Trigo; F. Serna; F. García; J.L. Peña; J.M. García*
T4-115	**High performance gas separation membranes with aging and plasticization resistance.** *A. Tena; A. E. Lozano; A. A. Marcos-Fernández; J. G. de la Campa; J. de Abajo; L. Palacio; P. Prádanos; A.Hernández*
T4-116	**Gas separation membranes derived from rigid, high-free-volume, fluorinated polyimides.** *M. Juan y Seva; C. Álvarez; Á. E. Lozano; J. de Abajo; J. G. de la Campa*
T4-117	**Direct patterning of regioregular poly(3-hexylthiophene).** *Y. Saito; T. Higashihara; M. Ueda*
T4-118	**Asymmetric porous membranes from PEG modified aromatic polyamides.** *S. Molina; A. Martínez-Gómez; Á. E. Lozano; J. G. de la Campa; J. de Abajo*
T4-120	**Photophysical properties of some copoly(1,3,4-oxadiazole-ether)s.** *A. Airinei; R. I. Tigoianu; M. Homocianu; C. Hamciuc; E. Hamciuc*
T4-121	**Spectral-luminescent properties of polyurethanesiloxane polymers doped by Rhodamine 6G.** *A. I. Akhmetshina; I. M. Davletbaeva; A. M. Gumerov; T. N. Kopylova; L. G. Samsonova*
T4-122	**Acrylates block copolymers with N-trityl-L-serine methyl ester and pyrene prepared by ATRP.** *E. C. Buruiana; V. Podasca; T. Buruiana*
T4-123	**Hybrid composites based on photopolymerizable urethane dimethacrylates and silver nanoparticles.** *T. Buruiana; V. Melinte; F. Jitaru;; L. Balan; E. C. Buruiana*
T4-124	**Organic-inorganic gels for heterochain polymers modification.** *O. R. Gumerova; R. S. Davletbaev*
T4-125	**Novel polymetacrylamides containing a triazole moiety. Application to the extraction/elimination of metal cations from aqueous media.** *M. Trigo; A. Gómez; P. Estévez; S. Vallejos; H. El Kaoutit; F. Serna; F. García; J. L. de la Peña; J. M. García*
T4-126	**Polyurethanes based on sterically hindered esters of boric acid.** *O. Y. Emelina; R. S. Davletbaeva*
T4-127	**Epoxy polymers for medical applications. In vitro biological properties.** *F. Gonzalez Garcia; M. E. Leyva; A. A. Alencar de Queiroz; O. Z. Higa*
T4-128	**Polymer chemosensoring materials with crown-ether derivatives for advanced application in environmental monitoring.** *D. O. Soloveva; I. S. Zaitsev; M. S. Tsarkova; A. N. Timonin; S. Y. Zaitsev; S. K. Sazonov; A .I. Vedernikov; S. P. Gromov*
T4-129	**Gradient in viscoelastic properties of polymers to control adhesion.** *F. Tanguy; R. Even; I. Uhl; A. Lindner; C. Creton*
T4-130	**Comparative study for tin and zinc catalysts for lactide polymerization.** *J. Wojtaszak; J. Ejfler; I. Czeluœniak*
T4-131	**Magnesium catalysts design for ring-opening polymerization of lactides.** *J. Ejfler; S. Szafert; K. Mierzwicki; P. Sobota*
T4-132	**Fluorene-derivative containing polymers as sensory materials for the colorimetric and fluorogenic sensing of analytes.** *H. EL Kaoutit; P. Estévez; S. Vallejos; M. Trigo-López; F. C. García; F. Serna; J. L. de la Peña; J. M. García*
T4-133	**Study of surface energy of polypropylene films treated by corona at ambient temperature and above.** *H. C. de Sena; J. S. C. Campos*

T4-134	**Background and new opportunities with the aromatic thermosetting copolyesters.** *Z. Parkar; J. Economy*
T4-136	**Effect of acrylic copolymer dispersants bearing epoxy groups on dielectric properties of carbon black-filled epoxy system.** *B. T. Son; J. Y. Bae*
T4-137	**Synthesis and characterization of novel graphited polythiophene.** *A. Takahashi; K. Ohshimizu; T. Higashihara; M. Ueda*
T4-139	**Synthesis and characterization of thianthrene-based poly(phenylene sulfide)s with very high refractive index over 1.8.** *Y. Suzuki; K. Murakami; S. Ando; T. Higashihara; M. Ueda*
T4-140	**Surface and foam characteristics of PPG-b-PDMS-b-PPG tri-block copolymer as an anti-foaming agent.** *B. Kekevý; H. Berber; H. Yıldırım*
T4-141	**Synthesis of water-soluble polyamide dendrimers for DNA sensors.** *Y. Ito; C. Y. Chen; T. Higashihara; W. C. Chen; M. Ueda*
T4-142	**Synthesis and characterization of polyurethane-based shape memory polymers with low transitional temperature for medical applications.** *M. Ahmad; J. K. Luo; B. Xu; H. Purnawali; P. J. King; P. Chalker; Y. Q. F;, W. M. Huang; M. Miraftab*
T4-143	**Amphiphilic multiarm star block copolymer via Diels-Alder click reaction.** *N. Cakir; A. Dag; H. Durmaz; G. Hizal; U. Tunca*
T4-144	**Synthesis and characterization of biodegradable polyester resins.** *S. Theiler; H. Keul; M. Möller*
T4-145	**MWCNT- epoxy composite- electrodes for environmentally friendly detection of pharmaceutical compounds.** *A. Remes; F. Manea; A. Pop; N. K. K. Kowlgi; S. J. Picken; J. Schoonman*
T4-146	**Electrospun nanofibers of a biodegradable poly(ester amide). Scaffolds loaded with antimicrobial agents.** *A. Rodriguez-Galán; M. Roa; A. Díaz; J. Puiggalí; L. J. del Valle*
T4-147	**Surface modification of titanium dioxide by a modified emulsion/dispersion polymerization with an aid of ultrasonication.** *A. J. Ho; M. J. Kim*
T4-148	**The sulfobetaine-type surfactants applied for Nafion 212 on PEMFC.** *T. H. Chiang; Y. M. Hsieh; L.M. Chen*
T4-149	**Semiconducting properties of irradiated polyethylene sheets.** *F. Latif; M. H. Yaakob; R. Mohamed; K. Z. Mohd Dahlan*
T4-151	**Thermal conductivity of plastic materials in embedded electronics applications.** *J. Sarlin; M. Koponen; A. Sitomaniemi*
T4-152	**Modification of polysulfones by click chemistry: amphiphilic graft copolymers and their protein adsorption and cell adhesion propertie.** *L. Torun; G. Yilmaz; H. Toiserkani; D. Odaci Demirkol; S. Sakarya; S. Timur; Y. Yagci*
T4-154	**Chalcone Modified Urethane Acrylates.** *H. A. Önen; B. Güler; I. E. Serhatlý*
T4-155	**Usage of grafted chitosan beads as adsorbents for copper(II) ions removal from aqueous solutions.** *A. Bal; B. Ozkahraman; I. Acar; G. Guclu; M. Özyürek*
T4-156	**Effect of glass fiber and glass beads content on mechanical and tribological properties of polyamide-6.** *A. Mimaroglu; H. Unal*
T4-157	**The Influence of Nature of Nickel Complexes and Halide-Containing Initiators on the Polymerization of Vinyl Monomers** *Natalya Valetova, Galina Malysheva, Ilya Ilitchev, and Dmitry Grishin*
T4-158	**First linear-soluble poly (p-phenylenemethylene) via boron ester of benzyl alcohol.** *D. Gunes; Y. Yagci; N. Bicak*
T4-159	**Block-brush copolymers via romp and sequential double click reaction strategy.** *A. Dag; H. Sahin; H. Durmaz; G. Hizal; U. Tunca*

T4-160	**New mixed matrix composite membranes made from polymers able to undergo thermal rearrangement processes. Gas separation study.** *B. Bayón Alonso; L. Escorial López; Á. E. Lozano; Y. M. Lee; P. Prádanos; A. Hernández; L. Palacio*
T4-161	**Effects of types and amounts of plasticizer on the curing kinetics of unsaturated polyester.** *Z. Dogruyol; M. A. Kaya; S. Keskin Dogruyol; H. Yildirim; N. Arsu*
T4-162	**Use of waste polymer as thickener agent in lubricating greases.** *J. E. Martín Alfonso; C. Valencia; M. Sánchez; J. Franco; C. Gallegos*
T4-163	**Thermal properties of polymer composites containing ultrasonicated cellulose.** *D. M. Panaitescu; A. N. Frone; C. I. Spataru; D. Donescu; P. Stanescu; M. D. Iorga*
T4-164	**Application of microencapsulated phase change materials to improve thermo-regulating properties of textiles.** *L. Sanchez-Silva; J. F. Rodriguez; P. Sanchez; A. M. Borreguero*
T4-165	**Removal of crystal violet from aqueous solution by thermosensitive hydrogels: Investigation the effect of hydrophilic comonomer amount.** *B. Ozkahraman; I. Acar; S. Emik*
T4-166	**The synthesis and physico-chemical properties of dextran phosphates.** *M. Zhyhala; N. Yurkshtovich; N. Golub; V. Alinovskaya; T. Yurkshtovich; R. Kosterova*
T4-167	**New branched oligophenylenefluorenes for luminescent applications.** *I. Khotina; A. Kovalev; A. Shapovalov; N. Kushakova*
T4-168	**Synthesis, morphological characterization and antimicrobial application of nanostructured membranes of cellulose acetate.** *S. Nista; K. Segala; L. Cordi; O. Bagnato; N. Duran; L. Lona; L. Mei*
T4-169	**Synthesis and characterization of silicon containing membranes for PEM fuel cells.** *M. A. Kaya; H. Yildirim*
T4-170	**Optical and transport properties of poly(thiophene-3-ylacetic acid) and its sodium salt.** *J. Cerar; D. Bondarev; P. Nachtigall; J. Vohlidal; V. Vlachy*
T4-171	**Influence of type of methacrylic esters on properties of acrylic core/shell dispersions.** *K. Burja; E. Žagar; S. Skale*
T4-172	**Synthesis and self-assembly of block copolymers bearing o-nitrobenzyl side groups.** *O. Bertrand; J. Schumers; C. Fustin; J. Gohy*
T4-173	**Zinc metal as catalyst for direct grafting of vinyl acetate from PVC.** *G. Cankaya; N. Bicak*
T4-174	**Development of stimuli-responsive polymers for liposome based drug delivery systems.** *P. Alves; J. Coelho; H. Gil; P. Simões*
T4-175	**Rapid removal of copper from ATRP mixtures by chemical reduction with wetted zinc powder.** *F. Canturk; N. Býçak; B. Karagoz*
T4-176	**Solid supported benzoquinone as a click component for facile immobilization of amino acids and proteins.** *K. Yuksel; G. Cankaya; O. Sirkecioglu; N. Bicak*
T4-177	**Preparation and characterization of a polyetherimide/polyaniline composite.** *E. M. Alexandrino; M. I. Felisberti*
T4-178	**Cationic homo and copolymerization of indene and other olefins.** *F. J. Bento Brum; M. M. C. Forte; F. N. Laux*
T4-179	**Poly(ethylene imine) tedhered microspheres for selective extraction of aldehydes from organic mixtures.** *B. Gure; D. Gunes; B. Karagoz; N. Bicak*
T4-180	**Sulfonated polystyrene brushes tethered to PS-DVB microspheres as new generation of ion exchange polymers.** *O. Ozer; A. Ince; N. Bicak*
T4-181	**Butyl sulfonium sulfate as cationic initiator for synthesis of poly(cyclohexeneoxide)-b- poly(2-methyl-2-oxazoline) copolymers.** *C. Elci; O. Sirkecioglu; N. Bicak*
T4-182	**Modeling of precipitation co-polymerization of water-soluble polymers in organic solvent.** *R. Mazarro; P. Arosio; G. Storti; M. Morbidelli*

T4-183	**Ultrafast relaxation dynamics of exciton in poly-p-phenylenevinylene oligomers.** *F. Moura; P. Neto; W. Cunha; L. Roncaratti; R. Gargano; G. Silva*
T4-184	**Corrosion and adhesion study of hybrid coatings on 3l6l stainless steel.** *D. del Angel; M. Dominguez; A. Torrres; A. Flores*
T4-185	**Enhancement on redox-stability and electrochromic performance of aromatic polyamides incorporating 3,6-dimethoxycarbazolyl-substituted triphenylamine units.** *S. Hsiao; H. Wang*
T4-186	**Synthesis and properties of novel triptycene-based polyimides.** *S. Hsiao; H. Wang*
T4-187	**Preparation of conducting polypyrrole/polytetramethylene ether (ptme) composites.** *W. M. De Azevedo; J. Batista; E. H. L. Falcão*
T4-189	**Synthesis of new membrane of fuel cells based on sulfonated block copolyimide.** *M. Oroujzadeh; S. Mehdipour-Ataei*
T4-190	**Functional polyHIPE materials for metal adsorption.** *E. H. Mert; M. A. Kaya; H. Yýldýrým*
T4-191	**Development of gel-like dispersions for bio-lubricant applications using castor oil and different cellulose pulp samples.** *N. Nuñez; J. E. Martín-Alfonso; J. M. Franco; C. Valencia; M. J. Díaz; C. Gallegos*
T4-192	**Modification of high ortho novolac: a novel si/acrylate modified resin and its surface coating properties.** *S. Emik; T. B. Ýyim; S. Özgümüþ*
T4-193	**Polyynic benzoxazines. Synthesis and polymerization.** *S. Szafert; N. Gulia*
T4-194	**Investigation long-chain and short chain crosslinkers on microgel networkd with precipitation polymerization method.** *H. Es-Haghi; H. Bouhendi; g. Bagheri marandi; M. J. Zohurian-Mehr; K. Kabiri*
T4-195	**Synthesis and characterization of hybrid acrylic copolymers with and without (isobutyl)propylmethacrylate polysilsesquioxane (POSS).** *A. Carvalho; E. Veludo; J. Machado; M. H. Gil*
T4-196	**Synthesis, characterization and applications of *N*-vinyl pyrrolidone and itaconic acid based hydrogels.** *I. Acar; M. Evren; G. Güçlü; K. Güçlü*
T4-197	**Removal of cationic dyes from aqueous solution by *N*-vinyl pyrrolidone and crotonic acid based hydrogels.** *I. Acar; M. Akar; G. Güçlü*
T4-198	**Biodegradable thermo-sensitive polyurethane-based foams for tissue engineering.** *J. Girones; J. A. Mendez; J. San Roman*
T4-199	**Development of green coatings made from biopolymers for environmental friendly packaging.** *B. Rullier; J. Bonino; M. Menu; M. Gressier; F. Ansart*
T4-200	**Post-curing of photo-polymeric dental composites - effects on mechanical and dielectrical performance.** *J. Steinhaus; B. Moeginger; D. Lyssek; B. Hausnerova*
T4-201	**Hybrid chitosan-hydrolised collagen films for burn injuries. A preliminary study.** *E. Franco-Marquès; J. A. Méndez; J. Gironès; M. A. Pèlach*
T4-202	**Preparation of poly (norbornene) and poly-(dicyclopentadiene-co-norbornene) polyHIPEs.** *S. Kovacic; P. Krajnc; C. Slugovc*
T4-203	**Influence of different cross-linking mechanisms on the material properties of a silicone-based TPA-functional polymer for optical waveguides.** *S. Feldbacher; R. Woods; S. Bichler; V. Satzinger; V. Schmidt; G. Jakopic; G. Langer; W. Kern*
T4-204	**Supramolecular block copolymers: synthesis and investigation of the crystallization behavior.** *E. Ostas; K. Schröter; T. Thomas Thurn-Albrecht; G. K. Gupta; I. Gunkel; M. Beiner; W. Binder*
T4-205	**New thio-click hyperbranched polymers as macroinititators for the dual curing of cycloaliphatic epoxy resins.** *D. Foix; X. Ramis; À. Serra; M. Sangermano*

T4-206	**Synthesis of new methacrylates bearing phosphonic acid groups for an application in dental materials.** *Y. Catel; U. Fischer; N. Moszner*
T4-207	**Resonance effect on conductivity of poly(esters)s containing silarylene and thiophene moieties after polarized by application of an external field.** *C. González-Henríquez; L. H. Tagle; C. A. Terraza; A. Cañete; A. Leiva; A. Barriga; U. Volkmann; A. Cabrera; E. Ramos; M. Pavez*
T4-208	**Poly(amide-imide)s containing silarylene and L-aminoacid moieties. Relation with electrical conductivity and raman active vibrations.** *C. González-Henríquez; L. H. Tagle; C. A. Terraza; A. Barriga; U. Volkmann; A. Cabrera; E. Ramos; M. Pavez*
T4-209	**Synthesis, characterization and thermal studies of halogenated poly(imide-diamides) containing silicon in the main chain.** *L. H. Tagle; C. A. Terraza; D. Coll; A. Tundidor-Camba; A. Leiva*
T4-210	**Inclusion of cytidine in nanoparticles as a model for HIV drugs.** *J. P. Fuenzalida Werner; I. Moreno Villoslada; F. Goycoolea; H. Nishide*
T4-211	**Thioxanthone containing novel dendritic photoinitiators.** *T. Parali; Z. Dogruyol; G. Temel; N. Arsu; M. Tulu*
T4-212	**Characterization, melting and crystalline properties of isotactic (4,2)-enchained poly(1-butene) .** *C. Ruiz-Orta; R. G. Alamo*
T4-213	**Synthesis and properties of a self-doped polyacetylenes via the activated polymerization of ethynylpyridines by the ring cleavage reaction of cyclic compounds.** *Y. Gal; S. Jin; J. Park; W. S. Lyoo; K. T. Lim*
T4-214	**Porous polymer surfaces with superhydrophobic/superhydrophilic micropatterns: towards genome-on-a-chip cell microarrays.** *F. Geyer; U. Liebel; E. Ueda; P. Levkin*
T4-215	**Photoelectrochemical properties of doped polyaniline: application to hydrogen production upon visible light.** *Z. Benabdelghani; G. Rekhila; M. Trari; A. Etxeberria*
T4-216	**Poly(2-isopropenyl-2-oxazoline): hydrogel formation and potential applications.** *V. Schenk; L. Ellmaier; F. Wiesbrock*
T4-217	**Ionic liquid based membranes: water sorption properties.** *K. Fatyeyeva; S. Rogalskyy; O. Tarasyuk; S. Marais*
T4-218	**Thermophysical, electrical and mechanical properties of ethylene-vinylacetate copolymer (EVA) filled with wollastonite fibers coated by silver.** *I. Krupa; V. Cecen; R. Tlili; A. Boudenne; L. Ibos; J. Prokes*
T4-219	**Synthesis of functionalised polymer microspheres with ultra-high specific surface areas and their applications in selective chemical extractions.** *P. A. Cormack; A. Davies; N. Fontanals*
T4-220	**Synthesis and in vitro biocompatibility of copolymers, telomers, and hydrogels of polyvinylpyrrolidone with sulphonic and carboxylate groups.** *M. Gomez; C. Elvira; Y. Rochev; H. Reinecke; A. Gallardo*
T4-221	**Addition of polymer to viscoelastic solutions of living micellar chains.** *V. Pletneva; V. Molchanov; O. Philippova*
T4-222	**Copolymerization of monomer systems based on *N*-vinylpyrrolidonefor advanced applications.** *D. Soloveva; V. Zaitseva; A. Shtonda; T. Tyurina; I. Opeia; S. Z. Yu*
T4-223	**A Study of cationic polymerization of 1-(2-hydroxyethyl)aziridine.** *A. Sakalyte; M. Giamberini; J. A. Reina*
T4-224	**Homeotropic alignments of nematic liquid crystals on polar substrates.** *K. Song; Y. J. Kim; M. Lee*
T4-225	**Surface properties of silica modified by silane with polybutadiene oligomer tail.** *M. Castellano; A. Turturro; A. Bertora; E. Marsano; L. Conzatti; G. Colucci*

T4-226	**Reinforcement of SBR with silica modified by silane with polybutadiene oligomer tail.** *M. Castellano; A. Turturro; E. Marsano; A. Bertora; P. Stagnaro*
T4-227	**Modulation of the charge carrier transport in conjugated polymers by means of polar additives.** *P. Toman; W. Bartkowiak; J. Pfleger*
T4-228	**Thermal and mechanical properties of flexible bioplastics based on modified starch and gelatin.** *F. Fakhouri; R. Cardoso; D. Costa; F. Yamashita; L. H. Innocentini-Mei; F. P. Collares-Queiroz*
T4-229	**Desarrollo de una espuma polimérica atóxica con propiedades de resilencia.** *J. Heba; C. García; L. Warcok; M. F. Gómez; M. Calatayud; O. Ferré*
T4-230	**Thermoplastic elastomers based on graft copolymers.** *G. Tuzcu; M. van Duin; B. Klumperman*
T4-232	**Fluorescent labeling of calcium alginate beads with rhodamine 6G assisted by polyaromatic-anion.** *E. Araya-Hermosilla; I. Moreno-Villoslada; F. Oyarzun-Ampuero; S. Orellana; A. Yañez; H. Silva*
T4-233	**Structure, morphology and transport properties of nanocomposites films prepared from starch, montmorillonite and silver nitrate.** *F. Gouanve; M. Meyer; E. Espuche*
T4-234	**Design of novel, fluorescent-tuneable, pH-sensing, water-insoluble, lineal copolymers synthesized by ATRP and its application in the development of pH-sensing nanofibres made by electrospinning.** *A. L. Medina Castillo; J. F. Fernández Sánchez; A. Fernández Gutierrez*
T4-235	**Block copolymer surfactants in emulsion polymerization: the influence of the miscibility of the hydropho block on kinetics, particle morphology and film formation.** *A. Muñoz-Bonilla; S. I. Ali; A. del Campo; M. Fernández-García; A. M. van Herk; J. P. Heuts*
T4-236	**Side-chain liquid-crystalline copolyethers with tapered mesogenics groups.** *S. Bhosale; J. A. Reina; M. Giamberini; M. Rasool*
T4-237	**Hybrid electrospun fibres showing spin-crossover properties.** *D. Lopez; G. Mitchell; M. Rubio; A. Roig*
T4-238	**Dissolution modeling of smart nano-scale coated polymer particles in polymer flooding process.** *A. Ramazani; M. Ashrafizade; S. Sadeghnejad*
T4-239	**Nanoclay composite barrier coating for plastic substrate of flexible display .** *S. S. Kim; H. Ra*
T4-241	**New phenol functionalized polyamides: a new polymer family for multiple applications.** *S. Jeol; F. Touraud; C. Corriol; J. Marchand*
T4-242	**Optical CO_2-sensing film for clinical applications based on a fluorescent pH-sensitive and water-insoluble lineal copolymer.** *P. Contreras-Gutierrez; A. Medina-Castillo; J. Fernandez-Sanchez; A. Fernandez-Gutierrez*
T4-243	**Properties of conductive layers printed by ink-jet printing.** *M. Rom; J. Janicki; S. Przybylo; E. Sarna; R. Fryczkowski*
T4-244	**Polymethacrylamides´s synthesis. Dendronized polymers.** *N. Alvarado; D. Radic*
T4-245	**Zinc dithiocarbimates as accelerators for natural rubber vulcanization.** *L. M. Cunha; M. M. Rubinger; M. R. Oliveira; L. L. Visconte*
T4-246	**Characterization of gas-barrier coated polyethersulfone substrate for flexible display application.** *Y. Ahn; M. Kim; S. Paek; Y. C. Kim*
T4-247	**Aromatic polyimides containing methyl substituents and study of their physical properties.** *S. Chisca; I. Sava; V. Musteata; M. Bruma*
T4-248	**Synthesis and photophysical properties of donor-acceptor block copolymers.** *E. Bicciocchi; M. Chen; E. Rizzardo; K. Ghiggino*
T4-249	**New highly thermostable phthalonitrile-containing aromatic polyamides and poly(amide imide)s for high performance applications.** *I. Carja; C. Hamciuc; E. Hamciuc; T. Vlad-Bubulac*
T4-250	**Polyaniline synthesis using fenton reagent: effect of substitution of aniline.** *M. Blaha; J. Zednik; J. Svoboda; J. Vohlidal*

T4-251	**UV cured acrylic membranes reinforced by cellulose microfibrils for lithium batteries.** *A. Chiappone; R. Bongiovanni; J. Nair; C. Gerbaldi; E. Zeno*
T4-252	**Photoinduced surface relief gratings of azopolymers with rigid and flexible chains.** *I. Sava; N. Hurduc; L. Sacarescu; V. Damian*
T4-253	**Heterocyclic polynaphthaleneimides containing siloxane groups in the main chain.** *R. Rusu; M. Damaceanu; M. Bruma*
T4-254	**Study on the crystallization of poly(nonamethylene azelate) and its copolymers incorporating pimelate moeities .** *A. Díaz; L. Franco; R. Díaz; M. T. Casas; J. Puiggalí*
T4-255	**Combination of ionic and covalent cross-links on elastomeric ionomers: Effect on the structure-properties relationship.** *M. Alonso Malmierca; L. Ibarra; A. Rodríguez; I. Mora-Barrantes; J. López Valentín*
T4-256	**Preparation of HDPE/MMTHDTMA/PVA nanocomposites: morphology, structure and mechanical properties.** *M. Carrera; E. Erdmann; H. Destéfanis; J. Pastor Barajas*
T4-257	**Nitrate remove from drinking water using polymer/MWCNTs nanocomposites.** *N. Mousavi Rad; R. Sedghi; R. Sharifi; M. Reza Nabid*
T4-258	**Influence of the swelling behavior on the electrochemistry of redox hydrogel gels.** *G. Osterwinter; C. Bunte; O. Prucker; J. Rühe*
T4-259	**Non aqueous polyHIPEs as novel polymer separators for lithium ion batteries.** *N. Shirshova; E. Kot; A. Bismarck; J. H. Steinke*
T4-260	**Natural antioxidants for polymer.** *A. Masek; A. Kosmalska; M. Zaborski*
T4-261	**Polymers silver electrodes plating.** *J. S. Campos; E. H. Geraldo*
T4-262	**Synthesis and characterization of a ionic polymers derived from disubstituted acetylenes.** *R. Sivkova; D. Bondarev; J. Zedník; J. Sedlaček; J. Vohlídal*
T4-263	**Polyacetylenes with cyclopropyl pendant groups: precursors for polyacetylene-based polymer networks.** *V. Hanková; E. Slováková; J. Zedník; J. Vohlídal; J. Sedláèek*
T4-264	**The studies of polymer nanocomposites based on thermoplastics and binary conductive nanofillers.** *E. Beyou; V. Levchenko; Y. Mamunya; G. Boiteux; P. Alcouffe; E. Lebedev*
T4-265	**Synthesis and complexation properties of terpyridine derivatives: building of supramolecular polymers .** *T. Vitvarova; J. Zednik; P. Stenclova; J. Vohlidal; J. Svoboda*
T4-266	**Study on the copolymerization of potassium chloroacetate and potassium n-chloroacetyl-6-aminohexanoate.** *S. Murase; A. Rodríguez-Galán; L. Franco; J. Puiggalí*
T4-267	**Solvent-free aqueous polyurethane dispersions.** *I. Fernandes; M. Barreiro; M. R. Costa*
T4-268	**Thermoresponsive polyether-grafted hyaluronan: synthesis and reversible gelation behavior.** *J. Areguian; R. Auzely-Velty*
T4-269	**Electrochemical response of host-guest assemblies of polysaccharides immobilized on surfaces.** *J. Mergy; G. Dubacheva; P. Labbé; L. Guérente; R. Auzély-Velty*
T4-270	**Semiconducting materials based on block and graft copolymers having donor and acceptor functionalities for molecular electronics.** *J. Kallitsis; S. Kourkouli; A. Stefopoulos; A. Andreopoulou; A. Siokou*
T4-271	**Study on adsorbing chromium (VI) into hyperbranched copolymers from aqueous solution.** *M. Luzón; T. Corrales; C. Peinado; V. San Miguel; F. Catalina*
T4-272	**Synthesis and characterization of a molecularly imprinted polymer optosensor for TEXs-screening in drinking.** *F. J. Sainz-Gonzalo; A. L. Medina-Castillo; J. F. Fernández-Sánchez; A. Fernández-Gutiérrez*
T4-273	**Synthesis and properties of aromatic poly(disubstituted acetylene)s.** *J. Zednik; Z. Duchoslavova; J. Svoboda; J. Sedlacek; V. Hankova; D. Vrbata; J. Vohlidal; R. Sivkova*

T4-274	**Composite polymer materials for stabilization of washing liquid of oil and gas wells.** *S. Negmatov; K. Negmatova; B. Sobirov; S. Isakov; H. Qobilov; M. Negmatova; J. Haydarov*
T4-275	**Developing of antifriction wear-resistant polymer composite materials and products from them for working bodies of facilities of mechanization of the cotton industry.** *N. Abed-Negmatova; D. Musabekov; G. Gulyamov; S. Negmatov; M. Negmatova; S. Kodirov; B. Sobirov*
T4-276	**Developing of wood polymer composite materials and sliding bearing for cotton machines and mechanisms.** *D. Musabekov; N. Abed-Negmatov; G. Gulyamov; S. Negmatov; A. Shernaev; S. Kodirov; B. Sobirov*
T4-277	**Polymer reagents for stabilization of drilling mud, used in the process of drilling of oil wells.** *K. Negmatova; G. Sharifov; S. Isakov; S. Negmatov; B. Sobirov; K. Rahimov*
T4-278	**Atom transfer radical polymerization of polymerization of MMA and styrene initiated by 3,5-bis(perfluorobenzyloxy)benzyl 2-bromopropanoate.** *T. Cakir Canak; M. Selcukoglu; E. Hamuryudan; I. E. Serhatli;*
T4-279	**Release behavior of biodegradable polyesters reinforced with triclosan loaded polylactide micro/nanofibers.** *L. J. Del Valle; A. Díaz; M. Royo; A. Rodríguez-Galán; J. Puiggalí*
T4-280	**Adhesive properties of low tg polymers bearing hydrogen bonding moieties.** *S. Pensec; J. Courtois; H. Wang; C. Fonteneau; G. Ducouret; L. Bouteiller; C. Creton*
T4-281	**Preparation of cationic polymer brushes on silicon wafer surface via RAFT polymerization.** *S. Demirci; T. Çaykara*
T4-282	**Engineering of magnetic poly(ε-caprolactone) nanomedicines against arthritis.** *E. Saez-Fernandez; V. Gallardo; M. A. Ruiz; A. V. Delgado; J. L. Arias*
T4-283	**Development of a poly(ε-caprolactone)-based magnetic biodegradable nanoplatform against cancer.** *E. Saez-Fernandez; V. Gallardo; M. A. Ruiz; A. V. Delgado; J. L. Arias*
T4-284	**Fabrication of pH responsive copolymer brushes on silicon wafer surface via reversible addition-fragmentation chain transfer polymerization.** *S. Kýnalý Demirci; S. Demirci; T. Çaykara*
T4-285	**Microencapsulation of butyl stearate with melamine-formaldehyde resin: Effect of decreasing pH value on composition and thermal stability of microcapsules.** *B. Ališ; U. Šebenik; M. Krajnc*
T4-286	**Polymerization of octamethylcyclotetrasiloxane in a microtube reactor with liquid-liquid slug flow pattern.** *E. Šinkovec; M. Krajnc*
T4-287	**Conductive polymer composites obtained from urea–formaldehyde resin and copper powder.** *G. Pinto; A. Maaroufi; R. Benavente; J. M. Pereña*
T4-288	**Ruthenium olefin metathesis initiators bearing one or two N_2O chelating coligands in the triggered polymerization of DCPD.** *J. Wappel; C. Slugovc*
T4-289	**Biocide finishing of poly(isoprene) by thiol-ene click chemistry.** *J. Kienberger; N. Noormofidi; C. Slugovc*
T4-290	**From emulsion templating of poly(cyclooctene) towards elastic, porous monolithic materials.** *F. Preishuber-Pfluegl; C. Slugovc; P. Krajnc*
T4-291	**Water-soluble polymers prepared by Ring opening metathesis polymerization.** *K. Gallas; T. Wrodnigg; C. Slugovc*
T4-292	**Thermal studies of interpenetrating methacrylate/epoxy resins.** *N. M. Florea; A. Lungu; H. Iovu; R. Stan*
T4-293	**Electromechcanical performance of epoxy/vapour grown carbon nanofiber composites||for pressure sensor applications.** *A. Ferreira; P. Cardoso; A. Paleo; D. Klosterman; J. Covas; F. Van Hattum; S. Lanceros-Mendez*
T4-294	**Study of the basalt fibers' damage assessment due to different sizing removal processes.** *J. Kano; R. Hernandez; A. M. Zaldua; T. Guraya; I. Mondragon*
T4-295	**Synthesis and study of new poly(amide imide)s as advanced materials.** *I. Bacosca; E. Hamciuc; V. E. Musteata; M. Bruma*
T4-296	**Synthesis of bimodal polypropylene through binary metallocene catalysts.** *R. van Grieken; A. C. Carrero; B. P. Paredes; M. E. Lopez*

T4-297	**Ethylene-propylene copolymers synthesized with homogeneous and supported metallocene catalyst in the whole range of compositions.** *J. Arranz-Andrés; I. Suárez; R. Benavente; E. Pérez*
T4-298	**Microstructure characterization and influence on gamma form content of polypropylene copolymers and terpolymers.** *S. Caveda; R. Benavente; E. Pérez; E. Blazquez; B. Peña; R. van Grieken; I. Suárez*
T4-299	**Synthesis and analysis of properties of Poly(vinyl alcohol)composites.** *G. Nasar; M. Saleem Khan; U. Khalil*
T4-300	**Synthesis and characterization of conjugated ionic polymers with potential applications in optolectronic devices.** *D. Bondarev; J. Zedník; J. Vohlídal; J. Pfleger; S. Kazim; V. Sluneèková*
T4-301	**Synthesis and FTIR analysis of nanocomposite UV crosslinkable acrylic pressure sensitive adhesives|.** *J. Kajtna; M. Krajnc*
T4-302	**Synthesis and photo-responsive behavior or spiropyran end-functionalized polymers by ATRP.** *C. Ventura; R. Byrne; F. Audouin; D. Diamond; A. Heise*
T4-303	**Synthesis of hybrid materials via photopolymerization of benzoin functionalized silica nanoparticles.** *M. D. Karahasanoðlu; A. Önen; Ý. E. Serhatlý*
T4-304	**Hybrid photosensitizers for the removal of trace pollutants from water.** *A. Karewicz; D. Bielska; M. Kumorek; K. Szczubia³ka; M. Nowakowska*
T4-305	**Structure and conductivity of the copolymers of 2-methoxyaniline with aminobenzoic and aminobenzenesulfonic acids.** *D. Pahovnik; I. Mav-Golez; M. Zigon; J. Vohlídal*
T4-306	**Morphological characterization and mechanical properties of poly(lactic acid) blends.** *M. Taipina; M. Ferrarezi; L. Silva; M. D. Gonçalves*
T4-307	**Photocatalytic activity of TiO_2 nanocomposites on degradation of water pollutions.** *M. R. Nabid; R. Sedghi; S. Gholami*
T4-308	**Spectroscopic and thermodynamic study of phase transition in solutions of acrylamide/ nisopropylmethacrylamide-copolymers.** *J. Stastna; L. Hanykova; J. Spevacek*
T4-309	**Innovative perfluoropolyether-based copolymers: another breakthrough in fluorine chemistry.** *M. Avataneo; P. A. Guarda; G. Marchionni*
T4-310	**Novel liquid crystal ionomers for polymeric electrolyte membranes in direct methanol fuel cells.** *A. Martinez-Felipe; L. Santonja-Blasco; R. Teruel-Juanes; P. Henderson; M. Giacinti-Baschetti; G. Sarti; C.T. Imrie; A. Ribes-Greus*
T4-311	**Crosslinked PVA membranes for direct methanol fuel cells.** *A. Martinez-Felipe; L. Santonja-Blasco; M. Rosado-Gil; A. Ribes-Greus*
T4-312	**Developing of effective multipurpose polymer-bitumen compositions.** *S. Negmatov; B. Rahmonov; B. Sobirov; A. Abdullaev; Y. Salimsakov; M. Negmatova; A. Sobirov*
T4-313	**Nanostructures, morphology and properties of Poly[N-(2-cyanoethyl)pyrrole].** *G. Fabregat; E. Armelin; C. Alemán*
T4-314	**Development of effective technologies of heat and frost resistant composite materials for sealing the joints and cracks of asphalt roads, bridges and airfields.** *B. Rahmonov; S. Negmatov; B. Sobirov; A. Abdullaev; Y. Salimsakov; R. Soliev; D. Mahkamov; A. Bozorov; A. Sobirov*
T4-315	**Study of composition and technology of highly filled composite polymeric materials for asphalt roads, which can be used in hot climates and increasing their operation life.** *B. Sobirov; B. Rahmonov; S. Negmatov; A. Abdullaev; K. Inoyatov; Y. Salimsakov; D. Mahkamov; R. Soliev*
T4-316	**Compatibility studies of poly(ether imide) with liquid crystal mixtures.** *F. Çakar; H. Ocak; B. Bilgin-Eran; Ö. Cankurtaran; F. Karaman*
T4-317	**Development of polyester coating using branched polymers and silanes.** *J. Gamez-Perez; M. Puig; J. Gracenea; A. Jiménez; J. Suay*

T4-318	**Synthesis, structure and properties of poly(urethane-urea-siloxane)s.** *V. Antic; M. Balaban; M. Pergal; I. Francolini; A. Martinelli*
T4-319	**Physical aging of melt-blown PLA fibres.** *J. Janicki; M. Rom; J. Fabia*
T4-320	**Recovery of copper with sulfonated microcapsules containing DEHPA.** *Á. Alcázar; A.M. Borreguero; M. Carmona; A. de Lucas; J. F. Rodríguez*
T4-321	**A comparison of the morphology and thermoresponsive switching behavior in thin films of cyclic and linear poly(N-isopropylacrylamide).** *D. Magerl; X. Qiu; F. Winnik; M. Rawolle; G. Herzog; S. V. Roth; P. Müller-Buschbaum*
T4-322	**Incorporating nanostructured polypyrrole counter electrodes into dye-sensitized solar cells.** *S. S. Jeon; C. Kim; j. Ko; S. S. Im*
T4-323	**The preparation of nanofiber composites of Poly(butylene succinate)/TS-1 zeolite for drug delivery system.** *S. Hwang; E. Yoo; S. Im*
T4-324	**Morphology control of poly(p-oxybenzoyl) crystals using direct polymerization of p-hydroxybenzoic acid in the presence of boronic anhydrides.** *M. Kihara; S. Kohama; S. Umezono; K. Wakabayashi; S. Yamazaki; K. Kimura*
T4-325	**Selective synthesis of aromatic copolyester using reaction-induced crystallization under shear flow - Influence of shearing on composition of copolyester.** *T. Ichimori; S. Yamazaki; K. Kimura*
T4-327	**Facile, single-step preparation of versatile, high surface area nanoporous hybrid materials.** *I. Teasdale; I. NIschang; O. Brueggemann*
T4-328	**Emulsion polymerization of styrene: Simulation the effects of mixed ionic and non-ionic surfactant system in presence of coagulation .** *S. Feiz; A. H. Navarchian*
T4-329	**Wear resistance optimization of PU/TiO_2 coatings on aluminium surfaces.** *M. Taheran; A. H. Navarchian; R. Shoja Razavi*
T4-330	**Changes of supermolecular structure and selected properties of polymer matrix of polyamide fibres caused by addition of LCO modifier.** *M. Baczek; J. Janicki*
T4-331	**Kinetic study on photopolymerization of acrylates by Photo-DSC and RT-FTIR: the effect of thioxanthone based dendritic photoinitiators and light intensity.** *Z. Doğruyol; T. Parali; M. A. Kaya; Mm. Tülü; N. Arsu*
T4-332	**Effect of nanofillers on curing kinetics and thermal properties of epoxy amine thermosets.** *A. K. Ghosh; G. Van Asche; B. Van Mele*
T4-333	**Preparation of organometallic polymers with conjugated building blocks.** *P. Stenclova; J. Zednik; T. Vitvarova; J. Vohlidal; J. Svoboda*
T4-334	**Synthesis of porous polymeric organic frameworks (POFs) with C_{3v} symmetry and controlled pore size.** *E. Verde; E. M. Maya; J. G. de la Campa; J. de Abajo; Á. E. Lozano*
T4-335	**Enhancing properties of piezoelectric polyimides by copolymerization.** *M. San Sebastián; A. Maceiras; J. L. Vilas; T. Breczeswki; M. A. Perez-Jubindo; M. R. de la Fuente*
T4-336	**Plastics with reduced flammability, containing graphite halogen-free additives.** *P. Jankowski; M. Kêdzierski*
T4-337	**Water transport properties in biodegradable copolyesters.** *N. Follain; E. Dargent; F. Chivrac; F. Girard; S. Marais*
T4-338	**Isothermal crystallisation study of P3HT:PCBM blends as used in bulk heterojunction solar cells based on fast scanning calorimetry techniques .** *N. Van den Brande; F. Demir; S. Bertho; B. Van Mele; D. Vanderzande; J. Manca; G. Van Assche*
T4-339	**Solvent and substrate contributions to the formation of breath figure patterns in polystyrene films.** *E. Ferrari; P. Fabbri; F. Pilati*
T4-340	**Collapse of polyelectrolyte star. Theory and modeling.** *O.V. Rud; A.A. Mercurieva; T.M. Birshtein*

T4-341	**Polylactide and β-tricalcium phosphate composite fibers by electrospinning technique for tissue engineering applications.** *L. Tammaro; R. Wyrwa; J. Weisser; U. Müller; M. Schnabelrauch*
T4-343	**Azobenzene block copolymers and blends: microstructure, photoinduced anisotropy and holographic storage.** *C. Berges; E. Blasco; N. Gimeno; P. Forcén; L. Oriol; M. Piñol; C. Sánchez; R. Alcalá*
T4-344	**Diastereoselective synthesis of azanorbornenes from enantiomerically pure precursors and subsequent polymerizations.** *E. Rossegger; F. Stelzer; F. Wiesbrock*
T4-345	**Screening of new developed copolymers as potential antidotes against radionuclides.** *Z. Farmazyan; G. Harutyunyan; L. Hayriyan; V. Sargsyan; K. Stepanyan; A. Pogosyan*
T4-346	**Poly(ferrocenylsilane) hydrogels.** *M. Hempenius; X. Sui; C. Cirmi; J. Song; G. J. Vancso*
T4-347	**Synthesis and characterization of stimuli-responsive amphiphilic block copolymers.** *E. Blasco; C. Berges; R. Alcala; C. Sánchez; L. Oriol; M. Piñol*
T4-348	**Development of active flexible packages by the incorporation in bulk of antimicrobial natural additives.** *R. Gonzalez-Leyba; B. Galindo-Galiana; C. Gadea-Tomás; F. Martí-Ferrer*
T4-349	**Synthesis of superparamagnetic magnetite/poly(butylcyanoacrylate) (core/shell) nanoparticles for drug delivery purposes.** *D. Alioto; M. Lopez-Viota; E. Saez-Fernandez; M. A. Ruiz; J. L. Arias*
T4-350	**Batch foaming and cellular structure of biodegradable PLA/Graphene Nanocomposites.** *E. Gimenez; A. C. Cárcel; L. Cabedo; W. Zhai; C. B. Park*
T4-351	**Synthesis and photopolymerization of hydrolytically stable crosslinkers for dental composites.** *A. Altin; D. Avci*
T4-352	**Plasma modification of MWCNTs and their use in the preparation of PA6/MWCNT nanocomposites.** *R. Scaffaro; A. Maio*
T4-353	**Flexible nanoskin-core poly(ethylene-co-acrilic acid)/polyaniline hybrids.** *R. Scaffaro; G. Lo Re; C. Dispenza; M. A. Sabatino; L. Armelao*
T4-355	**Associative and segregative phase behaviour of poly(N-diethylacrylamide)/poly(4-vinylphenol) mixtures. Effect of solvent.** *L. Ruiz Rubio; N. Rioja; M. T. Garay; M. Rodríguez; E. Bilbao; J. E. Figueruelo*
T4-356	**Formation study of biocomposite films synthesized from chitosan.** *J. A. Cavallo; M. López-González; M. C. Strumia; E. Riande; C. G. Gómez*
T4-357	**Self-curable PDMS-containing PU oligomers for water repellent textile treatment.** *R. Wu; J. Hwang; K. Chen*
T4-358	**Novel reactive polymeric supports for synthesis of polymer drug conjugates.** *G. Tanriver; R. Sanyal*
T4-359	**Thiol reactive hydrogels for biomolecular immobilization via photopolymerization.** *T. N. Gevrek; E. Park; A. Sanyal*
T4-360	**Dynamic covalent reorganization of polymer/polymer systems: alcoholysis catalyst effect on kinetic and secondary reactions.** *F. Becquart; M. Taha; S. Touhtouh*
T4-361	**Mechanical properties of crosslinked hybrid PVA membranes for DEFCs applications.** *A. Gomes; J. C. Dutra Filho*
T4-362	**Study of natural aging of PVC flat-plate absorber used for low cost solar collectors.** *J. R. Bartoli; B. R. Prado; R. C. Pereira*
T4-364	**Synthesis of organic/inorganic composite hydrogels with embedded clay particles.** *M. Kurecic; S. Hribernik; M. Sfiligoj Smole*
T4-365	**SEC-MALS and molecular dynamics characterization of an amphiphilic poly(acrylic acid-b-styrene-b-styrene-b-acrylic acid) symmetric block-copolymer synthesized by RAFT.** *M. P. Tarazona; G. Marcelo; J. G. Martinho; J. P. Farinha;*

T4-366	**Development of conducting nanofillers based on polypyrrole and nanoclays.** *L. Cabedo; I. Mróz; J. M. Lagarón Cabello; E. Giménez Torres*
T4-367	**Strippable deactivating coatings: case of modified polyvinylalcohol.** *Z. Farmazyan; G. Harutyunyan; L. Hayriyan; V. Sargsyan; N. Dalalyan; K. Stepanyan; K. Pyuskyulyan; J. Abramyan; I. Shahazizyan*
T4-368	**Production and characterization of starch and starch based composite biodegradable films crosslinked by glutaraldehyde.** *I. Gonenc; F. Us*
T4-369	**Validation of an elasto -viscoplastic model for polyvinilidene fluoride (PVDF).** *V. Gonçalez; I. Pasqualino; M. Costa*
T4-370	**Characterization of poly(lactide-co-glycolide) (PLGA) obtained via ring-opening polymerization: effect of the LA/GA molar ratio.** *J. C. Ramirez-Contreras; E. Vargas-Reyes; P. Hernández-Belmares; J. C. Ortiz-Rodriguez*
T4-371	**Internal and external gelling method for alginate hydrogels preparation with planar geometry.** *E. Papajová; Z. Kroneková; M. Stach; D. Chorvát; C. Hoesli; D. Horne; J. Piret; I. Lacík*
T4-372	**Porous methacrylate copolymers as stationary phases for HPLC.** *M. Grochowicz; M. Maciejewska*
T4-373	**Crosslinked membranes of PVA/MMT for direct ethanol fuel cells.** *A. Gomes; J. C. Dutra Filho; G. Gomes*
T4-374	**Synthesis and characterization of polymeric microspheres based on styrene / divinylbenzene containing silver nanoparticles.** *K. Segala; D. Cruz; L. Cordi; O. Bagnato; N. Duran; L. Lona; L. Mei*
T4-375	**Photorresponsive bifunctional side chain polymers.** *J. Royes; L. Oriol; M. Piñol; R. M. Tejedor*
T4-376	**Characterization of the functional properties of commercial polyhydroxyalkanoates (PHA).** *Y. Corre; S. Bruzaud Grohens*
T4-377	**Preparation and characterization of polystyrene-graft-polyethylene glycol copolymers as solid–solid phase change heat storage material.** *A. Biçer; C. Alkam; A. Sari Karaipekli*
T4-378	**Synthesis and characterization of poly (fatty alkyloylethylmethacrylate-co-methylacrylate) as solid-solid phase change materials for thermal energy storage.** *T. Güngör; Ö. F. Ensari; C. Alkan*
T4-379	**Polyethers as phase change materials for passive thermal energy storage.** *D. Kahraman; C. Alkan; Ö. Ülkü*
T4-380	**Synthesis of paramagnetic polymers using ionic liquid chemistry.** *M. Döbbelin; V. Jovanovski; L. J. Claros Marfil; G. Cabañero; J. Rodríguez; D. Mecerreyes*
T4-381	**Environmentally friendly polyurethane foams.** *Y. Savelyev; L. Markovskaya; I. Yanovych; E. Akhranovych*
T4-382	**Effect of salt concentration on strength and morphology of natural degradable additive PP film upon immersion in water.** *M. Rahmad; S. M. Zarith; A. F. Abdullah*
T4-383	**Synthesis of flexible polymer-ceramic composites for RFID tagging of people.** *C. Ortiz; M. Suárez; S. Ver Hoeye; E. De Cos; M. Fernández; C. Vázquez; R. Camblor; G. Hotopan; R. Hadarig; F. Las Heras; J.L. Menéndez*
T4-384	**Multifunctional properties of PLA composites based on silver nanoparticles and crystalline cellulose: role of crystal micro and nano-dimension.** *E. Fortunati; I. Armentano; Q. Zhou; A. Iannoni; E. Saino; L. Visai; L. Berglund; J. Kenny*
T4-385	**Solid-state polymerized conducting polymers for highly efficient, iodine-free dye-sensitized solar cells.** *J. Kim; J. Kwan Koh; B. Kim; J. Hak Kim; E. Kim*
T4-386	**Towards innovating polymer materials for a new generation of organic laser sources.** *F. Lincker; V. Barret-Vivin; D. Kreher; F. Mathevet; A. Barsella; A. Boeglin; A. Fort; A. Attias*

T4-387	**Preparation and characterization of waste leather reinforced polymeric composite .** *S. Nahar; M.A. Khan; F. Karim; R. Islam; S. Hussain; A. K. Deb; H. Lal Paul; F. Pervin; S. Rahman*
T4-388	**Studying PMMA/PVC polymer blend for its use as lithium polymer electrolyte.** *L. Zubizarreta; A. García Bernabé; M. Gil Agustí; P. Llovera*
T4-389	**Ionic conductivity vs. thickness on the cast Nafion® polymer.** *M. Gil-Agustí; L. Zubizarreta; J. Calleja-Langa; R. Iserte*
T4-390	**Chitosan-collagen sponge-like 3d scaffolds as potential biomaterials for tissue engineering.** *M. Ramos; V. Zamora-Moral; S. Madrigal-Carballo; M. Lopretti; M. Sibaja*
T4-391	**Studies on toughening of polylactic acid by melt-blending with thermoplastic polyurethanes.** *K. Hsieh; C. Huang; Y. Lai; J. Han*
T4-392	**Multifunctional PDMS-PEG coatings for the finishing of cotton.** *R. Ronge; A. Körner; M. Möller*
T4-393	**Osteoconductive and bioresorbable composites based on poly(L,L-lactide) and pseudowollastonite.** *D.T-J Barone; Z.Luklinska; O. Persenaire; J-M. Raquez; Ph. Dubois*
T4-394	**Onion-like superabsorbent microspheres with PS-DVB core and PAA-b-crosslinked(PMMA) capsules via SI-ATRP.** *A. Ince, B. Karagoz, N. Bicak*

TOPIC 5: Chemistry and Physics of Nanomaterials and Nanotechnologies

T5-001	**Morphology and fracture behaviour of phenoxy/layered silicate nanocomposites.** *M. A. Corres; A. Mugica; M. Zubitur; M. Cortázar*
T5-003	**Quantum-chemical study of the low molecular polyethylene fluorination.** *L. Ignat'eva; V. Bouznik*
T5-004	**Characterization and thermal properties of poly(L-lactid acid)/clay bionanocomposites.** *A. Oyarzabal; A. Mugica; M. Zubitur; M. Cortázar*
T5-005	**Textile strain sensors based on conductive polymer nano-composite.** *C. Cochrane; M. Lewandowski; V. Koncar*
T5-006	**Influence of the aminopropylisobutyl POSS nanoparticles on the thermal behavior of isotactic.** *R. Bouza; C. Ramírez; L. Barral; B. Montero; R. Bellas*
T5-007	**Microstructural and morphological analysis of SBR/nanoclay composites.** *R. Bellas; R. Bouza; J. Díez; J. López; C. Ramírez; M. Rico*
T5-008	**Preparation and characterization of polyethylene nanocomposites including titanium oxide nanoparticles.** *P.A. Zapata; F.M. Rabagliati*
T5-009	**A new way to improve PC/ABS blends: use of nano-sepiolite.** *F.C. Basurto; D. García-López; N. Villarreal-Bastardo; J.C. Merino; J.M. Pastor;*
T5-010	***In situ* formation of polystyrene magnetic particles via batch suspension polymerization.** *J.S. Neves; F.G. Souza Jr.; P.A.Z. Suarez; A.P. Umpierre; F. Machado*
T5-011	**Cracking in thin polymer films promoted through physical ageing.** *M. Chowdhury; C. Calers; A.C.M. Yang; U. Steiner; G. Reiter*
T5-012	**Strategy to improve the mechanical properties of electroactive materials: preparation of PEDOT-montmorillonite and multilayer PEDOT/poly(*N*-methylpyrrole)/montmorillonite exfoliated nanocomposites.** *F. Estrany; D. Aradilla; D. S. Azambuja; M. T. Casas; C. A. Ferreira; C. Alemán*
T5-013	**Effect of binary organoclay mixture on the properties of ABS-clay nanocomposites prepared by melt intercalation.** *D. Galvan; J. R. Bartoli; M. A. D'Avila; M. Mazzuco; F. Massucato*
T5-014	**Synthesis, characterization and nonlinear optical properties of micellar nanohybrids based on Pd nanoparticlesand carbazole-containing block copolymers.** *M. Demetriou; T. Krasia; I. Papagiannouli; S. Couris; G. Chatzikyriakos*
T5-015	**Inducing microdomain orientation of thermoplastic elastomer in As-spun electrospinning fibers through study cases of SEBS triblock copolymer.** *W. Rungswang; M. Kotaki; S. Sakurai; S. Chirachanchai*
T5-016	**Computational modeling of nanocomposites' mechanical behavior at different environments parameters (moisture and thermal loadiing).** *K.M. Simeonova*
T5-017	**Fluoroalkyl end-capped oligomers/polyaniline and /phenyl-capped aniline dimer nanocomposites: controllingphotochromism between these nanocomposites induced by UV-light-responsive titanium oxide nanoparticles.** *H. Sawada; T. Tsuzuki-ishi; M. Iizuka; M. Yoshida*
T5-018	**Hybrid materials based on unsaturated polyester resins and polyhedral oligomericsilsesquioxanes (POSS).** *F. Constantin; S.A. Garea; H. Iovu*
T5-019	**Micellization and gelation of PEO/PPO block copolymers and their carboxyl-terminal derivatives.** *J. Dybal; A. Sturcova; A. Braunova; M. Pechar; A. Jigounov; J. Kriz*
T5-020	**A plasma reactor for the surface modification of silica based fillers: description and the apparatus and EPR investigation of reactive intermediates.** *A. Buttafava; D. Dondi; D. Grassi; F. Pepori; A. Faucitano*
T5-021	**Effect of sodium dodecylbenzene sulfonate on carbon nanotubes dispersion.** *V. Ghamgosar khorshidi; G.R. Bakhshandeh; A. Salimi; Gh. Naderi*

T5-022	**Optical and electrochemical properties of temperature fractions of nanodispersed polytetrafluoroethylene Forum®.** *A. Tsvetnikov; L. Matveenko; S. Suchoverchov; V. Kuryaviy; D. Opra; K. Galkin; S. Gnedenkov*
T5-023	**Influence of dopants on properties of polypyrrole nanocoated poly(styrene-*co*-methacrylic acid particles).** *I. Carrillo; M. González-Tejera; J. Fierro; E. Sánchez de la Blanca; I. Redondo; M. García; E. Enciso*
T5-024	**Effect of silane grafting and post cross-linking of HDPE on compatibilization and oxygen barrierity of HDPE/clay nanocomposite.** *A. Sharif Pakdaman; J. Morshedian; Y. Jahani*
T5-025	**PLA/PCL/montmorillonite nanocomposite systems: morphology and properties.** *V. Vascotto; A. Brunetin; R. Sulcis; P. Schiavuta*
T5-026	**Synthesis and characterization of superparamagnetic and thermoresponsive hydrogels based on functionalmethacrylates and oleic acid-coated magnetite nanoparticles.** *T. Krasia-Christoforou; P.C. Papaphilippou; A. Pourgouris; O. Marinica; A. Taculescu; G.I. Athanasopoulos; L. Vekas*
T5-027	**Biosensory function of self-assembled fluorescent nanotubes.** *C. Kim; J. Lee; S. K. Park; H. S. Kim*
T5-029	**Luminescent gold–poly(thiophene) nanoaggregates prepared by one-step oxidative polymerization.** *J.H. Kim; Y. J. Jung; S. J. Lee; S. M. Lee; H. Park; I. W. Cheong*
T5-030	**The influence of thermodynamic quality of solvent on properties of molecular nanoobjects.** *A. Amirova; E. Belyaeva; A. Kovina; E. Tarabukina; N. Sheremet'eva; A. Muzafarov; A. Filippov*
T5-031	**Colloidal crystallization of poly(*N*-isopropylacrylamide) microgels.** *H. Takeshita; S. Nakano; M. Miya; K. Takenaka; T. Shiomi*
T5-032	**Effect of orientation on structure and thermal properties of constrained polypropylene nanocomposite fibres.** *A. Marcincin; K. Marcincin; M. Hricova; A. Ujhelyiova; E. Borsig.*
T5-033	**Polyurethanes from agroindustrial wastes: pineapple case.** *J. Vega-Baudrit; S. Madrigal; L. Benavides; M. Sibaja-Ballesteros*
T5-034	**Hybrid block copolymer precursors carrying reactive triethoxy silyl side groups: synthesis, micellar behaviour and hydrolysis-condensation.** *C. G. Gamys; E. Beyou; E. Bourgeat-Lami*
T5-035	**Mechanical and thermal properties of nanocomposites based on heterophasic polypropylene/multiwalled carbon nanotubes functionalized with itaconic acid or monomethylitaconate.** *M. Yazdani-Pedram; J. Miranda; R. Quijada; P. Toro; R. Benavente*
T5-036	**Microspherical aniline oligomers and their nitrogen-containing carbon analogues.** *Z. Rozlívková; M. Trchová; E. N. Konyushenko; J. Steskal*
T5-037	**Porous titanium dioxide nanocomposite materials.** *O. Gaer; J. U. Wieneke; M. Ulbricht*
T5-040	**Nitrate remove from drinking water using polymer/MWCNTs nanocomposites.** *M. R. Nabid; S. J. Tabatabaei Rezaei; Y. Bide*
T5-041	**Spherulite growth rate in polypropylene/silica nanoparticle composites: effect of particle morphology and compatibilizer.** *H. Palza; J. Vera; M. Wilhelm; P. Zapata*
T5-042	**Supramolecular assembly of end-functionalized polymer mixture confined in nanospheres.** *J. Huh; C. Park; W.H. Jo*
T5-043	**Graphene-wrapped conductive nanospheres.** *S. Lee; K. Kim; S.A. Ju*
T5-044	**Behavior of ZrO_2/SiO_2 nanoparticles on the properties of the PVC/ABS blend.** *M.A. Reyes Acosta; A. Flores Vela; J.L. Rivera Armenta; A.M. Torres-Huerta; M.A. Domínguez Crespo*
T5-046	**Coarse-grained molecular dynamics simulations of Nylon-6 nanofibers.** *A. Milani; M. Casalegno; C. Castiglioni; G. Raos*

T5-047	**Testing 'double percolation' of carbon nanotubes in copolymer latexes by means of reverse addition fragmentation transfer polymerisation.** *G.T.H. Hill; G. Van Assche; B. Van Mele; C.E. Coning; M.C. Hermant*
T5-048	**Aqueous microgels modified by wedge-shaped amphiphilic molecules: hydrophilic microcontainers with hydrophobic nanodomains.** *L. Li; C. Cheng; X. Zhu; A. Pich; M. Möller*
T5-049	**Simulation of end-coupling reactions at a polymer-polymer interface: the kinetics and mechanism of interfacial roughness development.** *A. Berezkin; D. Guseva; Y. Kudryavtsev*
T5-050	**Low temperature process of Inkjet-printed ZnO Oxide transistor.** *S.C. Lim; S.Y. Kang; J.Y. Oh; S.D. Ahn; H. Kim; K.I. Cho*
T5-051	**Electrospinning of poly(γ-benzyl-L-glutamate) nanofibres: the effect of polymer molecular weight and spinningconditions in various solvents.** *J. Svobodova; F. Rypacek*
T5-052	**Investigation of structure and resistance of electroless copper sulfide nanoparticles in different deposition time. NSC 99-2221-E-036-002-MY3** *C.Y. Huang; Y.M. Fan; C.S. Tsai; K.Y. Tsao; C.P. Chang*
T5-053	**Study of the film formation and mechanical properties of the latexes obtained by miniemulsion co-polymerizationof the butyl acrylate, methyl acrylate and 3-methacryloxypropyltrimethoxysilane.** *J.M. Ramos-Fernández; C. Guillem; A. Lopez-Buendía*
T5-054	**Investigation of porous structure and thermal properties of sulphur containing copolymers.** *B. Podkoscielna*
T5-055	**Unexpected enhancement of polymerization rate in solution polymerization with nano CeO_2 particles.** *M. Aguirre; M. Paulis; J. R. Leiza*
T5-056	**Stimuli-responsive and electically conducting hydrogel nanocomposites from *N*-isopropylacrylamide and polyaniline.** *K. Depa; A. Strachota; P. Bober; J. Stejskal*
T5-057	**Instantaneous electric dipole moment in conjugated polymers.** *L. Roncaratti; R. Gargano; P. H. Oliveira Neto; W. Ferreira da Cunha; G. M. e Silva*
T5-059	**Effect of reaction parameters on the conductivity of nano polyaniline particles using Taguchi experimental design.** *R. Arefinia; A. Shojaei; H. Shariatpanahi .*
T5-060	**Influence of different nanofillers on the phase behavior of epoxy/polystyrene blends.** *M. Culebras; I. S. Monzó; C. M. Gómez*
T5-061	**Successive AGET ATRP of cationic methacrylate and PEO macromonomer yielding water soluble stiff cylindrical molecular brushes with cationic tail.** *C. Visnevskij; A. Baceviciute; R. Makuska*
T5-062	**Preparation and optical properties of novel bioactive photonic crystals obtained from core-shell hydrophilic microspheres.** *T. Basinska; M. Goseka; M. Griffete; M. Mangeney; M. Chehimi; M. Slomkowski*
T5-063	**Microspheres of poly(3-hydroxybutyric acid-*co*-3-hydroxyvaleric acid) loaded with holmium-166 for braquitherapy.** *J. R. De Souza; J. R. Martinelli; J. A. Osso Júnior; N. Nascimento; M. De Burgos Martins De Azevedo*
T5-064	**Microspheres of poly(lactic acid) loaded with holmium-166 for braquitherapy.** *G. Pires; J. R. de Souza; J. R. Martinelli; J. A. Osso Jr; N. Nascimento; M. De Burgos Martins De Azevedo;*
T5-066	**Exciton diffusion length in conjugated polymers.** *P.H.O. Neto; W.F. da Cunha; L. F. Roncaratti; F.V. Moura; R. Gargano; G.M. e Silva*
T5-067	**Bamboo charcoal supported silver particle by polyol process.** *C. Tzu Hsuan; L. Guan-Ting*
T5-068	**Theory of polyelectrolyte solutions.** *A. Karatrantos*

T5-069	**A new method for size controlled synthesis of zinc oxide nanocrystallites and their nanocomposite films.** *B. Karagoz; N. Bicak*
T5-070	**Influence of SiO_2 nanoparticles on ionic conductivity of PEI-LiTFSI electrolytes.** *I. Bayrak Pehlivan; C.G. Granqvist; P. Georen; R. Marsal; G. A. Niklasson*
T5-071	**Disiloxyl and dihydroxyl functionalized polymers by controlled/living polymerization methods.** *N.A. Mputumana; G. J. Summers*
T5-072	**Structures of the thermo-responsive poly(*N*-isopropylacrylamide) grafted from cotton fabric substrate.** *H. Yang; H. Zhu; D. Wang; J. H. Xin*
T5-073	**Raspberry–like silica particles to design superhydrophobic surfaces.** *R. de Francisco; N. García; T. Pilar*
T5-074	**Preparation and characterization of polyester resin-layered silicate containing reactive groups.** *S. Calvo; C. Arribas; R. M. Masegosa; M. G. Prolongo; C. Salom*
T5-075	**Analysis of polyhedral oligomeric silsesquioxanes, POSS, influence in properties of epoxy thermoset materials.** *B. Montero; A. Serra; C. Ramírez; X. Ramis*
T5-076	**Obtaining of biodegradable polymer films containing silver nanoparticles.** *Kh. E.Yunusov, A. A. Atakhanov, A. A.Sarymsakov, S. Sh.Rashidova*
T5-077	**First-principles simulations of IR spectra of polymers: nylon-6 polymorphs.** *A. Milani; C. Castiglioni; C. Quarti*
T5-078	**Covalent modification of MWCNT for styrene-isoprene-styrene block copolymer-based nanocomposites.** *M. Ilcikova; M. Mrlik; A. Juhari; K. Koynov; K. Csomorova; J. Mosnacek;*
T5-079	**Influence of montmorillonite (Cloisite 30B) content on water and oxygen barrier properties of polylactic acid films.** *N. Tenn; N. Follain; K. Fatyeyeva; S. Alix; J. Soulestin; S. Marais .*
T5-080	**Organo modified clay - biodegradable PHB/PCL nanocomposites: morphology, mechanical and barrier properties evaluation as function of blend composition.** *A. Botana; M. Mollo; P. Eisenberg*
T5-081	**Behavior of polyelectrolyte solutions in a wide temperature range.** *S.K. Filippov; T.A.P. Seery; P. Cernoch; J. Panek; P. Stepanek*
T5-082	**The influence of nanoparticles on the crystallization behaviour and the local deformation mechanism of poly(ε-caprolactone).** *M. Eriksson; P. Pichon; T. Peijs; H. Goossens*
T5-083	**Preparation and characterization of PLA-hydrotalcite nanocomposites.** *R. Scaffaro; L. Botta;*
T5-084	**Investigation of relationship between morphology and thermal stability of polystyrene & polymethylmethacrylate/Na-MMT nanocomposites prepared by emulsion polymerization.** *M. Rezaei; H. bouhendi; V. Haddadi-Asl; M. Nekomanesh-Haghighi*
T5-085	**Viscoelasticity of graphite oxide based suspensions in PDMS.** *A. Guimont; E. Beyou; G. Martin; P. Sonntag; P. Cassagnau*
T5-086	**Synthesis and characterization of new polyamides bearing 2,2'-thio, sulfinyl and sulfoxobis(1- naphthoxy) units in the main chain under microwave irradiation.** *E. Rostami*
T5-087	**Optical properties of 83 Titanium mono layers on glass substrateby Kramers Kronig method.** *H. Kangarlou; M. Motallebi Aghdam*
T5-088	**Production and investigation of optical and structural properties of MgF_2/TiO_2/glass and MgF_2/Ag/glass multi layers.** *H. Kangarlou; E. sattarpoor Isa Kan*
T5-089	**Synthesis of thermoresponsive nanocomposite hydrogels by alternative methods.** *B. Ferse; A. Große; K. Arndt*
T5-091	**PVDF/copper nanocomposites: preparation and properties.** *J. Arranz-Andrés; E. Pérez; M. L. Cerrada*

T5-092	**The effect of organoclay nature on the nanostructure andmechanical properties of polyamide-12 nanocomposites.** *N. Aramburu; J. I. Eguiazabal; J. Nazabal*
T5-093	**Crystallization studies on clay nanocomposites of Nylon 47.** *L. Franco; L. Morales; M. T. Casas; J. Puiggalí*
T5-094	**Characterisation and cure kinetics of epoxy-clay nanocomposites cured using an anionic initiator.** *F. Roman; Y. Calventus; P. Colomer; J. M. Hutchinson*
T5-095	**Biocompatible nanofibrous constructs targeted for controlled delivery of selected drugs.** *J. Michalek; J. Sirc; R. Hobzova; M. Pradny; N. Kostina; V. Holan; M. Munzarova*
T5-096	**Effect of dispersed phase modulus on brittle/tough transition of toughened polypropilene based nanocomposites.** *A. Zabaleta; I. González; J. I. Eguiazábal; J. Nazabal*
T5-097	**A low-temperature preparation of polymer-ZnO hybrid materials and/or ZnO nanoparticles from poly(zinc-methacrylate).** *G. Ambrozic; S. D. Skapin; M. Zigon; Z. Crnjak Orel*
T5-098	**Thermal stability of PMMA/ZnO nanocomposites.** *A. Anzlovar; Z. Crnjak Orel; M. Zigon*
T5-099	**Influence of the epoxy /amine stoichiometry on the thermomechanical properties of nanocomposites based on high T_g epoxy and organophilic clays.** *M. A. García del Cid; M. G. Prolongo; R. M. Masegosa; C. Arribas; C. Salom*
T5-100	**Biodegradable polyesters reinforced with mesoporous silica particles.** *J. Campos; M. R. Ribeiro; A. Deffieux; F. Peruch; J. . Lourenzo; M. L. Cerrada*
T5-101	**Fluorinated epoxy resin nanocomposites reinforced with amine functionalized MWNTs.** *C. M. Damian; S. A. Garea; C. Andronescu; A.M. Pandele; E. Vasile; H. Iovu*
T5-102	**Fluorescent polynorbornene/oxazine-1 loaded fluoromica nanocomposites by *in situ* polymerization for solution processable electronics.** *G. Leone; U. Giovanela; W. Porzio; C. Botta; G. Ricci*
T5-103	**Novel rheological and electrical results of polyamide/graphene nanocomposites.** *J. Canales; M. Fernandez; M. E. Muñoz; A. Santamaria*
T5-104	**Evaluation of polymeric micelles as potential carriers of antifungal agents.** *A.F. Olea; I. Fuentes; H. Carrasco; R. Martínez; I. Montenegro*
T5-105	**Isothermal titration calorimetry as a tool for elucidating the cobalt bis(dicarbollide) interaction with hydrophilic polymers.** *M. Uchman; K. Prochazka; M. Gradzielski; P. Matejicek*
T5-106	**Synthesis of polymeric nanoparticles by miniemulsion evaporation for the development of optical sensing phases.** *M. Marín Suárez Del Toro; J. F. Fernández Sánchez; T. Galeano Díaz; A. Fernández Gutiérrez*
T5-107	**NAOB® – Nanocomposites of natural rubber filled with organophillic clay and other reinforcers carbonous materials.** *G. R. Martín Cortés; F. José Esper; A. de Almeida Cutrim; A. de Almeida Dantas; W. Theodoro Hennies; F. R. Valenzuela Díaz*
T5-108	**Hierarchical structure and its formation process in liquid crystalline block copolymers.** *T. Shiomi; H. Takeshita; S. Adachi; S. Taniguchi; K. Takenaka*
T5-109	**Polyimide/silica nanocomposite thin films for advanced applications.** *E. Hamciuc; C. Hamciuc; I. Bacosca; L. Okrasa*
T5-110	**Dynamic mechanical relaxations and free-volume holes in polypropylene/carbon nanotubes composites.** *G. Zamfirova; N. Djourelov; J. M. Pereña; R. Benavente; E. Pérez; M. L. Cerrada; S. Peneva; V. Gaydarov*
T5-111	**New nanocomposites based on unsaturated polyester resin and modified halloysite.** *A. Ghebaur; S. A. Garea; H. Iovu*
T5-112	**Influence of silane treatment on the filler-coupling agent interactions.** *A. Lungu; N. Florea; C. Parvu; E. Vasile; H. Iovu*

T5-113	**Sphere-to-cylinder transition in mixed PS-*b*-PEO/TiO_2 micellar systems.** *D. Scalarone; M. Lazzari; F. Caldera; O. Chiantore*
T5-114	**Microstructure analysis of the layers containing nanoparticles hybrids ZnO-SiO_2, TiO_2-SiO_2 on textile fabrics.** *J. Sojka-Ledakowicz; J. Olczyk; A. Walawska; T. Jesionowski*
T5-115	**Synthesis of multi-walled carbon nanotubes using hydrocarbon as carbon sources in an arc discharge.** *M. Teymourzade; H. Kangarlou; K. Kazemikia;*
T5-116	**Synthesis of novel macroporous copolymer resins via aggregation/ breakage and post-polymerization.** *A. Lamprou; I. Koese; M. Soos; G. Storti; M. Morbidelli*
T5-117	**Crystallization kinetics of polypropylene nanocomposites.** *H. P. Nogueira; E. M. Alexandrino; M. I. Felisberti*
T5-118	**Magnetite-montmorillonite hybrid materials for wastewater treatment.** *G. Marcelo; I. Larraza; M. Lopez; T. Corrales; C. Peinado*
T5-119	**Analysis of the dispersion of nanofillers in PVC plastisols via rheological and morphological characterizations.** *C. Barres; A. Gueye; J. Duchet-Rumeau*
T5-120	**Intermolecular Interactions in polyacrylic acid solutions and gels.** *D. Shaltykova; E. Kalacheva; E. Shadrova; D. Kaldybekov; Z. Konyrbayeva*
T5-121	**Polymeric ionic liquids: homo- and copolymers in water.** *E. Karjalainen; H. Tenhu*
T5-122	**Functional poly(vinylpyrrolidone)s for the controlled synthesis of Ag nanoparticles.** *A. Ledo-Suárez; I. Rielo-Rodríguez; M. A. López-Quintela; M. Lazzari; M. G. Tardajos; H. Reinecke; A. Gallardo*
T5-123	**Study of nanocomposites processing containing polyaniline and carbon nanotube as use with radar absorbing structures.** *L. Folgueras; M. Rezende*
T5-124	**Single macromolecule as neural network.** *S. Panchenko; I. Suleimenov*
T5-125	**Novel fluorescence properties of syndiotactic polystyrene and its derivative.** *T. Sago; H. Itagaki*
T5-126	**Polymers as nanocarbon presursors in template method characterization and sorption properties of the obtained products.** *M. Sobiesiak, B. Podkościelna, M. Podgórski, A.M. Puziy, O.I. Poddubnaya, C.A. Reinish, M.M. Tsyba*
T5-128	**How affect the shape and modifier of clay on polymer blends?.** *R. Gallego; D. García-López; J. C. Merino Senovilla; J. M. Pastor*
T5-129	**Role of polymer-to-filler grafting in dispersion of CNTs in rubbers..** *P. Verge; S. Peeterbroeck; L. Bonnaud; P. Dubois*
T5-130	**Synthesis of colloidal stable silica containing blockcopolymer-nanoparticles.** *N. Köken Öz; K. Tauer; N. Weber*
T5-131	**Characterization of conducting polymer nanocomposites with poly(vinylidene fluoride) used in devices electroluminescents.** *A. Linardi Gomes; J. Sinézio de C. Campos; E. Armelin; C. Aleman; R. A. Ricci Jr; M. Beny P. Zakia; M. A. Canesqui; A. R. Vaz; J. G. Filho; J. A. Diniz*
T5-132	**Formation and size tuning of colloidal microcapsules via host-guest molecular recognition at the liquid-liquid interface.** *K. M. Turksoy; A. Sanyal*
T5-133	**Characterization, bioactivity and *in vitro* cellular response of sol-gel silica-polymer hybrid nanocomposites.** *S. Iváshchenko; D. M. García Cruz; A. Campillo Fernández; M. Monleón Pradas; J. L. Escobar Ivirico; G. Gallego Ferrer*

T5-134	**Unusual blue-shifted photoluminescence of MDMO-PPV films.** *H. Méndez; C. Hernández; B. Páez-Sierra; J. C. Salcedo-Reyes*
T5-135	**The thermodynamics of formation and structure peculiarities of nanostructured polyurethane/poly(2-hydroxyethyl methacrylate) interpenetrating polymer networks.** *L. Karabanova; Y. Gomza; S. Nesin*
T5-136	**Polyurethane urea nanocomposites: synthesis and characterization.** *A. Cuellar-Burgos; F. A. Mesa-Rueda; J. E. Perilla-Perilla*
T5-137	**Applications of broadband dielectric spectroscopy in polymer nanoscience.** *A. Serghei; F. Kremer; T. P. Russell*
T5-138	**Charge transport mechanism and thermal properties of novel polycyanurates/MWCNTs nanocomposites.** *L. Bardash; G. Boiteux; J. Ulanski; R. Grykien; I. Glowacki; A. Fainleib; P. Cassagnau*
T5-140	**Templating functional nanoporous materials with macromolecular architectures of controlled degradability.** *R. Majdoub; D. Grande*
T5-141	**Preparation and characterization of EVA nanocomposites obtained from montmorillonite and methylene-blue.** *M. Beltrán; A. Marcilla; V. Marchante; V. Benavente; I. Pelaez*
T5-142	**Nanostructures in polymer surfaces controlled by mechanical orientation.** *C. Fuentes; J. Feznández-Blasquez; A. Del Campo*
T5-143	**Estimation of cross-link density into networks in the polymerization of acryl-furanic compounds by mathematical modelling.** *J. Lanje*
T5-144	**Polymer shell nanocapsules for footwear applications.** *M. Sánchez; F. Arán; C. Orgilés; A. Marcilla*
T5-145	**Stable dispersions of chemically functionalized carbon nanofibers in waterborne polyurethanes.** *E. Orgilés-Calpena; F. Arán-Alís; A. M. Torró-Palau; C. Orgilés-Barceló*
T5-146	**Conformation and aggregation behavior of polymer-coated gold nanoparticles studied by dynamic light scattering experiments and Monte Carlo computer simulation.** *R. Pamies; J. G. Hernández Cifre; J. García de la Torre*
T5-147	**Chain dimensions, entanglement features and linear rheology of short chain branched polyethylene models: simulations and experiments.** *J.F. Vega; J. Ramos; J. Martínez-Salazar*
T5-148	**Particles composed of oppositely charged polyelectrolytes: effect of polymer molecular weight.** *F. Lima; A. Morán; F.E. Antunes; H. Chaimovich; M.G. Miguel; B. Lindman*
T5-149	**Transparent flexible electrodes using carbon nanotubes.** *J. Figueras; J. Pérez-Puigdemont; O. López; A. Fabregas; A. Abiad-Monge; N. Ferrer-Anglada*
T5-150	**Mesoporous Cuo as new catalyst for advanced energetic composites of polyurethane matrix.** *J. L. de la Fuente*
T5-151	**Evaluation of the phase inversion in HIPS/silver nanoparticles nanocomposites through UV-Vis spectrophotometry.** *G. Morales; F. Soriano*
T5-152	**Biopolymers / clays nano-biocomposites: impact of clay organo-modification on the morphology and properties of these hybrid materials.** *E. Pollet; L. Averous*

TOPIC 6: Bioinspired Polymers, Bioengineering and Biotechnology

T6-001	**Production of poly(lactic acid) microsphere loaded with holmium-166 for braquitherapy.** *G. Pires; J. Martinelli; J. Osso; N. Nascimento; M. de Burgos; M. Azevedo*
T6-002	**Morphology and properties of porous thermosensitive cryogels based on poly(*N*-isopropilacrylamide) systems.** *H. Peniche; F. Reyes; G. Rodriguez; M. R. Aguilar; C. Peniche; J. San Román*
T6-003	**Biologically inspired polymer scaffold development for artificial skin.** *M. Marimuthu; J. An; S. Kim*
T6-004	**Phenol biosensor based on electrochemically controlled integration of tyrosinase in a redox polymer.** *H. B. Yildiz; J. Castillo; D. A. Guschin; L. Toppare; W. Schuhmann*
T6-005	**Characterization and properties of PCL / PDIPF matrices for biomedical applications.** *J.M. Fernandez; S.M. Cortizo; A.M. Cortizo; G.A. Abraham;*
T6-006	**Reducing fibrillation tendency of polyvinyl alcohol fiber by incorporating cellulose nanowhiskers.** *A.J. Uddin; J. Araki; Y. Gotoh*
T6-007	**Synthesis and characterisation of well-defined optically active methacrylate-based block copolymers.** *M. Achilleos; D. Kafouris; S. Holder; T. Krasia-Christoforou*
T6-008	**Immobilization of soy bean peroxidase into nanotubes of natural halloysite and its application in the polyaniline synthesis.** *J. Romero-Garcia; E. Tierrablanca-Maldonado; R. Cruz-Silva*
T6-009	**Bioactive alginate-nanosiver-anthocyanin hybrid composite.** *J.H. Choi; S.Y. Seo; G.H. Lee; S.G. Lee; E.J. Oh; H.Y. Chung; J.H. Yeum; S.I. Han*

OPENING CONFERENCES

Life without Polymers

Christopher K. Ober

Cornell University, MSE, 310 Bard Hall, Ithaca, NY 14853

cko3@cornell.edu

Polymers play a vital role in all aspects of today's society. It is therefore difficult to imagine life without polymer materials. Nevertheless, it is a valuable exercise to consider the impact that polymers have on life today, particularly in the role of advanced technology.

The field of polymer science and engineering is a vibrant contributor to the world economy, not only in its own right, but also because of the wide array of industries and technologies made possible by the use of polymer materials. Polymers have unique, molecularly definable properties and process advantages unattainable in any other kind of material. Their attractiveness comes, in part, from the wide varieties of structure, molecular weight, and functionality available via rational synthesis of polymers and their characteristically broad range of processing modes. Polymers thus offer the potential for high performance at lower cost, sustainable use, and in many cases possible replacement of other materials in many fields. Polymers have become indispensable items in everyday life in uses ranging from clothing, paints, secure food packaging to major parts of automobiles but also as essential components in virtually every emerging advanced technology. A recent workshop report from the US National Science Foundation neatly summarizes the many contributions made by polymer science and future possibilities[1].

Polymers are needed to address many of the most critical challenges we face today in areas such as:

- Energy;
- Sustainability;
- Clean water;
- Healthcare;
- Informatics;
- And security.

A major opportunity for the field of polymer science lies in the direct integration of functional polymers into an energy-generating device. Polymers will play an important role in the shift to alternate fuels and energy sources. Polymers serve as the basis of advanced batteries, the membranes used in efficient, low temperature fuel cells and as the polymer photovoltaic diodes (solar cells) for energy production that are now being developed.

Polymers are ideally positioned to impact most of the key aspects of economic, social, institutional and environmental sustainability. Polymers play a central part in the membranes used in water purification and desalination. Polymers are critical components in food production and in the storage of delicate, time sensitive materials such as food and medicine. Polymers are being developed that come from biological sources, do not compete with food for their feedstock as many biofuels do, and can be much more readily recycled than in the past. Polymers are used because they are light, robust, low cost, extremely effective materials.

Polymers possess another critically important attribute, namely their similarity to biomacromolecules, the molecular basis of living organisms. In healthcare recent advances in biomedicine in areas such as artificial skin for wound healing and new methods of drug delivery such as that used in drug eluting stents are vitally dependent on discoveries in the creation, processing and understanding of polymers. As a result of the features they share with biomolecular materials, the impact of polymers will continue to grow, as their use expands further into human tissue repair, disease detection, food supply monitoring and other aspects of homeland defense, and future medical technologies. In the near future, advances in polymers will enable superior healthcare to reach greater numbers of people in a more economical manner.

Without polymers our lives, our health, our well being would be severely diminished. Most of the things we depend on would no longer be available. Simply put, without polymers much of life as we know it would no longer be possible.

---

Smart Polymer Applications in Drug Delivery and Diagnostics

Allan S. Hoffman[a], Patrick S. Stayton, Paul Yager, Anthony Convertine, James Lai, Michael Nash, Craig Duvall and Danielle Benoit

Department of Bioengineering, University of Washington, Seattle, WA 98195 USA
also WCU Distinguished Professor, Kyungpook National University Medical School, Daegu, South Korea

hoffman@uw.edu

In the first part of my talk I will describe our work with smart polymer carriers for intracellular delivery of biomolecular drugs. Such drugs include peptides, proteins and nucleic acid drugs (eg, pDNA and siRNA). Many of these drugs act at intracellular sites; however, the effective intracellular delivery of these "fragile" drugs remains a significant challenge. Endocytosis of drug formulations usually results in localization within the endosome, where the predominant fate is fusion with lysosomes and enzymatic degradation of the biomolecular drug. Inspired by the principle behind the ability of many viruses to deliver their genomic cargo from the endosome to the cytosol, we have designed and synthesized a family of biomimetic, "smart" acid-responsive polymeric carriers that can enhance the escape of fragile biomolecular drugs from the endosome to the cytosol.

In the second part of my talk I will describe our application of smart T- and pH-responsive polymers for point-of-care (POC) immunoassays. In this work, we have synthesized smart polymers using RAFT polymerization techniques, and conjugated them to: a) capture antibodies, b) porous membrane surfaces, c) magnetic nanoparticles, and d) gold nanoparticles. We have also coated the smart polymer-antibody conjugates onto magnetic and gold nanoparticles. These smart nanoparticles are used to capture and concentrate the target, biomarker molecules and then to release them as a concentrated pulse for downstream assay. We have used microfluidic devices and lateral flow strip assay formats for these POC assays.

Plant Oils: The Perfect Renewable Resource for Polymer Science?!

Michael A. R. Meier

Karlsruhe Institute of Technology (KIT), Institute of Organic Chemistry, Karlsruhe, Germany

m.a.r.meier@kit.edu

In ages of depleting fossil reserves and an increasing emission of greenhouse gases it is obvious that the utilization of renewable feedstocks is one necessary step towards a sustainable development of our future. Especially plant oils bear a large potential for the substitution of currently used petrochemicals, since a variety of value added chemical intermediates can be derived from these resources in a straightforward fashion taking full advantage of nature's synthetic potential. Here, new approaches for the synthesis of monomers as well as polymers from plant oils as renewable resources will be discussed.[1]

For instance, we could show that different chain length α,ω-diester monomers can be obtained from fatty acid esters via olefin cross-metathesis (CM) with methyl acrylate taking advantage of natures "synthetic pool" of fatty acids with different chain lengths and positions of the double bonds.[2] Similarly, we could show that the cross-metathesis with allyl chloride and other functional olefins allows for the synthesis of α,ω-difunctional compounds. Moreover, thiol-ene click chemistry offers a complementary approach for the introduction of different functional groups to fatty acids in a straightforward and efficient manner, as demonstrated for the functionalization of the castor oil derived methyl 10-undecenoate with a variety of thiols.[3] The thus obtained renewable platform chemicals are valuable starting materials for a variety of polyesters and polyamides.

Moreover, olefin metathesis as well as thiol-ene click chemistry were used to prepare renewable polymers. For instance, we could demonstrate the synthesis of telechelics as well as ABA triblock copolymers via ADMET in a one-step procedure.[4] During these ADMET polymerizations we observed more or less pronounced olefin isomerization side reactions. Therefore, we developed a strategy to monitor and quantify these side reactions during ADMET polymerizations and were able to correlate their amount to the applied catalyst as well as reaction conditions.[5] In a subsequent study, we could also demonstrate how to efficiently supress these unwanted side reactions.[6] Very recently, we could show that ADMET, a typical step-growth polymerization, can be used to prepare block- and star-shaped polymers by taking advantage of the CM selectivity between terminal olefins and acrylates.[7] Moreover, thiol-ene chemistry is also perfectly suited for the polymerization of fatty acid derived monomers, as will be shown with the synthesis of biopolymers with tuneable degradation behaviour.[8] Last but not least, we recently reported a strategy to highly functionalized renewable monomers and polymers based on multi-component reactions that offers manifold synthetic opportunities for polymer chemistry.[9]

In summary, we will thus demonstrate the versatility of plant-oil derived platform chemicals for the synthesis of a large variety of monomers and polymers. Plant oils are therefore a perfectly suited renewable resource for the polymer industry.

Carbohydrate-based polycondensation polymers

Sebastián Muñóz-Guerra

Departament d'Enginyería Química, Universitat Politècnica de Catalunya, ETSEIB, Diagonal 647, 08028 Barcelona

sebastian.munoz@upc.edu

Polyamides and polyesters are thermoplastics of primary importance for both domestic and technological applications, in which they are consumed in huge amounts. In terms of sustainability, the total or partial replacement of the petrochemical monomers currently used for the industrial production of these polymers by others of natural origin is highly desirable. However to do it without detriment of the genuine properties and at acceptable costs is very challenging.

Carbohydrates constitute an excellent platform for the synthesis of step-growth polymers because their easy accessibility and wide variety.[1] If properly modified and protected, sugar derivatives may be used in polycondensation to produce thermoplastic polymers with inedited properties. First incursions in this area were made in the sixteen of the past century,[2] and more recently a good number of works exploring the potential of both acyclic and cyclic carbohydrate-based monomers in the synthesis of step-growth polymers have been reported.[3]

In these last years we have prepared an assortment of bifunctional monomers from easily accessible monosaccharides and used them as building-blocks for the synthesis of linear polyamides and aromatic copolyesters.[1] Both asymmetrical configurations and configurations containing a two-fold axis leading to non-stereoregular and stereoregular chains respectively, were explored (Figure 1).

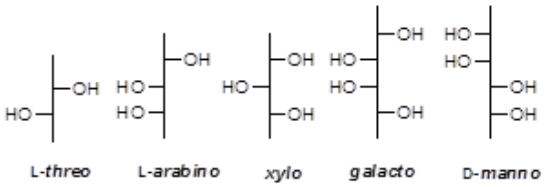

Figure 1. Sugar configurations explored in the preparation of polyamides and polyesters.

Polyaldaramides (**PAld-*n,m***) were prepared by polycondensation in solution from 1,*n*-alkanediamines (*n* = 4 to 12) and aldaric acids activated as pentachlorophenyl esters with their secondary hydroxyl groups protected either as methyl ether or as cyclic methylene acetal (Figure 2).

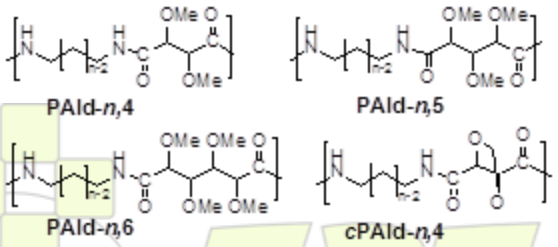

Figure 2. Polyaldaramides prepared from aldaric acid derivatives.

Most of polyaldaramides were crystalline polymers regardless the configuration of the aldaric acid. They adopt a common crystal structure made of kinked chains with the sugar unit located at the kinks and the polymethylene segment arranged in *all-trans* extended conformation.[4] These polyamides display higher hidrophilicity and hydrodegradability than their unsubstituted nylon homologues, and in some cases they show appreciable biodegradability.

Alditols with the secondary hydroxyl groups protected in the same way as done in aldaric acids were reacted in bulk with terephthalic acid or its dimethyl ester to obtain aromatic copolyesters derived from poly(ethylene terephthalate and poly(butylene therephthalate) (Figure 3).[5]

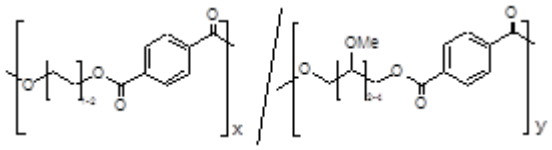

Figure 3. Sugar containing PET and PBT copolyesters.

PET and PBT copolyesters containing alditols units had a random microstructure for all compositions and showed increased solubility and hydrodegradability. Their *T*g were largely sensitive to composition, and both crystallinity and crystallization rate of the copolyesters decreased with the content in sugar residues. Crystalline copolyester have the same crystal structure than their parent homopolyesters with the alditols units being excluded from the ordered phase.

Dedicated to Prof. Cor E. Koning on the occasion of his Dutch Polymer Institute Invention Award.

On the Importance of Carbon Allotrope Network Organisation in Nanocomposites

Joachim Loos

Kelvin Nanocharacterisation Centre, Scottish Universities Physics Alliance (SUPA) and School of Physics and Astronomy, University of Glasgow, Glasgow, G12 8QQ, Scotland, UK

joachim.loos@glasgow.ac.uk

Polymer composites filled with carbon allotropic nanoparticles like carbon black (CB), carbon nanotubes (CNT) and graphene are applied as lightweight and easy processable materials with specific functionality. For very low nanofiller loading substantial improvement of the mechanical, thermal and electrical behaviour can be achieved. For instance, polyolefin composites could be prepared reaching electrical conductivity in the semiconductive range already for nanofiller concentrations far below 1 wt.%. However, until today critical processing parameters influencing nanofiller distribution and network formation in the polymer matrix are not clearly identified. One reason for our limited knowledge in this field is the difficult access to local morphological data that allows for identification of the individual nanofiller particles, their interface organisation in contact with the polymer matrix, their local functional properties and the overall macroscopic network organisation. In this study I will introduce some examples on how smart tuning of the involved processing conditions/routes helps tailoring the electrical properties of CNT and graphene filled composites, and I will introduce several advanced microscopy methods that allow for in-detail observation of the formed nanofiller networks with nanometer resolution in all three dimensions.

ABSTRACTS

PLENARY LECTURES

Macromolecular Engineering for Nanostructured Materials via ATRP

Krzysztof Matyjaszewski

Carnegie Mellon University, Pittsburgh, PA, 15213, USA

matyjaszewski@cmu.edu

Copper-based ATRP (atom transfer radical polymerization) catalytic systems with polydentate nitrogen-based ligands are among most efficient controlled/living radical polymerization systems.[1] Recently, by applying new initiating/catalytic systems, Cu level in ATRP was reduced to a few ppm. Various reducing agents, including metals, organometallic species, sugars, amines, phenols or even some monomers and ligands, as well as radical initiators have been successfully applied.[1-2] Similar control can be achieved with ppm of Fe-based catalysts.[3]

ATRP of acrylates, methacrylates, styrenes, acrylamides, acrylonitrile and many other vinyl monomers provides polymers with molecular weights in a large range $200<M_n$ 20,000,000 and with low dispersities.[4] Polymers can be formed quantitatively in bulk, in solution and in dispersed media. Water can serve both as solvent for many water soluble polymers and also as medium for microemulsion, miniemulsion, dispersion and suspension polymerization.[5] Block, graft, star, hyperbranched, gradient and periodic copolymers, molecular brushes and various hybrid materials as well as bioconjugates have been prepared.[5-6] The (co)polymers made by ATRP have many potential applications as components of advanced materials such as coatings, elastomers, adhesives, surfactants, dispersants, lubricants, additives, but also as specialty materials in biomedical and electronic areas and will affect the market of ~$20 billion/year.[7] Macromolecular engineering comprising design, synthesis, characterization and applications of nanostructured multicomponent polymeric materials prepared via ATRP will be presented.

A holistic view on the biodegradable macromolecular design

A.-C. Albertsson

Fibre and Polymer Technology Royal Institute of Technology, KTH

aila@kth.se

Biodegradable polymeric materials have formidable potential in a broad spectrum of applications, from high volume disposable items to specialized biomedical purposes. Presented here is a holistic perspective on how to engineer and optimize the polymer structure, from a nano-molecular to a macro-functional level. Our research approaches comprise all steps from macromolecular design, adopting new monomers, better initiator systems, creating polymers with advanced structures to surface modification, device formulation, production of scaffolds and assessments of in vivo behavior and degradation pattern. A range of pathways have been used to synthesize polymers with various architectures with the aim to control and vary the properties and function. Varying the chemistry and architecture changes the polymer behavior with respect to their physical, thermal, and mechanical properties. Ring-opening polymerization, anionic polymerization, enzymatic polymerization and living and controlled radical polymerization using a range of initiators and catalysts have allowed us to attain materials with narrow molecular weight distributions, varying architectures, easily controlled compositions, hydrophilicity, conductivity, and mechanical properties. Synthesis strategies are further developed to offer benign conditions. Strategies for covalent surface modification and are also developed and utilized for the subsequent biofunctionalization and/or nanopatterning.

The prepared biomaterials show great potential for usage in porous scaffolds in tissue engineering applications with respect to cell attachment, proliferation and stem cell differentiation. In any biological environment, the human body included, the fate of a degradable polymer is of imperative concern. The amount, diversity and structures of generated degradation products directly influence the environmental adaptability of a material. Chromatographic tools are developed to probe how the polymer structure, formulation, additives and processing affect the degradation in terms of rates, mechanisms, product patterns, and reproducibility.

Layered Polymeric Systems – Lessons From Biology

Eric Baer

Department of Macromolecular Science and Engineering.
Center for Layered Polymeric Systems
Case Western Reserve University

Lessons from biology have revealed that natural materials systems have architectures that are specifically designed to accommodate a unique spectrum of required properties. These architectures always have many scale levels that are bound together by interfacial coupling or adhesion. In recent years, new synthetic approaches have been used to develop macromolecular architectures that "self-assemble" into nano-scale morphologies. This lecture addresses another approach – the "forced-assembly" of synthetic polymers by continuous nanolayer coextrusion. Films can readily be created with thousands of layers containing two or more alternating polymers using a multilayer coextrusion system illustrated in Figure 1. Layer thicknesses have been made in the range of several microns down to less than ten nanometers by varying the number of layers and the layer composition.

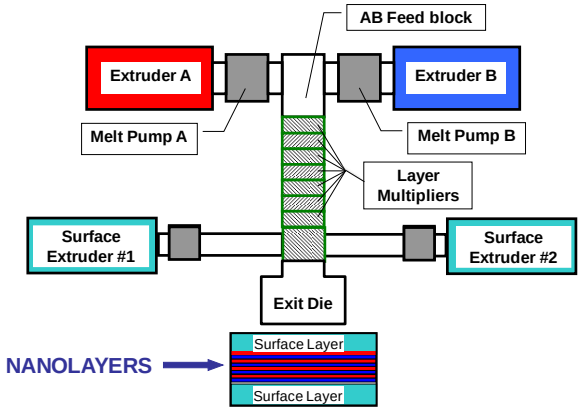

Figure 1: Two component multilayer coextrusion system comprised of extruders, pumps, feedblock, multiplying dies, surface layer extruders, and exit die.

Nanolayered films are of interest because of a potential for developing materials systems with novel mechanical, transport, electrical and optical properties. Since the radius of gyration of macromolecules can readily exceed the nanolayer thickness, the surrounding layers can be used to impart dimensional constraint at the molecular level. The novel effects that accompany a decrease in layer thickness from the microscale to the nanoscale will be illustrated with three examples related to the polymer interphase, confined crystallization, and finally, the development of graded index lens (GRIN) systems inspired from biomimetics.

When two immiscible polymers are brought into intimate contact, highly localized mixing creates an "interphase" region that is of considerable importance to polymer blends. We characterized the size and properties of the interphase by reducing the layer thickness in nanolayer assemblies to the size scale of the interphase. Films that were completely interphase were obtained with the thinnest nanolayers.

Confined two-dimensional crystallization of polymers presents unique challenges and opportunities due to the long chain, covalently bonded nature of the macromolecules. We discovered a unique morphology that emerges as confined polymer layers are made progressively thinner. When the thickness is confined to 20 nm, the PEO crystallizes as single, high aspect ratio lamellae that resemble single crystals. This may be the first time that large polymer single crystals are obtained by melt processing. Unexpectedly, the unique crystallization habit imparts two orders of magnitude reduction in the gas permeability.

The unique capabilities of biological optics arise from sophisticated features such as gradient index (GRIN) lenses and dynamic shape change. These GRIN lenses comprise thousands of layers that vary in protein concentration. It is reported that the human eye comprises greater than 20,000 layers and can change shape to accommodate near and far focus. The refractive index range (Δn) within a spherical lens in a human eye is about 0.03. In other cases like fish eye and octopus eye lenses, larger Δn compensates for an inability to change shape. The refractive index range within octopus eye is about 0.15 and fish eye is about 0.22. We have developed new nanolayered polymeric lenses with bio-inspired designs that have the structure and the properties of biological lenses. Specifically, polymeric nanolayered systems will be described that are used to mimic the lens in an octopus eye.

Ordered Supramolecular Polymers and their Hybrids with Covalent Chains

Samuel I. Stupp

Departments of Chemistry, Materials Science and Engineering, and Medicine
Northwestern University

s-stupp@northwestern.edu

Supramolecular polymers formed through self-assembly of monomers offers the potential to create ordered aggregates that can collectively emulate the shape persistence of proteins and many other filamentous structures in biological systems. One of the targets by several groups has been been the design of monomers that can self-assemble into conducting nanowires of interest in electronic applications. Efforts in our laboratory have also focused on fibrils that present groups with known biological functionality in highly favorable orientation and density, resulting in unprecedented efficiency of cell signaling for regenerative medicine. The future of the field needs to include programming of molecules for self-assembly that create more complex structures with order on scales that exceed the dimensions of the supramolecular polymers they form.

Another important goal is the design of hybrid structures that integrate supramolecular and covalent polymers as well as supramolecular and inorganic structures. This lecture discusses self-assembly pathways that produce cell-like objects or virus-like structures containing both supramolecular and covalent polymers and potential for biomedical functions. The lecture will also describe crystals of supramolecular polymers, and hybrid structures of supramolecular polymers with inorganic semiconductors with great potential in solar energy applications

Radical Polymers for an Organic-based Rechargeable Battery and Photovoltaic Cell

Hiroyuki Nishide

Department of Applied Chemistry, Waseda University, Tokyo169-8555, Japan

nishide@waseda.jp

We have focused on aliphatic polymers bearing organic robust radicals as pendant groups per repeating unit. For the radical groups, tetramethylpiperidinoxyl (TEMPO), nitronyl nitoxide, galvinoxyl, and viologen are typically employed. The so-called radical polymers are characterized by an ultimate population of unpaired electrons or singly occupied molecular orbitals, which allow efficient redox-driven electron transport throughout the polymer layer through self-exchange reactions. The high electron-transport reactivity of radical polymers provides very fast charge-propagation and reversible charge-storage in a rechargeable battery. A pair of two radical polymers with different redox potentials are used as a cathode- and an anode-active material in this organic radical battery. Organic and Li-ion free batteries offer several advantages over conventional batteries, including higher safety, adaptability to wet fabrication processes, easy disposability, and capability of fabrication from less-limited resources. Challenges toward a slim, paper-like battery and bust-power battery by molecular designing of the radical polymers will be demonstrated. We are also fabricating dye-sensitized photovoltaic cells to replace the iodine-containing electrolyte and/or the titanium oxide semiconductor in Graetzel-type one with the radical polymer layers for charge-separation and -transport in the cell. The cells displayed significantly high open-circuit voltage of almost 1 V. Radical polymers are emerging as a new class of electroactive materials useful for various kinds of wet-type energy storage and conversion devices.

c.e.koning@tue.nl

Introduction

Striving for a more sustainable society and in their search for sustainable materials, many academic and industrial research groups focus their activities on biomass-based or renewable polymers. The most obvious approach is to synthesize renewable monomers, e.g. by using fermentation technology or by submitting biomass to mature industrial chemical engineering processes, and subsequently replace petrochemistry-based monomers by these renewable monomers in existing industrial processes and polymerization plants. Until quite recently any biomass like e.g. starch, suitable to be transferred into polymerizable chemicals, was considered as being attractive, but more recently it is realized that the generation of new monomers from biomass should not compete with the food chain, and sources like castor oil, cellulose and other biomass that cannot be digested by most living creatures is strongly preferred.

This work describes the synthesis and characterization of renewable polyesters, polyamides, polycarbonates and poly(urea urethane)s and also presents a selection of the physical and mechanical properties of powder coatings, injection moldable plastics and melt-spun fibers manufactured from these biobased polymers.

Experimental

Materials 1,4;3,6-Dianhydro-D-glucitol (isosorbide, IS, 98+%) was a gift from Roquette Frères. All other renewable monomers used in this study were either synthesized by FBR (Wageningen) or purchased from Aldrich and used as received.

Results and Discussion

Hyperbranched, fully biobased polyesters (Fig.1) were successfully synthesized from succinic acid, isosorbide and glycerol via bulk polycondensation. These renewable polymers were evaluated as solvent-casted films and as powder coatings and showed very promising properties. With respect to the yellowing behavior in sunlight, important for outdoor applications, these materials outperform the commercial petro-based powder coatings. Also by bulk polycondensation isosorbide-based polycarbonates were made. Coatings based on these renewable polymers showed superior toughness, solvent resistance, UV-resistance and gloss. Promising melt-processable, semi-crystalline (*Tm*=160-230°C), renewable polyamides were made from the isoidide diamine, putrescine and sebacic acid (Fig. 2)

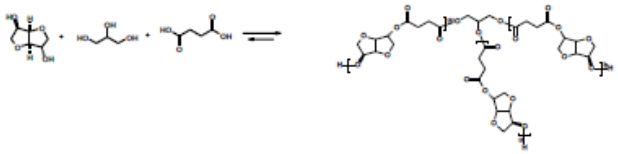

Fig 1. Renewable amorphous, branched polyester from isosorbide, glycerol and succinic acid for powder coatings.

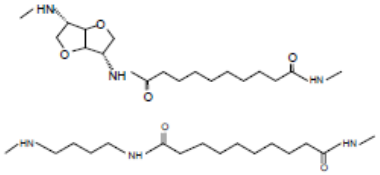

Fig 2. Repeat units of renewable, semi-crystalline polyamides from isoidide diamine, putrescine and sebacic acid.

Fully biobased poly(urea urethane)-polyester multiblock copolymers, consisting of renewable elastomeric polyester blocks and renewable urea-urethane blocks as physical cross-links, were prepared via an isocyanate-free route. These materials exhibit promising properties as renewable and biodegradable thermoplastic elastomers.

By enzymatic polymerization of the biobased macrocyclic musk lactone cyclopentadecanolide, high molecular weight aliphatic polyesters were synthesized and melt-spun into strong fibers which after drawing exhibited a tensile strength of 0.6-0.7 GPa.

Conclusions

Fully or nearly fully biobased cycloaliphatic polyesters, polycarbonates, polyamides, poly(urea urethane)s and linear aliphatic polyesters have been successfully synthesized and showed very promising behavior when evaluated as coatings, plastics or fibers, sometimes even outperforming their petro-based counterparts.

This work forms part of the research program of the Dutch Polymer Institute.

Design of Intelligent Surfaces for Cell Sheet Tissue Engineering

Teruo Okano, Ph.D.

Institute of Advanced Biomedical Engineering and Science. Tokyo Women's Medical University
8-1 Kawada-cho, Shinjuku-ku, Tokyo 162-8666 Japan

tokano@abmes.twmu.ac.jp

Our research has been focused on constructing a novel form of co-culture consisting layered tissue structure. For our goal, we first developed unique tissue culture dishes which equipped their inner-bottom surface coated with the temperature-responsive polymer poly(*N*-isopropyl acrylamide) (PIPAAm). The "intelligent surface" of these dishes possessed the hydrophobicity similar to regular tissue culture polystyrene dishes at 37℃. However, the surface reversibly became hydrophilic at a lower temperature and spontaneously released the cultured cells as a single layer without the need for trypsin or EDTA, thus leaving the cell layer with extracellular matrix (ECM) intact. All the cultured confluent cells were harvested as a single contiguous cell sheet from the temperature-responsive culture dishes and readily applied to other biological and non-biological surfaces, thanks to the intact ECM. We here propose this novel system of cells and cell-layers arrangement called "cell sheet engineering."

We initiated human clinical studies of cell sheet engineering therapy using oral mucosal cell sheet for treatment of cornea epithelium deficient disease and recovery from endoscopic submucosal dissension surgery for esophageal epithelial cancer, and we also succeeded in treating cardio-myopathy using myoblast cell sheet. However, these applications only required primarily two dimensional manipulations of the cultured cells without prevascularized networks, which would be essential for the development of biological structures to treat or replace dysfunctional organs and tissues in human patients, the next stage of cell sheet tissue engineering. While they were vital, there were no known feasible methods to introduce effective vascular networks to sustain the fundamental functions of the regenerated organs and tissues, e.g., the liver and capillary blood vessels. Therefore, a new strategy was required, and the construction of cell sheets which had more than one type of cells became necessary in attempt to create the desired prevascular networks in three dimensional biological constructs.

In order to overcome the challenges of developing crucial and functional prevascular networks, first the copolymers with different phase transition temperatures were coated on the surface of culture dishes to produce a patterned dual phase thermo-responsive cell culture surface using electron beam polymerization method and porous metal masks. On the patterned surface of the dishes, site-selective adhesion and growth of hepatocytes and endothelial cells yielded a patterned co-culture layer based on the hydrophobic-hydrophilic surface chemistry regulated by simple temperature change. In addition, the recovered co-cultured cell sheets could be modified and multilayered, and other types of cells could even be inserted between the cell sheets. The experimental results demonstrated that this method could provide a new approach for the development of organ-like structures with the essential vascular networks found in normal human organs. Therefore, cell sheet engineering with the intelligent surface is a highly promising tool for tissue engineering and regenerative medicine.

Trainer project: research on self- and inteligent healing materials

Pilar Martí; Directora de Tecnología Química.Repsol YPF.

Pmartip@repsol.com

Repair or healing is a well-known property in Nature, which provides inspiration for both academic and industrial researchers to invest in the development of artificial materials with self-healing capability. These self-healing materials attempt to mimic the ability of living organisms to heal an injury by themselves.

And this is the purpose of the TRAINER* project. Thirteen Spanish companies from different sectors (construction, renewable energies, transport,...), are part of this consortium, among which Repsol along with 21 research centres and universities collaborate under the leadership of ACCIONA. The project was launched in 2010 and will be completed by the end of 2013. The consortium is working on the development of self-repairing systems and their implementation in different materials, not only polymers but also others such as concrete and asphalt. Besides, specific tests and protocols for evaluating the healing capability of the new materials developed are an important outcome and contribution of this project.

Materials are often internally or superficially damaged by mechanical causes (impacts, scratches, sudden temperature changes, etc.) and/or environmental factors (corrosion, UV radiation, humidity, temperature, etc.). Maintenance can be costly and time-consuming, especially in cases that require the replacement of the damaged part. Traditional measures establish high safety factors, periodic inspections and preventive maintenance. The implementation of the technologies developed in the TRAINER project would reduce CO_2 emissions, waste generation, costs and risks associated with maintenance and repairing operations. Additionally, service stops would be avoided, thus reducing costs and increasing end user satisfaction.

Following the chronological order of appearance in the state of the art of self-regeneration technologies for materials, there are three generations:

- 1st generation: The first developments of this technology published in 2001 are based on micro-capsules embedded in the matrix containing the healing agent. The healing agent spreads after rupture of the capsule due to the propagation of a crack and repairs the failure.
- 2nd generation: In 2007 a new generation emerged mimicking the human body's vascular network through the incorporation of hollow fibers containing the healing agent.
- 3rd generation: In 2009, a new concept was introduced based on the recombination of the broken bonds to regenerate the deteriorated material.

The TRAINER project aims to overcome barriers in the implementation of the present self-healing technologies and also to develop novel healing agents such as microorganisms, expansive agents, conductive fibers, etc. that will suppose a major technological breakthrough in the state of the art.

*(*CENIT project funded by the Centre for the Development of Industrial Technology (CDTI) and the Ministry of Science and Innovation of Spain*).

Self-Assembling Processes of Organic-Inorganic Nanobuilding Blocks and Supramolecular Units as New Routes for Nanostructured Polymer Networks

J.F. Gerard[1], J. Duchet[1], J. Galy[1], J. Bernard[1], L. Dai[2], F. Lortie[1]

[1]Ingénierie des Matériaux Polymères – UMR CNRS #5223

jean-francois.gerard@insa-lyon.fr

Self-assembling processes could be used to generate nanostructures within polymer networks in order to design innovative materials. In fact, non-conventional physical behaviours and combination of functionalities could be expected from the definition of morphologies of polymer networks at nanoscale. This lecture will review the different routes for nanostructuration of polymer networks and offer new approaches for designing inorganic-rich or organic supramolecular nanostructures from self-assembling processes.

Pre-formed nano-objects such as organic or inorganic nanoparticles or nanotubes are usely considered. Nevertheless, poorly ordered nanocomposites are obtained and the final dispersion depends strongly to the mixing procedure. Another route deals with the *in situ* generation of inorganic-rich nanodomains from a reaction-induced phase separation occurring during sol-gel reactions of (functional) metal alkoxides. The morphology could be tailored from the reaction conditions such as temperature, pH, concentration, etc. A third promising route to hybrid materials involves well-defined inorganic clusters such as polyhedral oligomeric silsesquioxanes (POSS), 1-3 nm $(SiO_{1.5})_n$ structures that can be considered as the tiniest silica nano-objects. Non-reactive organic substituents (such as isobutyl, iBu, or cyclohexyl, Cy) on the POSS cages will be used to trigger supramolecular assembling process whereas a reactive group will be used to covalently connected the metal-oxo cluster to polymer backbones via (co)polymerization with organic monomers, such as methacrylate ones. The ability to the POSS-cages to self-assemble in poly(MACyPOSS-co-MMA) copolymers and in well-defined hybrid block copolymers poly(MACyPOSS-b-MMA) and poly(MAiBuPOSS-b-MMA) synthesized by RAFT polymerization exhibiting high POSS weight content will be demonstrated. In a second part, the self-assembling of functional (amine or epoxy) POSS or the previous O/I block copolymers in epoxy networks will be evidenced. The hybrid block copolymers self-assembled within the epoxy precursors into micelles possessing an inorganic core and a PMMA corona. Thanks to the presence of the PMMA blocks that remain miscible until the end of the reaction, curing of the resulting blends afforded nanostructured hybrid organic/inorganic networks with well-dispersed inorganic-rich nanodomains with diameters on the order of 20 nm. Such an approach offers a new route for designing nanocomposites based on polymer networks as matrices from the in-situ generation via self-assembling of inorganic nanoparticles..

The second approach for nanostructuration of polymer networks consists in self-organization and freezing of a multi-scale hydrogen-bonded and π-stacked assemblies in an epoxy-amine network matrix. The self-assembly units are ureidopyrimidinones (UPy) introduced from a ureido-pyrimidinone-terminated polyoxypropylene ami-ne which can introduce both covalent crosslinks in the final network and supramolecular crosslinks from the self-assembling of the UPy units. The UPy-functionalized amine can self-assemble in the epoxy monomer (diglycidyl ether of Bisphenol-A) as a gel-like behaviour is observed for a critical content of associating units and below 90°C, i.e. the temperature above which the dimer's hydrogen-bonds are destroyed. This UPy-functionalized amine has been considered at different contents to nanostructure epoxy (DGEBA) non-functionalized amine reactive systems. After polycondensation, transparent materials have been obtained and characterized. The 3D-polymerization induces a (reaction-induced) phase separation between the associative UPy units and the polyoxypropylene chains. RIPS occurs from a decrease of solubility the supramolecular macromolecules into the growing network species. As the α-NH_2-ω-UPy-polyoxy propylene are mixed with the corresponding neat polyoxypropylene diamine, no phase separation is observed as the later ones improve the miscibility of UPy units all along construction of the networks, i.e. during curing. Nevertheless, SAXS evidences the existence of nanoscale domains with correlation distance between scattering objects depending upon concentration. Such an homogeneous (nano)phase separation leads to the construction of networks based on multifunctional nano-objects as supramolecular crosslinks in addition to the covalent ones. As a consequence, the mechanical properties in the rubbery state could be fully tailored from the coexistence of these physical and chemical crosslinks by changing the UPy content and temperature. In fact, the crosslink density could be tuned below and above 90°C, the temperature at which the dissociation of UPy occurs. Temperature-tuned crosslink density networks (as the association and dissociation processes of supramolecular assembling are fully reversible) could be designed from such a route for intelligent materials and integrated in devices.

Cyclic and Multiblock Polystyrene-*b*-Polyisoprene Copolymers by Combining Anionic Polymerization and Azide/Alkyne "Click" Chemistry

Athanasios Touris and Nikos Hadjichristidis

Department of Chemistry, University of Athens, Athens, Greece
hadjichristidis@chem.uoa.gr

Introduction

The unique characteristics of alkyne/azide "click" reaction[1] have contributed considerably to the popularity of "click" chemistry within the polymer and materials science communities. However, in the case of anionic polymerization, apart from the use of post- polymerization reactions to introduce active "clickable" groups, with subsequent loss of the lithium site, "clickable" groups have never been simultaneously present with the lithium-propagating sites. Such species would have the potential to take advantage of both the lithium and active "clickable" sites, thereby combining two ideal methods, for the synthesis of well-defined complex macromolecular architectures.

Along these lines, we report here a new strategy for the synthesis of well-defined cyclic block and multiblock copolymers of polystyrene (PS) and polyisoprene (PI).

Experimental Part

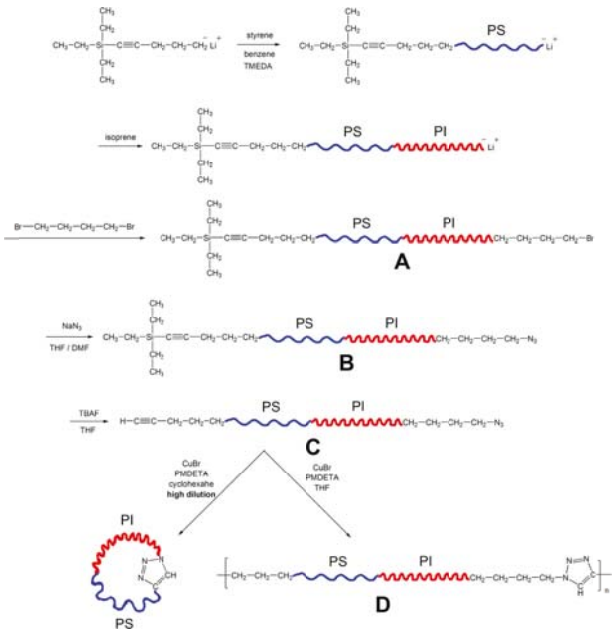
The purification of monomers, solvents and other compounds used here, to the standards required for anionic polymerization, has been described elsewhere.[2] All manipulations were done in vacuo in all-glass vessels, washed with *n*-BuLi, and rinsed with solvent. Additions were made through break-seals and removals through heat sealing of constrictions. Size exclusion chromatography (SEC) experiments were conducted at 40 °C in THF at a flow rate of 1 mL/min. All nuclear magnetic resonance (NMR) spectra were recorded in chloroform-*d* at 25 °C with a Varian Unity Plus 300/54 NMR spectrometer. A Perkin-Elmer Spectrun One model was used for the FTIR characterization.

Results and Discussion

Synthesis of the initiator 5-triethylsilyl-4-pentynyllithium (TESPLi). The synthesis of TESPLi, from (5-chloro-1-pentynyl)trimethylsilane and lithium, was conducted in benzene, as it is very well documented[3] that pentynylalkyllithiums undergo intramolecular cyclization reaction, at room temperature in hexane.

The general reactions for the synthesis of the linear diblock precursor, the cyclic diblock, and the multiblock copolymer are given in the **Scheme.**

Intramolecular "click" cyclization of α-acetylene-ω-azido-PS-*b*-PI. The reaction was conducted in cyclohexane ($c < 6 \times 10^{-5}$ g/mL), which is a rather poor solvent for the PS, a condition which favors the intramolecular reaction {M_n(PS)=8.1K, M_n(PS-b-PI)=14.9, PDI=1.05}.



The successful cyclization reaction was evidenced by: a) the shift of the SEC trace of the cyclic copolymer to a slightly higher elution volume and b) the disappearance of the azido and acetylene characteristic peaks in FTIR spectrum. The unreacted linear precursor α-acetylene-ω-azido-PS-*b*-PI was eliminated with an azido-functionalized Merrifield resin.

Intermolecular "click" coupling of α-acetylene-ω-azido-PS-*b*-PI. The intermolecular "click" reaction was conducted in THF, a good solvent for both blocks, which favors the intermolecular coupling reaction and thus leading to multiblock copolymers. The evolution of the reaction was monitored by SEC {highest peak, M_p=849K, DP=57}.

Conclusions

By using TESPLi and appropriate post-polymerization reactions, anα-acetylene-ω-azido-PS-*b*-PI was prepared, which led to cyclic block (intra-click, dilute cyclohexane solution) and multiblock (inter-click, concentrate THF solution) copolymers. These are only two architectures out of myriads this strategy (combination of two ideal methods) can produce.

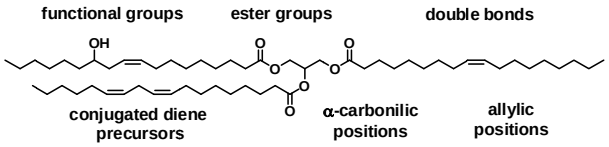
Universitat Rovira i Virgili
Marcel.li domingo s/n, Tarragona, Spain

juancarlos.ronda@urv.cat

The replacement of petroleum-based raw materials by renewable resources constitutes a major contemporary challenge in terms of both economical and environmental aspects[1].Natural vegetable oils are considered to be one of the most important classes of renewable sources because of the wide variety of possibilities for chemical transformations, universal availability, and low price and they are preferred by the chemical industry as alternative[2]. The main components of the triglyceride vegetable oils are saturated and unsaturated fatty acids which in its pure form are also available as platform chemicals for polymer synthesis

To convert vegetable oils and their derivatives to useful polymeric materials, three main different approaches can be used: the direct polymerization of the double bonds, the chemical modification and posterior polymerization and the polymerization of monomers synthesized using vegetable oil-derived platform chemicals. The purpose of our research is to develop new biobased thermoplastic and thermosetting polymers from vegetable oils by using these three approaches.



The direct polymerization of vegetable oils themselves is generally considered difficult due to their lack of active functional groups. Moreover the aliphatic nature and the light crosslinking that characterize the triglyceride-based materials make them incapable of displaying the necessary rigidity and strength required for structural applications. These drawbacks can be overcome for instance by cationic copolymerization of natural oils with styrene and divinylbenzene[3]. Even the resulting materials have the appropriate properties for a specific application, they must be inherently safe to be commercialized which involves to posses flame resistance and non toxic characteristics. One approach that we have explored is the preparation of styrene-soybean oil based copolymers containing phosphorus, silicon or boron as effective environmentally friendly flame-retardant systems.

The functionalization of the triglyceride double bonds is another common strategy for obtaining high performance polymeric materials and various chemical pathways for functionalising triglycerides have been described. We developed an environmentally friendly chemical procedure to obtain an enone-containing triglyceride from high oleic sunflower oil that could be an interesting alternative to epoxidized vegetable oils to produce thermosets. We studied their chemical crosslinking through aza-Michael and phospha-Michael reactions using aromatic diamines and aromatic secondary phosphine oxides in order to infer flame retardancy to the final material in the second case.

The use of fatty acids or its chemical derivatives to obtain useful polymers has also been considered by us. Starting from 10-undecenoic acid or 10-undecenyl alcohol, we synthesized a set of glycerol derived α,ω-dienes and trienes containing free hydroxylic groups. Acyclic diene metathesis (ADMET) polymerization of these monomers has been shown as an efficient tool for the synthesis of polymer architectures that are not available using other polymerization methods[4]. It has been demonstrated that ADMET polymerization can proceed in the presence of heteroatoms and a variety of functional groups, as long as the terminal olefins are far enough apart from them. So we used this synthetic procedure to prepare a set of lineal and branched polyether and polyester polyols with different molecular weight and hydroxyl content that were used to prepare conventional and segmented polyurethanes with shape memory properties in some cases. The transformation of fatty acids in the corresponding oxazolines and its living cationic polymerization has also been explored as a convenient route to produce polyols with control of molecular weight, hydroxyl content and hydroxyl group distribution which allows tuning the properties of the resulting polyurethanes.

Finally, 10-undecenoic, 10-undecynoic and oleic acid derivatives have been exploited as platform chemicals to obtain renewable diols, polyols, diacids and polyacids that have been used to produce linear and crosslinked polyurethanes and polyanhydrides. The coupling between a thiol and a carbon double or triple bond has received recently a growing interest. Thiol-ene and thiol-yne couplings comply with most of the requirements of the concept of a click reaction[5] and so it has been used with hydroxyl and carboxyl-functionalized thiols such as 2-mercaptoethanol, 1-thioglycerol and 3-mercaptopropanoic acid to obtain well defined functionalized structures.

Superparamagnetic iron oxide nanoparticles with appropriate surface chemistry can be used for numerous in vivo applications, such as magnetic resonance imaging (MRI) contrast enhancement, immunoassays, detoxification of biological fluids, hyperthermia, drug delivery, and cell separation. All of these biomedical applications require nanoparticles with high magnetization values, a size smaller than 100 nm, and a narrow particle size distribution. These applications also need peculiar surface coating of the magnetic nanoparticles, which has to be nontoxic and biocompatible, and must also allow for a targetable delivery with particle localization in a specific area. Such magnetic nanoparticles can bind to drugs, proteins, enzymes, antibodies, or nucleotides and can be directed to an organ tissue or tumor using an external magnetic field. In this way, due to the existing interest in new hybrid particles in the colloidal range based on both magnetic and polymeric materials for applications in biotechnological fields, an overview on the preparation and characterization of hybrid (polymeric/inorganic) nanoparticles will be presented focusing on the preparation of magnetic polymer nanoparticles and silica/polymer nanoparticles by different polymerization processes developed to achieve a better control in the morphology of the nanocomposite particles. The different morphologies (from a typical core-shell to a homogeneously distributed morphology) obtained depending on reaction conditions will be revised, emphasizing on the reaction conditions and polymerization processes in dispersed media used [1-6].

In brief, this contribution is focused on the synthesis, characterization, and biotechnological applications of hybrid nanoparticles. The challenge in all the synthesis strategies is their optimized production depending on necessity or biotechnological application in which they could be used. The target is the optimization of the encapsulation of the inorganic nanoparticle into the polymeric matrix (shell) avoiding the production of pure polymeric nanoparticles.

Synthesis of Multicompartment Nanoparticles

Alex M. van Herk, Syed Imran Ali, Hans Heuts

Eindhoven University of Technology
P.O. Box 513, 5600 MB Eindhoven, The Netherlands

a.m.v.herk@tue.nl

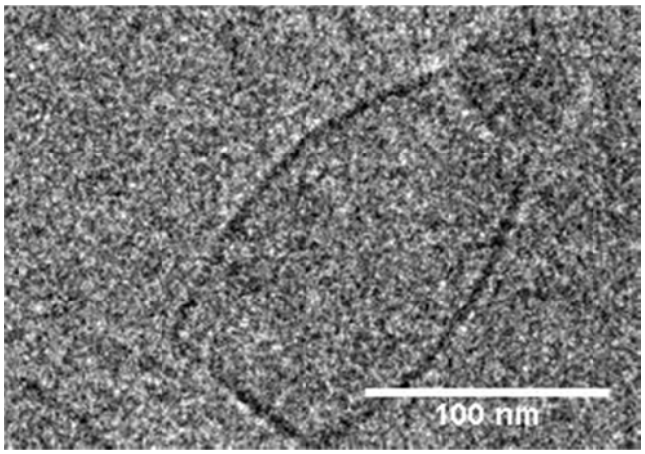
In the field of encapsulation of many types of particles like pigments, fillers and clay particles [1,2] tremendous progress has been made and applications of encapsulated inorganic particles are known, for example in car coatings. Core-shell latex particles are applied for many decades.

A new challenge is in the encapsulation of clay platelets striving towards a high aspect ratio of the resulting nanostructured particles. One is struggling with surface tensions there and the thermodynamic driving force to small surface area. Similar problems exist in the field of vesicle polymerization [3]. After careful studies it turned out to be very difficult to produce a thin wall of polymer inside the hydrophobic domain of the vesicle double layer. The most common structure produced is that of the parachute, a latex particle connected to the vesicle structure. Apparently only with strong interactions or covalent bonds between the surfactant and the polymer one is able to produce hollow particles through vesicle polymerization. The field of vesicle polymerization opens many possibilities to produce many different and interesting new nanostructured particles. The phenomenon of phase separation in latex particles not only is controlled by thermodynamic factors (mainly interfacial tensions) but alsoby kinetic factors. Specialty applications like intraocular eye lenses bases on transparent latices are showing the enormous potential of nanocomposites in the area of specialties [4].

So the field of emulsion polymerization is maturing to a science where control on a nanolevel becomes common practice and moreover the synthesis and application of these nanostructured particles can be on bulk scale.

Added to this is the introduction of controlled radical polymerization techniques as an additional means to control molecular microstructure and morphology in latex systems. It will be shown that many different multicompartment structures can be produced while applying the general principles of thermodynamics and kinetics in emulsion polymerizations. One example are the so-called nanobottles where a hollow structure is combined with a latex particle, making a lid for the ‘nanobottle’.

The use of RAFT agents has made it possible to produce flat latex particles during clay encapsulation [5] and responsive nanocapsules [6].



One of a kind nanobottle produced in vesicle polymerization (normal particles look more spherical)

Synthesis and Characterization of Multivalent Dendritic Glycopolymers and their Use in Life Science Applications

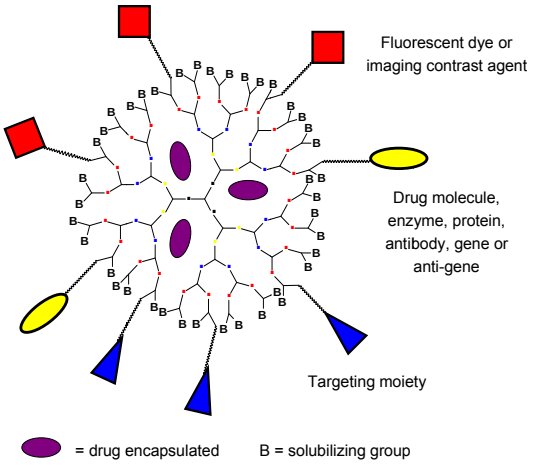
Brigitte Voit and Dietmar Appelhans

Leibniz-Institut für Polymerforschung Dresden e.V., Hohe Strasse 6, 01069 Dresden, Germany

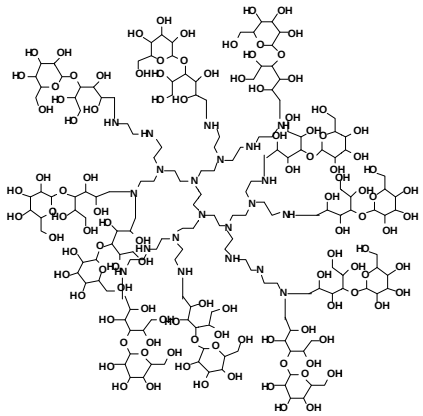
e-mail: voit@ipfdd.de

Introduction Dendritic polymers – both, perfectly branched dendrimers and hyperbranched polymers - can be prepared in a broad variety of structures and exhibit interesting properties like high solubility and functionality, dense globular structure and low solution viscosity.[1] The high control over structure, molar mass and size in dendrimers renders them specifically interesting as functional nanomaterials in biomedical applications.

Results and Discussion Very high biocompatibility as well as specific interactions can be achieved by modifying e.g. poly(propylene imine) dendrimers with dense sugar shells through reductive amination.[2,3]The materials have been synthesized successfully varying the dendritic scaffold and the degree of modification[2,4,5] and we were able to demonstrate their usefulness as nanoscopic delivery system for drugs, biomacromolecules, metal clusters and nanoparticles as well as RNA and DNA into cells in in-vitro and in-vivo experiments.[6]Also, nanodiamands[7] as well as various nanoparticles, prepared in the presences of dendritic glycopolymers, can be decorated with a highly biocompatible oligosaccharide shell.



In addition, densely maltose shelled glycodendrimers showed very promising effects to prevent prion aggregation, a first step in the potential treatment of prion and Alzheimer disease.[2,8]Ongoing work is directed to the understanding of the interactions of dendritic glycopolymers towards drugs and biomolecules in solution, including their aggregation behavior under physiological and serum conditions, but also the uptake behavior of the dendritic glycopolymers and their nanocarrier properties towards cells and organs. Further studies are engaged in the bio-distribution and blood circulation of those dendritic glycopolymers and their drug complexes with regard to selective targeting of the drug-nanocarrier complexes towards organs and brain under in-vivo conditions.



Maltose modified polyethylene imine

Hyperbranched (hb) polymers like polyethylene imine (PEI), which are less well-defined but more easily available than the perfectly branched dendrimers, can as well be modified with various sugar moieties and are highly promising in the field of biosensors and diagnostics.[5] We were able to prove that stable films can be prepared on surfaces which show extremely low unspecific protein adsorption, and allow e.g. the selective adsorption of ATP and other biological relevant molecules.[9] These materials can be further decorated with specific binding units.

*richa@quijote.ugto.mx

Application of biocatalysis to the synthesis of biodegradable polyesters from lactones has been studied in the Polymer group of the University of Guanajuato for the last five years. An efficient process to quantitatively isolate *Yarrowia lipolytica* (YLL) strains was developed in our laboratory, and the extracted lipase was proved to induce ring-opening polymerization (ROP) of lactones (Barrera *et al*, (2008))[1]. Recently, research has been focused to (a) studies on the immobilization of YLL onto different matrices (b) kinetics studies of ROP of lactones under different reaction conditions using immobilized YLL (reaction times, solvent effect, temperature)[2], (3) studies on acylation of isosorbide by immobilized YLL[3]. and (4) chemo-enzymatic synthesis of polyester urethanes

Keyword: Yarrowia lipolytica lipase (YLL); biocatalysis; biodegradable polymers; isosorbide; ROP (ring-opening polymerization)

Introduction

Polymerization reactions catalyzed by enzymes proceed through quimioselective, regiospecific and stereoselective pathways. Lipases are one of the most versatile biocatalysts that bring about a wide range of bioconversion reactions, including ring-opening polymerization (ROP) of cyclic esters. *Yarrowia lipolytica* is a yeast species widely used in industrial applications. Strains of this yeast secrete a set of proteins (alkaline or acid proteases, lipases) that can be quantitatively isolated from the production culture medium[1].

In this presentation, results on the synthesis of biodegradable polyesters using YLL as biocatalyst will be discussed.

Materials and Methods

Polymerizations were carried out in 10 mL vials previously dried and purged with dry nitrogen. In a typical run, monomer (ε-CL), catalyst (immobilized enzyme) and in some cases solvent or ionic liquid were added under dry nitrogen atmosphere. Vials were stoppered with a rubber septum and placed in a thermostated bath at predetermined temperatures and time periods.

Immobilization of lipases: Before immobilization, Lewatit 1026 beads were activated with ethanol (1:10 beads: ethanol), washed with distilled water and dried under vacuum for 24 h at room temperature. The beads (1g) were shaken in a rotatory shaker in 15 mL of lipase solution with 0.1568 mg/mL of YLL at 4ºC for 24 h. After incubation, the carrier was filtered off, washed with distilled water and then dried under vacuum for 24 h at room temperature.

Final polymers were crystallized from chloroform/methanol, separated from the insoluble enzyme by filtration through 10-15 µm glass-fritted filters and dried under vacuum. Molecular weights and conversions during reaction were monitored by ^{1}HNMR. The crystallized polymers were in general analyzed by FT-IR, MALDI-TOF, DSC, WAXS, solution (proton and carbon-13) and solid-state-NMR.

Results and Discussion

Lipase performance is improved in the presence of ionic liquids[2]. Immobilization of enzymes in general improves biocatalytic performance. Immobilized Yarrowia lipolytica lipase (YLL) catalyzes bulk ring opening polymerization of ε-caprolactone in the presence of isosorbide. Biodegradable amphiphilic oligomers can be obtained using this methodology[3]. PCL diols can be synthesized using immobilized YLL. These diols can be quantitatively converted to biodegradables polyurethanes[4].

Conclusions

Various methods to obtain biodegradable polyesters using YLL as catalyst were developed. Information on chemical structure and morphology were derived using different characterization techniques.

RAFT polymerization and Various Click Reactions to Develop a Micellar Drug Delivery System for Albendazole

Martina Stenzel, Yoseop Kim, Yue Zhao, Firdaus Mohd Yhaya

Centre for Advanced Macromolecular Design (CAMD), University of New South Wales, Sydney, Australia

Introduction

Albendazole (ABZ), methyl[5-(propylthio)-1-H-benzimidazol-2yl]carbamate, is a benzimidazole derivative containing a broad activity spectrum against intestinal helminth infections. Recently, it has been discovered that ABZ is also highly effective as anti-cancer agent.

Treatment is however hampered due to the poor aqueous solubility of ABZ. The encapsulation of a drug into a polymer matrix such as nanospheres and microspheres is expected to increase the efficacy of a drug as well as to decrease potential side effects. The slow release of drug from the carrier ensures its long-term supply. Block copolymer micelles have been widely studied as a drug carrier system. micelle to protect the drug from immediate renal elimination. Here, the development of a drug delivery system for albendazole is discussed. The block copolymers are synthesized via RAFT polymerization [1], but in order to achieve a more stable drug carrier, micelles were crosslinked using amine- or thiol-isocyanate click reactions. In addition, to increase drug loading and delay drug release, the polymers are conjugated with β-cyclodextrin, which can host ABZ as guest.

Results and discussion

Group Contribution Method was used to estimate the partial solubility parameters for the drug (ABZ) and various polymers. Poly(methyl methacrylate) (PMMA) was identified as an optimum candidate using this predictive tool while poly(lauryl methacrylate) (PLMA) was calculated to have only a low compatibility with ABZ. Block copolymers were prepared via reversible addition fragmentation chain transfer (RAFT) polymerization resulting using poly(polyethylene glycol methyl ether methacrylate) as the water-soluble block and various ratios of MMA and LMA to determine the optimum polymer composition of the core of the micelle to achieve highest drug loading. Drug loading of the micelles with ABZ confirm that the different compatibilities affect the loading and retention time of the drug with most drug being loading in micelles with PMMA in the core while increasing amount of LMA decrease the amount of loaded drug and also lead to faster drug release. The micelles are readily taken up by tumour cell, OVCAR-3, although the uptake abruptly stops when the concentration reaches a certain critical low value. The uptake could be enhanced by decorating the micelles with RGD, which could be conjugated to the polymer endgroup when a aldehyde containing RAFT agent was employed.

However, the low stability of the drug carrier and the associated low uptake of micelles at low concentration led to the further evolution of the current drug carrier. The stable micelles, which can be created by crosslinking, should in addition have features that encapsulate the drug safely in the blood stream, but release the drug rapidly once the micelle has been taken up by the cell. A block copolymer, with reactive isocyanate units was prepared via the RAFT process and self-assembled into micelles. Addition of 1,8 diamino octane leads to crosslinking of the micelles, but also to excess amine groups that can respond to changes of pH value. The drug, albendazole (ABZ), was encapsulated tightly at pH7, but released suddenly at pH5. Cell experiments using OVCAR-3 cell lines show the efficient uptake of these nanoparticles and the fast release of the drug.

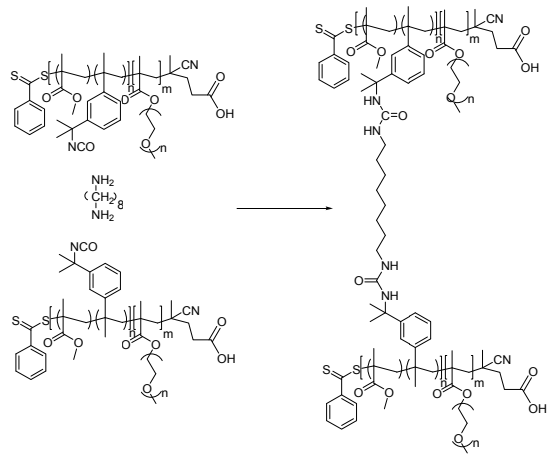

Figure 1: Synthesis of pH-responsive core-crosslinked block copolymers micelles; excess diamines will lead to amine pendant group

Instead of using amine-isocyanate click reaction, this approach has also been tested using thiol-isocyanate click reaction, which will not result in pH-responsive, but in a system with disulfide groups.

An alternative route to generate drug delivery carriers is by attaching monofunctional β-cyclodextrin to a reactive polymer. Two techniques were employed, azide-alkyne click reaction and thiol-ene reaction, both leading to high conjugation yields. The β-cyclodextrin polymers were found to enhance the toxicity of ABZ/

Conclusion

The combination of RAFT polymerization with various click reaction can be used to build up molecular architectures for a specific drug delivery problem shown here using the drug albendazole. Both approaches, cross-linked micelles and micelles with β-cyclodextrin, were found to be equally promising carriers

Hybrid Brushes Nanoparticles: synthesis and properties

Julieta Paez, Ariel Cappelletti and Miriam Strumia

IMBIV (Conicet). Facultad de Ciencias Químicas. Universidad Nacional de Córdoba. Ciudad Universitaria. (5000) Córdoba. Argentina.

mcs@fcq.unc.edu.ar

Introduction

Recently, the preparation of organic-inorganic hybrid materials that utilizes various supramolecular driving forces has been progressing rapidly. In particular, organic molecular or nanoscale materials that are tethered on solid supports such as spherical particles, thin solid films, or metal surfaces form self-assembling monolayers with specific functions. This possibility of the creation of well-defined nanohybrid materials with specific properties is of great significance for fundamental research and for their use in numerous potential applications, such as engineering, communications, robotic and medicine for therapeutic drug delivery and the development of treatments for a variety of diseases and disorders. The rise of nanomaterials correlates with further advances in these disciplines[1].

One of the fundamental aspects of research in nanochemistry is the synthesis and morphological control of metallic nanoparticles (NPs). The funtionalization the surface of NPs and to improve the particles compatibility with different environments by the proper attachment of organic monomer or polymer groups has therefore attracted much interest.

In nanochemistry, the term "dendronization" describes the covalent or supramolecular interaction between dendrons and non-dendritic substrates, allowing the preparation of new hybrid materials with outstanding properties.[2] In this context, making use of dendritic structures as building blocks is based on the possibility of systematically and rigorously controlling properties of the system such as size, shape, number and type of functional groups. Following this approach, it has been reported the preparation of protein-resistant surfaces,[3] and the design of electroactive surfaces as well. Moreover, the combination of dendritic molecules with metallic or oxide nanoparticles has led to the construction of hybrid materials with a huge variety of applications, for example in the preparation of nanoelectronic materials, sensor devices, or nanocatalysis, among others.[4]

Our research group is working on the chemical modification of polymers and different substrates using dendritic molecules as building blocks. In aprevious work[5], we presented the study of the hydrophobic/hydrophilic balance of a family of dendrons synthesized in our labs bearing a different number and nature of functional groups on their surface. The selection of the structure in the construction of these molecules was based on a synthetic strategy to generate a branched effect on the properties of the resulting building block and the subsequently constructed product. Similarly, we reported[6-8] the use of some of those grafting molecules to modify the chemical/physical properties of linear and crosslinked polymers, films and electrodes. Important changes on the properties of these dendronized products were observed and they are strongly dependent on the chemical nature of the dendrons used.

In this occasion, we will describe different synthetic routes used to obtain functionalized gold and magnetic NPs. The methodologies of "*grafting from*" and "*grafting to*" were choosed for the chemical surface modification of the NPs. They were modified by polymerization of thermosensible monomers and by the covalent bond of different dendrons previously synthesized in our labs. The characterization and the physical/chemical properties were determined. The results found and the comparative analysis on the surface chemical modification of the gold and magnetic nanoparticles, will be presented.

Organocatalysis of Polymerizations: The Contribution of *N*-Heterocyclic Carbenes

Jean Raynaud, Julien Pinaud, Maréva Fèvre, Joan Vignolle, Daniel Taton and Yves Gnanou,

Université de Bordeaux & Centre National de la Recherche Scientifique
Laboratoire de Chimie des Polymères Organiques, 16 avenue Pey-Berland
Pessac cedex, F-33607 France

gnanou@enscpb.fr

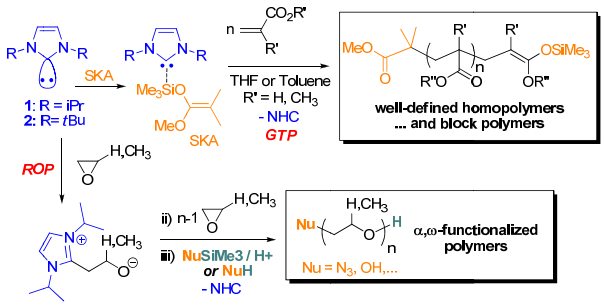
Introduction:

Carbene chemistry has received a considerable attention in molecular synthesis, and more recently, in macromolecular chemistry as well. Among organocatalysts, *N*-heterocyclic carbenes (NHCs) have emerged as the most efficient and versatile for a variety of organic transformations.

Results and discussion:

After Hedrick, Waymouth *et al.* established that NHCs could catalyze the ring-opening polymerization (ROP) of cyclic esters, we have expanded the use of these organic activators to various polymerization reactions, including ROP of epoxides,[1-3] group transfer polymerization (GTP) of (meth)acrylics,[4] and step-growth polymerization of terephtaldehyde.[5]

For instance, NHCs can trigger the GTP of both methacrylic and acrylic monomers initiated by a silyl ketene acetal (SKA) both in polar and apolar media,[4] by an associative (concerted) mechanism allowing the synthesis of all acrylic block copolymers by sequential GTP.[4]



NHC-induced GTP of (meth)acrylics and ROP of epoxides

The same NHCs can serve either as organic initiators or as true organocatalysts for ROP of both ethylene and propylene oxides, *via* the formation of a zwitterionic imidazolium alkoxide intermediate.[1-3] Use of a functionalizing agent of NuE-type (e.g. Nu= -OH; $-N_3$; $-OCH_2C{\equiv}CH$ and E= -H or $-SiMe_3$) as a quencher [1-3] or as a chain moderator at the beginning of the reaction,[2] gives a direct access to well-defined heterodifunctionalized poly(ethylene oxide)s and poly(propylene oxide)s.

The lecture will also describe the design of recyclable poly(NHC)s generated from polymeric ionic liquids (PILs) that are anionic-responsive polyelectrolytes. These poly(NHC)s have been evaluated for homogeneous and heterogeneous catalysis of model reactions, namely benzoin condensation and transesterification.

Conclusions:

This presentation summarizes the recent advances in organocatalyzed polymerizations. It highlights the advantages associated with the use of organic catalysts and namely of NHCs which now appear as viable substitutes for classical metallic catalysts, in a context where the demand for sustainable and environmentally-friendly reactants and processes steadily increases. The lecture will unveil and review those among NHCs that can trigger polymerization and also monomers amenable to organocatalysis by these NHCs. Will also be thoroughly discussed the mechanisms involved in each pair of NHC and monomer and the controlled/ living character for chain polymerizations.

Self-Assembly of Nanocomposite Polymer Latex and Structural Color Films

*Bo You, Lingli Duan, Zhehong Shen, Limin Wu**

Department of Materials Science and the Key Laboratory of Molecular Engineering of Polymers of MOE , Fudan University, Shanghai 200433, China

lmw@fudan.edu.cn

In recent years, the assembly of colloidal spheres into two-dimensional and three-dimensional ordered structures has attract great attention since it is a simple, cost-efficient strategy to fabricate crystal films for some important potential applications, such as photonic crystals, biosensors, templates, and even paints, photonic papers and cosmetics due to the structural colors of the crystal films.

Recently, we have report for the first time that the "soft" polymer spheres can also form three-dimensional ordered structure with the aid of nanosilica particles. In this method, monodisperse "soft" polymer spheres colloids are synthesized by surfactant-free emulsion polymerization and then blended with colloidal silica to obtain nanocomposite polymer latex. When this nanocomposite polymer latex is cast on a glass substrate and dried at room temperature, these "soft" polymer spheres could periodically arrange, forming three-dimensional ordered films in large-scale area.

Figure 1 shows the cross-sectional SEM images and the typical TEM image of the polymer films with various nanosilica contents. It can be seen that the pure latex polymer film appears no visible ordered structure (Figure 1a), just as typical polymer latex. When 2 wt%, 5 wt% or even 10 wt% of nanosilica was blended with this polymer latex, the films present an ordered array of polymer spheres in the cross-sections (Figure 1b−1d). But more nanosilica would cause irregular array (Figure 1e). The typical TEM image (Figure 1f) clearly indicates a hexagonal face centered cubic (fcc) array of the polymer spheres. The corresponding live Fast Fourier Transform Algorithm image, as displayed in the inset of Fig. 1f, also strongly suggests that the three-dimensional ordered structure exists in the nanocomposite film. The reason why the "soft" polymer spheres can self-assemble into three-dimensional structure with the aid of nanosilica particles, is probably attributed to the interaction between the −SiOH groups of nanosilica particles and −COOH groups of polymer spheres. It is this interaction that nanosilica particles can be adsorbed on the surfaces of the polymer spheres, which can interdict the deformation and coalescence of "soft"

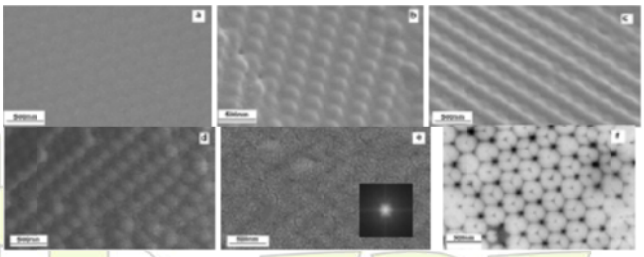

Figure 1. The cross-sectional SEM images and TEM image of films with various nanosilica contents. a) pure polymer, b) 2 wt%, c) 5 wt%, d) 10 wt%, e) 20 wt%, f) typical TEM image of the film.

These ordered films display brilliant green color, while the pure polymer film appears colorless and transparent just as the typical latex polymer film and too much nanosilica causes a white film. And the peak position of the stop band and the color of the film depend on the refractive index contrast between polymer and nanosilica, relatively filling ratio and the diameter of polymer spheres. For example, when the sphere size increases from 180, 210, 240, 260, 270, 310 to 340 nm, the film exhibits different brilliant colors transiting from blue to red (Figure 2). And their corresponding photonic band red-shifts from a wavelength of 435, 450, 505, 530, 545, 605 to 640 nm. This means that the structural color is tunable.

Figure 2. The photographs of films with various sizes of polymer spheres.a) 180, b) 210, c) 240, d) 260, e) 270, f) 310, g) 340 nm

Furthermore, we can fabricate a reversible solvatochromic--responsive coatings and films, as demonstrated in Figure 3.

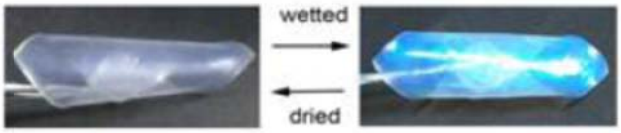

Figure 3. Reversible color change of the crystal film

And the chroma of the structural colors can be obviously improved by doping carbon black into the self−assembly of colloidal polymer spheres and nanosilica particles, as shown in Figure 4.

Figure 4. Intuitionistic comparison between the structural colors of CC films and peacock feathers. The CC films with carbon black (up) and without carbon black (down)

ABSTRACTS

INVITED LECTURES

Topic 2: New Analytical and Characterization Tools

New Opportunities with Spectroscopic Imaging

Sergei G. Kazarian

Department of Chemical Engineering, Imperial College London, UK

s.kazarian@imperial.ac.uk

FTIR spectroscopic imaging has emerged as a powerful tool for characterisation of polymeric materials. This talk will outline the research we are developing in this area with focus on micro- and macro ATR (Attenuated Total Reflection)-FTIR spectroscopic imaging applied to heterogeneous materials. Main advantage of micro ATR-FTIR imaging using a germanium microscope objective is its enhanced spatial resolution. The advantages of macro ATR-FTIR imaging include its versatility and the relative ease of sample preparation. Recent new developments in macro ATR-FTIR imaging with the use of inverted prism crystals show good potential with applications to polymer interdiffusion, mixing and phase separation, studies of polymer blends and layered polymeric structures. New opportunities exist to obtain ATR-FTIR images of the same sample from different depths using a diamond ATR imaging accessory. This approach involved the introduction of a movable aperture to restrict the angles of incidence to certain values. [1, 2]

Results and Discussions

A most recent application of this new approach has been demonstrated for layered polymeric structures. As the evanescent wave in ATR spectroscopy is not limited by diffraction, it was possible to resolve thin sandwiched polymer-layers non-destructively within a layered polymer system. Chemical images were obtained from the layers of different thickness of the sample by moving a lab-made aperture to specific positions on the condenser lens of the ATR accessory. Sequences of spectroscopic images illustrate the successive appearance of thin, sandwiched layers of polybutylmethacrylate (400 nm thick) and polycarbonate (300 nm thick) in different depths of the stack of polymer layers. The depth resolution of variable angle ATR-FTIR imaging in the z-direction is sufficiently high to detect surface roughness at the interface between different polymer layers. Two different stacks of polymers with reordered sandwichlayers were imaged simultaneously, demonstrating the potential of variable angle ATR-FT-IR for 3D-imaging of a sample with 3D-heterogeneity which can be a powerful analytical technique for characterisation of polymeric materials.

Another exciting recent application of this imaging approach has been demonstrated by the first FTIR images of flows in the channels of microfluidic devices. This opens many new possibilities of using macro ATRFTIR imaging as a novel detection method in the studies of microfluidics. [3, 4]

Conclusions

Significant potential exists in the applications of FTIR spectroscopic imaging to polymeric materials using attenuated total reflection in micro and macro imaging modes.

Macro ATR imaging with variable angle of incidence provided opportunity of destructive, three-dimensional chemical imaging of polymeric materials with high z-resolution. This approach may have considerable impact in the investigation of thin or buried layers in coating and lamination industry, in studies of polymer interdiffusion. Many opportunities are also present for applications of ATR-FTIR imaging in macro mode for studying dynamic systems.

Elucidation of Macromolecular Structure using the MHS Plot

Bassem Sabagh, Sandrine Olivier, Paul G Clarke.

Malvern Instruments

Bassem.sabagh@malvern.com

Abstract: The Mark-Houwink-Sakurada (MHS) plot is a powerful tool for analysing the structure of macromolecules because it describes the relationship between the intrinsic viscosity and the molecular weight of polymer molecules in solution.

$$IV = KM^{\alpha}$$

The traditional construction of the plot from discrete intrinsic viscosity and molecular weight measurements is a laborious and difficult task, but over the last 20 years, the introduction and then improvement and simplification of Triple Detection GPC has given rapid access to accurate MHS plots. This paper will describe how these plots are so easily accessed and illustrate how they are used to analyse the structure of a variety of polymers. It will look into the information that can be obtained and use this to compare samples qualitatively describing conformation, or quantitatively with calculation of branching number and frequency via the Zimm-Stockmayer approach.

The Use of Analytical Techniques in the Study and Development of Structural Adhesives

Senén Paz Abuín

GAIRESA

senen@gairesa.com

In a pure sense the adhesion is a measurement of the attractive/s force/s which maintains two surfaces intimately bonded[1]. According to this definition it is clear that if the attractive forces increase, the value of adhesion should increase in the same direction. In the case of solid surfaces, even a fractured material, it is highly difficult to reach a reasonable contact area between two surfaces. A liquid, capable to wet both surfaces, can fill all irregularities and make a new imperfections-free surface. This liquid can be very suitable for many purposes if it keeps the two surfaces bonded together through an adhesive/cohesive joint. Such a liquid, either in the initial state or when converted into a solid, is called an adhesive. Keeping in mind this idea of an adhesive, it is clear that mainly epoxy, acrylic and polyurethane prepolymers can be suitable as raw material for adhesives. They can wet most surfaces and develop different types of chemical groups capable of originating very high attractive and interactive forces with many solids.

The knowledge of the evolution of reaction is extremely important due to the great influence on final properties and behaviour of the adhesive. A partially cured or incompletely cured adhesive contains unreacted compounds that can result in reduced bond strength and poor environmental resistance and durability. Cure monitoring requires the measurement of a selected material property in order to assess the level of cure. Many different test methods are used to measure the cure rate and cure evolution of polymeric adhesives. The cure implies a study under different temperatures and conditions and several analytical techniques as Fourier Transform Infrared Spectroscopy (FTIR), Differential Scanning Calorimetry (DSC), Rheology and Dynamomechanical Analysis (DMA) can be used to follow the reaction.

1. FT-IR. Due to the fact that in the fingerprint region there are many bands, the near region[2] is the preferred option for quantification purposes.

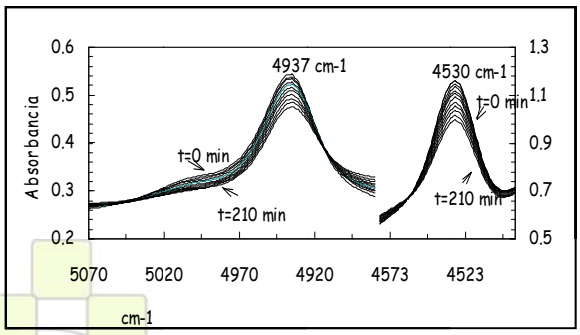

Figure 1. Quantitative FT-NIR experiment to follow the epoxy-amine cure

2. DSC. In spite of that this technique does not give information on the evolution of monomers separately, it is a very powerful method to follow the cure and thermal transitions[3].

3. RHEOLOGY. Rheological properties such as the viscosity and the dynamic modulus can be directly correlated to the evolving physical and mechanical properties of the polymer during cure[4]. Oscillation tests in a controlled stress rheometer can provide a total curing profile for polymeric adhesives.

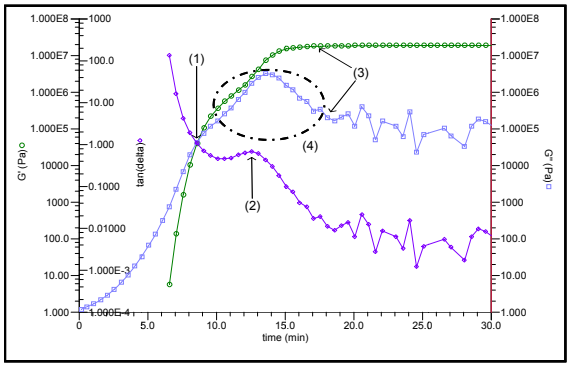

Figure 2. Stages in an epoxy-amine cure reaction by rheology

4. DMA. The cohesive body of an adhesive can be properly evaluated with the help of this technique. DMA is a sensitive probe of molecular mobility. Thus, measurement of loss modulus provides a convenient method for the identification of mechanical relaxation temperatures.

Solid State NMR Methods for Studying Functional Macromolecular and Supramolecular Systems

Hans Wolfgang Spiess

Max Planck Institute for Polymer Research, Ackermannweg 10, 55128 Mainz, Germany

spiess@mpip-mainz.mpg.de

Nanostructures are in the focus of current materials science. They occur in advanced synthetic as well as in biological systems through self-assembly of carefully chosen building blocks. Secondary interactions such as hydrogen bonding, aromatic π-π interactions, electrostatic forces and attachment to surfaces are of central importance. Despite being highly ordered on a local scale, such systems often do not crystallize. Therefore, their structures cannot be determined by conventional X-ray crystallography or neutron scattering. Alternatives are needed which should provide structural and dynamic information, preferably requiring only small amounts of as-synthesized samples, without the need of isotopic labeling.

High resolution solid state NMR can meet these requirements [1], provided that sufficiently selective information can be extracted from the corresponding spectra. For that purpose solid state ^{1}H, ^{13}C, and ^{15}N NMR techniques have been developed combining fast MAS and DQ NMR spectroscopy, which make use of the homonuclear and heteronuclear dipole-dipole couplings. These techniques have provided new insight in hydrogen bonded structures in the solid state [2], columnar stacking and molecular dynamics of discotics [3, 4], as well as self-assembly and dynamics of polypeptides [5]. For full structural elucidation, the spectroscopic data have to be combined with other techniques such as scattering and computer simulation [1]. The techniques will be introduced and the findings from NMR will be related to the function of such materials, such as proton conductivity [2] and photoconductivity [5].

Effect of (3,1) Chain-Walking Defects Compared with Other Regio and Constitutional Defects on the Crystallization and Melting of Isotactic Poly(propylene)

R. G. Alamo[*], *C. Ruiz-Orta, J.P. Fernandez-Blazquez, A. M. Anderson, G.W. Coates*

[1]FAMU/FSU College of Engineering, Department of Chemical and Biomedical Engineering, Tallahassee, FL, USA
[2]Department of Chemistry and Chemical Biology, Baker Laboratory, Cornell University, Ithaca, NY

alamo@eng.fsu.edu

Introduction. The commercial success of novel polyolefins and the extended range of applications compared to classical commodity polyethylenes and poly(propylenes) used in the past are due by in large to a variety of possible modifications of the basic material. These modifications are feasible in situ, i.e. in the polymerization reactor, due to the development of new catalysts able to copolymerize olefin monomers with non-polar and polar comonomers and at a much higher levels of incorporation while controlling molecular weight and comonomer distribution. Recently, a new family of polypropylene has been synthesized via living polymerization with late metal, nickel α-diimine catalysts. These polymers differ from polypropylene produced by early metal catalysts due to chain-walking events which often result in unique defect microstructures. The comparison of (3,1) *i*PP crystalline properties with those of random propylene ethylene (PE) copolymers is of interest due to the generation in the novel *i*PP of backbone ethylene runs via (3,1) enchainments that are, in principle, of a similar nature to the ethylene runs resulting from copolymerization with ethylene. Alternatively, if chain walking defects are generated as random events and are excluded from the crystalline regions, their melting and crystalline properties should parallel the behavior of propylene 1-hexene (PH) (< 13 mol% comonomer) and propylene 1-octene (PO) since both co-units are known to be excluded from the crystals. With complexes for the isotactic polymerization of propylene in hand, a detailed ^{13}C NMR study on polypropylene microstructure and crystalline properties was pursued.

Materials and Methods. Two series of (3,1) iPP were synthesized using two living nickel α-diimine complexes (*rac-1*and *rac-4*) activated with methylaluminoxane (MAO) as described in prior works (1,2). Detailed defect characterization was obtained from high resolution ^{13}C NMR spectra in tetrachloroethane-d_2 using a Varian spectrometer with a frequency of 700 MHz on ^{1}H. The total point defect content encompasses a range between 3 and ~ 18 mol% for both series. The melting peaks, T_m, heat of fusion, ΔH, and overall crystallization kinetics were followed by DSC. Levels of crystallinity, polymorphic behaviour and crystal thicknesses were obtained from wide and small angle x-ray diffractograms (SAXS, WAXD) using a Bruker Nanostar diffractometer operating at ambient temperature on samples that were previously isothermally crystallized either in the DSC or in thermostated baths. Molecular weights (M_n and M_w) and polydispersities were determined by high temperature gel permeation chromatography (GPC) in a Waters Alliance GPCV 2000 GPC equipped with a Waters DRI detector and viscometer.

Results and Discussion. The thermodynamic, structural and mechanical properties of isotactic polypropylene depend strongly on the type, content and distribution of defects (other than isotactic (1,2) additions) generated during synthesis. Novel iPP synthesized with late metal catalysts (*rac-1*and *rac-4*) contained unique defects characterized by isolated and successive groups of (2,1) and (3,1) enchainments, all identified by solution state ^{13}C NMR spectroscopy. Although the nature of the defects is similar to addition of ethylene units, the impact in sequence packing and development of the crystalline state is rather different. The ethylene unit enters the *i*PP crystal, while the (3,1) defect is rejected. Compared with earlier metallocene *i*PP, PH and PO copolymers used as control, *i*PP with chain-walking defects melt at lower temperatures and display a dramatic depression of crystallinity on a customary point defect molar composition per 100 monomers. These features, coupled with reduced crystallization rates, lower crystallite thicknesses and enhanced contents of crystallites in the gamma phase, are associated with a shortening of isotactic sequence lengths which are caused by the bulky nature of most (3,1) associated defects when compared with random copolymers. Chain-walking defects, such as (3,1) enchainments, decrease the level of *i*PP crystallinity at a much faster rate than the more common defects found in Ziegler-Natta or early metallocene made *i*PP as well as propylene random 1-alkene copolymers.

The experimental increasing gap in crystallinity between (3,1) *i*PP and propylene copolymers with increasing defect concentration is also explained by equilibrium basis. Plotted on the basis of Flory's equilibrium theory, the melting temperature-composition behavior of late metal catalyzed iPP closely follows the behavior of PH and PO random copolymers indicating that the defects are *random-blocky* or generated on a random fashion but of a defined blocky monomer nature.

Conclusion. In reference to defects generated in iPP by earlier metal catalysts, iPP synthesized with α-diimine Ni(II) late metal catalysts have (3,1) enchainments with well defined structures. These defects cause a shortening of crystallizable sequence length with a dramatic effect on decreasing crystallinity level.

Towards Complex and Integrated Platforms in Nanotechnology Employing Responsive Polymer-Metal-Semiconductor Hybrid Materials

G. Julius Vancso

University of Twente, MESA+ Institute for Nanotechnology, P.O. Box 7500 AE, Enschede, The Netherlands

g.j.vancso@utwente.nl

Nanotechnology deals with the design, fabrication, study, and applications of materials structures, platforms, and devices that have enhanced or novel properties and functions due to nanoscale control of the elementary materials objects that constitute them. These objects can include atoms, molecules, nanoparticles and their simple assemblies. Although these building blocks often can be further divided using physical or chemical methods, they constitute from the nanotechnological point of view the smallest i.e. elementary constituents. As breaking up matter to smaller units in materials nanotechnology is not sensible beyond these building blocks, nanotechnology has often been recognized as "the ultimate production technology".

At the early stages of nanotechnology focus was laid on surface structures and their assemblies. These could be studied and manipulated by scanning probe techniques "bottom up" from the length scale of the individual objects in a directly controlled fashion, either between two nanoobjects, or between a micro (or macro) object and a nanoobject. Top down miniaturization approaches, most notably in semiconductor industries, have reached control of structures at the length scales of single polymer chains,

e.g. in Intel's 3-gate transistors featuring 32-22 nm technologies. Due to the swift development of materials chemistry used in preparing the elementary nanotechnology building "bricks", as well as due to the tremendous progress in the development of experimental technologies such as scanning probe techniques, single molecule optics, optical tweezers, single molecule 3-dimensional (3D) NMR, etc..., a paradigm shift is emerging in materials nanotechnology. This paradigm shift expands the horizons of materials technology to include full 3D "bottom up" control of complex, integrated materials nanostructures for advanced functions. Essential for this paradigm shift is the use of complementary materials including hybrid systems of synthetic and biological polymers, metal-as well as semiconductor nanostructures, and other nanoobjects such as dendrimers, fullarenes, tailored nanotubes, etc. For advanced functions, on the other hand, addressability and responsiveness of the active elements of these integrated nanostructures become indispensable.

In this presentation we shall provide examples for complex, functional metal nanoparticle-polymer nanostructures first, from the perspective of macromolecular nanotechnology. Corresponding case studies obtained in our laboratories will include description of the design, synthesis, characterization and applications of a stimulus-responsive polymer brush-gel platform [1] grafted from the walls of a microreactor which is first used to obtain designer metal nanoparticles with catalytic activity, embedded in the brush gels. Such microreactors exhibit substantially enhanced catalytic activity in various reactions. Polymer-semiconductor nanocrystal integrated systems allow one to fabricate complex water soluble platforms featuring fluorescent semiconductor nanocrystals (Quantum Dots, QDs) as robust optical labels, versatile optical transducers and active constituents in medical applications and for possible initiation of controlled cancer cell apoptosis. As a representative example, huisgen 1,3-dipolar cycloaddition "click" reaction with functional quantum dots and magnetic nanoparticles in water is presented [2]. The introduction of "click" enabling groups on the surface of the nanoparticles is combined into one step with a transfer into water process. The reaction between acetylene and azide groups is used for the fabrication of covalent spherical assemblies encompassing QDs or iron oxide magnetic particles in solution. Finally, detection of an analyte via supramolecular host-guest binding and quantum dot (QD)-based fluorescence resonance energy transfer (FRET) signal transduction mechanism is demonstrated [3]. Surface patterns consisting of CdSe/ZnS QDs functionalized at their periphery with β-cyclodextrin (β-CD) were obtained by immobilization of the QDs from solution onto glass substrates patterned with adamantylterminated poly(propylene imine) dendrimeric "glue." Subsequent formation of host-guest complexes between vacant β-CD on the QD surface and an adamantyl-functionalized lissamine rhodamine resulting in FRET was confirmed by fluorescence microscopy, spectroscopy, and fluorescence lifetime imaging microscopy.

On the basis of the above examples we shall sketch possible avenues, and speculate about constituents of the technology toolbox needed to achieve the next leap in integrated materials nanotechnologies for complex functional systems.

lacabane@cict

Introduction

Low frequency molecular mobility reflects the various levels of organization of polymeric materials from micronic till nanometric scales. The mechanical parameters are very sensitive to molecular mobility so that the analyses of viscoelasticity by Dynamic Mechanical Spectroscopy (DMS) and Thermo Stimulated Creep (TSCr) give original data in apolar polymers. For polar polymeric materials, dielectric measurements take advantage of dipolar relaxation with kinetics that are characteristic of local environment. By combining Dynamic Dielectric Spectroscopy (DDS) and Thermo Stimulated Current (TSCu), a broad frequency range (10^{-3} to 10^{6}Hz) becomes accessible so that the whole range of molecular mobility can be explored.

Transition and molecular dynamics

In semicrystalline polyolefins, it is difficult to locate transitions in the amorphous phase. Those events are associated with anelastic relaxations with kinetics that are governed by the density of physical bonds: The discontinuity gives an order of magnitude of the glass transition. Data obtained by DMS and TSCr on a series of polyethylenes will be shown as example.

Heterogeneity of the amorphous phase of semi crystalline polymer with rigid chain

As example of semi crystalline polymer with a rigid chain, Poly(ether ether ketone) (PEEK) has been investigated by DDS and TSCu. For isolating the dipolar contribution from DDS data, the Kramers- Kronig transform has been used. The main α relaxation is observed close to the glass transition temperature Tg. The parameters of the relaxation times correspond to a delocalized cooperative mobility of the mobile amorphous phase.

At Tg+20°, a higher temperature component has been resolved: The kinetics are characteristic of the rigid amorphous phase confined by crystallites. This description of the PEEK heterogeneous amorphous phase significantly improves the understanding of mechanical behavior at a molecular level.

Influence of inorganic fillers on the structure of polymeric matrix in synthetic composites

Hybrid 0-3 composites Polyamide 11/ Barym titanate (PA11 / $BaTiO_3$) [1] might associate the ductility of PA11 and the piezoelectric properties due to $BaTiO_3$. Interesting piezoelectric coefficients have been obtained forparticles of 700 nm in diameter.The challenge is to maintain the volume fraction Φ of the ceramic low enough for preserving the mechanical properties of PA 11. Consequently, the physical structure of the amorphous phase of PA 11 has been analysed by TSCu.

The molecular mobility in the liquid state is not perturbed by $BaTiO_3$. In the glassy state, an evolution of the mobile amorphous phase is exhibited by the distribution of activation enthalpy. When Φ is increasing, the maximum value of the activation enthalpy is decreasing. This restriction of the delocalized molecular mobility shows that $BaTiO_3$ favours physical interactions. An optimum value for Φ is 24%.

Molecular interactions in natural composites

Dielectric relaxations in vegetal cell wall have been compared with the response of its major macromolecular components (cellulose and lignin) [2]. The objective is to extract information on macromolecular interactions in wood: Considering the polar character of the vegetal components, DDS and TSCu have been used.

Both cellulose and lignin dynamics are described by an Arrhenius law across the glass transition due to a significant density of hydrogen bonds. The comparison with the dynamics in the cell wall shows two different behaviours according to the frequency. At frequencies lower than the characteristic frequency (Fc) of the glass transition, two segregated components respectively due to lignin and cellulose are observed in the order of increasing temperature. Contrarily, at frequencies higher than Fc, a global response is recorded; it reflects molecular interactions between the various components.

Conclusion

The analysis of low frequency molecular mobility complements the characterization of polymeric materials despite their complexity and allows us to establish correlations between structure and mechanical or dielectric properties

Two-Photon Fluorescence Microscopy and Small Angle X ray and Neutron Scattering : tools for the structural characterisation of complex polymer architectures.

Isabelle Morfin,

Laboratoire Interdisciplinaire de Physique, UMR 5588 CNRS/UJF, Grenoble 1, France.

Nowadays, scientists are able to build more and more complex polymer architectures often used for biotechnological or biomedical applications. The complexity of such materials comes not only from the number of chemical or biological components involved in the preparation but also from the multi-scale structures found in materials. For the characterization, it is essential to use tools able to give information on the multi-scale structure, from the atomic to the macroscopic length scale but also on the internal structure, i.e. how the different components are organized ones compared to the others). The aim of the communication is to report the structural information extracted from several techniques, using examples coming from recent studies: Two-Photon Fluorescence Microscopy and Small Angle X-ray Scattering for cryogel and small Angle Neutrons Scattering for polyelectrolyteprotein complexes. We will focus on the particularities of each technique and will compare the respective advantages and disadvantages.

Combined Mechanical and Electrical Characterization of Polymers by Atomic Force Microscopy

Chunzeng Li, Adam Mednick, Samuel Lesko

Nano Surfaces Business, Bruker Corporation,112 Robin Hill Road, Santa Barbara, CA93117, USA

Combining co-localized information at the nanoscale is a major trend in polymer science, resulting in a better and more complete understanding of complex, multi compound materials such as organic electronic devices, lithium batteries or composite materials. So far, Atomic Force Microscopy has successfully achieved correlation of topography with phase repartition (Phase Imaging) or with electrical properties (Electric Force Microscopy / Kelvin probe / Conductive AFM). However, Phase Imaging does not lead to unambiguous mapping of mechanical properties and characterization of electrical conductivity remains challenging because of the use of Contact Mode which is known to disturb soft polymer surfaces.

To address those limitations, we present new AFM methods that combine real time and simultaneous mapping of topographic, electrical and mechanical properties together with unprecedented tip-to-sample interaction control. The AFM operation relies on Peak Force Tapping Mode: force curves are collected at 1kHz rate while scanning the surface. In this mode, the AFM feedback loop maintains a constant maximum interaction force (Peak Force) down to tens of pN allowing one to routinely image fragile samples at high resolution. Mechanical parameters such as Young's Modulus, adhesion, dissipation and deformation are extracted simultaneously from these force curves, resulting in complete mechanical maps. For conductivity mapping, the tip is connected to a high performance current allowing one to record current during the vertical modulation cycle at (and near) the Peak Force. The amplifier bandwidth reaches 15kHz at sensitivities as high as 20pA/V while retaining the capability to also measure larger currents (1μA).

To illustrate the synergistic power of these new methods, we will show a correlation between electrical conductivity and crystallinity of PEDOT:P3HT [poly(3,4-ethylenedioxythiophene:poly-3(hexylthiophene)] samples. Other examples presented include Lithium cathode composites for which the simultaneously acquired elastic modulus and conductivity maps unambiguously identify the 3 different functional components of the electrode (metal oxide, polymer binder and conductive additives).

Transient rheology: improving measurements at very short time.

A.C. Diogo,

Instituto Superior Técnico (Dep. Chemical and Biological Engineering), Technical University of Lisbon
Av. Rovisco Pais, 1049-001 Lisbon, Portugal

acdiogo@ist.utl.pt

Introduction

Stress relaxation experiments, creep-recovery experiments and start-up of shear flows are transient experiments which can be very useful in assessing constitutive models of linear and branched polymers, as well as for multiphase systems such as polymer blends, foams, emulsions, asphalts, and so on. A number of examples can be found in literature [1]; for instance, the double step strain experiment has been the touchstone for different constitutive models of polymer melts in the last decades [2]. On the other hand, transient experiments may provide fast and accurate means of getting some of the most important viscoelastic constants such as the zero-shear viscosity, the recoverable creep compliance, among others.

However, the analysis of the experimental data can be perturbed by interference of the apparatus response functions, in most of the cases. Moreover, the sensitivity to this interference is predominant at short times where the intensity of the signal is higher.

It is shown that the quality of the data can be significantly improved by a number of procedures based on deconvolution. Some examples are considered.

Stress relaxation

Stress relaxation measures the response to a step strain, either in shear or in extension. For shear, the relevant material function is the shear relaxation modulus G(t), given by the ratio between the time-dependent shear stress $\sigma(t)$ and the amplitude γ_0 of the step strain. No actuator can provide a perfect step strain: instead, a step-like transient function $\gamma(t)$ is generated, which can be measured, in general. Moreover, it is generally believed that after some characteristic actuator growth time t_1 ($\gamma(t)$ becomes constant after t_1) the shear relaxation modulus is given by $\sigma(t)/\gamma(t)$; the software of most rheometers indeed assumes it. The main issues are that $\sigma(t)/\gamma(t)$ is not equal to G(t) for $t < t_1$ as well as for $t > t_1$, and that $\sigma(t)/\gamma(t)$ may not approach G(t) even at very long times. Numerical simulation can easily provide several realistic examples where $\sigma(t)/\gamma(t)$ does not converge to G(t) even at very large t.

Since the strain $\gamma(t)$ provided by the actuator can be measured, the relaxation modulus G(t) can be extracted from the measured time-dependent shear stress $\sigma(t)$ and the strain growth function $\gamma(t)$ by deconvolution. A procedure to perform such deconvolution was developed, and used on different sets of data from a RMS-800 mechanical spectrometer. Here, a constant strain is attained after 80 ms from startup, but the convergence of $\sigma(t)/\gamma(t)$ to G(t) is much slower: it takes about 0.3 s after startup.

It is shown that our deconvolution procedure extends the available G(t) data for about two orders of magnitude (down to about 10 ms). In particular, it becomes possible to get rather accurate values of the zero shear viscosity η_0, by using the following equation

$$\eta_0 = \int_0^\infty dt'.G(t') \qquad (1)$$

As a matter of fact, equation (1) is quite sensitive to short time values of G(t). It must be stressed that eq.(1) provides a much faster way of getting the zero-shear viscosity as compared to the standard method.

Creep-recovery experiments

The rheological behaviour of foams, emulsions and other multiphase systems (e.g. bitumen) is mainly controlled by interface properties. Stress controlled rheometers are more appropriate for these systems since stresses are low and strain must be kept small enough. The number n of relaxation processes is small and so must be the number (n-1) of retardation times.

A creep experiment followed by elastic recovery does provide the needed information to get the time dependent creep compliance J(t). It is possible to get G(t) from J(t) once the retardation spectrum is discrete. The inverse problem difficulties are also avoided if the breadth of the retardation times is kept small. Preliminary data on bitumen shows that creep-recovery data as well as stress relaxation data can be analysed in terms of a few relaxation (retardation) processes. These processes can be correlated to bitumen microstructure as sensed by atomic force microscopy (AFM).

Conclusions

Transient experiments can provide fast and valuable information about a number of rheological material functions and rheological constants which are difficult to obtain by standard means. In particular, for multiphase systems or other systems where a reduced number of relaxation mechanisms can be identified, most of the difficulties which come from the inverse problem can be overcome. For these cases, transient data can give an insight on the dynamics of these relaxation processes.

Inducing Supramolecular Structures in Polymers by the Combined Effects of Nanoparticles and Flow

Gad Marom

The Institute of Chemistry, The Hebrew University of Jerusalem

gadm@vms.huji.ac.il

Introduction: The application of flow to polymers results in stretching and aligning some polymer chains, allowing them to form orientated structures that can eventually develop into orientated crystalline domains. This behavior is a function of several factors, including processing conditions (e.g., temperature, deformation rate, and deformation strain) and polymer properties (e.g., molecular weight and distribution). In polymers that are reinforced by acicular inclusions, such as short aramid fibers and carbon nanotubes, flow generates orientation of the acicular inclusions parallel to the flow lines – in addition to the shear flow that promotes chain stretching, disentanglement, and alignment. The combined effects of the aligned polymer chains on the one hand and the inclusion on the other can produce various types of supramolecular structures.

Experimental: A typical experimental procedure is based on melt mixing of polymer pellets filled with about 1.5 wt-% of nanoparticles, it was carried out in a twin-screw microcompounder (DSM, Netherlands). Mixing was performed at temperature above the melting point of the corresponding polymer for a period of about 10 min at about 100 rpm, according to the procedure published elsewhere [1]. This was followed by extrusion through a 900 □m die and drawing of fiber-like filaments with diameters decreasing from 900 μm to 30 μm (with corresponding draw ratios DR = 1 to 900). A range of experimental techniques based on electron microscopy and X-ray diffraction methods was used to analyze the structure morphology of the various polymers.s

Results & Discussion: This lecture will attempt to underline the main common factors that relate the mechanical performance to the structural morphology and, in turn, to the combined effects of flow and nanoparticles. An example of carbon nanotube (CNT) based polyacrylonitrile (PAN) composites shows how specific interfacial interactions in multi-component systems such as composites improve the chemical compatibility between the filler and the matrix. Scanning electron micrographs (SEM) attest to a fairly uniform dispersion of apparently single CNT within the PAN matrix. The study explains the nature of CNT/PAN interaction by a model of charge-transfer of CNT □-electrons from the highest occupied molecular orbital to the empty nitrile π** orbital of PAN [1-2]. Another example describes a nanocomposite monofilament composed of a nematic thermotropic liquid crystalline polymer (TLCP) mixed with carbon nanoparticles (CNP) prepared by melt extrusion [3-4]. It shows that the tensile strength and modulus of the fibers increase with the draw down ratio of the filament; specifically, a positive effect on the tensile modulus is displayed by fibrous CNP, achieving extremely values. At high draw down ratio, addition of CNP also increased the relative amount of orientated polymer chains and contributed to sharpening of the mesomorphic transition. Additionally, the solid state crystallization in drawn thermoplastic polyimide (PI) films is studied as a function of draw ratio (DR) under the effect of vapor grown carbon fiber (VGCF) nanoinclusions [5]. The nucleating effect of the nanoinclusions coupled with the orientation effect of drawing, as can be seen in the figure, generates a unique orientated layered lamellar structure, characteristic of smectic-like mesophase. The degree of draw induced orientated crystallization increases with the content of nanoinclusions and with the DR, and is reflected in the mechanical behavior of the film. Generally, the young's modulus and the yield point of the drawn crystalline films in the drawing direction are significantly higher compared with the noncrystalline counterparts. Finally, nanocomposite filaments composed of isotactic polypropylene (iPP) and VGCF were prepared by melt mixing extrusion, followed by melt drawing [6]. The effect of composition and flow on the morphology was investigated by X-ray diffraction and high resolution scanning electron microscopy. It is found that melt mixing followed by extrusion of monofilaments is a highly effective procedure for the preparation of uniform mixtures of individually dispersed nanofibers in a polymeric matrix. The extrusion process produces axial alignment of nanofibers and of stretched polymer molecules along the flow direction. The level of the alignment of both the nanofibers and the polymer chains can be raised further by extensional drawing up to almost perfect orientations at draw ratios of around 20. The orientated nanofibers together with the stretched polymer chains nucleate other polymer molecules to form a highly orientated crystalline bulk. The high anisotropic mechanical properties in the flow direction of the resulting nanocomposites are attributed to the combined contributions of the orientated crystalline structure and the nanofiber reinforcement.

Processing of thermosetting matrix nanocomposites: modelling and characterization of the electrical behavior

José M. Kenny, L.Torre, M. Monti*, M. Natali**

Institute for Polymer Science and Technology (ICTP-CSIC). Juan de la Cierva, 3 – 28006 Madrid, Spain

kenny@ictp.csic.es

*Materials Science and Technology Centre, University of Perugia. Pentima 4, 05100 Terni, Italy

Carbon nanotubes (CNTs), carbon nanofibres (CNF) and graphenes are carbon structures with extraordinary mechanical, chemical and electrical properties. These unique properties make these carbon nanoobjects (CNOs) extremely valuable in a wide range of end-use applications. However, the achievement of these properties requires a careful definition of processing routes and conditions able to produce nanocomposites with designed and controlled nanofiller dispersion, orientation and alignment.

In past years, we have contributed to demonstrate that although carbon nanotubes are difficult to disperse in liquid suspensions, they can be oriented by application of electric, magnetic and shear fields. These approaches have been applied for the production of thermosetting matrix films and bulk nanocomposites containing aligned nanotubes, which exhibit strong anisotropic properties. In particular, the measurement of the electric current during the electric field application to polymer nanocomposites mwith CNTs, before and during matrix curing, has been used an indicator of the formation of a CNT network oriented in the direction of the electric field itself. In fact, the electric field induces the formation of a dipole moment which results in a rotational force which tends to orient them in the field direction. Driven by the opposite charges of their ends, CNTs also gradually move closer toward each other, forming a network of tubes connected each other, head-by-head, aggregating in chain-like structures. This network represents a path for electric current.

We propose a physical modelling based, on classic electrodynamics and fluid dynamics, which describes all the phenomena appearing when a suspension of single-wall nanotubes in a viscous polymer is subjected to the action of a DC electric field, based on classical electrodynamics: rotation, orientation, migration, network formation and relaxation when the field is released. The main result of this modelling approach is the optimization of the processing conditions for the production of a bulk polymer nanocomposite with aligned carbon nanotubes via DC electric fields.

Polymers Processing Using Supercritical Fluid Technology

C. Domingo, C.A. García-González, A. López-Periago

Instituto de Ciencia de Materiales de Barcelona (CSIC), Campus UAB, Barcelona, Spain,

conchi@icmab.es

Introduction

Te architecture of a polymeric scaffold plays an important role in modulating tissue growth and response behavior of cultured cells. Required characteristics include high porosity and an interconnected 3D macroporous network necessary for cell proliferation, and high surface area to promote cell adhesion [1]. The main drawbacks of conventional scaffolds production methods involve a reduced capability to control pore size and pore interconnectivity. Technology based on supercritical carbon dioxide ($scCO_2$) has been already proposed for the processing of a great range of biopolymers with excellent control on morphology, surface properties and purity [2-4]. It is used to produce polymer foams by pressure-induced phase separation. Furthermore, spray processes involving $scCO_2$ have achieved considerable success in addressing polymer particles and fibers production. Finally, the potential role of CO_2 in assisting the blending of polymers has been studied. The main objective of this work is to follow a line of research that explores the possibilities of using the $scCO_2$ for the processing of different biopolymers: semi-crystalline, amorphous and blends, either pure or as a part of hybrid composites.

Materials and Methods

Poly(lactic acid) (L-PLA), poly(e-caprolactone) (PCL) and poly(methylmethacrylate) (PMMA) were the used polymers. Both the production of monolithic foams and the precipitation of fibers were attempted.

(i) Polymer foaming in $scCO_2$ was performed in a high pressure equipment running in the batch mode. In a typical experiment, the autoclave (70 mL, TharDesign) was initially loaded with ~ 1g of polymer. The system was heated with resistances to the selected temperature and pressurized at 20 MPa using a syringe pump (Thar SP240). The system was stirred at 300 rpm.

(ii) Fibers precipitation was carried out in a semicontinuous antisolvent equipment, where the spray chamber consisted on a high pressure vessel (Autoclave Engineers) of 5 cm i.d. x 25 cm long. The CO_2 was pumped using a reciprocating pump (Lewa EK3). Dichloromethane solutions of polymer were sprayed into the precipitation chamber using a reciprocating dual-piston minipump (Milton Roy LDC). Two types of nozzles were used for liquid solution injection: a plain orifice (disk) and a conical spray (swirl). The precipitated polymer was dried with a CO_2 flow.

Results and Discussion

Macroporous sponges of the amorphous PMMA were fabricated using $scCO_2$ as a porogen agent [5]. This type of processing led to a partially closed pore structure which is disadvantageous for cell-migration in 3-D scaffolds. However, for systems formulated with molecularly dispersed drugs, swellable polymers are mainly used as matrixes. Hence, the molecular impregnation of PMMA matrixes with active agents was studied using a similar $scCO_2$ process. Homogeneously distributed loadings of *ca.* 20 wt% of active agent in PMMA were obtained [6].

$scCO_2$ was also used for the solvent induced crystallization of L-PLA and for their thermal annealing and crystallization from the melt. The use of $scCO_2$ dropped the glass, crystallization and melting temperature of the raw material during processing. Treatment with $scCO_2$ at different temperatures allowed obtaining L-PLA samples having different structures with respect to the crystallinity, crystallite size, and crystal morphology [7]. For the semicrystalline L-PLA, the induced nucleation and/or crystallization effect in the amorphous fraction prevented the molecular dispersion of organic active compounds in the matrix.

The development of a $scCO_2$ antisolvent technique for the production of template-free fibrous polymeric scaffolds, as an alternative to macroporous sponges, has been carried out for PMMA and L-PLA homopolymers and PMMA/PCL blend [8]. A modification of the antisolvent technique was used to precipitate a composite of L-PLA loaded with hydroxyapatite nanoparticles used as reinforcing filler [9]. The introduction of small quantities of nanosized inorganic particles can significantly improve the mechanical and physical properties of the polymeric matrix. These composites have gained much recognition as bioactive bone grafts, owing to their compositional and structural similarity to natural bone.

How to use Block Copolymers for Processing of Thermosets and Composites?

J.P. Pascault, F. Lortie, D. Portinha, J.F. Gérard

Université de Lyon, F-69003, Lyon, France - INSA Lyon, F-69621, Villeurbanne, France - CNRS, UMR5223, Ingénierie des Matériaux Polymères.

(Jean-Pierre.Pascault@insa-lyon.fr)

Thermoset precursors are frequently formulated with modifiers like small molecules, oils, low- or high-molar mass rubbers or thermoplastics. One application which has been an interesting and challenging topic for over four decades is the toughening of thermosetting polymers for adhesives, coatings and composites [1-2]. In recent years, a new thermoset toughening approach using self-assembling amphiphilic block copolymers, BCPs has drawn significant attention. The incorporation of a small amount of dispersed microphase-separated BCP can produce significant improvements in fracture toughness without compromising other propertiesof the neat epoxy network [3-16].

Thermosetting polymers are widely used as matrices of fiber-reinforced composites constituting structural parts in the transportation industry. For instance, epoxies are largely involved in carbon-reinforced parts for aeronautical applications while polyesters are constitutive of SMC (Sheet Moulding Compound) for automotive applications. These composites have also to be improved in terms of impact resistance, damage tolerance and surface aspect, and the use of BCP may be a way of enhancing both mechanical and aspect properties of the parts.

But BCPs as modifiers of thermosetting polymers and fiber-reinforced composites have also many other interests [17,18]. By controlling the chemistry (choice of the thermoset precursors, right hardener and accelerator) and the processing (the Order Disorder Transition, ODT temperature of the BCP in the thermoset precursors), the initial viscosity of the formulation and the viscosity increase during the curing process, it is possible to develop innovative technologies like thermoplastic films or fibers, thermoset powders, prepregs for infusion or resin transfer molding (RTM). Depending on the involved reactive process (RTM or SMC), different strategies have been optimized to integrate the BCP and to obtain the desired BCP morphologies and localizations inside the final parts.

Some examples of the use of BCPs for preparing advanced (and also functional) materials will be given during this presentation.

"Functional polymers with capability to remove pollutant ions"

Bernabé L. Rivas

Polymer Department, Faculty of Chemistry, University of Concepción, Casilla 160-C, Concepción, Chile

brivas@udec.

The need to mitigate the environmental impact of industrial development has resulted in an important development of processes and technologies to remove pollulant ions from a variety of sources. Presently, there are various techniques available to separate metallic ions, including; differential precipitation, solvent extraction, distillation, ion exchange, flotation, and filtration membranes.

Ion exchange resins are the most widely used materials to remove ions from aqueous sources. They have several applications, such as in water softening, wastewater treatment, hydrometallurgy, and chromatography.

To face the problem of separation of ions bound to the polymer and non-bound, one of the most promising techniques used is the application of separation methods based on membrane processes (1-3). Membrane filtration easily allows this separation by means of the method known as the *liquid-phase polymer-based retention(LPR)* technique. Applications of water-soluble polymers, WSP, to the homogeneous enrichment or selective separation of various metal ions from dilute solutions have been reported. Ultrafiltration is found as the most suitable technique for LPR studies. To be used in homogeneous ions recovery, the appropriate water-soluble polymers may present high solubility in water, and easy and cheap route of synthesis, an adequate molecular weight and molecular weight distribution, chemical stability, high affinity for one or more metal ions, and selectivity for the metal ion of interest.

All the polymers are synthesized by radical polymerization, purified by membrane filtration, and characterized by FT-IR and ^{1}H-NMR spectroscopy. The molecular weight is determined by GPC.

The ion retention properties are investigated by LPR technique (washing and enrichment methods) under different experimental conditions.

Interactions of metal cations:Co(II), Ni(II), Ca(II), Mg(II), Pb(II), Cd(II), Zn(II), and Cu(II), and anion As(V) species with water-soluble polymers were studied at different pH and filtration factor, Z.

It is useful to quantify the separation process by plotting the retention of the metal species versus the filtration factor. The filtration factor (Z) is defined as the volume ratio of the filtrate (V_f) versus volume in the cell (V_o). Retention (R) is defined for any species as the fraction per unit of the species under study remaining in the cell during filtration. The ion (M) remaining in the cell during filtration consists of the sum of the ion bound to the polymer chain and the ion free in the solution.

To obtain the retention profiles a polychelatogen : ion 40:1.0 relationship is used. It corresponds to 0.2 mmol : 0.005 mmol. This ratio obeys to ensure an excess of the ligand groups respect to the ion. The ion retention ability of the water-soluble polymer depends strongly on the pH. As the pH increases the metal ion retention increases. This is due to at higher pH, the majority of carboxylic acid groups are non-protonated. Therefore, the carboxylate is more available to bind metal ions. Particularly, at pH >5, which is above to the pKa value for an acrylic acid.

The interactions between the polymer and the metal ions are mainly due to electrostatic forces and to formation of coordinating bonds. Other weak interactions may appear such as trapping metal ions in the bulk of the polymer phase.

Respect to the removal of metal ions at higher pH, as pH 5 and pH 7, increased the ability to bind metal ions and there is not an important decrease on the retention as increases Z. That means that the sulfonic/sulfonate-metal ion interaction is strong. The polymer-metal ion interaction may be intramolecular, intermolecular or both.

As(V) species are removed by polymers containing ammonium groups. The highest retention ability was observed at higher pH (6 and 8). The retention of arsenic occurs basically by ion-exchange between the counter ion of the ammonium group with the anion species of the arsenic.

The retention of arsenic(V) occurs basically for ion-exchange of the anioonic specie with the counter ion of the polycation.

In addition, water-soluble polymers containing carboxylic acid and sulfonic acid groups showed a high affinity for metal ions. It depends on the structure of the polymers and on the pH, and filtration factor, Z. The functional polymer group-metal ion interaction would occur through different mechanisms. For carboxylate groups should be by complexing process and for sulfonic acid it should be by electrostatic process.

Introduction: Stereolithography (SLA) is a rapid prototyping technique that allows the building of complex 3D structures. Designed porous structures that varying in shape, porosity, pore size, pore geometry and pore interconnectivity can be prepared at high resolutions. It is envisaged that flexible and elastic scaffolds that resorb in the body will be highly applicable in the engineering of soft tissues such as cartilage or cardiovascular tissues. Currently, no resins are available that can be processed by SLA to yield suitable porous structures.

This work describes the development of photo-crosslinkable resins based on biodegradable poly(trimethylene carbonate) (PTMC) and the processing of these resins by stereolithography to yield flexible porous and non-porous network structures.

Materials and Methods: Three-armed oligomers were synthesized by ring opening polymerization of TMC using glycerol as initiator. By varying the monomer to glycerol ratio, the molecular weight of the oligomers can be adjusted. The oligomers were functionalized using methacryic anhydride to yield photo-crosslinkable macromers.

Resins of the different macromers, varying in molecular weight between 3000 g/mol to 21000 g/mol, were formulated using a photo-initiator (Lucirin TPO-L, 5 wt %), a dye (Orasol Orange G, 0.15 wt %) and a non-reactive diluent. The resins were processed by SLA (EnvisionTec, Germany) at temperatures between room temperature and 65 ºC.

Results: Porous structures with different mathematically defined architectures were prepared from the different macromers. While the macromers with the lowest molecular weights could be readily processed at room temperature, the higher molecular weight ones required the addition of diluent or increased temperatures.

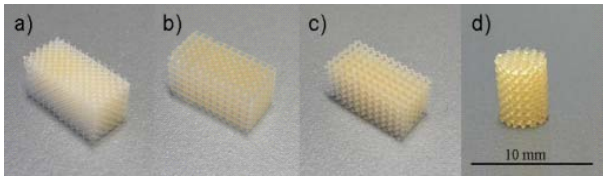

Fig.1. Scaffolds with different pore architectures prepared by SLA using PTMC3000.

a) diamond-, b) cubical-, c,d) gyroid geometry.

Disk-shaped specimens were used to assess the adhesion and proliferation behaviour of human umbilical vein endothelial cells (HUVECS) on extracted networks. After 3h of culture, the cells show good cell adhesion and proliferate well on the surfaces (Fig. 2). The SEM images show the stretched morphology the cells adopt. No substantial differences were found between networks prepared from the different macromers.

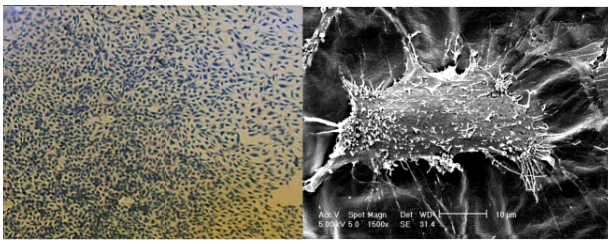

Fig. 2. Methylene Blue staining of HUVECS on PTMC21000 networks (left). SEM image of HUVEC on PTMC8000 networks (right).

Conclusions: PTMC macromers of different molecular weights were formulated into photo-crosslinkable resins, and successfully used to prepare 3D-structures with pre-designed pore characteristics. HUVECs show good adhesion and proliferation on these networks.

Electrospinning of Biopolymers: Biomedical, Pharmaceutical and Food Related Applications

Jose M. Lagaron

Novel Materials and Nanotechnology Group, IATA, CSIC, Avda. Agustín Escardino 7, 46980, Burjassot, Spain;

e-mail: lagaron@iata.csic.es

Abstract Body:

Looking genuinely at nature, nanofibers often serve as a basic platform where either organic or inorganic components are built upon. For instance, cellulose nanofibers would represent the building block in plants while collagen nanofibers in the animal body. The fiber structure exhibits, from a structural point of view, the certain ability to transmit forces along its length and, thus, reducing the amount of materials required. While strong enough for their designed purpose, nanofibers have the added advantage of giving high porosity to the natural supports which allows faster diffusion of chemicals to the inner structure. To follow this extraordinary nature's design, a process that is able to fabricate fiber nanostructures from a variety of materials and mixtures is an indispensable pre-requisite. Control of the nanofibers arrangement is also necessary to optimize such structural requirements.

Electrospinning is a physical process used for the formation of ultrathin fibers by subjecting a polymer solution to high electric fields. At a critical high voltage (5-25 kV), the polymer solution droplet at the tip of the needle distorts and forms a Taylor cone to be ejected as a charged polymer jet. This stretches and is accelerated by the electrical field towards a grounded and oppositely-charged collector. As the electrospun jet travels through the electrical field, the solvent completely evaporates while the entanglements of the polymer chains prevent it from breaking up. This results in the ultrathin polymer fibers deposition on a metallic collector to habitually assemble the fibers as non-woven mats.

Since the electrospinning is a continuous process, fibers when winded can be as long as several metres or even kilometres. The formed fibers are not only ultrathin and relatively large in length but also fully inter-connected to form a three-dimensional network.

The current paper will highlight some recent advances carried out within our research group in which various applications of the high voltage spinning processing technique making use of biopolymers and biopolymeric blends will be reviewed (1-10). These include examples in which new antimicrobial nanostructured fiber mats with strong biocide efficiency were successfully developed, as well as nanostructured systems for bone implant interfaces with significant bioactivity, antiinflamatory and antibiotic properties and also novel nanoencapsulation of active and bioactive food ingredients.

Recombinamer-based, complex and highly functional systems attained by mild, clean and biocompatible processing technology

J.C. Rodríguez Cabello

GIR Bioforge, Universidad de Valladolid, Edificio I+D, Paseo de Belén 1, 47011 Valladolid

E-mail: roca@bioforge.uva.es

Recombinamers are recombinant protein-based polymers. They are produced as recombinant proteins by genetically engineered microorganisms by the use of a synthetic DNA. This DNA has generally been designed and synthesised from the scratch and can contain both naturally and non naturally occurring DNA sequences. Generally speaking, the macromolecules obtained by this new technology are much more complex and much more controlled in composition and, therefore, show higher degree of functionality, than their synthetic polymer counterparts[1].

The peculiar properties of the recombinamers place them in the diffused interface among material science, nano(bio)technology, biomedicine, biomedical engineering and others. Additionally, the protein nature of those functional macromolecules and the biotech route by which they are produced enables the use of mild processing technologies[2]. For example, water uses to be the exclusive solvent, and the processing conditions are characterised by being moderate in parameters such as temperature or pH. Additionally, the molecular complexity of some of the recombinamers now-a-days produced can be used to drastically simplify the processing stages since, concepts of biological inspiration such as self-assembly are common in this new class of materials[3].

Examples of recombinamers designed and produced for different uses will be presented. Those include recombinamers with smart nature, self-assembling properties, acute bioactivity for advanced drug delivery and regenerative medicine, and biomimetic functionality such as that for biomimicked mineralization. Those can be processed to obtain from nanoparticles or nanofibres to macro-hydrogels under the easiness and cleanliness characteristic of this new class of materials.

Influence of Polymer Microstructure and Post-Treatment on the Performance of Latex-based Pressure Sensitive Adhesives

Marc A. Dubé and Lili Qie

Department of Chemical and Biological Engineering, Centre for Catalysis Research and Innovation University of Ottawa, Ottawa, ON Canada

Marc.Dube@uOttawa.ca

Introduction: Pressure sensitive adhesives (PSAs) produced via solution polymerization tend to have much better performance (i.e., much larger shear strength at similar tack and peel strength levels) than those produced via emulsion polymerization. This is because the gel network is continuous in solvent-based PSAs but discontinuous in emulsion- or latex-based PSAs[1]. Since the production and use of latex-based PSAs is more environmentally friendly than that of solventbased PSAs, significant effort has been made to improve the performance of latex-based PSAs so that they can replace their solvent-based counterparts. One approach involves the addition of functionalized monomers followed by post-treatment of the PSA films to encourage the reaction of the functional groups and transform the discrete gel into a continuous structure[1,2].

Tobing et al. [1,2]showed the influence of Mw (molecular weight of sol polymers), Mc (molecular weight between two adjacent cross-linking points) and Me (molecular weight between entanglements) on the production of a continuous gel network using latexbased PSAs. Post-treatment by heating the PSA films resulted in significantly larger shear strengths. However, up to now, the performance of post-treated PSAs has still not attained that of solvent-based PSAs.

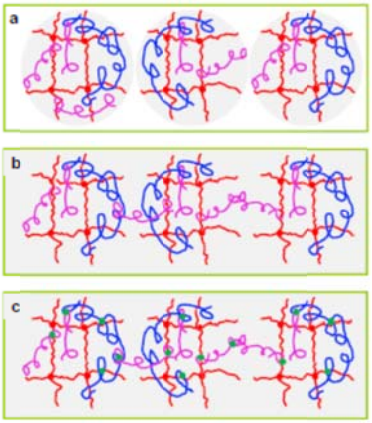
This study focused on improving the performance of heat-treated latex-based PSA films by optimizing the polymer properties of the original PSAs. The influence of very small and/or very large sol polymers was studied. In addition, PSAs with similar gel contents but different Mc and Mw were used to study if simultaneously increasing Mc and Mw could lead to the formation of a continuous gel network and larger shear strengths in the treated PSAs.

Materials and Methods: Butyl acrylate/acrylic acid/2-hydroxyl methacrylate (BA/AA/HEMA, weight ratio: 96/2/2) latexes were produced via starved seeded semi-batch emulsion polymerization. The microstructure of the latex polymers was controlled by varying the amount of chain transfer agent (1-dodecanethiol) and cross-linker (allyl methacrylate) used.

PSA films were cast using standard procedures[3] and were then dried and conditioned (24 h at 23ºC and relative humidity of 50%). For post-treatment, the PSA films were first heated at 90 ^{o}C for 10 min to remove water and then heated at a higher temperature (e.g., 120 or 126 ºC) to react the carboxyl and hydroxyl groups from the AA and HEMA units. The post-treated PSA films were also conditioned as above prior to testing.

The latexes were characterized for gel content, Mc, Mw and Me[3]. Tack, peel strength and shear strength of the PSA films were measured according to the Pressure Sensitive Tape Council standards[4].

Results and Discussion: In the figure below is a representation of the PSA film formation process. In “a”, the original latex is shown as separate particles with cross-linked networks (in red), very large sol polymers (Mw>20Me, in blue), and medium-sized sol polymers (2Me ≤Mw<20Me, in pink). In “b”, the PSA film shows how the medium-sized sol polymers have migrated and entangled with neighbouring networks. In the post-treated PSA film, “c”, new cross-linking points (in green) have formed. Improved connections between microgels in the untreated PSAs could be achieved by: (1) simultaneously and properly increasing Mc and Mw for similar gel content PSAs; (2) decreasing the amount of very small sol polymers (i.e., Mw < 2Me). The negative effect of very small sol polymers is due to its incapability to effectively entangle with microgels as well as other sol polymers; and (3) decreasing the amount of very large sol polymers (i.e., Mw > 20 Me), due to their lower mobility.



Conclusions: Post-treatment by heating was shown to be an effective way to improve latex-based PSA performance. The effectiveness of the post-treatment was observed to depend on the polymer microstructure (Mc relative to Me relative to Mw) of the untreated latexbased PSAs and on the gel content. Finally, it was possible, by optimizing polymer microstructure of the latex-based PSAs, to generate a treated latex-based PSA with even better performance than that of a solventbased PSA with similar polymer properties.

An urgent need in the 21st century is access to secure, sustainable sources of fresh water. Membrane-based desalination has been recognized as an energy efficient, low environmental impact route to produce clean water for a variety of applications. Additionally, ultrafiltration and microfiltration of aqueous streams have become important unit operations in many industries, including the water purification and wastewater purification industries. This presentation focuses on 2 new classes of polymers to attack critical problems in membrane-based water purification: (1) chlorine-tolerant desalination membranes and (2) fouling-resistant membrane nanolayers based on polydopamine.

Commercially available RO membranes are prepared mainly from aromatic polyamides (PA). However, PA membranes suffer from poor resistance to continual exposure to oxidizing agents such as chlorine. Chlorine is the most widely used oxidizing biocide in water treatment because it is inexpensive and highly effective when present in water at levels of a few ppm. Disinfection of feed water to membrane desalination units is required to prevent biofilm growth on the membranes, which significantly degrades their performance. However, PA membranes cannot tolerate continuous exposure to water containing more than a few ppb of chlorine. This presentation discusses results from a systematic study of the desalination properties of a new family of highly chlorine tolerant, sulfonated polysulfones. These polymers are prepared via a novel synthesis involving direct copolymerization of non-sulfonated monomers with a disulfonated monomer. By controlling the content of disulfonated monomer in the final polymer, desalination properties, such as water permeability and salt rejection, can be varied over a wide range. A family of materials, based on random copolymers, phase-separated block copolymers, blends, and crosslinked materials may be prepared from these starting blocks to provide a new platform for desalination membranes.

Across many platforms of membranes, fouling mitigation is a major challenge to be addressed to achieve the most energy-efficient, cost-effective membrane filtration processes. Previously, many surface modifications and functionalized polymers were reported to prevent fouling. However, most of these techniques and materials are practically difficult to implement in water purification membranes. We have discovered surface treatment methodologies that can be used to prepare high permeability polymeric membranes from all common water purification membrane classes. These surface-modified membranes have persistent tolerance to fouling by proteins and emulsified oil, two ubiquitous contaminants in a variety of wastewaters. These membranes were prepared by depositing bio-inspired, self-polymerized hydrophilic polydopamine nanolayers on their surfaces.To demonstrate scalability of this modification, the nanolayers were also applied to entire membrane modules. Upon nanolayer deposition, the membranes could be further functionalized using fouling-resistant macromolecules, such as poly(ethylene glycol), to promote improved fouling resistance and, therefore, high membrane flux. The simplicity, versatility, and broad applicability of the nanolayer deposition technique on membranes provide distinct advantages over other modification strategies to reduce fouling.

Bioinspired Reversible Adhesives

Aránzazu del Campo

Max-Planck-Institut für Polymerforschung. Ackermannweg 10, 55128 Mainz, Germany

delcampo@mpip-mainz.mpg.de

Amongst a number of animals, geckos, some insects and frogs have developed adhesive pads in the course of biological evolution. These consist of non-compact material in the form of either foam-like (wet adhesion) or fibre-like (dry adhesion) structures with a hierarchical arrangement of thin walls or fibres with decreasing dimensions when approaching the outer pad surface. They allow the animal to effectively attach to and easily release from surfaces during locomotion, even on vertical walls or across ceilings. In some cases, adhesion is also guaranteed under extreme environmental conditions such as hurricanes (gecko) or waterfalls (torrent frogs).

We will present micro and nanostructured surfaces as biomimetic models to study and understand the mechanisms behind these biological systems that may lead to practical exploitation of a new concept of adhesion. Bioinspired surface structures are combined with responsive materials to obtain reversible adhesive systems in both dry and wet conditions.

Macroporous Cryopolymer and Hybrid Hydrogels: Biomedical and Environmental Applications

S. Mikhalovsky, S. James, L. James, R. Shevchenko, I. Allan, I. Savina, R. Whitby, A. Cundy

University of Brighton, Brighton, UK

s.mikhalovsky@brighton.ac.uk

Introduction. Cryopolymer hydrogels are produced in a frozen solvent, usually water. Ice crystals formed are used as a porogen, which is removed by thawing rather than freeze drying. Cryopolymers thus obtained have large interconnected pores in the range of 10-200 μm size. The most interesting applications of cryopolymers are related to their porosity combined with mechanical strength unusual for hydrogels. Here a few examples of biomedical and environmental applications of cryopolymers and cryopolymer-nano-iron oxide hybrid materials are presented and discussed.

Regenerative medicine. Various artificial skin products are currently available, however they are costly and not very efficient. We have produced a novel supermacroporous gelatin cryopolymer scaffold with an ordered anisotropic pore structure. The material was characterised and assessed *in vitro* and *in vivo* in porcine full-thickness wound model as a skin substitute.

It was found to be biocompatible and non-toxic to human skin cells, supporting active cellular migration and proliferation. The keratinocytes formed a continuous differentiated layer on the surface of the gelatin scaffold, mimicking the native skin bilayered structure. Gelatin-based cryopolymers successfully integrated into the *in vivo* wounds exhibiting an early host cellular influx into the matrix, neocollagen deposition within the scaffold. A scaffold biointegration was followed by the scaffold remodelling, which occurred earlier when compared with Integra®, a commonly used commercial skin substitute.

The large size of interconnected gradient pores, biocompatibility and small production costs of gelatin cryopolymers make them a promising material for tissue engineering and regenerative medicine, to treat burns and chronic wounds.

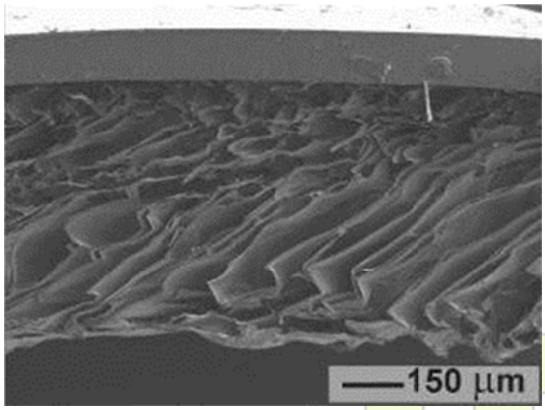

Figure 1SEM image of gelatin cryopolymer cross-section

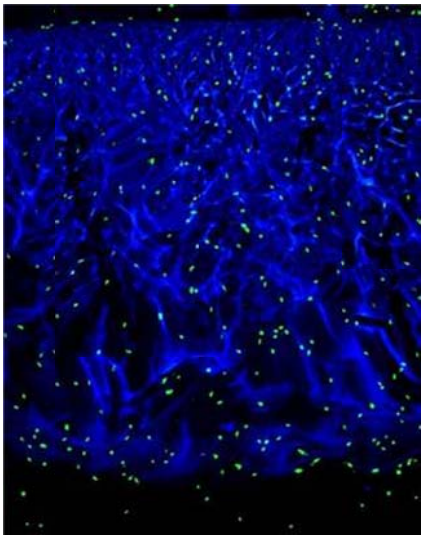

Figure 2 Confocal microscope image of gelatin cryopolymer populated with human skin fibroblasts

Environmental cleanup. Flexibility of cryopolymer synthesis allows manufacturing of various 3-D constructs, in which particles of other materials can be incorporated thus producing mechanically robust hybrid materials with low flow resistance. A filtration device made of a monolithic poly(hydroxyethylmetacrylate) macroporous cryopolymer with embedded iron oxide nanoparticles efficiently removed heavy element ions (arsenic, lead and copper) from water.

Polymer Electrolyte Membranes Based on Poly(phenylene ether)s with Pendant Perfluoroalkyl Sulfonic Acids

Kazuhiro Nakabayashi, Tomoya Higashihara, and Mitsuru Ueda

Department of Organic and Polymeric Materials, Tokyo Institute of Technology, 2-12-1-H120, O-okayama, Meguro-ku, Tokyo 152-8552, Japan

ueda.m.ad@m.titech.ac.jp

Development of polymer electrolyte membranes (PEMs) based on aromatic polymers have been investigated over the past decades to realize alternatives of sulfonated perfluoropolymers (e.g., Nafion® and Flemion®). For example, PEMs based on sulfonated multiblock copolymers have been widely studied as the promising polymer architecture for high-performance PEMs.[1]Recently, the introduction of perfluroalkyl sulfonic acids into aromatic polymers also demonstrated drastic improvement of proton conductivity due to its high acidity (pK_a~ –6).[2] Thus, as well as sulfonated multiblock copolymers, this approach can be a promising way to improve performances of aromatic PEMs.

Hence, in this work, novel poly(phenylene ether)s containing pendant perfluoroalkyl sulfonic acids with ion exchange capacity (IEC) of1.17–1.83 mequiv/g(**4a–5a**) were synthesized by the aromatic nucleophilic substitution reaction of a perfluoro monomer (decafluorobiphenyl or hexafluorobenzene) with 2,5-bis(4'-iodophenyl)hydroquinone, followed by the Ullman coupling reaction with potassium 1,1,2,2,-tetrafluoro-2-(1,1,2,2-tetrafluoro-2-iodoethoxy)ethanesulfonate (**PTES**). These poly(phenylene ether)s consist of the rigid polymer backbones with the high fluorine content and the flexible perfluoroalkyl sulfonic acid side chains, that is, the structure mimics that of the sulfonated perfluoropolymers (Figure 1). Their IEC values could be readily controlled by changing the equivalent of **PTES** in the Ullman coupling reaction. The structure of polymers was confirmed by ^{1}H and ^{19}F NMR spectra.

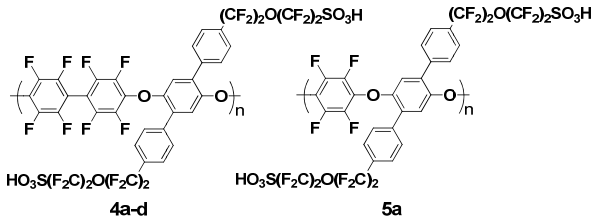

Figure 1. Structure of **4a–5a**.

The **4a–5a** membranes prepared by solution casting showed significantly low water uptake (19.3–28.0 wt %) and excellent dimensional stability even in the hydrated state, which were due to the strong hydrophobicity of the polymers (i.e., the high fluorine content). Besides, the high oxidative stability against hot Fenton's reagent (3% H_2O_2 aqueous solution containing 2 ppm $FeSO_4$ at 80 °C) was achieved. Humidity dependence of water uptake was evaluated in the **4a–5a** membranes at 80 °C. The **4a** and **4b** membranes with IEC = 1.17 and 1.38 mequiv/g showed low water uptake comparable to the Nafion 117 membrane in a whole range of relative humidity. The **5a** membrane with IEC = 1.83 mequiv/g showed the highest water uptake (24.0, 20.1, 12.6, and 8.8 wt % at 95, 80, 50, and 30% RH, respectively), which corresponded to λ (the number of water molecules per a sulfonic acid) = 7.3, 6.1, 3.8, and 2.7, respectively. These λvalues are as high as those of the Nafion 117 membranes. Figure 2 shows humidity dependence of proton conductivity of the **4a–5a** membranes at 80 °C. All membranes show high proton conductivity comparable to the Nafion 117 membrane at 95% RH. The proton conductivity of the **4a–d** membranes, however, decreases rapidly with decreasing relative humidity from 95 to 30% RH. On the other hand, the **5a** membrane with IEC = 1.83 mequiv/g maintains high proton conductivity comparable to the Nafion 117 membrane to 30% RH. The high λ values of the **5a** membrane should contribute to high proton conductivity. As for sulfonated aromatic polymers with the same IEC values, high proton conductivity like the **5a** membrane has never been achieved, which obviously indicates that the high acidity of perfluoroalkyl sulfonic acids contributes to drastic improvement of proton conductivity.

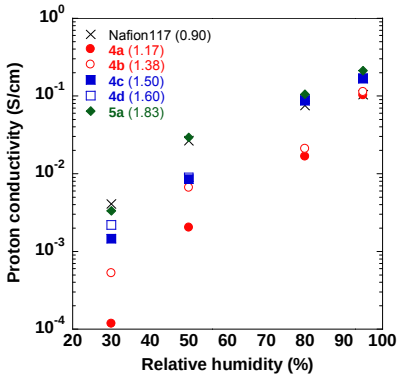

Figure 2. Humidity dependence of proton conductivity of **4a–5a** and Nafion 117 membranes at 80 °C.

In summary, novel poly(phenylene ether)s containing pendant perfluoroalkyl sulfonic acid with IEC = 1.17–1.83 mequiv/g (**4a–5a**) were successfullysynthesized. All membranes showed high dimensional and oxidative stability. Among them, the **5a** membrane with IEC = 1.83 mequiv/g accomplished high proton conductivity comparable to the Nafion 117 membrane in the range of 30–95% RH, which resulted from the strong acidity of perfluoroalkyl sulfonic acids.

Industrial product made of fossil fuel based synthetic raw materials have been produced in very large quanties and consumed since 1970s which is also the reality today. Fuels (petroleum, natural gas and coal) are considered as non-renewable resources. The annual consumption of fossil fuel feedstock is about about 7.3 Gton, and we are consuming about 93% of it for energy production. Only 7% is used for polymer and raw chemicals production. **Fossil fuel feedstock will finish** as a result of this very high consumption rates. More than 30% of the polymers produced are consumed for packaging (including agro-chemical uses such as mulching films) which has a relatively short life (< 1 year). This means that packaging waste accumulating in the environment quite rapidly which may cause very undesirable adverse effects that we have already facing today. **We have to be more environmentally conscious.** Even only because of these two main concerns one can easily prospect that naturally derived resources (also called biobased resources) will be again a major contributor to the production of industrial and commodity products. There is a great potential market of biobased polymers. They are mainly made of renewable resources of agricultural origin desirably agroindustrial waste not interfering with food chain. After use they are disposed of as organic waste, and return to the earth through processes of biodegradation and composting - completing a virtuous circle- **A very environmentally friendly approach.** Here, in this short presentation, one important biopolymer, i.e. starch, and important biodegradable polyester, polylactic acid and its clay nanocomposites are briefly overviewed.

Starch: Polysaccharides, such as starch, cellulose and chitin are in one of the most important categories of biobased polymers, as biopolymers. Corn is the primary source of starch, although considerable amounts of starch are produced from potato, wheat and rice starch in Europe. In order to produce thermally processable starch (thermoplastic starch, TS) several modifications have been proposed in which the starch -after milling of the raw material- is destructured and chemically modified (converting hydroxyl groups to aldehyde groups) to obtain amorphous (noncrystalline-more stable in aqueous media, since more hydrophobic). In order to further improve its processabilities and also final product properties (mechanical strength, gas permeability, etc.) TS is compounded with plasticizers (e.g., glycerol) and/or complexion agents (e.g., vegetable oils). Alternatively, several more hydrophobic biodegradable and nondegradable polymers are used to prepare blends that are more suitable for injection molding and blowing films. Compatibility is an important issue when these types of blends and laminates are considered, and therefore compatibilizers and other additives should be used as processing aids. The price of starch especially in US is competitive with petroleum therefore it has been processed into several compostable products.

Polylactic acid (PLA): Lactic acid is the most widely occurring carboxylic acid, having a prime position due to its versatile applications in food, pharmaceutical, textile, leather, and other chemical industries. Lactic acid is widely used in the food related applications but recently it has gained many other industrial applications like biodegradable plastic production. Lactic acid, is the monomer for PLA, may easily be produced by fermentation of carbohydrate feedstock. There is a huge list of studies for the production of lactic acid from different resources nicely reviewed recently.

Lactic acid is an α-hydroxy acids, and as being bifunctional molecules, it can be homopolymerized into linear polymers by heating with or without using a catalyst by direct polycondensation reactions (or in other terms by intermolecular esterification).This technique produces only low-molecular-weight polymers (oligomers). In order to produce polyesters with higher molecular weights that lactic acid is first converted to the respective cyclic dimer, i.e. "lactides". These processes are usually based on the transformation of lactic acids into a low molecular weight polymer by heating or also using a catalyst (e.g., antimony trioxide, zinc chloride), and then heating the polymer under reduced pressure to generate the desired cyclic ester. Then, ring-opening polymerization of cyclic dimers using various catalysts (e.g., stannous octoate) are being conducted, usually in bulk or in reactive extruders which is the main approach for the synthesis of polyesters with high molecular weights.

Polymer nanocomposites are prepared by dispersion of nano-sized materials (nanofillers) into the polymer matrix usually less than 10%. Layered clays and silicates (e.g., montmorillonite, hectorite, saponite) are the most widely used nanofillers. Incorporation of nanofillers, due to huge interfacial surface area improves polymer properties (such as mechanical properties; thermal stability; flame retardance; barrier properties, etc.) drastically. Dispersion of the layered silicates into discrete monolayers is hindered by the intrinsic incompatibility of hydrophilic layered silicatesand hydrophobic (usually) polymer matrices. Therefore they have to be **"intercalated"** or even converted into a better form, **"exfoliated**" using several organo-modifier, usually organic onium ions which are then dispersed in the polymer matrix (both in solution or in melt) to prepare the nanocomposites.

PLA is a very promising material, as also mentioned above, since it is commercially available with reasonable prices, exhibit good thermal plasticity and mechanical properties suitable for many applications including packaging films. However, some of its properties, like flexural properties, gas permeability and heat distortion temperature, are too low for widespread applications. Therefore, PLA have been one of the most widely studies bio-based polymers to prepare nanocomposites in order to improve its properties. Several parameters affect nanocomposite properties, includingboth organoclay type, size/shape and clay content, and also organomodifier type and content which will be discussed in this presentation.

Thermally Rearranged Polymer Membranes with Tuned Microcavities for CO2 Capture

Young Moo Lee

WCU Department of Energy Engineering, College of Engineering, Hanyang University, Seoul 133-791, Republic of Korea

ymlee@hanyang.ac.kr

Microporous materials have various beneficial properties (e.g. large surface area, high pore volume and appropriate pore width in the materials) for enhanced sorption, diffusion, and the improved permeation properties beyond conventional nonporous materials. Compared to inorganic microporous materials such as silica, alumina, zeolite and metal-organic frameworks (MOFs), organic microporous materials are advantageous in their synthesis, mass production, and processability for numerous applications. Since T. Matsura reported a novel poly[1-(trimethylsilyl)-1-propyne] with high fractional free volume in 1983, in the last few decades, polymeric materials retaining microporous characteristics have been developed: poly(substituted acetylene)s, amorphous fluoropolymers, polymers with intrinsic microporosity (PIMs) and thermally rearranged (TR) polymers.

Thermal rearrangement of ortho-functional polyimides is a robust and irreversible process to render thermally and chemically stable rigid-rod polymers. The thermal conversion in stiff, rigid heteroaromatic rings cause increase of free volume elements as well as change of polymer structure confirmed by various analytic method such as FT-IR, NMR, TGA, DSC, WAXD, density, PALS, SAXS and gas permeation measurements. TR-polymers have bimodal cavity sizes of 0.3-0.4 nm and 0.7-0.9 nm, and narrow cavity size distributions as a shape reminiscent of aquaporins which has bottlenecks connecting adjacent chambers so that those can yield both high permeability and high selectivity based on high diffusivity of small gas penetrants.

Most of all, the greatest benefit of these TR-polymers is the ability to control their separation performances for specific gas applications including CO_2 capture from flue gas by using various polymer structures and templating molecules with heating time and temperature. Copolymerizations with pristine polyimide or polypyrrolone in the main chain as well as the control of conversion ratio of precursors provide simple and convenient method to govern diffusivities and diffusion selectivities. Changes of ortho-functional groups also contribute to the physical properties because the side groups can affect the intermolecular distances and topologies of precursor and the resulting TR polymer membranes as well as act as templating molecules during thermal rearrangement. Moreover, other precursor polymers such as poly(hydroxyl amide) and schiff-base polymers can be thermally treated in solid states and bring in microcavities and high separation performances for specific gas pairs such as H_2/CO_2 and H_2/N_2.

Understanding of these diverse routes correlated with the cavity size and distribution of the materials can provide the evidence to the high gas separation performances and also the method of controlling the microcavities in TR-polymers for targeted applications. Here, gas transport properties of various precursors and TR-polymer membranes will be summarized overall and analyzed with microcavities.

Functional Polymers for Electronics and Packaging - Synthesis, Chracterisation and Application

Franz Stelzer, Robert Saf , Christian Slugovc, Gregor Trimmel, Frank Wiesbrock

Institute for Chemistry & Technology of Materials, Graz University of Technology, Stremayrgasse 9/Z5east

A-8010 Graz, Austria

franz.stelzer@tugraz.at

Functional polymers are gaining more and more importance concerning various fields of application. In this contribution we will present some examples of polymers developed for application as biocidic food packaging material, as matrix in hybrid photovoltaic cells or in sensor applications, as smoothening layer in printed boards and many more.

Our synthetic working horse is the ring opening metathesis polymerization (ROMP). Because of its living character it allows a far going control of polymer structures, sequences in copolymers and finally even morphology of the resulting block-copolymers.

Furthermore, in addition to these synthetic polymers some biopolymers will be presented that are produced via fermentation processes (PHAs), where the properties can be defined by applying a multi-step process. These polymers are modified chemically in order to meet the demands of the applications, in this case in medical applications.

In addition to traditional characterization methods some special methods especially connected to the applications will be presented and discussed.

Porous Polycyanurates: New Film Materials Derived from Old Polymers

Daniel Grande,[1] *Olga Grigoryeva,*[2] *Alexander Fainleib*[2]

[1] "Complex Polymer Systems" Laboratory, Institut de Chimie et des Matériaux Paris-Est, 2 rue Henri Dunant, 94320 Thiais, France (E-mail: grande@icmpe.cnrs.fr)

Introduction

Porous polymer films are widely used in many branches of industry as membranes, adsorbents and filters for separation, purification or filtration, as well as low-permittivity films for microelectronics.[1] Numerous advanced technologies require a combination of properties for polymer films, including high thermal stability, inertness, excellent resistance towards solvents and aggressive media, etc. Polycyanurates (PCNs) represent a family of thermosetting polymers that meet such requirements, in addition to their attractive intrinsic features, *i.e.* excellent dimensional stability, low dielectric constants (2.6-3.2), inherent flame-retardancy, and high adhesion to conductor metals and composites.[2] To the best of our knowledge, few reports on the design and synthesis of porous PCNs have hitherto been published.[3] Accordingly, engineering porous PCN thermosets still remains challenging.

Results and Discussion

We have undertaken a thorough investigation of the scope and limitations associated with the use of miscellaneous PCN systems as precursors to (nano)porous thermosetting film materials.[4,5] Three original approaches have been developed to prepare new mesoporous films. First, the PCN synthesis was performed in the presence of a reactive oligomeric modifier, *i.e.* poly(ε-caprolactone) (PCL). During the synthesis of PCL-modified PCN networks, PCL was partially incorporated chemically into the PCN structure. Porous frameworks were then derived from such PCN/PCL hybrid networks by hydrolysis of PCL segments under mild conditions (pH 7). Alternatively, the PCN-based films were bombed by α-particles, and subsequently the tracks formed were chemically etched to generate nanopores. The last route entails the preparation of pure PCN networks in the presence of high-boiling solvents, such as dimethyl or dibutyl phthalate, and their subsequent removal upon extraction.

The cyanurate-based precursors and the resulting porous films were characterized using FTIR, DSC, TGA, and pycnometry. In this communication, the potentialities afforded by these versatile and effective approaches will be addressed, and we will particularly focus our attention on the investigation of correlations between the structure and properties of the precursors and those of the corresponding porous thermosets. SEM and DSC-based thermoporometry analyses demonstrated the presence of well-defined mesopores (average diameters around 50 nm) within these novel film materials, and pore sizes generally ranged from 10 to 150 nm –at most– (*Figure 1* as examples).

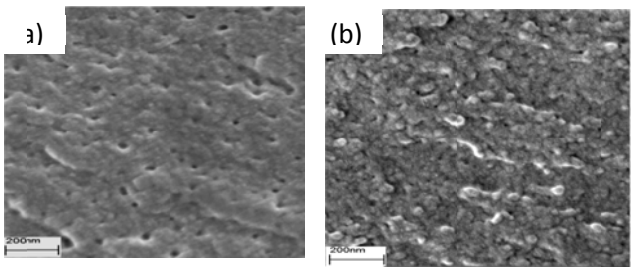

Figure 1. SEM images of nanoporous PCN-based films: (a) "track-etch" membrane, (b) membrane derived from the phthalate extraction in a PCN precursor.

Conclusions

While the most straightforward approach to these novel nanoporous PCN films relies on the use of high-boiling liquids as porogens, the narrower pore size distributions can be obtained by resorting to the track-etching technique. Such crosslinked film materials may find miscellaneous applications, and especially in membrane technologies requiring polymeric materials with thermal and dimensional stability.

Epoxy Polymers and Composites for Advanced Applications

Roberto J. J. Williams

Institute of Materials Science and Technology (INTEMA), University of Mar del Plata and National Research Council (CONICET), Av. J. B. Justo 4302, 7600 Mar del Plata, Argentina

e-mail: williams@fi.mdp.edu.ar

Introduction: Due to their excellent properties epoxy polymers are extensively used in traditional applications such as adhesives, coatings and composites. In recent years there has been an increasing use of epoxies in the development of advanced functional materials.[1] Some examples will be given in this presentation.

Reversible Epoxy Networks: The reaction of diglycidylether of bisphenol A (DGEBA) with an *n*-alkylamine leads to a linear epoxy polymer. However, linear chains can be assembled by tail-to-tail associations between *n*-alkyl groups leading to a network with physical crosslinks. The strength of the physical bonds decreases with temperature and with the length of the *n*-alkyl group.[2] By increasing temperature the material reversibly transforms from a gel to a liquid, a fact that may used to develop self-healing epoxies.

Shape Memory Epoxies: When epoxies are heated above their glass transition temperature (T_g) they can be deformed to a temporary shape by applying a relatively small stress. By fixing the deformation and cooling below T_g, a glass is obtained that stores elastic energy in chain conformations removed from their equilibrium values. When the material is released from any constraint and is heated again above T_g, a rapid recovery of the initial shape is obtained as chains recuperate their equilibrium conformations. But if the heating step is performed keeping the initial deformation, the material develops a recovery stress. Actuators based on epoxies can make use of the shape recovery or the stress recovery. They can be designed for large tensile elongations (e.g., 75 % or higher) or large recovery stresses (e.g. 3 MPa or higher). However, meeting both requirements simultaneously is a difficult task because changes in the crosslink density affect both variables in opposite ways. An epoxy formulation based on the reaction of DGEBA with *n*-dodecylamine (DA) and *m*-xylylenediamine (MXDA) gives a network with both chemical and physical crosslinks that can be used for a shape memory material verifying both requirements.

Epoxy Networks Containing Silver Nanoparticles (NPs): Ag NPs can be introduced into epoxy coatings to obtain specific electrical or antimicrobial properties. Different methods can be employed to obtain a uniform dispersion of NPs. A DGEBA/DA gel was swollen with a 6mM solution of $AgNO_3$ in THF/H_2O (90:10). After rinsing with THF and drying in vacuum, the epoxy network was heated at 100 ºC for 1 h, generating a uniform dispersion of Ag NPs with an average size close to 10 nm.[3] The reduction was performed by the secondary alcohols present in the epoxy backbone. The T_g increased from 20 ºC (neat epoxy) to 28 ºC (nanocomposite). A different strategy to obtain a uniform dispersion of Ag NPs in an epoxy matrix was to introduce reactive groups in the organic chains stabilizing the NPs. Silver NPs with an average size of 4nm and stabilized with an organic group containing secondary hydroxyls, were synthesized and dissolved in DGEBA. The epoxy was polymerized using a tertiary amine as initiator. Ag NPs were covalently bonded to the epoxy network through chain transfer reactions to the secondary hydroxyls of the organic ligands. The nanocomposites were strongly colored and showed a dependence of T_g on the concentration of NPs.[4]

Epoxy Networks Containing Single-Wall Carbon Nanotubes (SWCNT): Epoxy nanocomposites containing SWCNT exhibit significant improvements in mechanical, thermal or electrical properties. Surface functionalization of SWCNT enables to obtain an adequate dispersion of the nanotubes in the epoxy formulation. A problem that is present in some formulations is the different partition of the epoxy monomer and the hardener in the interphase, a process favored by the large specific area per unit volume. This leads to a heterogeneous network characterized by two relaxation peaks and a significant decrease of the glass transition temperature. This problem was avoided by a convenient functionalization of the SWCNT, producing a localized formation of bundles of nanotubes in the course of polymerization. The T_g of the nanocomposite was the same as the one of the neat epoxy.[5]

Epoxy Networks Containing POSS Crystalline Platelets: The dispersion of intercalated/exfoliated clays in polymers decreases their permeability due to geometrical effects. However, processing is difficult due to the initial high viscosity. An alternative is to produce the crystallization of an initially soluble precursor during polymerization. The feasibility of this idea was proved using a polyhedral oligomeric silsesquioxane (POSS) dissolved in the epoxy precursors.[6]

luc.gardette@univ-bpclermont.fr

Introduction. As the world energy demand continues growing and the cost of natural resources is rising, new solutions for cheaper and cleaner energy production are required. Among the various options, solar cells are expected to be a major contributor to fulfil the future needs. However, alternatives to silicon-based devices must be developed to reduce the power production costs. Devices that mediate energy conversion by way of light-sensitive organic polymers may be attractive because of the low cost of the materials and manufacturing methods required to produce the cells. Organic solar cells, although less efficient than silicon ones, exhibit a unique combination of properties including low cost, flexibility and large surface processability. Organic photovoltaic could then prevail for some applications alongside silicon, such as nomad or indoor. To achieve this objective, the control and the improvement of the initial properties are required, but the sustainability of these properties in conditions of use of the cell could be a lock to the emergence of these devices in the market. Organic solar cells (OSC) are indeed known to exhibit low resistance to environmental constraints, in particular to the combined action of sunlight, oxygen and water. Among all of the known conducting polymers used in organic solar cells, polyphenylenevinylene derivatives and poly(3-alkylthiophenes) have been the focus of particular attention due to their good electrical and mechanical properties [1,2]. It is however surprising that the photochemical behaviour of these polymers in the solid state remains so scarcely documented, since most of their applications are optical in nature. Similar to numerous other conjugated macromolecules, MDMO-PPV and P3HT have low photochemical stability, which leads to reduced operating lifetimes of OSCs.

Results and discussion. Understanding the degradation processes that result from the interaction of conducting polymers with solar light seems relevant to improve the stability of devices that integrate such polymers. We present results on the photochemical ageing of two polymers, poly(2-methoxy-5-(30,70-dimethyloctyloxy)-1,4-phenylenevinylene(MDMO-PPV) and poly(3-hexyylthiophene) (P3HT), and their blends with [60]PCBM (methano-fullerene[6,6]-phenyl C61-butyric acid methyl ester), a fullerene derivative [3-6].

We present in details the mechanism of photooxidation and photolysis of MDMO-PPV and P3HT monitored by various analytical tools, including IR spectroscopy, fluorescence emission, X-ray photoelectron spectroscopy, SEC, isotopic labelling experiments. The obtained results evidenced that P3HT is much more resistant to light irradiation than MDMO-PPV. This improved stability was explained on the basis of the different chemical structures of the two materials and, more precisely, considering their respective side chains. It was also observed that the degradation rate was strongly attenuated, and even nearly suppressed, when the polymers were blended with PCBM. This behaviour was attributed both to the radical scavenging properties of the fullerene and to its ability to quench excited singlet states. Complementary information was obtained by transient absorption spectroscopy [7]. It was demonstrated that the oxidation of both MDMO-PPV and P3HT proceeds via a free-radical chain reaction route, thus forming various oxidation products that were identified, and also includes cross-linking. It was shown that singlet oxygen played no decisive role in the phootoxidation [8]. The photodegradation mechanisms of these polymers were elucidated[9].

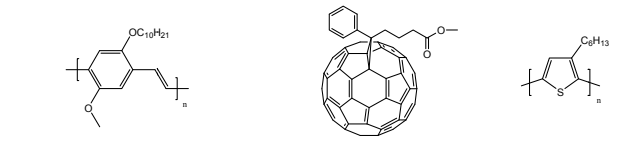

Figure 1. Chemical structures of MDMO-PPV, $PC_{60}BM$ and P3HT

Conclusion. The results showed that, if deposited on an inert substrate and well protected from oxygen, P3HT:PCBM based active layer should be intrinsically stable for long exposure periods. The extrapolation of the data obtained in conditions of artificial accelerated ageing to natural ageing suggested that the P3HT:PCBM blend would be stable for at least three years under use conditions if well protected from oxygen with a convenient

Topic 5: Chemistry and Physics of Nanomaterials and Nanotechnologies

A direct Way to Fabricate Polymer and Polymer-based Composite Nanostructures

Carmen Mijangos,Jaime Martin, Iwona Blaszczyk-Lezak, Yon Maíz, Javier Sacristán

Instituto de Ciencia y tecnologia de Polimeros, CSIC
Juan de la Cierva 3, 28006, Madrid

cmijangos@ictp.csic.es

One of the most promising aspects in the fabrication of polymer nanostructures is the ability to generate a variety of different morphologies with structural definition on the nanometric scale. The properties of the nanostructured materials will depend on both the nature of its molecular constituents and the precise spatial positioning of them and, as the structure becomes smaller than a characteristic length, may be different from those of the bulk. With recent progress in synthetic routes and continuous emerging technologies, it is possible to reproducibly fabricate polymer nanostructures such as spherical functional gels, polymer and polymer based composite nanotubes and nanowires, etc. These materials are initiating development of new miniature devices and functional materials that exhibit unique capabilities.

Nowadays, the self-ordered porous alumina template (AAO) is recognized as one of the most versatile external shape-defined process to fabricate 1D polymer nanostructures. During the last few years our group has been working on the fabrication of AAO templates of adjustable size and the subsequent polymer infiltration methods (1); the morphological and chemical characterization of polymer nanostructures (2); the determination of polymer properties under confinement (3,4); the potential applications of tailored polymer-based nanofibers and nanotubes (5,6) and, more recently, on recycling methods of AAO templates. This last aspect is motivated by the fact that in order to expand the use of nanostructured polymers and composites it is necessary to develop an easier and scale-up the fabrication process from laboratory to an industrial level. But because of the time needed for preparation and the price of aluminum, it is first necessary to try to recover used AAO templates.

The aim of this work is to give a brief presentation of the current progress and the most important aspects related tothe fabrication of 1D polymer nanostructures on the basis of our research group developments. It includes, i) examples of fabrication of polymer nanotubes and nanofibres of very different chemical nature and their nanostructured arrays, as well as, of polymer-based nanocomposites functionalised with magnetic, electrical, gold, etc, nanoparticles obtained by the same procedure; ii) the compositional distribution characterisation of polymer nanofibre&nanotubes, determined by confocal Raman microscopy; iii) related to confined polymer properties, we will show how the behaviour of polymer composites under nanoscale confinement seems to holdout a new perspective to deal with some classical problems in polymer composites physics, i.e. the early stages of the crystallization, the glass transition, and so on. iv) few examples on the perspectives to produce miniaturise polymer materials, directly related to applications and new strategies to prepare large are of 1D nanostructured polymers. v) the possibility of reusing the AAO template (recycling) by high temperature treatment of infiltrated AAO membranes.

Polymer films with nano- to micro-structured surfaces for marine biofouling-release coatings

Giancarlo Galli

Dipartimento di Chimica e Chimica Industriale, UdR Pisa INSTM,
Università di Pisa, via Risorgimento 35, 56126 Pisa, Italy

Email: gallig@dcci.unipi.it

Introduction

With an increasing drive towards environmentally benign, non-toxic marine coatings, there is an increasing interest in developing novel polymer coatings in which a functional, nanostructured surface can result in improved resistance to and release of marine biofoulig organisms.[1]

Most recent and innovative advances include use of hybrid polymer nanocomposites, biomimetic polymer-analogue platforms, lithographically patterned monolayers and plasma assisted chemical modifications of polymeric surfaces. Although highly diversified in their individual architecture and function, all such technologies share the underpinning concept to exploit the interactions intervening between the fouling organisms and the specific surface features at the nanoscale[2].

Materials and Methods

In keeping with this rationale, we devised novel low elastic modulus and low surface energy coatings by the homogeneous dispersion of variously engineered fluorinated polymer additives in an elastomeric polymer matrix. Surface segregation of low surface tension polymers in fact can be an additional tool to nanostructure a coating in such a way to comply with the nanosized cues of the foulants, thereby effecting an antifouling activity or favouring removal of those foulants that do adhere.

Results

We studied the surface morphological, topological and compositional nano- to micro-scale complexities of the polymer film surface[3,4] and show how they add to enhance release of marine biofouling organisms in laboratory bioassays[5,6].

Moreover, amphiphilic polymers were also used, as we perceive that the 'ambiguous' character of the coating surfaces, due to the simultaneous presence of hydrophilic and hydrophobic domains, would result in distinct biological performances against micro- and macro-organisms with contrasting tendencies to interact with the substratum.

Conclusion

The amphiphilic polymers can be formulated in fouling release coatings for application in the marine environment with a proven potential in field trials, notably for shipping.

Acknowledgments

This work would have not been possible without the dedicated efforts of my coworkers (E. Martinelli) or the collaboration with the research groups at the Universities of Birmingham (J. A. Callow and M. E. Callow) and Newcastle (A. S. Clare), Cornell (C. K. Ober) and Akzo-International Paint (D. Williams). I am indebted to E. Chiellini for his invaluable support.

Funding of the work from the EU-FP6 IP 'AMBIO' and, more recently, from the EU-FP7 Marie Curie ITN 'SEACOAT' and the Italian MiUR (fondi PRIN 2008) is gratefully acknowledged.

Mimicking nature using copolymers

Giuseppe Battaglia

Department of Biomedical Science.University of Sheffield

http://battaglia.group.shef.ac.uk/

We are interested in studying and developing self-assembled structures formed in water exploiting weak supramolecular interactions such as hydrophobic effect, hydrogen bonds, and columbic forces. We often take inspiration from biological structures such as extracellular matrix, cells and virus and try to reverse engineer their functionalities. This is achieved by working closely with synthetic chemists combining effective molecular and macromolecular design with our supramolecular engineering approach. We are interested in a variety of structures often polymeric such as hydrogels, polymer emulsions and polymer vesicles and micelles. Polymer vesicles and polymersomes have attracted most of our interest making us one of leading groups in the field. These are vesicles formed by the self-assembly in water of amphiphilic copolymers. We have characterized the different molecular parameters that control polymersome structural features as well as the kinetics and thermodynamics that regulate their formation. We have used this fundamental understanding to optimize methods of fabrication as well as to formulate new systems that comprise more functionality. In parallel to this, we are also working on series of projects aimed towards the engineering of soft materials with controlled topology, exploiting controlled polymer/polymer phase separation with the aim to generate cell-instructive and bioactive materials.

Synthesis and Functionalization of "Nanosponges" to Enhance the Efficacy of a Broad Range of Therapeutics

*David M. Stevens, Ghazal Hariri, Julia N. Dobish and Eva Harth**

Department of Chemistry, Vanderbilt University, Stevenson Center 7619, Nashville, TN, 37235-1822

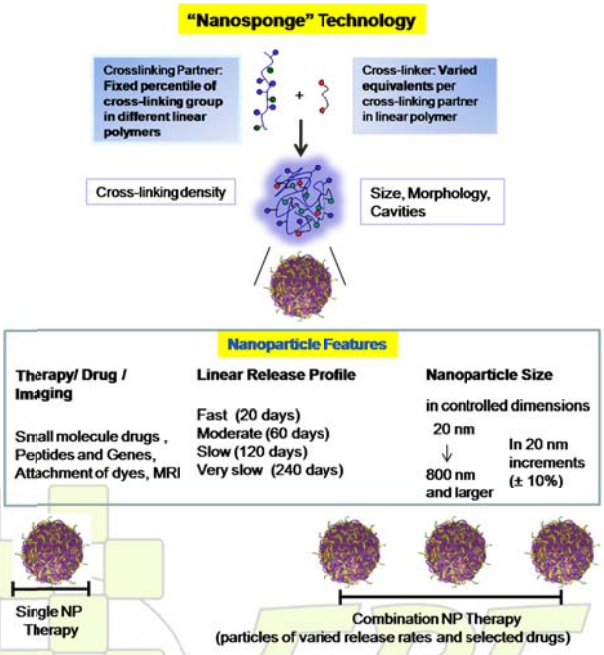
eva.harth@vanderbilt.edu

Controlled degradable nanoscopic structures have been investigated to design delivery systems that target, solubilize and increase the efficacy of therapeutics. Most of the current degradable polyester based nanoparticles are self-assembled structures that are difficult to further modify and tailor due to the dissolution of the 3-D architecture in organic solvents.

The developed strategy to design optimized drug delivery systems is to create tailorable nanoscopic networks that degrade and release the drug in linear fashion. The cross-linked, in organic solvents completely solvatized nanosponge, can be loaded after nanoparticle formation and is with this a valuable tool in drug discovery, drug efficacy and drug combination studies.

Based on an intramolecular crosslinking technique, the linear polyester precursor made from ring-opening polymerization procedures and functionalized monomers from the valerolactone family are cross-linked with diamines, diazides or dithiols to achieve a controlled nanoparticle formation depending on the amount of cross-linker reacted with the linear precursor.

In view of the tailorable degradation profile the cross-linking density of the prepared particle can be adjusted by the percentage of the cross-linking partner in the linear polymer precursor such as epoxides, alkynes and allyl groups. The versatility to react the two cross-linking partners makes the developed method a powerful tool to design a personalized drug delivery system.



We will present functionalization chemistries to target tissues and cells and will demonstrate the superior targeting ability of the nanosponge. The mentioned versatility in the ability to load a number of different drugs into the particles lead to the further optimization of drug therapies not only based on their increased targeting and solubilization but also newly discovered powerful drug combinations. The increased efficacy of therapeutics is presented in three tumor models and the efficacy of drug combinations are tested with a variety of newly discovered and traditional drugs.

The designed system with its versatility in the cross-linking chemistry provides a multitude of possibilities to attach ligands and load the particles with a broad range of therapeutics.

Microphase Separation for Diblock-Copolymers: Novel Aspects of an Old Problem

Alexei R. Khokhlov

Moscow State University, Moscow, Russia

khokhlov@polly.phys.msu.ru

In the first part of the talk, the review of the recent results concerning the microphase separation of the diblock copolymers in the bulk will be given. In particular, it will be shown (both theoretically and by computer simulation) that for the case of amphiphilic blocks the local chemical structure can dictate the global morphology of block copolymer melts. Furthermore, "inverse" morphologies are possible when minority component forms a matrix and majority complexes form micelles in the matrix.

In the second part of the talk I will discuss a simple and robust approach to control the orientation of cylindrical microdomains in diblock copolymer films. This approach is based on the so-called double phase separation occurring in the binary blend of incompatible compositionally asymmetric block copolymers and their selective adsorption on a homogenous surface. As a proof-of-concept, we performed mesoscale simulations, using dynamic density functional theory and dissipative particle dynamics, and show that the target morphology with perpendicularly oriented cylinders can be thermodynamically stable for rather thick films when the intrinsic hexagonal period of the majority bulk phase is commensurate with the surface-induced pattern formed by the strongly adsorbed minority component.

In the third part of the talk I will describe recent study of self-assembly of cylinder-forming diblock-copolymers near homogenous surfaces having periodically distributed regions of different wettability. The methods used were self-consistent field theory and dissipative particle dynamics. The patterned surfaces were demonstrated to provide an effective means to enhance the stability of vertically aligned cylindrical domains in thin films. The template-guided control over ordering and orientation is strongly dependent of affinity between the minority domains and the pattern. For some cases doubling the pattern frequency in the resulting array of microdomains is possible.

Morphology, nucleation and crystallization kinetics of biodegradable double crystalline PLLA-b-PCL diblock copolymers

Introduction

The crystallization process in double crystalline diblock copolymers can lead to structures within structures. Crystallization can be either confined within the copolymer microdomain structure for strongly segregated systems, or it can drive structure formation for weakly segregated melts (overwriting any previous microdomain structure) or homogeneous systems. In the case of double crystalline diblock copolymers, the situation can be even more complicated, since the crystallization of one block may affect the crystallization and morphology of the second block. In fact, the second block could be nucleated or its crystallization could be confined within the microdomain structure or within the previously formed lamellar stacks of the first block. Confined crystallization can lead to fractionated crystallization. The fractionated crystallization phenomenon has been explained as the crystallization of a series of micro domains at specific and independent supercoolings, i.e., the crystallization of the isolated domains of a semicrystalline polymer dispersed in an immiscible matrix, where the number of domains is higher than the number of active heterogeneous nuclei.

Experimental

The morphology, nucleation and crystallization kinetics of biodegradable and double crystalline poly(L-lactide)b-poly(ε-caprolactone) diblock copolymers (PLLA-b-PCL) was studied in a wide composition range by differential scanning calorimetry (DSC) and polarized light optical microscopy (PLOM).[1-4] We have also gathered previously information on their weak segregation strength by SAXS experiments in the molten state.[1-2]

Results, discussion and conclusions

The two blocks were found to be partially miscible according to the variations of their thermal transitions with composition. PLOM results showed that PLLA crystallizes in a wide composition range with a spherulitic superstructural morphology. Only when the PLLA content is as low as 10 wt % axialites are formed. These results were in good agreement with the overall crystallization kinetics obtained by DSC isothermal experiments and analyzed by the Avrami equation. Both overall crystallization rates and spherulitic growth rates of the PLLA block decrease with PCL content, since PCL acts as a diluent for the PLLA block in view of their miscibility.

Reorganization processes revealed as double melting peaks for the PLLA block (not observed for the PLLA homopolymer) were observed during heating scans performed after isothermal crystallization. The reorganization ability of the PLLA block was found to increase with PCL content, a fact that quantified the perturbation caused by molten PCL block chains during the isothermal crystallization of the PLLA block. The PCL block crystallizes within previously formed PLLA spherulites or axialites. In spite of the partial miscibility, unexpected and novel fractionated crystallization of the PCL occurs at contents of PCL in between 40-19 wt %. For the lowest PCL content (i.e., 19%), a homogeneous nucleation process was detected as indicated by the large supercooling needed for crystallization and by the first order crystallization kinetics obtained (i.e., Avrami index close to 1). Due to the partial miscibility, the glass transition temperature of the PLLA block ($T_{g,PLLA}$) decreases with PCL addition, so at PCL contents lower than 40 wt % the $T_{g,PLLA}$ values are close or higher than the crystallization temperature of the PCL block. Thus, PCL fractionated crystallization is induced by hard confinement of the PLLA amorphous and crystalline regions. This is the first time that a homogeneous nucleation process has been documented for a crystallizable component in a miscible or weakly segregated diblock copolymer. The PCL block can also be nucleated by previously formed PLLA crystals depending on the crystallization degree of the PLLA, which was varied by self-nucleation experiments. The crystallization rate of PCL strongly decreased with increasing PLLA content. The crystallization and morphology of the biodegradable polymers PLLA and PCL can be strongly influenced by coupling them in double crystalline diblock copolymers, a fact that will also influence their performance in possible biomedical applications.

Polymer Conjugates as Single agents or in Combination Therapy: Versatile Platform Technology for Tissue Repair and Cancer Therapy

María J. Vicent

Polymer Therapeutics Lab. Centro de Investigación Príncipe Felipe.
Av. Autopista del Saler 16 E-46012, Valencia (Spain)

mjvicent@cipf.es

Polymer conjugates are nanosized hybrids that covalently combine a bioactive agent with a polymer to ensure not only its efficient release to the required intracellular compartment, but also its availability within a specific period of time. Clinical proof of concept for these multicomponent constructs has been already achieved as anticancer agents, both as single agents or as elements of combinations[1]. Orthodox anticancer drugs were preferentially chosen in the development of the first conjugates[2]. The fast evolution of polymer chemistry and bioconjugation techniques and deeper understanding of cell biology opened up exciting new opportunities. However, many challenges still lay ahead providing scope to develop this platform technology further.

Delivery of new anticancer agents focusing on novel molecular targets and their combination, development of both new and exciting polymeric materials with defined architectures and treatment of diseases other than cancer, in particular looking at promoting tissue repair, are the most exciting and promising areas[3], and therefore, are the driven research lines in the Polymer Therapeutics laboratory at CIPF.

Our research lines include the design of novel nanoconjugates for the treatment of hormone-dependent

cancers by using novel concepts, such as, bioresponsive systems with controlled architecture and the active drug incorporated within a pH-triggered biodegradable polymeric mainchain[4] or the use of polymer-based combination therapy (endocrine + chemotherapy or antiangiogenics + chemotherapy in the same polymer)[5]. Novel polymeric carriers with controlled architecture and high versatility are also being developed.[6] On the other hand, the design of conjugates for other diseases[7] and in particular promoting tissue repair is a key area in the group, in this sense, novel hybrid systems are being developed for cardiorregeneration, ischaemia and neurodegenerative diseases.

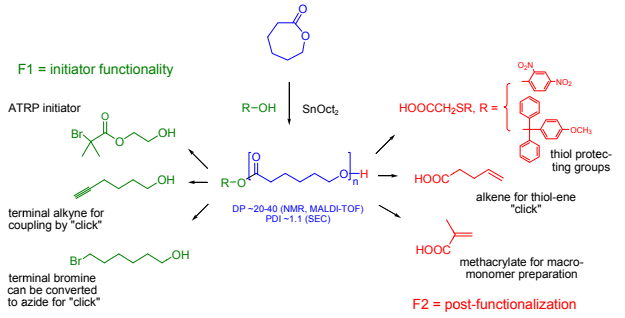
Nanomaterials Based on Poly(ε-caprolactone) - A Versatile and Intriguing Biomedical Building Block

Søren Hvilsted and Ikrakli Javakhishvili

Danish Polymer Centre. Department of Chemical and Biochemical Engineering. Technical University of Denmark

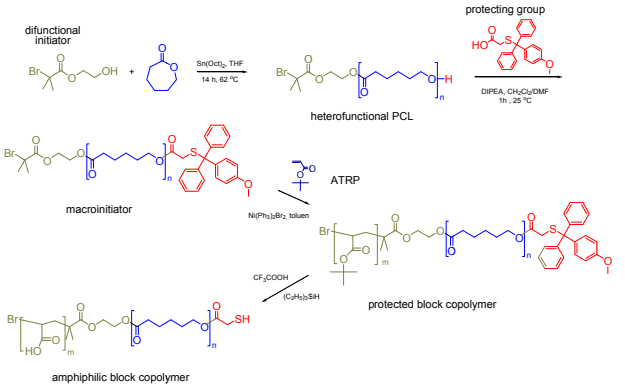
sh@kt.dtu.dk

The classical medical material workhorse, poly(ε-caprolactone) (PCL), has been employed as a viable scaffold for design of several novel nanomaterials with intri-guing, potentially therapeutic and biological properties. Living ROP strategies have afforded telechelic PCLs that can be utilized in either ATRP to make amphiphilic block copolymers or various "click" reactions resulting in multicomponent nanomaterials as outlined in Scheme 1. Three different examples will be elaborated.



Scheme 1. Various options for creating hetero bifunctional PCL building blocks by use of functional initiators (F1) and post-functionalization (F2).

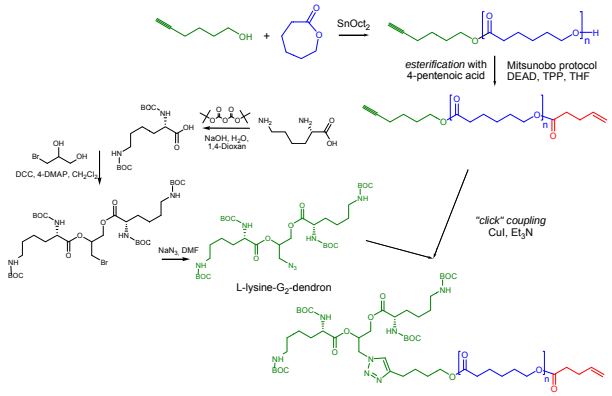
In the first case gold nanoparticles protected with a polymeric shell may combine ablative therapy and site-specific drug delivery in bladder cancer therapy [1]. This may be accomplished by tailoring the surface properties and the size of the gold clusters. The former may be addressed by devising polymeric ligands with desirable features and functional groups. Thus the preparation of the PCL-*b*-PAA corona will be outlined as shown in Scheme 2.



Scheme 2. Synthetic sequence for preparation of amphiphilic block copolymer precursor.

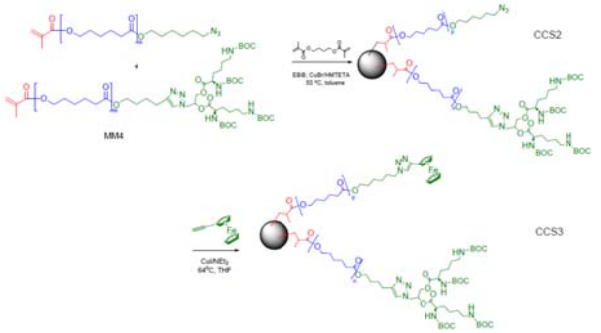
The synthesis of the effective macro-ligand that allows preparation of the stable gold cluster and provides nanoenvironment for hydrophobic anticancer drugs and mucoadhesive anchoring on mucous membranes is one of the objectives of this study.

The second approach is the ligation of biologically active moieties to the termini of a hydrophobic polymeric chain (PCL) to afford the amphiphilic linear-dendritic macromolecule that comprises rod-like, coil-like, and dendritic fragments [2]. Furthermore this may self-assemble in solid state as well as in aqueous solution. The facile route to linear-dendritic cholesteryl-*b*-PCL-*b*-(L-lysine)$_{G2}$ by thiol-ene and azide-alkyne "click" reactions is illustrated in Scheme 3. Here the driving motivation was to contrive a robust, facile, and effective synthetic strategy.



Scheme 3. Preparation of α-hexynyl-ω-pentenoate PCL, L-lysine-G_2-dendron, and the CuAAC coupling to the L-lysine-G_2-dendron-PCL.

Finally, the preparation of PCL-based miktoarm core-crosslinked amphiphilic star copolymers (CCS) with hydrophobic interior, charged hydrophilic surface, and targeting motifs are elaborated as shown in Scheme 4.



Scheme 4. Preparation of miktoarm CCS copolymers by copolymerization of functional macroinitiators.

Such nanoscopic core-shell type architectures are envisioned to be excellent candidates as drug delivery devices owing to the enhanced stability in biological fluids [3]. Moreover, they may permit site-specific delivery of their potential cargo due to the presence of biologically active moieties on the peripheries.

We present a systematic study of the synthesis of poly(β-benzyl-L-aspartic acid)s (PBAs) and poly(γ-benzyl-L-glutamic acid)s (PBGs) using monoamino functional nucleophilic initiators, such as a primary amine (n-hexylamine – HEX) and its hydrochloride salt (HEX–C), as well as simple multifunctional amines (1,6-diaminohexane,DAH, and tris(2-aminoethyl)amine, TAA, the lysine-based tetraamino dendritic initiator, LD4) [1]. Benzylic-protected aspartic acid and glutamic acid *N*-carboxyanhydrides (Glu NCA, Asp NCA) were used as the monomers. We studied both NCA ring-opening polymerizations (ROP) by varying the key reaction parameters, i.e., the monomer-to-initiator ratio, the initial monomer concentration, and the reaction temperature. The molar-mass characteristics of the reaction products were determined by size-exclusion chromatography coupled to a multi-angle light-scattering photometer (SEC-MALS). NMR and DSC were used for a determination of the monomer's purity. NMR spectroscopy was also used to determine the products' structure and as a complementary method to the SEC-MALS technique for a determination of the polypeptide number-average molar masses ($\overline{M_n}$).

Polypeptides (PBAs and PBGs) from Monofunctional Initiators

The polymerizations were run for 3 hours, with the exceptions for the slower reactions involving initiator HEX–C. The PBA–Hs obtained from the HEX -initiated Asp NCA polymerizations at room temperature had lower molar-mass averages than predicted from the [M]:[I] ratios (50, 100, 200), but the results are in agreement with the trend of $\overline{M_n}$ increase with the increasing [M]:[I] ratios. The molar-mass dispersities ($Đ_M$s) of PBA–Hs remain fairly low (below 1.30) but have a general tendency to increase somewhat with an increasing [M]:[I] ratio (from 1.04 for [M]:[I]=50 to 1.24 for [M]:[I]=200). PBG–H polymers with [M]:[I] ratios 50, 100, and 200 exhibited narrow molar-mass distributions (MMDs) and their $\overline{M_n}$ were in excellent agreement with the theoretical values. From the NMR and SEC-MALS data it can be seen that Glu NCA polymerizes much faster under the given experimental conditions than its Asp NCA analog.

When using HEX–C instead of HEX the polymerization rates are much slower than those of PBA-H and PBG-H polymerizations and almost free of side-reactions [2].The obtained PBA–Cs and PBG–Cs are all monomodal with narrow MMDs even for longer reaction times.

Differences in polymerization rates of both monomers were studied by the kinetics measurements using ^{1}H NMR spectroscopy. Both reactions can be described by the first-order kinetics. The HEX-initiated Glu NCA polymerization proceeded faster ($k_p = 1.4 \times 10^{-4}$ s^{-1}) than its analogous Asp NCA polymerization ($k_p = 5.5 \times 10^{-5}$ s^{-1}). A possible reason for this difference in the reaction rates could be the intramolecular H-bonding interactions, which are more pronounced in PBAs than in PBGs. The quasi-6-membered ring which can be completed with an N-H---O hydrogen bond is thermodynamically more stable than the 7-membered ring in the case of PBGs. The NH_2 terminus of the growing PBA macromolecule is thus somewhat deactivated in comparison to the PBG polymer.

Polypeptides from Di, Tri-, and Tetrafunctional Initiators

Using DAH we synthesized PBA2s and PBG2s with narrow MMDs ($Đ_M$=1.02–1.25), whose molar-mass averages were in fairly good agreement with the values calculated from the [M]:[I] feed ratios. The PBA3 polymers also have very narrow MMDs but slightly lower molar-mass averages than their calculated values.

Using the lysine-based dendrimer LD4 as an NCA polymerization initiator [M]:[I]=52, $\overline{DP}$ =13 per polypeptide arm, we prepared four-arm, star-like PBA–LD4 and PBG–LD4 with fairly narrow monomodal MMDs, ĐMs<1.3 (Fig.1).

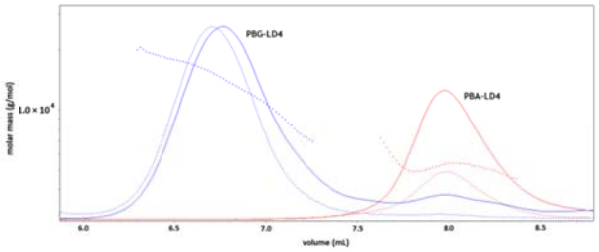

Figure 1. SEC-MALS chromatograms (– DRI response, - - LS response at 90° angle) and molar mass vs. elution volume curves for PBA–LD4 and PBG–LD4 polymers (points).

e-mail: loriol@unizar.es

Block copolymers (BCs) are of particular interest in the design of novel functional materials based on self-assembling properties. It is well-known that block copolymers can segregated into nanostructures either in bulk or solution. Besides, the incorporation of adequate functional moities in polymeric materials may allow the response of these materials to external stimuli. Furthermore, the response and the self-assemblies properties of BCs can be mutually affected.

On the other hand, light-responsive polymers have received great attention, being azopolymers (containing azobenzene as photochromic units) one of the most investigated, e.g. as optical data storage materials or photomechanical actuators[1]. Azobenzene molecules undergo isomerization between the *trans*and the *cis* states when they are irradiated in their absorption bands. Molecular motions and photoinduced anisotropy may be generated by irradiation using linearly polarized light.

We have previously described the synthesis and characterization of polymethacrylates having cyanoazobenzene as pendant groups, as well as the photoinduced anisotropy and holographic storage in thin films. Nevertheless, thick films are required for volume holography (higher storage capacity). For this last application, BCs can be a good alternative. The block copolymer architecture allows: (1) the confinement of azobenzene into nanodomains, which favors the cooperative motions induced by light, and (2) the dilution of the photochromic units, which allows the processing of thicker films.

We first accomplished the synthesis of linear-linear BCs (Figure 1) containing azobenzene units by ATRP using PMMA-macroninitiators[2]. BCs of high molecular weight have better been approached by a separate ATRP-synthesis of both blocks and coupling by a click reaction.

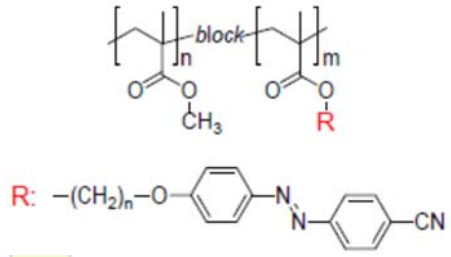

Figure 1. Chemical structure of linear-linear BCs

Synthesis, characterization, morphology and optical properties of films processed from these block copolymers will be discussed and compared with homopolymers.

In order to introduce a precise number of photochromic units, a new kind of azo-BCs were attempted having a linear-dendritic structure (Figure 2).

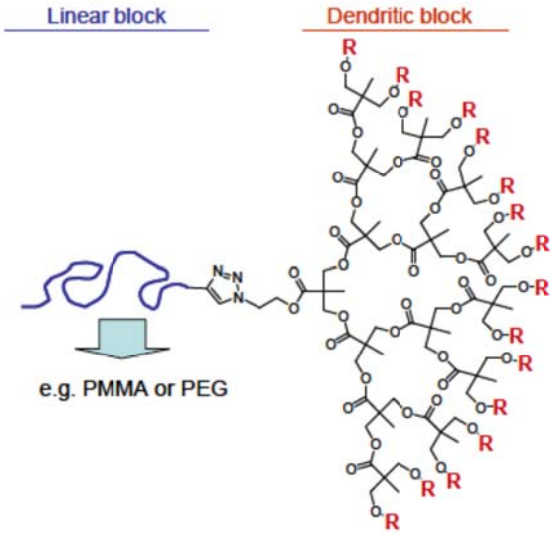

Figure 2.Chemical structure of linear-dendritic BCs.

The click coupling of linear and dendritic blocks (having photochromic units at the periphery) gives rise to different series of BCs[3]. In the case of amphiphilic BCS, self-assembly in aqueous solutions gives rise to different nanoobjects, ranging from nanofibers to vesicles, depending on the generation of the dendritic blocks (Figure 3)[4].

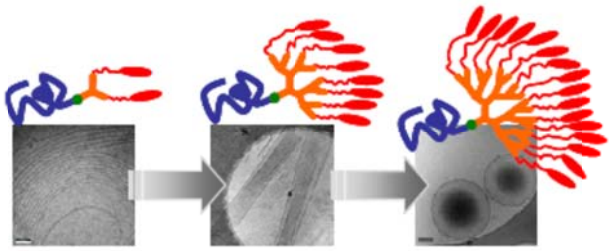

Figure 3.Self-assemblies of linear-dendritic BCs.

Topic 6: Bioinspired Polymers, Bioengineering and Biotechnology

Material considerations for annulus fibrosus and nucleus pulposus composite structures

Sanjukta Deb

Department of Biomaterials, Biomimetics & Biophotonics.King's College London, Dental Institute, Tower Wing, Guy's Hospital, London Bridge, London SE1 9RT, UK

Intervertebral disc (IVD) degeneration is a common problem that is the leading cause of low back pain worldwide, which seriously affects the health of the working population. The main approaches for treating the condition with discectomy and fusion provides good short term results however the altered biomechanics of the spine causes complications such as further degeneration. Artificial IVD discs have been developed to act as a functional prosthetic replacement unit for intervertebral units, however, current treatment modalities provide less than satisfactory outcomes.

The intervertebral disc (IVD) is composed of 3 distinct tissues, namely, the nucleus pulposus (NP), outer annulus fibrosus, and inner annulus fibrosus (AF), with cartilaginous end plates on the superior and anterior surfaces. Each of the components of the disc is composed of morphologically distinct cellular populations with a specific role. The different components of the healthy disc are an important determinant in the absorption and distribution of the forces arising in the spinal column. With disc degeneration a loss in fluidity occurs that compromises the elasticity resulting in the inability to absorb the normal compressive loads.

In this paper we report the synthesis of a set of novel hydrogels that have been synthesized using different methods of polymerization. Novel hydrogel scaffolds were synthesised using free radical solution and photo-polymerisation techniques under physiological conditions with the aim of creating a seamless construct that would comprise of a stiffer composite matrix forming the annulus fibrosus and a hydrogel forming the nucleus pulposus. In the first approach the monomer 2-hydroxyl ethyl methacrylate (HEMA) in conjunction with a phosphate containing comonomer, namely ethylene glycol methacrylate phosphate (EGMP) with ethylene glycol dimethylacrylate (EGDMA) as a cross-linker was used with the second approach involving the use of HEMA interacting with the adhesive, comonomer pyromellitic glycerol dimethacrylate (PMGDM) in 50% triethyleneglycol dimethacrylate (TEMA) as a crosslinker, introducing carboxyl groups into the copolymer. The different reaction conditions were explored to optimize a method that would allow the incorporation of biological entities during the polymerization reaction. Furthermore Bioglass particles were introduced to develop a composite with the phosphate containing hydrogels to enable the study of their interaction and produce a stiffer matrix suitable for annulus fibrosus.

Scaffold Functionalisation Strategies for Modulation of Inflammation

Abhay Pandit

Network of Excellence for Functional Biomaterials, National University of Ireland, Galway

Abhay.pandit@nuigalway.ie

Most degenerative diseases are characterised by an inflammatory response. Regenerative strategies employed to date do not attempt to address this response. Inflammatory response is often characterised by lack of oxygenation, apoptosis and presences of inflammatory cells. This microenvironment is often not-conducive for a regenerative response. An example of such a microenvironment is that of myocardial infarction (MI). Myocardial infarction (MI), which is literally the death of cardiac tissue due to lack of oxygenation, accounts for the majority of deaths associated with cardiovascular disease. This death of cardiac tissue leads to a loss of cardiac function as the damaged area becomes a non-contractile scar. Reversal of this process is the main aim of regenerative cardiac strategies such as stem cell transplantation. While initial studies were promising, subsequent clinical trials yielded disappointing results. Stem cell therapy may be limited by the poor survival rate of the cells after implantation into the infarcted heart, which is likely due to the inflammatory response. We have functionalised a collagen scaffold seeded with mesenchymal stem cells with an anti-inflammatory gene (interleukin-10 (IL-10)) to modulate the inflammatory response after implantation of a MSCs. IL-10 is considered the most potent anti-inflammatory cytokine produced naturally and has been used in a number of studies to decrease or control inflammation. It was hypothesized that IL-10 gene therapy could be used to increase the retention rate of stem cells in a collagen scaffold when delivered to the ischemic myocardium. The primary objectives were to develop a controlled release scaffold-based gene therapy system suitable for stem cell delivery to the infarcted myocardium. The efficacy of this system was evaluated by assessing stem cell retention, overall cardiac function and the inflammatory response. A crosslinked collagen scaffold was developed and optimised for rMSC culture in vitro. Non-viral plasmid-dendrimer polyplexes were optimized for transfection in both two and three-dimensional culture. When cells were seeded into polyplex loaded scaffolds, relatively high levels of transgene expression were observed for up to three weeks of culture. When the polyplex-loaded scaffolds were implanted in rat skeletal muscle, increased retention of rMSCs was observed. This was associated with decreased inflammation and a change in macrophage phenotype from cytotoxic to regulatory. Similarly, when the polyplex-loaded scaffolds were implanted over the surface of infarcted rat hearts, rMSC retention was increased, the inflammatory and remodelling responses were modulated and, most importantly left ventricular ejection fraction – a measure of cardiac function – was significantly improved. A similar strategy has been employed in peripheral nerve repair. A peripheral nerve conduit was fabricated with a neuro-regenerative factor and an anti-inflammatory factor. Down regulation of the inflammatory response permitted enhanced recovery of neural function. Thus, combining biomaterial, gene and cell therapy can improve functional outcomes if a key response such as inflammation is addressed. This combinatorial strategy can be utilised to provide functional efficacy in disease targets.

Recent Progress on the use of Natural Origin Polymers and Stem Cells in Tissue Engineering Strategies

Abstract

The selection of a scaffold material is both a critical and difficult choice that will determine the success of failure of any tissue engineering (TE) strategy. In our research we believe that natural origin polymers are the best choice for many approaches. In addition, we have been developing an all range of processing methodologies to produce adequate scaffolds for different TE applications. Furthermore an adequate cell source should be selected. In many cases efficient cell isolation, expansion and differentiation methodologies should be developed and optimized. In our research we have been using different human cell sources namely: mesenchymal stem cells from bone marrow, mesenchymal stem cells from human adipose tissue, human cells from amniotic fluids and membranes and cells obtained from human umbilical cords. The potential of each type of cells, to be used to develop novel regeneration therapies will be discussed.

Their uses and their interactions with different natural origin degradable scaffolds and distinct nano and micro-carriers, and smart release systems, will be described. A great focus will be given to the different sources of stem cells, the isolation of distinct sub-populations, ways of differentiating them, as well as their interactions with different 3D architectures and materials for culturing them. During the all lecture we will try to distinguish what is a fact, a trend and a real clinical open possibility. The use of bioreactors to control cell differentiation, as well as the surface modification of the materials in order to control cell adhesion and proliferation will also be illustrated. The results will be mainly based on our research in the areas of bone, cartilage and osteochondral tissue engineering. Several biomimetic and nanotechnology based strategies to engineer mineralized tissues will be described. We will also pay attention to the role of interfaces and controlled surface characteristics on the performance of different constructs.

Polyethylene Glycol Hydrogels for Therapeutic Vascularization

Edward A. Phelps and Andrés J. García

Petit Institute for Bioengineering and Bioscience, Georgia Institute of Technology

andres.garcia@me.gatech.edu

Clinically viable vascularization therapies will lead to better treatment for patients with peripheral artery disease and coronary heart disease as well as enhanced survival of cell and tissue transplants. Many clinical trials to induce new vascular growth have focused on delivery of a single angiogenic gene or growth factor, or activation and delivery of progenitor cells. We have engineered functionalized polyethylene glycol (PEG)-based hydrogel matrices with bioactive motifs to serve as engineered platforms for cell-demanded delivery of angiogenic growth factors and supportive environments for tissue ingrowth.

In one application, we have engineered PEG-maleimide hydrogels to incorporate VEGF as supportive matrices to improve pancreatic islet engraftment and vascularization. This hydrogel chemistry is advantagous for cell delivery due to mild crosslinking that occurs rapidly enough for in situ delivery, while easily lending itself to "plug-and-play" design variations. Precursor solutions of 4-arm PEG-maleimide were functionalized with RGDS adhesion peptide and VEGF.

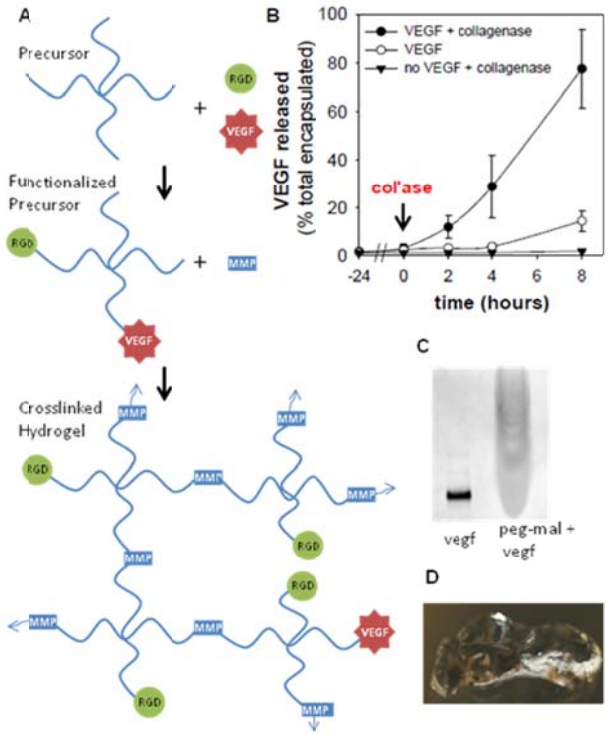

Fig. 1. PEG-maleimide hydrogel: (A) Reaction scheme. (B) VEGF release from hydrogels is MMP-dependent. Hydrogels were incubated in collagenase for different time points and VEGF in supernatant was quantified by ELISA. No VEGF was released prior to treatment with collagenase, indicating minimal passive (diffusion) release. (C) Western blot confirming pegylation of growth factor. (D) Sample of PEG-maleimide hydrogel.

The precursor molecules were crosslinked into a hydrogel by addition of cysteine-flanked MMP-degradable peptide sequences (Fig 1A). A collagenase gel degradation study measured release of growth factor from the matrix (Fig 1B). In a pilot *in vivo* study, approximately 500 islets isolated from inbred Lewis rats were transplanted into 3 sites in the small bowel mesentery of recipient Lewis rats by delivery in 5% (wt/vol) PEG-maleimide matrix with 2 μM RGDS adhesive peptide and 80 ng/mL VEGF or FGF. The matrix was crosslinked with MMP-degradable peptide *in situ* to adhere the graft to the mesentery tissue. After 7 days, the rats were perfused with fluorescein-lectin to label vasculature and the grafts were examined histologically for neovascularization, insulin expression, and immune / inflammatory response.

Release studies indicate that PEG-maleimide bound growth factors incorporated into the matrix were released primarily in a proteolytic manner (Fig. 1B). Islets/matrix delivered to the small bowel mesentery exhibited vascular reperfusion (as shown by lectin staining) by 7 days *in vivo*. Furthermore the hydrogel itself exhibited a high degree of vascular invasion (Fig 2A) with markedly stronger vascular response in grafts with FGF or VEGF. Immunostaining revealed a concentration of grafted islets expressing insulin at the transplant site (Fig 2B). Histological staining indicated vessel penetration into the bulk of the hydrogel with no fibrous encapsulation and low presence of primary inflammatory cells (negative for CD11b).

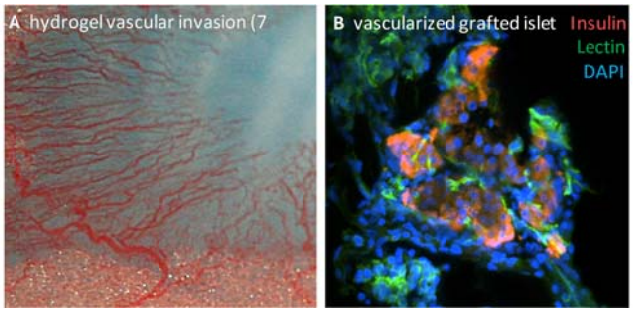

Fig. 2. (A) Hydrogel vascular ingrowth (7 days)

(B) Engrafted islet showing vascularization and insulin.

We present the use of an engineered matrix that supports islet activities and promotes vascularization *in vivo*. This project establishes novel biomaterial strategies for islet delivery that support islet viability and function via the induction of local vascularization. To our knowledge these PEG-maleimide hydrogels have never been used for cell culture or delivery.

Polymer-Silica Nanocomposites: Structure, Properties, Bioactivity and Biological Performance of Their Scaffolds

Manuel Monleón Pradas

Centro de Biomateriales, Universidad Politécnica de Valencia, Spain
Centro de Investigación Príncipe Felipe, Valencia, Spain

mmonleon@upvnet.upv.es

Introduction

Sol-gel silica polymer nanocomposites are an interesting class of materials in that their properties may be varied within a wide range of values, thus satisfying requirements which cannot be met with homo- or copolymers. If biomedical applications are considered, the important properties may be the mechanical strength, the dimensional stability upon water sorption, and the bioactivity, or ability to nucleate the growth of hydroxyapatite, the mineral component of bone tissues. A silica phase in an organic matrix can improve these aspects in one stroke. Depending upon the chemical functionalities of the matrix, materials more or less hydrophilic, and more or less rigid, can be modified to different degrees as a function of the silica content in the nanocomposite formulation. The silica phase obtained by a sol-gel reaction has terminal silanol groups in a number which depends on the connectivity of the network, and thus the silica to polymer ratio influences not only the mechanical properties of the composite, but also its hydrophilicity. Here we review work of our laboratory on a series of hybrid matrices and scaffolds made thereof aimed at regenerating mineralized tissue.

Materials and Methods

TEOS was used as precursor for silica. Different acrylate comomers (EA, HEA, CLMA and EMA) were employed to produce the nanohybrid matrices in a sol-gel reaction were both the silica network and the organic matrix polymerize simultaneously. Scaffolds with aligned channels of these matrices were obtained by a porogen-template method. The properties of the hybrid matrices and the silica structure therein were investigated by FTIR, DSC, dynamic-mechanical and dielectric relaxation measurements, contact angle, water sorption, EDS, SEM, AFM, thermogravimetry and densimetry. *In vitro* bioactivity was studied with SBF immersion tests. *In vivo* performance of nanohybrid scaffolds was studied in subcutaneous implants in nude mice with histological techniques.

Results and Discussion

Issues of interest in these systems include: the efficiency of the condensation reaction; the degree of interpenetration of both (organic and inorganic) networks; the topology and percolation threshold of the silica phase throughout the matrix; the confinement effects of the silica structure upon the mobility of the organic chains and the ensuing relaxation behaviour; the mechanical reinforcement effects as a function of silica contents; the effect of silica upon the specific hydrophilicity and surface energy of the material; the different silica structure build-up due to different hydrophilicity of the organic phase monomers; the specific mechanism leading to the *in vitro* bioactivity (hydroxyapatite nucleating ability) of the materials; the role of the connectivity of the silica phase in explaining the bioactivity of these systems; and finally, the interaction of the organic and the inorganic phase with cells *in vitro* and *in vivo*.

Conclusions

Sol-gel nanocomposites based on these organic matrices are finely interpenetrated networks with marked property changes at the percolating threshold; formulations around this composition exhibit better biological performance. Scaffolds with well defined pore order mimicking specialized bony tissues such as dentin can be made from these hybrid matrices, which get invaded by odontoblast-like cell processes *in vivo*.

Rational Design and Synthesis of Amphilphilic Biodegradable Polymers for Alveolar Bone Regeneration

Firas Rasoul[1,2], David Wang[1], David Hill[1,2], Anne Symons[3], Srinivas Varanasi[3] and Andrew Whittaker[1,2]

[1]Australian Institute for Bioengineering and Nanotechnology, [2]Centre for Advanced Imaging and [3]School of Dentistry. The University of Queensland, Brisbane, Queensland, 4072 Australia

f.rasoul@uq.edu.au

Alveolar bone is the supporting bone structure of the maxilla (top jaw) and the mandible (bottom jaw) which are the tooth-bearing bones in humans. The primary cause of alveolar bone loss is periodontal disease (Periodontitis) which is an inflammatory gum infection caused by the convergence of bacteria that adheres to and grows on the tooth surface below the gum line. It involves progressive and irreversible loss of the alveolar bone around the teeth and eventually leads to the loosening and subsequent loss of teeth. Periodontitis is very common and has a prevalence of 40-50% of the population above 30 years old. The principal goal for this research program is to develop an effective method for the treatment of periodontitis through controlled delivery of bone-healing bioactives from biodegradable hydrogels.

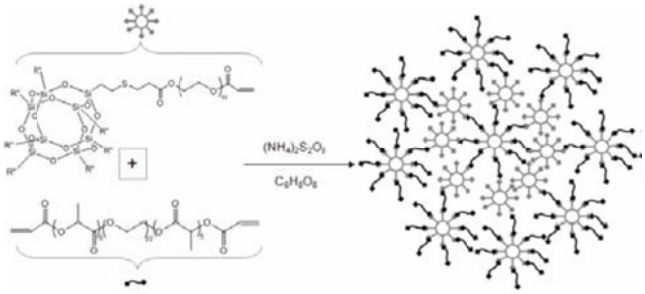

Figure 1: Copolymerization Reaction of Acrylated POSS-macromer with acrylated PLA-PEG-PLA tri-block copolymer

Hydrogels based on acrylated poly(lactic acid)-b-poly¬(ethylene glycol)-b-poly(lactic acid) (PLA-b-PEG-b-PLA) macromers were designed to maintain all of the advantages of a PEG-based material while also permitting tuneable degradability1. As the utilization of PLA-b-PEG-b-PLA based gels has increased, this characteristic of tuneable degradability has become extremely useful in the biomedical field to modulate the delivery rates of drugs or growth rates of cells encapsulated within cross-linked gel matrices.

However, PLA-b-PEG-b-PLA based hydrogels are falling short in some of their requirements for this particular application; such as high swelling ratios which can compromise the integrity of the dental implant, also high swelling ratios will results in high rates of degradation and therefore faster drug release.

In the current study we report the synthesis of new hydrogel copolymer systems based on multi-functional arms macromers as crosslinkers and acrylated PLA-b-PEG-b-PLA tri-block copolymer. Two examples of multi-functional arms macromers will be discussed: the first is based on polyhedral oligomeric silsesquioxane (POSS), which was pegylated through thiol-ene"click chemistry" followed by acrylation reaction to produce multi-functional arms "acrylated POSS-macromer" (see Fig 1) and the second is based on a hyperbranched polyester polymer (BoltornTM) which was also decorated with PEG using Cu(I) catalyzed azide-alkyne "click-chemistry" and then acrylated to produce "acrylated-Boltorn macromer". The effect of the multi¬arms macromers contents on the PLA-PEG-PLA hydrogels morphology, swelling ratios and degradation rates will be also presented. According to the developed degradation models of hydrogels based on polylactide and lactide copolymers, the hydrolytic degradation in aqueous media is known to be affected by two main parameters2, namely the kinetics of hydrolysis of the ester bonds within the hydrogel network, and the physical structure of the gel. Both parameters control the process of network degradation which makes the entire gel degradation process very complex. In the current study, it is important to understand the factors controlling the degradation behavior of the newly developed hydrogels including the effect of the molecular weight of the PEG segment (structural effect), the number of the lactide unites (kinetic effect) and the level of the multi-arms macromers in the hydrogel (morphological effect).

Furthermore, for the first time since the discovery of the Cu(I)-catalyzed click reaction, we have been able to show the presence of complexed Cu(II) residues in polymerized gels and that Cu(II) can play an important role in the hydrolytic degradation of polyester-based gels as elucidated by the cryoSEM and EPR spectroscopic studies (Fig 2). Moreover, the ability to tailor hydrogel cross-linking density can also be used to control network mesh size and diffusivities of encapsulated drugs. We have shown that multi¬functional arms macromers have tremendous effect on the hydrogel morphology and therefore on the rate of degradation. The results showed that hydrogels with high molar ratios of multi-arms macromers produce highly porous microstructures (Fig 2). This behaviour can be attributed to the formation of clusters of multi¬arms aggregates due to hydrophobic interaction, which give rise to phase separation during copolymerization process[3].

Polymeric Endograft for the Treatment of Abdominal Aortic Aneurysms

Daniel Cohn, Randa Abbas, Itai Pelled and Ram Malal

Institute of Chemistry, The Hebrew University of Jerusalem, Jerusalem, Israel

dcohn18@gmail.com

Introduction

The formation of aneurysms is an extremely dangerous degenerative pathology of arterial tissues, especially common in adult and elderly populations, whereby the wall of the artery weakens locally and largely expands. In more than 80% of the cases, the rupture of the aneurysmal sac is fatal.

Until 1991, the only treatment available entailed a fully open surgical procedure, whereby the dilated segment of the artery was replaced by an artificial vascular graft. An endograft consisting of a vascular prosthesis mounted on a stent and deployed intra-luminally at the aneurysmal site using a balloon, was implanted in 1991 for the first time.

This minimally invasive technique, called EndoVascular Aneurysm Repair (EVAR), represented a breakthrough in the field both conceptually as well as technologically. Unfortunately, though, there are various factors that restrict considerably the use of this technique, mainly. The key problems of these devices are the occurrence of renewed leakage into the aneurysmal sac (endoleaks), despite the presence of the stent/graft device and its migration downstream. Additionally, strict anatomical considerations pertaining to the dimensions of the artery both proximal and distal to the aneurysmal site, may prevent the use of the endograft.

This lecture will introduce a polymeric device for AAA treatment that will be deployed intra-luminally at the aneurismal site and then expanded so it tightly attaches to the aorta, proximally and distally to the aneurysm.

The implantation of these devices is divided into two parts: {a} the insertion through the iliac artery, navigation to the site and expansion stages, during which the flexibility of the device is critical, and {b} its performance at the aneurismal site, where the device is required to display appropriate mechanical properties.

Two strategies were pursued: (1) the device is thermally softened using a balloon filled with warm saline, so it can be easily brought to the site and then expanded, followed by its firm and conformable attachment to the arterial wall, proximally and distally to the aneurysm. While in its expanded configuration, the endograft is then cooled down to 37^{o}C and attains the mechanical properties and strong attachment required. (2) The endograft consists of an Expandable Component (EC) and a "Smart" Component (SC), with the latter being present within the former. The EC is responsible for the large change in dimensions the endograft undergoes during its deployment at the aneurysm. The SC is a low molecular weight, polymerizable or crosslinkable precursor that fulfills two different roles: {a} It acts as a plasticizer during the early stages of the procedure (navigation and expansion), rendering it with the required flexibility, and, {b} It stiffens the device after its expansion and snug attachment to the vessel wall, once it polymerizes or crosslinks, imparting to the endograft the necessary mechanical properties.

Materials and Methods

PEU thermoplastic elastomers softening between 50 and 60 degrees were used when following the first strategy, while polymethacrylates and polyacrylates performed as the EC, and methacrylates such as HEMA and EGDMA were used as the SC. The various polymers were characterized by NMR, DSC, GPC and their mechanical properties were determined using an Instron Universal Testing Machine. Their ex-vivo performance was assessed in pig aorta segments and the acute in vivo feasibility of the device was evaluated by implanting it in a pig for eight hours.

Results and Discussion

Following the basic working concept of this study, various expandable conduits were generated, differing in their composition, the technique used to produce them, their mechanical properties and expandability ratio. The straightforward expandability of the devices created was demonstrated in cadaveric pig aorta sections using a balloon filled with warm saline. The diameter of the conduits increased more than three times and they became tightly attached to the luminal surface of the vessel. Moreover, it was extremely difficult to pull them out, once deployed at the site.

Figure 1 present the mechanical behavior of a PMMA/HEMA system, where HEMA softens the PMMA expandable component during the early stages of the implantation procedure, and remarkably stiffens when it polymerizes, after the device is expanded and tightly attached to the aortic wall, proximally and distally to the aneurismal sac.

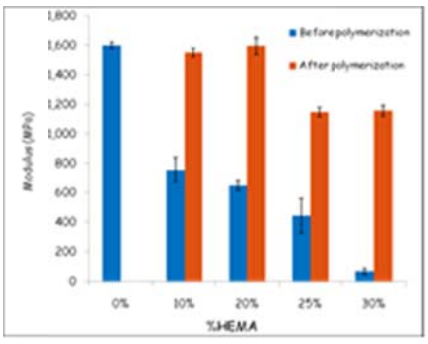

Figure 1.The mechanical behavior of an EC/SC PMMA/HEMA device.

The *in vivo* Proof of Principle of these devices, namely their ability to be deployed and inflated at the site following minimally invasive procedures that are routinely used in the clinic, and generate a stable and safe conduit, was demonstrated acutely (eight hours) in the abdominal aorta of pigs.

Additive manufacturing of wet-spun scaffolds for bone tissue engineering

Prof. Emo Chiellini

Laboratory of Bioactive Polymeric Materials for Biomedical and Environmental Applications (BIOlab), Department of Chemistry and Industrial Chemistry, University of Pisa, Italy.

emochie@dcci.unipi.it

Concept

The main result attained during the present research activity was the development of a layer-by-layer Additive Manufacturing (AM) technique allowing for a better control over shape, size and microarchitecture of tissue engineered polymeric scaffolds produced by wet-spinning. Layers composed of parallel fibers were fabricated by extruding a polymeric solution through a computer-controlled translating spinneret into a coagulation bath, and 3D structures were built up by collecting layers with different fiber orientation one on top of the other.

Motivations and Objectives

In recent years, some published studies have proposed non-woven polymeric meshes of wet spun microfibers, fabricated by physical bonding of prefabricated fibers or by a single-step method, as scaffolds for tissue engineering [1, 2]. However, these fabrication methods suffer from lack of structure reproducibility as well as control over external shape and internal morphology. The aim of the present activity was to develop an AM technique for the design and fabrication of wet-spun polymeric constructs, with customized architecture and shape, suitable for tissue engineering purposes.

Results and Discussion

Poly(ε-caprolactone) (PCL) and PCL/hydroxyapatite (HA) nanoparticles composite scaffolds, composed by layers of parallel microfibers with a diameter in the range 200 – 300 μm, were produced layer-by-layer with a 0-90° lay-down pattern (Figures 1a and 1b). Different architectures were obtained by changing the interfiber distance and fiber staggering between layers. The phase inversion process governing polymer solidification led to highly porous fibers both in the outer surface and in the cross section, with a pore size of few micrometers (Figure 1b). Uniaxial compression testing showed higher compressive modulus and strength of HA-loaded constructs in comparison with bare PCL constructs. Scaffolds with two different architectures were tested for their *in vitro* compatibility to MC3T3 preosteoblastic cells showing encouraging results in terms of cell adhesion, viability, ALP activity andmineralization. After 31 days most of the fibres throughout the scaffolds were completely covered by cells that were also able to colonize the inter-fibre gap, forming cellular bridging between adjacent fibres (Figure 1c).

staslomk@cbmm.lodz.pl

Introduction

Polymer nano- and microparticles found many applications in medicine. Dimensions of these objects are close to the dimensions of large proteins, intracellular organelles and whole cells. Therefore, such particles can be used as convenient tools probing properties of living systems on the cellular, subcellular and molecular level. Initially polymer microparticles were used for preparation of simple diagnostic tests (see Ref. 1,2 and references therein). Later it was found that particles composed of (bio)degradable polymers could be used also as drug carriers [3,4]. For all the mentioned above applications there are needed particles with tailored surface properties, allowing for their controlled interactions with tissue, cells and macromolecules of the immune system. The lecture will present results of our recent studies on preparation of nano- and microparticles with interfacial properties tuned for diagnostic purposes, drug delivery and tissue engineering. The attention will be focused on particles with shells containing hydrophilic polyglycidol suitable for controlled binding of proteins and other biomolecules.

Particles for diagnostic applications

Particles for diagnostic applications should allow for selective covalent immobilization of antibodies or antigens with elimination, or at least efficient reduction, of the adventitious protein adsorption during the diagnostic tests. In the last years we developed methods for synthesis of microspheres by copolymerization of styrene with polyglycidol macromonomers. In the lecture we will present our recent findings on the mechanism of particle nucleation, growth and formation of their interfacial layer. The TEM, SEM and AFM observations revealed that microspheres are decorated with nanoparticles, presumably formed at the early stage of polymerization. XPS studies did prove that the interfacial layer of microspheres is strongly enriched (up to 45 %) in polyglycidol. The high polyglycidol content and special morphology of particles' interfacial layer resulted in their superhydrophilicity and strong reduction of the uncontrolled protein adsorption. Moreover, activation of polyglycidol with trichloro-triazine allowed for the covalent immobilization of proteins yielding systems suitable for the immunotests.

Polyglycidol containing nnoparticles for drug delivery

Polyglycidol can be used also for protection of the outer layer of biodegradable nanoparticles. Particularly interesting are nanoparticles formed by dialysis of poly(L,L-lactide)-*b*-polyglycidol copolymer solutions against water. This approach allowed preparation of nanoparicles loaded with insulin and ovalbumin. Their diameters ranged from 25 to 70 nm, depending on the copolymer composition. It is worth noting that suspensions of the poly(L,L-lactide)-*b*-polyglycidol nanoparticles were colloidally stable for pH from 2 to 9. Kinetics of protein release revealed absence of the initial burst. Thus, the particles can be considered as interesting candidates for oral protein delivery.

Polyglycidol and poly(ethylene oxide) containing nanoparticles for scaffolds for tissue engineering

The proper adjustment of hydrophilic/hydrophobic balance of interfacial layer is important in the case of materials used for preparation of scaffolds for tissue engineering. Especially interesting are materials which could adapt hydrophilicity/hydrophobicity of their surface to the environment. Recently we developed the method suitable for preparation of nano- and microsilica with tethered pairs of polyglycidol (or poly(ethylene oxide)) and poly(L,L-lactide) chains. First, silica particles are modified with 3-glycidoxypropyl trimethoxysilane. This step yields particles with epoxy groups at their surface. An exposure of silica particles with epoxide groups to solution containing living poly(1-ethoxyethylglycidol) with alkoxide propagating species yielded silica with tethered polyether chains and alkoxide groups generated by opening the epoxide rings. The subsequent grafting of poly(L,L-lactide) from silica yielded particles with almost equal number of hydrophilic polyglycidol chains (formed by deprotection of hydroxyl groups in poly(1-ethoxyethylglycidol)) and hydrophobic poly(L,L-lactide) chains. In a similar way the silica particles with poly(ethylene oxide) and poly(L,L-lactide) chains were obtained. The coil-to-globule and globule-to-coil transition of polyether and polyester chains, induced by changing media surrounding silica particles resulted in adaptation of their surface properties to environment. The modified silica particles with adaptable interfacial properties were used for preparation of silica fortified scaffolds for the hard tissue engineering.

Introduction

Ferrocene and its derivatives are successfully used in various polymerization processes [1]. Ferrocenyl containing monomers have been synthesized and related polymers with improved electrophysical characteristics were synthesized [2]. In [3], effective initiation systems based on ferrocene and diacyl peroxides have been studied. To extend the range of using ferrocenyl containing substances and to study the influence of new azinylferrocenes (AFC) and ferrocenyl containing semiclathrochelates and clathrochelates of Fe(II) (FCC) on the process of radical polymerization of vinyl monomers (by the example of methyl methacrylate – MMA and styrene) are tasks of great interest and importance.

Materials and Methods

Azinylferrocenes and clathrochelates of Fe(II) were synthesized and purified as described in [4, 5]. The kinetic of bulk polymerization was studied by dilatometric and gravimetric methods. Molecular weight characteristics were determined by gel penetrating chromatography using a "Waters GPC 2000 System" chromatograph. Polymer microstructure was determined using ^{1}H NMR-spectra. Interactions of organic molecules were studied by IR, UV and NMR spectroscopy.

Results and Discussion

When catalytic amounts of AFC as modifying additives were used in the polymerization of vinyl monomers the synergic effect of metal containing and nitrogen containing groups on kinetic parameters of process and on molecular characteristics of obtained polymers was observed. It was shown that AFC in combination with diacyl peroxides form effective initiation systems, especially in polar MMA, which are more active in comparison with initiation systems based on unsaturated ferrocene, all other conditions being the same [3]. The increase of MMA and styrene polymerization rate in the presence of azo initiator (azo-bis-isobutironitrile - AIBN) is distinguishing feature of AFC. The influence of AFC on propagating and termination stages was confirmed by the results of study of interaction of AFC with monomers, by the increase of syndiotactic triads content in polymer chains (in the case of polymethyl methacrylate - PMMA) and by the increase of polymers thermo stability (in the case of PMMA and polystyrene).

The choice of ferrocenyl containing semiclathrochelates and clathrochelates of Fe(II) as modifying additives for radical polymerization of vinyl monomers caused by presence of both ferrocenyl group and ligand of special kind – macrocyclic clathrochelate with transition metal central atom – in their structure. It was found that ferrocenyl containing semiclathrochelates and clathrochelates of Fe(II) in combination with diacyl peroxides form initiation systems which are more active than ferrocene and its derivatives. The using of clathrochelates makes it possible to reduce the concentration of initiator. Concentration of added FCC was less by 1-2 order than in the case of using of ferrocene and its derivatives. By variation of initiation system components ratio high weight polymers and low weight polymers can be synthesized. Obtained polymers were characterized by high content of syndiotactic triads and high thermo stability. When AIBN was used as initiator, metal complexes additives at studied concentrations had almost no effect on kinetic parameters of MMA and styrene polymerization processes.

Conclusions

Thus, AFC and FCC are promising modifying additives for carrying out the radical polymerization of vinyl monomers. It is most probable, that polymerization follows the complex-radical mechanism.

Introduction

In the field of green chemistry development, scientists and especially chemists are facing new stakes and have to deal with new constraints. Among these constraints, we find new regulations concerning chemicals, and especially concerning reduction and substitution of Carcinogen, Mutagen Reprotoxic (CMR) classified substances. Among many of these substances we can note several molecules constituting of widely used plastics, and particularly bisphenol A (BPA) (CMR R3), one of the main components of epoxy resins.

BPA has been commercially used for over 50 years and is currently produced in huge quantities: over 3.3 Mt/y in the world. Since the year 2000, lots of publications studied the effects of bisphenol A on human health. Hundreds of publications deal with the toxicity of BPA in animal, human and environment. This recent awareness on BPA toxicity implies necessary changes in the world of epoxy resins. Major issues are to find alternative to the typical synthesis route for epoxy resins and to find substitutes to BPA. To find a substitute to BPA and amines are the two goals of this study. Polyphenols and especially condensed tannins extracted from waste produced by the wood and wine industries are proposed as substitutes to BPA to produce "green resins". Amines synthesized from renewable resources could be proposed as "green" hardener for these "green resins".

The aim of this study is to qualify natural tannins as potential substitutes to BPA. However, before working on tannins, we intended to focus on smaller molecules, such as catechin, tannins reactivity model molecule, to study the reactivity of polyphenols and their ability to produce epoxy resins (**¡Error! No se encuentra el origen de la referencia.**, **¡Error! No se encuentra el origen de la referencia.**). Indeed, catechin molecule corresponds to repetition unit of tannins.

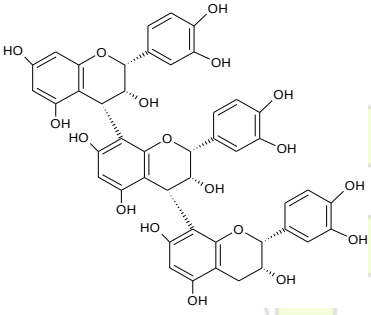

Figure 4 : tannins structure

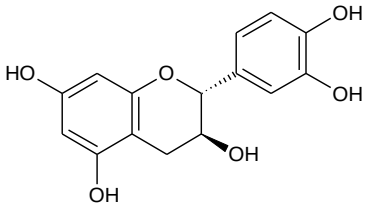

Figure 5 : catechine molecule

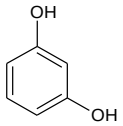

Figure 6 : resorcinol

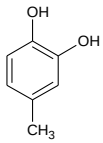

Figure 7 : methylcatechol

Results

We first studied the epoxydation of monoaromatic phenolic molecules such as resorcinol and methylcatechol that constitute the two aromatic rings of tannins (Figure 6, Figure 7). We obtained different yield of epoxydation owing to different positions and then different reactivity when reaction with amine hardener.

Then we studied the epoxydation of catechin, tannin monomer model. We synthesized glycidyl catechin. We isolated and characterized this new reactive molecule. We identified epoxydation loci and reactivity. Finally, we elaborated green resins from glycidyl tannins[i] with amine hardeners. We characterized these resins with mechanical and thermal properties and compared to classic resins made from diglycidyl ether of BPA (BADGE).

Conclusion

We obtained succeeded in replacement of BPA by natural tannins and elaborated epoxy resins from glycidyl tannins. We obtained similar thermal properties with epoxy resins elaborated from glycidyl tannins compares to resins from commercial BADGE.

Effective catalytic systems for Atom Transfer Radical Polymerization based on the carborane complexes of Ruthenium

Ivan Grishin[a], *Elena Turmina*[a], *Igor Chizhevsky*[b], *Dmitry Grishin*[b]

[a]Research Institute of Chemistry of Nizhny Novgorod State University,

[b]A.N.Nesmeyanov Institute of Organoelement Compounds Russian Academy of Sciences

grishin_i@ichem.unn.ru

Introduction

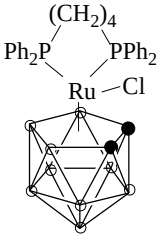
Atom Transfer Radical Polymerization **(ATRP)** is a very effective and convenient tool for obtaining polymer samples with predicted molecular-weight parameters, and controlled topology. It opens wide opportunities for the synthesis of polymer materials with unique properties. So, the development of novel catalytic systems for ATRP is an actual and challenging task. Here we report about the use of novel ruthenium carborane complexes in ATRP of methyl methacrylate and the obtaining block copolymers based on them.

Materials and Methods

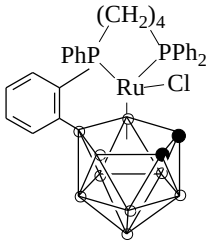
Ruthenium complexes were synthesized using standard Schlenk-line techniques under an atmosphere of dry argon. Monomers were dried over CaH_2 and distilled under reduced pressure prior to use. The polymerization was conducted at 80˚C in sealed glass tubes under reduced pressure in monomer bulk. The obtained polymer samples were purificated from monomer and catalyst by dissolving ion chloroform and precipitating in petroleum ether. The molecular-weight distributions of the polymers were analyzed by Size-exclusion chromatography on a Knauer instrument equipped with two polystyrene gel columns (Phenomenex, pore size 10^3-10^5Å).

Results and discussion

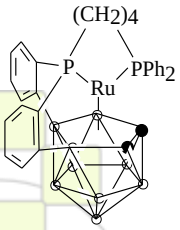
In this work paramagnetic ruthenium complexes **1-4** containing C_2B_9-dicarbollide ligand were used as catalysts for ATRP:



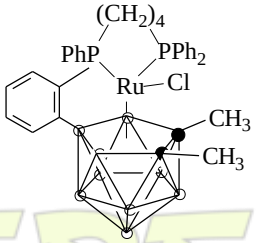
1



2



3



4

The obtained results have shown that these paramagnetic derivatives of ruthenium (III) are perfect catalysts for ATRP of MMA and allow to obtain polymer samples with polydisperstity of 1.1-1.2. The molecular weight of the obtained samples linearly increases with conversion indicating the "living" nature of the process. It should be mentioned that all the complexes show similar degree of control over process, but compound **2** is the most preferable one due to its higher stability.

The obtained poly MMA samples may be used as macronintiators for post polymerization and block-copolymerization with styrene and methacrylic monomers indicating "living" nature if the process. The obtained block-copolymers have unimodal molecular weight distribution indicating the absence of "dead" chains in the polymer.

It was established that amine additives can significantly increase the rate of polymerization in the presence of complexes **1-3** leaving process controlled. The use of amines as co-catalysts for ruthenacarboranes allows to decrease catalyst concentration ten times. We suppose that amine interacts with carborane complex of ruthenium giving novel organometallic species which are responsible for the reversible deactivation of growing chains.

It was shown that complex **4**, based on dimethylcarborane ligand is less effective catalyst than its nonsubstituted counterparts. The use of systems based on **4** results in the formation of polymers with M_w/M_n=1.4. We suppose that methyl groups are enough bulky to disturb the interaction between catalyst and growing polymer chain. This results in the loss control over polymerization. Moreover systems based on **4** and amines are incapable to control polymerization of MMA leading to polymers with broad polydispersity and high molecular weights.

Conclusions

A novel carborane complexes of ruthenium (III) were synthesized. These compounds have shown themselves as perfect catalysts for ATRP. Introduction of amine additives allow to increase polymerization rate and decrease catalyst concentration which is necessary for synthesis of polymers.

Introduction

The synthesis of polymers with controlled macromolecular architecture according to well tested models of chain growth [1] is important from both academic and industrial points of view. Upon correlation of structure with properties in such polymers and by application of the developed models, new polymeric materials with optimized physical properties can be obtained. An example of the application of such a strategy is PA6 with low [2] or high viscosity [3] recently produced by Rhodia. The present work reports the synthesis, according to chain growth models recently developed by some of the Authors [1], of star, tree and star-tree PA11 and PLA, together with their melt and solid-state characterization.

Materials and Methods

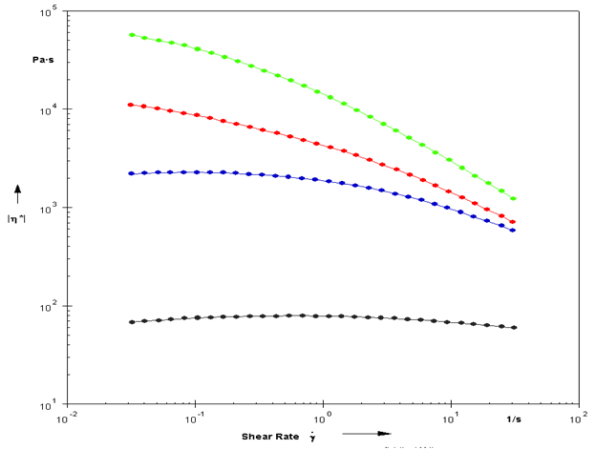
For the synthesis of PLA and PA11 with complex architectures, monomer and proper concentrations of multifunctional comonomers (pentaeritrol, cyclodextrin, trimethylolpropane) were polymerised at 190°C (2 hours) and at 270°C (4 hours), respectively, in inert atmosphere. Lactide present at equilibrium in PLA was eliminated at 150°C under vacuum. SEC analyses were performed at room temperature with a 6 column set using CH_2Cl_2 as eluent. PA11 was analysed after trifluoroacetylation. Specimens for stress-strain measurements were cut from compression molded films (0.2-0.4 mm thick).

Results and Discussion

The model predicts [1] that, when an AB monomer is polymerised in the presence of a comonomer having 6 reactive groups, all possible species (linear and thee-to-six branched chains) are present even at very high conversion. In this work, such model predictions were confirmed by SEC and NMR analyses, by oligomerisation and MALDI-TOF [4], not only for PLA and PA11, but also for PA6 and PA12 [5].

The model also suggests [1] a means to obtain star PLA having higher melt viscosity than commercially available PLA. As an example, the figure compares the rheological behaviors of a linear PLA (DPn = 950) with the one of two different star PLA (three arm and DPn = 400; 21 arms and DPn = 10000) and a star-tree PLA. It is worth pointing out that star-polycondensates are commonly synthesized for their low melt viscosity, due to their smaller hydrodynamic volume than their linear counterparts (with the same DPn) and to the absence of intermolecular entanglements. The example in the figure instead concerns a PLA with a high number of branches with very high arm length suitable for intermolecular interaction that results in a remarkable increase of melt viscosity.

Interestingly, tree- or star-tree-branched PLAs display even higher melt viscosities than equivalent star-shaped macromolecules. An analogous behaviour is shown by PA11 polymers with different architectures. The mechanical properties of PLA and PA11 are quite different (i.e. tensile modulus 2400 MPa and 1050 MPa, elongation at break 3-5% and > 100%, respectively), but the measurements carried out in this work on the synthesized polymers indicate that solid-state properties are not significantly affected by macromolecular architecture.



Melt viscosity of a three arm star (black curve), of a linear (blue curve), of a star-tree (red curve) and of a 21-arms branched (green curve) PLA's

Conclusions

PLA and PA11 with complex macromolecular architectures can be obtained according to the models originally proposed for PA6. The macromolecular architecture strongly affects the melt behaviour. The solid-state characterization results show that the rheological properties can be tuned to processing requirements without altering the material's mechanical performance.

Ring-opening co- and terpolymerization of an alicyclic oxirane with carboxylic acid anhydrides and CO2 in the presence of chromium porphyrin and salen or zinc aryloxide catalysts

Elham Hosseini Nejad, Rob Duchateau, Cor Koning

Department of Chemical Engineering and Chemistry, Laboratory of Polymer Chemistry, Eindhoven University of Technology, P.O.Box 513, 5600MB Eindhoven, The Netherlands

e.hosseininejad@tue.nl

In recent years polyesters have gained increasing attention due to their suitability for an ever-broadening range of applications ranging from packaging materials to biomedical devices. Polyesters can be synthesized via several routes. One path is the copolymerization of diols with anhydrides or dicarboxylic acids through step-growth polymerization, whereas another and very attractive path is to synthesize them through a catalytic ring-opening polymerization of the corresponding anhydrides and oxirane monomers, using different selective catalysts for this type of polymerization.

In this study, our primary main goal is to synthesize fully hydroxide end-capped aliphatic polyesters with relatively high Tg by the catalytic copolymerization of cyclohexene oxide (CHO) and different anhydrides such as phthalic anhydride (PA) or succinic anhydride (SA). While CHO residues will exhibit a rigid structure and result in relatively high Tg polyesters, the succinic anhydride residues will provide some flexibility to the polymer chain structure.

On the other hand, carbonate segments in polyester chains have also been very appealing during the recent few years due to the advantages they pertain to the polymer chain. The introduction of a carbonate linkage into the polyester chain has the beneficial effect of improving hydrolytic stability and impact strength. Like polyesters, polycarbonates are useful as biodegradable products and have shown to have adjustable degradation rates. So another pathway in this research is the catalytic terpolymerization of CHO and PA (or SA) with carbon dioxide (CO2) to obtain poly (ester-co-carbonate)s and investigate the properties of this class of copolymers.

Porphyrin and salen type catalysts have been used extensively in this research to investigate their selective role in both aforementioned attractive catalytic ring-opening polymerization pathways. On the other hand, a more environmentally friendly catalyst; viz zinc bis aryloxide (Zn(OAr)2) has also been investigated for the same co- and terpolymerizations.

Extensive characterization of the obtained polyesters and poly (ester-co-carbonate)s has been performed by conventional SEC, NMR and MALDI-ToF-MS methods. The results obtained show that the copolymerization of epoxides and anhydrides yields completely alternating polyesters whereas introducing the third monomer, CO2, into the polymerization reaction results in a terpolymer with a random/blocky structure.

Poly(ester-*co*-carbonate)

Polyurethane elastomers from castor oil and chemically modified yucca starch: synthesis and physical-chemical, physical-mechanical and thermical properties

Manuel F. Valero

Programa de Ingeniería Química, Universidad de La Sabana, Chía, Colombia.

manuel.valero@unisabana.edu.co

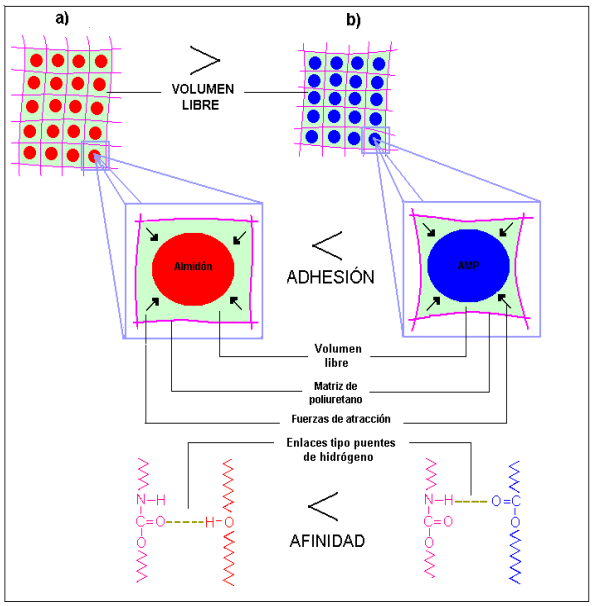
Abstract: Chemical modification of cassava starch was conducted through an acylation reaction by using pyridine and propionic anhydride to replace the functional groups of starch. The design variables were the temperature of preactivation, the pre-activation time and temperature of acylation. The process was carried out using a 23 factorial experimental design. The most favorable conditions for cassava starch modified by acylation with propionic anhydride are pre-activation temperature of 95 °C, pre-activation time of 2 h and acylation temperature of 65 °C. Under these conditions reached a rate of 38% replacement of hydroxyl groups by propionyl groups. The purpose of the modification was to replace the hydrogen in the hydroxyl groups of the molecule of amylose by a propionyl group of propionic anhydride in the acylation reaction. The original starch (S) and modified starch (AMP) were mixed with castor oil (CO) to obtain a suspension. The suspensions were characterized by means of tests based on The Fourier Transform Infrared Spectroscopy and the Hydroxyl Index. Polyurethane elastomers were prepared using suspensions of the mixture obtained from castor oil and yucca starch that was modified by a propionic anhydride reaction. By modifying the hydroxyl groups of starch ester groups of the PU properties varied.

The PUs were characterized by their physical-mechanical properties like tension- deformation and Shore A. hardness, thermal gravimetric analysis and swelling test. The density cross-linking of from swelling tests was determined by applying the Flory-Rehner equation. The goal of this work was to understand what the effect of changing the chemical structure of starch by acylation on the physical chemical properties, thermal and physicochemical properties of PU elastomers and compared with the counterparts obtained from oil-native starch suspensions, depending on the interfacial adhesion between the starch granule and the original and modified polyurethane matrix.

It was found that the increase in the tensile strength and shore A hardness is higher for PU from oil-AMP than for counterparts obtained from oil-pure starch, while elongation at break decreases for materials obtained from AMP-oil suspensions.

In PU systems suspensions obtained from castor oil-AMP was found that the decrease in crosslink density due to an increase in the interfacial adhesion between the PU and the AMP. Intermolecular forces present between groups were calculated by Coulomb's law based on links-length and the ratio of Van der Waals forces between two polar molecules.

These properties were due to increased interfacial adhesion present between AMP granules (dispersed phase) and the PU matrix (continuous phase) due to attractive forces (related to the polarity of the molecules) are higher for PU AMP that PU and native starch, under the synthesis conditions have the same NCO / OH and an equal percentage of modifying agent. The results of crosslink density from swelling tests of the materials obtained from oil-AMP suspensions support the increase in interfacial adhesion due to the crosslinking density increased with the concentration of AMP in response to increased affinity and not related to the change in the crosslinking of the polymer network.



New Aminovalerolactone-based Degradable Copolyesters for Biomedical Applications: Synthesis, Characterization and Biocompatibility.

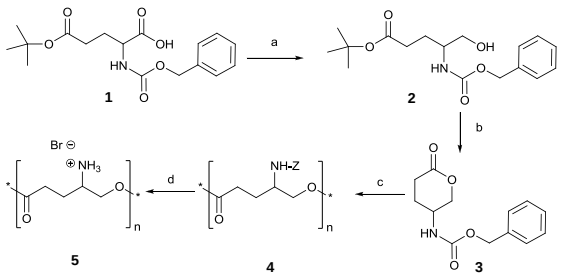
Benjamin.Nottelet@univ-montp1.fr

Introduction: As a consequence of their tremendous development in environmental and biomedical applications, most efforts have been focused in the recent years on the functionalization of biodegradable aliphatic polyesters. Among others, one possible strategy is to synthesize and polymerize lactones substituted by a group of interest. Various functional lactones have thus been described ranging from 4- to 7-membered functionalized monolactones or even dilactones of the substituted glycolide-type.[1,2] However, although amino-polyesters possess great potential for many biomedical applications due to their cationic nature (vectorization, transfection,…), only two examples of amino-functionalized lactones have been reported so far: one butyrolactone derived from serine,[3] and one glycolide-like derived from lysine.[4] But the number of steps required for their syntheses and their tricky required purification ultimately lead to poor yields.
We describe here a facile two steps synthesis of the novel 5-NHZ-valerolactone and its subsequent (co)polymerization to generate aliphatic amino-functionalized copolyesters. Biocompatibility, hemocompatibility as well as proof of concept for biomedical use are reported.

Materials and Methods: Synthesis of 5-NHZ-valerolactone was recently described by our group starting from ZGlu(OtBu)OH (**1**) (**Scheme 1**).[5] (Co)-polymerization was carried out by ROP using $Sn(Oct)_2$ as a catalyst and BzOH as an initiator under nitrogen. Amino-deprotection was achieved under acidic conditions with AcOH/HBr (33%). Biocompatibility and hemocompatibility were assessed according to previous protocols.[6,7]



Scheme 1. Synthesis of 5-NHZ-VL and of poly(NH3+-VL)

Results and Discussion: Consecutive activation of the ester and reduction of the free carboxylic group were obtained using *N,N'*-diisopropylethylamine/BOP and $NaBH_4$ to yield **2** after purification on column chromatography (yield 90%). The second step consisted in the simultaneous *in situ* carboxylic acid deprotection and intramolecular cyclization of **2** in a CH_2Cl_2/TFA (1:1) mixture at room temperature. The final 5-NHZ-valerolactone **3** (5-NHZ-δ-VL) was purified by column chromatography and recovered as white crystals (yield 55%).
3 was copolymerized with ε-caprolactone (ε-CL) to yield a family of poly(5-NHZ-VL_x-co-ε-$CL_{(1-x)}$) with x varying from 10 to 100 (**Figure 1**). Copolymers were obtained in good yields by ROP in bulk at 110°C under nitrogen for 24h. Molecular weights were slightly lower than expected with $\overline{Mn}$ ranging from 3500 to 8600 g/mol for x = 100 and x = 10, respectively. Amino-group deprotection led to the quantitative conversion of NH-Z group to free ammonium groups.

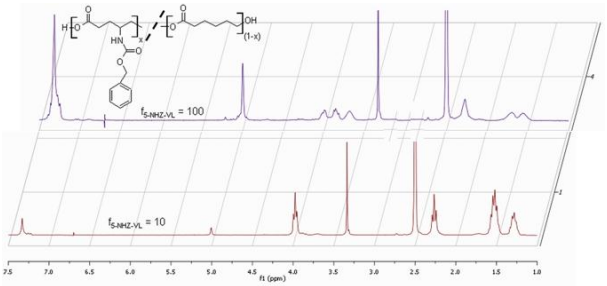


Figure 1. ^{1}H NMR (300 MHz; DMSO-d_6) spectra of poly(5-NHZ-VL_{10}-co-ε-CL_{90}) and poly(5-NHZ-VL)

Copolymers were tested for biocompatibility and hemocompatibility. No acute toxicity was found compared to poly(L-Lysine) with decreased toxicity with ε-CL content. Cell viability was unchanged for concentrations <100 µg/mL. Neither aggregation nor hemolysis was observed at 2mM (**Figure 2**). Small erythrocytes shape modification occurred only at concentrations > 10 mM. Finally, a model molecule was conjugated to poly(5-NHZ-VL-co-ε-CL) as a proof of the potential of this new class of aminated degradable polyesters to be used as macromolecular prodrugs.

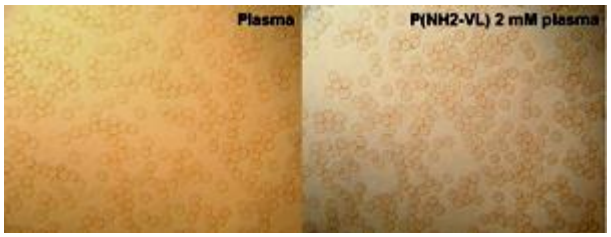

Figure 2. Hemocompatibility of poly(5-NHZ-δ-valerolactone)

Conclusion: Novel 5-NHZ-VL allows the easy synthesis of bio- and hemocompatible aminated degradable (co)polyesters which constitute a new class of cationic degradable polyelectrolytes for biomedical applications.

Renewable Hybrid Materials through Living Radical Polymerization

U. Edlund, J. Voepel, A.-C. Albertsson

Fibre and Polymer Technology Royal Institute of Technology, KTH

edlund@kth.se

The conversion of forestry biomass to added value materials and products is a conceivable and powerful route to realize the forest as a biorefinery and to provide renewable, inexpensive and ethically non-controversial alternatives in a future sustainable lifestyle. Non-cellulosic poly- and oligosaccharides from wood are typically released to the liquid fractions in a range of wood processing operations. Optional and customized strategies for extraction, upgrading and refining yield hemicelluloses of varying purities and types. This family of branched and highly hydrophilic heteropolysaccharides offers a great potential for chemical modification through numerous hydroxyl functionalities. Presented here is a new approach to covalent functionalization of hemicelluloses, offering a fast pathway to the design of thermoplastic glycopolymers with a high level of control.

Single-electron-transfer mediated living radical polymerization (SET-LRP) is a powerful and versatile synthetic technique for living and controlled polymerization, viable in a range of solvents and for a range of vinyl monomers. The mechanism involves a reversible activation of a halide-terminated macroradical into an active propagation chain caused by a single electron donated from the metal catalyst, typically a Cu species.

O-acetyl-galactoglucomannan (AcGGM) from spruce was synthetically converted to a macro initiator mediating the SET-LRP of vinyl monomers, achieving brush-like hybrid polymers. In a first step, some anomeric hydroxyl groups on the heteropolysaccharide backbone were functionalized with bromo- or chlorine moieties through immidazole assisted esterification. The resulting macro initiators were explored with respect to their potency in the SET-LRP of four different monomers in three different solvents using Cu^0 as a catalyst. The kinetics in terms of $\ln([M]_0/[M])$ over time is linear and conversions of up to 99,98% are achieved.

Synthetic Route Effect on Macromolecular Architecture: From Block to Gradient Copolymers Based on Acryloyl Galactose Monomer using RAFT Polymerization

pierre.escale@etud.univ-pau.fr

In recent few years glycopolymers (i.e. polymers carrying pendant carbohydrate moieties) have received increasing attention due to the numerous biological mechanisms in which carbohydrates are implicated such as cell to cell recognition, inflammation, signal transmission and infection[1]. These polymers could be also used for drug delivery nanoreactors, radio-labeled sugar-nucleotide donors and cell surface receptor[2].
Glycopolymers can be obtained by post polymerization glycosylation reaction or polymerization of galactose containing monomers.[3]
The purpose of the present study is to synthesize amphiphilic gradient and block copolymers by RAFT polymerization using a carbohydrate based monomer (AcGalEA) and styrene (Sty). The final aim is to compare the properties of the copolymers depending on their microstructure to self-assemble into Honeycomb films (Figure 1). The carbohydrate moiety will provide a bioactivity of the polymer film and the hydrophobic polystyrene part is required for the honeycomb film formation by the Breath Figure approach.[3-4]

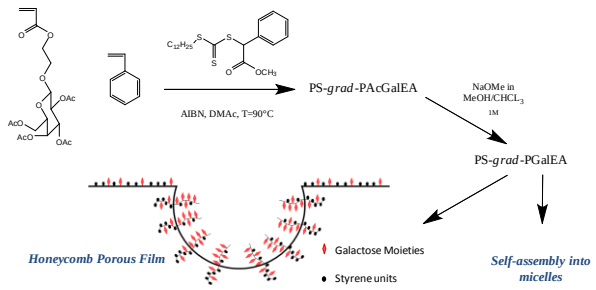

Figure 8- Schematic Approach to honeycomb structured porous film and micelles with glycopolymer based gradient copolymer.

Indeed, glycopolymers are not only of interest in solution because they could serve as screening devices when there are immobilized onto surface. Also, gradient copolymers, made in one pot synthesis, are of great interest because there are time and cost saving in comparison with block copolymers.
Here, we report for the first time the determination of the reactivity ratio of both monomers by comparing the results obtained with Skeist, Kelen-Tudos and Finemann-Ross methods. These three methods tend to a same conclusion: styrene is much more reactive than glycomonomer with r(Sty) = 0.7 ± 0.1 and r(AcGalEA) = 0.07 ± 0.01. Figure 2A displays the evolution of the AcGalEA composition in the monomer mixture ($f_{AcGalEA}$) as a function of the global conversion (X_n) and Figure 2B shows the evolution of the copolymer composition in styrene (F_{Sty}) as a function of the monomer mixture composition in styrene (f_{Sty}).

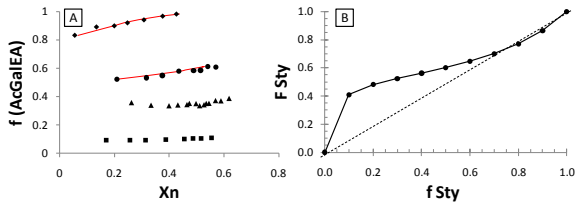

Figure 9- (A) Plots of $f_{AcGalEA}$ versus X_n for different initial S/AcGalEA compositions: (square) 90/10, (triangle) 70/30, (circle) 50/50, (rhomb) 20/80; (B) composition diagram: F_{Sty} versus f_{Sty}.

Considering the reactivity of both monomers, spontaneous gradient copolymer with high content in glycomonomer and forced gradient copolymer with high content in styrene can be obtained. The more hydrophilic gradient copolymer will be able to self-assemble into galactosylated micelles for drug delivery purpose or lectins complexation whereas the more hydrophobic one was appropriate to elaborate honeycomb porous films (Figure 3).

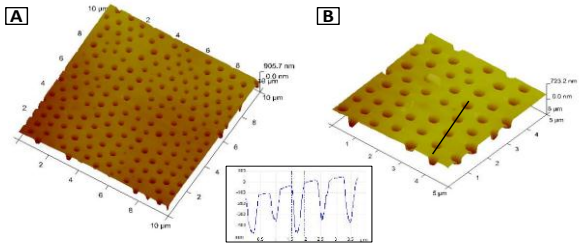

Figure 3- AFM images of honeycomb porous films made with PS-b-(PS-*grad*-PGalEA) copolymer.

BIO-INSPIRED CATIONIC POLYMERIZATION OF ISOPRENE IP INITIATED BY ALLYLIC ALCOHOLS / $B(C_6F_5)_3$

Samira OUARDAD, Frédéric PERUCH, Alain DEFFIEUX.

Laboratoire de Chimie des Polymères Organiques (LCPO), 16 Avenue Pey Berland, 33607 Pessac Cedex, France

ouardad@enscbp.fr

Introduction

More than 2500 plants are able to produce polyisoprenes (PI) but *Hevea Brasiliensis* is the only one to produce PI with high molar mass with a 100% 1,4-*cis* structure in sufficient yield. Whereas isoprene (IP) is the monomer employed for the chemical synthesis of PIs, isopentenyl pyrophosphate (IPP) is the monomer used for the biosynthesis of NR (Figure 1). From the polymer chemist point of view, these enzymatic processes can be seen as electrophilic additions, comparable to cationic polymerizations. Both during initiation and propagation reactions, the pyrophosphate moiety is released to give an allylic carbocation able to add IPP to yield a tertiary carbocation. One α proton is then eliminated to give back an allylic pyrophosphate. Moreover, it has been shown that divalent cations are necessary. In a "pseudo-cationic" pathway, they could act as Lewis acids, assisting the cationation[1,2].

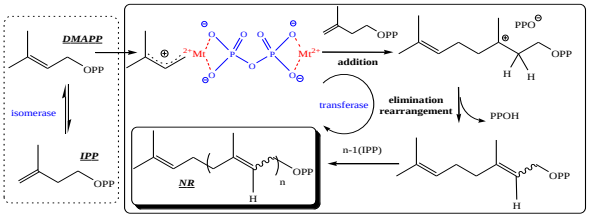

Figure 10. Biosynthesis of NR.

The goal of this study is to investigate the cationic polymerization of IP in the presence of different allylic alcohol initiators and in the presence of $B(C_6F_5)_3$ as Lewis Acid.

Experimental

Materials. 2-methyl-3-buten-1-ol, DMAOH (Aldrich) was dried over a sodium cube and cry-odistilled. Isoprene was dried over CaH_2 and cryo-distilled prior to use. $B(C_6F_5)_3$ (TCI Europe) was used as received. Dichloromethane (Atlantic Labo) was dried over CaH_2 and cryo-distilled prior to use.

Instrumentation. Size Exclusion Chromatography (SEC) was used to determine molar masses and molar masses distributions of polymer samples with respect to polystyrene standards. ^1H and ^{13}C NMR spectra were recorded on a Bruker Avance 400. Matrix-assisted laser desorption ionization time-of-flight (Maldi-Tof) mass spectrometry was performed using a Voyager-DE STR (Applied Biosystems) spectrometer.

Polymerization reactions. Polymerizations were carried out under a dry nitrogen atmosphere using standard Schlenk techniques.

Results and Discussion

Initiation step. The ability of $B(C_6F_5)_3$ to generate an allylic carbocation from DMAOH was studied by ^1H NMR, varying the DMAOH/LA ratio. At the initial stage, the chemical shift of the hydroxyl group is highly affected, in relation with the amount of the LA (Figure 2). Besides, the formation of isoprene is detected. This latter which is produced by rearrangement of an allylic carbocation, followed by proton elimination (Figure 2) and is a proof that allylic carbocations are formed by interaction of DMAOH and $B(C_6F_5)_3$

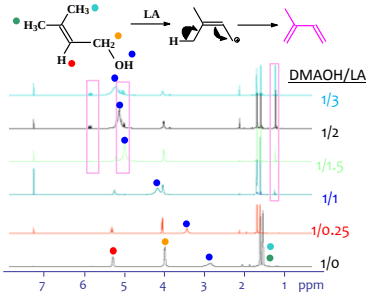

Figure 2. ^1H NMR spectra of DMAOH and $B(C_6F_5)_3$ at different ratios.

Polymerization

By combining NMR, Maldi-Tof and SEC a full characterization of the microstructures have been determined . Many side reactions have been characterized: Cyclization (by NMR), branching (by SEC), protic intiation andd transfer (by Maldi-Tof).

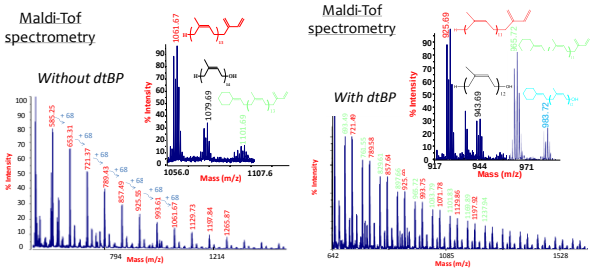

Figure 3. Maldi-Tof spectrum of polyisoprenes obtained with or without DtBp

Conclusions

It was shown that allylic alcohols associated to $B(C_6F_5)_3$ were able to initiate the cationic polymerization of isoprene. In all cases, only oligomers are formed, probably due to the presence of transfer reactions. They were characterized by NMR and Maldi-Tof spectrometry. The addition of isoprene proceeds via 1,4-*trans* addition, which is the opposite of the NR structure. Nevertheless, oligomers structure is fairly complicated with the presence of cyclized sequences and is not completely elucidated yet.

It was also shown that the polymerization yield is strongly reduced when a proton trap is added, due to the reduction of side protic initiation coming from protons generated during transfer reactions.

h.yeganeh@ippi.ac.ir

Introduction

Coatings with antibacterial properties are useful in many areas such as hospitals, food manufacturing, building trades and antifouling applications. There are several methods for the introduction of biocidal functions in polymers. Chemical grafting of a biocide to polymer matrix can provide many advantages for polymers, especially for biomedical applications such as non-volatility, good environmental and chemical stability, low toxicity, extended lifetime, lack of skin irritation and/or skin-permeability as well as better bactericidal activity due to higher density of biologically active groups [1, 2].

In the present work for the first time both quaternary ammonium groups with well-known biocidal function and reactive hydroxyl groups were introduced on the back bone of soybean oil. These new renewable resource based functional polyols were used for the preparation of polyurethane coatings via reaction with proper diisocyanate monomers. The biocompatibility and antibacterial properties as well as some mechanical and physical properties were evaluated for these new materials.

Materials and Methods

Quaternary ammonium containing polyols were prepared by reacting epoxydized soybean oil (ESBO) with diethylamine at 80 ºC using anhydrous zinc chloride as catalysis. This intermediate compound bearing tertiary amine groups was further quaternized with either benzyl chloride or methyl iodide. Polyurethane films were prepared via one-shot reaction of polyols and various diisocyanates including MDI, TDI, HDI and IPDI (Scheme 1).

Results and Discussion

The structure of prepared polyols was confirmed using ^{1}H-NMR and FTIR spectroscopies and elemental analysis. The physical, mechanical and viscoelastic properties of polyurethane films including gel content, phase transitions, tensile strength, elongation at break, surface hydrophilicity, and solvent resistance were evaluated. All of the cured films showed complete curing with gel content more than 95%. DMTA thermograms showed two phase structure with soft and hard segment glass transitions in the range of 0-15 °C and 140-170 °C respectively. According to stress-strain curves, the prepared films showed tensile strength and elongation at break of 5-9 MPa and of 16-87% correspondingly. The contact angle data of water droplet on the surface of films were in the range of 68-80 degree. Depends on the quaternizing group and diisocyanate structure the surface hydrophilicity of films were altered. Samples made from aliphatic diisocyanates and methyl iodide as quaternizing group showed higher surface hydrophilicity. The solvent resistant of coatings based on MEK rub test was excellent.

Cell culture test and MTT assay based on mouse L929 fibroblast cells were used to evaluate both cytotoxicity and cytocompatibility of the specimens. The evaluation of cell morphology showed cells survived and grew with spindle shape morphology, during full three days of the test, and none of the polymers appeared to give off any toxic or inhibitory leachates, since cells grew to confluence on the all samples. The MTT assay showed excellent level of biocompatibility with cells viability in the range of 95-120%. These are indications of noncytotoxcicity and cytocompatibility of prepared polyurethanes.

Examination of antibacterial property of specimens by shaking flask and agar plate methods using *Escherichia coli* and *Staphylococcus aureus* microorganisms showed strong dependency to the chemical structure of polyurethanes. Films prepared from benzyl chloride based quaternized polyol had no biocidal function, however, the samples made from polyol quaternized with methyl iodide showed significant bacterial reduction in the range of 79-88%. To find the reason behind this observation, the concentration of active quaternary ammonium groups was examined by measuring the halogen counter ion content using energy-dispersive X-ray analysis (EDXA). Although the EDXA maps showed uniform distribution of halogen atoms, the concentration of quaternary ammonium groups were much higher for methyl iodide based samples (0.53-0.60 mole %) than benzyl chloride based specimens (0.20-0.23 mole %). Therefore, sufficient concentration of quaternary ammonium groups was the determining factor.

Conclusions

It was concluded that via proper functionalization of Soybean oil, it is possible to use it for making polyurethane coatings with excellent biocompatibility and antibacterial properties. Simple chemical modification route, low cost of starting material and possibility to use an environmentally friendly and renewable resource based raw material are some fascinating features of these newly developed polyurethanes.

Dextran-Poly(deoxycholate) Block Copolymers as New Biodegradable Materials

Marieta Nichifor and Magdalena Cristina Stanciu

"Petru Poni" Institute of Macromolecular Chemistry, Iasi, Romania

nichifor@icmpp.ro

Introduction

Amphiphilic block copolymers able to form self-assembled core-shell nanoparticles have a great potential in application for drug and gene delivery. Presence of bioerodible blocks gives the possibility for a more efficient control of rate and site of the bioactive compound delivery.

In the attempt to obtain new biocompatible and biodegradable materials containing naturally occurring compounds, we have prepared amphiphilic block copolymers, with a polysaccharide (dextran) as the hydrophilic block and an oligoester of a bile acid - deoxycholic acid (**DCA**) - as a lipophilic block. These polymers based on natural compounds have the advantage of forming only biocompatible degradation products (mainly **DCA**, a product found in small intestin).

Materials and Methods

Cholic and deoxycholic acid, dextran of MW 6000 and the other reagents were from Aldrich and were used as received.

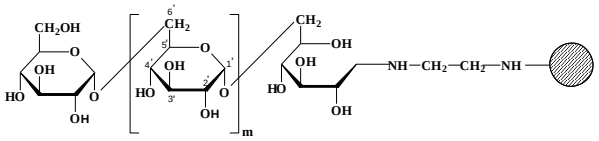
FT-IR (KBr pellets), ^{1}H and ^{13}C-NMR (in $CDCl_3$ or DMSO-d6) spectroscopical analyses were used for determination of polymer structure and composition. Size exclusion chromatography (with polystyrene standards and THF solvent) provided the polyester molar mass. Thermal decomposition (TG and DTG), thermal properties (DSC), X-rays diffraction spectroscopy, and electronic microscopy (SEM images) provided information about the physico-chemical properties of the block copolymers and their intermediate products. Degradation rate of polymers in the physiologically similar media (phosphate buffered saline of pH 7.4, 37°C), as well as the release rate of a model drug (diclofenac) from block copolymer nanoparticles, were studied by reverse phase HPLC.

Results and discussion

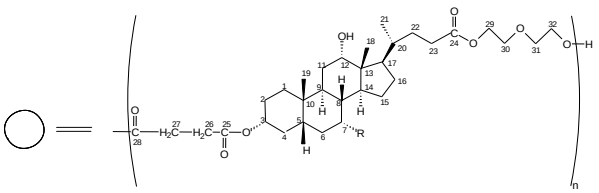
Preparation of the desired block copolymer required the synthesis of several intermediates:(i) 3α-(succinoyloxy) - 12α-hydroxy-5β-cholan-24-carboxylyc acid (**ScDCA**), (ii) the poliester of **ScDCA** and diethylene glycol (called here poly(deoxycholate or **PDCA**)), and (iii) dextran (MW 6000) aminated at the reductive end. The block copolymer (**Dex-PDCA**) was obtained by attachment of **PDCA** to aminated dextran. Chemical structures of the **PDCA** and **Dex-PDCA** were confirmed by IR and NMR spectroscopy and are depicted in Scheme 1.

PDCA had a molar mass of 3500, T_g = 48.24°C, started to decompose at 332 °C and was partially crystalline (about 30 % crystallinity). **Dex-DCA** had a T_g = 78°C, displayed two decomposition steps (T_i = 183 and 340°C), and was less crystalline than **PDCA** (Fig. 1).

Nanoparticles (100-400 nm), loaded or not with diclofenac, were prepared from **Dex-PDCA** by solvent diffusion method. The degradation of the polyester block, with formation of **DCA** and **ScDCA**, was slow (about 20% in 24 h), and followed zero order kinetics. The release rate of diclofenac loaded in nanoparticles was only slightly higher than polyester degradation rate, indicating a predominance of erosion as a release mechanism, with a small contribution of drug diffusion.



Dex-PDCA



PDCA

Scheme 1. Chemical structure of the dextran-poly(deoxycholate) block copolymer

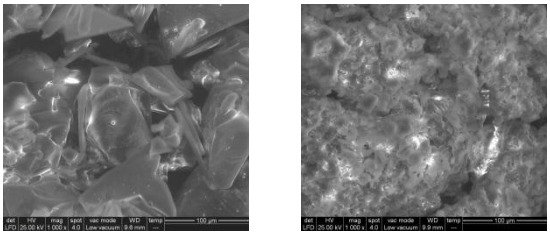


Fig. 1. Electronic micrographs of PDCA (left) and dex-PDCA(right)

Conclusion

Newly synthesized biodegradable amphiphilic block copolymers containing two natural compounds, dextran and deoxycholic acid, can form nanoparticles with potential application as carriers for drug delivery systems. The release of the drug is controlled mainly by erosion, and can be easily tailored by changing the length of the two blocks.

Alfons.smeets@chem.kuleuven.be

Introduction

Π-Conjugated polymers (CPs) are becoming increasingly viable candidates for replacing silicon based materials in electro-optical applications, such as field effect transistors (FETs), light emitting diodes (LEDs) and photovoltaic cells (PVs). In order to achieve satisfactory performance and stability of these devices, the supramolecular organization of the active material is of great importance. Therefore, conjugated block copolymers and supramolecular structures based on CPs, for example core shell particles, should provide the desirable supramolecular properties for these applications.

Materials and Methods

Contemporary methods to prepare block copolymers and supramolecular structures rely on living polymerizations and either consist of subsequent addition of different monomers or by performing endcapping with functional groups, which are then employed in coupling reactions. However, these methods cannot be generally applied to CPs, as only a few of them can be prepared through living polymerizations. We want to circumvent this limitation by introducing the desired functional group at the start of the polymerization, using a functional initiator. Subsequent post-polymerization reactions should then allow the preparation of block copolymers or supramolecular structures of choice. Because a living polymerization is no longer a necessity, the scope of this protocol would be expanded to many different CPs.

Results and Discussion

From a synthetic point of view, the protocol is based on a nickel complex carrying the desired functional group, which initiates the polymerization while inserting the functional group at the beginning of each chain. More specifically, we first synthesized nickel initiators with (protected) alcohol, amine, carboxylic acid and ethynylene functionalities. These initiators were then used to initiate the polymerization of poly(3-alkylthiophene)s, poly(3-alkoxythiophene)s, poly(3-thioalkylthiophene)s and poly(*para*-phenylene)s. Through post-polymerization reactions we were able to quantitatively convert the alcohol moiety to tosylates and azides. Finally, we coupled azide functionalized poly(3-alkylthiophene)s with ethynylene functionalized poly(3-alkoxythiophene)s, forming block-copolymers composed of electronically different blocks (Figure 1).

Conclusions

We successfully established a protocol for the synthesis of nickel initiators with different functional groups and subsequently employed those initiators for the synthesis of different CPs with different functional groups[1]. We also demonstrated that the functional groups could be used in post-polymerization reactions to form block-copolymers.

Step growth polymerization of starch-derived dianhydrohexitol stereoisomers: versatile platform for the design of linear polymers and polymer networks with original properties.

Céline Besset,[1,2,3] Etienne Fleury,[2,3] Jean-Pierre Pascault,[2,3] Julien Bernard,[2,3] Eric Drockenmuller[1,3]

[1]: Université de Lyon 1, [2]: INSA de Lyon, [3]:Ingénierie des Matériaux Polymères (IMP)

eric.drockenmuller@univ-lyon1.fr

Introduction

Starch-derived 1,4:3,6-dianhydrohexitol stereoisomers (i.e. isosorbide, isomannide, and isoidide) are particularly interesting difunctional building blocks (Figure 1).[1]

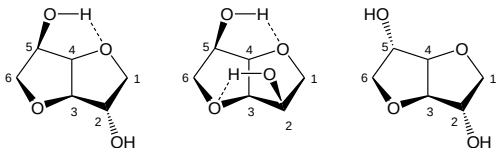

Figure 1: 3D structure of (from left to right) isosorbide (SR), isomannide (RR) and isoidide (SS) dianhydrohexitols.

Results and Discussion

Taking advantage of organic chemistry procedures several homo- or hetero-difunctional monomers suitable for click chemistry polyaddition were prepared. In a first approach diazide, dialkyne and α-azide,ω-alkyne monomers of every dianhydrohexitol stereosiomers were obtained in high yields (Figure 2).

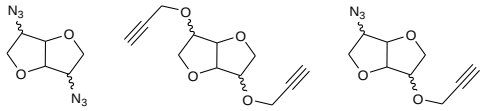

Figure 2: Diazide, dialkyne and α-azide,ω-alkyne dianhydrohexitol monomers suitable for click chemistry polyaddition.

Linear polytriazoles and corresponding networks were then obtained by copper catalyzed azide-alkyne cycloaddition (CuAAC) as well as thermally initiated 1,3-dipolar Huisgen cycloaddition (Figure 3). The influences of monomer stereochemistry, processing conditions and polyaddition regiospecificity on the physico-chemical properties of the resulting polymers have been thoroughly examined using ^{1}H NMR, DSC, TGA, SEC and rheological measurements.[2]

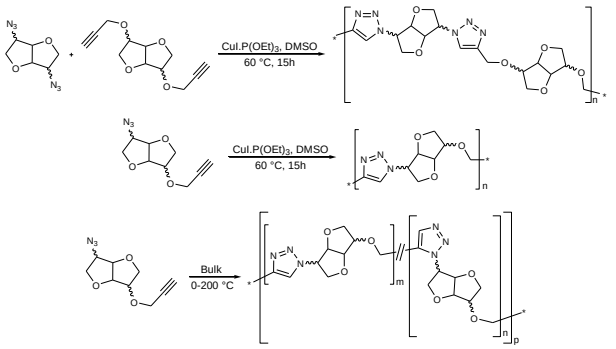

Figure 3: Polyaddition of diazide, dialkyne and α-azide,ω-alkyne dianhydrohexitol monomers.

Following the discussion of these preliminary results, our latest results regarding their polyaddition of functionalized bio-sourced monomers using other types of click chemistry processes will be presented.

New Functional Materials from Polysaccharides Modified by Copper Catalyzed Azide-Alkyne Cycloaddition

Monica Bertoldo[1], *Giovanni Zampano*[2], *Samuele Nazzi*[1], *Federico La Terra*[1], *Francesco Ciardelli*[3]

[1]Istituto per i Processi Chimico Fisici, Consiglio Nazionale delle Ricerche, via G. Moruzzi, 1 56124, Pisa Italy

[2] c/o,MENARINI SpA,Firenze,

[3] SPIN_PET;srl.Pontedera Italy

monica.bertoldo@ipcf.cnr.it

Natural macromolecular materials such as polysaccharides are very attractive not only for environmental reasons but also for their physical and chemical properties. Indeed peculiar reactive groups such as amines, amides, carboxylic and sulfonic acids are present , in addition to typical hydroxyl groups. These last provide polysaccharides with specific properties such as gelling capability, positive or negative charge, chelating ability, mucoadhesive property, etc.... The reactivity of these groups offers also many opportunities to modify polysaccharide by introducing new functionalities. However, the mentioned modification can affect some original properties which can be partially or totally lost. In this contribution some examples are presented concerning polysaccharide modification with preservation of the original polysaccharide structure. The very selective copper catalyzed azide-alkyne cycloaddition (click) [1] was used as key step.

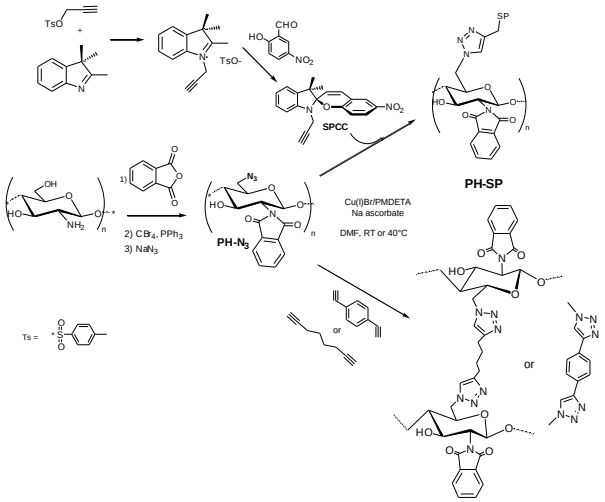
Materials and Methods

Chotosan (~300 kDa, DAC 0.75) amylose from potato and glycogen from mollusc were purchased from Aldrich. Modified polysaccharides were characterized by FT-IR and NMR spectroscopies, elemental analysis and TGA. TEM, dynamic and static light scattering, UV-Vis and swelling analyses were carried out to characterize the new polysaccharide properties.

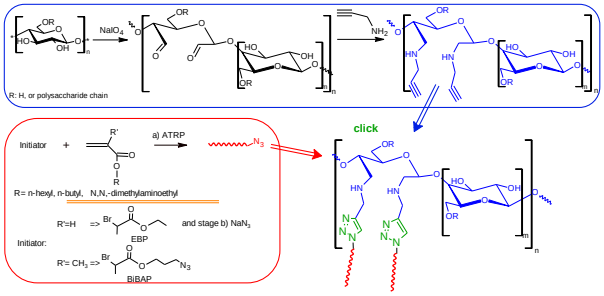
Results and Discussion

Two different modification strategies were adopted, respectively of chitosan (scheme 1), a polysaccharide bearing amine and amide groups into its backbone, and of linear amylose and hyperbranched glucan glycogen (scheme 2), bearing just hydroxyl groups in their backbone. The first step in chitosan modification was a reaction with phtalic anhydride to protect the amine groups and to make chitosan soluble in organic solvents such as DMF and DMSO. The derivative was then brominated and successively azidated in two consecutive "one pot" reactions [2]. This azido-functionalized chitosan (PH-N_3) was then converted to new functional materials under click condition (scheme 1). In particular, a biopolymer exhibiting distinct photocromic response and a very low thermal decay of the photogenerate state [3] was obtained by covalent bonding of a chromophoric spiropiran derivative bearing an alkyne group (SPCC). Gels with pH dependent swellability (higher at acid pH) were prepared by crosslinking with dialkines and amine deprotection at 80°C with hydrazine [2].

Periodate oxidation and subsequent reductive amination with propargylamine was adopted for the controlled functionalization of glucans with alkyne groups, while ATRP polymerization was exploited to obtain end-azide functionalized poly(meth)acrylates to be used as "click" reagents. Finally, polysaccharide-g-polymethacrylate copolymers were prepared by "click" grafting "onto" method with complete grafting yield (scheme 2) [4].



Scheme 1: Chitosan modification strategies



Scheme 2: Preparation of graft copolymers by "click" promoted grafting "onto" method

The most amphiphilic among amylose graft copolymers self-assembled in water yielding nanoparticles with ca. 30 nm diameter, while glycogen natural nanoparticles became the core of core-corona nanoparticles stable in toluene dispersion.

Production of Polyether Polyols with Phosphorous Initiators

M.M. Velencoso[1], M.J. Ramos[1], J.C. García-Martínez[2], A. de Lucas[1] and J.F. Rodriguez[1]

[1]Institute of Chemical and Environmental Technology (ITQUIMA), Department of Chemical Engineering, University of Castilla-La Mancha, Avda. Camilo José Cela s/n 13004 Ciudad Real, Spain

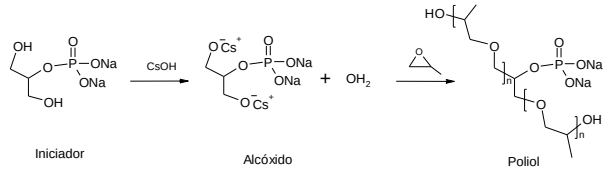
Maria.MVelencoso@uclm.es

Polyurethanes (PUs) are an important class of polymers that have wide application in a great number of different industrial sectors. One of the main concerns of PUs producers are the complement of flammability regulations. Phosphorous compounds have been widely used as flame retardant materials because of their high flame-retardancy efficiency, lower production of corrosive and toxic gases in flames, and lower destruction to the earth's environment (1). Therefore there is an increasing interest on the incorporation of phosphorous compounds as additives or even as moieties on the PUs formulations to improve their flammability resistance.

The aim of this work was the synthesis of polyols including a phosphorous moiety in order to obtain a polyol with high flame retardancy. For this purpose, an appropriate phosphate as initiator was selected. A study of the ring-opening polymerization process and the structural characterization of products obtained were made. This kind of phosphorylated polyether has not been previously described in literature.

In the reaction has been used glycerol phosphate calcium salt and glycerol phosphate disodium salt as initiators and caesium hydroxide and potassium tert-butoxide as catalysts of the process (Sch. 1).



Sch. 1. Synthesis of polyether polyol

The kinetic studies revealed that there was a linear relationship between the propylene oxide consumption and time. Fig 1 presents the dependence of reaction time on propylene oxide consumption for catalyst/initiator molar ratio of 1:2 CsOH.

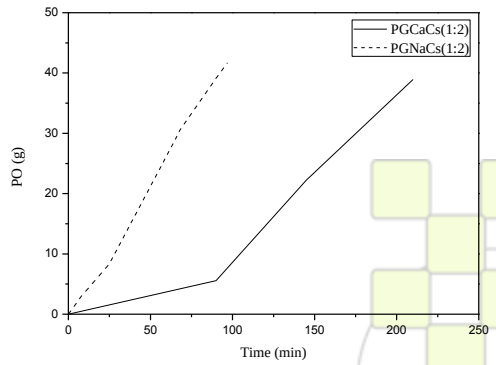


Fig 1. Relation of reaction time with propylene oxide consumption using CsOH with molar ratio 1:2.

It can be seen (Fig. 1) that the rate of addition of propylene oxide for sodium salt was higher than calcium salt. In both cases the reaction rate during the induction period is much slower than in the case of the commercial process using glycerol as initiator. This apparent lower reactivity during the first step could be attributed to low homogeneity of the glycerol phosphate salt hydrate. The solubility of propylene oxide (PO) in the reaction mass is an important parameter, because the reaction takes places in the liquid phase and the gaseous monomer is transferred from the gas phase to the liquid phase (2). From this point, the optimum amount of polyol to dissolve the initiator solution is formed in the reactor thereby increasing the consumption of PO, avoiding the problems of miscibility and diffusion of PO. The number and weight average molecular weight of the different polyols obtained ranged between 1500-5000 g/mol and 3500-9500 g/mol, respectively. The polydispersity indexes were between 1.2 and 1.6 (3, 4).

The IR spectra of the products obtained showed the characteristics bands of polyols, similar to conventional ones obtained using glycerine as initiator (5). ^{1}H NMR of polyols showed a new signal at 4 ppm, corresponding to the link P-O-C**H** and also the ^{31}P NMR presented a single signal at -3.60 ppm for glycerol phosphate calcium salt and at -0.02 ppm for glycerol phosphate disodium salt (6). So that, NMR data revealed that the phosphate was incorporated into the polymer chain.

Towards Ring Opening Metathesis Polymerisation: Special Initiators for Special Applications

Anita Leitgeb[1], *Eva Pump*[1], *Anna Szadkowska*[2], *Karol Grela*[2] *and Christian Slugovc*[1]*

[1] Graz University of Technology, Institute for Chemistry and Technology of Materials, Stremayrgasse 9/5, A-8010 Graz, Austria

[2] Institute of Organic Chemistry, Polish Academy of Science, Kasprzaka 44/52, 01-224 Warsaw, Poland

anita.leitgeb@tugraz.at

Ring opening olefin metathesis polymerisation has gained much attention due to a great potential for the synthesis of specialty polymers. Since the introduction of ruthenium based initiators the robustness of this versatile polymerisation method has largely increased. An outstanding functional group tolerance and stability at ambient conditions allow for the use of demanding, highly functionalized monomers as well as bulk polymerisation of the commodity material DCPD (dicyclopentadien).[1] Regarding industrial processes like ink jet printing or RIM (reaction injection moulding) the introduction of a thermal trigger that will allow polymerisation only above a certain temperature has been a major subject in initiator design.[2]

Within this contribution various olefin metathesis catalysts based on commercially available complexes like M2, M31 or the Hoveyda-Grubbs catalyst will be presented. The effect of ligand modifications such as the introduction of electron shifting groups or change of the sterical impact are discussed in the context of ring opening metathesis polymerisation. An emphasis will be given on latent complexes featuring a chelating carbene ligand.

Monomers used comprise various norbornene derivatives and DCPD. Obtained poly(norbornenes) have been investigated by means of gel permeation chromatography, thermal switchability of the initiators was investigated by dynamic thermal analysis techniques. Moreover, the impact of the catalyst loading on mechanical properties of poly(DCPD) has been investigated.

The synthesis of functional polymers from renewable resources has attracted considerable attention from polymer scientists throughout the world, because of their potential attributes as substitute petrochemical derivatives. With petroleum production facing exhaustion day over day, scientists and technologists focus their attention on renewable resources because these materials may act as potential raw materials for the manufacture of polymers in the 21st century.

In the polyurethane industry, conventional polyether polyols, which account for 80% of the total worldwide consumption of oligopolyols, are mostly produced from petroleum-based alkylene oxides. Due to uncertainty about the future cost of petroleum as well as the desire to move toward more environmentally friendly feedstocks, many recent efforts have focused on replacing all or part of the conventional petroleum based polyols with those made from renewable resources such as vegetable oils and Natural Rubber.

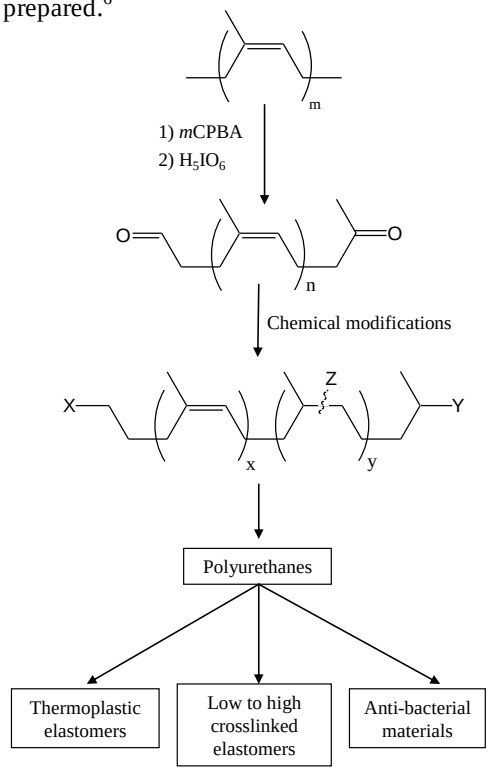
Materials and Methods

The general procedures of synthesis of Telechelic Liquid Natural Rubbers (TLNR) and their polyurethanes as well as the characterization methods were described elsewhere.[1-6]

Results and discussions

Telechelic Liquid Natural Rubbers (TLNR) can be considered as precursors of a very wide range of polymers. The selective cleavage of high molecular weight polymers for the obtaining of TLNR and the chemical modification of such oligomers has been the center of a lot of activities.[1]

During the last decade, our group focused its work on selective degradation of natural and synthetic Rubber (cis-1,4-polyisoprene) using well controlled oxidative chain-cleavage leading to new carbonyltelechelic cis-1,4-polyisoprene (CTPI). Chemical modifications of carbonyl end-groups and carbon-carbon double bonds led to new hydroxyl and amino telechelic cis-1,4-polyisoprenes with various functionalities in terms of number and distribution as well as with various degree of hydrogenated and epoxidiezed moieties.[2,3] Polyurethanes with different soft and hard segment backbones based on these new oligomers and different isocyanates were synthesized and their thermo-mechanical properties were investigated.[4-6] A large property spectrum was obtained including elastomers, thermoplastic and thermosets properties. Moreover, polyurethane materials bearing ammonium groups and exhibiting antibacterial properties against Staphylococcus epidermidis and Pseudomonas aeruginosa were also prepared.[6]



Scheme 1. Synthesis of new polyurethanes from Natural Rubber.

Conclusion

This work showed the potentialities of making new polymer materials from natural Rubber, a renewable resource.

Chitosan-*graft*-Polyaniline-Based Hydrogels: Elaboration and Properties

Pierre Marcasuzaa, *Stephanie Reynaud*, *Jacques Desbrières*

IPREM / Equipe de Physique et Chimie des polymères, Hélioparc, 2 avenue du Président Angot, 64053 Pau Cedex

pierre.marcasuzaa@univ-pau.fr

Intrinsically conducting polymers are of great interest for a large number of applications. But among the major drawbacks are their low solubility in common solvents and their poor mechanical properties. Elaboration of composites associating a matrix, bringing its mechanical properties, and polyaniline, as the conducting polymer, is a way of overcoming these disadvantages. For that, differents works related the synthesis of PANI in hydrogel (PAA, PVA…)[1-4]. But, in lot of cases, aniline is introduced in the network, which is before synthesized, and polymerized in order to obtain conducting composite. The main problem of these composites is the heterogeneousness of PANI inside of gel, and the mobility of conducting chains which leads to observe migration phenomena. In order to avoid these negatives points, the aim of this work is to obtain an homogeneous conducting hydrogels where PANI is linked covalently with the network.

To reach our objective[5], the idea was to incorporate PANI onto a polymer which is able to be cross-linked. Chitosan is a good candidate to obtain required properties. Indeed, chitosan holds amine groups which are able to initiate aniline polymerization, morever this natural polymer is well-known to react with a cross-linking agent (di-aldehyde) to lead to a tri dimensional network (**Figure 12**).

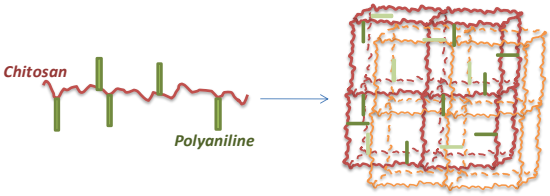

Figure 12: Schematic representation of copolymer and hydrogel structures.

At first, this talk will treat about the optimization of grafting reaction between chitosan and PANI, the characterization of obtained copolymer and a method to determinate the rate of PANI grafted onto chitosan. This study demonstrates that, with appropriate conditions, more than 99% PANI is grafted onto polymer and chitosan keeps his coating properties after grafting. The copolymer exhibits a conductivity of 10^{-1} S.cm. But, it becomes insulating below 33 % of PANI. This phenomena can be explained by a break of conducting way which is demonstrated by microscopy.

At second, it will be shown the cross-linking conditions between copolymer and glutaraldehyde. The kinetic of gelation is followed by rheological measurement. It was shown that cross-linking reaction is most efficient when precursor polymer is a blend of chitosan and chitosan-*graft*-PANI. Conductivities values as high as the precursor graft copolymer were obtained after dehydration and drying of hydrogel. Different properties of this hydrogel were studied. Results obtained for swelling tests make the composite hydrogel eligible for the development of applications as the inclusion and release of active matter as already demonstrated for semi-interpenetrating polyacrylamide-PANI gels[2,6]. More specifically, the presence of intrinsic conducting polymers within these hydrogels allows electrochemical control release of active matter[2]. The hydrogel was actually used like actuators. In this work, we studied the ability of the composite hydrogel to convert mechanical work into electrical energy, as referred to previous articles, and the so called "reverse actuators". Experiments demonstrated the feasibility of a mechano-electric actuator using our new composite hydrogel as sensing material (Figure 13).

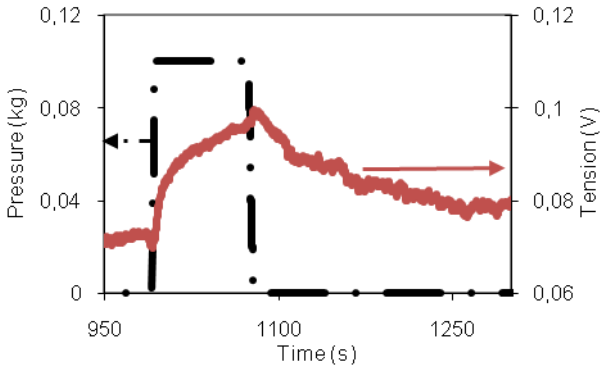

Figure 13: Pressure testing as an actuator.

This work allowed to obtain different forms of conducting materials from film to tri dimensional network (**Figure 14**). The particularity of these material is the covalent link between matrix and conducting polymer. Thus, problems of diffusion and heterogeneity are avoided. Hydrogels of Chitosan-*graft*-PANI exhibit rheological, swelling and mechano-electric properties.

Figure 14: Images of PANI based film and hydrogel.

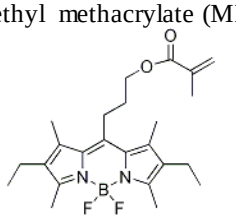
BODIPY-Conjugated Thermo-Sensitive Fluorescent Polymers Based On 2-(2-methoxyethoxy)ethyl methacrylate

Marta Liras, Isabel Quijada, Olga García, Rodrigo París,

Instituto de Ciencia y Tecnología de Polímeros (CSIC) Juan de la Cierva, 3 28006 Madrid SPAIN

martaliras@ictp.csic.es

A methacrylic monomer containing the dye 4,4-difluoro-4-bora-3a,4a-diaza-s-indacene (BODIPYMA)[1] was synthesized to provide fluorescence properties to three different thermo-sensitive families of polymers based on 2-(2-methoxyethoxy)ethyl methacrylate (MEO2MA).



BODIPYMA

Initially, linear random terpolymers of MEO2MA, oligo(ethylene glycol) methyl ether methacrylate (OEG8-9MA) with Mn= 475 g mol^{-1}, and a very low proportion of BODIPYMA were synthesized by atom transfer radical polymerization (ATRP).

Polymers based on MEO2MA and (OEG8-9MA) are thermo-sensitive.[2] They undergo a thermal transition in water solution, becoming reversibly nonsoluble when the solution temperature is higher than the LCST. The LCST values (cloud points) of the synthesized polymers were determined by turbidimetry. As expected, these values linearly increase when the MEO2MA ratio in the polymer decreases.[3] But the most important issue here is that the system shows a remarkable increase in the fluorescent intensity when the polymer collapses, which means at temperatures above the LCST. Thus, Figure 1 shows the dependence of the absorbance at 600 nm (cloud point determinations) and the quantum yield of fluorescence on the temperature for each polymer water solution.

Apart from the relevant change in the optical and luminescent properties of the polymers in water solution at the LCST, it is also important to point out that this change is reversible. Second, a family of diblock copolymers was formed by the ATRP of MEO2MA and a very short block of BODIPYMA. They also behave as a fluorescent thermometer in water but, in this case, the fluorescence quantum yield decreased due to the intermolecular π-π stacking of BODIPY dyes that produces H- aggregates.

In addition, a MEO2MA-BODIPYMA based hydrogel was prepared to show that the optical and fluorescence properties also exhibit a sudden and reversible change at the volume transition temperature (VTT) of the hydrogel. In this case, this transition takes place independently on the BODIPYMA units. However, the novelty of the present system is again that the hydrogel is fluorescent due to the presence of BODIPY side groups. Analogous to their homologues linear polymers, the intensity of the fluorescence depends on the temperature. Thus, for temperatures higher than the VTT the equilibrium swelling decreases, the system becomes opaque and the fluorescence emission intensity increases. Therefore, it is experimentally demonstrated that the cross-linked structures show the same interesting results of fluorescence observed for the linear polymers. It is important to mention that the VTT of this kind of hydrogels can also be easily modulated by the incorporation of low proportion of other oligo(ethylene glycol) side chain macromonomers, as it was found previously by our research group.[4]

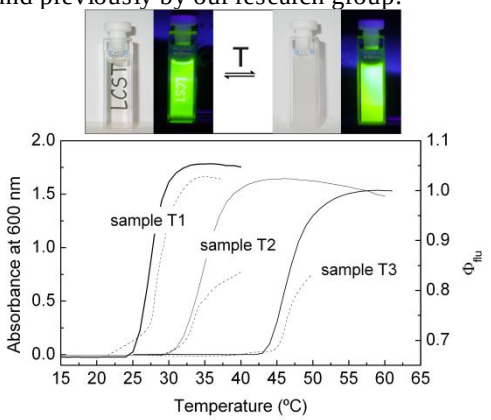


Figure 1. Absorbance at 600 nm(solid lines) and fluorescence quantum yield (dashed lines) vs temperature of the P(MEO2MA-co-OEG8-9MAco-BODIPYMA) terpolymers dissolved (0.36 mg mL-1) in PBS (pH 7, μ = 0.1 M). Photographs under visible and UV irradiation taken at temperatures below LCST (left part) and above LCST (right part) of sample T1 are included.

In conclusion, three different families of thermo-sensitive polymers based on MEO2MA with a very low proportion of a fluorescent monomer based on BODIPY have been synthesized to study their thermosensitive/fluorescent behavior in aqueous solution: (i) Well-controlled random P(MEO2MA-*co*-OEG8-9MA-*co*-BODIPYMA) terpolymers, in which the monomeric feed ratio establishes the values of the LCST. In this system, the intensity of the fluorescence strongly increases in a reversible way at the LCST. (ii) Well controlled diblock P(MEO2MA-*b*-BODIPYMA) copolymers, in which the H-aggregation between the BODIPY units reduces the emission properties. (iii) A random P(MEO2MA-*co*-BODIPYMA) hydrogel that becomes opaque and exhibits an increase of the fluorescence intensity rising the VTT, in the same way that its linear homologues.

Malic Acid as Key Building Block for the Synthesis of OH-Functional Polyesters

Christian Hahn, *Helmut Keul*[*], *Martin Möller*[*]

Institute for Technical and Macromolecular Chemistry, RWTH Aachen University and

DWI an der RWTH Aachen e.V., Pauwelsstr. 8, 52056 Aachen, Germany

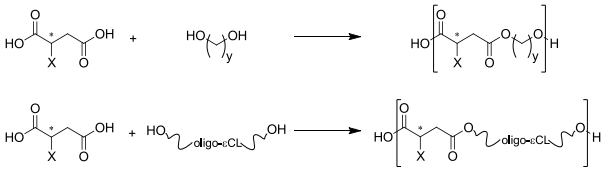
E-mail: keul@dwi.rwth-aachen.de

Introduction

Much interest in current research is focused on bio-based, biocompatible and biodegradable materials. It is often an important requirement to have functional groups in the polymer chain as they allow further functionalization and/or modification and therefore lead to tailor-made materials which are particularly useful in the biomedical field. To prepare such materials multifunctional building blocks are needed. Malic acid, a natural hydroxy-dicarboxylic acid, is a building block suitable for the preparation of hydroxy-functional polyesters. A wide range of copolymers, which are accessible by using dicarboxylic acids with hydroxy or similar functions as building blocks, will be presented.

Materials and Methods

Hydroxy-functional polyesters were synthesised in a polycondensation reaction using mono- and polydisperse diols, based on oligocaprolactone (OCL) or alkane diols, and malic acid as hydroxy-functional dicarboxylic acid (Scheme 1). The reactions were performed at 60 °C either in bulk or in solution with scandium triflate [$Sc(OTf)_3$] as catalyst, which discriminates between primary and secondary OH-groups.[1] OCL used as diol was afore oligomerised by means of ring-opening polymerisation using an alkane diol as initiator and $Sc(OTf)_3$ as catalyst.



X = H, OH, Hal, SH; y = 6,8,10,12

Scheme 1: Polycondensation reaction of a mono- or polydisperse diol and malic acid without participation of the secondary OH-groups by using $Sc(OTf)_3$ as catalyst.

Results and Discussion

The thermal properties of the malic acid based polyesters were analysed by means of DSC and compared with their non-functional analogues based on succinic acid. Thus the influence of the OH-groups onto the thermal properties was studied. Malic acid based polyesters show a wide range of thermal properties – highly crystalline to completely amorphous – depending on the monomer ratio, adjusted in the feed (Table 1).

The thermal properties, which are important for many material properties, are easily adjustable in a certain range by varying the monomer type and ratio. This precisely leads to the desired hydroxy-functional polyester.

Table 1: SEC and DSC data of several polyesters.

[a)] SEC in THF using PMMA standards, [b)] hexane diol, [c)] without precipitation, [d)] precondensation in $CHCl_3$ with a dean-stark-apparatus, [e)] octane diol, [f)] decane diol, [g)] dodecane diol, [h)] 5 mol-% $Sc(OTf)_3$ instead of 1 mol-%.

To show the prospects these new hydroxy-functional polyesters offer, additionally a wide range of post polymerisation modifications starting from the OH-groups was performed. For example L-lactide (LLA) was grafted directly from the free OH-groups. Here trans-esterification was suppressed by the use of $Zn(oct)_2$ as catalyst.[2] The direct reaction of the OH-group with an acid chloride showed elimination as a competitive reaction depending on the base used.[3]

Conclusion

Malic acid as monomer in a polycondensation with scandium triflate as catalyst makes it possible to directly synthesise hydroxy-functional polyesters.

First, investigations of the thermal properties were systematically performed to get a deeper understanding of the behaviour of these new polymers.

Further modifications of these polyesters show the possibility of preparing tailor-made materials especially for medical applications.

Synthesis of Biobased Polyols by Thiol-ene "Click Chemistry" from Vegetable Oils

Desroches Myriam, Caillol Sylvain, Auvergne Rémi, Boutevin Bernard

Institut Charles Gerhardt Montpellier UMR 5253 - Equipe Ingénierie et Architectures Macromoléculaires, Ecole Nationale Supérieure de Chimie de Montpellier, 8 rue de l'Ecole Normale 34296 Montpellier Cedex 5, France

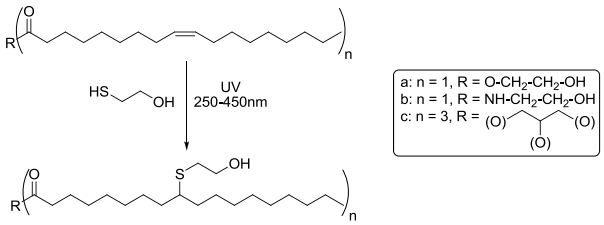
myriam.desroches@enscm.fr

Introduction

Polyurethanes are versatile plastics which are traditionally prepared by reacting an oligomeric polyol and a diisocyanate. Whereas the isocyanate component is always derived from petrochemical feedstocks, the polyol component can be provided from bio-based resources[1]. Vegetable oil-based polyols are synthesized from varied oils which, except castor oil, have to be chemically modified to meet the polyurethane production requirements. Transesterification[2] and epoxydation[3] are already industrially used for the production of polyols from oleochemicals.

The thiol-ene reaction represents another attractive toolbox for the functionalization of unsaturated vegetable oils[4, 5]. Indeed, this reaction of click chemistry[6] requires mild conditions and leads to high yields with basic purification procedures.

Our team used 2-mercaptoethanol to functionalize vegetable oils[7], ester[8] and amide oleo derivatives.



2-Mercaptoethanol photo-addition onto fatty compounds bearing one double bond per chain

The synthesized oleo polyols were used as precursors for polyurethanes.

Materials and Methods

Photochemical thiol-ene reactions were performed in quartz reactors of 20 mL equipped with an Ultracure 100SS plus/ Novacure lamp (unfiltered radiation between 250 and 450 nm) and a magnetic stirrer under air for 6 hours. The total reaction mixture weight was 5 g. During the reaction, the conversion of double bonds was monitored by ^{1}H NMR spectroscopy (vinyl proton signals at 5.40 ppm). After reaction, the viscous liquid was dissolved in ethyl acetate (20 mL) and extracted with water (3×20 mL) to eliminate the excess of 2-mercaptoethanol. The organic layer was dried over anhydrous magnesium sulfate and filtered. A pale yellow viscous liquid was recovered after evaporation of the solvent under reduced pressure (3.10^{-2} mbar).

Polyols were characterized by NMR ^{1}H, ^{13}C, FT-IR, LC-MS, SEC THF, and titrations. Polyurethanes were analyzed by ATG and DSC.

Results and discussion

To evaluate the efficiency and the robustness of thiol-ene reaction, experimental parameters were varied, such as the irradiation intensity (ranging from 0.5 to 15.0 W/cm^2), the thiol/double bond ratio (ranging from 1.2/1 to 5.0/1), the solvent/double bond ratio (ranging from 0/1 to 500/1) and the number of double bonds per fatty chain. It was especially shown that the higher the content of polyunsaturated fatty chains, the lower the rate of 2-mercaptoethanol grafting. Side reactions, identified by NMR, FT-IR, LC-MS, and iodine titration, were upon disulfide formation, double bond isomerization, and inter and intramolecular bond formation. Despite these side-reactions, by-products were found to exhibit alcohol functions. Optimized conditions were then applied to functionalize vegetable oil, fatty ester and fatty amide. Thus, the formed polyol mixtures were used to synthesize polyurethane with methylene diphenyl-4,4'-diisocyanate.

Polyurethanes based on modified vegetable oil, fatty amide diol and fatty ester diol were analyzed by ATG and DSC. The thermal properties of elastomeric products were found to be similar to those from a commercial polyol (Desmophen 1150).

Conclusions

2-Mercaptoethanol was efficiently grafted onto vinyl groups of vegetable oils and derivatives to yield various biobased polyols. The thiol-ene reaction was performed under mild conditions. The oleo polyols were then used to synthesize polyurethanes. The synthetic method can readily undergo incorporation of different reactive functions onto vegetable oils and their derivatives, thus leading to functional precursors suitable for polymer synthesis.

Crosslinking of Epoxidized Natural Rubber by Dicarboxylic Acids: Monitoring Crosslinking Density, Polar Interactions and Kinetics Rate

Myriam Pire[1], *Sophie Norvez*[1], *Ilias Iliopoulos*[1], *Benoît Le Rossignol*[2] *and Ludwik Leibler*[1]

myriam.pire@espci.fr

Epoxidized natural rubber (ENR) is a material of great interest obtained from renewable resources. It exhibits a dual functionality for cross-linking (double bonds and epoxy sites) while retaining most of the properties of natural rubber. In this work, the crosslinking reaction of ENR with dodecanedioic acid was followed by rheology and the properties of the cured materials were tested by dynamic mechanical analysis, stress-strain experiments, and DSC measurements.

We first studied the crosslinking of simple binary blends of dodecanedioic acid and ENR of different grades (10 and 25% mol epoxide groups), as well as the mechanical properties of the resulted materials after curing at 180 °C [1]. Properties of cured rubbers are governed by crosslinking density and glass transition temperature. It was found that mechanical properties were optimal for a certain amount of diacid (Figure 1). For high concentrations of crosslinking agent, DSC measurements on ENR25 revealed a nonlinear behaviour in the increase of glass transition temperature. By comparing crosslinking with dodecanedioic acid and reaction with monofunctional lauric acid, this behaviour was attributed to polar interactions due to free carboxylic groups of pending diacid grafts.

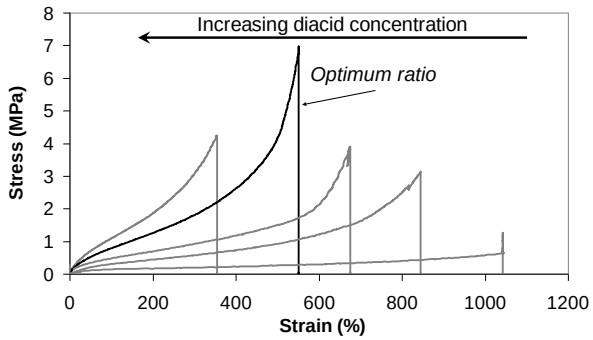

Figure 1: Strain-stress measurements for vulcanized ENR10-dodecanedioic acid blends, containing increasing amount of diacid.

The long heat treatment (3 hours at 180 °C) has however detrimental effects on the mechanical properties of cured rubbers. Curing behaviour of blends of ENR and dodecanedioic acid was thus investigated in presence of usual catalysts of the acid-epoxy reaction. Among all the accelerators tested, 1,2-dimethylimidazole (DMI) was found the only one able to activate in bulk the crosslinking of these high molecular weight elastomers. As seen on Figure 2, the rate of the reaction was efficiently accelerated in presence of DMI. An equimolar amount of accelerator and carboxylic functions was required to give rise to optimum tensile properties. This was associated to a non-catalytic crosslinking mechanism involving the quantitative formation of an imidazolium carboxylate. The formation of this intermediate was further highlighted by DSC experiments.

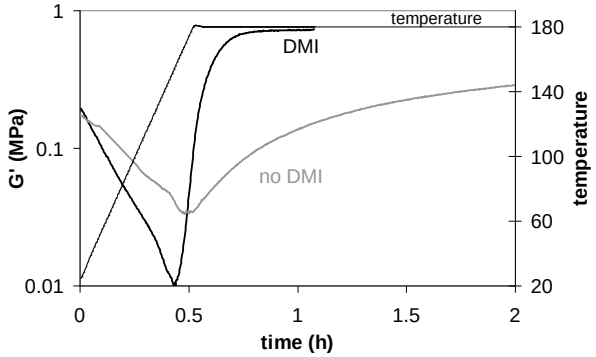

Figure 2: Effect of 1,2-dimethylimidazole (DMI) on the crosslinking of ENR25 with dodecanedioic acid.

Our system thus enables the efficient crosslinking of functionalized natural rubbers without the use of sulphur or any non-environmentally-friendly vulcanization additives.

Synthesis of terpolymers based acrylamides by RAFT polymerization and their application in the synthesis of goldnanoparticles

V.J. González-Coronel, J.A. Corcino-Campos, E.R. Rodríguez, N. Tepale-Ochoa,

Facultad de Ingeniería Química, Benemérita Universidad Autónoma de Puebla

valeriajordana@yahoo.com.mx

Introduction

Recent developments in controlled radical polymerizations enable the synthesis of functional polymers with controlled molar mass, narrow molecular weight distribution, and well-defined architectures and functionalities. The systems include atom transfer radical polymerization, nitroxide-mediated radical polymerization, and reversible addition-fragmentation chain transfer (RAFT) polymerization. Among these controlled radical polymerizations, RAFT has been successfully applied for controlled polymerization of acrylamide derivatives, such as N,N-dimethylacrylamide, N-isopropylacrylamide, and N-acryloylmorpholine.

In this study, we investigated radical polymerization of a acrylmide with a monosubstituted acrylamide, in the presence of a chain transfer agent (CTA).

Experimental Section

The terpolymers were prepared by reversible addition-fragmentation transfer radical polymerization using acetonitrile as solvent. The PAm-b-PDAm-b-Pam was synthesized starting from the preparation of RAFT agent benzyl dithiobenzoate (BDB) (Figure 1)which was synthesized according to the method in the literature. [ref]

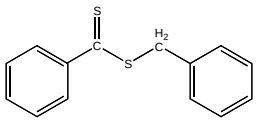

Figure 1. Benzyl dithiobenzoato

Preparation of PAm-b-PDAm-b-Pam

The PAm-b-PDAm-b-Pam was obtained in three steps. First Am, BDB and acetonitrile were added into a 1000mL reactor equipped with condenser and mechanical stirrer. The mixture was vigorously agitated, purged with nitrogen during 1 h, and heated to 82°C under agitation. Then, the initiator ACVA was added to the mixture to start the reaction, and bubbling was maintained during all the polymerization reaction, this step was run for 5 h. The polymer obtained was insoluble in acetonitrile. The polymer was recovered by filtration and washed with methanol to remove traces of residual monomer and initiator, and finally filtered and dried under reduced pressure at 40°C for 48 h. In the second step were added the PAm, dodecilacrylamide (DAm) and acetonitrile. The procedure was similar than the first step. The block copolymer was recovered, washed and dried. In the next step were added PAm-b-PDAm, Am. The reaction was run like in the past steps.

Preparation of gold nanoparticles

The synthesis of gold nanoparticles has been achieved at 25°C and different polymer concentration (0.5,1,1.5 and 2 wt. %) were studied. The formation of gold nanoparticles were monitored by observing changes (in time function) in the absorption spectra using a UV-visible spectrometer (Perkin Elmer, Lambda 35); the absorption band centered at ≈220nm that originates from the gold (III) chloride solutions and the band centered at ≈540nm that originates from the surface plasmon of the gold nanoparticles.

Results

The transfer agent was characterized by ^{1}H NMR. The Mn of each block of the terpolymer was obtained by ^{1}H NMR. The composition of the terpolymer was $AM_{5500}DAM_{1000}AM_{5000}$. Also we determined the Tg by DSC.

Table 1. Terpolymer properties

Block	Time (h)	%conversion	Mn ^{1}HNMR	Tg °C DSC
PAm	2	72	5500	60.68
PDam	1	80	6500	67.41
PAm	2	78	11500	62.94

The gold nanoparticles was characterized by SEM and TEM, and the average diameter was 99 nm.

Preparation of Furfuryl Functionalised Polystyrenes by Atom Transfer Radical Polymerization and Their Use in the Surface Chemical Modifications of Multi-wall Carbon Nanotubes by "grafting to"

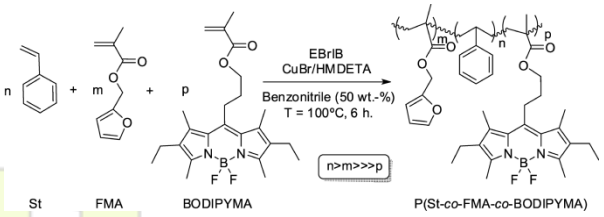
rparis@ictp.csic.es

Atom transfer radical polymerisation (ATRP) is one of the most powerful and versatile controlled radical polymerisation methods employed for the preparation of very diverse and well-controlled polymeric materials[1]. One the main advantages of ATRP is that it can be used to obtain functionalised polymers. Thus, four different synthetic strategies can be employed: i) use of functional monomers, since ATRP is generally tolerant of various functional groups, ii) post-polymerisation modification of monomeric units, using monomers with "protected" groups, iii) use of functional initiators and iv) end-group transformation by post-polymerisation nucleophilic substitution reactions, obtaining well-defined α and/or ω end-functionalized polymers.

In addition, ATRP has been extensively used for the incorporation of polymers onto several surfaces. Thus, three main routes have been employed for this aim, called "*grafting from", "grafting to" and "grafting through"* [2,3]. The former methodology establishes the incorporation of an ATRP-initiator on the surface and then, the polymerisation process obtaining a very high surface grafting density. The second requires a functionalised polymer that, in a second step, is incorporated to the surfaces by chemical reactions. Its advantage is the previous control over the properties of the grafted polymers. The third and the least used route is based on the incorporation of actives species for polymerisation on the surface.

Several approaches for the preparation of functionalised polymers by ATRP have been used by our research group. In fact, they have been attached to different surfaces in order to improve some of their properties. Thus, silica nanoparticles, polyhydroxyalkanoates and so on, were coated with polymers prepared by ATRP.

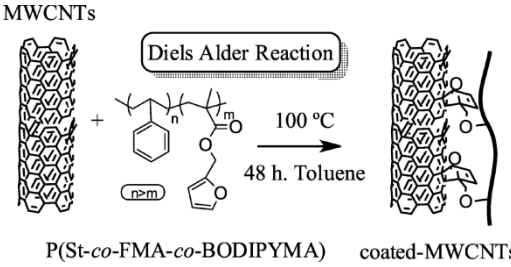
In this contribution a simple and single-step "*grafting to*" approach based on a Diels-Alder (DA) reaction is described to functionalise multi-wall carbon nanotubes (MWCNTs) with polystyrene (PSt). Thus, several fluorescent and furfuryl functionalised PSts were synthesised by the ATRP of styrene, furfuryl methacrylate (FMA) and low proportion of a fluorescent monomer (BODIPYMA) in a first step.



Scheme 1: Preparation of furfuryl functionalised and fluorescent styrene-based polymers, P(St-*co*-FMA-*co*-BODIPYMA), by ATRP.

Thus, several P(St-*co*-FMA-*co*-BODIPYMA) polymers were prepared in a controlled way using different monomer feed compositions. All of them were characterized by FT-IR, NMR, GPC, TGA, DSC, absorbance and fluorescence measurements, observing that their properties were those expected.

In a second step, these furfuryl functionalised PSts were covalently attached onto pristine MWCNTs. Furfuryl (diene) groups of FMA monomeric units allowed the chemical attachment of the PSt polymer onto the as-synthesised nanotubes by a DA reaction. On the other hand, the incorporation of fluorescent groups in the polymer offers two main advantages. It permits to determine the attachment of the polymer onto the nanotubes and, in further applications, it will allow to follow the dispersion of these modified MWCNTs in a matrix.



Scheme 2: Modification of MWCNTs with P(St-*co*-FMA-*co*-BODIPYMA) polymers by Diels-Alders reaction.

The efficiency of the proposed MWCNT functionalisation with the described methodology based was verified by FT-IR, Raman spectroscopy, TEM, AFM and fluorescence techniques. As an example, some results of TEM and fluorescence measurements are included in Figure 1, where it can be observed the polymeric coating (left) and the fluorescence of the modified carbon nanotubes (right).

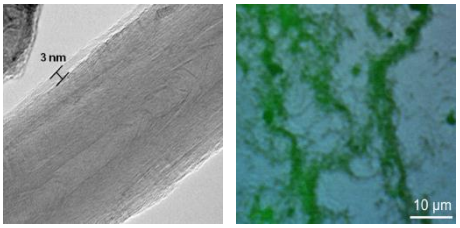


Figure 1: (left part) TEM image and (right part) combined light and fluorescent microscopy of modified MWCNTs.

Cationic Polymerization of Isobutylene Using $AlCl_3OBu_2$ as a Coinitiator: Synthesis of Highly Reactive Polyisobutylene

Sergei V. Kostjuk, Irina V. Vasilenko, Alexander N. Frolov

Research Institute for Physical Chemical Problems of the Belarusian State University

kostjuks@bsu.by or kostjuks@rambler.ru

Introduction. The low-molecular weight polyisobutylenes (M_n<5,000 g mol^{-1}) with high content of the vinylidene end groups, i.e. so-called highly reactive polyisobutylenes (HR PIB*s*), represent the most important industrial class of isobutylene (IB) polymers due to their use as a raw material for manufacturing of lubricants and fuel additives. Recently, BASF, the worldwide leader in the production of HR PIB*s*, increased the capacity for their production mainly due to the new fuel requirements. These polymers under trade mark Glissopal® with M_n ranging between 550 and 2300 g mol^{-1}, molecular weight distribution (MWD) less than 2.0 and containing 75–85% of *exo*-olefin end groups are produced via cationic polymerization of IB using alcohols/BF_3 initiating system. In this work we report new $AlCl_3$-based initiating systems, 2-phenyl-2-propanol (CumOH)/$AlCl_3OBu_2$ and H_2O/$AlCl_3OBu_2$, for the synthesis of HR PIB containing 88-95 % of *exo*-olefin terminal groups under mild experimental conditions. These initiating systems are originated from our systematic investigations of the controlled cationic polymerization of styrene using of complex of $AlCl_3$ with Bu_2O as an coinitiator.[1,2] The use of such kind of complexes of $AlCl_3$ allows to solubilize the Lewis acid in polymerization media and decrease its instantaneous concentration that leads to totally different behavior of these complexes in the polymerization processes in comparison with a neat $AlCl_3$.[1,2]

Results and discussion. Table 1 summarizes the main results obtained during the cationic polymerization of isobutylene using $AlCl_3$-based initiating systems.

Table 1. $AlCl_3OBu_2$-coinitiated cationic polymerization of IB in CH_2Cl_2/*n*-hexane 80/20 v/v during 3 min [a]

run	T (ºC)	conv (%)	M_n (g/mol)	M_w/M_n	*exo* (%)
1	–60	85	2330	1.81	86
2	–40	62	1560	1.46	91
3[b]	–40	73	1200	1.20	90
4	–20	49	1150	1.16	91
5[c]	–20	46	1750	2.25	92

[a] Conditions: [CumOH]=18 mM; [$AlCl_3OBu_2$]=22 mM; [IB]=0.91 M; [b] [CumOH]=36 mM; [$AlCl_3OBu_2$]=44 mM. [c] no initiator; time: 7 min.

The increase in the reaction temperature from –60 ºC to –20 ºC led to the gradual decrease of monomer conversion, molecular weight (from M_n=2300 g mol^{-1} to M_n=1150 g mol^{-1}) and to the narrowing of MWD down to M_w/M_n<1.2 at –20 ºC. Importantly, increasing the temperature did not influence significantly the content of *exo*-olefin end groups (see Table). Higher initiator concentration resulted in higher monomer conversion and narrower molecular weight distribution (MWD) (compare runs 2 and 6). In the absence of initiator, the cationic polymerization of isobutylene proceeded at lower reaction rate than with initiator affording polymers with high content of vinylidene end groups (92 %) and acceptable MWD (M_w/M_n=2.25) (runs 4, 5).

A mechanism of IB polymerization with CumOH/$AlCl_3OBu_2$ initiating system was proposed.[3] According this mechanism, free Lewis acid, which is generated by dissociation of $AlCl_3OBu_2$ complex, participates in the initiating and propagating steps of reaction.[3] Basically, the polymerization proceeds in two stages. During the first stage, a fast polymerization occurs due to the initiation by cumyl alcohol followed by β-H abstraction by Bu_2O to generate double bond-terminated PIB and $H^+AlCl_3OH^-$. The latter species either participate in a competitive initiation of the polymerization, which is considerably slower than CumOH-initiated polymerization, or decompose with the formation the week Lewis acid $AlCl_2OH$, which is inactive in the polymerization.[3] We also propose that the predominant formation of *exo*-olefin terminal groups occurs through reaction of growing carbocation with free base (Bu_2O), which is formed due to the $AlCl_3OBu_2$ complex dissociation. Indeed, the decrease of the basicity of corresponding ED in $AlCl_3$×ED leads to a dramatic lowering of *exo*-olefin end group content: Bu_2O (pK_a=–3.59, *exo* =91 %); EtOAc (pK_a=–6.5, *exo* =53 %); Ph_2O (pK_a=–6.54, no *exo*-olefin end groups).

Conclusions. CumOH in combination with $AlCl_3OBu_2$ provides a very efficient initiating system for the synthesis of HR PIB*s* (M_n=1000–5000 g mol^{-1}) with rather narrow MWD (M_w/M_n=1.2–1.9) containing 86–95 % of *exo*-olefin end groups at elevated reaction temperatures (–40…–20 ºC). The predominant formation of *exo*-olefin-terminated polyisobutylenes during the cationic isobutylene polymerization with CumOH/$AlCl_3OBu_2$ initiating system is consistent with a selective β-H abstraction by free Bu_2O formed due to the dissociation of $AlCl_3OBu_2$ complex.

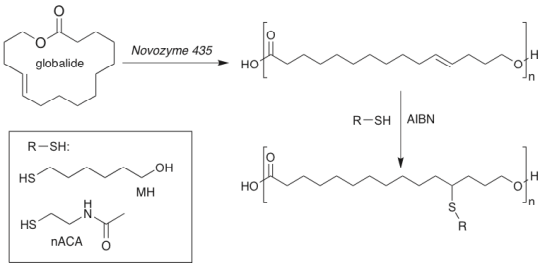
Introduction: Aliphatic polyesters have received significant recent attention owing to their use in a number of biomedical applications, with key research focussed particularly on their use as degradable drug delivery vehicles and in tissue engineering.[1] Despite the suitability of incorporating polyesters into biomaterials, their use in highly sophisticated biomedical applications is hindered by the difficulty of polyester side-chain functionalisation. Material modification to allow specific interactions within biological systems significantly enhances biomaterial performance, potentially offering the material a dynamic role in its application.

In this work we propose the chemically straightforward modification of aliphatic polyesters by utilising highly efficient and robust thiol–ene 'click' reactions directly on unsaturated polyesters obtained from ring-opening polymerization (ROP) of the unsaturated macrolactone globalide (Gl).[2]

Results and Discussion: The ROP of globalide was carried out in toluene with Novozym 435 (*Candida antarctica* Lipase B (CALB) immobilised on macro-porous resin) to a molecular weight of 16000 g mol^{-1} and a polydispersity of 2.5.[3] The thiol–ene functionalisation of polyglobalide (PGl) was undertaken by a thermally initiated reaction catalysed by AIBN in the bulk above the melting point of PGl or with a minimum amount of solvent when required to enable complete reactant miscibility. Obtained thiol–ene functionalised polymers were characterized by ^{1}H NMR, DSC and GPC analysis.



Scheme 1. Polymerisation of globalide and thiol–ene reaction of polyglobalide with 6-mercapto-1-hexanol (MH) and *N*-acetylcysteamine (nACA).

6-Mercapto-1-hexanol (MH) and *N*-acetylcysteamine (nACA) were selected as suitable candidates for the introduction of a primary alcohol and amine functionality to the polymer *via* the methodology proposed (Scheme 1). The ^{1}H NMR obtained for MH and nACA functionalised PGl reveals characteristic peaks corresponding to the repeat units of PGl and signals from the thiol fuctional groups, which suggests a successful reaction. By comparing the integration of the peaks that correspond to the double bond in PGl at around 5.4 ppm with the peaks representative of the methylene group adjacent to hydroxyl terminal group, it was determined that the fraction of thiol–ene coupling was in excess of 95%.

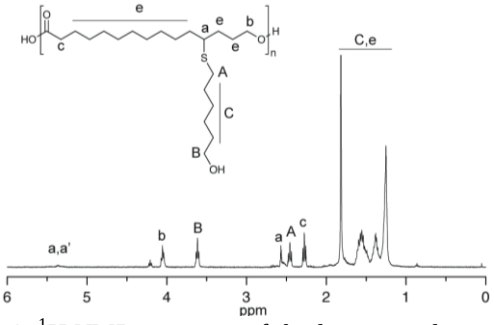


Figure 1. ^{1}H NMR spectrum of thiol-ene coupling product of PGl and 6-mercapto-1-hexanol.

Moreover, using multifunctional thiols transparent cross-linked films were obtained under UV radiation from PGl homo and copolymers.

Figure 2. P(Gl-co-CL) (30/70) obtained via thiol-ene cross-linking using UV radiation for 15 min

Conclusions: Thiol–ene click chemistry may be utilised to functionalise and cross-link unsaturated polyester obtained by enzymatic ROP of macrolactones. This approach therefore readily enables the highly efficient and chemically simplistic biofunctionalisation of a polyester compound to yield significant products of potential biomedical importance.

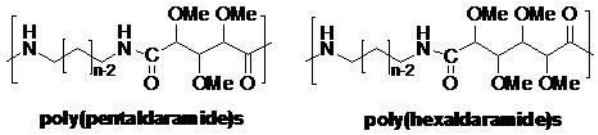
Introduction

The incorporation of carbohydrate units into polycondensates is attracting a great interest as a tool for the development of sustainable polymers with improved properties. Here, we present a systematic study on the conformation and crystal structure of polyaldaramides, which are polyamides prepared from alkanediamines and aldaric acids (sugar-based monomers). The influence on the structure of both the size of the polymethylene segments and the nature of the monosaccharide-based unit is considered.



Scheme 1. Chemical structure of polyaldaramides.

Materials and Methods

The polyaldaramides studied in this work include derivatives of pentoses (LAr and DXy) and hexoses (D-Gal and DMan). Their synthesis and chemical characterization have been reported in detail elsewhere.[1,2] The crystal structure has been analyzed by combination of transmission electron microscopy, X-ray (WAXS) and electron diffraction (ED) techniques, and force-field based atomistic simulations.

Results and Discussion

These polyaldaramides were stretched in more or less oriented fibers that were analyzed by WAXS and crystallized from solution to render lamellar single crystals susceptible to be analyzed by electron diffraction.

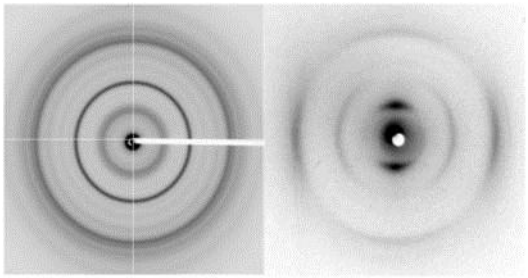


Figure 1. Powder (left) and fiber (right) WAXS obtained for PA-10LAr.

The analysis of the X-ray and electron diffraction patterns produced by crystallized samples of these polymers is consistent with a crystal structure characterized by the occurrence of a highly contracted conformation of the chains. Thus, the axial repeat of the structure appears to be shorter than the length that should be expected if the chains were in a fully extended conformation[3].

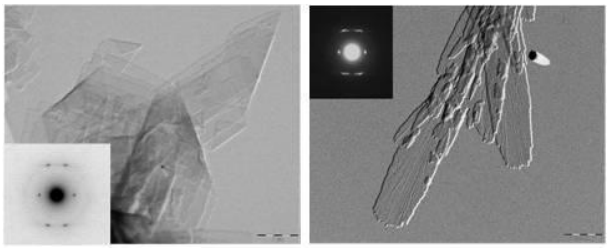

Figure 2. TEM of lamellar crystals of PA-10LAr (left) and PA-12-Mn (Inset: DE from lamella).

Molecular modeling simulations show that in this type of polymers, the monosaccharide-derived moieties tend to adopt a skewed arrangement that leads to a folded conformation in which the polymethylene segments of the same chain are bending with respect to each other. The resulting crystal structure consists on chains arranged in sheets with intermolecular hydrogen bonds between the amide groups.

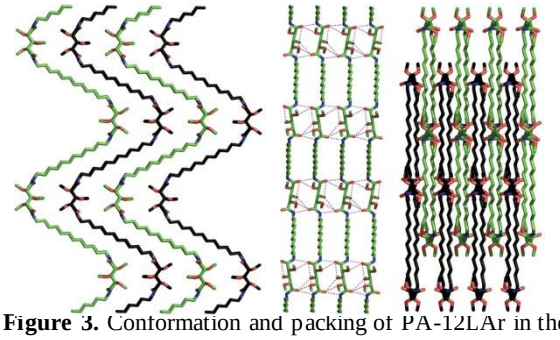

Figure 3. Conformation and packing of PA-12LAr in the crystal lattice obtained from molecular modeling simulations.

Conclusions

The presence of aldaric units within the backbone of polyaldaramides favors the adoption of folded conformations with the sugar moieties located at the skew of the bended chain. Such conformation allows an optimal occupancy of the space in a stratified structure.

One-pot Multistep Reactions Based on Thiolactones: Extending the Realm of Thiol-Ene Chemistry in Polymer Synthesis

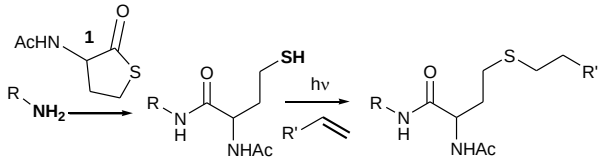
Pieter Espeel, Fabienne Goethals, and Filip E. Du Prez

Department of Organic Chemistry, Polymer Chemistry Research Group, Ghent University, Krijgslaan 281 S4-bis, B-9000 Ghent, Belgium

Filip.Duprez@Ugent.be

Introduction

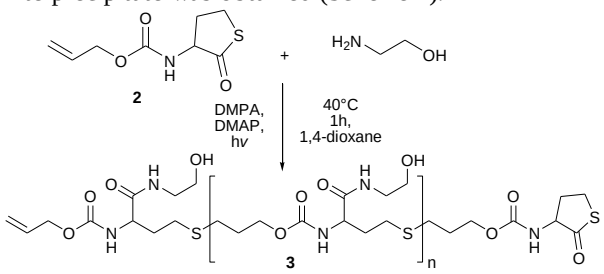
Recently, many organic reactions, generally labeled as 'click' chemistry and originally developed and applied in the synthesis of low-molecular-weight compounds, infiltrated the toolbox of synthetic macro- and supramolecular research groups.[1-3] As Malkoch et al.[4] expressed the need to increase the range of available 'click' reactions that can be achieved without the need of metal catalysts and to develop libraries of compatible reactions, our ongoing interest is to develop an efficient one-pot process based on metal-free radical thiol-ene chemistry. In addition to the fact that the availability of thiols as starting materials is rather limited, thiols usually have an unpleasant smell and a poor shelf life due to oxidation reactions. Therefore it can be advantageous to generate thiols *in situ* and convert them in a one-pot process. The readily available *N*-acetylhomocysteine thiolactone **1** was already used for the introduction of sulfhydryl groups in natural proteins, through the nucleophilic ring-opening by the ε-NH_2 groups of lysine residues.[5] We anticipated the ability to adapt this methodology and combine it with the radical thiol-ene process in a one-pot fashion as a mild approach for the synthesis of polymeric architectures starting from stable amine containing compounds, as very recently published in *JACS*.[6] This *amine-thiol-ene conjugation* (Scheme 1) as a simple, efficient, and modular linking process is considered to be a relevant extension of the currently quite popular thiol-ene chemistry, especially in polymer science.



Scheme 15 – General concept of the Investigated Metal-Free One-Pot Reaction: Nucleophilic Opening of a Thiolactone (Aminolysis), Followed by a Radical *Thiol-Ene* Conjugation

Results and Discussion

In the first stage of this study, the one-pot two-step sequence was performed on low-molecular-weight model compounds in order to investigate the reaction kinetics and to analyze the composition of the obtained reaction mixture. Encouraged by the positive results of this model study, we investigated the synthesis of a monomer containing both a double bond and a thiolactone unit. Since a thiolactone moiety can be considered as a precursor of a thiol functionality, the combination with a double bond results in an AB' type monomer. The valorization of the reactivity of this monomer, *N*-(allyloxy)carbonylhomocysteine thiolac-tone (Alloc-TL) **2**, upon aminolysis and subsequent UV-curing, would enable us to develop convenient and accelerated protocols for the synthesis of novel polymeric architectures. Radical (photo)polymerization reactions between a thiol and an alkene occur in a stepwise fashion. In order to obtain high-molecular weight polyaddition compounds, the ratio between the involved functional groups should equal 1. The aminolysis of the thiolactone in the Alloc-TL monomer **2** to generate a thiol should therefore efficiently reach full conversion. In the presence of a 2-fold excess of the nucleophile ethanolamine and DMPA as photoinitiator, the polyaddition occurred and, after 1h of UV-curing, a white precipitate was obtained (Scheme 2).



Scheme 2 – Stepwise Photopolymerization of the Alloc-TL Monomer **2** in a One-Pot Process Yielding a Hydroxyl-Functionalized Polymer **3** with a Polyurethane Backbone

A mild and efficient one-pot polyaddition process yielded a polymer **3** with a polythioether/polyurethane backbone and pendant hydroxyl groups with a molecular weight of 7.8 kDa (^{1}H NMR). It should be noted that standard synthetic methods for the synthesis of functionalized polyurethanes would certainly require a protection/deprotection strategy. To further extend the scope of this thiolactone methodology in material science, polymer networks based on the AB' type monomer **2** were targeted. The use of 4,9-dioxadodecanediamine as a cross-linker yielded a clear, non-tacky and mechanically stable network film.

Conclusion

We have demonstrated that a thiolactone entity can serve as a precursor for thiols in a one-pot amine-thiol-ene reaction. Functional, linear polymers and networks were obtained using this methodology.[6] Further investigations will focus on the development and valorization of the analogous *amine-thiol-yne reaction*. Moreover, we are strongly convinced that this methodology will be useful for the modification of double/triple bond containing materials.

Polymeric Platforms Based on Thiolactone Monomers for Post-Polymerization Functionalization

Pieter Espeel, Lionel Petton, Milan Stamenović, Fabienne Goethals and Filip E. Du Prez

Department of Organic Chemistry, Polymer Chemistry Research Group, Ghent University, Krijgslaan 281 S4-bis, B-9000 Ghent, Belgium

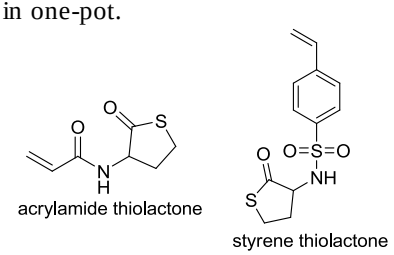
pieter.espeel@ugent.be

Introduction

At the beginning of the 21st century, polymer science is entering a new era. Never before has the need for polymeric structures that are both functional and modular been so important. In order to meet the challenges required for new applications, polymer chemists have to come up with original routes that are straightforward and wide in scope. It is with this aim in mind that we developed a strategy to produce controlled polymers that are amenable to very efficient post-polymerization functionalization. In order to make the strategy as universal as possible, different monomers and polymerization techniques were used. The polymeric platforms created could then be used to form networks or introduce desired functional groups through thiol-click chemistry.

Results & discussion

The new copolymers are based on thiolactone containing monomers, inspired by a new one-pot efficient conjugation methodology developed in our laboratory[1] (**Scheme 16**). The two monomers (styrene-thiolactone and acrylamide-thiolactone) were synthesised from a bioresource material. The advantage of the thiolactone group is that it allows for the introduction of thiol groups along the backbone while preventing side reaction from occurring. As long as the thiolactone ring remains closed, the polymer is stable under air and at room temperature for prolonged times. However, in the presence of an amine, the ring opens and a thiol is generated. The key point is that the opening of the thiolactone followed by reaction of the thiol can be performed in one-pot.



Scheme 16 Thiolactone monomers

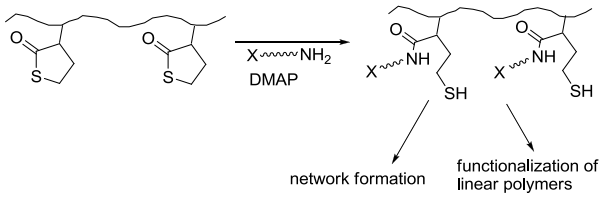
Controlled-radical polymerization methods were chosen for their ease of use and flexibility to synthesize the copolymers. The versatility of the methods employed, namely nitroxide-mediated polymerization (NMP) and reversible addition-fragmentation chain transfer (RAFT) polymerization, allow for the production of a wide range of polymer structures for post-polymerization functionalization. Furthermore, random copolymerization gave control over the density of the thiolactone side groups within the polymer chains.

The following copolymers were synthesised: poly(styrene-*co*-styrene thiolactone), poly(*N*-isopropylacrylamide-*co*-acrylamide thiolactone) and poly(methyl methacrylate-*co*-styrene thiolactone).

RAFT copolymerization of styrene with styrene thiolactone was performed in dioxane at 70°C using S-1-dodecyl-S'-(α,α'-dimethyl-α"-acetic acid) trithiocarbonate (DDMAT) as RAFT agent and AIBN as radical initiator. Copolymers of $M_n \approx 12{,}000$ g/mol and polydispersities (PDI) as low as 1.1 were obtained. The polymerization proceeded faster for higher amounts of styrene thiolactone (up to 20 mol%). Different compositions were studied to determine the reactivity ratios of the two comonomers under those conditions. A similar procedure was applied to synthesize poly(*N*-isopropylacrylamide-*co*-acrylamide thiolactone).

Methyl methacrylate (MMA) cannot by homopolymerized in a controlled manner by NMP[2]. However, small addition of styrene thiolactone was found to control the polymerization of MMA by NMP. The copolymers were synthesized with MAMA-SG1 in DMF at 80°C and high conversions were obtained in about 3h. The amount of styrene thiolactone in the polymer feed was varied from 5 mol% to 15 mol%.

The different polymers were then used to generate networks or to introduce other functional groups by opening thiolactone units along the backbone to generate thiols (**Scheme 2**).



Scheme 2 Post-modification of the thiolactone containing copolymers

Conclusion

New and versatile thiolactone containing copolymers were synthesized by NMP and RAFT polymerization. As these thiolactone units represent latent thiol functionalities, these copolymers were used as efficient platforms for post-polymerization modifications.

Marcel.li Domingo s/n, 43007 Tarragona (Spain)

gerard.lligadas@urv.cat

Introduction

The field of polymers derived from non-petrochemical feedstocks has recently attracted a great deal of interest from both economic and environmental sense. Vegetable oils, made up of triglycerides molecules, are considered to be one of the cheapest and most abundant biological sources available, and their use as annually renewable platform chemicals has numerous advantages, including low toxicity and inherent biodegradability.

Polyanhydrides (PAs) are useful biodegradable vehicles for localized drug delivery.[1] In aqueous media the breaking of the anhydride bonds resulting in gradually polymer fragments collapse and release drugs in a controlled manner. Fatty acids are good candidates for the preparation of biodegradable and biocompatible PAs, as they are natural body components.[2] Unfortunately, fatty acids are monofunctional and cannot serve as monomers for polymerization. One methodology to convert fatty acids into PA precursors is by dimerization of unsaturated fatty acids such as oleic and erucic acid. Alternatively, dicarboxylic fatty acid derivatives can also be obtained by modification of hydroxyl-containing fatty acids with cyclic anhydrides.

Due to its ability to add a broad range of functionalities in lieu of double bound, thiol-ene coupling is a promising route that can be used for the synthesis of novel PA intermediates from renewable resources.

Materials and Methods

Three novel oleic and undecylenic acids-based polyacids (Figure 1a) were synthesized using photoinitiated thiol-ene click chemistry. OLS, UDS and UDTGS were used to prepare linear and crosslinked PAs via melt-condensation under vacuum. The characterization of these polymers was performed using a combination of NMR spectroscopy, FTIR and thermal analysis. The hydrolytic degradation of some of these polymers in phosphate buffer of pH 7.4 at 37ºC was investigated by GPC, gravimetry, FTIR and ESEM. The release characteristics of drugs from some of these PAs were determined using rhodamine B as model hydrophobic compound.

Results and Discussion

OLS, UDS, and UDTGS polyacids were synthesized in high yields applying thiol-ene coupling with 3-mercaptopropionic acid, and were used to prepare homo and copolyanhydrides. OLS and UDTGS homopolymers were isolated as a viscous liquid and rubbery solid, respectively.

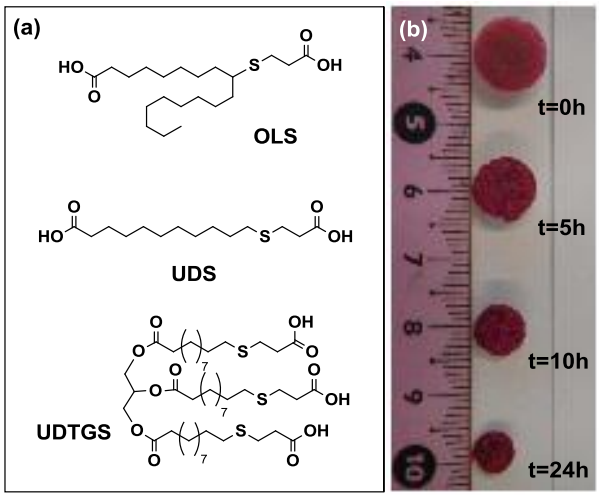

Figure 1. (a) Chemical structures of fatty acids-based polyacids. (b) Reduction in the size of rhodamine B loaded PA (UDS:UDTGS, 80:20) device with time.

Linear UDS and crosslinked UDS:UDTGS, 80:20 PA formulations showed melting points at around 75ºC and therefore were considered to be suitable for drug incorporation via melting process and delivery through degradation process. Hydrolytic degradation study revealed that both PAs show a fast decrease in the weight and anhydride content during the first hours of degradation, loosing 70% and 50% of its initial weight after 24h. When rhodamine B was incorporated into PA devices, UDS:UDTGS 80:20 PA showed a more sustained release of drug during the first stages of degradation in agreement with its crosslinked structure but in both cases up to 90% of loaded drug was released after 3 days. The progressive size reduction of the PAs devices over time (Figure 1b) and the porous eroded surface observed by SEM suggest a degradation mechanism governed by surface erosion.

Conclusions

Thiol-ene click chemistry has been applied to oleic and undecylenic acids to prepare biobased polyacids as PAs precursors. The studied PA systems showed fast-degrading properties and therefore could be useful in specific fast-acting applications such as wound care.

cypress@cperi.certh.gr

Polylactide is a well-known biodegradable polymer with a broad range of applications, including packaging, surgical sutures, drug delivery systems, internal bone fi xation, etc. It is produced either from lactic acid by direct polycondensation or via ring-opening polymerization of lactide with the latter being the most widespread method. In order to extent the applications range of biodegradable polymers very high molecular weight PLA should be produced. The preferred route of preparation is the bulk polymerization of L-lactide in the presence of a suitable catalyst such as stannous octoate (Sn(Oct)2). In addition, branched or star-shaped polylactides that exhibit different physical and degradation properties compared with the linear polylactide may be produced via the utilization of various co-initiators (e.g., pentaerythritol, 1,4 butanediol, polyglycidol, etc.).

The present work deals with the experimental and theoretical investigation of the ring-opening polymerization of lactide with Sn(Oct)2 as a catalyst for the production of high molecular weight polymers with improved physical and mechanical properties. It should be pointed out that the production of high molecular weight polylactides strongly depends on the high purity of all reagents employed since the presence of reactive impurities or traces of moisture can significantly lower both the polymerization rate and the polymer molecular weight. For this reason, high vacuum technique and very careful purification procedures were used for all reagents. Initially, the homopolymerization of lactide was experimentally studied at various temperatures (i.e., 140, 160 and 180 0C) and different monomer to initiator concentration ratio values (i.e., [M/I] = 5000, 10000 and 20000). The monomer conversion was determined by using 1H NMR spectroscopy and the corresponding molecular weight distributions by GPC. Subsequently, co-intitiators with different number of hydroxyl groups were utilized to obtain branched or star shaped polymers. The produced polylactides were fully characterized concerning their thermal and mechanical properties (i.e., DSC, TGA, DMA). It is demonstrated that the polymerization temperature, the monomer to initiator ratio as well as the co-initiator type greatly affect the monomer conversion and the molecular properties of the produced polymer, during the ringopening polymerization of L-lactide, which in turn affect its end-use properties. It should be pointed out that in the absence of co-initiator the obtained molecular weights were higher than those presented in the open literature (e.g., Mw = 700000 with PD < 2.5, at 160 0C and [M/I] = 10000) indicating the efficiency of the purification procedure.

Moreover, a comprehensive mathematical model was developed based on a detailed kinetic mechanism to simulate the dynamic evolution of the monomer conversion and molecular weight developments (i.e., Mn, Mw, PD). The proposed kinetic mechanism of the ring-opening L-lactide polymerization comprises a series of elementary reaction steps, including catalyst activation, chain initiation, propagation, chain transfer to wat er and octanoic acid, transesterification, etc.

Dynamic material balance equations were derived to describe the conservation of the various molecular species (i.e., monomer, catalyst and moments of the live and dead polymer number chain length distributions) during the polymerization. The predictive capabilities of the proposed kinetic model for the ringopening polymerization of L-lactide are demonstrated by a direct comparison of the theoretical predictions with experimental results on monomer conversion and molecular properties (Figures 1, 2).

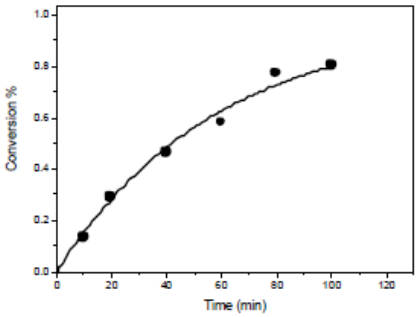

Figure 1: Comparison between model prediction and experimental data on monomer conversion (Monomer/Catalyst = 20000, 160 ^{0}C).

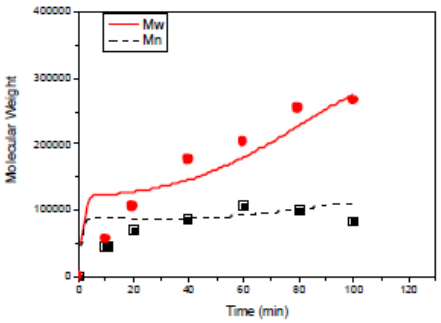

Figure 2: Comparison between model prediction and experimental data on number and weight average molecular weight (Monomer/Catalyst = 20000, 160 ^{0}C).

Controlled synthesis of reactive polyethers: application to free-isocyanate polyurethanes

Brocas Anne-Laure, Cendejas Gabriel, Deffieux Alain and Carlotti Stéphane

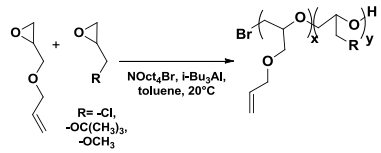
Université Bordeaux, Laboratoire de Chimie des Polymères Organiques, CNRS, ENSCBP, 16 avenue Pey Berland, 33607 Pessac Cedex, France

brocas@enscbp.fr

Polyurethane materials, thanks to their versatile properties, found many applications in various areas like building, coating, automobile or aeronautic industries. Because of the increasing energy demand, the decrease of petroleum products and recent regulations, newroutes for the synthesis of bio-based polymers and materials derived thereof have to be developed. The approach presented here is based on the use of epoxides like epichlorohydrin (ECH) and glycidol issued from glycerol directly coming from vegetal oils. These epoxides allow the synthesis of glycidyl methyl ether (GME) and also reactive allylglycidyl ether (AGE).

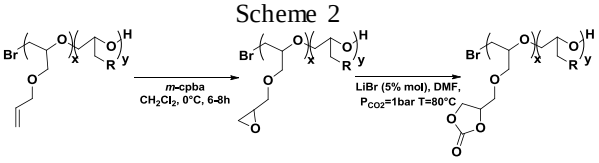
In this presentation, the controlled copolymerizations between AGE and ECH or GME or protected glycidol will be discussed. The synthetic approach was based on monomer-activated anionic polymerization[1,2,3](scheme 1). The method required an organic initiator (tetraoctylammonium bromide) and an activator (triisobuylaluminum) in slight excess (~2 eq) compared to the initiator to get fast (a few hours) and controlled polymerization in hydrocarbons.

Scheme 1



Functional copolymers, with various compositions and molar masses from 2000 to 30000 g/mol were prepared. In addition, complete conversions and low dispersities were obtained. The pendant allylic unsaturation enables various functions to be introduced, in particular, epoxide and cyclic carbonate groups by reaction with metachloroperbenzoic acid and carbon dioxide (scheme2).

Scheme 2



The occurrence of the different functionalizations was checked by ^{1}H (figure1) and ^{13}C NMR analysis. It showed the total disappearance of double bounds after the epoxydation reaction, then the disappearance of epoxides after reaction with $CO_2$and the formation of new signals attributed to the ethylene carbonate group.

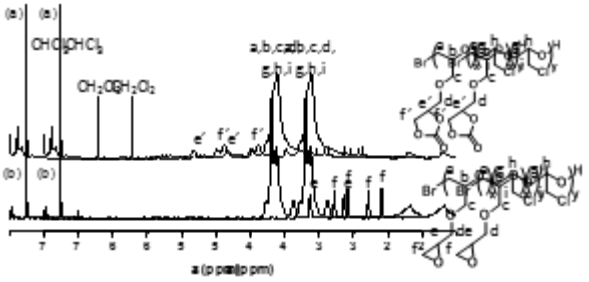


Figure 1: ^{1}H NMR (400MHz, $CDCl_3$) spectrums

Five members cyclic carbonate groups were then reacted with primary amines to form hydroxyurethane functions. As shown in Figure 2, the reaction was followed by FT-IR spectroscopy with the disappearance of the peak corresponding to carbonyl group at 1795 cm^{-1} and the appearance of peaks characteristic of the urethane functions at 1710 and 1610 cm^{-1}.

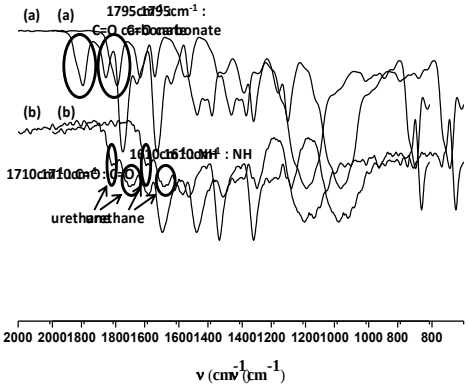

Figure 2: FT-IR spectrums

The mechanical properties of various reactive polyethers and crosslinked polyurethanes were then investigated.

Introduction: During the last decades, biopolymers and particularly starch-based materials showed growing interest in replacing oil-based materials. Their large availability and very low cost make thermoplastic starch one of the main renewable resource materials to be used as a raw material or to be blended with synthetic polymers. Compared to other natural polymers, their processing properties are very complex since they involve numerous physical processes and chemical reactions [1-2]. Gelatinization, which is closely connected to the other phase transitions, is the main phenomenon involved in the conversion process from starch to thermoplastic starch since it refers to the destruction of the crystalline structure that includes granular swelling, native crystalline melting and molecular solubilization [2].

Materials and Methods: Wheat starch from Sigma-Aldrich at 10% moisture content was employed during all this study. Several plasticizers such as glycerol, propylene glycol and polyethylene glycol 200 (PEG 200 - Mw = 200 g/Mol) were evaluated and compared. Rheology experiments were carried out on a controlled stress AR2000 (TA instruments) rheometer equipped with a Peltier module, in oscillatory mode with parallel-plate geometry. The swelling of the granules was monitored thanks to an optical microscope equipped with a video camera and a heating plate.

Results and Discussion: Time sweep measurements at different volume fractions at constant temperature and frequency using glycerol as the plasticizer have been done to characterize the influence of the volume fraction on the sol-gel transition. The gelation process is directly influenced by the volume fraction. To determine the maximal packing fraction (Φ_m) in the suspension, rheological experiments and precisely frequency sweep tests were carried out. By fitting the Krieger-Dougherty equation [3] on the experimental data of the evolution of the zero-shear viscosity as a function of volume fraction for suspensions of particles we were able to calculate Φ_m and the intrinsic viscosity [η] which we found equal to 0.341 and 2.5 respectively.

As a consequence of the formation of an elastic, three dimensional polymer network, the increase of G' is wider than the G'' and thus the tangent delta is decreasing progressively with time. Viscoelasticity experiments have been performed at several frequencies at constant temperature and volume fraction to characterize the independency of tan (δ) with frequency at the gel point. The gel point can be determined from the crossover of the different curves. In this case tan (δ) ≈ 2.2 leading to a relaxation exponent equal approximately to 0.73. This value is very close to that obtained by De Gennes, meaning that this gelation process is described by percolation and supports De Gennes analogy between the viscosity of the gelation bath and percolating superconductivity.

The gelation time is greatly influenced by the temperature. When the gelation is kinetically controlled, apparent activation energy of gelation (Ea) can be obtained from the integration of the kinetic Arrhenius equation. The gelation times were determined from the crossover of the elastic and viscous moduli of the isothermal experiments by assuming that the relaxation exponent was constant as a function of temperature. As expected the variation logarithmic of t_{gel} versus the inverse of the absolute temperature was linear for each volume fractions. To predict the t_{gel} evolution with temperature for any composition of the system, we have re-scaled the Y-axis with a shift factor, acquired from the Dickinson model [4], to obtain a master curve. From the linear regression we have been able to calculate the apparent activation energy that we found equal to Ea = 112 KJ.mol^{-1}.

In addition to the rheological experiments, the kinetic of gelatinization has been monitored using an optical microscope. During isothermal heating (from 60 to 100°C), the growth of an isolated grain in glycerol has been observed. In the same way that we did with the rheological results, we were able to calculate an activation energy that we found equal to 100 KJ.mol^{-1}.

Conclusions and References: To characterize the sol-gel transition occurring during the gelatinization of starch using glycerol as a plasticizer, dynamic rheology and optical microscopy were used. The maximal packing fraction was calculated and was found to be equal to 0.341. Thanks to isothermal frequency sweep tests, the relaxation exponent has been determined and the value (n = 0.73) provided us the information that the gelation process was described by the percolation theory. The apparent activation energy was worked out by both instruments and the variation of t_{gel} for any composition of glycerol/starch suspension was described using the Dickinson model.

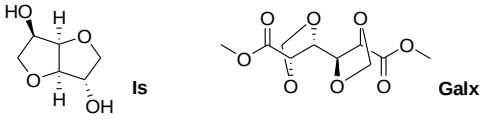
Introduction

The use of cyclic monomers derived from carbohydrates has been scarcely explored, with most of work made up to now devoted to isosorbide,[1] which is obtained by dehydration of D-glucitol. Other types of cyclic carbohydrate-derived monomers are those generated by intramolecular acetalization of either alditols or aldaric acids.[2] Dimethyl 2,3:4,5-di-*O*-methylene-galactarate (Galx) is a bicyclic acetalized aldarate which has not yet been explored to prepare polyesters.

Scheme 1. Chemical structure of isosorbide (left) and dimethyl 2,3:4,5-di-*O*-methylene-galactarate (right).



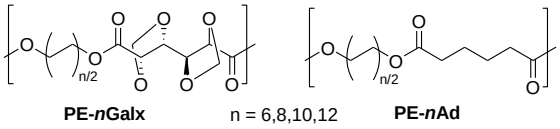
Materials and Methods

The monomer Galx was obtained by reacting commercial galactaric acid with paraformaldehyde, methanol and sulphuric acid. Poly(alkylene 2,3:4,5-di-*O*-methylene-galactarate) polyesters (PE-*n*Galx) were obtained by melt polycondensation of Galx with an aliphatic α,ω-alkanediol (1,6-hexanediol, 1,8-octanediol, 1,10-decanediol or 1,12-dodecanediol).

Results and Discussion

PE-*n*Galx polyesters were obtained with intrinsic viscosities between 0.51 and 0.62 $dL \cdot g^{-1}$ and weight-average molecular weights ranging from 34,700 to 43,100.

The thermal behavior, mechanical properties and biodegradability of these polyesters were evaluated and compared with those displayed by their homologous n-alkylene adipate polyesters (PE-*n*Ad).



Scheme 2. Chemical structure of PE-*n*Galx (left) and PE-*n*Ad (right).

Glass transition temperatures (T_g) of PE-*n*Galx varied from -17 to 6 ºC, decreasing with an increase of the length of the polymethylene chain, which acted as soft segment. T_g of PE-*n*Galx were invariably higher than those observed for PE-*n*Ad.

All PE-*n*Galx from synthesis were semicrystalline, and melting temperatures were in the range of 70-86 ºC. The introduction of cyclic acetal groups improved the thermal stability of polyesters, thus increasing onset temperature ($^oT_{5\%}$), temperature for maximum decomposition rate (T_d) and remaining weight at 600 ºC.

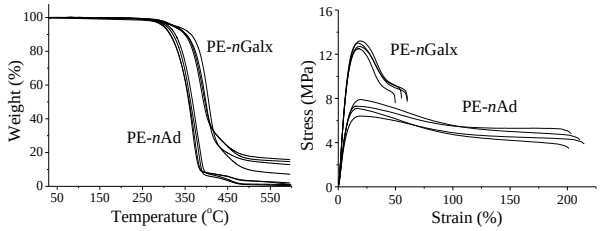


Figure 1. Compared TGA traces (left) and stress-strain curves (right) of PE-*n*Galx and PE-*n*Ad.

Regarding mechanical properties, the presence of the cyclic acetal units in the polyester chain caused an increase in the elastic modulus and the tensile strength of the polyesters, and produced a reduction in the elongation at break at the same time.

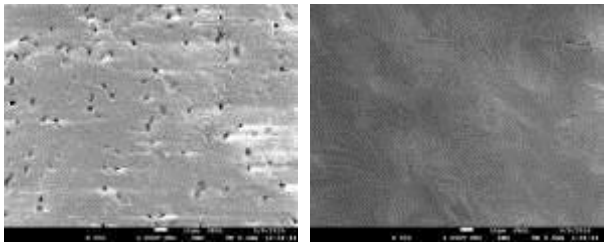

Figure 2. SEM micrographs of PE-8Galx (left) and PE-8Ad (right) after hydrolytic degradation at pH 2.0 for 56 days.

The hydrolytic degradation in aqueous buffer (pH 2.0, 7.4 and 10.5) and the enzymatic degradation in the presence of either lipase from porcine pancreas or lipase from *Pseudomonas fluorescens* were evaluated. The degradation study revealed that PE-*n*Galx were biodegradable polyesters, and that they degraded faster than PE-*n*Ad.

Conclusions

Aliphatic polyesters derived from a novel carbohydrate-based cyclic monomer, which might be an alternative to isosorbide, displayed thermal and mechanical properties highly influenced by the presence of the cyclic groups, and were hydrodegradable and biodegradable.

Controlled Release of Polyphenols from Cellulose-Based Hydrogels

D. Ciolacu, A. Oprea, G. Cazacu, M. Cazacu

"Petru Poni" Institute of Macromolecular Chemistry, Alea Gr. Ghica Voda 41A, 700487, Iasi, Romania

dciolacu@icmpp.ro

Introduction: Cellulose is considered an almost inexhaustible source of raw material for environment friendly and biocompatible products [1]. Cellulose based superabsorbent hydrogels are finding increasing interest in the scientific and industrial field due to their biodegradable character and the high swelling capacity [2,3]. Lignin, a natural phenolic polymer, is the second most abundant polymer after cellulose. There is an increasing interest in the potential health application of lignin, such as antitumoral, antiviral, anticarcinogenic activities, as well as, antibacterial and antiparasite action [4,5]. The aim of this paper is to present the preparation of novel cellulose-lignin hydrogels with special properties and to demonstrate their possible application as delivery device by incorporating the polyphenols from grapes seeds.

Materials and Methods: Microcrystalline cellulose (Fluka), C, was dissolved in 8.5% NaOH solution, at –30°C. Steam explosion lignin from aspen wood (L) was supplied by ENEA, Italy. Epichlorohydrin (Fluka) was used without further purification. Polyphenols (PF) were obtained by extraction from grape seeds from the *Chambourcin* type and analysed according to ISTA methods. For the preparation of cellulose/lignin hydrogels (CL), the cellulose was firstly dissolved in alkaline solution at low temperature (-30ºC). Different percents of lignin (Table 1) and epichlorohydrin were added in the obtained cellulose solution, under continuously stirring. The obtained composition was kept for 8h, at 80°C when cross-linking occurred. The hydrogel was washed successively with warm and cold water and then the sample was dried in vacuum, at room temperature.

Results and Discussion: By chemical crosslinking of CL mixtures, in presence of epichlorohydrin, hydrogels with high swelling capacities were obtained, maximum swelling degree in a mixture water:ethanol = 19:1 ranging between 2300-3060 % wt. (Figure 1).

Table 1. The main characteristics of the obtained hydrogels

Sample	Reaction mixture composition		Hydrogel features	
	C, g	L, g	Yield, %	Qmax, %
C	0.500	0.000	99.90	1145
CL1	0.375	0.125	99.91	2358
CL2	0.335	0.165	99.52	2446
CL3	0.250	0.250	92.34	2642
CL4	0.165	0.335	78.28	2737
CL5	0.125	0.375	71.70	3061

Direct evidence for the cross-linking reaction is the formation of ether bonds between cellulose and lignin, as FT-IR spectrum of hydrogels revealed by the increasing intensity of the aryl ether band (C-O-C stretching) at 1265 cm^{-1}, and alkyl ether bands at 1120 cm^{-1} (C-O-C stretching) and 1062 cm^{-1} (C-O stretch from alkyl substituted ether) (spetra not shown). The DSC curve of hydrogels determines a shifting of the endothermic peak between the corresponding temperatures of the initial samples, fact which certifies the formation of the cross-linked network. These hydrogels proved to be suitable to incorporate grapes seed polyphenols from water/ethanol solutions. The amount of the incorporated polyphenols was estimated by UV-VIS spectral measurements and the obtained values increased as a function of swelling capacity of the hydrogels.

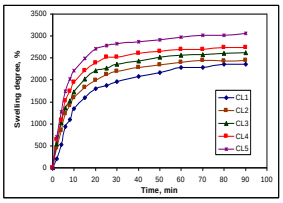

Fig. 1. Variations of the hydrogel's swelling degrees as a function of time and composition

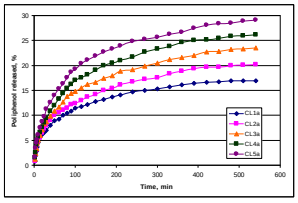

Fig. 2. Release profiles of polyphenols from CL hydrogels in water:ethanol medium, at 37 °C

Spectral studies regarding the release of polyphenols from CL hydrogels showed its dependence on the lignin content from matrices (Figure 2). Thus, higher lignin content leads to increasing the percentage of released polyphenol. A simple, semi-empirical equation using Korsmeyer and Peppas model was used to kinetically analyze the data regarding the polyphenols release from systems. Both the swelling and polyphenols release can be controlled by the composition of the hydrogels.

Conclusions: The cellulose-lignin based hydrogels were investigated by FT-IR and UV-VIS spectroscopy, differential scanning calorimetry (DSC) and optical microscopy. The obtained hydrogels may be potential candidates for biomedical applications.

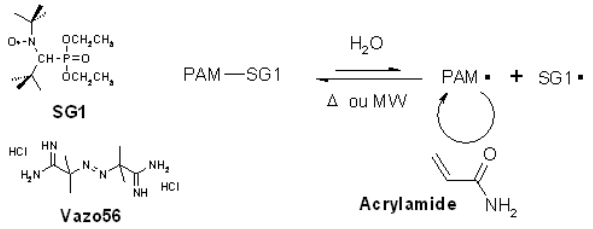
Microwave-Assisted Nitroxide-Mediated Radical Polymerization of Acrylamide in Aqueous Solution

Julien Rigolini, Bruno Grassl, Laurent Billon, Stephanie Reynaud and Olivier F. X. Donard

Institut Pluridisciplinaire de Recherche sur l'Environnement et les Matériaux (IPREM) UMR 5254 CNRS / Université de Pau et des Pays de l'Adour (UPPA), Hélioparc Pau Pyrénées, 2 Avenue du Président Angot, 64053 Pau Cedex 09, France

julien.rigolini@univ-pau.fr

In a recent work[1], we demonstrated that the combined use of microwave irradiation as a heating source and water as a solvent provides a reasonable living/controlled polymerization of acrylamide by nitroxide mediated polymerization (NMP). To conduct the reaction, a combination of a conventional hydrosoluble radical initiator (Vazo56) and a β-phosphonylated nitroxide (SG1) were employed.



When using the DYN mode which corresponds to a dynamic control of the temperature with a high initial microwave power, no specific microwave effect was observed even for temperatures ranging between 90° and 105°C. While the Arrhenius plots obtained by both the DYN mode and conventional heating (CH) were in good agreement at 90°C, a deviation was noticed at 105°C and was attributed to the experimental errors. The absence of microwave effect was explained by the DYN parameters themselves, *i.e.*, a high microwave power at the beginning of the polymerization increasing the bulk temperature to the set point as quickly as possible. Upon reaching the target temperature, the microwave power decreases or completely shuts off to maintain the target bulk temperature, T_p, without exceeding it.

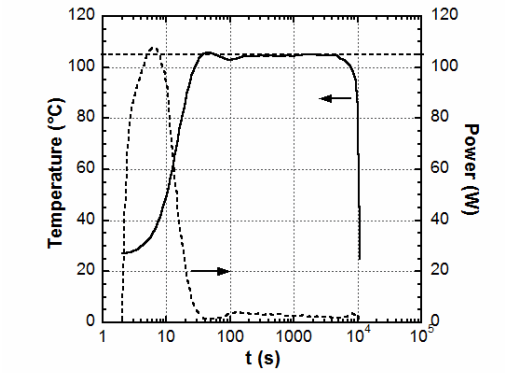


Figure 1: Temperature and power profiles during microwave irradiation in DYN mode.

In the absence or near absence of microwave irradiation, we concluded that classical thermal chemistry was taking over and that the full advantage of microwave synthesis was lost. It is however worth noticing that the temperature was only measured by an external IR sensor. The use of IR sensors may be inappropriate for temperature measurements in microwave-heated reactions[2]. The reason for this is that they may easily lead to a misinterpretation of the results since the real reaction temperature is unknown in particular when operating with simultaneous air cooling. The existence of a microwave effect was ascertained with a complementary series of reactions carried out between 130 and 160°C using the DYN mode and a microwave apparatus equipped not only with an external IR sensor but also with an internal temperature sensor, an optic fiber, which allowed the monitoring of the bulk temperature of the reactive media[3].

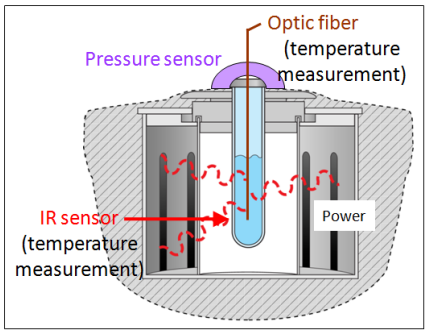

Figure 2: Schematic of the Monowave 300 from Anton-Paar GmbH used in this study.

Using the microwave-assisted nitroxyde-mediated polymerization, we also extended the field of AB hydrophilic diblock copolymer. Using a tertiary SG1-based macroalkoxyamine, we were able to synthesize in homogeneous aqueous media poly(acrylamide-*b*-sodium 2-acrylamido-2-methylpropanesulfonate), *i.e.* a neutral-*b*-anionic diblock copolymer, and poly(acrylamide-*b*-3-dimethyl(methacrylamidopropyl)ammonium propanesulfonate), *i.e.* a neutral-*b*-zwitterionic diblock copolymer[3].

Introduction

The development of biobased polymers that bring unique properties desired by consumers at acceptable prices is a major challenge and opportunity. Recently, Gross and collaborators reported the development of an engineered *Candida tropicalis* strain capable of producing commercially viable yields of ω-hydroxyfatty acids. This required the identification and elimination of 16 genes from the diploid yeast *Candida tropicalis* genome. After reintegration of a P450 and process optimization, volumetric yields higher than 150 g/L of 14-hydroxytetradecanoic acid (14HA) was produced using methyl myristate as substrate.[1] In this work, 14HA was used in two-step polycondensations to obtain novel copolyesters with 1,4-cyclohexylene units or terephthalate moieties along chains. The introduction of aliphatic or aromatic rings into the main chain aims at improving thermal and mechanical performances.

Materials

14-hydroxytetradecanoic acid (14HA) was prepared by a literature method.[1]
1,4-dimethyl cyclohexanedicarboxylate (DMCD) (containing 100 and 22 mol% of trans isomer), dimethyl terephthalate (DMT), 1,4-butanediol (BD), titanium tetrabutoxide (TBT) were purchased from Aldrich.

Results and Discussion

Scheme 1 describes the synthetic route to prepare two series of novel fully aliphatic and aliphatic/aromatic terpolymers built from 14HA/BD/DMCD and 14HA/BD/DMT, respectively. The biocontent of terpolyesters is from 14HA, however, it is anticipated that commercial sources of bio-BD will soon be available.[2] The presence of cyclohexane and phenyl rings along chains results in corresponding copolyesters with attractive thermo-mechanical properties: for example, P14HA-*co*-PBT and P14HA-*co*-PBCHD, containing 20 mol% of 14HA, have melting temperatures of about 190 and 135°C, respectively. In contrast, homopolyesters of 14HA melt at about 91°C. Elastic modulus of the copolyesters, measured by DMTA, is similar to that of PBT or Ecoflex (poly(butylene terephthalate-*co*-butylene adipate)). Moreover, the 1,4-cyclohexylene units show some further advantages: they provide copolyesters with resistance to weather, light, and support material biodegradability.[3] Finally, according to the cis/trans isomeric ratio of the aliphatic rings, the phase behaviour of copolyesters can change from a semicrystalline, at high trans content, to amorphous copolyesters when the cis isomer predominates. Therefore, by modifying the stereochemistry of the aliphatic ring, the molecular structure or the copolymer composition can be specifically manipulated in order to fine-tune copolyester physical-mechanical properties.

Conclusions

Novel biobased copolyesters were successfully synthesized. They contain long aliphatic chains, which impart flexibility and rapid crystallizability. In conjuction with biobased 14HA aliphatic repeat units, copolyesters contain aliphatic or aromatic rings, which enables to molecular design of materials with adjustable physico-mechanical properties. Thus, by judicious selection of monomers, there is ample ability to fine-tune material properties so a desired balance of material rigidity, ductility, sufficiently high melting point and good mechanical performance can be realized.

Pyridinium and Picolinium Ionic Liquids as a Media for Biphasic Ethylene Polymerizaton

Katarzyna Dziubek, Wioletta Ochędzan-Siodłak, Krystyna Czaja

Opole University, Faculty of Chemistry, Opole, Poland

katarzyna.dziubek@pwr.wroc.pl

Introduction

Two-phase solvent systems are attractive alternative to homogenous and heterogeneous catalysis. In these systems the catalyst is retained in one phase and the product remains in another, which allows the catalyst recovery and easy product separation [1].

In the last decade, particular attraction has been devoted to biphasic systems, in which one phase constitutes a ionic liquid. Ionic liquids have been shown to have a significant benefit over conventional solvents due to a variety of interesting and useful physical and chemical properties depending on the choice of either cation and anion of ionic liquid [1, 2].

In our recent search, we have focused our attention to the biphasic polymerization of ethylene with using ionic liquids as a medium of titanocene catalyst activated by alkylaluminium compounds. The studied ionic liquids constituted by the chloroaluminate anion and pyridinium cations with different number, length, and the position of the alkyl substituent at the pyridinium cation.

It was found that not only the performance of polyreaction but also the properties of the obtained PE depend on physical properties, especially viscosity, of the ionic liquids, which again, depends on the structure of the pyridinium cation. Furthermore, the pyridinium ionic liquids has recently been shown to be generally more environmentally friendly, regarding their biodegradation pathway, than the most popular imidazolium analogues [3].

Materials and Methods

As presented previously [4, 5]

Results and Discussion

In our investigations, the alkylpyridinium (C_n-py) and alkylpicolinium (C_n-3-mpy, C_n-4mpy) chloroaluminate ionic liquids (where alkyl was butyl or octyl) were applied in the biphasic ionic liquid/hexane ethylene polymerization as a medium for titanocene (Cp_2TiCl_2) catalyst activated by $AlEtCl_2$ and $AlEt_2Cl$ alkylaluminium compounds. It was found that the catalyst was immobilized in the ionic liquid phase and no catalyst leakage was observed. Polyethylene (PE), formed in the ionic liquid phase, has been progressively transferred to the hexane phase. Thus, the polymer was characterized by a high purity and can be easily separated from the reaction mixture by simple decantation. The structure of the ionic liquid cation, the kind of alkylaluminium compound, and the activator/catalyst (Al/Ti) molar ratio have a considerable effect on the polymerization performance.

In the biphasic systems, where [C_4-3-mpy][$AlCl_4$], [C_4-4-mpy][$AlCl_4$], and [C_8-4-mpy][$AlCl_4$] picolinium ionic liquids were applied, the PE yields were higher that those with use of imidazolium analogues, previously investigated [4]. An increase of the total polymerization yield with an increase of Al/Ti molar ratio was observed, regardless of the ionic liquid used. It was found that the ionic liquid with the alkyl substituent at the para (*gamma*) position is favoured. Maintenance of the PE product in the ionic liquid phase at higher activator/catalyst molar ratio is a disadvantageous feature of these biphasic systems, despite of a satisfactory total yield of PE.

The total PE yield decreases when the pyridinium ionic liquid ([C_4-py][$AlCl_4$] or [C_8-py][$AlCl_4$]) were used as a medium for catalyst. It should be noted, however, that the greater amount of PE was obtained in hexane phase, regardless of activator/catalyst molar ratio, which is the great advantageous feature of systems.

These results are related to physical properties, especially viscosity, of the ionic liquids used. The viscosity of the studied ionic liquids increases with the length and number of alkyl substituents. Low viscosity improves the dispersion of the ionic liquid in the hexane phase and increases the access of the monomer to the active site. For that reason the best results was obtained for ionic liquids with butyl alkyl chain in pyridinium cation.

Additionally, regardless of the ionic liquid used, for the same activator/catalyst molar ratio the polymerization yield was much higher when $AlEtCl_2$ was applied than $AlEt_2Cl$.

The structure of the ionic liquid cation has an influence also on the PE yield and properties. A distinguishing feature of the PE produced were the high bulk density (up to 520 g/dm^3) and the high crystallinity degree (≈95%), non-typical for polyethylene obtained over metallocene catalyst.

Conclusions

The studied ionic liquids as a medium metallocene catalyst enable to develop an unique system for the metallocene-catalyzed biphasic ethylene polymerisation with wide-range control of the polyreaction and the product properties.

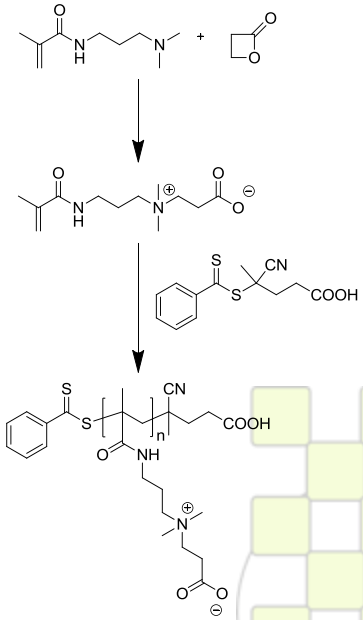
Introduction

Water-soluble zwitterionic polycarboxybetaine polymers (poly(CB)) are a highly interesting class of materials being applied to a broad range of biomedical and engineering applications. Among other zwitterionic polymers, poly(CB) is unique, emerging as the only ultra-low fouling material known allowing the preparation of biosensors, fouling resistant nano-particles, and non-adhesive surfaces for bacteria.[1, 2] Poly(carboxybetaine methacrylate) and poly(carboxy-betaine acrylamide) have been prepared via ATRP however a controlled polymerization has not been yet achieved. Herein the first successful living/controlled RAFT polymerization of the novel (3-acryloylamino-propyl)-(2-carboxy-ethyl)-dimethyl-ammonium (carboxybetaine methacrylamide) (CBMAA-3) monomer in acetate buffer is presented.

Materials and Methods

CBMAA-3 polymerizations were performed in acetate buffer, pH 5.2, at 70 or 25ºC using variable ratios of 4-cyanopentanoic acid dithiobenzoate as chain transfer agent (CTA) and 4,4'-azobis(4-cyanovaleric acid) or 2,2'-azobis[2-(2-imidazolin-2-yl)propane] dihydrochlo-ride as initiators (I) with target molecular weigths in the range between 55000 and 222000 g mol^{-1}. The conversion was determined by on-line ^{1}H-NMR. After 48 hour dialysis, samples were lyophylized and the absolute M_n, *PDI* and hydrodynamic radius were determined by aqueous size exclusion chromatography (ASEC-MALLS) and dynamic light scattering.



Scheme 1. Preparation and polymerization of CBMAA-3.

Results and Discussion

Poly(CBMAA-3) was obtained with M_n ranging from 14000 to 250000 g mol^{-1} in acetate buffer with conversions exceeding 90% in 24 hours. The controlled/living character of the polymerization was evidenced by a linear increase of the molecular weight with conversion with concomitantly decreasing *PDI*s. No induction period was observed when the CTA/I ratio was 2 and the propagating species concentrations was constant as evidenced by a linear first order relation.

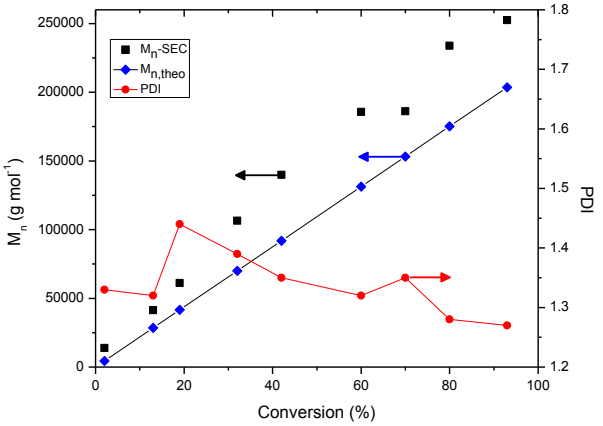


Figure 2. M_n (black squares) and *PDI* (red circles) determined by ASEC-MALLS and theoretical M_n (blue diamonds) as function of conversion (CTA:I 2:1)

Conclusions

The novel carboxybetaine monomer CBMAA-3 was synthesized for the first time and was utilized for the first living/controlled polymerization of carboxybetaine monomers. Aqueous RAFT polymerization afforded polymers with high molecular weight and low *PDI*.

Zinc Powder-Alkyl Halide: A Novel Initiation System for Living Radical Polymerization of Vinyl Monomers

Gokhan Cankaya, Niyazi Bicak

Istanbul Technical University, Department of Chemistry, Maslak 34469 Istanbul, Turkey

bicak@itu.edu.tr

Introduction: Synthesis block copolymers based mainly on controlled radical polymerization (CRP) techniques, such as ATRP, RAFT and NMP methods. Among those ATRP is most favorable due to its good control over the chain growth[1]. However ATRP is almost confined to styrenic and acrylic monomers and it can not be employed in polymerization of vinyl ester or vinyl amide monomers. Therefore preparation of block copolymers constituting with monomers polymerizing by different mechanisms is difficult task and can be achieved by end-group transformation of the first block to be used as macro-initiator.

In this presentation we'll introduce activated zinc powder-alkyl halide as novel initiation system applicable for controlled/living polymerization of vinyl monomers, including vinyl acetate.

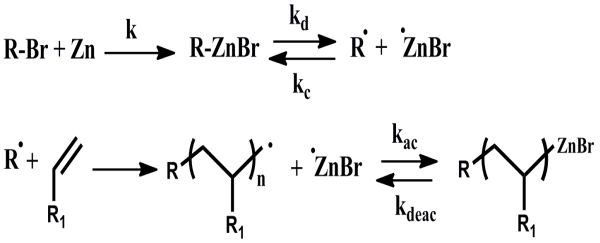
Result and Discussion: The initiation of VAc, MMA and styrene in the presence of ethyl bromoacetate or benzyl bromide was demonstrated to be effective in dry conditions around 70 °C. The zinc-alkyl halide system is sluggish to start the polymerization at room temperature (Table-1). The system does not give polymers in the presence of trace water, due to reductive dehalogenating effect of the activated zinc. This was evidenced by a model reaction of zinc with ethyl bromoacetate in the absence of the monomer.

Table-1: The polymerization yields (in bulk) of Zn-ethylbromoacetate initiation system in various conditions.

Monomer	*Water*	*Condition*	*Yield*
VAc	-	RT/ 48 h	No polymer
VAc	+	70 °C /24 h	No polymer
VAc	-	70 °C /24 h	81 %
MMA	-	RT/ 24 h	No polymer
MMA	-	70 °C /6 h	59 %
Styrene	-	55 °C /24 h	No polymer
Styrene	-	90 °C /8 h	48 %

Kinetic investigations revealed about 2 h of induction periods and nearly first order kinetics ($k=1.82\times10^{-5}$ 1.79×10^{-5} and 4.26×10^{-5} s^{1} for VAc, styrene and MMA respectively) in bulk conditions.

GPC traces of the resulting polymers showed relatively narrow polydispersities ((PDI: 1.12-2.6) up to 60-80 % conversions. Logically cationic, radicalic or insertion mechanisms can be considered for this polymerization system. However, polymerizability of MMA eliminates the cationic mechanism. In order to determine the mechanim operating, polymerization of MMA was studied in the presence of 0.5 mL methyl isobutyl ketone, which is well-known radical inhibitor. Surprisingly no polymer was obtained after 24 h of reaction. This result clearly eliminates the insertion mechanism and the system works in radicalic fashion as depicted in Scheme-1. Recently Arriola *et al.* demonstrated radical generation of dialkyl zincs by ESR and used atactic olefin polymerization the presence of a hafnium complex[2].



Scheme-1: Possible mechanism of the polymerization system with zinc-alkyl halide.

Regarding with reaction of alkyl halides with zinc metal, the polymers obtained by this method must bear ZnBr end-group which is highly reactive towards hydrogen donating compounds such as water or acids.

Indeed, the polymers isolated in ordinary conditions were not living due to easy destruction of the reactive end groups by hydrogen transfer. However, chain extension of PVAc (obtained by EBA and zinc powder) with MMA yielding PVAc-*b*-PMMA revealed livingness of the system in dry conditions, as evidenced by molecular weight increment in GPC traces and ^{1}HNMR spectrum of the resulting polymers (Fig-1).

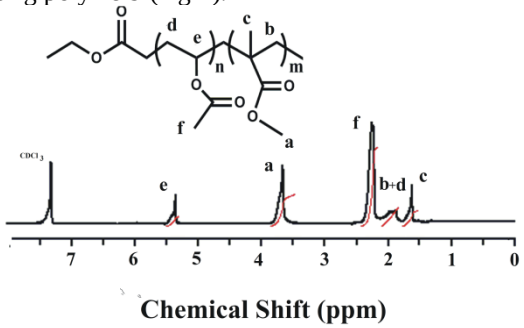


Figure-1: ^{1}HNMR spectrum of the polymer obtained by chain extension of PVAc with MMA.

Conclusion: The initiation system described is a living radical system which is especially useful for synthesis of block copolymers of VAc with ATRP grown acrylic and styrenic pre-polymers by direct initiation from their terminal haloalkyl groups.

Microwave-Assisted Synthesis of PAMAM Type Dendrimers & Their Analytical Applications

*Cemil Dizman[1], Tezcan Paralı[2], Ali Serol Ertürk[3], Metin Tülü[3] **

[1]Istanbul Technical University Dept. of Chem., Istanbul 34469, İstanbul
[2] Fatih University Dept. of Chem., Istanbul 34500, Turkey
[3] Yildiz Technical University, Dept. of Chem. Istanbul 34220, Turkey

Dendrimers are highly branched three dimensional supra(macro)molecules with well-defined structures constructed around a multifunctional central core. These structural characteristics exhibit good physical and chemical properties. Their synthesis are arising from a core, symmetrically additions of new groups help the dendrimer to grow exponentially. The functionalities of the dendrimers depend on cores, terminal groups and internal void spaces. PAMAM-type dendrimers with different functional groups on their peripheries by using Newkome[1] and Tomalia[2] repeating units were synthesized. Depending on the necessity, conventional and microwave-assisted reaction methods have been alternatively used. Poly (ethylene glycol) diacid 600, Jeffamine® (polyoxypropylene triamine), Trimesic acid, and Tren (tris (2-aminoethyl) amine) have been chosen as the cores. In order to prevent any undesired lactam formation, all amidation reactions related to Behera's amine[1] have been carried out under normal pressure and at room temperature. Acryl groups have been added to the corresponding amines by Michael addition reaction under microwave conditions. First and second generation dendrimers of corresponding cores have been successfully obtained[3]. After the characterization of the dendrimers, the metal complexing properties were studied for Cr(III), Co(II), Ni(II), Cu(II),Zn(II), Cd(II), Pb(II) and Ag(I) ions in aqueous solution using the Liquid-Phase Polymer-Based Retention (LPR) method.

General Outlook

In general, most divergently generated 1-2 branched dendrimers were assembled by addition of simple nonbranched monomers by means of a Michael reaction, whereas most of the 1-3 branched dendrimers have been prepared using preformed 1-3 branching (mini)dendrons or monomers, which were constructed via a predendron. Utilizing these precursors or monomers in the convergent synthesis with a central core gives the synthetic advantage of having fewer reactions occurring within a single molecule. This greatly reduces the number of branching and focal defects within the macromolecule, compared with those constructed using the purely divergent method of synthesis, yielding near uniformity and monodispersity in many cases. Upon construction of the layers or generations as they are commonly called, the number of surface groups on a tetravalent core for a 1-3 branched dendrimer increases faster than that of a 1-2 branched dendrimer. Using branched monomers offers unique opportunities to instill controlled polyfunctionalization and localized steric hindrance or protection.

The novel features of these fractal-like molecular architectures are their rich chemistry associated with the untappedinternal regime(s) as well as limitless uniform and combinatorial surface possibilities. There is unlimited potential for a wide range of utilitarian applications. Since these 1-3 branched dendritic assemblies generally utilize branching centers associated with the starting monomer, the creation of new novel functionalized monomers and their subsequent combination to generate different synthetic patterns will open doors to vast new families of synthetically generated structural organic architectures. The creation of new monomers will afford new avenues to specific nanostructures that will spark the imagination of future inventors[4].

rosario.mazarro@chem.ethz.ch

Introduction: Poly(lactic acid) (PLA) is typically produced either by direct polycondensation or by Ring-Opening Polymerization (ROP). For high molecular weight polymers and large-scale applications, ROP is the reaction of choice and it is in fact used in various commercial processes.[1-3] PLA can effectively replace conventional plastics in several different applications. In addition, it has the key advantage of degradability, which makes it environmentally compatible[4] and suitable for medical applications.[5]

The most popular industrial catalyst is Stannous Octoate ($Sn(Oct)_2$). However, although some debate in the scientific community, cytotoxicity and difficulties in removal from the resulting polymer have limited its use in several cases, especially in the case of biomedical applications.[6,7] Several groups are currently studying alternative and more biocompatible catalysts, as recently reviewed by Williams et al.[8] Among them, Zinc Octoate ($Zn(Oct)_2$) seems to be an attractive substitute of Stannous Octoate.[9,10] However, most of these studies are purely experimental, with almost no discussion about the corresponding mechanisms and kinetic scheme and very uncertain parameter values.

Aimed to study the kinetics of ROP of PLA using $Zn(Oct)_2$ as catalyst, a set of experimental data of bulk melt ROP of D,L–lactide using methanol as co-catalyst has been collected at different temperatures (140-180°C). The values of the Arrhenius parameters for propagation and intermolecular transesterification reactions are reported and a previous model[11] based on the "alkoxide initiation mechanism"[12] has been successfully applied to simulate the experimental results of conversion and molecular weights.

Results and Discussion: The livingness of the reacting system in the examined temperature range has been checked up to conversion values around 90%.

The activation energy and the pre-exponential constant of the propagation reaction were determined as: E_p = 68.33 ± 8 kJ mol^{-1} and k^0_p = 1.90 10^{11} L mol^{-1} h^{-1}. The measured value of activation energy is quite similar to the literature ones for L-lactide polymerization with $Sn(Oct)_2$.[13,14] Nevertheless, the reaction rate using $Zn(Oct)_2$ is slower than the one with $Sn(Oct)_2$, as previously observed by Penczek et al.[10] A model which includes catalyst activation, reversible propagation, reversible deactivation, inter-molecular transesterification and non-radical random chain scission has been developed to describe the evolutions of conversion and molecular weight distribution. Comparing experimental results and model predictions, the reliability of the model and of the corresponding parameter values is proved.

Conclusions: As expected, the "alkoxide initiation mechanism" has been successfully applied to the model description of D,L–lactide ROP using $Zn(Oct)_2$ as catalyst and an alcohol as co-catalyst.[12] In addition, the relevance of some side reactions, mainly transesterification and thermal non-radical random chain scission, has been verified all over the studied temperature range. On the one hand, the transesterification rate constants have been estimated. On the other hand, the role of non-radical random chain scission has been experimentally observed mainly at higher temperatures: a decrease of average molecular weight along with a broadening of the molecular weight distribution (Figure 1). According to the estimated values of the activation energies of the main reactions, an increase in temperature favors always the broadening of the molecular weight distribution by a major contribution of the abovementioned side reactions.

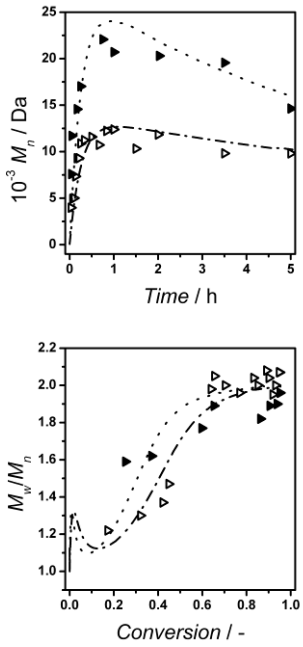

Figure 1. Number-average molecular weight versus time (above) and dispersity versus conversion (below) for D,L-lactide polymerization at 180°C, M/C = 10,000 and different ROH/C ratios. Symbols: experimental data. Lines: model results.

ROH/C: ▷ and dash-dotted line = 100; ▶ and dotted line = 50.

Emulsion Polymerization of Oleic Acid-based Monomers

Mónica Moreno, M. Goikoetxea, M. J. Barandiaran

POLYMAT, University of the Basque Country, Avda. Tolosa 72, 20018, Donostia-San Sebastián,Spain

monica.moreno@ehu.es

Introduction. The macromolecular materials that surround us today are mostly derived from petrochemical feedstock. However, the dwindling of fossil resources in the early future, together with the likely increase in price and the sense of urgency related to sustainability has pushed the scientific community to develop new synthetic routes to produce polymeric materials using renewable resources[a].
Vegetable oils, which are triglycerides composed by fatty acids, are one of the most promising renewable resources. Among the several known vegetable oils, olive and sunflower oil are the most abundant commodity oils in the Mediterranean basin. The oleic is the main component of these oils and therefore, it appears as a strong candidate as bio-based starting material.
The aim of this work is the synthesis of emulsion polymers by using oleic acid based-monomer. This strategy combines the advantages of bio-based monomers with a solvent-free polymerization technique. Nevertheless, the oleic acid double bond is not reactive enough for free radical polymerization and the incorporation of a more reactive group is required. For this purpose glycidyl methacrylate (GMA) was used since it allows the incorporation of a vinyl group at the end of the polymeric chain through a simple addition reaction between the carboxylic acid and the epoxide group of GMA[b]. On the other hand, because diffusion through the water phase of highly hydrophobic monomers is limited, conventional emulsion polymerization is precluded, and miniemulsion polymerization was found to be a suitable technique to overcome this drawback.

Materials and Methods. Stoichiometric amounts of oleic acid and glycidyl methacrylate, both purchased from Aldrich, were used to synthesize the monomer, methacrylated oleic acid. The synthesis was carried out with two different metal complex catalysts (Figure 1). Acid number titration was used to measure the amount of unreacted acid in the system. Miniemulsification of the monomer mixture and the aqueous surfactant solution was performed by sonication followed by high pressure homogenization. The miniemulsion homopolymerization reactions as well as the copolymerization reactions with the renewable monomer α-methylene γ-butyrolactone (TCI Europe), were performed in a stirred jacketed tank glass reactor equipped with a condenser and a nitrogen inlet. In all the reactions Dowfax 2A1 (Dow Chemicals) was used as emulsifier.

Results and discussion. The monomer synthesis was successfully carried out with two different transition metal catalysts, as ^{1}H-NMR spectroscopy reveals. It was also found that the aliphatic chain unsaturation was not affected during the functionalization process.

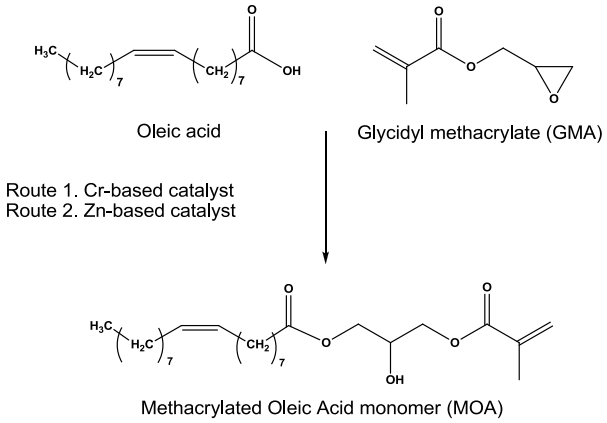

Figure 1. Synthesis of the oleic acid-based monomer

In order to analyze the role of the two catalysts in the polymerization process and the end-polymer properties, a comparative study of the polymerization kinetics as well as polymer microstructure of the two different monomers was developed by varying the initiator type. All the polymerization reactions led to high conversion. To further improve the thermal and mechanical properties of the homopolymers, the copolymerization reaction with a high Tg and bio-based monomer such as α-methylene-γ-butyrolactone is reported. The copolymers were synthesized with 5, 10 and 15% weight based monomer of comonomer and their mechanical properties were evaluated by means of tensile strength experiments as well as stickiness and hardness measurements. The thermogravimetric analysis results suggest that either the homopolymers or the copolymers presented high thermal stabilities.

Synthesis of functionalised hyperbranched polymers via Catalytic Chain Transfer Polymerisation and Thiol-ene Click Chemistry

Jasmin P. Menzel[1], *David Haddleton*[1], *Ezat Khoshdel*[2]

[1] University of Warwick, UK
[2] Unilever R&D Port Sunlight, UK

j.p.menzel@warwick.ac.uk

Introduction: Catalytic Chain Transfer Polymerisation (CCTP) is an excellent tool to synthesise vinyl terminated polymers with low molecular weights and various architectures. Using dimethacrylates hyperbranched polymers can be formed via cascade trimerisation.[1-3] In combination with thiol-ene click chemistry[4,5] a wide range of highly functionalized polymers can be synthesised with possible applications in hair and personal care or medical sciences.

Materials and Methods: All polymerisations and thermal thiol-ene click reactions were carried out under inert atmosphere. Schlenk flasks were degassed by three freeze-pump-thaw cycles.

Polymerisations: The monomer(s) (1 eq) and initiator dimethyl 2,2'-azobis(2-methylpropionate (V-601) (0.01 eq) were dissolved in an equivalent volume of 1,2-dichloroethane (DCE). A stock solution of cobalt oxime boron fluoride (COBF) in DCE was then added. Polymerisations were carried out for up to 24 h at 70 °C and samples for GPC and ^{1}H NMR were taken at regular intervals.

Phosphine catalysed thiol-ene click reactions: Thiol (1.1 eq) was added to a crude polymer mixture, followed by addition of the catalyst dimethylphenyl-phosphine (DMPP) (0.2 eq). Samples for ^{1}H NMR were taken every 30 min until completion of the reaction. Thiols used were benzyl mercaptan, 1-dodecanethiol and triisopropylsilanethiol.

Thermal thiol-ene click reaction: The initiator (0.5 eq,), macromer and thiol (5 eq) were dissolved in methylethylketone and heated to 70 °C after degassing. Samples for ^{1}H NMR were taken every 30 min until completion of the reaction. Thiols used were 11-mercapto-1-undecanol, thioglycerol, thioglycolic acid, 11-mercaptoundecanoic acid, and PEG monomethyl ether thiol (MW 1000 g/mol).

All samples were analysed by GPC (eluent THF or $CHCl_3$, both on 2 Mixed-D columns) and ^{1}H NMR (Bruker, 400 MHz).

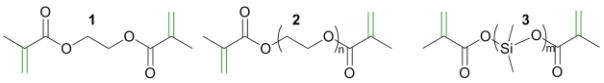

Fig. 1: Ethylenglycol dimethacrylate (EGDMA) (**1**), polyethylenglycol dimethacrylate (PEGDMA)(**2**), polydimethylsiloxane dimethacrylate (PDMSDMA) (**3**).

Results and Discussion: In this work highly functionalised hyperbranched polymers with low molecular weights were synthesised via CCTP of EGDMA and PEGDMA and subsequent DMPP catalysed Thiol-ene click reactions with different thiols (Fig. 2). GPC and ^{1}H NMR analysis showed that polymerisation up to a conversion of nearly 82 % (64 %) is possible without gelation, providing molecular weights up to 7700 g/mol (14000 g/mol) for EGDMA and PEGDMA respectively. Thiol-ene click reactions showed complete conversion in ^{1} H NMR, except for triisopropylsilanethiol where steric hindrance might have prevented inner double bonds to react.

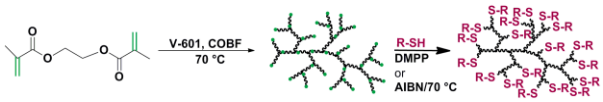

Fig. 2: Polymerisation of EGDMA and subsequent thiol-ene click reaction

Furthermore the macromonomer PDMSDMA was synthesised and functionalised via thermal thiol-ene click reactions because the catalyst DMPP caused hydrolysation of the macromonomer. Hydrolysation in different solvents over time was monitored by ^{1}H NMR (Fig. 3). It started within a few hours in DMSO whereas the compound was stable for weeks in $CHCl_3$. This shows that after functionalisation via thiol-ene click reactions small molecules can be released over time, leaving behind the plain PDMS polymer. Possible applications for this concept can be found in personal care industry or medical sciences.

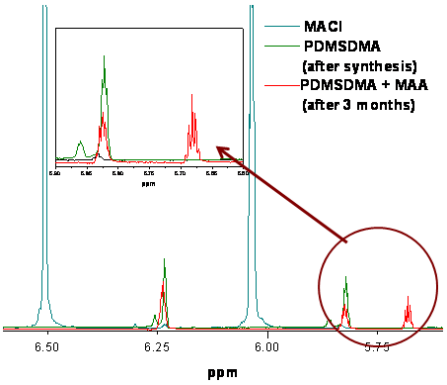

Fig. 3: Vinyl peaks of methacryloylchloride (MACl) (blue), PDMSDMA after the synthesis (green) and after partial hydrolysation into PDMS and methacrylic acid (MAA) (red).

Polymerisation of the PDMSDMA macromonomer and subsequent functionalisation are currently being investigated and will lead to even more interesting materials.

Reaction and Mass-transfer in Polycondensation Process of PA-MXD6

Zhenhao Xi[1,*], *Yong Zhao*[1] *and Ling Zhao*[1]

[1] State Key Laboratory of Chemical Engineering, East China University of Science and Technology

zhhxi@ecust.edu.cn

Poly(m-xylene adipamide) or PA-MXD6 is finding increasing use in multilayer food packaging applications due to its inherent high oxygen barrier properties, excellent heat resistance and its comparable rheology and processing conditions to polyethylene terephthalate, e.g. for use in carbonated beverage bottles. The main polycondensation reaction of PA-MXD6 is a reversible reaction which can be written as $C_E + C_E \Leftrightarrow Z + g$, and the volatile by-products especially the water have to be continuously removed to obtain desired high molecular weight. As reaction and mass-transfer are coupled in polycondensation process, the rate depends not only upon the chemical kinetics of polycondensation reaction but also upon the mass-transfer of volatile by-product through the melts. With the sharp increase of melts viscoelasticity and the decrease of the amount of by-product, the removal of the small molecules become more and more difficult, and the polycondensation process change to be mass-transfer controlled gradually. The complex interconnection between the chemical reaction and mass-transfer problem in PA-MXD6 melt polycondensation process poses a serous challenge to make process control and optimization.

In the paper, a realistic model has been proposed for the melt polycondensation process of PA-MXD6. Since chain growth reaction is equilibrium controlled, if the small molecule is removed in time, the concentration of end groups would decrease and DP would increase, chain growth reaction would go forward and reach new reaction equilibrium. By the assumption that the process could reach pseudo-steady state between the reaction and mass-transfer, the overall apparent rate of PA-MXD6 melt polycondensation process can be inferred as,

$$\frac{d[g]}{dt} = k_T([Ce]^2 - \frac{4[Z][g]^*}{K})$$, and

$$\frac{1}{k_T} = \frac{1}{k} + \frac{[Z]/K}{K_L s_w}$$

where K_L is the mass transfer coefficient, denoting the interfacial area per unit weight of polymer, k is the rate constant of forward reaction and K reaction equilibrium constant, and $[Ce]$, $[Z]$, $[g]^*$ represent the concentration of end groups, amido groups and concentration of the small molecules at the gas-liquid interface respectively.

The characteristics of reaction and the effects of mass-transfer of the PA-MXD6 melt polycondensation process were studied by using stagnant film experiments in this paper, see Fig.1. The experiments were carried out using pre-polymers with different molecular in the range of the temperature 240-280℃, pressure 50-1500Pa and film thickness 1-10mm, and the change of end groups in melts with time of the process were investigated, see Fig.2. It was shown experimentally that the devolatilization in this process is form-devolatilization. The results indicated that with thinner film which means the greater mass-transfer specific interfacial area, the intrinsic viscosity increases faster; the apparent rate of the polycondensation process was also increased under high temperature and low degree of vacuum. Based on the experiments, the parameters of above model were fitted and the apparent kinetics of polycondensation process could be showed as follows,

$$\frac{d[g]}{dt} = (\frac{1}{\frac{1}{0.2418e^{-40703/RT}} + \frac{1}{1.0611Ks_w}})([Ce]^2 - \frac{4[Z][g]^*}{K})$$

And the interfacial concentration of small-molecules $[g]^*$ can be calculated by the limit of reversible reaction as follows,

$$[g]^* = A\exp(E_g/T) \times P = 9.5513 \times 10^{-8} \exp(1396.1/T) \times P$$

Introduction

Fluorinated polymers play an important and innovative role in various technological and scientific industrial sectors. They may show outstanding and peculiar properties when high demanding requirements, such as thermal and chemical stability, are needed.

The development of new materials needs the support of analytical tools suitable to give precise and useful structural information.

In this respect vibrational spectroscopy (IR, Raman) contributed in the past and is still contributing in the determination of chemical composition, microstructure (sequence of monomers/chemical groups) and functional end groups [1-3]. More recently, the approach of Two Dimensional Correlation spectroscopy [4,5] has been successfully applied to the study of different phenomena:

i) kinetics of chemical reactions (deblocking and crosslinking) [6]
ii) spectral trends as a function of composition [7]
iii) hydrogen bonded systems and aggregation phenomena [8]

The description of the above topics is here presented and summarised.

Materials and Methods

The examples reported are related to Perfluoropolyether products available on the market with the trademark names of FOMBLIN® and GALDEN®. Their chain backbone has the general chemical formula: $(CF_2CF_2O)_n(CF_2O)_m$ (statistical copolymers with n>m).

Most of their applications are in the field of high vacuum and lubrication technology.

Results and Discussion

The kinetic experiment (carried out on a sample inside the spectrometer) was aimed to follow the formation of the three dimensional urethane network. Fluorinated macromeric diols and hydrogenated isocianate structures reacted to build up the material.

The kinetic model has been developed using intensity data and 2D correlation maps, mainly the asynchronous maps. The experiments and data analysis allowed to achieve information on reaction order and helped to select the best blocking agent and time/temperature conditions for effective crosslinking.

The normal modes analysis as a function of composition allowed to identify characteristic normal modes (Raman active) arising due to the presence of peroxide groups. The overall effect of such moieties have been studied and analysed in details also by means of DFT modeling [7]. Indeed, QM modeling has been necessary to provide detailed eigenvectors description: as a matter of fact, most of the vibrations in fluorinated polymers may be considered as cooperative (not topologically localised) normal modes of vibration. The information obtained allowed to identify a localised normal mode due to the -O-O- bond stretching of peroxide moieties which is useful for analytical purposes.

The third example is focused on the study of fluorinated macromers with amidic functional groups; we observed clear spectroscopic evidences of aggregation throught hydrogen bonding. The nature and the amount of aggregates strongly depend on chemical environment, concentration and temperature. By means of accurate experimental data and QM modeling the experimental findings have been explained; three possible types of dimers and two types of trimers have been proposed for the description of the relevant aggregates. The 2D correlation approach has been applied using as perturbation both concentration and temperature [8]. The study allowed us to describe the fluorinated system also from a quantitative point of view, providing the aggregates distribution.

Conclusions

The approach combining IR and Raman experimental data with QM molecular modeling (DFT calculations) allowed to identify and assign normal modes suitable for analytical purposes in the characterisation of Fluorinated Polymers. The use of Two Dimensional Correlation spectroscopy provided us complementary piece of information with respect to usual 1D spectroscopic data and suggested further investigation on the observed spectral features.

High Temperature Asymmetrical Flow Field-Flow Fractionation (HT-AF4) - New possibilities for characterizing polyolefins

Tino Otte, Thorsten Klein, Evelin Moldenhauer

Postnova Analytics, Max-Planck-Str. 14, D-86899 Landsberg/Lech (Germany)

Tino.Otte@postnova.com

In many applications which require particular mechanically stability polyolefins with ultra-high molar mass (UHMWPE) are used. These materials often contain molecules with masses above 10^6 g/mol. Depending on the polymerization technique the material can additionally be highly branched. These two facts make a correct analysis by the common HT-SEC-procedures impossible. Shear degradation and late co-elution of large material occurs in HT-SEC caused by the porous column packing and the implemented frits.

Asymmetrical Flow Field-Flow Fractionation (AF4) is a powerful technique which widely overcomes the above mentioned limitations of SEC. The recently developed High Temperature-AF4 system from Postnova Analytics now offers the possibility to analyze ultra-high molar mass or excessively branched polyolefins correctly over the whole size range without disturbing effects like shear scission or abnormal elution.

The size-separation is determined by the different abilities of the molecules to diffuse in a cross-flow field. An empty channel is used for size separation instead of a packed column which makes the separation very gentle.

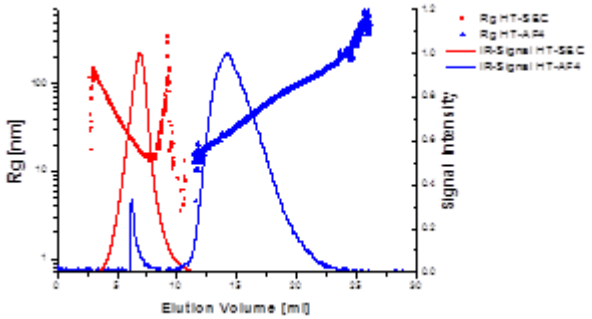

Fig. 1: Comparison of HT-SEC- and HT-AF4 separation of an UHMWPE sample

For detection infrared (IR) and static light scattering (SLS) detectors are used.

In Fig. 1 a fractogram from HT-AF4 is compared with the corresponding SEC elugram of the same UHMWPE sample. It is visible that larger radii can be detected by HT-AF4 while the SEC results are prone by shear degradation and abnormal late elution of branched species visible as a re-increase of the radius at high retention times.

While comparing results from both techniques the advantages of HT-AF4 over HT-SEC will be demonstrated in this presentation.

The efficiency of the adjustable cross-flow gradient will be shown especially with regard to the enhanced separation of the high molecular weight species. Finally the quality of the new HT-AF4 membrane is validated with narrow distributed standards and reference material.

Characterization and Applications of Aromatic-Aromatic Interactions between Water-Soluble Polymers and Low Molecular-Weight Molecules

Polyelectrolytes are suitable building blocks that can lead to nanoscale structures by means of their association with complementary charged polyelectrolytes, multivalent counterions, surfactants, or low molecular-weight molecules susceptible to undergo self-association such as liquid crystals and dyes. Long-range electrostatic interactions may be considered primary interactions between polyelectrolytes and their counterions. However, when additional secondary interactions such as hydrogen bonding, coordination binding, or aromatic-aromatic interactions are held, the general picture for the polyelectrolyte-counterion interaction may change dramatically, and is by means of these secondary interactions that supramolecular assemblies based on charged molecules can be achieved with controlled structure and geometry. Nanoscale architectures with different functionalities may thus be designed under the so-called ionic self-assembly (ISA).[1]

Aromatic-aromatic interactions are one of the principal noncovalent forces governing molecular recognition and biomolecular structure. They are important in the stabilization of DNA and its association with intercalators. They also play an important role in protein stabilization and protein functionality, as in enzymes, trans-membrane channels, etc. The major contribution to aromatic-aromatic interactions arises from van der Waals interactions, including solvofobic effects, while short-range electrostatic interactions determine the geometry of the interaction. As a result of the planar geometries of aromatic molecules, the molecular surface/volume ratio is high compared to that of spherical particles. Then, the aggregation of aromatic groups in water may produce the release of higher amounts of surface-solvating water molecules and, consequently, an increase on the favorable entropic and enthalpic contributions to the free energy by means of classical and nonclassical hydrophobic effects. In addition to these solvent contributions, site-specific interactions such as short-range electrostatic interactions, hydrogen bond formation, π-π interactions, or cation-π interactions may also contribute to the free energy and define the geometry of the complexes.

By means of these short-range interactions, site-specific binding between the counterion and the polymeric aromatic functional groups is held, and hydrophobic ion pairs are formed; these ion pairs tend to aggregate depending on the polyelectrolyte / counterion ratio, a fact that may be crucial for the behavior, structure, and properties of the systems.[2,3]

Under appropriate conditions the self-stacking tendency of aromatic counterions such as charged dyes may be overcome by the polymers, thus inhibiting the cooperative binding tendency of the counterions and showing a high dispersant ability. The dispersant ability of polyaromatic-ions may be of potential use in controlling counterion properties such as redox, luminescent, and acid-base properties. On the other hand, trapping low molecular-weight molecules as drugs, dyes, or other functional molecules in polymeric matrices of nano-, micro-, and macrometric size may need strong interactions between the species. Thus, new materials containing functional molecules, whose properties may be tuned to afford a desirable functionality, may be synthesized.

Raman Structural Analysis of Olefin – Based Materials

Yu.V. Zavgorodnev, K.A. Prokhorov, G.Yu. Nikolaeva, E.A. Sagitova, and P.P. Pashinin

A.M. Prokhorov General Physics Institute, Russian Academy of Sciences, 38 Vavilov St., 119991 Moscow, Russia

nikolaeva@kapella.gpi.ru

Introduction

We present Raman study of polymeric materials such as polyethylene (PE), isotactic polypropylene (PP), random ethylene/olefin and propylene/olefin copolymers, PE/clay and PP/clay nanocomposites, and PE/PP blends. These materials are successfully used in industry, and its applications could be expanded, if the materials properties would be additionally improved or adjusted to pre-specified consumer requirements. This task can be efficiently solved by minor modification of the current material production technologies.

Raman spectroscopy is very informative and convenient technique for evaluation of a polymer structure in terms of the chemical composition, the degree of crystallinity, the phase and conformational states, and the orientational order of macromolecules. One of important advantages of this method is the possibility to analyze the state of macromolecules in both crystalline and amorphous phases.

Results

For PE and isotactic PP we carried out theoretical and experimental study of the intensity dependence of some Raman lines on the degree of molecular orientation. It was found that the second and the fourth coefficients in the expansion of the orientation distribution function could be determined by measurement of two depolarization ratios of the Raman lines. These depolarization ratios should be measured at parallel and perpendicular orientations of the axis of molecular orientation with respect to the direction of the laser polarization.

We studied Raman spectra of the samples, oriented uniformly to certain draw ratios, and spectra, recorded in the sample necking region during the spatial scanning from isotropic part to oriented one. Degree of molecular orientation in the crystalline and amorphous phases of PE and isotactic PP is shown to grow rapidly in the initial stages of plastic deformation and change insignificantly afterwards.

For intercalated PE/clay and PP/clay nanocomposites, the presence of the filler, that is modified clay, results in reduction of the orientational ability of the macromolecules, localized in the amorphous phase of the polymer matrix. The filler does not affect the orientational ability of the PE and PP crystallites.

For the first time we proposed the novel Raman method to determine the crystallinity of uniaxially drawn PE and PE/clay nanocomposites [1]. It is based on the analysis of two spectra, recorded at parallel and crossed polarizations of the exciting and scattered radiation. This allows discriminating the influence of the molecular orientation and the degree of crystallinity on the Raman intensities.

For neat PE and PE/clay nanocomposites, the degree of crystallinity is found to enhance with the increasing draw ratio. The results of the Raman method are shown to be in a good agreement with the data, obtained by the differential scanning calorimetry (DSC).

It was found out that the Raman method of analysis of neat isotactic PP structure [2] can be also applied for propylene/olefin copolymers, namely, for evaluation of the content of crystalline phase of isotactic PP and conformational composition of macromolecules. In this case, the Raman method data are in a good agreement with the investigation results of our samples by X-ray analysis and DSC.

The degree of crystallinity of the olefins copolymers was shown to depend on the relative content and chemical structure of the comonomers, and the type of the catalyst, used for the synthesis. For the propylene copolymers we have observed reduction in the content of crystallites of isotactic PP as well as in the content of the isotactic chains in the amorphous phase with decrease in the propylene content. The content of the isotactic chains in the crystallites is found to decrease faster than that in the amorphous phase. At the same propylene content, value of the total amount of the macromolecules in the helical conformation decreases with increase in length of the side chain of the incorporated monomer.

For the first time, we have measured and analyzed Raman spectra for the neat γ modification of the isotactic PP with the degree of crystallinity around 70%, and compared it with the spectra for the neat α and smectic modifications of the isotactic PP. Although the Raman spectra for the α and γ modifications were found to be very similar, the identification of the polymorph modifications was possible and could be based on measurement of the peak positions and relative intensities of the doublet, assigned to the asymmetric stretching vibrations of the CH_3 groups.

Raman spectra of the reactor and melt-mixed PE/PP blends were also studied. For both series it was shown that the ratio of the integral intensities of two Raman lines, assigned to the fundamental vibrations of the PE and PP, can be used for quantitative analysis of the PE and isotactic PP contents in the blends.

Semiflexible Macromolecules in Nanoslit Confinement

P. Cifra

Polymer Institute, Slovak Academy of Sciences, Dúbravská cesta 9, 845 41 Bratislava 45, Slovakia

cifra@savba.sk

Recent experiments in nanofluidic channel devices are used to manipulate and analyze single DNA macromolecules. The experiments in nanofludic devices are oriented towards the channel or the slit-like confinements. The understanding of macromolecular confinement of real excluded volume chains started, however, by a prediction of behavior for pure slits by Daoud and de Gennes (1). Only recently we go back to the situation of pure slit and we verify experimentally by single molecule experiments the basic principles, which are modified, however, for semi-flexible chains relatively to the original predictions for flexible macromolecules.

Important question remains still opened for the semiflexible chains under the slit confinement. Is there a clear chain stretching transition of the coil size in slit in the range between a weak and a strong confinement, similar to that in channel as predicted by Odijk for the semiflexible chains? Some recent experiments show this behavior also in the slit (2), but other experiments and simulations (3), show only a broad and gradual crossover from the de Gennes blob regime to a strong confinement regime with no distinct transition as that predicted and observed for the channel. The radius of gyration of excluded volume chain of N segments in blob regime in direction parallel to the slit of width h is predicted to behave as $R_{g\parallel} \sim N^{x} h^{-y}$, with exponents $x = 0.75$ and $y = 0.25$. We refine here molecular simulation results on slit confinement for stiff macromolecules and find only a weak transition between the blob regime and the regime of strong confinement approximately at the ratio $h/P \approx 1$, where P is the persistence length of the chain. This weak transition is visible as a change in the slope of coil size *vs* h and occurs at the same ratio as corresponding pronounced coil size transition in the channel. The scaling of coil size in the blob regime deviates also from the theoretical prediction.

For a flexible chain the exponent y is close to 0.25 as predicted for the blob regime but the scaling with N shows a mixed 2D/3D regime. The 2D exponent $x = 0.75$ is found only at a strong confinement of h close to the monomer size, while at confinement in the blob regime the exponent is 0.72. For stiffer chains we observe for the blob regime considerably smaller exponent than predicted $y = 0.25$. The strong confinement regime starts approximately at $h/P \approx 1$, similar as in the channel but the crossover is not like the saturation-like/chain stretching transition in channel according to Odijk. Instead, at stronger confinement there is only a smaller change of coil size with increasing confinement than in blob regime. The scaling with N at confinement approximately of the transition shows exponent 0.61 instead of 0.75. This change is attributed to a crossover of dimensionality and also to deviations of stiffer chains from the excluded volume regime towards the ideal chain statistics.

Both flexible and semiflexible chains indicate thus that in the slit we have only a pseudo-2D behavior in accordance with recent experiments (4) on DNA in slits of h=110 nm, approximately one Kuhn length of chain. Accepted predictions for the blob regime in slit, however, assume a 2D-behavior. More details on the chain behavior are revealed by a structure factor of the chain and orientation correlations along chain. At the smallest scale the chain behaves as a rigid rod, within the scale of the blob size (of the slit width h) structure factor corresponds to a chain in 3D and on a larger scale the coil has the expected 2D-character.

In this report we answer the question what is the main effect responsible for the observed differences from theoretical predictions. Our results indicate a combination of two effects. The first is the crossover of dimensionality, a quasi-2D-behavior of the chain in slit. The second is the tendency of stiff chain towards the ideal chain statistics as observed for the free chain and also the chain confined in channel(5), which also contributes to the lowering of the exponent x for the coil size in slit together with the crossover of dimensionality. While these results apply for realistic chain lengths also much longer chain simulations are still needed to investigate the long chain limit behavior of semiflexible macromolecules. Our results provide deeper understanding for single macromolecule manipulations in nanofluidic devices with respect to different shapes of nanoconfinement and different stiffness of macromolecules.

spevacek@imc.cas.cz

Introduction: It is well known that some polymers with amphiphilic character, including poly(vinyl methyl ether) (PVME), exhibit in aqueous solutions a lower critical solution temperature (LCST). These polymers are soluble at lower temperatures but heating above the LCST results in phase separation which, especially for polymer concentrations $c \geq 1$ wt%, manifests itself by milk-white turbidity of solutions. On the molecular level, phase separation is a macroscopic manifestation of a coil-globule transition followed by aggregation and formation of so called mesoglobules [1]. Their thermosensitivity makes these polymers interesting for biomedical and technological applications, e.g., as drug release polymers. Of various methods used in investigations of phase separation behaviour, NMR spectroscopy can play an important role providing information on phase-separated globular structures and interactions in these systems [2]. Several years ago we used ^{1}H NMR spectroscopy to investigate changes in the structure and dynamics during temperature-induced phase separation in PVME/D_2O solutions. [3,4] Here we present some new results especially on behaviour of water during the transition using NMR methods combined with optical microscopy.

Materials and Methods: PVME (Aldrich, molecular weight M_w = 60 500, $M_w/M_n \cong 3$, 59% of isotactic diads) was used to prepare PVME/D_2O solutions in the range c = 6-50 wt %. ^{1}H NMR spectra were recorded with a Bruker Avance 500 spectrometer operating at 500.1 MHz. A modified double pulsed-field-gradient spin-echo (DPFGSE) NOE pulse sequence [5] was used in one-dimensional exchange ^{1}H NMR experiment. Photomicrographs were obtained under nitrogen atmosphere using an Olympus BX51 microscope equipped with Olympus MP5Mc/OL digital camera.

Results and Discussion: For semidilute D_2O solutions of PVME (c = 2-10 wt %) we have found that ^{1}H NMR spin-spin relaxation times T_2 of HDO molecules at temperature above the LCST phase transition (309.5 K) are 1 order of magnitude shorter than those at temperature below the phase transition (305 K). This shows that at temperatures above the transition there is a portion of HDO bound in globular-like structures. In all cases there was a single line of HDO in ^{1}H NMR spectrum and the T_2 relaxation curves were exponential, indicating a fast exchange between bound and free sites. The exchange time τ_{ex} = 1.2 ms was found for PVME/D_2O solution (c = 6 wt%) from dependence of spin-spin relaxation rate on the time interval between pulses in CPMG pulse sequence. For highly concentrated PVME/D_2O solutions (c = 20-60 wt%) the existence of the separate signal of the bound HDO with ~0.74 ppm smaller chemical shift in comparison with the main HDO signal suggests a slow exchange process. To detect a slow exchange in highly concentrated PVME/D_2O solutions (c = 20-50 wt%) we applied an one-dimensional exchange ^{1}H NMR experiment with selective excitation of the main HDO signal and detection of the changes in the intensity of the signal of the bound HDO as a function of the mixing time in the modified DPFGSE NOE pulse sequence. These measurements have shown that the residence time of bound water τ_B is independent of polymer concentration in the range c = 20-50 wt% with $\tau_B \cong 2$ s, i.e., a three orders of magnitude larger value than the residence time of bound HDO in semidilute PVME/D_2O solution with c = 6 wt%. To explain this substantial difference we assumed that exchange between free and bound water is associated with diffusion process and that the observed difference in the exchange rate might be mainly in connection with different size of globular-like structures in both cases. The evidence supporting this hypothesis was obtained by optical microscopy which revealed that very large agglomerates are formed in highly concentrated PVME/D_2O solutions with dimensions ~20 times larger than the diameter ~2.5 μm of the mesoglobules formed in PVME solution with c = 6 wt%.

Conclusion: We have found that at temperature above the LCST transition the exchange between water bound in mesoglobules and free water is in highly concentrated PVME/D_2O solutions ($c \geq 20$ wt%) three orders of magnitude slower in comparison with semidilute solution. This substantial difference is in accord with our optical microscopy findings that globular-like structures are in highly concentrated solutions ~20 times larger than in PVME solution with c = 6 wt%.

Co-crystallization process of syndiotactic polystyrene/naphthalene revealed by the measurements of angular distributions of polarized fluorescence intensities

Tomohiro Sago[1*] *and Hideyuki Itagaki*[1,2]

Department of Chemistry, [1]Graduate School of Science and Technology, and [2]School of Education, Shizuoka University, 836 Ohya, Suruga-ku, Shizuoka 422-8529, Japan

f5944001@ipc.shizuoka.ac.jp

Introduction

Syndiotactic polystyrene (sPS) is known to have five crystalline forms (α, β, γ, δ and ε). In particular, the δ and ε crystalline forms are nanoporous and can cocrystallize with guest molecules in clathrate or intercalate form.

The measurements of polarized fluorescence of a chromophore in a film by rotating it around the excitation light beam, abbreviated as PFR method, are quite efficient for the determination of the arrangement of the chromophores oriented in the film. We have already successfully applied this PFR method to some systems where fluorescent molecules are highly oriented: guest molecules in a clathrate crystalline form of polymer [1] and molecules doped into polymer films [2]. In the present study, we monitored the change of positions of guest naphthalene (NP) molecules in sPS accompanied with co-crystallization process due to the exposure of NP vapors to stretched sPS films by using PFR together with WAXD mesurements.

Experimental Section

sPS films were prepared by hot-pressed method and stretched uniaxially at drawing ratio, $\lambda \approx 3$ by manual stretching machine. Drawn samples were exposed to NP vapors by changing temperatures and exposure time.

Fluorescence depolarization was measured on a Hitachi F-4500 spectrofluorometer. All the films containing NP were stuck on a holder with a circle hole whose diameter was 2.0 mm. Films were rotated by every 10° in the same plane whose center was at 60° to the exciting beam.

Results and Discussion

No crystallization occurred when sPS films were exposed to NP vapor at room temperature. Nevertheless, PFR method clarified well that the NP molecules staying in the films were distributed not uniformly but rather with a sort of orientation in the stretched amorphous sPS. On the other hand, some regular structures were found to be produced when the films were exposed at 60°C or 80°C (Figure 1). The WAXD patterns of the films exposed by NP vapor at 60°C and 80°C for 120 hrs show trans planar mesomorphic form and sPS/NP δ co-crystalline form, respectively. We examined the exposure time dependence on crystallization due to NP vapor exposure by means of PFR and WAXD.

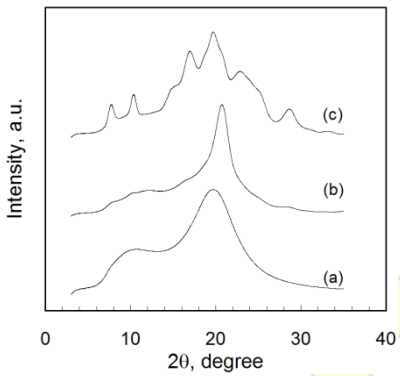

Figure 1. WAXD patterns of stretched sPS films that were exposed of NP vapor at 60ºC for 3 hrs (a), 120 hrs (b) and at 80ºC for 120 hrs (c).

Although WAXD measurements could not monitor the initial process of developing structure at all, the crystallization of sPS/NP δ cocrystals or the reaction of forming a mesomorphic structure of sPS with NP were found to proceed even after the exposure of NP at 60°C for 3 hrs by PFR method. Furthermore, we could follow the structural change with the progress of exposing time by measuring NP orientations. The NP molecules staying in the amorphous region were shown to be oriented due to the formation of a trans planar mesomorphic phase. Finally, we have succeeded to show the detail of the amorphous region of the film exposed at 60°C for 120 hrs where most NP molecules being absorbed in sPS are staying with an oriented arrangement (Figure.2). It suggested most NP molecules were oriented with an inclination: the short and long axes of NP molecule were 79º and 169 º against the stretching direction, namely the direction of the sPS polymer chains.

Moreover, we will show the PFR change that was observed along with the formation of sPS/NP cocrystals when drawn sPS films were exposed by NP vapor at 80ºC.

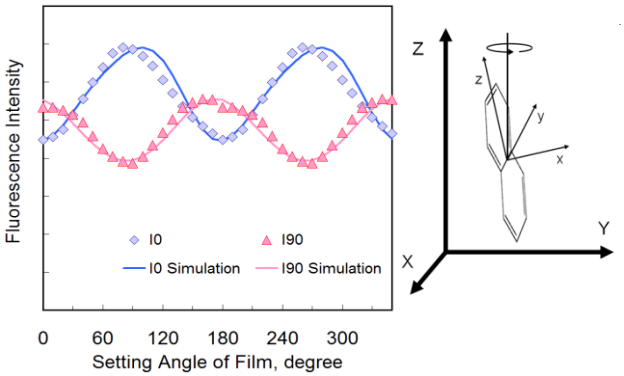

Figure 2. Angular distributions of I0 (◆) and I90 (▲) of NP in the film exposed to NP at 60ºC for 120 hrs. The solid lines show the best fitting curves of I0 and I90 for the simulated position of the NP molecule in an sPS film (Z is the stretching direction and X is the depth direction of the film).

Introduction

Mass spectrometry has become an important tool for the characterization of different macromolecules in recent years based on the development of electrospray ionization mass spectrometry (ESI-MS)[1], matrix-assisted laser desorption ionization mass spectrometry (MALDI-MS)[2-3] and atmospheric pressure chemical ionization (APCI). Although involving different processes in ion formation, all of these techniques generally allow the ionization of various macromolecules with little or no fragmentation, enabling accurate molar mass determination by making the unfragmented structure amenable to mass separation. A combination of these techniques to high-resolution mass analyzers such as quadrupole-time-of-flight (Q-TOF) instruments provides exact molar masses for the polymers analyzed with mass accuracies in the ppm region. As a result, valuable information on the chemical constitution of the macromolecule can be derived. Data from ESI, MALDI and APCI can be utilized to determine the size of repeating units as well as end group masses, average molar masses and polydispersity index values. Further structural characterization of the polymer requires oligomer ions to be fragmented in collision-induced dissociation (CID) experiments[4-5].

Materials & Methods

The polymerizations of different 2-ethyl-2-oxazolines have been performed using the microwave-assisted living cationic ring-opening polymerization. ESI-Q-TOF-MS and APCI-Q-TOF MS measurements were performed with a micrOTOF Q-II (Bruker Daltonics) mass spectrometer equipped with an automatic syringe pump from KD Scientific for sample injection. MALDI-TOF MS experiments were performed with an Ultraflex III TOF/TOF (Bruker Daltonics, Bremen, Germany) equipped with a Nd:YAG laser and a collision cell.

Results & Discussion

In this study, ESI-Q-TOF-MS, MALDI-TOF-MS, and APCI-Q-TOF-MS have been used for the detailed characterization of various poly(2-oxazoline)s with different end groups, which were synthesized via a microwave-assisted living cationic ring-opening polymerization. The detailed tandem mass measurements were performed to evaluate these methods as structural characterization tool for the detailed analysis of poly(2-oxazoline)s. The results obtained provided an understanding about the fragmentation mechanism of the poly(2-oxazoline)s. Tandem mass analysis of the poly(2-oxazoline)s revealed the elimination of small molecules such as ethene and hydrogen in their fragmentation patterns. Moreover, a McLafferty rearrangement can be a possible fragmentation route for these polymers. The information gained from this study will also help to build a tandem MS product ion library of poly(2-oxazoline)s with different end groups including fragmentation pathways which will provide necessary knowledge for the future to make a fast and automated identification of these polymers possible.

Characterisation of viscoelasticity and dynamics in polymers and proteins using DLS microrheology

Carlos A Rega, Samiul Amin and Hanna Jankevics

Malvern Instruments Ltd, Malvern WR14 1XZ, Worcestershire, UK

samiul.amin@malvern.com

The ability to precisely detect the onset of protein aggregation and draw insights into microstructural characteristics of the evolving microstructure plays a critical role in a variety of biotechnological applications, with therapeutic protein stability being a key one[1].

Rheological techniques are very sensitive to evolution of an aggregating network and although such techniques are being utilized in other fields such as foods, their use has been limited in the biotechnology area. This is primarily due to large sample volume and moderately high viscosity requirements in traditional mechanical rheometry techniques.

We propose the application of a method based on optical microrheology for the detection of the onset of protein aggregation and for developing an understanding of the nature of the evolving network structure. Optical tracer microrheology relies an determining the behaviour of tracer particles embedded in the sample of interest, and originates, with the seminal work of Phillies [2], and has evolved significantly over the last decade [3,4]. The tracer microrheology approach overcomes the limitations of mechanical rheometry, as measurements can be effectively carried out on comparatively dilute samples and require only small sample volumes.

The technique relies on the determination of the mean square displacement of the tracer particles, from which several properties of the sample can be determined, such as viscosity, the exponent of the tracer mean squared displacement power law fit and the viscoelastic modulus.

Sample viscosity can be directly obtained from the slope of the mean squared displacement using the Stokes-Einstein relation in the Newtonian regime. For non-Newtonian samples the frequency dependent viscoelastic modulus and complex viscosity can be calculated using the Generalised Stokes-Einstein relation. The elastic modulus G' emerges as a key parameter in the detection of the on-set of protein aggregation and in understanding the nature of the evolving microstructure.

Choosing the correct probe chemistry and size is highlighted as an important part of the experimental design.

In this work we present applications of the technique to the determination of the viscoelastic modulus of PEG model solutions. We also use the tracer microrheology technique to determine the transition from purely viscous (Newtonian) behaviour to viscoelastic behaviour in a range of concentrations of BSA, as well as to track the gelation process during thermal denaturation of BSA.

Relating Performance and Structure of Nanocomposites by new Methods in Time-Resolved X-ray Scattering

N. Stribeck, A. Zeinolebadi, M. Ganjaee Sari

Dept. of Chemistry, University of Hamburg, 20146 Hamburg, Germany

norbert@stribeck.de

Introduction

Structure evolution in nanocomposites during exposure to load can be monitored with increasing time- and spatial resolution at synchrotron light sources by X-ray scattering. In such experiments voluminous data series are collected. Each scattering pattern must be evaluated. For this purpose automated analysis methods are required. We apply newly developed methods [1-3] to mechanical tests of pure polymer materials and nanocomposites containing multi-wall carbon nanotubes. We are aiming at the elucidation of structure evolution mechanisms. The experiments have successfully been carried out recently. Results from a quantitative automated analysis will be presented in the contribution in movies and graphs.

Methods

Small-angle X-ray scattering (SAXS) of materials with uniaxial orientation is monitoring mechanical tests. The recorded 2D patterns are normalized and corrected for the machine background. Blind areas are filled either considering symmetry or by 2D extrapolation [4]. Applying spatial frequency filtering, the Laplacian, and Fourier transform the multidimensional chord distribution is computed [4]. The peaks in the CDFs can be associated to information related to size and arrangement of domains in the material. Movies of the peak evolution help with the choice of relevant peaks. Chosen peaks are tracked automatically. Their shape and position is automatically evaluated [1] and yield information on the nanostructure evolution. Macroscopic mechanical parameters are related to the nanostructure parameters.

Materials

Commercial thermoplastic polyurethanes (TPU) (Trelleborg Sealing Solutions) and polypropylene (PP) Moplen HP400R (LyondellBasell Industries) are the basic materials. Nanocomposites have been manufactured from these materials by blending with multi-wall carbon nanotubes (MWCNT) in different amounts and with varying compatibilization.

Results

It is observed that the mechanical properties of the TPU can considerably be improved by addition of small amounts of MWCNT, whereas the preparation of nanocomposites from the PP does not show a considerable change of the properties.

Already the raw SAXS patterns exhibit clear differences between the different preparations. Moreover, the pattern evolution is different for both basic material if nanocomposites and pure polymers are compared.

Conclusions

From a full analysis of the scattering pattern series as a function of mechanical load we expect novel insight in the mechanisms of structure evolution in two classes of polymers as a function of nanofiller content and blend composition similar to those documented in a previous study [5].

In-situ SAXS Investigation of Transient Nanostructure of Thermoplastic Polyurethane Elastomers During Thermal Treatments

N. Stribeck, A. Zeinolebadi, M. Ganjaee Sari

Dept. of Chemistry, University of Hamburg, 20146 Hamburg, Germany

zeinoleb@chemie.uni-hamburg.de

Introduction: Thermoplastic polyurethane elastomers (TPEs) are a class of polymers with versatile applications as medical devices, piezoresistive sensor elements, shape memory materials, and many others. Segmented polyurethanes are able to form several morphologies due to their special molecular architecture. Usually the soft domains form a rubbery matrix while the hard segments phase separate (crystallize) into hard domains and act as physical cross-links. Physical and mechanical properties of TPEs depend on their morphology; namely shape, size and orientation of the domains. Hence, understanding the mechanisms of morphology development has a crucial role in obtaining the desired microstructure and properties. Thermal annealing is a simple route by which the microstructure can be easily varied. During heating (cooling) TPEs go through several transitions. Accordingly, it is important to follow the transient structures in order to devise the optimum pathway toward the desired morphology. Therefore, it is essential to apply characterization methods by which the variations of microstructure can be monitored without disturbing the heating process and affecting the microstructure. X-rays do not interact with polymers and x-rays can be applied to investigate microstructure development of polymeric materials under thermal/mechanical loads from molecular level up to several hundreds of nanometers [1-4]. Thus, it is possible to follow transient microstructures of polymers and study mechanisms of microstructural developments.

Materials: Commercial grade polyurethane (soft segments: linear polycaprolactone diol, chain extender: HQEE and Hard segments: MDI) is used. The soft segment/hard segment ratio is 7/1. The material has a hardness equal to 95 based on Shore A scale. The granules are injected molded into dog-bone form at 205 °C.

Experimental Methods: SAXS is performed at the synchrotron beamline A2 at HASYLAB, Hamburg, Germany. Scattering patterns are collected by a two-dimensional position sensitive marccd 165 detector. The TPE sample is first scanned during heating up to 250 °C in order to find transition temperatures. The samples are then heated in different thermal cycles. In cycle A the sample is heated up to maximum temperature of 215 °C and then kept at this temperature for 2 minutes and then rapidly cooled down to 150 °C and kept at this temperature for 10 minutes and finally quenched to room temperature. In cycle B and C the maximum temperature is raised to 235 °C and 250 °C, respectively and the rest of the the program is the same as in cycle A.

Results: The peak intensity of SAXS patterns increased with increasing temperature until ca. 215 °C. This was attributed to the enhancement of contrast between the soft segment matrix and hard segment domains. At about 215°C the two meridional peaks disappeared and a broad strong meridional streak appeared. This pattern was attributed to dispersed laminar structures. This structure existed until 245 °C and above this temperature a typical pattern of an amorphous melt was observed. Based on these initial observations, three different thermal treatment cycles were designed in order to follow transient structures during heating and cooling. By quenching the sample from 215 °C to 150 °C a highly oriented structure developed and it was stable during quenching to 30 °C. Cooling the sample from 235 °C resulted in the same observation as the first cycle. However, cooling the sample from 250 °C resulted in a completely isotropic structure.

Conclusions: By applying synchrotron x-ray radiation it is possible to follow nanostructure transition of TPEs during heat treatment. It has been shown in this study how to obtain a highly ordered material from a partially oriented material by a simple heat treatment. The investigation of the influence of heat treatments on the mechanical and physical properties are in progress

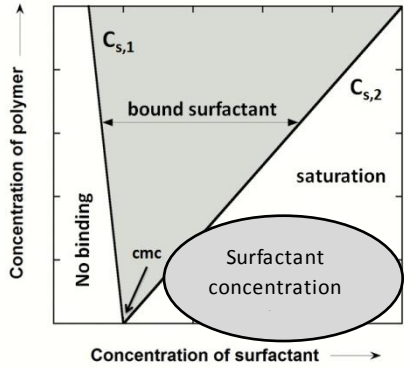
Determination of the Macromolecular Dimensions of Hydrophobically Modified Polymers by Micellar Size Exclusion Chromatography Coupled With Multiangle Light Scattering

Guillaume Dupuis[1-2], Julien Rigolini[1], Gérald Clisson[1], David Rousseau[2], René Tabary[2], and Bruno Grassl[1]

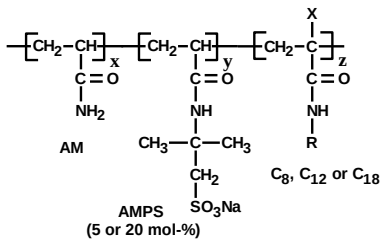
1: Institut Pluridisciplinaire de Recherche sur l'Environnement et les Matériaux (IPREM) UMR CNRS, Université de Pau et des Pays de l'Adour (UPPA) 5254, Hélioparc Pau Pyrénées, 2 Avenue du Président Angot, 64053 Pau Cedex 09, France
2: IFP Energies Nouvelles, 1 & 4 Avenue de Bois Préau, 92852 Rueil-Malmaison, France

bruno.grassl@univ-pau.fr

The present work demonstrates that the use of a nonionic surfactant in the mobile phase together with light scattering coupled to size exclusion chromatography (SEC) provides an accurate determination of macromolecular dimensions of hydrophobically modified water-soluble polymer and polyelectrolyte, *i.e.*, weight-average molar mass M_w and polydispersity I_p. This method, called micellar SEC, is based on the dissociation of the aggregates in aqueous solution and the formation of mixed micelles between the surfactant and the polymer hydrophobic groups.

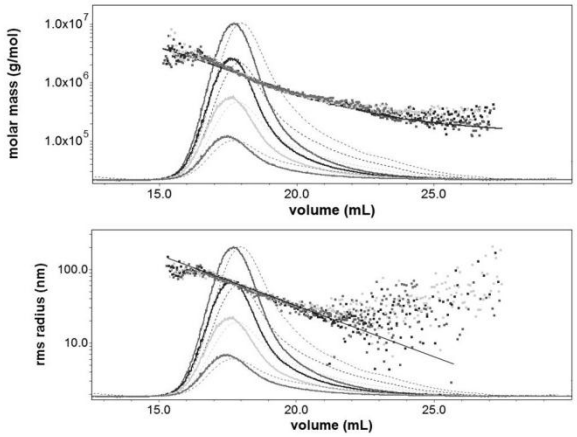


The methodology and its application are presented for synthetic sulfonated polyacrylamides (5 and 20 mol % of AMPSNa) modified with three hydrophobic alkyl side groups (C8, C12, and C18) and with Triton X-100 as a nonionic surfactant and are discussed according to the associativity of the polymers.



R	X	z (mol%)
C_8 : $C(CH_3)_2CH_2C(CH_3)_3$	H	0 or 0.5
C_{12} : $(CH_2)_{11}CH_3$,	CH_3	0, 0.1, 0.2, 0.5 or 1.0
C_{18} : $(CH_2)_{17}CH_3$,	H	0, 0.1, 0.2, 0.5 or 1.0

The method consists in the measurement of the apparent refractive index increment of the polymer-surfactant complex ($(dn/dc)_{app}$) in the mobile phase with surfactant by injecting different volumes of polymer-surfactant solution. The measurements are made using classical light scattering and concentration detectors such as multi-angle light scattering (MALS) and refractometer instruments.



The figure above shows representative chromatograms obtained for a highly associative polymer (insoluble in aqueous media) along with molar mass and *rms* radius for four amounts of injected mass. The apparent *dn*/*dc* is determined by linearization of the refractometer surface signal and the injected mass. This value is used in the ASTRA software to extract the molar mass and the *rms* radius according to the following modified Zimm-Debye equation:

$$\left(\frac{K\left(\frac{dn}{dc}\right)_{app}^2 c_p}{I(q,c_{ps})}\right) = \frac{1}{M_{w,p}}\left(1+\frac{q^2R_{g,ps}^2}{3}\right)$$

The results are compared to those obtained by classical SEC in 0.1 M $NaNO_3$ and by static light scattering (SLS) in formamide solution. First of all, MSEC-MALS allows the characterization of all the samples even those insoluble in salt solution. Secondly, the values of the weight-average molar mass determined by each of the mentioned techniques are very close. Also comparing the results obtained from MSEC-MALS and SLS shows the non-retention of the surfactant-polymer complex on the columns.

Characterization of Nanogels by a combination of Light and Small-Angle X-ray Scattering

G. Roshan Deen[1], Thomas Alsted[2], Walter Richtering[3], and Jan Skov Pedersen[2]

[1]Natural Sciences and Science Education, NIE, Nanyang Technological University, Singapore 637616.
[2]Department of Chemistry and Interdisciplinary Nanoscience Center (*iNANO*), Aarhus University, Aarhus Denmark.
[3]Institute of Physical Chemistry, RWTH Aachen University, Aachen, Germany.

Introduction

Polymer nanogels are cross-linked particles with a three-dimensional network structure that are swollen in a suitable solvent. Over the last decades these materials have been studied in relation to theoretical studies of soft matter and in applied fields such as in materials science for drug delivery, separation media, coatings, cosmetics, and sensors[1]. Depending on the type of monomers used in the synthesis of nanogels they can be made to respond to a variety of external stimuli such as pH, temperature, ionic strength, illumination, magnetic field etc [2,3]. Among the monomers reviewed in the sysnthesis of nanogels, *N*-isopropyl acrylamide (NIPAM) is the most widely studied owing to its excellent temperature-responsive behaviour.

In this work, thermo-responsive nanogels of PNIPAM were prepared by an emulsion polymerization method. The purpose of this work is to investigate the systematic influence of the added surfactant on the final size and structure of the nanogel particles. A further aim of the study is to demonstrate that the nanogels can be structurally characterized by a combination of static light scattering (SLS) and small-angle X-ray scattering (SAXS) techniques. This combination can be of a great advantage as SLS and SAXS are laboratory based techniques as opposed to small angle neutron scattering (SANS) that is carried out at large scale facilities.

Materials and Method

The nanogels particles were prepared by emulsion polymerization at 70 °C for 5 h. Different sizes of nanogels were obtained by systematically varying the amount of emulsifier in the reaction mixture. The reactants feed used in the synthesis of the nanogels are summarized in Table 1.

Table 1. Monomer feed ratios in the synthesis of nanogels at 70 °C.

Nanogel	NIPAM (g)	MBA (g)	SDS (g)	KPS (g)	Water (mL)
A	7.86	0.15	0.15	0.32	500
C	7.87	0.15	0.23	0.31	500
D	7.87	0.15	0.41	0.31	500

Static and dynamic light scattering measurements were performed on a commercially available instrument (ALV, Langen, Germany) consisting of an ALV/CGS-8F goniometer equipped with an ALV-6010/EPP multi-tau digital correlator. SAXS measurements were performed on the NanoSTAR instrument (Bruker AXS) at Aarhus University[4], which is optimized for solution scattering. The instrument in the high-resolution (low-*q*) configuration provides a range of scattering vector moduli *q* from 0.004 to 0.22 $Å^{-1}$ with a flux of 106 photons per second.

Results and Discussion

The light scattering results of the nanogels as function of emulsifier content are summarized in Table 2. With increase in the emulsifier content, nanogels of smaller size are obtained.

Table 2. Light scattering results of the nanogels in water (0.01 wt %) at 20 °C.

Nanogel	Emulsifier (g)	R_g (nm)	R_h (nm)[a]
A	0.15	117.7	153.0
C	0.30	97.2	119.0
D[b]	0.40	58.0	82.1

[a]measured at θ = 90°, [b]molar mass = 2.8×10^7 g mol^{-1}.

The combined SLS and SAXS data for the nanogel is shown in Figure 1 for the lowest (25 °C) and highest temperature (40 °C).

A very large change in the scattering with temperature is observed. One also sees a large difference in size between the two temperatures as the Guinier region is at much lower *q* values at 25 °C compared to 40 °C. The described model[6] fits the data very well at all temperatures. The radical volume fraction of the particles was also determined. At 25 °C, the particles are swollen with a broad graded outer surface. The values of *z*-average radius of gyration calculated agreed well with that obtained from Zimm analysis.

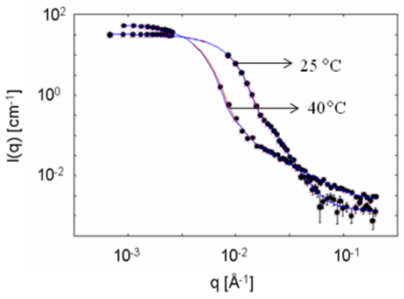

Figure 17 Combined SLS and DLS data for nanogel dispersion.

Conclusion

The combination of SLS and SAXS as applied to the microgels in the present study is an attractive method for particle characterization on a very broad length scale of almost three orders of magnitude as it spans a very large range of scattering vector from $q = 0.0004$ to 0.22 $Å^{-1}$.

ABSTRACT

Several techniques were used to study the photo-oxidation of acrylic-melamine used for automotive applications: spectroscopy, micro-hardness, DMA, HS-SPME-GC-MS, and AFM. This set of attractive complementary techniques allows us to propose a new mechanism of degradation.. In order to quantify degradation, mechanical analysis were performed, which confirmed that crosslinking reactions are prevalent during ageing. Quantitative correlations were made between the main relevant criteria of degradation, from the chemical structure to the mechanical properties.

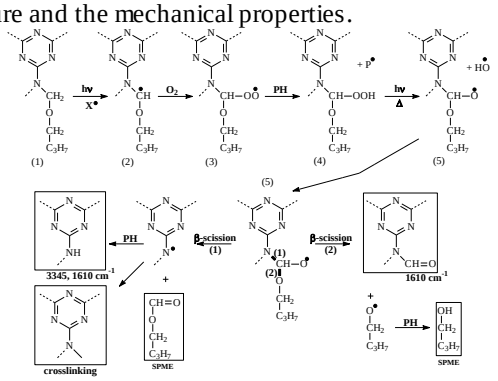
EXPERIMENTAL

A high solid thermoset acrylate polymer was used in this study. It was a solvent-based acrylic-melamine which is commonly employed as automotive clearcoat. It consists of a mixture of an acrylate-polyol copolymer and a butyl-oxylated melamine crosslinker.. Irradiations were carried out in artificial ageing conditions. The ageing device used was a SEPAP 12/24 [1] unit from Atlas.

RESULTS & DISCUSSION

1. Proposed mechanism of degradation of acrylic-melamine clearcoat

UV, IR and micro-hardness measurements of the irradiated samples were performed. The obtained results indicated that the degradation of the melamine ethers at 1085 cm^{-1}, the apparition of a CN bond at 1250 cm^{-1} and the increase of the micro-hardness are linked and can be directly correlated. On the basis of these results and on results obtained in previous works [2], we propose a new mechanism of degradation. As reported in scheme 1, this mechanism can explain the close relationship between the modifications of the chemical structure and the mechanical properties.



Sch. 1. Mechanism of photo-oxidation of acrylic-melamine.

2. Evolutions of the physical properties by DMA, DSC and AFM

DMA, DSC and AFM measurements were performed. By DMA, an increase of Tanδ, a decrease of Mc (average molecular weight between two crosslinking points) and so an increase of the crosslink density ρ was demonstrated. As shown in figure 1, these results were confirmed by the increase of Tg and surface hardness measured by DSC and AFM.

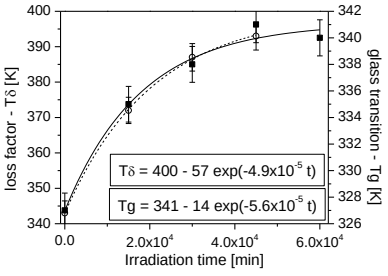


Fig. 1. Tg (black square) and Tδ (circles) versus irradiation time.

These sets of data, whatever the studied scale, confirm the network densification as well at the extreme surface of the clearcoat as in the bulk.

3. Calculation of correlation factors

Relationships between the molecular changes and the mechanical properties were attempted by using previous degradation criteria. Tg, Tan δ and micro-hardness were quantitatively correlated using *Fakirov et al.* [3] linear law. Different criteria (which were based on chemical, mechanical or physical properties) were studied using a first order kinetic law. The obtained degradation rates k were compared. As shown in table 1, very good agreement was found between all the data, which is consistent with the photo-oxidation mechanism proposed above. These kinetic constants were finally compared with k values from previous works [4-6] to validate our results.

Tab. 1. Degradation rates k for the various parameters.

Parameters	k ($min^{-1}.10^{-5}$)	standard error ($min^{-1}.10^{-5}$)	C.coeff - X^2
COC (1085cm^{-1})	4.5	± 0.1	1
CN (1250cm^{-1})	3.0	± 0.2	0.99
Hv	3.0	+/- 0.7/0.5	0.99
Tg	5.6	-	0.99
Tδ	4.9	-	1

CONCLUSIONS

This paper deals with the photo-oxidation of acrylic-melamine clearcoat. On the basis of both spectroscopic analysis/identification of the photoproducts and characterisation of the mechanical properties, we have shown that chain scissions process is not the predominant route of degradation. It has been shown that the increase of the mechanical properties can be attributed to the degradation of the residual unreacted melamine ethers, which induce the formation of new crosslinks. These new crosslinks lead to a global increase of the polymer network density, which explains the formation of cracks, as observed during the service life of coatings. We have also proved that all these evolutions are well correlated, from the microscopic scale to the macroscopic scale.

Introduction: Polymeric coatings are applied for esthetical and protective reasons on cars, planes, walls, etc. Good barrier properties for water are needed for protection. Several developments have renewed the interest in water migration. Coatings have become highly complex multilayered structures and the market has shifted to waterborne products, which are more susceptible to water. Standard techniques (gravimetry, EIS) only access average or surface properties (FTIR). They are useful for homogeneous single films, but data interpretation is difficult for multilayer and multiphasic films. Knowledge of the water distribution is crucial for better understanding. NMR imaging with a resolution of 3-5 µm is now possible with the GARField method [1]. Recently we have proven that this technique is very useful for studying cross-linking reactions in polymer layers [2] and water migration [3,4]. The presented study illustrates how water migration in multilayer coatings can be traced with NMR imaging.

Materials and methods: Water uptake and drying experiments were performed on two-layer polymeric films typical for automotive applications. In all cases the top coat (TC) was a cross-linked acrylic/PUR film and the base coat (BC) consisted of acrylic, polyurethane and pigment particles. Profiles with a resolution 5 µm were obtained with GARField NMR. Polymer-water interactions were studied on the basis of T_2 relaxation of the NMR signal.

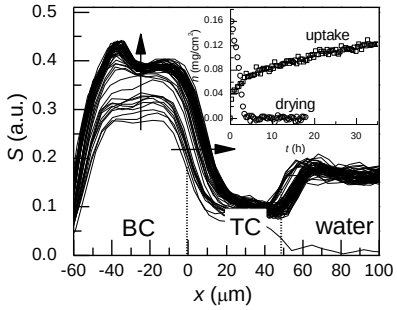

Figure 1 – *NMR profiles of a two-layer coating during water uptake. BC and TC refer to the base and top coat respectively. The vertical and horizontal arrows mark the water uptake and swelling of the BC layer. Total amounts of water in the BC layer during uptake and drying are plotted in the insert.*

Water migration: The measured signal profiles for water uptake in a typical sample are presented in the Fig.1. The base coat takes up water and swells. Water is already observed near the base coat/substrate interface in the first profiles, indicating a quick redistribution of water in this BC layer. Therefore, the kinetics of water uptake is determined by penetration through the top coat. The total amount of water in the base layer during uptake and drying is calculated from the profiles, see the insert of Fig. 1. Whereas uptake takes 100 hours before saturation, drying occurs in less then 5 hours. This asymmetry can be understood on the basis of the non-linear shape of the sorption isotherm.

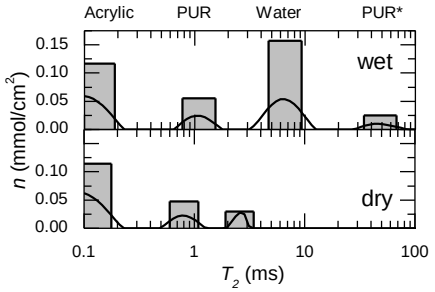

Figure 2 – *T_2 spectra of a wet (upper) and dry (lower) base coat. The lines represent spectra and the height of a bar is a measure for the intensity of a peak.*

State of water and plasticization: A typical T_2 relaxation spectrum of the wet base coat is shown in Fig. 2. Peaks of water, acrylic and the polyurethane phases are visible. The state of the water depends on the water content: the mobility of water strongly increases with the water content. Whereas at low water contents water is bounded to the polymer matrix, water is organised in big clusters at high water contents. In a completely saturated sample water has a diffusion constant a ten times smaller then the diffusion constant in liquid water. The spectra also make clear that the PUR particles in the base layer are plasticized by water.

Conclusion:
GARField NMR is very useful for probing water uptake in multilayer coatings. A huge difference in uptake and drying rates has been observed, which can be understood on the basis of the non-linear shape of the sorption isotherm.
The T_2 spectra show that water goes from a bound to a mobile state with increasing water content. Further, plasticization of the polyurethane particles is observed.
GARField NMR proves to be a versatile tool for studying water in coating films with a high spatial resolution.

NMR for Determination the Structure of New Polysulfones

Gorbunova M., Vorob'eva A., Muslukhov R.

Institute of Technical Chemistry, Ural Branch of Russian Academy of Sciences
Institute of Organic Chemistry Ufa Scientific Centre of Russian Academy of Sciences

mngorb@newmail.ru

The primary motivation for determining the structure of a polymer chain is to relate the structure to the performance properties of the polymer in end use. If a polymer chain is completely characterized and the structural basis of its properties is known, the polymerization can be optimized and controlled to produce the best possible properties from the chemical system. NMR spectroscopy has proven to be the most effective technique in chemical structure characterization, which not only permits the determination of the copolymer composition but also provides information on detailed structure of the copolymer chains.

The interest in the purposive synthesis of polyfunctional polymers is growing steadily. It is conditioned by a wide set of useful properties of mentioned polymers [1–3]. Among allyl monomers only quaternary salts of diallylammonium found an application as monomers for the synthesis of polyfunctional polymers [4]. *N*-allyl derivatives of hydrazine, diethylaminoguanidine, aminophosphonium salts are promising as monomers from this point of view. Results of investigations concerning synthesis of new polysulphones and determination of their structure by NMR are shown in presented paper.

Allyl compounds, destinguished by a tendency to degradative chain transfer to the monomer, are known to exhibit low activity in reactions of radical polymerization [5]. It was determined that new monomers – *N,N*-diallyl-*N'*-acylhydrazines, 2,2-diallyl-1,1,3,3-tetraethylguanidiniumchloride, tris(diethylamino) diallylaminophosphonium tetrafluoroborate and chloride are active in copolymerization with sulphur dioxide exhibiting high electron-acceptor activity. The study of copolymerization of new monomers with SO_2 showed the content of copolymers obtained to be of no dependence on the monomers ratio, reaction conditions - temperature, nature of initiator, medium, polymerization degree and to correspond to DAAH:SO_2 ratio 1 to 1.

Composition constancy regardless of the monomer ratio in the reaction mixture allowed to suppose that copolymerization of new allyl monomers with SO_2 proceed via formation of the complexes.

The shifts of the signals of the double bond carbon atoms denote distribution of π-electron density in molecule and formation of donor-acceptor complex [monomer···SO_2]. Magnetic equivalence of the carbon atoms of allyl groups indicates the complex structure to be symmetric.

The carried out investigations have shown that these new allyl monomers copolymerize with SO_2 both double bonds participating with formation of cis-, trans-stereoisomeric pyrrolidine structures in a cyclolinear polymer chain. The cyclolinear copolymers obtained are soluble due to the intramolecular cyclization of allyl monomers during the formation of the polymer chain and to the absence of intermolecular crosslinks.

Our results indicate that the proposed approach based on ^{13}C NMR - spectroscopy is suitable for the characterization of new polysulphones.

Introduction

The glass transition is a ubiquitous phenomenon in many materials.[1] Despite its high importance and considerable research efforts, a full understanding of this property is still lacking. In thin polymer films, interfaces complicate things as they alter the glass transition in their vicinity. Experimental approaches to study the influence of interfaces on relaxation of polymer chains are thus very challenging.[2] As a result, the glass transition at interfaces has mainly been investigated using simulations.[3]
In our contribution, we present single molecules fluorescence spectroscopy as a new methods to investigate such interfacial effects on the glass transition of polymers.

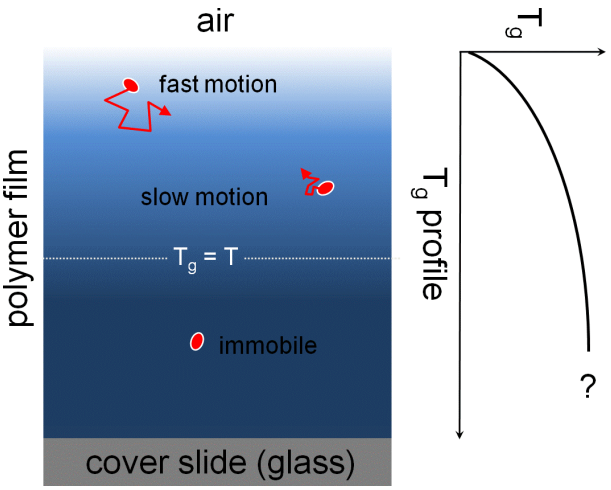
Materials and Methods

Polystyrene (M_W = 3000 g/mol, polydispersity = 1.07, bulk T_g 69 °C) was dissolved in toluene, and a sub-nM amount of perylene diimide derivatives was added as fluorescent probes. This solution was spin-coated onto ITO-glass slides, and the film tension was allowed to relaxed at 80 °C for 24 h. The fluorescence of single molecules was observed using a fluorescence microscope set to widefield-illumination and recorded with a CCD camera. Observation of the motion of single molecules at different temperatures and tracking of their motion allowed us to determine the distribution of their diffusion coefficients. To investigate the influence of the interfaces, different film thicknesses were prepared and measured. Their thickness was determined using AFM.

Results and discussion

The dynamics of single perylene diimide dye molecules embedded in a thin polystyrene film was detected using widefield fluorescence microscopy. We measured the translational diffusion coefficients of single dye molecules in thin polystyrene films up to temperatures of 150 °C and analyzed their distributions. It was shown that translational motion of different molecules was homogeneous at high temperatures and became heterogeneous at T < 105 °C.[4] We attribute the observation of heterogeneities to differences in the glass transition temperature T_g which is known to vary in the vicinity of interfaces (in our case the polymer-air and the silicon glass-polymer interface).

At high temperatures the T_g profile is obscured since the function of viscosity versus temperature is rather flat in this range. Thus, we found a homogeneous distribution of single molecule diffusion coefficients. However, when the temperature approaches bulk T_g, the molecules gradually become immobile starting from high T_g regions in the center of the film to low T_g regions at its polymer-air interface. This distance dependent relaxation time profile of the film results in significant spatial heterogeneity of single molecule motion (see Figure).



We found that interface effects in our systems reach quite far, up to ca. 100 nm, into the polymer films. Assuming a homogeneous distribution of dye molecules in the polymer film, we could construct a T_g profile and compare these profiles for films of different thicknesses.

Conclusion

We demonstrated the power of single molecule fluorescence microscopy to investigate interface-dependent glass transition profiles in thin polymer films. Our results show that surface effects have to be accounted for when motion in thin polymer films is measured and conclusions on heterogeneities are drawn.

TD-NMR investigation of nanoconfined soft phase in SEBS.

Michele Mauri, *Lucio Mauri and Roberto Simonutti*

Dipartimento di Scienza dei Materiali, Università di Milano-Bicocca, Via R. Cozzi 53 20125 Milano (Italy)

michele.mauri@mater.unimib.it

Introduction: Polymer chain dynamics can be investigated effectively by Time-Domain NMR (TD-NMR). The application of advanced pulse sequences based on exciting multiple-quantum coherences provides rich information, like crosslink density in rubbers, even with moderate technical requirements (e.g. low magnetic field). In this work we address directly the mobility of soft ethylene-butilene phases confined by glassy polystyrene (PS) blocks.

Materials and Methods: We studied two samples of polystyrene-block-poly(ethylene-co-bu-1-ene)-block-polystyrene triblock copolymers (SEBS) with 20 and 65% (mol) butene content in the midblock. Samples were cast from toluene, letting polymer organize in the lamellar morphology. [1] TEM and SAXS confirmed a lamellar structure, with alternating PS and EB blocks with few nanometers thickness. All TD-NMR experiments were performed on a Bruker Minispec mq20. DSC was performed with a Mettler-Toledo calorimeter, at 10 K/min.

Results and Discussion:
DSC analysis (Fig. 1) showed a broad endothermic transition in the sample with 20% butene (SEBS_L) upon heating from 221K to 300K. The transition was absent in the high butene copolymer (SEBS_H) that displays only a T_g at around 230K.

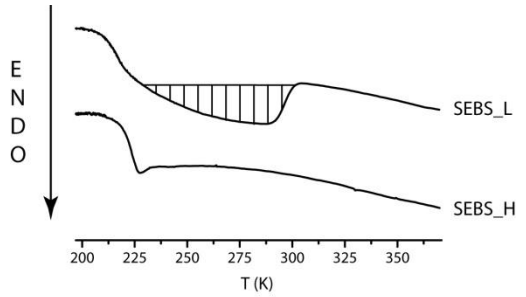

Figure 1: Comparison of thermal analysis of the copolymer samples. SEBS_H and SEBS_L contain High and Low percentage of butyl respectively.

This peculiar transition was observed in literature [2] and attributed, on the basis of indirect evidence, to a complex pseudo crystalline rearrangement of the mobile phase starting immediately above the glass transition.
Between 230 and 370K, the PS layers are below T_g and have a distinctively short T_2 while EB phase is comparatively softer, and can be investigated in depth by MQ experiments. Double quantum coherence intensity (DQ) of the mobile phase alone is normalized against a reference curve [3] and plotted versus excitation time in Fig. 2. The resulting dataset was fitted as a sum of contributions from protons with different residual dipolar coupling (D_{res}). Tichonov regularization procedure provides a distribution of D_{res} without any preliminary assumption on its functional form.

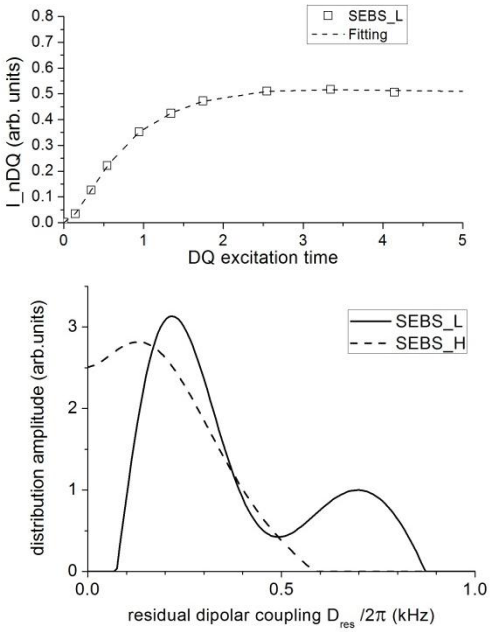

Figure 2: (above) best fitting of the normalized DQ intensity. (below) RDC distribution at 353K for the two samples.

In SEBS_H the D_{res} are rather disperse but centered around a single value. SEBS_L instead has a bimodal distribution. Because of the extremely high number of butyl side chains in the SEBS_H, the mobile phase is fully amorphous. SEBS_L, while having a number of bulky side groups that is too large for proper crystallization, exhibits areas of increased order that are compatible with a rotator phase.

Conclusions:
TD-NMR relaxometry of the EB phase of SEBS_L detects the presence of two populations of protons that are distinguished by their motional regime. This behaviour, reminiscent of EP copolymer rotator phase, is recorded directly for the first time and is probably made possible by tethering of the EB chains on both sides to PS blocks and by the resulting confinement.

Acknowledgements: We thank Prof. Kay Saalwaechter and Walter Chassé for kindly providing the nDQ fitting program and for inspiring discussion.

"Kinetics of the Aqueous phase polymerization of N-Vinylformamide "

Julieta Zataray, José Carlos De la Cal, Jose Ramon Leiza

POLYMAT-The University of the Basque Country

julietapaulina.zataray@ehu.es

INTRODUCTION

Functional polymers such as polyacrylamides, poly(N-vinylamides), poly(acrylic acid), and their copolymers find widespread applications in pharmaceuticals, waste water treatment, consumer products, paper manufacturing, and cosmetics.[1] These polymers are mostly produced by free-radical polymerization. Despite their importance, the reaction systems have been the focus of only a relative small number of academic studies.

N-Vinylformamide (NVF) is an isomer of acrylamide, is of interest because it has low toxicity, and high reactivity for homo- and copolymerization.[2] The monomer was developed as a precursor for the synthesis polyvinylamine.[3]

The goal of the present work was to study the kinetics and the mechanisms involved in the polymerization of NVF in aqueous media. For this purpose, the effect of temperature, concentration of initiator and concentration of NVF in the kinetics and molecular weight distribution (MWD) of the polyNVF produced was experimentally assessed.

A mathematical model to predict the kinetics and MWD for the aqueous phase polymerization of NVF has been developed.

MATERIALS AND METHODS

NVF monomer (Aldrich inc.) was distilled under vacuum and stored at ≤10˚C before polymerization. The free radical initiator, 2,2'-azobis(2-methylpropio-namidine)dihydrochloride (AIBA) (Aldrich Inc.) was used as received. Distilled water was used for the preparation of the polymerization solutions.

Monomer in distilled water was heated to the reaction temperature under constant stirring and nitrogen atmosphere. Once the reaction temperature was reached to the set value, polymerization was initiated by the addition of a know amount of AIBA initiator in distilled water.

All the experiments were carried out in a commercial calorimetric reactor (RC1, Mettler-Toledo). The thermal polymerization conversion was determined by the integration of the heat generation rate.

SEC-MALS for the MWD analysis was performed in the mixed eluent water/acetonitrile.

RESULTS AND DISCUSSION

The kinetics and MWD obtained in the experiments carried out at different temperatures ([I]=1.47 x 10^{-3} mol•l^{-1} and [M]=1.27 mol•l^{-1} or 9 wt%) and at different initiator concentrations ([M]=1.27 mol•l^{-1} or 9 wt% and 70˚C) presented the expected trend, which is increasing temperature and initiator concentration the polymerization rate increased and the molecular weights decreased. However, by increasing the monomer concentration the results were not expected. The conversions and Mw of the experiments were the concentration of the monomer was varied, is presented in figure 1.

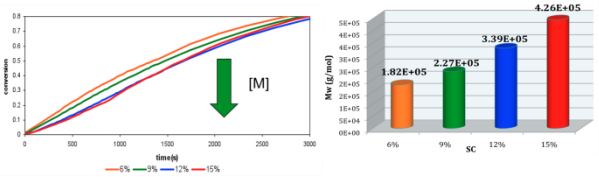

Fig.1.Time evolution of the thermal conversion (left) and Mw (right) of NVF aqueous solution polymerization, [I]=1.47x10-3 mol•L-1,T=70˚C.

As it can be seen in the conversion plot, the conventional solution polymerization was not as expected.

The mathematical model was used to analyze the whole set of experiment results. It was found that the model predicts all the trends observed when the propagation rate coefficient (Kp) was considered to depend on the temperature and monomer concentration (recently reported by PLP-SEC studies [4]) and chain transfer to polymers was taking into account.

CONCLUSIONS

Free radical polymerization kinetics of NVF was investigated in aqueous phase.

It was found that behavior of this polymerization differs from the conventional solution polymerization in organic solvents. This feature is consistent with the results previously obtained for other water-soluble monomers like non-ionized methacrylic acid, and N-Vinyl pyrrolidone [5]

Characterization of Polyfurfuryl Alcohol Resin - A New Biomass-Based Resin for Advanced Composite Materials

Domínguez, J.C.; Madsen, B.

Materials Research Division, Risø National Laboratory for Sustainable Energy, Technical University of Denmark, Frederiksborgvej 399, DK-4000 Roskilde, Denmark

jucar@risoe.dtu.dk

Furfuryl alcohol is the most widely used furanic compound for production of resins due to the simple reduction process used for its synthesis from furfural.[1] Furfural can be obtained from pentosan-rich biomass, such as sugar cane bagasse. Therefore, polyfurfuryl alcohol resins, produced from furfuryl alcohol monomer through condensation reactions, become a relatively cheap and easily produced eco-friendly type of thermosetting polymer that can be used to manufacture advanced composite materials for structural applications, such as rotor blades for wind turbines. The furan resin composites can be reinforced with traditional fibres such as carbon and glass fibres, or with natural fibres such as flax and jute fibres to make fully biomass-based composite materials.

The process development of composite materials is traditionally performed by a trial-and-error methodology based on practical experience. This methodology can be expensive and time-consuming and, ultimately, the developed composite materials might not be fully optimised. Therefore, a more rational and scientific methodology is needed to establish the optimal processing conditions with a reduced amount of experimental work. A general model for the process development of composite materials which includes several sub-models was proposed by Kenny (see Figure 1).[2]

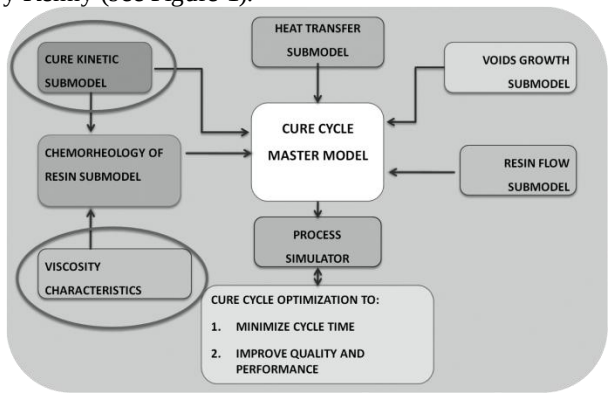

Fig. 1. General model for process development of composite materials.[2]

In order to develop such a process model, knowledge of the chemical and physical phenomena that govern the behaviour of the resin when used as matrix in the composite should be achieved. Thus, initial characterization of the resin is essential to enable a correct choice of operating conditions used in the manufacturing process of the composite materials.

The work presented here is part of a larger study of polyfurfuryl alcohol resin. It involves the determination of the curing kinetics of the resin, as well as its rheological and chemorheological parameters (the boxes indicated by ellipses in Figure 1).

Polyfurfuryl alcohol (FA) resin was supplied by TransFurans Chemicals BVBA (Belgium). The kinetics of the curing process of the FA resin was studied using a STA449 F1 Jupiter TGA-DSC equipment with low pressure pans. Non-isothermal DSC runs were carried out from 30 to 250°C using seven different heating ramps under Ar atmosphere: 4, 6, 8, 10, 12, 16 and 20°C/min. Sample weight was fixed between 30 and 35mg. Three different amounts of catalyst were tested: 2, 4 and 6% w/w.

Rheological runs were performed using an AR Rheometer with either a 25 or a 60 mm ϕ upper plate and a peltier lower plate. Normal force was zeroed and fixed during the tests to prevent contact loss between sample and plates. Gap was changed automatically to maintain constant normal force.

An nth order model was applied to analyse the values of the degree-of-cure of the resin obtained from the DSC curves. The values of the activation energies calculated for the curing of the FA resin were in the range between 187 and 193 kJ/mol for the amounts of catalyst tested.

The viscosity of the FA resin as a function of temperature was found to be linear in the range from 0 to ca. 30°C, as predicted by the Andrade model. As the temperature is increased above 30°C, the relation begins to deviate from being linear. This deviation may be due to that the tested temperature range is within the range T_g+100°C. Therefore, a WLF model was applied to the measured viscosities as well as a VTF model to describe the viscosity dependence on temperature of the FA resin.

Future work is planned to complete the characterization of the FA resin by isoconversional methods. In addition, the chemorheological behaviour of the resin will be analyzed. Finally, the general process model will be used to select the best possible operating conditions for the manufacturing of FA resin composite materials.

Didier.devaux@etu.univ-provence.fr

Safety is the ever-growing concern in electrochemical energy storage systems with, for example in liquid electrolyte battery technologies, the possibility of leaks, flammable reaction products and internal short-circuits. A solution to this problem is the development of solid polymer electrolytes (SPE). In fact, the major drawback of SPE is that mechanical strength and conductivity generally vary in opposite manner. Ionic conduction in solid polymer electrolytes depends on the movement of polymer chains [1]. High chain mobility results in high ionic conductivity but poor mechanical properties. Therefore, both properties are usually in conflict. Among the dry SPE materials available, poly(ethylene oxide) PEO and its derivatives are the most widely studied because PEO contains ether coordination sites and has a flexible macromolecular structure, which assists in dissociation of salts and improves ionic transport. A strong research effort has been devoted to the improvement of not only the ionic conductivity but also of the mechanical strength of PEO based polymer electrolytes at room temperature. Notably to improve the mechanical properties of low molecular weight (M_w) PEO, many attempts have been made to graft it to a synthetic polymer backbone to produce block copolymers [2] or comb-like polymers [3, 4]. The idea is that the polymer backbone gives the mechanical stability while preserving locally the high molecular dynamics of the small grafted PEO chains. Despite many efforts were devoted in this direction, up to now, none of the systems proposed in the literature fulfils the targeted criteria. The objective of the study is thus to model at a given temperature the ionic conductivity of such polymeric systems depending on their overall architecture and molecular weight.

For this purpose, we studied the ionic conductivity of model electrolytes based on linear PEO complexes with LiTFSI in comparison with the results of branched poly[(meth)acrylate of ethylene oxide] doped with the Li salt, using different lengths of grafted EO as well as different molecular weights. Isotherms conductivity at different temperatures enable to monitor the influence of the EO chain length and the impact of the macromolecular architecture (linear vs. branched). Based on the seminal work of Shi and Vincent[1], the data are modelled using a molecular dynamic concept in polymers which is:

- Above a critical weight, M_w^*, (called De Gennes region [5]) the conductivity is considered as constant due to chain entanglement. The backbone flexibility pilots the chain dynamic leading to the introduction of a specific excluded volume concept which depends on the architecture of the host polymer.

- Below M_w^* (called Rouse region [6]), the conductivity decreases linearly with $1/M_w$. In this domain, the macromolecular friction coefficient and the impact of the end-groups, determined by rheological experiments, significantly affect the ionic dynamic.

Introduction : Elastomeric blends are frequently used in the rubber industry, especially in tire manufacturing, in order to balance the properties that can not be obtained with any single elastomer. Such compounds can be used notably for tire tread band. The aim of this work is to investigate the morphology of two types of blends and to find a relation, as general as possible, between morphology and properties.

Materials and Methods : Three elastomers were used for this study : polybutadiene CB 22 (high 1,4-cis isomer) from Bayer (PB), styrene butadiene rubber (SBR) and natural rubber (NR), both supplied by Michelin. Two types of blends were realised in an internal mixer (Rheomix R600) at 80°C with a filling factor of 70 % : PB/SBR and NR/SBR from 100wt % PB and NR to 100wt % SBR by steps of 10 % (weight fraction). In this study, the blends are uncured and unfilled. All these blends were analysed by differential scanning calorimetry (DSC Q10 from TA Instruments) between -170°C and 100°C under helium with a 25mL/min flow. Solid state rheology was carried out between -130°C and 0°C with a strain control (ARES from Rheometrics). Pictures of morphology (for NR/SBR blends) were obtained by transmission electron microscopy (Hitachi H800-3) with a 200kV acceleration voltage. For the TEM analysis, samples were prepared with an ultra-cryomicrotome, at -120°C with a diamond knife.

Results and Discussion :

In the PB/SBR blends case, the microscopy [1] and the melt state rheology [2] were not relevant. There was no contrast between the two phases and no extra-elasticity of the storage modulus G' at low frequencies. However, some important variations of glass transition temperature, Tg PB and crystallization temperature, Tc PB, were observed in solid state rheology and DSC, respectively. These changes in Tg are linked with a change of morphology and/or a composition effect. These variations originate from the difference between the volume expansion coefficients of the two elastomers [3]. Three domains which correspond to different morphologies are observed : a droplet/matrix system under 30wt % and over 65wt % of SBR. These limits are confirmed by the selective extraction of the SBR phase. The DSC analysis shows a strong decrease of Tc PB when the quantity of SBR increases in the blend, which is explained by a partial miscibility of the two components. (This drop in Tc can not be explained by confined cristallization for low fractions of SBR) [4]. This partial miscibility leads to an interphase between the two components. The superposition of these results highlights a complex morphology with droplet/matrix systems which border a complex transition with interphases percolation (between 30wt % and 65wt % of SBR).

In the NR/SBR blends case, the close chemical structure prevents the selective solvent extraction, and none of the components crystallize. Nevertheless, the variation of Tg NR is similar to the one of Tg PB previously observed in solid state rheology. These variations of Tg NR show a change of morphology around 25wt % and 60wt % of SBR. The two elastomers NR and SBR are totally immiscible so the TEM analysis give good micrographs of the morphology over the entire composition range of NR/SBR compounds. The TEM micrographs are in good agreement with the solid state rheology results. The morphology changes from a droplet/matrix system to a co-continuity-like morphology and then a matrix/droplet system.

Conclusions : The superposition of different analytical methods was necessary for having an overview of the morphology of PB/SBR and NR/SBR blends on the entire composition range. The Tg from solid state rheology is a new way for investigating the morphology of elastomer blends. The knowledge of the morphology will now be used for studying the influence of fillers on the morphology. Carbon black will be added to these compounds. Its location and the blends morphology will be studied.

Non-linear rheological parameters for characterization of molecular structural properties in polyolefins

K. Klimke, S. Filipe, A.T. Tran

Borealis Polyolefine GmbH,
Innovation & Technology,
St.-Peter- Strasse 25, 4021 Linz, Austria

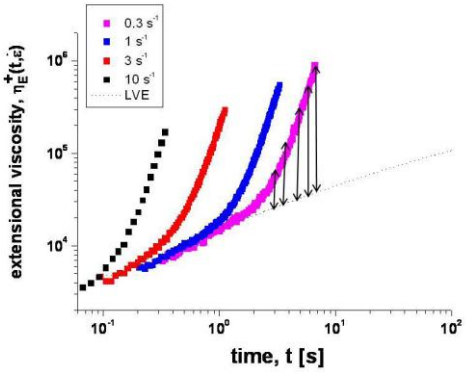
katja.klimke@borealisgroup.com

Introduction: The appropriate tailoring of molecular structure and topology requires suitable and sensitive analytical techniques with the ability to provide insight into the amount and type of long-chain branching (LCB) incorporated during either in-reactor polymerization or post-reactor modification.

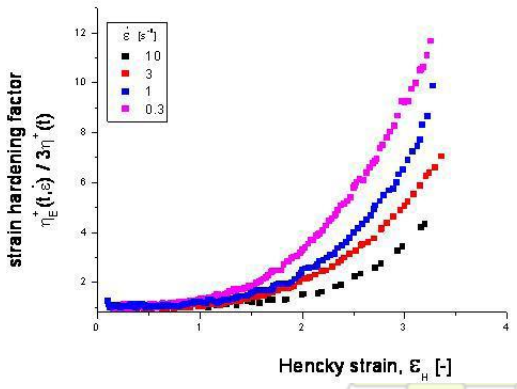
Materials and Methods: A series of different industrial polyethylene and polypropylene based systems were analyzed with respect to their rheological behavior under both uniaxial extensional flows and Large Amplitude Oscillatory Shear (LAOS). The uniaxial extensional flow experiments were used to calculate the Strain Hardening Factors (SHF) while the LAOS experiments measured the LAOS Non-Linearity Factors (LAOS-NLF).

Results and Discussion:

SHF: The SHF parameter provides a measure of the non-linearity in a material by calculating the deviation of the uniaxial extensional viscosity with respect to the linear viscoelastic envelope (LVE) [1, 2].

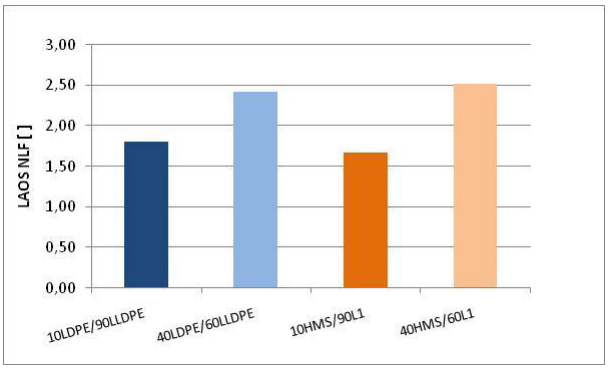


It was found that the SHF parameter can provide not only a quantitative but also a qualitative description of LCB.



The absolute SHF values were found to increase with increasing LCB content (as measured via the standard Rheotens method). However, additional analysis of the complete set of SHF curves, measured at different Hencky strain rates, also allowed insight into the quality or "homogeneity" of the branching.

LAOS-NLF: The LAOS-NLF parameter detects the non-linearity in a material under shear and is an indirect measure of the amount of LCB in the system [3, 4].



The LAOS-NLF parameter was found to provide a good quantitative description of LCB. The measured LAOS-NLF values correlated well with the LCB content. Due to its high speed and accuracy the LAOS-NLF method also has the potential to be used for quality control purposes.

Conclusions: A qualitative and quantitative description of the molecular topology for both polyethylene and polypropylene was shown to be possible by the use of specific non-linear rheological parameters determined from uniaxial extensional flow and LAOS experiments.

Rheology Behavior and study of Payne Effect in natural Rubber/Regenerated Cellulose/ Montmorillonite clay nanocomposites

Roberta M. Mariano (MSc.)[1], *Regina C. R. Nunes*[1]*(DSc.), *Leila L. Y. Visconte*[1] (DSc.)

Introduction

Sodium montmorillonite (Na-MMT) clay minerals have been used as reinforcement in rubber compositions *in nature* and in the organofilled form [1]. By exfoliating these layered silicates in water, which is accomplished by mechanical stirring at high speeds, it is possible to have the separated layers of Na-MMT and the formation of an aqueous suspension. This exfoliation process of Na-MMT can be observed by wide angle x-ray diffraction [2]. The gain in strength given by the clay-rubber nanocomposites is attributed to the structure resulting from the rubber and clay, built during processing [1,2].

Natural rubber (NR) elastomeric nanocomposites with regenerated cellulose (CEL) have been developing by this research group allowing that two polymers, one amorphous (NR) and other extremely crystalline, are incorporated in nanomaterial forms showing good physical and mechanical properties [3]

In this work, Na-MMT clay was added as filler, to nanocomposites of NR and CEL II (regenerated cellulose) in amounts varying from 0 to 5 phr (per hundred resin). NR/CELII/MMT nanocomposites were prepared by co-coagulating NR latex, montmorillonite aqueous suspension and cellulose xanthate.

Materials and Methods

Natural rubber latex (solid content 61.9%) was kindly supplied by Comércio e Beneficiamento de Látex Talismã Ltda – São Paulo, Brazil; Na-montmorillonite (Na-MMT) (Volclay SPV 200) from Wyoming, EUA was provided by Bentonit União Nordeste S. A.; and cellulose xanthate (cellulose content 9.8%) by Vicunha Têxtil S/A, São Paulo, Brazil. The vulcanizing ingredients and others additives were used as received.

Na-MMT was purified according to the literature [4]. The clay was previously exfoliated in water and the resulting suspension was then added to the mixture of NR latex with cellulose xanthate.

Results and discussion

Morphological and mechanical properties of the NR nanocomposites with and without cellulose were evaluated and an increase in tensile strength, elastic modulus as well as tear strength were observed. The rheological properties were also studied. It was observed that the addition of cellulose to NR / MMT compositions promoted increase in storage modulus as well as in the other parameters studied. By studying the Payne effect it was observed good filler-filler and filler-matrix interactions, thus allowing the identification of the best clay content to be present in the elastomeric composition [5]. Figure 1 shows the variation of storage modulus with the amplitude of deformation. It can be observed an increase in storage modulus on increasing MMT addition, attributed to the occurrence of the Payne Effect. The graph shows that the concentration limit of MMT addition is 3 phr.

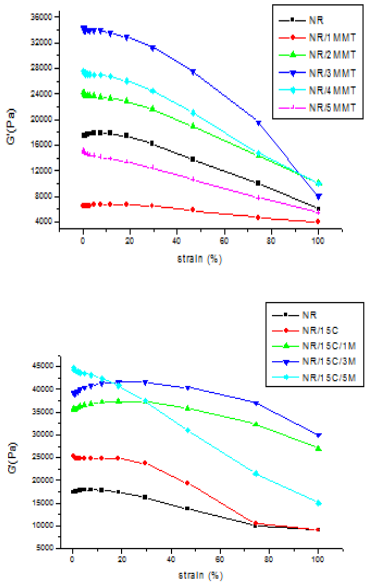

Figure 1. Payne effect study by strain sweep analysis of NR/CELII/clay nanocomposites.

Conclusions

The results show the advantage in using cellulose as a nanopolymer as well as MMT as nanofiller. The results showed that the concentration limit of MMT addition is 3 phr, which corroborates the XRD analysis. This effect can also be found in other compositions with addition of cellulose.

Two-dimensional liquid chromatography of complex polymers: PDMS-PS block copolymers

Muhammad Imran Malik, Pritish Sinha, Gareth W. Harding, Harald Pasch*

Department of Chemistry and Polymer Science, University of Stellenbosch, South Africa

Fax: +27218084967, e-mail: imran@sun.ac.za

Polymers are complex materials with distributions in many properties. These distributions include molar mass distribution, chemical composition distribution, functionality type distribution etc. amongst others. Naturally, these distributions can have enormous effects on the final properties of the materials. The development of reliable and fast characterization methods for such complex polymeric systems is one of the challenges for polymer scientists and technologists. Better and faster characterization methods lead to better and faster screening of products and helps enormously in developing improved synthesis procedures. A single technique is not sufficient for the comprehensive analysis of such complex polymers since SEC provides only relative MMD irrespective of chemical composition and the spectroscopic techniques like NMR, FTIR etc. provide only average chemical composition without any information of molar masses. Furthermore, it is more time consuming to do an analysis of two different properties by two independent runs. In addition, it has been shown previously that important information can be missed during the analysis of block copolymers if each single technique is used independently. In principle one needs N number of techniques or dimensions for the analysis of N number of properties. There must be a hyphenation of these techniques or there must be modes of characterization which are capable of analyzing the products according to a single property, ideally without or at least with only minimal effects of the other distributions.

In this study, PDMS-PS block copolymers are characterized by two-dimensional liquid chromatography. Comprehensive two dimensional liquid chromatography using LCCC as first dimension and size exclusion chromatography as second dimension reveals very important information about composition and molar masses of different fractions which were not possible by using both techniques independently.

Furthermore, by an offline approach; fractions are collected from first dimension and subjected to analysis in the second dimension. Block copolymer fractions are subjected to LCCC of the other block in the second dimension to see if there is any homopolymer of second block present in the sample. Fractions from LCCC are also analyzed qualitatively as well as quantitatively by FTIR. Different collection modes of FTIR namely ATR, transmission, reflectance and transmission in solution are compared for qualitative as well as quantitative analysis of fractions and raw samples.

Imaging Polymer Nanostructures with Scanning Transmission X-ray Spectro-Microscopy

Introduction

Polymer composite materials are of great, and increasing, technological importance in many industries. In particular, there is currently much interest in the development of polymer-based optoelectronic devices such as LEDs, lasers, FETs and solar cells. [1] However, the morphology of such materials is complex, often displaying three dimensional composition structure or molecular alignment effects. The structure of the polymer film incorporated into a device can strongly affect its performance characteristics, e.g. via the connectedness between of polymer domains and to the device electrodes, or due to anisotropic material properties due to molecular alignment. [2]

Scanning transmission x-ray spectro-microscopy (STXM) has proven to be a powerful tool for the investigation of polymer nanostructures due to its high resolution and variety of strong contrast mechanisms. Of particular interest to polymer imaging, is the molecular-structure based contrast that is achieved by tuning the incident photon energy to near-edge resonances that correspond to electronic transistions from the C 1s orbital to unoccupied π* and σ* anti-bonding orbitals. This mechanism allows strong contrast to be achieved (without labelling) between materials which differ only in molecular structure.[3,4]

Materials and Methods

STXM spectro-microscopy was performed at the PolLux beamline at the Swiss Light Source, Paul Scherrer Institut, Villigen, Switzerland.[5] The Swiss Light Source are open-access facilities, available to all researchers and free of charge for non-proprietary work.[52] TEM grid-supported films of poly(9,9'-dioctylfluorene-co-bis(N,N'-(4,butylphenyl))bis(N,N'-phenyl-1,4-phenylene)diamine) (PFB) and poly(9,9'-dioctylfluorene-co-benzothiadiazole) (F8BT) were mounted in the sample chamber. The transmitted X-ray intensity through the film was recorded using a scintillator and photo-multiplier tube and measured as a function of energy (280.0 to 320.0 eV with a resolution of 0.1 eV) and sample position (with X-ray focus better than 25 nm diameter and X-Y sample position resolution better than 1 nm).

Computation of quantitative composition maps for blend samples was achieved by fitting each pixel of the sequence of images to known spectra of the component materials. For computation of domain orientation and molecular order a rotation stage was used to rotate the sample with respect to the fixed linear polarization of the synchrotron.

Results and Discussion

Recent work at the PolLux STXM has demonstrated two new developments in the imaging of thin polymer films. Figure 1 demonstrates simultaneous imaging of the sample bulk and surface regions has been enabled by the installation of a channeltron detector (operated in TEY mode) next to the standard phosphor-coated PMT detector.[6] Secondly, Figure 2 displays a mapping of the molecular orientation within an annealed F8BT polymer film.[7] This molecular orientation mapping has been achieved via imaging at the energy of an anisotropic resonance combined with rotation of the sample and can be extended to include the out-of-plane direction through knowledge of the physical constraints of the sample material.

Comprehensive Molecular Characterization of Complex Polymer Systems with Liquid Chromatography

Dušan Berek

Polymer Institute, Slovak Academy of Sciences, 84541 Bratislava, Slovakia
Dusan.Berek@savba.sk

Molecular characteristics of macromolecules that co-determine the end-use properties of resulting polymeric materials are molar mass, chemical structure (composition) and physical architecture. All molecular characteristics of synthetic polymers exhibit a distribution. *Complex polymers* possess more than one distribution in their molecular characteristics. Typical examples are various copolymers, functional, and stereoregular polymers, as well as blends of linear homopolymers. A mixture of a complex polymer with other macromolecular substances of distinct nature is called *complex polymer system*. The quantitative data on molecular characteristics of distributed polymers are assessed by the separation methods; the field is at present dominated by high performance liquid chromatography (polymer HPLC). Molar mass distribution of synthetic polymers is most often determined by size exclusion chromatography, SEC called also gel permeation chromatography. SEC separates macromolecules according to their size in solution, which depends not only on molar mass but also on other molecular characteristics of polymers to be characterized. Therefore, SEC cannot directly produce exact, quantitative data on the molar mass averages and distributions of complex polymers and complex polymer systems. Still, SEC provides valuable information on the *tendencies* of molar mass evolution during polyreactions. As a rule, SEC cannot discriminate polymer species of different nature that possess similar size in solution. Quantitative assessment of minor (<1%) constituents of multicomponent polymers systems with help of SEC is not possible even if their molecular sizes differ substantially. This results from the low sensitivity of the SEC detectors and from the limited both sample capacity and selectivity of the SEC columns. To quantitatively characterize complex polymers and complex polymer systems, the exclusion, entropy controlled separation mechanism of SEC is to be combined with one or several interaction, enthalpy driven separation mechanisms. This approach is called coupling of retention mechanisms, and the resulting procedures are designated *coupled methods of polymer liquid chromatography*. The representatives of coupled methods of polymer HPLC are *eluent gradient liquid chromatography*, EG LC, *liquid chromatography under critical conditions of enthalpic interactions*, LC CC and *liquid chromatography under limiting conditions of enthalpic interactions*, LC LC. The principle, advantages and limitations of LC CC and LC LC methods will be elucidated and compared in the contribution. The coupling of separation mechanisms within one single HPLC column is often insufficient for separation of complex polymers, and especially for separation and molecular characterization of complex polymer systems. It is necessary to combine two different HPLC procedures executed in two independent chromatographic systems. Such combination is denoted *two-dimensional polymer high performance liquid chromatography*, for short 2D-LC or also LCxLC. Principles and limitations of the existing 2D-LC procedures will be briefly reviewed. A novel approach will be presented, namely a combination of LC LC and SEC, LC LC x SEC called *sequenced two-dimensional polymer liquid chromatography*, S2D-LC. The procedure includes fast separation of multicomponent complex polymer systems with help of appropriate LC LC procedure into defined fractions while the latter are in their entirety online transported into SEC column(s). In this way, constituents of complex polymer systems can be comprehensively characterized as to their amount and molar mass average and distribution. Minor macromolecular admixtures well below one percent can be analyzed with help of S2D-LC: this was not possible by the existing analytical methods. Typical examples of sequenced two-dimensional separations will be presented; the separation and molecular characterization of parent homopolymers in block copolymers being the important application. The aim is to facilitate the start-up experiments by selection of appropriate chromatographic system for S2D-LC and to prevent misleading, erroneous results.

Introduction

Polyamides or nylons are important engineering plastics because of their mechanical properties. Water acts as a solvent on nylon and therefore it is important to understand the water uptake process. Our study is also concerned with the uptake of electrolyte solutions because of the well known effect of ions on the mechanical properties[5] of nylon.

Materials and Methods

The water uptake process is measured using ^{1}H-MRI imaging on thin films (200 μm) of nylon 6. The used GARField[1] set-up is especially developed for measuring on thin films. This set-up enables us to follow water distributions non-destructively in time. The spatial resolution (1D) is in the order of 10 μm and the time resolution is 17 minutes.

Water Uptake

The diffusion coefficient and the moisture content profiles (inset) as obtained from the NMR measurements are shown in the figure below. Profiles show the penetration of water from the top (left side of inset figure). The moisture content (Θ) is defined as the percentage of mass increase with respect to the dry mass.

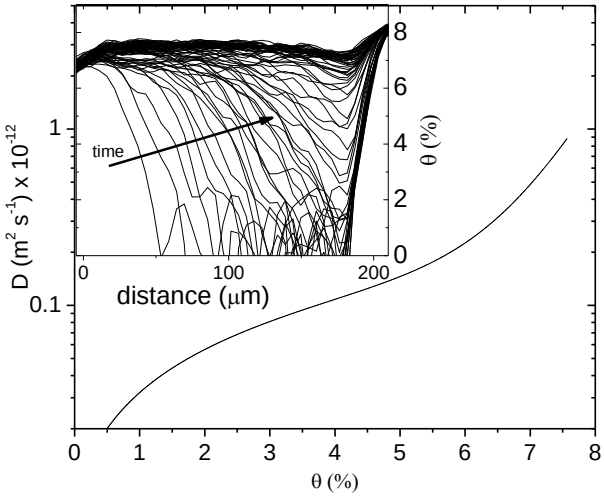

Figure 1: The relation between diffusion coefficient and moisture content. Moisture content profiles (inset).

The relation between the moisture content and the diffusion coefficient is obtained by application of the Boltzmann transformation[2]. The relation for the diffusion coefficient appeared to be highly non-linear, in contrast to other studies[2,3]. To investigate plasticization the nylon is exposed to heavy water (D_2O). In this way only hydrogen nuclei on the polymer backbone appear in the MRI signal. This reveals that the polymer contributes half of the signal during a water uptake measurement. Only a small part of the amorphous phase is plasticized enough to be detected which leads to the conclusion that the amorphous phase is heterogeneous[4] and water is absorbed into preferential zones.

Ion Ingress

Ion uptake has been studied with different salt solutions.

In the figure below profiles are shown of a nylon film is exposed to a 5M $CuCl_2$ solution. Two stages can be observed in the process. In figure 2 the first and second stage are indicated as solid and dotted lines. The first step (1) is the ingress of water in the film indicated by a signal increase at the top of the film. A second stage (2a,b), slower than the first one, is the ingress of Cu^{2+} into the nylon. The presence of copper is given away by the signal lowering (2b). The magnetic field of the copper ion causes a fast relaxation and blanks the hydrogen signal.

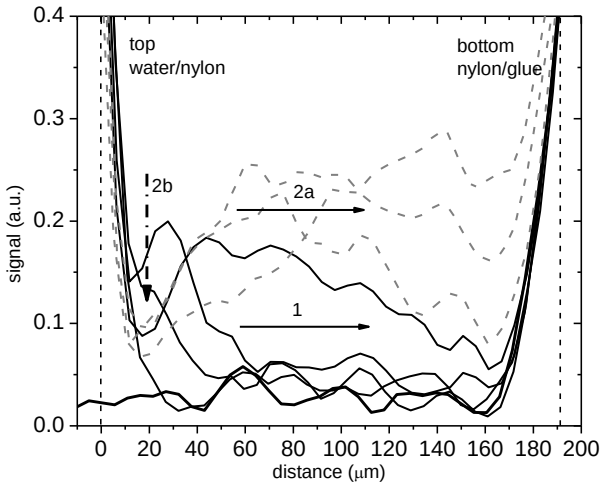

Figure 2: A nylon film exposed to a 4M $CuCl_2$ solution. Water precedes (1) the copper ions into the film (2).

For mono-valent salts such as NaCl, LiCl and KCl no ion ingress or interaction is detected. The absence is caused by the preferential hydration shell of the ions in water. Divalent ions however, can form complexes and interact with the amine group on the polyamide.

Conclusion

Water and electrolyte uptake in nylon 6 has been measured using MRI. The NMR signal is quantified and the relation between the moisture content and the diffusion coefficient is extracted. Based on the ingress of ions a distinction can be made between mono-valent or divalent ions. The paramagnetic effects of the copper ions gives away its presents while moving through the nylon.

Recent progress of polymer investigation using SAXS and WAXS laboratory setups

Pierre Panine and Sergio Rodrigues*

XENOCS SA, 19 rue François Blumet, F-38360 Sassenage, France

Keywords : small angle x-ray scattering, collimation, microfocus source, multilayer optic

pierre.panine@xenocs.com

The quality of a small angle scattering setup, the experimental time and its ultimate performances expected at low values of q-wave vector are strongly related to the flux density on the sample and the propagation towards the detector of the beam used for the experiment. In the laboratory, two strategies are coexisting, the first one is to use a convergent beam focused on the detector and the second is based on a parallel beam and long sample-to-detector distances. In the convergent case, the flux level is privileged while in the parallel beam configuration lowest values of wave vector are sought. The aim of this paper is to present the recent progress of single reflexion multilayer optics [1] and collimation devices [2]. The decisive contribution of scatterless slits in the optimization of SAXS setup will be also described. Advantages in term of brightness preservation and range of wave vector reachable, both for compact-focused and for long-collimated setups will be reviewed. Advantages of improved collimation and of new optics for the study of macromolecular solutions and for solid polymer films will be described. Performances and data of experimental SAXS and WAXS measurements on various platforms will be presented.

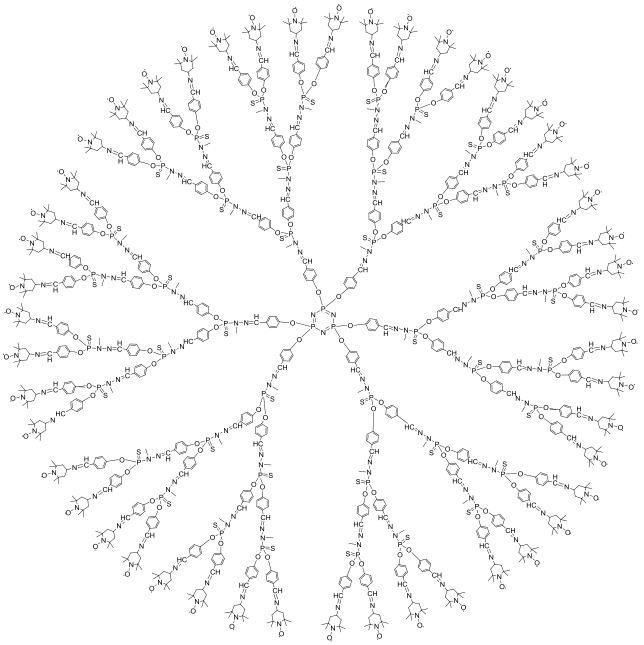
Dendrimers are a very special class of hyper branched macromolecules for which, in many cases, we can control the number of substituents and their distribution on the dendrimer surface. Our interest is focussed in the study of molecular materials based on organic radicals and their magnetic or electric properties.

There are only a few examples of self- assembled monolayers based on organic radicals[1] and fully functionalized dendrimers with organic radicals to study the magnetic behaviour.[2]

We present a series of dendrimers built with phosphorus as branching points and with ending groups that can be easily functionalized. Moreover fully branch substitution can be controlled.[3]

Molecules with many unpaired electrons, which possess high-spin ground state and stability at room temperature, are particularly challenging and promising targets. The interaction between pendant stable radicals
at the exterior of the dendritic surface and their dynamic behaviour can be studied using Electron Paramagnetic Resonance (EPR) spectroscopy. This is very important to understand the magnetic properties of these functionalized dendrimers. Here we describe four generations of phosphorus dendrimers with stable radicals ending groups as well as the crystal structure of the zeroth generation obtained by X-ray diffraction. The nitroxyl radicals at the exterior of the phosphorus containing dendrimers are found to exhibit an exchange interaction, which depends from the core and the generation of the dendrimer.



Extended structure of dendrimer **3-Gc$_3$T**

A New Generation Dual Controlled-Stress/Rate Extensional Rheometer for Polymer Melts

R. J. Andrade, P. Harris and J. M. Maia

Department of Macromolecular Science & Engineering, Case Western Reserve University, 2100 Adelbert Rd., Cleveland, OH 44106, USA

e-mail: ricardo.andrade@case.edu, patrick.harris@case.edu, joao.maia@case.edu

INTRODUCTION

Over the last 30 years Extensional Rheometry has been continually at the forefront of research in Rheometry because of its relevance to real-world flow situations and the difficulty in performing well-controlled, physically relevant experiments. In fact, the rheological properties of polymer melts in extensional flows are recognized to have a great relevance for polymer processing even when the elongational component of the flow is present to very low extents. Our group has been working in this area since the late 1990's, having developed its own experimental capability in the form of a controlled-rate extensional rheometer that is based on the Meissner principle of extension between pairs of counter-rotating rollers [1] while keeping sample length constant, albeit in our case the extension is only performed at one end, and adapts onto a rotational TA Instruments Weissenberg rheogoniometer [2]. Recently we introduced a second generation instrument working under the same basic principle but able to perform experiments in controlled stress mode in addition to the usual controlled strain [3-4].

In this work we introduce our third generation rheometer, which is a dual controlled-stress/rate extensional rheometer for high viscosity systems, again adapted to a rotational rheometer and based on the Meissner principle, but that this time uses two pairs of counter-rotating rollers to ensure deformation homogeneity. Due to its unique combination of geometrical set-up and feed-back control loop it now is possible for the first time to perform experiments on polymer melts both in controlled rate and controlled stress modes up until the point of physical rupture, whilst guaranteeing optimal deformation homogeneity, which is not the case with other instruments such as the SER, the Munstedt type of rheometers and even our previous ones. The new instrument is designated the CSER – Controlled Stress Extensional Rheometer.

MATERIALS AND METHODS

The polymer used in this work was a low-density polyethylene, reference material, Lupolen 1840H, which is a benchmark melt, and is the only material characterized in the literature in both controlled rate and controlled stress deformation modes [5-7]. The test temperature was 150 ^{o}C.

RESULTS AND DISCUSSION

The focus of the presentation will be on the validation of the CSER concept, which will be accomplished *via* the comparison of the results for LDPE with those obtained both by other authors [5,7] and with our previous instrument [3]. We will show that samples can be indeed deformed homogeneously until physical rupture occurs and that this allows us to study not only the flow behavior in both tensile creep and controlled-rate situations, but also the failure and rupture mechanisms, especially the transition from ductile to cohesive rupture at high strain rates and/or tensile stresses.

Introduction

The wide use of polymers in many industrial and domestic fields causes ecological problems connected with their utilization. Some synthetic plastics including polyolefins, as low density polyethylene (LDPE), are characterized by relatively high stabilities under both photochemical and environmental conditions for tens of years. Thus, in the presence of sunlight LDPE undergoes a series of reactions such as photolytic, photo-oxidative and thermo-oxidative, leading to chemical degradation. And as consequence its brittleness, loss of brightness, colour change, opacity and crack formation [1]. In the laboratory, this degradation might be accelerated by ultraviolet (UV) irradiation of LDPE. During irradiation activated molecules are formed, and then processes such as chain scission, cross-linking and oxidation take place [2]. The main process is the reduction in molecular weight, however the formation of carbonyl, hydroxyl and vinyl groups take also place in the LDPE molecules [3]. The presence of chains with very low molecular weight and functional groups promote and accelerate the LDPE biodegradation.

Material and Methods

In this study, LDPE film placed in both coloured and white part of store bags has been analysed. These LDPE bags have been cut into small pieces. Then, sample is irradiated with a UV source in order to cause an accelerated aging, which simulates ca. 10 year-equivalent weathering. For evaluation of the samples before and after treatment different conventional techniques have been employed such as: Fourier transformed infrared spectroscopy (FTIR) to analyse the absorption peak of functional groups, and gel permeation chromatography (GPC) to determine the molecular weigh and its distribution. As new, the analytical technique temperature rising elution fractionation (TREF) applied to diluted solution have been also used to study in and quantify the number of chains with different molecular weight. Finally, standard biodegradation experiments have been carried.

Discussion and Conclusion

Simultaneous exposure to UV light and oxygen gave as result the photo-oxidative degradation of LDPE films. As a consequence an increase of functional groups and a shift in molecular weight distribution to lower values were observed, as expected. TREF results show three crystallization peaks corresponding to three chains set with molecular weights which differ in one or more order of magnitude. Beside this, the ratio among areas under crystallization peaks indicates the photo-oxidative degradation is a homogeneous and independent process of characteristic chain (Figure 1).

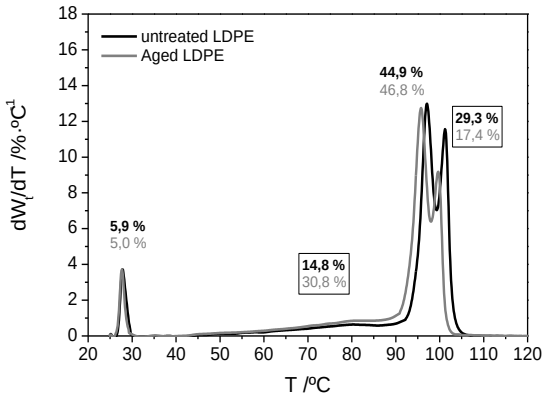

Figure 1. TREF profiles of LDPE film untreated (black color) and after accelerated aging (gray color). Areas under each crystallization peak are also indicated.

Microstructure characterization of polyolefins by high temperature HPLC

Benjamin Monrabal

Polymer Char, Valencia SPAIN

benjamin.monrabal@polymerchar.com

The introduction of single site catalysts in the polyolefins industry has opened new possibilities in polymer design through multiple reactor-catalyst systems. Very often this approach results in bimodal or trimodal composition distributions and unique composition-molar mass dependence; the performance of these resins is very sensitive to small microstructure variations. The analysis of the Chemical Composition Distribution has been, in those cases, the most important analytical task.

Typically the Chemical Composition Distribution is analyzed by crystallization techniques such as temperature rising elution fractionation. TREF (1), crystallization analysis fractionation, CRYSTAF (2) and crystallization elution fractionation, CEF (3).

The application of high temperature HPLC has been extended in the past years to the analysis of the composition distribution in polyolefins by Solvent Gradient Interaction Chromatography (4-9) and a new mode of separation by Thermal Gradient Interaction Chromatography combined with carbon based column has been introduced recently with significant success for the analysis of less crystalline polyolefins (10-11).

Recent advances in high temperature HPLC applications to Polyolefins will be presented and compared to existing crystallization techniques.

raarayah@gmail.com

Complex formation between rhodamine 6G and the polyelectrolytes poly(sodium 4-styrenesulfonate) (PSS) and poly(acrylic acid-*co*-maleic acid) (P(AA_1-*co*-MA_1)) is investigated by UV-Vis spe ctroscopy of absorbance and emission, and diafiltration. The responses in the presence of divalent metal ions were assessed with the aim of developing sensors to metal ions in aqueous environments.

It was found that the self-aggregation properties of R6G on the environment of theses polyelectrolytes change as a function of their relative concentrations and the presence of charged aromatic groups in the polymers.[1-2] In the case of the R6G-PSS complex, short-range aromatic-aromatic interactions with the benzene sulfonate groups are dominant, and the dye tends to distribute randomly on the polymeric binding sites. Association of these ion pairs can be controlled, with a consequent modulation of the system fluorescence. When long-range electrostatic interactions dominate the overall interaction between the dye and polyelectrolyte as in the case of P(AA_1-*co*-MA_1), a higher local concentration of the dye around the polymer can be found, resulting in dye self-aggregation and fluorescence quenching. When non fluorescent complexes are irradiated with UV light, a photochromic change is observed. The fluorescence of the system P(AA_1-*co*-MA_1) / R6G is enhanced, but not that of the system PSS / R6G.

The irradiated P(AA_1-*co*-MA_1) / R6G complex showed fluorescence quenching in the presence of Hg^{2+} at micromolar concentrations (Figure 1), but not in the presence of Cu^{2+} or Cd^{2+}. This behavior is attributed to a new conformational ordering of the dye on the surface of the polymer due to the influence of the metal. Contrarily, the R6G-PSS complex did not show any spectroscopic change in the presence of the metals. This behavior can be due to the high capacity of the functional aromatic groups of the polymer to held short-range interactions with the dye.

The standardization of this photochromic reaction can be tuned to develop new applications in analytical chemistry and to create devices sensitive to hazardous heavy metals in aqueous environment with high selectivity.

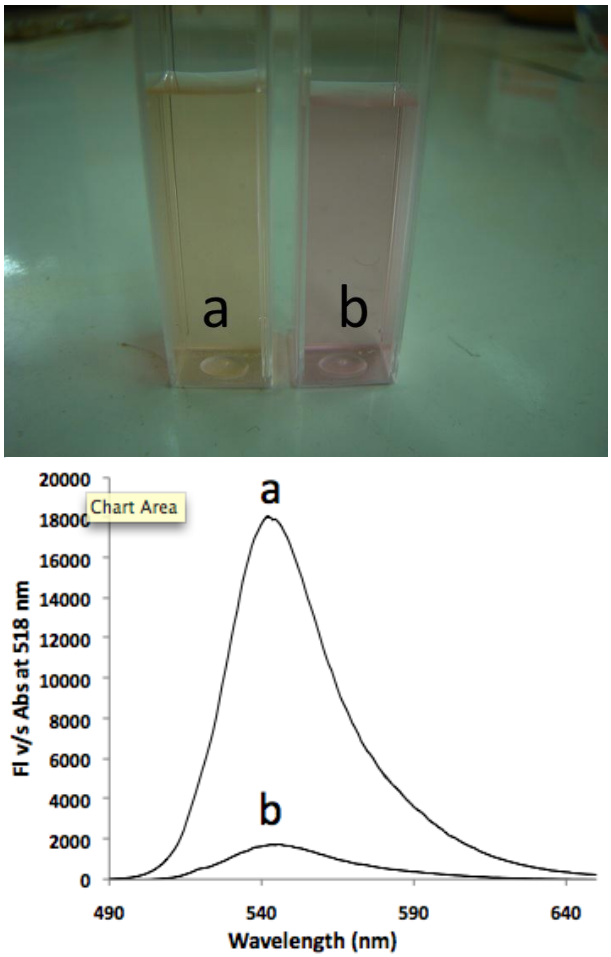

Figure 1: Emission at 600 nm versus absorbance at 520 nm (excitation wavelength) of irradiated R6G $1x10^{-5}$ M in presence of $1x10^{-4}$ M of P(AA_1-co-MA_1): (a) in absence of Hg^{2+} and (b) in prescence of $1x10^{-6}$ M of Hg^{2+}.

Local thermomechanical analysis of polymers on the sub-µm scale using heated SFM-probes

Thomas Fischinger and Sabine Hild

Department of Polymer Science, Johannes Kepler University Linz, Altenbergerstrasse 69, 4040 Linz, Austria

Thomas.Fischinger@jku.at

Instruction: Detailed information of physical and chemical properties of advanced polymers are needed to satisfy the demands of our lifestyle. Therefore, thermal analysis methods are mainly used, to provide important and reliable data. However, up to now mainly bulk properties have been detected. In order to close this gap a combination between common thermal analysis and Scanning Force Microscopy (SFM) referred to as Micro Thermal Analysis (µTA)[1)] has been designed to close this gap. In particular, due to the development of a new generation of heatable cantilever probes, in our work analysis in the sub-µm range has been realized and a variety of promising applications are offered.

Materials and Methods: Our method is based on an appropriate temperature calibration, which provides a reliable correlation between measured deflection signal and tip-temperature. For this purpose different calibration methods, such as tracking of the raman peak shift as a function of temperature as well as measurements on standard materials, has been investigated. Thermoplastic polymer standard, covering a range from 60 °C to 250 °C, serve for calibration.
With our basic experimental set-up, see Figure 1a, conventional Local Thermal Analysis (LTA) in an unpresented range of scale is available. Thus a precise detection of transition points such as melting point and softening point is possible. However, the determination of the glass transition point has reached its limits here.

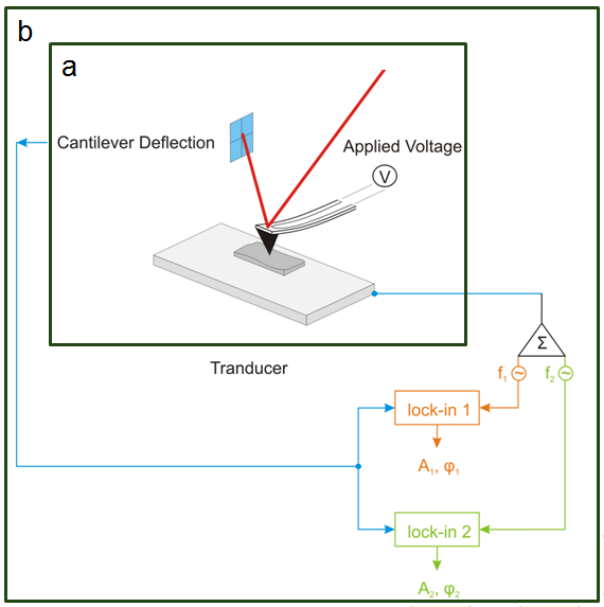

Figure 18: a) Typical LTA measurement results of a thermoplastic polymers, b) Simplified scheme of the Dual AC Resonance Tracking System.

Therefore, the LTA method is being replaced by a new technique. Dual AC Resonance Tracking (DART)[2)] is a combination of atomic force acoustic microscopy[3)] and band excitation[4)], which enables the unambiguous detection of temperature-induced changes in the contact stiffness of the tip–surface junction. As illustrated in Figure 1b, the sample is attached to a transducer element, which is modulated by two frequencies around resonance frequency. Changes in phase transition through the thermal probe, however, influence the contact stiffness of the tip-sample system and the resonance frequency. Consequently, phase transition phenomena can be detected by tracking of the resonance frequency.

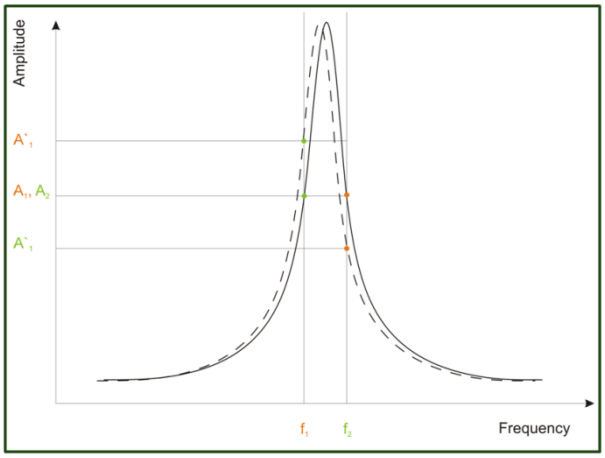

Figure 19: Resonance frequency tracking of the tip-sample system.

Results and Discussion: LTA curves measured on thermoplastic polymers, have been verified as an appropriate method to measure phase transition points. Therefore, the maximum of the derivative with respect to z-sensor signal has been proven to describe the melting point accurate. Furthermore this method is used for tip-temperature calibration. However, there is an insensitivity of glass transition detection, that results from changing contact area between tip and sample, while feedback loop keeps the force of the cantilever constant. In cotrast, the DART system is controlled by the frequency shift and independent of influences such as thermal extension and varying contact area.

Introduction

Heterogeneous systems composed of two or more phases show interfacial polarization, termed the Maxwell-Wagner-Sillars effect (MWS) (1). In heterogeneous polymeric materials interfacial polarization is almost always present. Phenomenological behavior of electrical relaxation processes in PVA hydrogels obtained by freezing/thawing technique was examined, using electric modulus (2).

Experimental

PVA with molecular weight of approximately 89,000 to 98,000 and a degree of hydrolysis 99+% (SIGMA-ALDRICH) was used to prepare 15% wt PVA hydrogel by freezing/thawing technique at 4,6 and 12 cycles. The crosslinked polymer is produced by the clustering of chains caused by the association of polar group of the dissolved polymer followed by polymer crystallization (3).

Results and discussion

The dielectric spectra obtained from -50 °C to 25 °C shows a broad secondary relaxation process, figure 1, associated to local mobility, β relaxation, which is related to the terminal polar groups (OH) this process is strong affected by the freezing/thawing cycles applied. The interfacial relaxation processes in PVA hydrogels are best described by the Havriliak-Negami model.

The Creep Behavior of Linear Low Density Polyethylene

Yakov Unigovski[1)], *Arthur Bobovitch*[2)] & *Emmanuel Gutman*[1)]

[1)] Ben-Gurion University of the Negev, 84105, Beer-Sheva, Israel
[2)] Syfan Saad (99) Ltd

e-mail: yakovun@bgu.ac.il

Introduction

The effect of density *d* and processing parameters on the creep behavior of linear low-density polyethylene (LLDPE) films with a broad range of densities has not been studied in-depth yet.

Materials and Methods

Creep behavior of 40- and 80-micron-thick films of linear low-density polyethylene with density of 0.902, 0.912, 0920 and 0.930 g/cm^3 produced by blowing and casting processes was investigated at room temperature and 70^{o}C. As a criterion for ductile creep failure, strain-to-failure was chosen, which amounts to the maximum elongation characterized by necking of the whole sample.

Results and discussion

At room temperature under the stress of 8 MPa, strain-to-failure increases by one order of magnitude (from 0.08 to 0.80) with a decrease in density from 0.930 g/cm^3 to 0.902 g/cm^3. The most marked decrease in the total strain and creep compliance as a function of *d* was found with the density increase more than 0.912 g/cm^3 both at room temperature (RT) and 70^{o}C (Fig. 1).

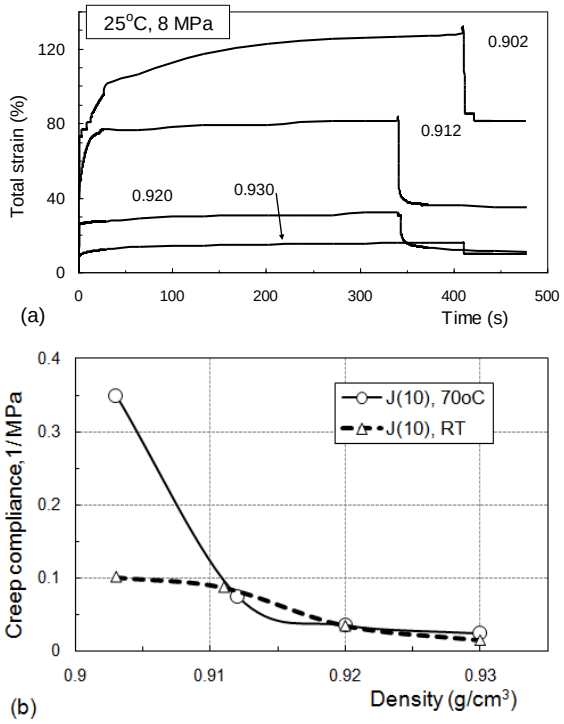

Fig. 1. Total strain (a) and creep compliance for 10 s (b) depending on the film density and the temperature.

Processing affects creep deformation much less significantly in comparison with density. The crystalline structure of cast films is much more deformed as compared to that of blown ones due to a higher cooling rate in the casting process and a higher orientation in cast film. That is confirmed by a much broader peak of orthorhombic reflection (110) in cast films in comparison to that of blown films.

It is found that under loading at room temperature, some amount of orthorhombic phase in films with the densities of 0.902 g/cm^3 and 0.912 g/cm^3 transforms into the monocline phase. For the last film a short-term loading for 0.3 h at room temperature leads to the appearance of a marked reflection (010) of monocline phase near the angle 2θ of 19.5^o (Fig. 2). With a longer test duration, the intensity of the (010) peak decreases slightly and then remains unchanged up to 165 hours (Fig. 2). Two other reflections of the monoclinic phase are heavily overlapped with the second orthorhombic reflection. Monoclinic reflection does not appear at 70^{o}C due to the instability of this phase at elevated temperatures. However, for the film with the highest density (0.930 g/cm^3) both creep load and the test temperature do not affect the morphology of orthorhombic phase.

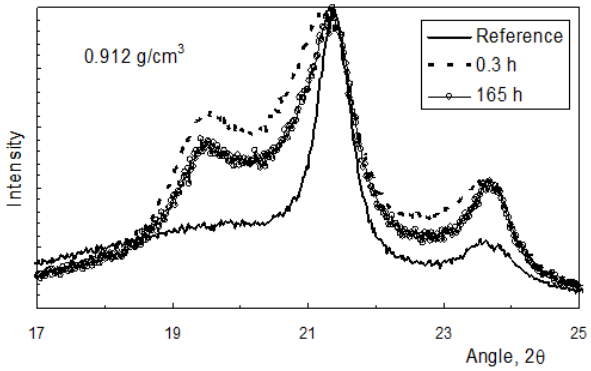

Fig. 2. X-ray patterns for the blown film with density of 0.912 g/cm^3 before and after the creep tests.

Calorimetric spectra for the polyethylene show that the crystallinity percentage and melting peak temperature of blown films increase from 29.7% to 39.7% and from 87.0^{o}C to 122^{o}C, respectively, with density increasing from 0.902 g/cm^3 to 0.930 g/cm^3. The crystallinity of blown films was slightly higher than that of cast films with the same density that can be attributed to a lower cooling rate at the production of blown films in comparison with the cast film processing.

Conclusions

-The creep strain of films is higher at lower densities, in the interval from 0.930 g/cm^3 to 0.902 g/cm^3.

-The secondary crystallization of the monoclinic phase (strain-induced crystallization) was found in films with density less than 0.920 g/cm^3 under the action of the applied stress at room temperature.

-The cast films have a less perfect crystalline structure than blown ones. However, processing affects creep much less significantly in comparison with density.

The Advantages of TOPEM in Studying the Cure of a Trifunctional Epoxy Resin (TGAP)

J M Hutchinson, F Shiravand, Y Calventus, I Fraga

Departament de Màquines i Motors Tèrmics, ETSEIAT, Universitat Politècnica de Catalunya

hutchinson@mmt.upc.edu

Introduction Epoxy resins are versatile thermosetting polymers which are widely used in various applications, including the matrix material of polymer layered silicate (PLS) nanocomposites. For high performance applications, such as the aerospace industry, there has been interest recently in the use of a trifunctional epoxy resin, triglycidyl *p*-amino phenol (TGAP), which not only has excellent mechanical properties as a result of a very highly cross-linked network structure, but also exhibits a very high glass transition temperature, T_g [1,2]. An important consequence of this last aspect is that conventional differential scanning calorimetry (DSC) cannot detect either the vitrification which occurs during isothermal cure or the $T_{g\infty}$ of the fully cured and highly cross-linked material. These are important drawbacks, since the cure kinetics is a crucial aspect of PLS nanocomposite fabrication. In this paper, we show how TOPEM, an advanced temperature modulated DSC technique, overcomes these problems, and allows a clear description of the cure kinetics of this epoxy resin.

Materials and Methods The TGAP epoxy resin (Araldite MY0510) is cured with 4,4-diamino diphenyl sulphone, DDS (Aradur 976-1), both from Huntsman Advanced Materials, in a mixture with excess epoxy (1:0.9 molar, 1:0.52 mass, epoxy:DDS). Isothermal cure temperatures of 120ºC and 150ºC were used, for times from 1 to 6 hours, followed by a second scan (non-isothermal) to obtain complete cure, and a third scan to determine $T_{g\infty}$. In the DSC experiments (DSC821e, Mettler-Toledo), the second and third scans were made at 10 K/min from 50 to 300ºC. In the TOPEM technique (DSC823e, Mettler-Toledo), stochastic temperature pulses are superimposed on the isotherm, or on the underlying heating rate of 2 K/min from 50 to 300ºC, with an amplitude of alternately ±0.5 K and random intervals between 15 and 30 s. The frequency-dependent heat capacity, C_{p0}, is obtained from the analysis, which allows vitrification to be identified during isothermal cure, and vitrification and devitrification during the non-isothermal second scan [3].

Results and Discussion A typical isothermal cure at 150ºC in the DSC is shown in Figure 1(a). Though not evident here, the sample vitrifies, as can be seen by the appearance of a glass transition and a residual cure reaction in the second scan, shown in Figure 1(b). In the third DSC scan, it is not possible to identify $T_{g\infty}$.

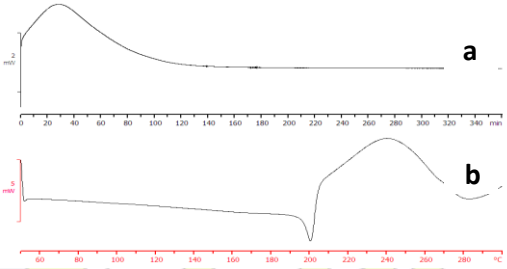

Figure1. DSC cure, 150ºC (a), DSC 2nd scan (b)

With TOPEM, on the other hand, vitrification during the first scan is clearly evident from the change in C_{p0}, as seen in Figure 2. The vitrification time of ~100 min is in excellent agreement with the value that can be found from a series of DSC experiments with increasing cure times to determine the time for which T_g in the second scan is equal to the cure temperature.

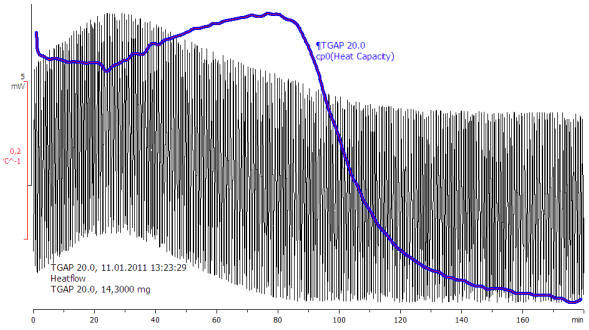

Figure 2. TOPEM isothermal cure at 150ºC

The second scan in TOPEM, shown in Figure 3, is also much more informative than is DSC. The C_{p0} curve shows three separate transitions: the glass transition of the sample after isothermal cure, vitrification almost immediately after that as the T_g increases during the residual cure, and then another devitrification at 256ºC. This temperature corresponds very closely to $T_{g\infty}$.

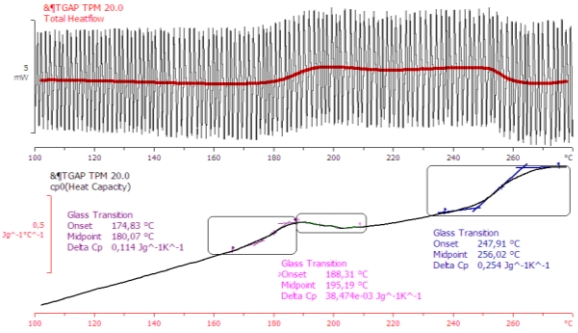

Figure 3. TOPEM second scan

Conclusions TOPEM has significant advantages over conventional DSC in characterising the isothermal cure of TGAP/DDS systems. Not only can the vitrification time be identified directly, but also the T_g of the fully cured resin can be determined with precision.

A better comprehension of the mechanisms of deformation of polymers is a requirement with the optimization of their mechanical properties [1]. We propose the Raman micro-spectroscopy to characterize the microstructure of isotactic polypropylene (thermoplastic semi crystalline) during its deformation by uniaxial traction.

A testing bench, coupling a tensile testing machine controlled by the VidéoTractionTM system and a Raman spectrometer (Figure 1) was especially developed to satisfy two experimental requirements, often neglected in former work:

I) First of all, the use of the VidéoTractionTM system gives access the true mechanical behavior of material by the instantaneous measurements of the deformation in the necking of the test-sample [2].

II) Moreover, the measurement by Raman diffusion practiced in real-time with the deformation of the test-sample makes it possible to make correspond a microstructural state in a state of deformation true all while being freed from the relieving of material observed during characterizations post-mortem [3,4].(figure 2)

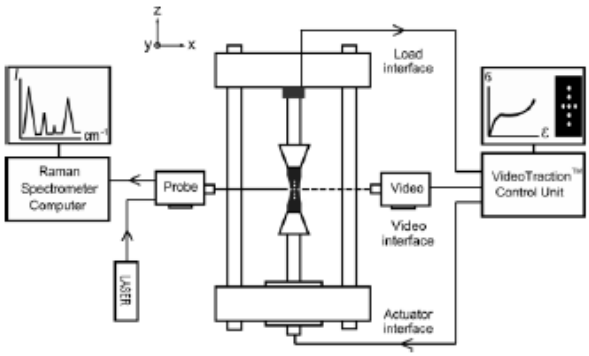

Figure 1: Schematic view of the experimental set-up coupling the VidéoTraction™-controlled tensile machine and a Raman spectrometer

On the basis of preliminary result validating the use of Raman spectral signatures suitable for the quantification of the rate of crystallinity, of the orientation of the macromolecules (amorphous and crystalline phase) and of the voluminal damage, we could follow the microstructural evolution of isotactic polypropylene during its deformation [3,4]. The results of this work make it possible to consolidate and specify certain descriptive models of the microphone-mechanisms concerned in the deformation of isotactic polypropylene and more generally of semicrystalline polymers [5,6]. (Figure 3)

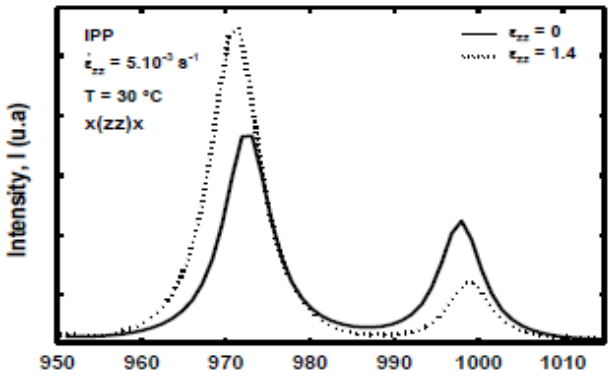

Figure 2: Polarized x(zz)x Raman spectra of iPP stretched at different strain levels.

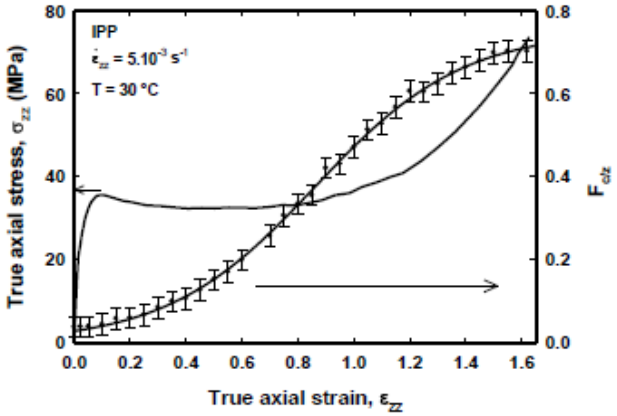

Figure 3 : Evolution of the true axial stress, σzz, and the orientation function of the crystalline phase, $F_{c/z}$, in function of the true axial strain, ε_{zz}, of iPP uniaxially stretched at T = 30 °C under a constant true strain rate ε_{zz} = 5.10-3 s^{-1}.

Lastly, this study brings an answer to the present needs (industrial and academic) for a fast, reliable method analytical, nondestructive and easily integrated in processes of workings such as the injection or extrusion.

Introduction

Extrusion is one of the most applied technologies for polymer processing of nanocomposites (NC). Application markets for NC are in automotive, electrical and electronic and packaging sectors. NC can offer improvements in several of the properties of thermoplastics including flame retardancy, tensile strength, modulus, barrier and heat distortion temperature, surface properties and electrical properties.

During the processing there is a need to control the dispersion of the nanofillers in the polymer matrix and to control the influence of the processing conditions on the dispersion in real time. The crucial point is the determination of the degree of exfoliation of the nanofillers as an indicator for the dispersion. Spectroscopic on-line measurements at different positions along and at the end of the extruder can determine the state of dispersion during processing. Our concept was to calculate the shear thinning exponent (STE) from shear viscosity measurements as a quantitative degree for the state of exfoliation. The STE was than correlated with on-line near infrared (NIR) and Ultrasonic measurements using multivariate data analysis. These methods are described in [1-4].

Materials and Methods

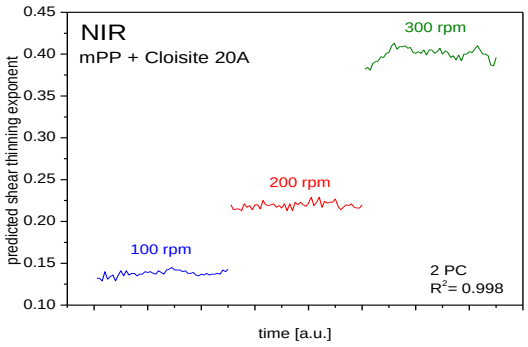
The polymers used are different polypropylenes (PP HP500 and HP522) modified with maleic anhydride (mPP). For the determination of dispersion we measured the degree of exfoliation of different nanoclays in mPP. These nanoclays were layered silicates (montmorillonite, MMT) without and with different organic modifications (Cloisite 15A and 20A, Dellite 67G).

All experiments were done at two twin screw extruders (Leistritz Micro 27 and a Maris TM45) with measuring adapters at the die and at two different positions along the extruder. These adapters were assembled with sensors for NIR and ultrasonic measurements. For the variation of the process conditions we used different screw profiles, different screw speeds, different processing temperatures and different output rates during extrusion.

For the off-line determination of the NC dispersion we used Raman Imaging, Electron microscopy and rheologic measurements by an oscillatory rheometer to measure the shear viscosity. The initial slope at low frequencies was used to calculate the shear thinning exponents (STE) [5] between 0 and 1. A value better 0.8 of the STE indicates a good exfoliation state and a low value below 0.2 indicates a bad exfoliation state.

Results and Discussion

Shear viscosity measurements at low frequencies show a pseudo-solid behavior for NC with layered silicates [5]. With decreasing frequency, an increasing viscosity is induced by interaction of the single layers of the layered silicates. The initial slope (0.05 – 0.20 Hz) of this increasing viscosity was used to calculate the STE as a quantitative degree of exfoliation. The STE were correlated with the on-line NIR and Ultrasonic spectra and show a good correlation between on-line data and off-line STE measurements. It was possible to determine the degree of exfoliation for different modified nanoclays in mPP. The investigation of the NC at the different process conditions could show the strong influence of these conditions on the exfoliation behavior of the NC. This is shown in the Figure for the real time determination of the STE for the NC mPP/Cloisite 20A at different screw speeds (100 to 300 rpm) calculated using NIR spectra.



Furthermore we investigated the dispersion process in real time along the extruder at different measurement points. The NIR and the Ultrasonic data at these different positions illustrate the improvement of the exfoliation of modified nanoclays in the mPP matrix along the extruder.

Conclusions

NIR and Ultrasonic spectroscopy can determine on-line in real-time in the melt during extrusion the degree of exfoliation of polymeric NC. It is possible to measure different dispersion states caused by different processing conditions and different modified nanofillers and to describe the dispersion process along the extruder.

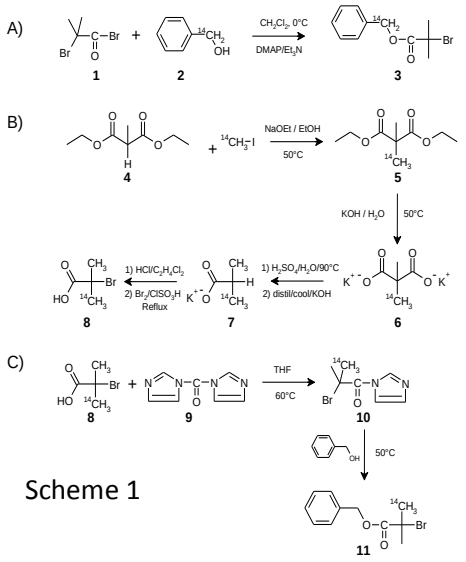
Introduction: Controlled polymerisation has been utilised for many years to generate polymers of increasing complexity for potential applications requiring increasingly stringent operating conditions or technical performance. Areas such as energy generation, data storage, light harvesting, tissue engineering, drug delivery and stimuli-responsive encapsulation/release have been the focus of much research.

Applications involving the interaction of polymer-based technologies with biological systems are often studied for their therapeutic benefit, eg drug delivery, enhanced bioavailability or efficacy. It is extremely rare that the polymers themselves are studied for residence time within the body, accumulation in tissues or cellular interactions. This is due to the difficulty in monitoring the fate of polymers used as drug carriers or tissue scaffolds etc.

To visualise and quantify the behaviour of a polymer in a highly dilute environment, it is not uncommon to label with a fluorescent dye, however it is clear that such a hydrophobic modification may affect water-soluble polymer behaviour. Radio-labeling of polymers has also been utilised, providing high levels of detection, however it is common for radio-labels to be introduced to polymers by reaction with the preformed polymer. Such chemical modification results in the evaluation of the modified polymer and extrapolation to unmodified polymer behaviour. Reactive labelling approaches also generate a distribution of labelled products which can lead to inaccuracies.

Recently we have employed ^{14}C radio-labeled Atom Transfer Radical Polymerisation (ATRP) initiators to generate polymers of controlled chain length with a single radio-labelled site (the chain end) and have studied the behaviour of the materials in simple surface adsorption experiments. Mechanistic understanding of the utilisation of ATRP initiators throughout the polymerisation has been developed and considerable variation of adsorption behaviour has been observed, driven by the nature of the initiator-derived end group.

Results and Discussion: Initially we sought to create a generic strategy for ^{14}C-labeled ATRP initiator synthesis and establish the validity of our approach through labelling at different sites within the same initiator. ^{14}C-labeled benzyl-2-bromoisobutyrate was therefore synthesised using two strategies (one utilising ^{14}C-labeled benzyl alcohol and the second involving the synthesis of ^{14}C-labeled 2-bromoisobutyric acid (Scheme 1)), and used in the polymerisation of 2-hydroxypropyl methacrylate. Through this approach it was possible to establish that all data generated through monitoring of radioactivity was consistent, indicating no cleavage of the ester end-group during polymerisation. The utilisation of the initiator



Scheme 1

throughout the polymerisation was also studied and the surprising result that new chains were being formed at high monomer conversion and long polymerisation times was observed using a combination of radio-TLC and liquid-scintillation during GPC analysis.

Two further ^{14}C-labeled ATRP initiators were synthesised

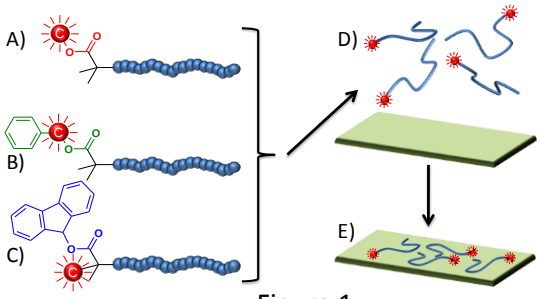


Figure 1

and, together with the benzyl-2-bromoisobutyrate, used to polymerise N,N-diethylamino ethyl methacrylate to near-identical chain lengths (Figure 1). The adsorption of the materials was then studied in a simple experiment using hair, filter paper and photographic paper. It was clearly shown that the nature of the end-group considerably directed the adsorption of the polymer. If adsorption had been measured by fluorescence and the observed behavior attributed to the unmodified polymer, the adsorption would have been considerably overestimated.

Data monitoring the ATRP polymerisation, characterisation of the initiators and polymers and the adsorption of the materials onto various substrates will be shown.

Molecular structure and local dynamic in impact polypropylene studied by preparative TREF and subsequent 2D solid-state NMR spectroscopy

Introduction

Isotactic polypropylene (iPP) shows poor impact strength and is brittleness at low-temperatures, which limits its applications. Increase in the low-temperature impact strength of polypropylene (PP), is a key to further broadening its and end-use properties in areas like infrastructure, automotive and packaging. Therefore, in the last years, the development of new systems such as random or heterophasic polypropylene copolymers (called also impact polypropylene), which show an improved balance between properties, represent therefore one of the major challenges to PP industry [1].

Extensive investigations have been focused to study the compositional heterogeneity, chain and phase structure as well as phase morphology by using different analytical techniques for this kind of impact polypropylene [2-4]. Several papers based on ^{13}C nuclear magnetic resonance (^{13}C NMR) in the liquid state, transmission electron microscopy (TEM), scanning electron microscopy (SEM), X-ray diffraction (XRD), have been published on the characterization, but only little information about local morphologies and local molecular mobility in the solid state is known. In particular, the broad variety of methods available in solid state NMR ranging from simple ^{13}C CP-MAS measurements to multidimensional experiments have not been applied so far.

Material and Methods

In this work, we try to deep in the microstructure, structure-properties relationship and local dynamic of four impact polypropylenes (P-EP-1, P-EP-2, P-EP-3 and P-EP-4), with different ethylene content, by using preparative Temperature rising elution fractionation (TREF). Once the raw material has been fractionated in several components according to its chemical composition distribution, subsequent characterization by multidimensional solid state NMR spectroscopy has been carried out, in order to provide additional information non-accessible by other techniques. Thus, and by combination of ^{1}H wideline NMR, cross polarization (CP) and ^{13}C MAS spectroscopy in a 2D experiment is possible to obtain information about the mobility of the different structural units, being potentially valuable for many industrial applications.

Discussion and Conclusion

The complete characterization of the impact polypropylene by using different analytical techniques has been undertaken. First of all the raw materials were analyzed but little information were extracted. The study of the fractions using conventional techniques like analytical TREF, differential scanning calorimetry (DSC) and gel permeation chromatography (GPC) showed different families in each fraction. Despite these interesting differences in comparison with the raw materials, to get a more comprehensive sense of the molecular structure and species mobility subsequent analysis of the fractions by NMR solid-state using 2D WISE experiments were developed. Accordingly, fraction 1 resulted to be composed by sequences of elastomeric ethylene/propylene rubber (EPR) with high ethylene content and atactic PP, which however could as well be a sequence in the EPR. Fraction 2 contains long ethylene sequences with capability to crystallize and propylene segments with also capacity to crystallize but not highly isotactic (Figure 1). Fraction 3 consists of reasonably highly iPP, incorporating some small amount of ethylene sequences into the PP matrix, and finally fraction 4 is constituted by the matrix of iPP.

Mass Spectrometry Reveals the Degradation Product Patterns of Biodegradable Polyesters

Anders Höglund, Minna Hakkarainen and Ann-Christine Albertsson

Department of Fibre and Polymer Technology, School of Chemical Science and Engineering, Royal Institute of Technology, Stockholm, SE-100 44 Sweden.

anhog@kth.se

Controlling the degradation rate and the release of degradation products are crucial steps in the design of biodegradable polymers. Today, much is known of the factors affecting the degradation and degradation rate, and the continuous development of mass spectrometry techniques (e.g. MALDI-TOF-MS, ESI-MS) has paved the way for characterizing individual polymer chains on a molecular level. However, despite the large research efforts within the field of polymer degradation, less attention has been paid to the low molar mass products formed during the degradation. This is a key aspect to take into consideration in the design of new materials.

In this work, different polymer modification techniques were used to control the release rate of monomeric and oligomeric degradation products of various homo- and copolymers of lactic acid (LA), ε-caprolactone (CL) and 1,5-dioxepan-2-one (DXO). The influence of architecture, hydrophilicity, surface modification and plasticization on the degradation product patterns were revealed by different mass spectrometry techniques. Gas Chromatography-Mass Spectrometry (GC-MS), Electrospray Ionization-Mass Spectrometry (ESI-MS), and Matrix Assisted Laser Desorption Ionization-Time of Flight-Mass Spectrometry (MADI-TOF-MS) were used to monitor the released monomeric and oligomeric degradation products.

The results showed that the release pattern of monomeric degradation products was tailored by varying the distribution of the more hydrolysis susceptible DXO units.[1] Cross-linking entailed a shift in the degradation product patterns from water-soluble oligomers toward monomeric hydroxyacids, and the hydrophilicity of the networks could be altered to control the degradation product patterns.[2] The PDXO-PCL-PDXO triblock ESI-MS spectra were similar to the corresponding PDXO spectra, indicating preferential hydrolysis of the DXO blocks which was also confirmed by NMR.[3]

Oligomers up to heptadecamer were observed after hydrolysis of hydrophilic PDXO,[4] whereas only oligomers up to hexamer were observed after hydrolysis of hydrophobic PCL.[3] Large amounts of oligomers with attached cross-linking agent were detected after prolonged hydrolysis of DXO-rich networks showing an extensive disruption of the network structure.[5]

It was also shown that surface modification leads to rapid formation of water-soluble degradation products, and the degradation product pattern of acrylic acid surface grafted PLA varied with hydrolysis time.[6] Plasticizing PLA with a hydrophobic plasticizer protects the material against hydrolytic degradation but the plasticizer still migrates to aging medium and there undergoes further hydrolysis contributing to the spectrum of degradation products.[7]

Carbon dioxide plasticized polymer melts. An interpretation of the plasticizing effect by means of the free volume concept

Duscher Bernadette[a,b], *Schausberger Alois*[b], *Stadlbauer Wolfgang*[a]

[a] Transfercenter für Kunststofftechnik GmbH, Franz-Fritsch-Str. 11, A-4600 Wels,
[b] Institute of Polymer Science, Johannes Kepler University Linz, Altenberger Str. 69, A-4040 Linz

Bernadette.Duscher@jku.at

Introduction Carbon dioxide is well known for its particular properties as a processing solvent. According to its noticeable solubility in polymer melts it is used for polymer modification, blending as well as plasticizing during the process. Furthermore it is well established as a physical foaming agent especially for long chain branched polymers. Dissolving carbon dioxide strongly affects the rheological properties of the melt and causes viscosity reduction. Hence processing properties of polymer/CO_2 – solutions exhibit a remarkable change.

Materials Commercially available polymers (polypropylene - PP, polystyrene - PS) with varying molar mass distribution and different glass transition temperatures are used. Isotactic PPs with different molecular structures are investigated.

Pressure is brought to bear upon the cell via a carbon dioxide pressure cylinder. By this working pressure is up to 40 bar.

Methods A newly developed pressure cell is used for rheometry in shear. The setup used is developed to perform rheological experiments with a common MCR rheometer by Anton Paar. With a plate-plate-system in the pressure cell material functions in rotation and oscillation are measured. By this means widespread rheological information is gained. Gas diffusion processes and pressure effects are observed as well as the effect of gas dissolution on the material functions of poymer melts. Relations based on the free volume concept are used to interpret the experimental results.

Results Depending on the concentration of dissolved carbon dioxide dynamic functions can be shifted to the dynamic moduli of the neat polymer. By this a mastercurve is constructed and the shift factors a_c for the shift on the frequency axis and b_c for the shift on the modulus axis are determined.

In case of linear polymers (polystyrene, polypropylene) this time-concentration-superposition is simple, i.e. the shifted curves correspond in the investigated frequency range. By use of a generalized Doolittle relation of Fujita and Kishimoto[1] the concentration dependent horizontal shift factors are calculated

$$\ln a_c = B(1/f_c - 1/f_2) \qquad (1)$$

For this purpose the relation

$$f_c = f_2 + A/M_{n,c} \qquad (2)$$

is used. A is the product of the free-chain-end volume per mole and the density of the polymer.[2] The rheological properties of carbon dioxide plasticized polymer melts as well as the molar plasticizing activity A of an additive can be predicted.

By the use of a van-Gurp-Palmen-plot modified by Mavrides and Shroff[3] the shift factors a_c and b_c can be determined independently of each other. Hence, an additional shift along the modulus axis is found. By this, the relation of Schausberger[4] is applied

$$G_{0,d} = \rho RTw^2 / M_{e,0} = G_{0,u} w^2 \qquad (3)$$

and the vertical shifts $b_c = w^2$ are calculated. (w is the weight fraction of the entangled polymer).

The solubility parameters are in accordance to literature.[5,6]

Discussion The setup used is an appropriate possibility to determine time-concentration dependent horizontal and vertical shifts independently of each other. The shift factors are interpreted similarly to the shift created by solvents and additives. The moduli are reduced by the square of the polymer weight fraction and the frequency (time) shift is interpreted with the aid of the free volume concept. In this context long chain branched polymers show particular properties.

Development of a thermoplastic starch to be used in the co-injection process.

E. Benavent, B. Galindo, O. Menes, A. Pascual, F. Marti

Instituto Técnologico del Plástico C/ Gustave Eiffel, 4; 46980 Paterna (València).

fmarti@aimplas.es

Introduction. Packaging plays a vital role in modern integrated product supply systems. It does not only protect a product from the production line to the consumer (impact on health and safety), but also facilitates production, distribution and storage. Packaging technology is currently making huge strides in the development and application of new products and processes. About 15% of the total enterprises of the EU plastic sector are devoted to packing goods. In fact, *long life rigid/semi-rigid plastic* in food and drink packaging market represents a very important share of the current global packaging market.

COBAPACK project[1] aims to develop a new high barrier long life, low cost, recyclable packaging through a special injection molding process (co-injection) specially addressed to applications in the food sector. The core of the new packaging will be made of a renewable material (native thermoplastic starch) whereas the skin layer is polypropylene providing the required physic-mechanical and chemical properties for its optimum production and use.

Starch is an inexpensive abundant product available annually from different crops. Due to its high molecular weight, starch must be destructurized (to destroy its cristallinity) applying shear stress, heat and plasticizers in order to be processed as a thermoplastic.

The processability and properties of the unmodified starch have been studied[2]. However, there are very few products for packaging applications manufactured with non-chemically modified starch due to its low melt strength, moisture sensitivity, high tendency to stick to metal surfaces and limited mechanical and thermal properties[3].

Materials and Methods. For this work four different types of native starch (potato, maize, pea and wheat) was studied using glycerin as a plasticizer. The percentage of glycerin was between 25-50% w/w. To avoid sticking problems during injection molding a low amount of inorganic filler was used.

The selection of the most suitable native starch for the project was carried out in a twin screw extruder with a diameter of 16 mm. A pre-mix of starch and plasticizers is needed to ensure that all the plasticizer is completely absorbed by the starch. The destructurization process of the starch must be optimized for pilot plant scale twin screw extruder. The screw design and machine parameters were optimized employing a compounding simulation software.

The viscosity of the different compounds was characterized by capillary rheology at a temperature of 180 ºC and shear ratebetween 10 and 5000 1/s.

The main thermal, mechanical and oxygen barrier properties of selected thermoplastic starches were determinated.

Results, Discussion and Conclusions Figure 1 shows the rheological curves of the prepared compounds.

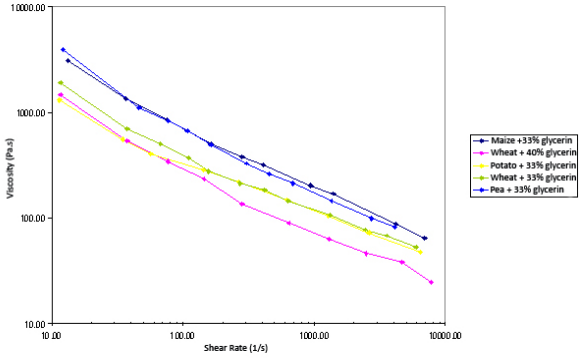

Figure 1. Capilary rheology curves of five different starch-glycerin compounds

Taking into account the ranges of viscosity and shear rate for the injection process it can be concluded that wheat starch with 40% wt of glycerine is the best compound.

However, compounds with 33% wt glycerin have good processing properties. Starch with 40% wt glycerin is very sticky, which makes the dosage of the material in the injection machine more difficult[4]. Starchwith 33% w/w glycerin has good oxygen barrier properties and limited thermal and mechanical properties. Protection of starch to be used in the packaging industry is needed.

Figure 2 shows a co-injected package obtained using wheat starch compound as core layer and polypropylene as skin layer.

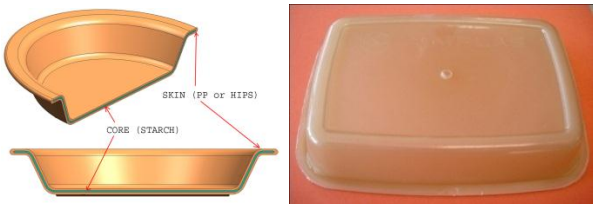

Figure 2 Co-injected package obtained in the COBAPACK project.

Thermosetting resins play an important role in lot of industry branches such as aerospace, automotive light weight constructions, wind energy plants and other. Each of these branches has different requirements on process parameters and curing degree. Nevertheless, all they have some common: reducing of the production costs. One of the possibilities is the optimization of the cure process with the aim to decrease the cyclus time and energetical input decrease. Therefore an effective, at the best online, process control method is necessary.

The methods used for monitoring the progress of the cure can be divided into the two main categories: methods based on measurement the changes in chemical level such as monitoring concentration of reactive groups consumed or produced during the reaction, and methods based on monitoring the effects of network formation on to the parameters of physico-mechanical properties of the substrates. Only a few of them can be used to follow the whole curing process from the beginning of the reaction till the end of network structure building. From the data of mechanical properties is then possible to win the knowledge about chemical structures and their changes. Technically there is a problem with the wide scale of material properties: they change often in logarithmic scale, the sensors have linear sensitivity. Therefore combination of different measurements or methods with building of mastercurve from single experiments is necessary.

IR spectroscopy deals with atomic and molecular bond twisting and vibration, DSC registers the reaction heat flow, rheometry, DMA and other mechanical methods obtained their information from macromolecular chain and block “stiffness” as reaction on oscillatory deformation within their frequency band. So the question on compatibility of the results of different methods is still entitled.

DSC is the most used method for curing monitoring, but this method is not always useful in the final stages of curing. It looks likely that the chemical bond building heat that excreats during the final stage of the reaction are too small to be detected by DSC, but the result of these structural changes is strong enough to affect properties that can be measured. There are also some proposals, that the change of properties at the final stage of curing is related to relaxation that proceeds without thermal effects.

Observing curing process with rheological methods, changes in modulus and/or complex viscosity are measured. These changes draw up by many orders of magnitude. However, interpretation of the data in compliance with changes in chemical structure is not quietly simple. The results from different studies of epoxy resin cure analyzed with rheological methods can be summarized into the development of a methodology to predict the relative reactivity of curing systems from the complex dynamic viscosity value development during the process.

DMA became widespread for curing control with the works of Gillham. This method deals with rubber elasticity and glass transition, what results on dependence of rubbery modulus and T_g of network formation. With DMA method is not always possible to receive absolute values of modulus because due to the low viscosity of monomers/oligomers at the early process stages it is necessary to use special soft carriers and only relative characterisation can be provided.

With IR spectroscopy the dynamic of the curing process can be observed by changes of different specific chemical bonds such as decrease of the absorption bands of the oxirane ring.

Ultrasonic technique is used successful since a long time in non destructive testing and medicine. In the last years there are new developments on hardware, what allows investigation of curing processes. Generally ultrasonic waves act as a high frequency dynamic-mechanical deformation of material (compression deformation). If during the chemical reactions, such as curing, physical changes of material occurs, the evolution of the changes of an elastic compression modulus L^* can be monitored. This modulus is related to the complex bulk K^* and shear G^* moduli and can be displaced with one of its parameters: ultrasonic longitudinal velocity.

Therefore it is necessary to compare the results of various methods used by cure monitoring and after that to receive the relationships between the results obtained with different methods and optimize the measurement parameters for each of the methods. Nevertheless, it must be noted, that also within one and the same method using different parameters from the same experiment differences in the curing parameter values are not rarely.

The curing process was studied on different commercial, room and high temperature curing epoxy resin compounds using five measuring methods:

DSC, IR, rheology with a plate–plate geometry by oscillation, DMA and ultrasonic measurements. The objective of the study was to compare the effectiveness and sensitivity of these methods and the correlation of the results of the methods with each other.

The results obtained with all 5 methods will be compared and the advantages and disadvantages explored. Their practical usability for prepreg characterisation will be discussed. Our experimental data demonstrate that the obtained results give comparable results of curing kinetics and curing grades.

Modeling of Phase Separation of Polymer Blends Using Spectrum Method

*M. Ali Parsa, Majid Ghiass**

School of Chemical Engineering, Iran University of Science and Technology (IUST), Iran

majidghiass@iust.ac.ir

Introduction: Polymer blends are a very important class of engineering materials with specialized applications. [1-4] The morphology of the final polymer blend is either a droplet-like or bicontinuous pattern is a key characteristic of the properties and application of the polymeric material. It is very demanding to develop a quantitative realistic model to predict the polymer blend system, capture and control the desired morphology in a phase separation process. The Cahn-Hilliard nonlinear theory has been effectively employed for quantitative modeling of the dynamics of temperature-induced phase separation of polymer (TIPS) blends.[5] For incompressible polymer blend the Flory-Huggins lattice model have been extensively successfully applied to determine the free energy of the polymer system. The solution of nonlinear Cahn-Hilliard equation provides the information for dynamic morphology evolution of a polymer blend during the temperature-induced phase separation process, TIPS. For the unsymmetric blends with different molecular weights (chain length), which is very common in blend processes, the phase equilibrium information leads to an unsymmetric phase diagram which introduces mathematical complexities in computational procedures for determination of the spatial dynamic concentration field. This research provides a new mathematical framework to model the dynamic behavior of temperature-induced phase separation for unsymmetric polymer blends.

Method of Solution: Substitution of the Flory-Huggins free energy model in the Cahn-Hilliard equation leads to a nonlinear fourth order dynamic pde whose solution provides information of the concentration in a phase separation domain. Several attempts have been employed to solve this equation by conventional finite difference, finite elements, and even stochastic methods.
Here we used the discrete cosine method (DCT) which is a general procedure for solution of the partial differential equation.[5,6] The DCT method, among the spectral methods, provides a very robust, and computationally feasible algorithm for solution of the Cahn-Hilliard equation.

Results: To solve the Cahn-Hilliard equation, a 2D square 256×256 grid field has been selected. To validate the applicability of the model, the properties of an industrial relevant polymer blend system, polystyrene (PS) and polyvinylmethylether (PVME) which have been widely experimentally studied, have been used [1-4]. Figure 1 shows a LCST behavior for this system in which polymer blend phase separates into two equilibrium phases upon temperature increases (Fig. 1)

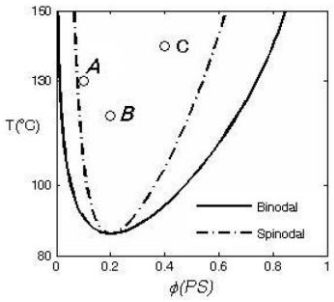

Figure 20. Phase diagram of PS/PVME blend

The phase separation dynamic has been studied for different initial concentrations which lead to different final morphologies of the polymer blend. Figure 2 shows a 2D image represents the dynamic phase separation as microstructure evolution of a PS/PVME blend at the initial concentration of 0.2 and at temperature 120°C namely an on-critical quench. The Figure shows the initial sudden appearance of microdomains followed by growth and coalescence leads the formation of larger droplets.

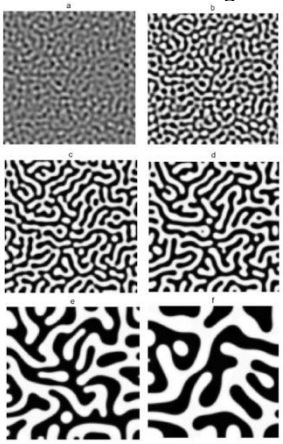

Figure 21. Morphology evolution during temperature-induced phase separation of a PS/PVME blend

Conclusion: A dynamic mathematical model for study of the kinetics of phase separation upon temperature changes in phase separation of a polymer blend of PS/PVME has been developed and solved with use of the discrete cosine transform method to predict the microstructure evolution of phase separated blend.

Introduction:

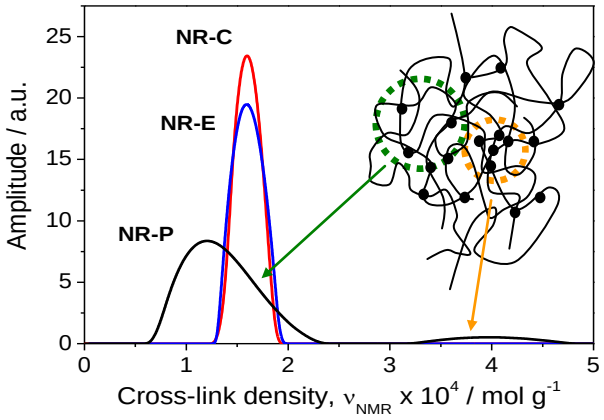
Elastomers are important polymeric materials because of their unique long-range elasticity. This property is obtained after the vulcanization process, where a plastic polymer is transformed into an elastic material by formation of a three-dimensional network of cross-links that connect the different polymeric chains. For this reason, it is not surprising that the most important properties of rubbers depend on the network structure, and its study allows us to reach a better understanding of the correlation between the micro-structure and the macroscopic properties of rubber compounds.

As long as the detailed reaction pathways of the most-used processes in rubber technology are unclear and remain too complex to be unveiled, the most useful approach to control and to be able to obtain tailor-made properties of elastomeric materials is clearly the direct study of the meso-scale network structure formed during the vulcanization reactions. A complete description of the network structure should contain information about non-elastic network defects, number of cross-links, their chemical nature and functionality, the spatial distribution of cross-links, and information about entanglements. The main problem is the difficulty to obtain this local information from a complex matrix in solid state. In this sense, it has been demonstrated that solid-state NMR could be considered as a powerful tool to study the structure and chain dynamics in elastomers[1]. This information is encoded in the dipolar coupling constant. Nowadays, the double quantum (DQ) NMR experiments are the most versatile and powerful tool to study, not only the residual dipolar couplings, related with both chemical (cross-links) and physical (entanglements) constrictions, but also their distribution and associated dynamics[1].

Results and Discussion:

By the use of DQ experiments (performed in inexpensive low field NMR spectrometers) it was quantitatively demonstrated that sulfur-based and peroxide vulcanization systems for dienic elastomers, e.g. NR and BR, are characterized by different reaction pathways, leading to substantial variations in the fraction of elastically non-active network defects, the vulcanization efficiency, the spatial distribution of cross-links, and the segmental dynamics. While sulfur vulcanization generates rather homogeneous networks, peroxide-cured systems exhibit a heterogeneous and even bimodal structure (Figure 1) with unexpectedly high amounts of network defects[2].
These results can be explained via the radical mechanism that dominates peroxide vulcanization process[3], as it partially leads to polymerization-type cross-linking involving addition to the double bonds, leading to highly cross-linked clusters which we could observe directly by NMR. The final structure of the network strongly depends on the polymer backbone structure, temperature, and proportion of cure system.

Figure 1 Effect of vulcanization systems (C: conventional, E: efficient, P: peroxide) on the distribution



of cross-link density in NR samples. Note that the samples have the same average cross-link density.

Deeper studies about the evolution of the network structure during the vulcanization process reveal that sulphur vulcanization is heterogeneous process based on located nucleus of cross-linking. However these cure systems generate, at the end of the process, networks with extremely narrow cross-links distribution and excellent elastic properties. On the opposite side, peroxide vulcanization is a homogeneous (random) process. However in the last steps, higher cross-linked areas (clusters) are formed because the existence of polymerization-type reactions. This fact generates network inhomogeneities that deeply affect the elastic properties of these materials.

Introduction:

Over the last years, the conducting polymers found a new interest from both academic and industrial points of view due to their interesting properties and possible applications, in the conversion of solar energy into electrical and/or chemical forms. In order to diminish the dependence of the fossil fuels and in this way the greenhouse gases, the solar power is considered as eco-friendly energy, an attractive alternative due its large abundance and consistency [1,2].
For this purpose, the use of polymer semiconductors as photoactive electrodes and photovoltaic devices attracts much attention of a large scientific community [3]. Such materials are not only able to function in a similar way to inorganic semiconductors but have additional advantages including environmental friendliness, low cost, light weight, easy fabrication, and potentially manufacturable as large-area coatings. They have been considered as promising materials for organic light conversion devices, in particular, for solar cells and photodetectors.

Our aim in this contribution was focused on a study of photoctalytic process in order to product the hydrogen using polymer semiconductor materials such as doped polyaniline (emeraldine salt).

2. Experimental

The powder was cold pressed into pellets under 1 kbar. In order to minimize the contact resistance, silver paint was deposited on the back pellet by spot welding a copper wire. The pellets were mounted in Teflon holders to give a projected surface area of 1.32 cm^2.
PEC measurements were done in NaOH (1 M) electrolyte under potentiostatic conditions using a three electrode cell with a large Pt counter electrode and a saturated calomel reference electrode (SCE). The electrode potential was monitored by a computer controlled potentiostat (Voltalab PGZ 301, Radiometer).
The electrode was illuminated through a flat optical window by a 200 W tungsten lamp.
Prior each run, A nitrogen stream was passed over the solution to remove dissolved oxygen, the purging rate was maintained constant at 10 mL mL^{-1} during 35 min.
50 mg of powder (PANI) was suspended by magnetic stirring in a double walled Pyrex reactor in 250 mL of aqueous Na_2SO_3 (0.1 M) solution.
The light source was an assembly of three tungsten lamps which are predominantly in the 400-900 nm (max. 650 nm), disposed around the reactor.
Hydrogen in the outgoing gas was identified by gas chromatography. The amount was collected volumetrically with a water manometer in an inverted burette via water displacement. Blank runs were carried out and no hydrogen was evolved in the dark.
The experiments were repeated three times with very reproducible results

Results and discussion:

The photoelectrochemical properties of polyaniline (emeraldine-salt) (PANI) doped was investigated by the photocurrent technique and capacitance measurements in various electrolytes. The volume evolved of H_2 as showed in Figure 1 reveals the applicability of this material for the photocatalytic conversion. The photocatalytic properties have been evaluated for the first time according to the H_2 evolution under visible light.

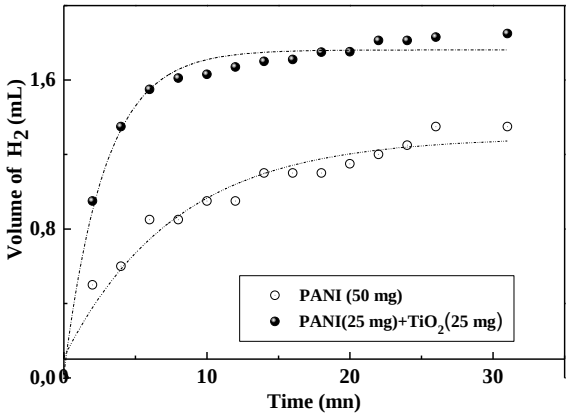

Figure 1: Volume evolved H_2 versus irradiation time on Na_2SO_4 solution (0,1 M)

Therefore, favorable valence band position for water reduction makes the PANI as an ideal photocathode. Our results indicate that the doped PANI is able to generate incident photon to chemical chemical efficiency of 4% under an intensity of 20 mW cm^{-2}.

Abstract: The Differential Scanning Calorimetry (DSC) was used as a useful method for the study of the global crystallization of the reinforced blends based on the dispersion of polypropylene (PPh) in a short glass fibber reinforced polyamide 66 (SGFR PA 66) as a matrix and with the presence of polypropylene grafted maleic anhydride (PP-g-MAH) as a compatibilizer. These reinforced blends were previously prepared by the twin screw extruder (TSE) and injected in the moulding machine to get specimens from which the all samples were taken. The new approaches emanating from the modern metallurgy were performed and applied for the study of the global crystallisation; these later are named Temperature-Time-Transformation (T.T.T) diagrams of the relative (absolute) crystallinity under isothermal conditions and Continuous Cooling Transformation (CCT) diagrams under non-isothermal conditions. Using these diagrams, the overall crystallization was described and it is found that the compatibilizer affects greatly the crystallization behaviour of the minor phase (PPh), in which, 2.5 wt. % of PP-g-MAH should be enough to enhance the crystallization temperature. The increasing of the crystallisation aptitude gives evidence of improvement of mechanical properties. Meanwhile the major phase (PA 66 component) still no affected by the presence of the PP-g-MAH having the lower melting point.

Key words: Polypropylene, polyamide 66, reinforced blends, glass fibber, compatibilizer, crystallization, DSC, TTT and CCT.

Abstract

The high annual consumption requirements of polypropylene and polyethylene explain the significant percentage of these materials in the total solid waste stream and become their blends an important deal of study from the viewpoint of recycling [1-5]. It has been shown that is possible the improvement of mechanical properties of polyolefin blends without the use of compatibilizers, just by controlling composition and processing conditions [3, 6-8].

The aim of this work is study ternary blends like as PP/LDPE/HDPE by changes in composition without a chemical compatibilization.

Experimental design chosen was a mixture design called simplex-centroid using statsgraphics software, besides was decided it to add additional runs (the extreme vertices) in order to improve the surface response methodology. There were five replicates of each blend. The idea of this design is to find the optimum setting of the experimental components according to the response variables (compressive strength, flexural strength, modulus, etc). Figure 1, shows the ternary blends used in this study.

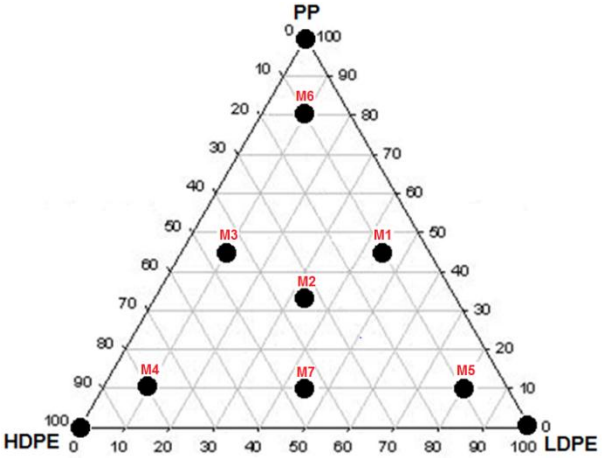

Fig 1. Experimental design region used in this study.

All the blends were performed in a Haake Rheomix 600 at 60 rpm at temperature of 200°C. Morphology blends was studied by SEM (Scanning electron microscopy) and mechanical properties were tested in an Instron 3366.

In figure 2 is present it M4 Blends (10PP/80HDPE/10LDPE) morphology, show it a heterogeneous morphology suggesting immiscible polymer blends. However, the identification of phases could not be possible due to chemistry similarity of polyolefins.

Figure 3 shows the flexural modulus of the blends. The blend 4 (M4) had a flexural modulus value higher than the target PP. This ternary blend displayed the highest and synergistic level of flexural modulus (1432 MPa) among all blends (pure and ternary) studied.

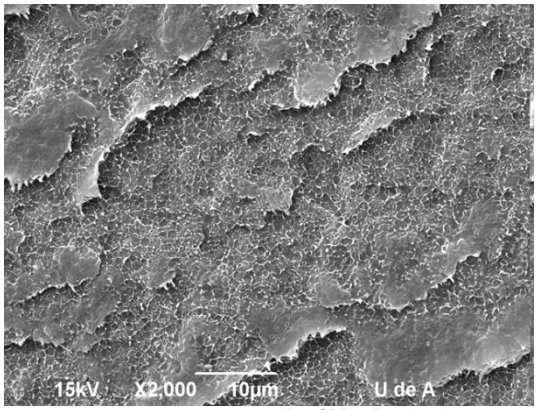

Fig 2. SEM micrograph of blend 4 (M4)

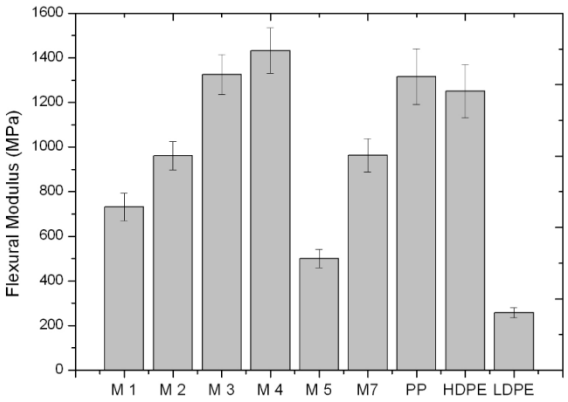

Fig. 3. Flexural modulus of ternary blends and their constituents.

Formation of Self-Assembled Buffer Layer from Fullerene End-Capped Poly(ethylene glycol) for High Performance of P3HT/PCBM Heterojunction Solar Cells

Jae Woong Jung and Won Ho Jo

Department of Materials Science and Engineering, Seoul National University, Seoul 151-742, Korea

whjpoly@snu.ac.kr

One of the most important issues of polymer solar cells (PSCs) is lower efficiency than conventional Si-based solar cells or dye-sensitized solar cells. Various approaches for morphology control such as thermal annealing, solvent annealing, and use of additive, have been proposed to increase the efficiency. These methods have been very effective to afford nano-scaled phase-separated morphology in horizontal direction (parallel to film surface). However, the methods have a limitation to control the vertical distribution of the components in active layer, although the vertical distribution is very critical for effective transport of charge carriers.

It has been agreed that an ideal bulk heterojunction (BHJ) PSC must have the vertical distribution of components where the p-type conjugated polymers are rich near the anode and n-type fullerenes are rich near the low work-function metal cathode. This ideal vertical morphology renders holes and electrons to move more efficiently to anode and cathode, respectively. However, such ideal vertical distribution in the active layer cannot be developed during film casting due to the lower surface energy of P3HT (26.9 mJ/m^2) than PCBM (37.8 mJ/m^2).

We report here enhanced performance of PSC by controlling the vertical morphology with the addition of a self-assembled additive. We synthesized fullerene end-capped poly(ethylene glycol) (PEG-C_{60}) (Figure 1) and added it to P3HT/PCBM blend.

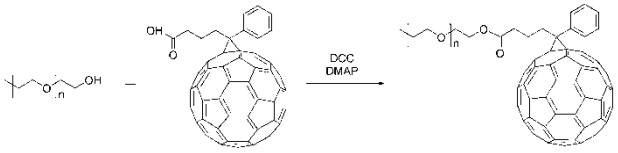

Figure 1. Synthesis Scheme of PEG-C_{60}.

Since it has been reported that the addition of small amount of PEG in P3HT/PCBM blend induces spontaneous vertical phase separation with formation of PEG thin layer on top of the P3HT/PCBM, it is expected that PEG-C_{60} molecules also migrate to the surface of the P3HT/PCBM active layer to form nano-scaled buffer layer between active layer and metal cathode (see Figure 2a). As this buffer layer with high dielectric constant induces an interfacial dipole between active layer and metal cathode, the vacuum level of the cathode is increased and the energy barrier for electron collection is decreased (see Figure 2b). Consequently, the exciton dissociation at the interface and the charge collection at the cathode become more efficient, affording increased open circuit voltage (V_{OC}) and short circuit current density (J_{SC}). Another important feature with addition of PEG-C_{60} is to induce segregation of PCBM near PEG-C_{60} layer, which makes an ideal vertical distribution of PCBM in the active layer: P3HT becomes rich near the anode and PCBM becomes rich near the cathode. Furthermore, since the PEG-C_{60} layer may protect the active layer from oxygen as well as the invasion of Al to the active layer during metal deposition, the stability of PSC will be improved.

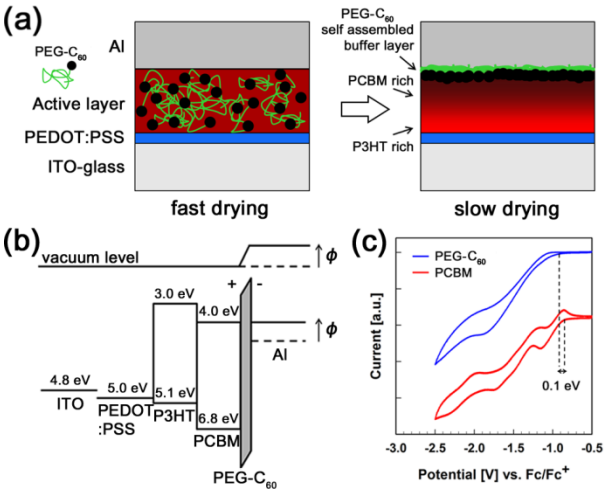

Figure 2. Schematic illustration of (a) bulk hetero- junction solar cell with PEG-C_{60} as buffer layer and (b) the energy level diagram of the polymer solar cell with PEG-C_{60} buffer layer. (c) Cyclic voltammetry reduction curves of PEG-C_{60} (blue) and PCBM (red).

To investigate the effect of PEG-C_{60} buffer layer on the performance, the power conversion efficiencies (PCEs) of PSCs with different amount of PEG-C_{60} were compared. While the reference device (0 wt% PEG-C_{60}) exhibits 3.60% PCE, the device with 5 wt% PEG-C_{60} shows 4.41% PCE (see Table 1). The enhancement of V_{OC} by addition of PEG-C_{60} is originated from the effect of dielectric buffer layer between active layer and metal cathode, and the increase of *FF* is due to development of an ideal vertical-morphology. Therefore, it is concluded that both the formation of buffer layer and the development of ideal vertical-morphology in the active layer enhance the device performance.

Table 1. Performance of PSCs with different amount of PEG-C_{60}.

PEG-C_{60} [wt%] [a]	V_{OC} [V]	J_{SC} [mA/cm]	*FF*	PCE [%]
0	0.61	10.17	0.58	3.60
5	0.66	10.27	0.65	4.41

Cryostructured Polymer/clay Aerogel Materials

David A. Schiraldi, Matthew D. Gawryla, Yuxin Wang, Jack R. Johnson III
Department of Macromolecular Science and Engineering, Case Western Reserve University,
Cleveland, OH-44106, United States.
Das44@case.edu

Introduction

Traditional polymer foams are largely based on petrochemical feedstocks, require environmentally-unfriendly foaming agents, are generally flammable and difficult to recycle or biodegrade. Over the last several years we have been developing polymer/clay aerogel composites, materials which match foam mechanical properties, but offer significant environmental and performance improvements over existing products.

Materials and Methods

Sodium montmorillonite clay (Nanocor PGW grade, Na-MMT), and a wide range of commercial polymers were used as received. Deionized water (DI water) was prepared using a Barnstead RoPure reverse osmosis system.

In a typical aerogel preparation, 5 g Na-MMT was mixed with 100 mL DI water in a Waring laboratory blender to prepare 5 % wt/v clay suspension. An equal volume of an aqueous polymer solution was combined with the clay suspension with mechanical stirring, then this mixture to 18 mL polystyrene cylindrical vials and frozen using low temperature cooling baths. The samples were then freeze dried using a Virtis Advantage EL-85 lyophilizer with an initial shelf temperature of 25^{o}C, condenser temperature of -80^{o}C and an ultimate 5 µ bar vacuum.

The microstructure of clay aerogels were imaged using an FEI Quanta 3D scanning electron microscope. Prior to imaging, all samples were sputter coated with gold and were studied with the microscope operating at 5 kV.

Compressive tests were carried out using an Instron 5566 Universal testing machine with a crosshead speed of 1mm/min. Skeletal density measurements of these clay and PVOH/clay aerogels were carried out using an Ultra pycnometer 1000.

Results and Discussion

Polymer/clay aerogels exhibiting bulk densities in the range of 0.05 – 0.15 g/cm3 were readily prepared by freeze drying of aqueous polymer/clay suspensions. These materials made use of biopolymers, such as casein, pectin, natural rubber latex and poly(hydroxybutyrate) as well as synthetic polymers including poly(vinyl alcohol), poly(ethylene oxide), poly(ethylene imine), expoxies, poly(ether-amides) and poly(amide-imides). Thermal conductivies in the range of 0.025 – 0.05 W/m-K were typical of these composites, depending in large part upon the bulk density of the material. Compressive moduli from 50 kPa to over 100 MPa are also possible, depending on the composite density and polymer composition. The spacing of polymer/clay composite layers were determined to be highly sensitive to both the freezing temperature and the ionic strength of the starting solutions employed. When the milk protein, casein was used, it was found that the polymer/clay aerogel is biodegradable with or without chemical crosslinking of the polymer; with crosslinking, mechanical properties of the casein aerogel can match those of commercial expanded polystyrene foam products. Incorporation of nanocrystalline cellulose whiskers can improve aerogel mechanical properties, as can addition of cut fibers. Single walled carbon nanotubes increase both mechanical and electrical properties of the aerogels. Functionalization of the clays with metal nanoparticles can result in composite materials that are magnetic and/or catalytically active. Post-treatment of the aerogels with inorganic precursors can generate layered, bio-mimetic mineralized structures.

Conclusions

Freeze-drying can be used to prepare low density, cryostructured polymer/clay aerogels, which can serve as replacements for traditional polymer foams. These materials exhibit very low thermal conductivities, low flammability, and can range from elastomeric to rigid mechanical properties. By utilizing bio-based and biodegradable polymers in such composite materials, and using water as the processing solvent, environmentally benign materials for consumer, packaging, and industrial applications can be produced. The effects of processing parameters, along with post freeze-drying processing steps will be discussed, opening up the possibility for producing highly functional (conductive, magnetic, catalytic) materials.

Preparation of Polyether-block-amide Copolymer/organoclay Composite via Freeze-drying

Yuxin Wang , Saeed M. Alhassan, David A. Schiraldi
Department of Macromolecular Science and Engineering, Case Western Reserve University, Cleveland, OH-44106, United States.
Das44@case.edu

Introduction

Polymer/clay nanocomposites have long been studied since nylon-6/clay composites originally burst onto the scientific scene. As an alternative to directly melt mixing polymer with clay, or to a solvent-casting method, would be an 'aerogel method' in which clay is added to a polymer solution, the mixture freeze-dried to produce a porous, lamellar aerogel, with a typical density in the 0.08 to 0.15 g/cc range, then this structure would be pressed into a film. This method allows for producing composite containing very high levels of aligned fillers.

Materials and Methods

Polytetramethyleneoxide-block-nylon12 copolymer (Pebax® 2533) was used as received from Alkema. Sodium montmorillonite (MMT) clay (Nanocor, PGW) was modified with dodecyltrimethylammonium bromide (DTAB) from Sigma Aldrich. Deionized (DI) water used was prepared using a Barnstead ROpure low-pressure reverse osmosis which was connected to NANOpure ultrafiltration system. 2 g organoclay was mixed with 50 mL t-butanol using the blender. 4 g Pebax® was dissolved in 50 mL t-butanol at 80°C with reflux and vigorous stirring. Then this organoclay suspension was mixed with Pebax® solution using a low shear rate hand mixer. This final suspension was poured into 18 mL polystyrene cylindrical vials and frozen in ethanol/dry ice cooling bath. All aerogels were prepared via freeze-drying process using a Virtis Advantage Model EL-85 lyophilizer, with an initial shelf temperature of -70°C and an ultimate temperature at 25°C with 5 μ bar pressure.

The microstructures were imaged using an FEI Quanta 3D scanning electron microscope. The finished Pebax®/organoclay aerogel samples were compression molded into films along vertical direction at 180°C using a Carver Laboratory Press (Model C). Films were characterized in terms of clay dispersion and gas barrier properties and mechanical properties. X-ray diffraction (XRD) patterns were obtained using Rigaku diffractometer (RINT 2000 series) with CuKα source (1.5418 Å). Oxygen flux was measured with a MOCON OX-TRAN 2/20 at 25°C, 0% relative humidity and 1 atm. Tensile tests were conducted using an Instron 5566 Universal testing machine at a crosshead speed of 10 mm/min.

Results and Discussion

PEBAX®/organoclay aerogels with organoclay contents varing from 0.5 vol% to 16.7 vol% (1wt % to 33.3 wt%) were prepared and compression-molded into films. XRD showed no clay intergallery peak around 5-6° (2 theta) for 0.5 vol% organoclay composite, indicating complete exfoliation. When clay loading was increased to 1 and 2 vol%, two domains appeared. One with unexfoliated clay (2 theta ~ 5.2° and d-spacing is 1.6 nm) and one with intercalated clay (2 theta ~ 2.5° and d-spacing is 3.5 nm). The existence of domains has been observed in polymer-clay aerogel. However, for film prepared from traditional blending, no exfoliation has been achieved even at the lowest clay loading.

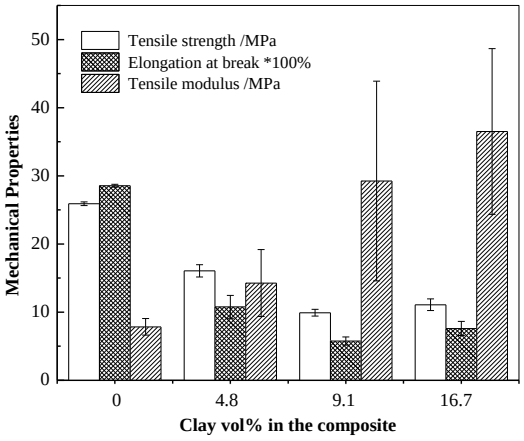

Figure 1.The tensile properties of Pebax® composite films via freeze-drying

Up to 16.7 vol% organoclay was added via freeze-drying method, creating homogenous films. As organoclay amount increased, increases in tensile modulus were observed (Figure 1), which is consistent with clay reinforcement. The tensile strength and elongation at break decreased due to the rigidity or less deformability of filler under external force.

Gas permeability of both oxygen and carbon dioxide were also studied. Addition of 16.7 vol% organoclay decreased O_2 permeability by approximately 60% and CO_2 permeability by 70%.

Conclusions

Freeze-drying method showed its superiority by environmentally processing and higher levels of aligned fillers, compared with traditional polymer/clay blending method. Both mechanical and gas barrier properties for O_2 and CO_2 were improved.

Controlled chain-cleavages of polydienes by oxidation and by metathesis: Application on the waste tires rubber recycling

Faten Sadaka[1], *Irène Campistron*[2], *Albert Laguerre*[2], *Jean-François Pilard*[2]

[1]ICMUB-UMR CNRS 5260, University of Bourgogne- 9 avenue Alain Savary, 21078 Dijon, France

faten.sadaka@u-bourgogne.fr

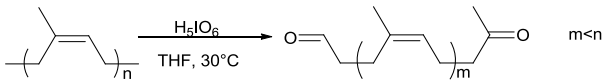
Only in the EU, USA and Japan around 6 millions tons per year of scrap tires are produced[1]. The huge quantity of waste tires presently produced in the world will certainly increase in the future as the associated automotive industries grow. Since polymeric materials do not decompose easily, disposal of waste polymers is a serious environmental problem. Two major approaches to solve this problem are the recycle and the reuse of used and waste rubber, and the reclaim of rubber raw materials[2]. All of these recycling methods are effective and have been successful; however, they lead to environmental pollution.

The overall aim of our work was to find a method to recycle waste tires rubber by chemical controlled degradation focusing on efficient methods easier to implement, with an appropriate cost for industrial development. Two methods are choosen: the degradations using periodic acid[3] (H_5IO_6) and by metathesis[4].

The studies have firstly been carried out on polyolefins as standard raw materials because of the complexity of the formulations of waste tires.

The first degradation pathway consisted on the use of periodic acid in THF medium for the degradation of *cis*-1,4-polyisoprene (PI), Natural Rubber (NR) and carbonyltelechelic natural rubber (CTNR). In fact, periodic acid is an interesting reagent used for the selective cleavage of weak epoxidized units[5]. However, in our work we realized this degradation on one-step reaction.

As expected, we obtained telechelic polymers with aldehydic and ketonic chain ends showed by ^{1}H NMR spectroscopy (scheme 1).

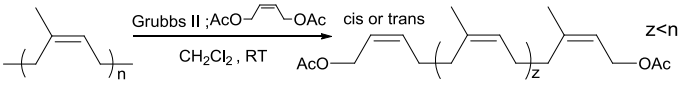


Scheme 1: Oxidative cleavage of Natural Rubber using periodic acid

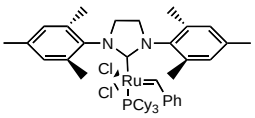
The molecular weight and molecular weight distribution of polymers have been determined using size-exclusion chromatography. The telechelic polymer weights decrease with the increase of time reaction or the increase of periodic acid quantity.

This method allows us to obtain end-functionalized polyisoprenic oligomers in a high yield in a specific range of molecular weight (500–7 000 g.mol^{-1}).

The second approach involved degradation by metathesis reaction on PI and styrene-butadiene rubber (SBR) using second generation Grubbs catalysts in presence of 1,4-diacetoxy-but-2-ene as chain transfer agent, to achieve acetoxytelechelic oligomers (scheme 2).



Grubbs II:



Scheme 2: Metathetic cleavage of cis-1,4-polyiso-prene using Grubbs II catalyst.

The degradation by metathesis is a complementary approach; it allows high molecular weight liquid polyisoprene (molecular weight > 100 000 g.mol^{-1}) to be obtained in a well controlled manner.

These modeling allows us to show the feasibility of degradation, the efficiency of the oxidizing agent or initiator and to determine the optimal conditions for the degradation reaction. We then extended the reaction to crumbs and granulates waste tires rubber. The results of this work have been the subject of a patent[6].

Email: m_yama@jaist.ac.jp

Abstract

An extruded polypropylene (PP) sheet in which PP molecules and crystalline lamellae orient perpendicular to the flow direction is obtained by addition of a specific nucleating agent, *N,N'*-dicyclohexyl-2,6-naphthalenedicarboxamide. According to the measurements of dichroic ratio of infrared absorption, Hermans orientation function of crystalline phase is a large negative value whereas that of amorphous phase is close to zero. The sample shows anomalous anisotropy in dynamic tensile modulus, in which the storage modulus in the machine direction (MD) is lower than that in the transversal direction (TD) in the low temperature range and vice versa at high temperatures. Moreover, the tensile test reveals that Young's modulus and yield stress in MD direction are larger than those in TD direction at room temperature. These results indicate that PP crystallites are mechanically connected in MD direction. It can be explained by the existence of tie chains in the flow direction.

Introduction

β-form crystal of isotactic polypropylene (PP) is widely accepted in terms of mechanical properties to achieve pronounced toughness,[1,2] which is one of the most important properties for PP. In general, addition of β nucleating agents and control of mixing and processing conditions are inevitable to obtain PP with high level of β form crystals. Recently, our research group succeeded to prepare PP sheets in which c-axis of PP orients perpendicular to the flow direction employing a new type of a β nucleating agent. The nucleating agent exists as needle crystals in a molten PP, which orients to the flow direction at extrusion processing by hydrodynamic force. Then, PP molecules crystallize on the surface of the nucleating agent in which the growth direction of lamellae is perpendicular to the long axis of the needle nucleating agent. Furthermore, c-axis of PP molecules in crystalline phase also orients perpendicular to the long axis of the needle crystals as shown in *Fig.1*.[1,2]

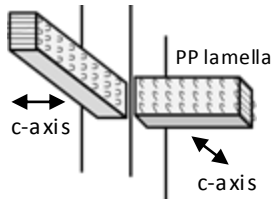

Fig.1: PP lamellae on a

Materials and Methods

Commercially available PP was used in this study. Further, *N,N'*-dicyclohexyl-2,6-naphthalene dicarboxamide (New Japan Chemical, NJ Star[TR] NU-100) was employed as a β nucleating agent. Mixing of PP with 0.1% of the nucleating agent was performed at 260°C by a twin-screw extruder. The mixed pellets were fed into a single screw extruder equipped with a T-die controlled at 200°C to obtain a sheet sample with a thickness of 200 μm. The molecular orientation of extruded sheets was characterized by the infrared (IR) dichroism, dynamic mechanical analysis (DMA), and tensile testing.

Results and Discussion

The molecular orientation of the extruded sheet is characterized by dichroic ratio of infrared absorption peaks at 841 and 973 cm^{-1}, which are ascribed to crystalline and amorphous regions, respectively. Hermans orientation function, *F* is evaluated to be -0.053 (crystal) and 0.007 (amorphous), demonstrating that PP molecules in crystalline phase orient perpendicular to the flow direction. On the contrary, orientation function of amorphous chains is closed to zero, i.e., random orientation on average. The temperature dependence of tensile storage modulus *E'* shows that the magnitude of *E'* in MD is significantly lower than that in TD in the low temperature region whereas vice versa at high temperatures. A similar phenomenon was reported for injection-molded PP, although the order of modulus was completely opposite to our result. This seems to be reasonable because the present sample shows perpendicular orientation to the flow direction. Moreover, the obvious crossing behavior in E' can be explained by the oriented crystalline phase. Because the crystalline lamellae and PP chains in the lamellae orient perpendicular to the flow direction, suggesting that the fragmentation of the lamellae can not be avoided in TD stretching. It is expected that the yield stress in TD is higher than that in MD. However, it is found from the experimental results that the yield stress in MD is higher. The result indicates that many amorphous chains connect neighbor lamellae along to the flow direction. The MD orientation of PP chains during processing is responsible for a large amount of tie chains.

Conclusions

Anisotropy of dynamic mechanical properties is studied employing an extruded sheet of PP containing *N,N'*-dicyclohexyl-2,6-naphthalenedicarboxamide. It is found that PP molecules orient perpendicular to the flow direction and thus the mechanical anisotropy is opposite to those of conventional processing products. Further, crystallites are connected each other along to the flow direction, although both crystalline lamellae and PP chains in crystals orient perpendicular to the flow direction. The amorphous chains which orient to the flow direction by the applied flow are responsible for the mechanical connection.

New methodology to produce a Polyetherimide (PEI) *via* Chloro-Displacement by SABIC Innovative Plastics

Patricia Forcén

SABIC Innovative Plastics

patricia.forcen@sabic-ip.com

SABIC Innovative Plastics has recently launched the production of a polyethermide (PEI) by a novel synthetic pathway demonstrating SABIC's commitment to innovation.

Traditionally, the synthesis of polymers has primarily been approached by ionic, free radical, or condensation step-growth polymerizations in the industry. These synthetic routes mainly produce commodity polymers. The need for high tech devices and designs requires polymers with higher mechanical and thermal performance. This has driven industry to the innovation of new and more sophisticated monomers and the subsequent development of new polymerization methodologies.

One example is the commercial production of a high performance polyetherimide ***(Fig. 1)*** via a chloro-displacement process by SABIC Innovative Plastics.

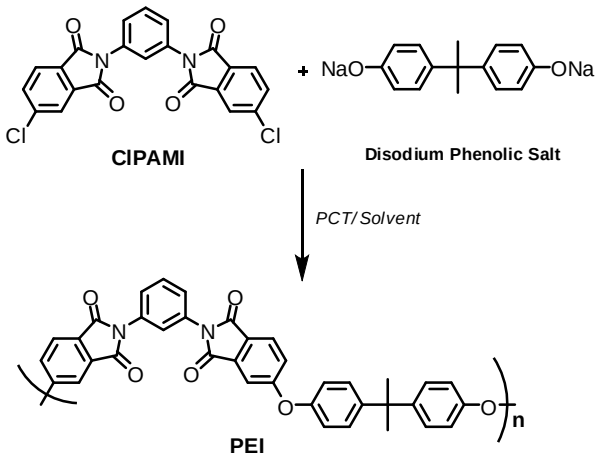

Fig.1

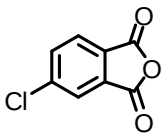
A previous methodology [1] was by the condensation of a proprietary dianhydride (Bis-DA), synthesized by nitro-displacement from 4-nitro-N-methylphthalimide (4-NPI) and the disodium salt of 4,4'-dihydroxy-2,2-diphenylpropane (disodium phenolic salt) with m-phenylene diamine (mPD) to produce PEI.



4ClPA

The new route [2] to obtain this polymer is by the reaction of the disodium salt of 4,4'-dihydroxy-2,2-diphenylpropane, with a di-halo-aromatic molecule, 1,3-bis[N-4-chlorophthalimido)]benzene (ClPAMI), using a phase transfer catalyst (PTC) in the nucleophilic displacement reaction ***(Fig. 1)***. The ClPAMI compound is made by reacting a di-amino compound, mPD, with a halophthalic anhydride, 4-chlorophthalic anhydride (4-ClPA), which has recently been produced on a commercial scale with a high purity ***(Fig. 2)***.

Fig.2

This new chloro-displacement process not only permits the synthesis of this particular polyetherimide, it also allows the opportunities to synthesize other novel polymers that were previously difficult to obtain with the traditional polymerization approaches.

Moreover, this route has also led to the availability of an array of intermediates that are now finding there way into other markets. (i.e. ClPA is a key intermediate for production of other molecules such as: specialty monomers, chain extenders, hardeners or cross linkers) allowing this SABIC technology to expand beyond thermoplastic applications.

Abstract: Polypropylene (PP) was functionalized in the melt by grafting polar monomers. 2,5-bis (tertbutylperoxy)-2,5-dimethylhexane (Luperox 101) and dicumyl peroxide (DP) were used as radical initiators. A Haake Rheomix mixer and corotative twin screw extruder were used for the experiments. The polar monomers used in this work were itaconic acid (IA), 2-hydroxyethyl methacrylate (HM), 3-allyloxy-1,2-propanediol (AP) and 2-octen-1-ylsuccinic anhydride (OY). The existence of grafting PP was confirmed by FTIR and Elemental Analysis. The degree of grafting obtained was 4% by weight of PP for IA, 4% for AP, 9% for HM and 2,1% for OY. Thermal analysis indicates the polarity of PP increase by grafting reaction and GPC showed that the grafting was not accompanied by a M_w decrease.

Introduction: The radical functionalization of polypropylene by reactive extrusion is a very challenging industrial process. The occurrence of side reactions such as chain scission makes the grafting process quite critical for the production of grafted polymers with high graft contents while preserving the mechanical properties or processability. Besides, it is also very challenging to control the chemical structure of the grafts during processing and the co-existence of several types of grafts is usually observed in commercial products [1-3].

The well studied modification of PP is with maleic anhydride, but grafting reaction is accompanied by chain scission, and the grafting degree and efficiency are relatively low.

The purpose of this work was to study the melt functionalization of PP by reactive extrusion with (IA), (HM), (AP) and (OY). Some properties of modified PP were also reported.

Experimental: Polypropylene homopolymer Moplen HF500R was kindly supplied by LyondellBasel Industries. IA, HM, AP and OY were purchased from Sigma Aldrich. Free radical initiator Luperox 101 was generously supplied by Arkema, dicumyl peroxide initiator was obtained from Aldrich.

PP was functionalized with polar monomers with Luperox 101 and DP as initiators in a reactive melt polymer processing. The grafting reactions were carried out in a Haake Rheomix mixer and corotative twin screw extruder. Prior to any analysis, the modified PP was purified. The evidence of grafting as well as an estimation of its extent, expressed as weight percent of grafting, was determined by FTIR spectroscopy. Molecular weights were determined by high temperature gel permeation chromatography (GPC). The thermal properties of modified PP were determined by DSC under a nitrogen atmosphere. The rheological measurements were performed using a Rheometric Scientific ARES N2 with parallel plate geometry.

Results and Discussion: The evidence of grafted polar function in PP was confirmed by FTIR. For the grafting reactions carried out in Haake Rheomix, the FTIR spectrum of the grafted PP with acid shows two absorption bands in carbonyl region. The absorption band at 1712cm^{-1} is due to stretching vibrations of the carbonyl groups of carboxylic acid. The second absorption band centered at 1770cm^{-1} is due to carbonyl absorption band coming from monomer grafted as anhydride during the grafting reaction. In the case of PP grafted alcohol, the FTIR spectrum showed an absorption band at 3640cm^{-1} due to stretching vibrations of hydroxyl groups of the alcohol. For PP grafted anhydride, the appearance of a low absorption band near 1792cm^{-1} is assigned to symmetric C=O stretching of anhydride functions grafted on PP. FTIR has been combined with elemental analysis to get an estimate of the grafting rate expressed as weight percent wich reaches 4wt% for PP grafted acid, 4wt% for PP grafted alcohol and 2wt% for PP grafted anhydride. In the same way, an estimate of the grafting rate was determined for the grafted PP prepared by twin-screw extruder. When IA was used as functional polar monomer, a maximum of 3% of grafting was reached. A maximum of 6,7% by weight of HM was incorporated in PP and grafting of AP is estimated to be 1,2%

The control of chain scission was verified by GPC, the molecular weight remains about constant. In order to characterize grafted PP, a sample of each modified PP was analysed by DSC and rheology. Thermal properties indicate slightly higher crystallinity of the functionalized polymer due to the polarity of modified PP.

Conclusion: It is concluded from this study that IA, AP, HM and OY can be successfully grafted onto PP in the melt without M_w decrease. The combination of FTIR with elemental analysis determines the extent of grafting obtained where higher percentage of grafting was obtained for HM.

kerrilee.allan@flinders.edu.au

Introduction:
Capillary electrophoresis (CE) separates components in a solution based on charge and size, however, DNA has a constant mass to charge ratio regardless of base pair length. At present DNA is separated using polymer gel filled capillaries, however, these have a limited life time due to the deterioration from run to run, the inability to regenerate the gel, and the formation of air bubbles[1]. Consequently in order to overcome these issues, recent research is focusing on direct surface modification of the capillary to selectively retard DNA based on size[1]. In particular, extensive research is being conducted into the use of surfaces modified with polymers in order to manipulate DNA transport through the capillary[2-3]. These dynamic-type coatings are becoming the method of preference for capillary surface modification due to the wide range of polymers available and the capacity for capillary regeneration[4-6]. Here we describe a capillary electrophoretic method of separating double-stranded oligonucleotides (oligo-dsDNA) with 1 - 4 base pair resolution using a fused-silica capillary dynamically coated with *Poly*(ethylpyrrolidine methacrylate-*co*-methyl methacrylate) PEPYM-*co*-PMMA copolymer. Separation is compared to analysis using a capillary coated with a novel PEPYM-*block*-PMMA copolymer.

Materials and Methods:
PEPYM-*co*-PMMA copolymer was synthesised by free-radical co-polymerisation of EPYM (25%) and MMA (75%) in THF using benzoyl peroxide as the radical initiator. PEPYM-*block*-PMMA was prepared by RAFT polymerisation by first synthesising a PMMA macro-RAFT agent in DMF using 2-cyanoprop-2-yl dithiobenzoate as the RAFT agent and 4,4′-azobis(4-cyanovaleric acid) as the initiator. The block copolymer was prepared in the same way from the PMMA macro-RAFT agent and EPYM. The copolymers were characterised by NMR, FTIR and GPC. The dynamic coating was prepared by dissolving the copolymer in ethanol with aqueous ammonia and formic acid (1 mg/ml) and flushing the polymer solution through the capillary using the CE system.
All DNA separations were carried out on an Agilent 3D Capillary Electrophoresis Instrument with diode array UV detection at 260 nm and negative polarity (cathodic flow) at -131.6 V/cm.

Results and Discussion:
Isolation of the copolymers resulted in a fine yellow powder, with free radical polymerisation exhibiting greater yields than RAFT polymerisation. FTIR analysis of copolymers of EPYM and MMA indicated the presence of the ester bonds, pyrrolidine ring, and C-H stretching. These results were confirmed by ^{1}H NMR.

In order to determine the effectiveness of the coating, the electroosmotic flow (EOF) was determined for the buffer in both a non-coated and coated capillary. Results show a reduction in EOF for the coated capillary due to the replacement of the surface silanol groups with polymer reducing the negative surface charge distribution. In addition, the shorter strands of DNA are screened more by the positively charged dynamic coating than longer strands, and hence are retained by the capillary surface to a greater extent (Figure 1).

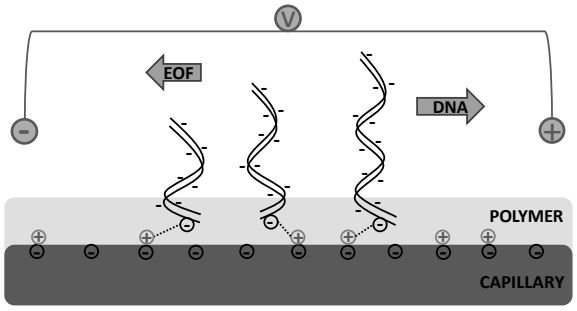

Figure 1: Proposed charge dependent separation of DNA strands due to polymer interactions.

The DNA interaction with the surface differs for the random and block copolymers. This is most likely due to the copolymer arrangement on the surface.

Conclusions:
Capillaries dynamically coated with random and block copolymers of EPYM and MMA are capable of separating short strands of dsDNA with well resolved peaks. The migration times of the ds-oligonucleotides decreased with increasing size and all oligonucleotides investigated exhibited very good reproducibility, less than 1 % RSD (n = 3). This coating can be simply accomplished within one hour affording a greatly reduced capillary preparation time and was shown to effectively reduce the EOF. A capillary lifetime of over 70 injections was observed.

daniele.dondi@unipv.it

Introduction

In normal thermal sulphur vulcanization, silica-rubber chemical links are not formed unless coupling agents like bis (3-trietoxy silyl propyl) tetrasulfide (TESPT) are used. A different situation applies when high energy ionizing radiations are used as initiator since reactive species are formed in both silica and the rubber matrix thus allowing silica-rubber chemical reactions to take place.

The aim of this work is to exploit the γ ray induced vulcanization of SBR-silica blends to develop silica-rubber chemical links, with a focus on the mechanism leading to said links and on the cured blends mechanical properties. Related to the mentioned aim is also the attempt to enhance the formation of silica-rubber chemical links through the grafting onto silica of vinyl rich polybutadiene olygomers with the role of free radical scavengers.

Materials and Methods

Silica Zeosil 1165 with a surface area 160 m^2/g was used as received from Rhodia. Blends were prepared by mixing 30-40 % of pristine and modified silica with 40 % SBR (30% styrene, 45 % vinyl and 25 % aromatic oil). Modified silica was prepared (1-3) by impregnation and subsequent radiation grafting of polybutadiene olygomers with average molecular weight $\overline{M}_n$ = 5000 and 1000 and vinyl double bond content 20% and 45% respectively.

γ irradiations were performed under nitrogen atmosphere in a 60-Co source with total doses ranging from 100 to 400 kGy.

Information concerning the mechanism of crosslinking and silica-rubber chemical links were obtained by EPR spectroscopy and 13-C, 29-Si CP/MAS NMR spectroscopy.

Mechanical behaviour of compounds was investigated by tensile and dynamic-mechanical measurements.

Results and Conclusions

During the irradiation, radicals and radical-ions are formed both in silica and the rubber matrix. In silica a powerful free valence migration mechanism exists leading to radicals decay and diffusion toward the surface. The species attaining the surface react with SBR vinyl double bonds thus generating grafted radicals and silica-rubber chemical links. When modified silica is used, the formation of silica-rubber chemical link is enhanced since a greater fraction of silica radicals escapes mutual coupling being scavenged at the surface by polybutadiene vinyl bonds. With SBR blends containing pristine silica, the crosslinks yields, as determined by the Flory-Rhener method, grows almost linearly with the radiation dose attaining a value > $2.5x10^{-4}$ moles/kg at about 400 kGy (both physical and chemical links, fig 1). When using modified silica, lower initial yields are observed followed by an acceleration period which ultimately leads to a full recovery of the overall crosslinks yields with respect to pristine silica. The initial lower yields are thought to arise from the weakening of the silica-rubber physical links due to the attenuation of the silica surface energy by the olygomer grafting. The subsequent acceleration is related to the taking over of the mechanism leading to silica-rubber chemical links. Mechanical measurements are consistent with this interpretation showing that blends containing modified silica show lower initial mechanical strength followed by a faster response to the radiation dose.

In order to evaluate the effect of the radiation dose on the dispersion of pristine and modified silica, a thorough investigation by TEM has been carried out.

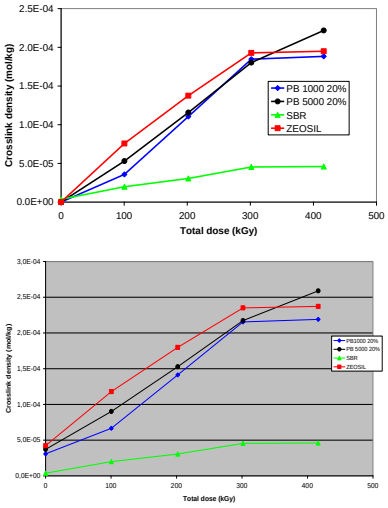

Fig 1 Crosslinks density vs. radiation dose for SBR blends containing pristine and modified silica. The curve pertaining pure SBR is shown for comparison

niloofar.reshad@yahoo.com

Abstract: The electrospun nanofibers have attracted great attention since they were employed in a wide variety of applications, such as scaffolds for tissue engineering, sensors, molecular electronics, and protective clothing.[5] Electrospinning, a versatile route which can be applied to various polymers, polymer blends, sol-gels, and composites, is well known to be a useful tool to prepare nanowebs of the ultrathin fibers having a diameter of about few hundred nanometers.[6] Incidentally, considering the variety of polymerization techniques, one cannot ignore the prominent role of controlled/"living" radical polymerization (CRP) in the synthesis of polymers with narrow molecular weight distribution and well-defined topology. CRP has attracted much attention in recent years for providing simple and robust routes to the synthesis of tailor-made polymers. In this context, nitroxide-mediated polymerization (NMP), reversible addition-fragmentation chain transfer polymerization (RAFT), and atom transfer radical polymerization (ATRP) have extensively been studied. Some advantages of the latter over the former systems are the applicability to a wide variety of monomers and systems of polymerization and its being less sensitive to impurities. [7]

The SEM and TEM images of polystyrene nanocomposite nanofibers prepared via electrospinning technique are depicted in **Fig. 1** and **Fig. 2** respectively. The morphology and average diameter of the prepared nanofibers can easily be observed in **Fig. 1**. Fibers with the average diameter ranging from 450-700 nm are obtained by this process. The smallest variations in the accelerating voltage, solution flow rate, and the distance between needle and collector result in the instability of the nanofiber morphology and thereby production of nanofibers with uneven diameters. The TEM results confirm the intercalation of clay layers in the polymer matrix of polystyrene nanocomposite nanofibers (**Fig. 2**); the clay layers are specified by the tactoids in the TEM image. The light and dark areas represent polystyrene matrix and silicate layers respectively. The lack of space between the clay platelets and the polymer matrix affirms that there is an interaction between the clay layers and the host polymer matrix; this facilitates delamination of the clay stacks by the polymerization process.[8]

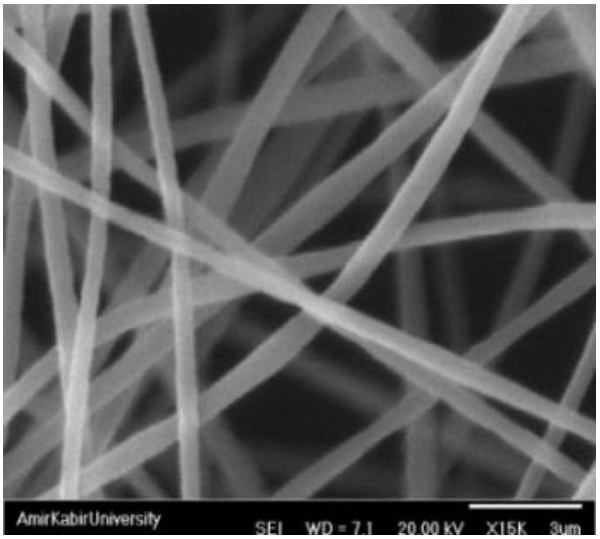

Figure 1. SEM image of the polystyrene nanocomposite nanofibers containing 4 wt% of nanoclay

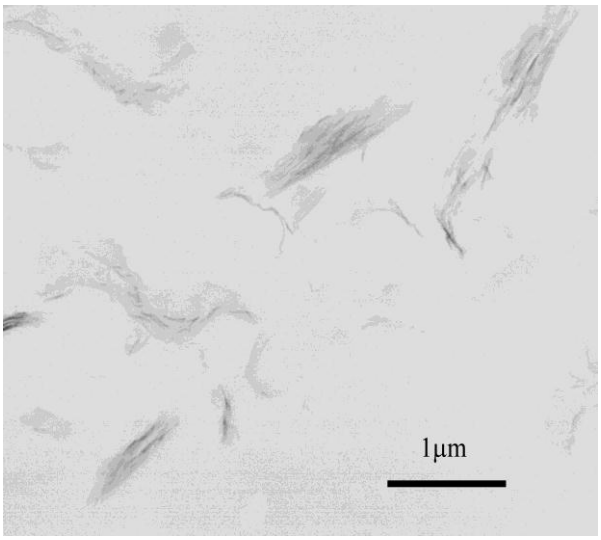

Figure 2. TEM image of the polystyrene nanocomposite nanofibers containing 4 wt% of nanoclay

To summarize, ATRP and electrospinning were jointly employed to produce "fit for function" polymeric nanofibers. The delamination of nanoclay stacks was achieved during the ATRP process and nanofibers with the average diameter ranging from 450-700 nm were obtained by electrospinning of the synthesized nanocomposite.

E-mail: kourosh.m.a@gmail.com

Introduction: It has been recognized for quite some time that crosslinked polyethylene has superior properties such as higher operating temperature and better chemical and environmental resistance in comparison with uncrosslinked PE [1]. However the main drawback of crosslinked PE of common degree of crosslinking (above 60% of gel content) is that its crosslinking must occur in the final product, i.e. crosslinked PE cannot be processed and its products cannot be recycled. Better flowability of partially crosslinked PE leads to processable raw materials and recycleable products with desired properties [2]. So, it is of crucial importance to find the optimum limit of crosslinking in such materials.

Partially crosslinked PE can be used in low shear processes such as rotational molding (to produce tanks), film blowing (to produce packaging films) and processing of crosslinked PE foams (to achieve high quality closed-cell structure) [3, 4]. In this work limit of crosslinking degree of HDPE for flowing through an extruder was determined. Crosslinking was achieved by both chemical and physical methods. Some properties of prepared lightly crosslinked PEs were determined and compared.

Materials and Methods: High density polyethylene with density of 0.956 gr/cm^3 and melt flow index (MFI) of 1.2 gr/min was partially crosslinked through a chemical method using dicumyl peroxide in HAAKE SYS 90 HIB internal mixer and an irradiation method with electron beam by Rhodotron TT200 Ion Beam Application.

At first, the processability of crosslinked products was assessed using a single extruder, HAAKE SYS 90 HIB, equipped with a rod die.

In chemical method various amounts of DCP were mixed with the polymer and fed into the reactive extruder in order to form strands after crosslinking occurrence, while in physical method the irradiated granules were directly used for flowability.

Gel content of flowable lightly crosslinked samples were determined. Some typical amounts of peroxide and irradiation doses were selected to give close values of gel contents.

Rheological behavior of samples was studied using Rheometer, MCR300, from Paar Physica Co. Molecular weight of uncrosslinked polymer and partially crosslinked samples (the sol fraction) were determined by Ubbelohde viscometer. MCR was used as an alternative method to calculate an approximate value for Mw from readings of zero-shear rate viscosity. MFI at different loads was also measured for an estimation of

Results and Discussion: Chemical and irradiated samples of up to 40% gel content were found to still flow through the employed rod die of 0.5 cm in diameter. Hence for properties investigation, only samples with less than 40% gel were chosen, some of which are shown in Figure 1. The results obtained from MFI, viscometry and rheology indicated that with increasing of crosslinking degree in both methods higher and broader molecular weight polymers were obtained [5]. Molecular weights were estimated from zero-shear rate viscosity using the relationship $\eta_0=k.Mw^{\alpha}$ with k and α parameters obtained for rubbery behavior are indicated in Table 1.

It was also observed that with increasing the amount of peroxide or radiation dose, molecular weight of the sol fraction was decreased compared to the neat polymer, i.e. crosslinking mostly occurred between longer chain molecules and chain scission in shorter ones. Moreover, the sol fractions of irradiated samples had lower molecular weight than those of peroxide crosslinked samples of the same gel content. Rheological results showed that while zero-shear rate viscosity was increased with crosslinking, its shear sensitivity was also increased. This indicated the higher flowability of partially crosslinked samples in the processing shear range. G' and G" curves versus frequency implied a solid-like behavior in low shear rates with a yield stress. Higher value of G' in comparison with G" (tan δ<1) over whole frequency range confirmed a rubber-like behaviour of samples in the molten flow.

Figure1

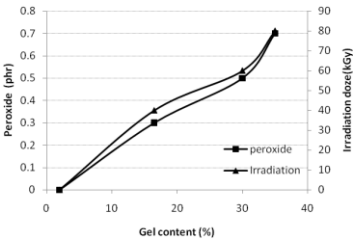

Table 1

Samples	η_0 (Pa.s)	M_w(gr/mol)
0.3 DCP	2255100	1110530
0.5 DCP	4181100	1329540
0.7 DCP	4656700	1371960
40 KGy	738650	802100
60 KGy	1917800	1059300
80 KGy	1613400	1007240

Conclusions: Crosslinked HDPE samples of less than 40% gel content are still processable in conventional single screw extruders. Although the average molecular weight increases with crosslinking, the sol fractions have lower molecular weight in comparison with the uncrosslinked samples.

The effect of crosslinking on Mw of sol fraction and polydispersity index is more pronounced in the irradiation method.

In the processing shear range, shear sensitivity and hence flowability increases while elasticity also increases for lightly crosslinked HDPE.

Precision design of novel copolymers and nanohybrids by Cobalt Mediated Radical Polymerization (CMRP)

Christophe Detrembleur, Marie Hurtgen, Yasmine Piette, Jean-Michel Thomassin, Christine Jérôme, Antoine Debuigne

Center for Education and Research on Macromolecules (CERM), University of Liège, Sart-Tilman B6a, 4000 Liège, Belgium

christophe.detrembleur@ulg.ac.be

Introduction. Cobalt Mediated Radical Polymerization (CMRP) using bis(acetylacetonato)cobalt(II) ($Co(acac)_2$) is the most efficient technique for controlling the radical polymerization of vinyl acetate until high molar masses and low polydispersity.[1-4] In this process the cobalt complex ($Co(acac)_2$) reversibly forms a Co-C bond at the chain-end of the polymer. At any time, a large number of polymer chains capped by a cobalt complex are in equilibrium with a tiny amount of propagating species such that irreversible termination reactions that occur between radicals by coupling or dismutation are avoided. The reversibility of the deactivation is ensured by homolytic cleavage of the Co-C bond by thermal treatment or radical exchange. By carefully adjusting the polymerization conditions, this CMRP process allows to control efficiently both conjugated (n-butyl acrylate (nBuA)[5], acrylonitrile (AN)[6]) and non-conjugated monomers (vinyl acetate (VAc)[1-4], N-vinyl pyrrolidone (NVP)[7]) using the same cobalt complex. Block copolymerization between these two monomers families is also possible by the fine-tuning of the Co-C bond at the polymer chain-end by metal coordination, giving access to novel copolymers.[1]

The importance of this system in the field of the macromolecular engineering is best illustrated by the recent development of a fast, efficient and quantitative radical polymer chain coupling reaction called Cobalt Mediated Radical Coupling (CMRC)[8-10]. Treatment of well-defined polymers prepared by CMRP by a conjugated diene such as isoprene exclusively leads to the coupling product with high coupling efficiencies (~ 95%) even when the molecular weight of the precursor is high (about 25000g/mol)[8-10]. This Cobalt-Mediated Radical Coupling (CMRC) method also proved efficiency for preparing symmetrical triblock copolymers when applied to a diblock precursor and for the efficient mid-chain functionalization of polymers.

Results and discussion. This communication aims at presenting recent advances in the field of CMRP, more particularly in the precision design of novel copolymers for advanced applications. Recent developments in our laboratory have demonstrated the possibility to promote the n-butyl acrylate homopolymerization with control until high molar masses (~ 6 10^5 g/mol) in mild conditions using $Co(acac)_2$ as controlling agent.[5] In the frame of synthesizing novel materials useful for bio-applications, we were interested in controlling the polymerization of poly(ethylene oxide) methyl ether acrylate (APEO) and in copolymerizing this monomer with vinyl acetate. We will show that controlling the APEO polymerization is not trivial and the reactivity of the CMRP system for APEO is different than that of nBuA. After discussing the optimal conditions for control, we will describe the synthesis of poly(vinyl acetate)-b-poly(poly(ethylene oxide) methyl ether acrylate) (PVAc-b-PAPEO), a novel block copolymer of interest in the field of drug delivery systems and surfactants.

Conditions for controlling the vinyl chloride (VC) homopolymerization and for synthesizing poly(vinyl chloride)-b-poly(vinyl acetate) (PVC-b-PVAc) block copolymers in mild conditions by CMRP will also be described. These new results open new avenues in the design of novel PVC based block copolymers.

In the last part of the talk, we will report on the preparation of novel well-defined nanohybrids of fullerene and carbon nanotubes grafted by poly(vinyl alcohol) based copolymers for photodynamic cancer therapy and electromagnetic protection purposes, respectively. A universal radical grafting onto approach of poly(vinyl acetate) based copolymers prepared by CMRP in mild conditions is used for the formation of the nanohybrids.

Conclusions. This talk will therefore emphasize the versatility of the CMRP process for the precise design of unprecedented copolymers and nanohybrids of interest using a cheap and commercially available cobalt complex ($Co(acac)_2$). Ways for adjusting the reactivity of the system in regards to the polymerized monomers will be highlighted.

Synthesis and Characterization of Poly (alkyloyloxyethylmethacrylate-co-methylacrylate) as Solid-Solid Phase Change Materials for Thermal Energy Storage

Tuğba Güngör Ertuğral[1], *Ömer Faruk ENSARİ*[2], *Cemil ALKAN*[2]

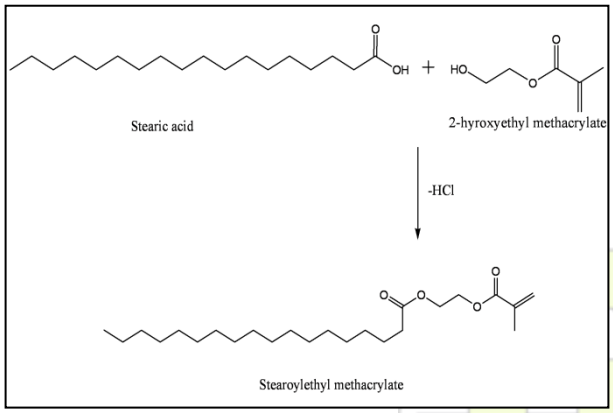
tuba.gungr@hotmail.com

Phase change material is a substance with a high heat of fusion which, melting and solidifying at a certain temperature, is capable of storing and releasing large amounts of energy. Heat is absorbed or released when the material changes from solid to liquid and vice versa; thus, PCMs are classified as latent heat storage (LHS) units. Total amount of energy absorbed or released by a phase change material can be calculated by equation 1.

$$Q = m\Delta H_M + \int_i^M mC_p dT + \int_M^f mC_p dT \quad (1)$$

PCMs should be encapsulated for usage and they are mostly encapsulated in polymers for the ease of application. Polymeric solid solid phase change materials are promising for their easy applicability and expected long lasting property. In this work, 2-hydroxyethyl methacrylate esterified with acyl chlorides of three different fatty acids to obtain monomers with phase changing property at convenient temperatures with high storage density so that copolymerization of these monomers with methylacrylate will result in polymers with solid solid phase changing property at variable phase change temperatures. 9 different polymers have been synthesized as a result of the reaction between produced monomers and methylacrylate at 3 different weight ratios. Produced copolymers were characterized by structural and thermal aspects. For the synthesis of the novel PCMs, myristic acid, palmitic acid, and stearic acid were chosen and they were transformed to acyl chlorides by thionyl chloride in the presence of dimethylformamide catalyst. Fatty acid acyl chlorides were bound to 2-hydroxyethylacrylate monomer from hydroxyl group as shown in the following Figure.



FT-IR and NMR spectroscopy techniques were used to characterize the produced PCMs structurally as molecular weight measurements were done using Gel Permeation Chromatography (GPC) technique. Molecular weight of the polymers produced decreased by the fatty alkyloylethylmethacrylate monomer content and with increasing paraffinic side length. Phase change temperatures and enthalpies and degradation temperatures of the synthesized PCMs were investigated using Differential Scanning Calorimetry (DSC) and Thermal Gravimetric Analysis instruments respectively and it was found that produced polymers have potential to be used as thermal energy storage materials and stable up to considerably high temperatures. On the other hand structural and thermal consistency of the polymers was confirmed by FT-IR and DSC measurements after accelerated thermal cyclings.

Thermal conductivity of the polymers was found to be in the range of the thermal conductivities of fatty acids.

Besides polarize optical microscopy was used for morphology investigation of polymers below and above phase transition temperatures.

Key words: 2-hydroxyethyl methacrylate, methylacrylate, phase change material, fatty acid

Introduction. Cu-mediated ATRP has become one of the most powerful tools for the synthesis of well-defined polymer materials. However, one remaining drawback of ATRP is the difficulty to effectively separate the homogeneous ATRP catalysts from products. Therefore it can limit one of the processes of choice for large-scale production of special polymers such as thermoplastic elastomers and materials with medical and pharmaceutical applications, among others. Although many post-polymerization purification workup methods have been devised to remove the soluble catalyst from the polymer,[1-3] a solid, recoverable, and recyclable catalyst is the most attractive solution. However, these techniques offer limited control over the polymerization of vinyl monomers, originating from the heterogeneous nature of the process.

We believe that immobilized catalysts (using functional polymers that interact with the transition metal as stabilizers) can overcome this diffusion limitation. In our case the catalyst is copper complexes coordinated with nitrogen atoms of the pyridine units of poly-2- and poly-4-vinylpyridine. Moreover, the catalysts based on copolymers with styrene or C12-C14 esters of methacrylic acid, and the non-soluble in organic solvents copolymers cross-linked with divinylbenzene (2%) were obtained. Such supported catalysts would act similarly to homogeneous catalysts and can be considered as an "quasi-soluble".

Materials and Methods. The poly-2- and poly-4-vinylpyridine, 2-vinylpyridine were got from Sigma-Aldrich. The poly-2-vinylpyridine-co-styrene was synthesized in bulk at 70^0C initiated with AIBN (1 mol%). The poly-2-vinylpyridine-co-divinylbenzene, poly-2-vinylpyridine-co-styrene-co-divinylbenzene and poly-2-vinylpyridine-co-methacrylate C12-C14-co-divinylbenzene were prepared via emulsion polymerization in the presence of sodium dodecylsulphate (0.5 mass%, Sigma-Aldrich) and AIBN (1 mol% to monomer mixture) as initiator at 70ºC for 5 hours. The catalytic complexes were prepared by ligand change reaction. The polymerization of methyl methacrylate (MMA) was performed in a glass tube equipped with magnetic stirrer under vacuum. The catalytic complex, monomer, ethyl-2-bromoisobutyrate (EBiB, initiator) and solvent were put to the tube, then degassed and heated during adjusted time. Poly(MMA) was separated via fractional precipitation to methanol in the case of soluble homopolymers and was extracted from the mixture with catalyst via acetonitrile after precipitation to hexane in the case of insoluble homopolymers. The cross-linked catalysts were separated via filtration through PTFE membrane filter. Purified polymers were dried under vacuum.

Synthesized poly(MMA) was characterized by SEC with two Phenomenex phenogel column 7.8×250 mm, 10 μm (10^3 and 10^5 Å) on Knauer WellChrom equipment with RI and UV-detectors.

Results and Discussion. The influences of temperature, the ratio of the components in the initial mixture, the nature of solvents and polymer matrix on the polymerization have been investigated.

The polymerization in polar solvent (DMSO) is characterized in high polymer yield and PDI values, and in non polar solvents (benzene and dioxane) in low rate. In Single Electron Transfer – Living Radical Polymerization (SET-LRP) the balance between dormant and active chains is provided by an outer-sphere heterolytic SET-mediated by the appropriate choice of solvent. THF is the optimal solvent that allows the controlled radical polymerization of MMA to provide.

We suppose that the lack of controllability of the immobilized catalysts in ATRP may be caused by the change of coordination angle. The best results were achieved in the presence of soluble and insoluble poly-2-vinylpyridine-co-styrene copolymers. The backbones, connecting with different donor functions bonded to the same Cu ion, are enough long and enough flexible to provide the desired stability for the metal species.

Kinetic studies of the polymerization were performed with both of copolymer catalyst systems. These homogeneous catalysts produce polymers with low PDI. In the presence of the cross-linked catalysts the level of control over the polymerization decreased insignificantly. The molecular weights of the resulting polymer increased linearly with conversion, indicating a living character of polymerization.

Conclusions. It has been established that temperature in the range 90-110^0C, the molar ratio MMA : initiator : Cu = 100 : 1 :1, THF as the solvent and the catalysts based on the copolymer of 2-vinylpyridine with styrene (soluble or non-soluble) are the optimal conditions for providing the controlled polymerization. The immobilized catalysts were removed by simple filtration or sedimentation, and can be recycled, affording a colourless transparent polymer solution.

Abstract

The usage of natural fibers as reinforcement in thermoplastic composites has gained a rapid growth in the last few years, due to a several advantages that the natural fibers offer over conventional inorganic fibers, such as, abundance, renewability, low density, high specific strength and stiffness, almost no health hazards, and relatively low cost [1, 2]. However, one difficulty that have prevented a more extended utilization of natural fibers, and it is a challenge for cellulose fiber reinforced thermoplastic composites, is a lack of good interfacial bonding between the hydrophilic nature of fibers to a hydrophobic matrix [1]. This study is focused on evaluating the effect of coupling agent by mechanical properties of cellulose fiber and polystyrene composites.

In this study, cellulose fiber/polystyrene composite were processed on a twin-screw extruder, with 10wt%, 20wt% and 30wt% of cellulose fiber, with 2wt% of SMA, poly(styrene-co-maleic anhydride) with 30wt% of maleic anhydride groups, as a coupling agent and without SMA. Flexural and unotched IZOD impact test were performed according to ASTM D790-03 and ASTM D256, respectively(Fig.1).

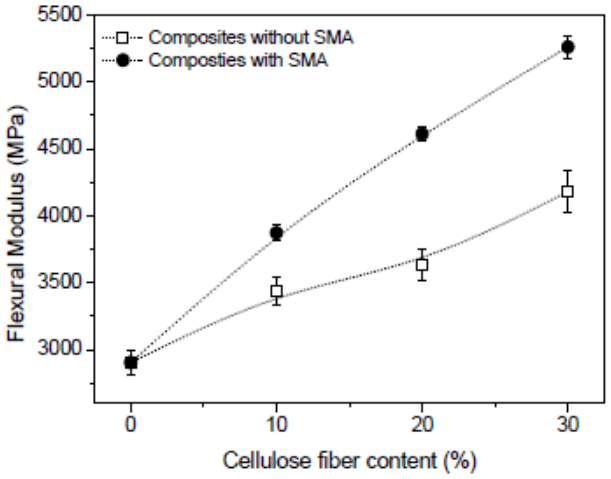

Figure 1: Flexural modulus of PS/Cellulose composites

The flexural modulus as a function of fiber content is shown in Figure 1. The modulus increases almost linearly when increasing the fiber content; this behavior may be related to the fact that the cellulose fibers have a greater modulus than the matrix [2]. The modulus also increases, significantly, with the addition of SMA, as related by Bengtsson et al, the increase in modulus upon the addition of SMA is most likely caused by an improvement in Dispersion of cellulose fibers on the polystyrene matrix [1].

However, another explanation is an improvement on the interface between the fibers and the matrix caused by the coupling agent, which leads to a better efforts transference from the matrix to the fiber, increasing the flexural modulus [3].

From to analyse the be less dependent on the fiber content, as also reported by several researches. The improvement on the interfacial adhesion improves the impact strength, since weak interface is the weakest part of the composites; however, a strong interfacial adhesion will reduce polymer mobility and prevent fiber pull-outs from the matrix leading to a decrease in impact strength (Fig.2)[1].

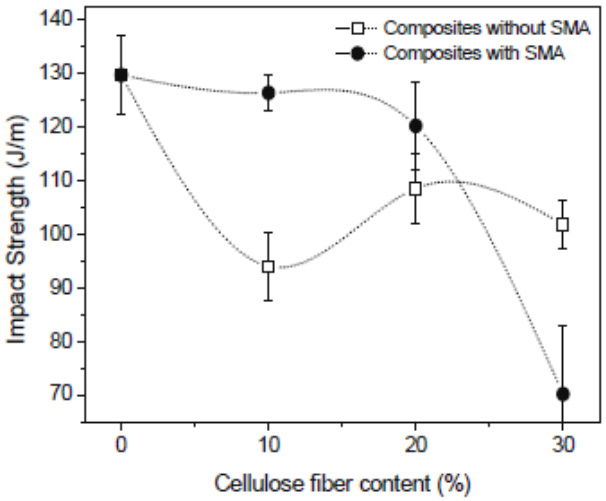

Figure 2: Impact strength of PS/Cellulose composites

The results confirm that SMA promoted a better fibermatrix interfacial interaction, due to a number of polar groups introduced into de matrix resulting in the interfacial adhesion improvement between cellulose fiber and PS matrix, reflecting on mechanical properties improvements.

sandrine.ausset@etu.u-bordeaux1.fr

The production of electric and electronic equipment is one of the fastest growing areas of manufacturing industry. These advanced technologies generate a huge volume of waste of electric and electronic equipment (WEEE). In order to contribute to a sustainable development, the European Commission adopted the 2002/96/EC and 2002/95/CE directive. Among other principles, these regulations require an increasing rate of materials recycling. WEEE contain about 15-30% plastics [Achilias2009; Vilaplana2008], that is why it is necessary to develop efficient processes to recycle these plastics. The recycling of WEEE plastics is a complex technological challenge for many reasons. Firstly, WEEE plastics are composed of approximately 15 different types of engineering polymers. It is difficult to obtain an all-pure material from real deposits and sorting is never completely achieved. Indeed, with efficient sorting technique, a significant amount of impurities remains in the recycled material, reducing its mechanical properties. Secondly, in recycled plastics issued from WEEE, many grades of polymers exist. If a recycled plastic without impurities could be elaborated, its mechanical properties would be automatically lower than the virgin plastic.

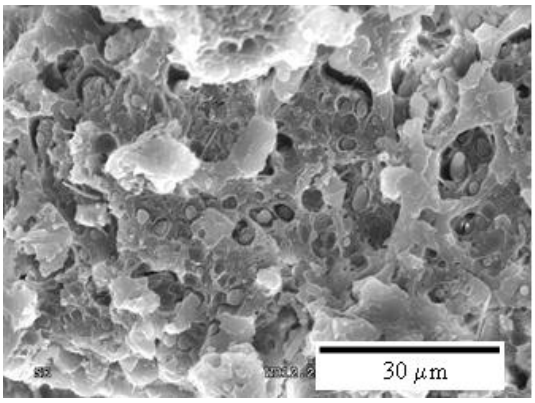

Figure 22: SEM micrograph of impact fractured surfaces of ABS-PC containing 5wt% of HIPS.

A way to solve this problem and upgrade recycled plastics is firstly to compensate for the impurities inclusion by adding compatibilizer or specific additives. Secondly, recycled plastic blends can be developed in order to associate their properties into the recycled matter.
In this work, mechanical recycling of polymers from real waste deposits is studied i.e. neat ABS, PC-ABS alloys, blends between ABS and PC. The aim of our work is to discuss, illustrate and compare the mechanical behaviour, mainly impact strength, of either new or aged recycled material. The presentation deals with blend properties (morphologies vs impact strength) and optimization of blending process to produce competitive recycled materials. Examples of PC-ABS blends over the whole concentration range will be discussed and analysed in terms of process, morphology and mechanical properties.

Polymers with hydrogen bonding moieties via ROMP

Steffen Kurzhals, Wolfgang H. Binder

Martin-Luther-University Halle-Wittenberg, Faculty of Natural Sciences II, Institute of Chemistry / Chair of Macromolecular Chemistry / Von-Danckelmann-Platz 4 / 06120 Halle / Saale, Germany

Steffen.Kurzhals@chemie.uni-halle.de

Supramolecular polymers[1] represent an interesting group of materials due to their reversible assembly and disassembly which allows them to respond on external stimuli. These materials are held together by weak interaction e.g. hydrogen bondings, metal-ligand bonding which are directive forces. This allows to transform a random chain assembly into an ordered structure. By combining the supramolecular interaction with a functional polymer it might be possible to improve its properties e.g. conjugated polymers. These polymers, which find application in display technology or solar cells, are attractive alternatives to inorganic analogues due to their lower manufacturing costs and lower weight.

The aim of this work is the synthesis of functionalized polymers (polynorbornenes, poly-*p*-(phenylene vinylenes) via ring opening metathesis polymerization (ROMP) (Figure 1) to prepare sheet like structures. The polymers should be modified with hydrogen bonding donors and acceptors (e.g. thymine, barbiturate) which are introduced via quenching reaction with symmetric olefins.[2] The quenchers are synthesized from the corresponding α-olefins via homometathesis under microwave irradiation. This method for the introduction of functional groups offers a facile approach to functional polymers with no need for post functionalization reactions.

As model system for the introduction of hydrogen bonding moieties we have chosen a norbornene-derivate which could be polymerized in a living fashion with commercial available Grubbs catalysts (1st- and 3rd-generation) as judged by the control over the molecular weight and the small polydispersities (1.1-1.3). These living polymers were then reacted with an excess of the symmetric quenching agents. Quantification via MALDI-TOF MS[3] revealed an increasing fraction of functionalized polymer with time and amount of added quencher.[4] Additionally, the desorption ratios showed a strong influence of the end group on the desorption of the different polymer species. After proving the successful incorporation of the functional moieties in the polymer backbone we transferred this quenching approach to conjugated poly-p-phenylene vinylenes. Since the synthetic access to the corresponding cyclic olefins is limited, we have chosen a 7 step process for the preparation of the barrelene derivates starting from commercial available myo-inositol.[5,6] Various metathesis catalysts (Grubbs, Umicore and Schrock) are investigated for the preparation of soluble PPV-precursor polymers aiming at a living polymerization, which is a requirement for the crossover reaction with the symmetric olefins.

Nature provides us with the prime examples of lightweight, strong, stiff and yet tough materials. The unique and exceptional properties are realized via a hierarchical ordering of hard (inorganic) and soft (organic, polymeric) building blocks. Nacre serves as an excellent example with its highly ordered brick and mortar structure. In terms of materials science, nacre is considered to be a perfect marriage of hard and soft materials and thus biomimetic materials of this structure are in the focus of research. Significant efforts have been devoted to the generation of nacre-mimics by various sequential multilayer techniques. Although the materials exhibit superior properties, their preparation suffers from being laborious, step-wise and extremely time-consuming. Days to weeks are necessary to prepare films with thicknesses of only a few micrometers. Thus, all these strategies face tremendous obstacles to allow a transfer of concepts beyond the laboratory scale. To promote these structures into true 21st century biomimetic materials with advanced properties, we have to think of more innovative strategies.

Herein, we will show how to overcome many obstacles and how to create large-area brick-and-mortar nacre-mimics (Figure 1a) with sub-millimeter thicknesses and potentially unlimited lateral dimensions via continuous roll-to-roll processes. We combine concepts of colloid chemistry with hierarchical self-assembly and well-developed up-scaled preparation strategies. Our concept makes use of solution-based self-assembly of polymers onto nanoclay platelets to create ideal building blocks with intrinsic hard/soft character. Subsequently, these core-shell bricks are forced to self-order on a second length scale. The resulting materials show a highly ordered layered arrangement of the platelet-shaped inorganics, surrounded by an organic polymer matrix (Figure 1). Due to the utilization of well-defined building blocks, the structures are composed of an optimized hard/soft ratio and a majority fraction of hard reinforcing material. Hence, the resulting material properties demonstrate outstanding stiffness and strength, being in the range or even surpassing the values of natural nacre. We will also show how the mechanical characteristics can be tuned and improved via chemical and physical crosslinking.

The strategy allows for the rapid, economic and environmentally friendly production of nacre-mimetic sub-millimeter thick films with superior material properties.

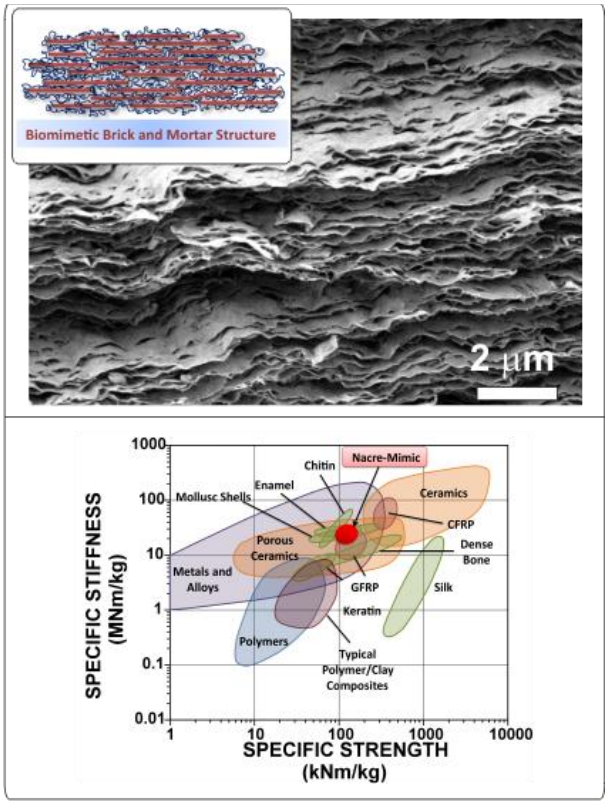

Figure 24. Top: SEM image demonstrating the strongly aligned layered orientation of the platelet-shaped inorganics. The inset schematically shows the biomimetic brick and mortar structure. Bottom: Specific mechanical property selector chart adapted from Ashby et al. The mechanical properties of our materials are in range with strong biological materials and can compete with metals, ceramics and glass fiber reinforced composites (GFRP).

*Corresponding author's email: J.Luo@bolton.ac.uk

Polyurethane shape memory polymers (SMPUs) are one of the most studied and developed shape memory polymers (SMPs), and have found tremendous applications in engineering, space exploration and medical devices owing to their superior properties of large deformation, light weight, low density, low cost and easy processing etc. Chemical resins are available commercially for synthesis of SMPUs, and ready-made SMPU products can be also obtained and used for various applications. However, the waste and disposal of SMPUs have been treated no exception as to other polymers, and little effort has been made to study the recycle and re-usage of SMPUs, and to investigate the relevant physical and chemical properties of the SMPUs. With the increasing concerns over the impact on environment and global warming caused by chemical synthesis, disposal and waste, recycling of polymers becomes increasingly important and urgent. Meanwhile, successful recycle of SMPUs would increase the value of SMPs and further widen their applications. This paper is to report recycling of SMPUs and the relevant study on the material properties of the recycled SMPUs.

Recently we have developed various polyurethane-based shape memory polymers (SMPUs) with low transitional temperatures, Tg, suitable medical application in human body using polyols as soft segment and combination of diisocyanates: isophorone diisocyanate (IPDI) and 4,4′-diphenylmethane diisocyanate (MDI) as hard segments. This is continuous work of the development.

The SMPUs used for the recycling experiments were SMPUs made from poly(caprolactone) (PCL) and MDI/IPDI hard segment[5]. The PCL-samples were used for various thermal mechanical, tensile and shape memory (SME) tests and are longer suitable for further use. The used PCL-SMPUs with different MDI/IPDI rates were dissolved in various solvents, and it was found that N,N-dimethylformamide (DMF) is the best solvent which dissolves the SMPUs and form resin-type polymers without losing originality significantly. The details of the process will be reported at conference. The processed polymer resins were recast into thin films for various characterizations: thermo-gravimetric analyzer (TGA), differential scanning calorimetry (DSC), X-ray, SEM, tensile tests and SME tests.

It was found that the recycled SMPUs with original largely retained their properties of the freshly made samples regardless the concentration of polyols, and concentration ratios of MDI to IPDI used. TGA measurements showed slight changes in material loss rate at high temperature, while DSC showed Tg and heat of fusion increased slightly at recycle as summarized in Table (samples with -R are the recycled ones), indicating increased crystallinity once recycled.

Thermal mechanical and tensile tests showed the recycled SMPUs retained most of the SME effects with deterioration rates less than 10% with results shown in Fig.1-3. Since the recycled SMPUs with proper MDI to IPDI ratios still possess high performance such as 830% elongation at break, high than 80% shape recovery rate and fixity, they can be used for various applications as the original shape memory polymers do.

SAMPLE	Peak Temp. (Tpm) (°C)	ΔH (J/G)	Stress at break (MPa)	Strain at break (%)
PCL (P)	**53.03**	**65.27**

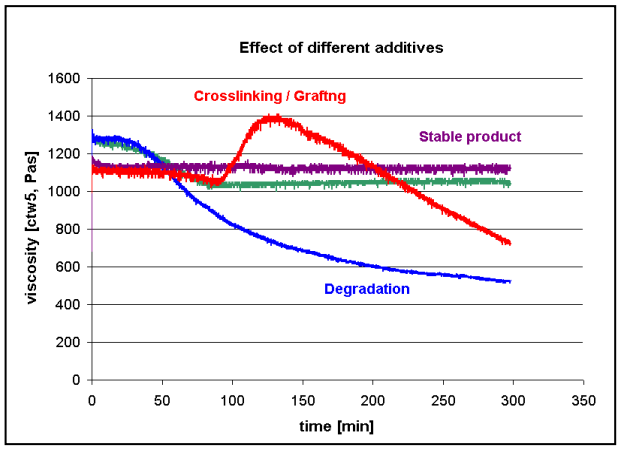
Advances in Small Scale Processing Equipment for Polymers and Additives

Bernd Jakob - Thermo Fisher Scientific, Karlsruhe, (Germany)

bernd.jakob@thermofisher.com

Abstract: The use of a conical twin screw extruder with backflow channel combines the aspects of mixing and extrusion in a batch process. With a small force feeder and a conveyor belt the micro compounder operates continuously producing a strand or a small sheet. With a total filling volume of 7 ml and a built in slit capillary die the applications focus is on compounding and reactions of small amounts of polymers in the molten stage. Two great areas of application: mixing and rheological recording of the melt characteristics are combined in the micro compounder. For further tests the polymer melt can be transferred into a micro injection moulding machine to shape different kind of test specimens for further analyses.

Compounding: To analyze small batches different test setups are possible. Either continuous or batch processes with defined mixing times can be selected. Co- or counter rotating screws are used to melt and mix the polymer pellets or powders. The influence of additives is show in graph 1.



Graph 1 The Effect of different additives

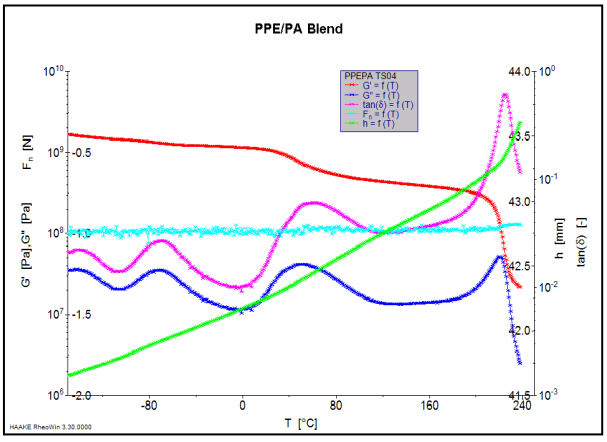
The effect of different additives is obvious. *One compound is stable for 5 hours and no change in the viscosity is observed*. Where as the other compound degrades after about 30 minutes visible by a decreasing the viscosity. A third compound shows a viscosity increase after about 120 minutes due to a reaction of the product followed by degradation

Viscosity: The backflow channel of the micro compounder is designed as a slit capillary. Two pressure transducers in the backflow channel measure the pressure drop. From this pressure drop a shear stress is calculated. To determine the shear rate, the mass flow in the flow is correlated with the screw speed of the Thermo Scientific Haake MiniLab. To record a flow and viscosity curve, different screw speeds are set and the pressure drop (shear stress) at those different screw speeds is measured.

The correlation between the screw speed and the mass flow is for each polymer slightly different. So the calculated shear rate and therefore also the calculated viscosity can only be a relative value which is accurate enough to compare different batches.

Test Specimens: With the compound produced in the Haake MiniLab various test specimens can be produced very efficiently with the Thermo Scientific Haake MiniJet, a micro injection moulding machine. The instrument is build as a piston injection machine with a removable heated cylinder with injection piston to collect the melt from the Haake MiniLab. Also pellets or powders can be molten direct in the heated cylinder. The amount of required sample material is minimized to less than 5 g Almost the whole amount of polymer melt is completely trans-formed into test specimens. This is a major advantage as the waste material of conventional screw driven injection moulding machines can be avoided by this principle. With the exchangeable moulds disks, plates, DMA and tensile bars can be prepared for hardness tests, breaking strength,

Dynamical Mechanical Analyses (DMA): For testing of the solid polymer according to DIN/ISO 6721-1 a DMA bar is mounted with solid clamps in the Thermo Scientific Haake MARS monitoring the effect of additives over a wide temperature range. The effect of the additives is seen in the shift of the glass transition temperature. In graph 2 the result of a DMA test is shown.



Graph 2 DMA test of a PPE/PA Blend

Conclusion: The micro compounder Haake MiniLab is a useful tool to process small amounts of polymers and additives. Especially in the stage of development of new products and the screening process for promising candidates of new compounds reproducible results are obtained in a shorter time. For further tests the compound can be shaped to a variety of different test specimens with the micro injection moulding machine Haake MiniJet.

Role of Rheology on Quality of Polymeric Articles

Faezeh Aghazadeh[1] *and Hossein Hosseini*[2]

[1] R&D Center, Tabriz petrochemical Company, Tabriz, Iran
[2] Department of Chemical Engineering, University of Tabriz, Iran

f.aghazadeh@hotmail.com

Polymer processing for production of all forms of polymeric articles has found a great place in chemical industries. Thermoforming process is one of the most popular techniques in this field. The fundamental defects inherent to the thermoforming technology are wall-thickness variation and warpage of the products. A nonlinear viscoelastic rheological model is implemented for developing the process model. This model describes deformation process of a sheet in thermoforming process. Because of relaxation pause after plug-assist stage and also implementation of two stage thermoforming process have minor wall-thickness variation and consequently minor warpage and better mechanical properties of thermoformed articles. For model validation, a quantitative relation between stress and technical parameters of plug-assist thermoforming is determined by comparison of theoretical and experimental results. This model could be suggested for prevention from some technical defects such as wall thickness variations, physical instability during inflation-shrinkage, and warpage exhibited in the final part of a polymeric article.

It is well known that the stage of vacuum-forming with a pre-stretched sheet occurs too quickly for experiencing of relaxation processes in the polymeric sheet. This will result in this fact that almost all accumulated deformations in polymeric sheet within this stage are elastic. Consequently, the minimization of the accumulation may be realized only by minimizing of the general deformations accumulated in polymeric sheet during this stage. For practical purposes, this means that the profile of the pre-stretched sheet should be maximally approximated by the profile of the final product which could be assured based on the application of a plug with the respective radius.

In contrast to the second stage, the stage of plug-assisted can be regulated in the sense that it is technically possible to control the motion of the plug. This creates a practical opportunity that at this stage to organize the relaxation process of elastic deformations accumulated in a polymeric sheet during the process of plug-assist forming. The essence of the simplest of many variants used in the realization of this process lies in the creation of a relaxation pause period between the first and the second stage. During this period the accumulated elastic deformations are completely or partially relaxed and consequently minor wall-thickness variation. So, because of relaxation pause after plug-assist stage and also implementation of two stage thermoforming process have minor wall-thickness variation and consequently better mechanical properties of thermoformed articles.

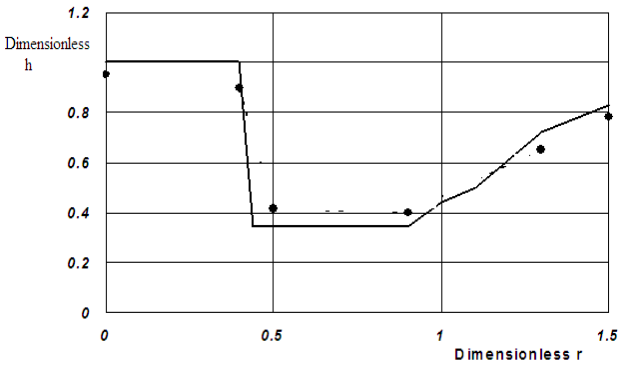


Fig.1. Comparison of model simulation (___) and experimental (●) wall-thickness distribution for PP (h_0 = 1mm).

Re-Use and recycling of PLA and its mechanical properties

Reinhard Forstner, *Julia Pleiner*

Transfercenter für Kunststofftechnik, Franz-Fritsch-Straße 11, A-4600 Austria

Reinhard.forstner@tckt.at

Introduction: In recent years Poly-(lactic acid) as a green polymer has attracted scientific and industrial attention since PLA can be processed similar to polyolefins and is known to be compostable. Polylactide, an aliphatic polymer, which can be obtained from renewable resources by fermentation [1,2] and was mainly used in medical applications [3] Meanwhile PLA has entered the packaging market and pushes also into technical applications such as housings of cell phones. In production in house waste material is produced in amounts of several tons/a, which is a costly problem for the industry.
The goal of this study was to investigate the mechanical and thermal degradation of PLA in a re-use situation in a lab compounder to mimic recycled material or the re-fill of in-house waste.

Materials: In this study two different PLA grades with different molecular weight and melt flow rate of MFI~8 (PLA 1) and MFI~30 (PLA2) were used.

Methods: The PLA grades were compounded and re-compounded in a parallel twin screw lab compounder up to fifteen times and samples were taken at five, ten and fifteen repetitions. For each fraction tensile, impact and flexural properties were determined according to ISO standards and dynamic mechanical viscosity as well as gloss measurements were performed.

Results: The results showed that the moduli and the impact properties hardly changed for all repetitions. Only the tensile strength and the flexural strength decreased as well as rheology data showed a decrease of zero shear viscosity with increasing numbers of repetitions, which indicated a change in molecular structure.

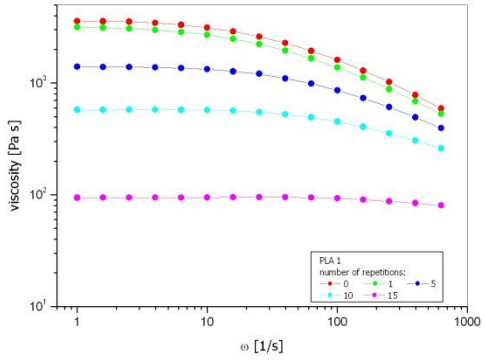

Figure 1: Viscosity data of PLA 1

Molecular weigth of the re-used fractions were calculated from viscosity data, which confirmed the decrease of the molecular weigth with increasing numbers of repetitions.

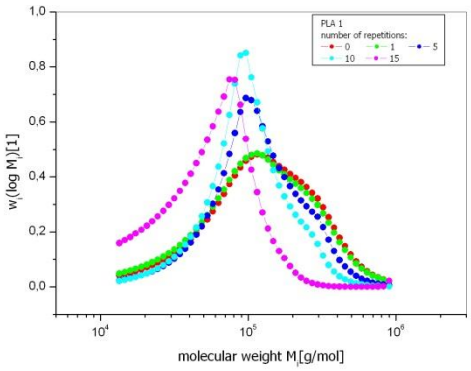

Figure 2: calculated molecular weight distribution

Conclusions: As this study showed, PLA can be reprocessed several times with hardly any change to mechanical properties, but serious change in viscosity and molecular weight respectively.

sonja.neuhaus@psi.ch

Introduction

A strategy for creating a polymer brush / nanoparticle composite layer on a flexible polymer foil substrate is presented. Polymer brushes with carefully selected functionality are ideal templates for the formation of nanoparticles, as the size of the particles should be limited by the metal content of the brush matrix and the confined space therein.

Materials and Methods

Poly(4-vinylpyridine) (P4VP) brushes were grown from poly(ethylene-*alt*-tetrafluoroethylene) (ETFE) foils. (Hydro)peroxide radicals for the initiation of a free radical polymerization were created by exposure of the foils to EUV light at the Swiss Light Source (SLS) or by activation with cold, atmospheric-pressure helium plasma [1]. The pyridine moieties abundant in the polymer brush were used to complex iron. In a subsequent annealing step under alkaline conditions, iron oxide nanoparticles were created.

Results and Discussion

The different steps of the production sequence as well as the resulting polymer brush / iron oxide nanocomposites were characterized with a number of methods. Upon iron complexation, a strong shift of the ring skeleton vibration bands was observed with attenuated total reflectance-infrared micro-spectroscopy (ATR-IR) (Figure 1). The initial spectrum was retrieved after the oxidative treatment, suggesting that the pyridine ligands were regenerated and again available for complexation. UV spectra recorded in transmittance proved that the amount of iron oxide could indeed be increased by multiple loading and oxidation steps.

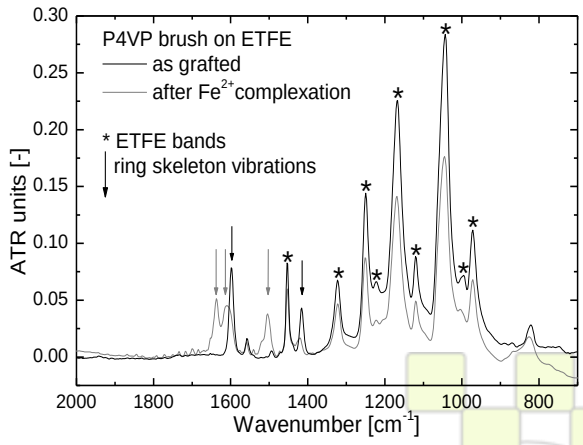

Figure 1: ATR-IR spectra of P4VP brushes as grafted, after the complexation of iron and after the oxidative treatment.

Microtome cuts of the samples were prepared in order to image the P4VP / iron oxide composite layer with transmission electron microscopy (TEM) (Figure 2). Particle sizes were found to be in the range of 1 nm, but larger clusters were observed as well. The presence of iron in the brush was confirmed by energy dispersive x-ray spectroscopy.

In a further step, the composite material will be investigated using the unique capabilities of the scanning transmission x-ray microscope (STXM) at the PolLux beamline of the SLS. Apart from element specific imaging of the nanoparticles and the interface to the substrate with high resolution, x-ray absorption spectra will help to identify the type of iron oxide produced. Moreover, the nanoparticles will be tested for their magnetic properties with x-ray magnetic circular dichroism measurements.

Conclusion

Ultimately, the aim is to implement several types of functionalities on one surface. In the presented approach, the *chemical* functionality of the brush is used for capturing iron for subsequent particle formation. It will be interesting to see whether the particles endow the brush with *magnetic* responsiveness as shown for an anionic polymer brush on a silicon/gold substrate [2].

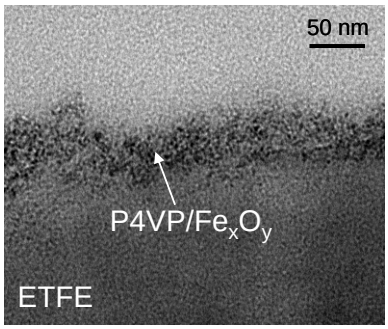

Figure 2: TEM image of a microtome cut showing a P4VP brush with iron oxide nanoparticles on ETFE.

orlando.santana@upc.edu

Introduction: Poly(lactic acid) (PLA) is a semi-crystalline biodegradable polymer that has been used for several years in medical and biocompatible applications, packaging, food and agriculture. Due to the chiral nature of lactic acid, two types of monomer (L or D) could be used in PLA synthesis. Control of the ratio of L to D monomer has a large effect on material properties primarily through affecting the percent of crystallization.

One of the main drawbacks of PLA is its high sensitivity to hydrolytic degradation during processing (similar to PET). Moreover, due to its linear molecular architecture has a low melting strength which limits its application on single-use disposable items produced by low density foaming, vacuum thermoforming, highly oriented film and blow molding. It is well known that the branching and low degree cross-linking of molecules can offer the enhancement of rheological properties, and give new opportunities for PLA markets. Following the PET approaches, there have been studied some reactive modifications during processing with chain extenders or branching agents. Among these, the glycidyl acrylates-based copolymers have shown excellent versatility in these issues.

The aim of this communication is to show some results of the rheological, thermal and mechanical properties of two grades of PLA modified by a glycidyl methacrylate-based branching agent. In order to study the scaling-up of processing conditions (main key problem for industrial processing), the modifications have been made by: a) internal mixer at laboratory scale and b) pilot plant scale (twin screw extrusion - continuous calendar).

Materials and methods: Two extrusion grades of PLA from NatureWorks (PLA 2002D and PLA4032D) with similar MFI (7 g/10min at 210ºC/2,16 kg) differing only in the L:D ratio (96:4 and 98:2 respectively) have been used in this study. As branching agent it has been used a low molecular weight copolymer Styrene-acrylic-glycidyl methacrylate kindly supplied by BASF (Joncryl 4003-C) with a EEW of 443. It was added in a proportion of 0.5 and 1 % wt of PLA.

Previous to any processing PLA and branching agent were dried for 5 h at 80ºC in a PIOVAN hopper with dew point of -40ºC. Two processing systems were used:

a) Internal mixer compounding (laboratory scale, 50 g/batch): T = 180ºC, 50 rpm, N_2 atmosphere, t = 15 min. Sheet (1 mm in thickness) were compression molding at 180ºC during 10 min.

b) Twin screw extrusion-continuous calendar (pilot plant scale): L/D =36, plane temperature profile at 180ºC, variable screw rotation speed (80, 60 and 40 rpm (residence time of 2, 3 and 4 min). Sheets of 0.9 mm in thickness were obtained.

Rheological measurements were performed on a AR-G2 RDA (TA Instruments) in parallel plate geometry at 180ºC and 1 % of strain (Linear viscoelastic range, LVR). N_2 atmosphere was used during the tests.

For the thermal characterization it was used a DSC Pyris 1 (Perkin-Elmer) at 10ºC/min per scan. Additionally, thermal fractionation (SSA) were performed in the same equipment. Dynamic Thermo-mechanical tests were conducted in a Q-800 DTA (TA Instrument) at 2ºC/min of heating scan (from 30 to 170ºC) at 0.5 % of strain and 1 Hz (LVR). MWD has been determined by GPC (25ºC, HFIP) and from the relaxation spectrum obtained from the master rheological curves

Results: One of the interesting aspects focused on the rheological properties obtained. As shown in Fig. 1, the rheological changes achieved are consistent with a branching system. At high shear rate region (>100s^{-1}) (range of extrusion) it seems that as higher the D enantiomer content, the greater the increase in viscosity. This trend seems reversed at low shear rate. However, differences on MWD between grades must be considered. These and other aspects of change and the comparison of results with extruded systems will be discussed during the presentation.

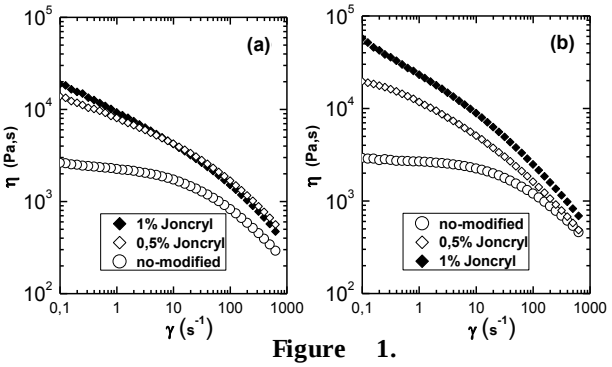

Figure 1. Rheological curves,after Cox-Merz correspondence of **a)** 2002D and **b)** 4032D preparations at 180ºC.

pcosta@fisica.uminho.pt

Rubbers and thermoplastic elastomers play an important part in industrial applications and biomaterial development. The thermoplastic elastomer styrene-butadiene-styrene (SBS) is widely studied and used due to its interesting characteristics, in particular, its high elongation at break and insulation properties. In order to increase the application range of this material to sensors and actuators, for example, it is necessary to tailor its electrical response. One possibility to tailor conductivity in SBS is to add carbon nanotubes (CNT) to the polymeric matrix. Several theoretical and experimental studies showed that the composites reinforced with carbon nanofillers have the percolation threshold lower than with other conductive materials. In this work, SBS/CNT composites were prepared by solution casting at various concentrations raging to 8 wt% of incorporation of CNT. The dielectric properties (dielectric constant and losses), electrical conductivity and piezo-resistance were measured for all composites. The dielectric constant increases with the inclusion of CNT, being $\varepsilon' \sim 50$ for the higher concentrations of CNT while de pure SBS is around the $\varepsilon' \sim 2$. The addition of CNT increases considerably the initial modulus of the composite compared to neat SBS, being ~160 MPa for the composite with 5% CNT and around 50 MPa for nonfilled SBS. The elongation to break, on the other hand is above 1000%, even for the nanocomposites with higher concentrations of CNT. The performance of the composites as piezo-resistive sensors was also evaluated through the measurement of the longitudinal gage factor.

Introduction

One of the main issue of high molecular weight or strongly filled polymers is their very high viscosity. For these polymers, sintering is often required instead of injection or extrusion. This process needs a long time (few hours) at high temperature (170 °C for UHMWPE) to sinter the polymer.

The High Velocity Compaction (HVC) is an original and in development processing. The melting of nascent polymer powder occurs by impacting the powder in a heated die. Parameters are the energy, the number and the frequency of impacts. HVC allows obtaining a part close to the final shape in a few minutes. Quick processing and low starting temperature (~115 °C) prevent the thermal degradation of the polymer. The main advantage of HVC is the possibility to adjust the quantity of nascent phase remaining in the material after processing. DSC measurements allow to evaluate the recrystallized phase fraction (Fr) [1].

In this study we are going to show that HVC can process a UHMWPE 6 x 10^5 g/mol to 10.5 x 10^6 g/mol with only small changes in process parameters. Moreover it is possible to choose the mechanical behavior (fragile or ductile) and the mechanical properties of the material by adjusting the ratio of nascent powder which remains in polymer. SAXS and WAXS allow to understand relationship between micr structure and properties of HVC materials.

Materials and methods

Ticona provided the different powder of UHMWPE (GHR 8810 and GUR's 4113, 4120, 4130, 1050, 4170). Tivar 1000 obtained by hot-compaction is our reference material. Before compaction, we heat the powder

DSC analysis has been performed on a Perkin Elmer DSC 7 at an heating rate about 10 °C/min.

Tensile tests have been realised with an Instron device at 0.2 s^{-1}.

Results

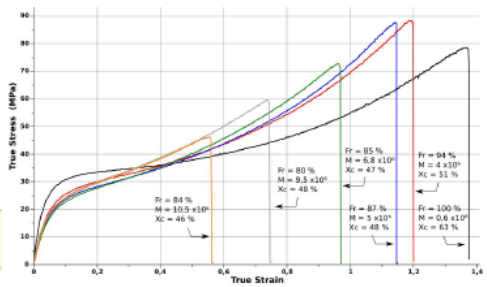

Figure 1: Tensile test for all grades with the same process parameters (M: molecular weight, Fr: recrystallized fraction, Xc: crystallinity)

Fig. 1 shows that we can be sinter all of our powder with the same parameters. Nevertheless the recrystallised fraction depend on the grade: Fr vary from 80% to 100% and the break occurs for a true strain between 0.58 and 1.39.

Fig. 2 shows, for one UHMWPE, the variations of the mechanical behavior according to the recrystallized phase ratio. For Fr = 46 %, the mechanical properties are lower because of a lack of interparticular cohesion.

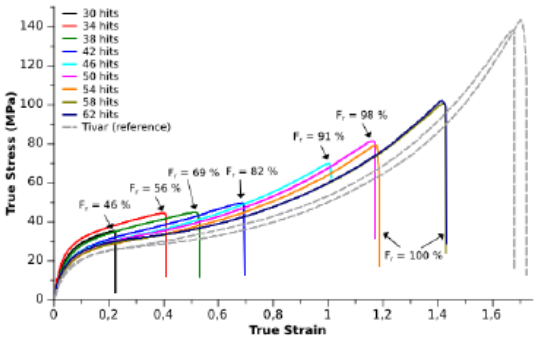

Figure 2: Mechanical behavior according to the recrystallized phase ratio and the number of hits

Discussion

The ratio of residual nascent phase drives the mechanical behavior (fig. 2). HVC material can be described as an "autocomposite", the residual nascent phase acts as filler [2]. With a large amount of residual nascent phase Young modulus can be 70 % higher than material processed by hot-compaction.

Surprisingly, when the material is completely melt during the process (Fr = 100 %), it is stiffer than the reference material. Is also highlighted by microindentation test, depth penetration is 30 % higher on Tivar than nascent phase free HVC material. According to the x-ray scattering studies, this stiffening is not due to some residual stress but more due to the thickening of the crystals.

Conclusion

HVC can process, with the same parameters, a wide range of UHMWPE grades. Surprisingly the quality of sintering seems to be nearly independent of the molecular mass. The materials obtained are autocomposites where the nascent phase acts as filler.

However, it has been shown that even when the nascent phase is completely melted, the stiffness of the HVC material remains higher than the reference. The result is probably due to the higher crystallite thickness observed on the HVC material. The thermo-mechanical treatment applied to the powder during HVC is probably the cause of this thickening.

Coil-Coil Block Copolymer: For a series of asymmetric coil-coil block copolymers of poly(styrene)-*b*-poly(methacrylic acid) (PS-*b*-PMAA) type, effects of polydispresity of the minority block (PMAA) on the melt self-assembly in the strong segregation limit SSL have been addressed. It was observed that in a PMAA volume fraction window of $0.03 \leq \Phi_{PMAA} \leq 0.30$ spherical microdomains exist in disordered liquid-like state and ordered liquid-crystalline state with body-centered-cubic BCC symmetry. Polydispersity of the minority block has two main effects. First, the existence of a BCC phase at a high value of Φ_{PMAA} (=0.30), where conventionally cylindrical hexagonally ordered microdomains are expected (Figure 1, left). This can be explained by the fact that polydispersity in PMAA blocks reduces entropic elasticity of these microdomains and facilitates formation of an interface curved toward them. Second, an increase in polydispersity index of minority PMAA block (PDI_{PMAA}) results in a linear increase of relative microdomain size (defined as the ratio of the observed microdomain size to the one calculated from SSL model of Helfand and Wasserman for monodisperse blocks, R/R_{HW}) and a linear decrease of relative interfacial area per molecule ($A_{mol}/A_{mol.HW}$) (Figure 1, right). When one of the blocks is polydisperse (in our case PMAA block) the entropic penalty paid for packing the chains at the interface becomes lower, compared to the case of monodisperse blocks. This is because shorter blocks do not extend so far from the interface, which gives a chance for longer blocks to fill the space further away from the interface without sacrifice in configurational entropy. The net result is that polydisperse chains will pack more densely, which leads to a lower interfacial area per molecule and, consequently, an increase in the microdomain size.

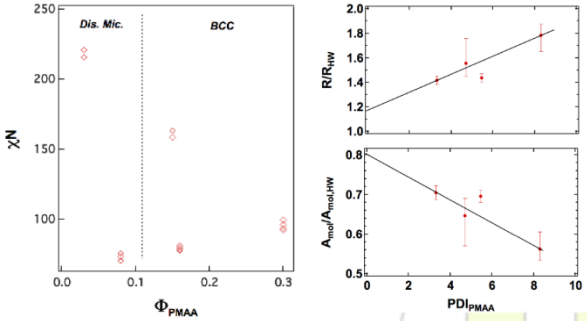

Figure 25: (left) phase diagram of PS-*b*-PMAA block copolymer with polydisperse PMAA block, (right) relative size (top) and interfacial area per molecule (bottom) of PMAA domains vs. PDI_{PMAA}

Coil-Amphiphilic Comb Block Copolymer: Recently Khokhlov *et al.* [1] reported computer simulation results of diblock copolymers in which one of the blocks is non-polar and the other is made of composite amphiphilic (non-polar/polar) repeat units. They found that the existence of amphiphilic monomer units induces two main effects: 1) microphase separation on a short length scale (inside the block with composite amphiphilic monomer units), and 2) microphase separation on a large length scale (between non-polar and amphiphilic blocks) with a considerable asymmetry in phase diagram with respect to Φ_{Amph}. Our aim is to test experimentally these theoretical predictions. For this purpose we have attached non-polar alkyl chains to the PMAA block of the previously presented PS-*b*-PMAA block copolymers via electrostatic interactions. This is achieved by an ion-exchange reaction between the acidic groups of the PMAA and the hydroxide form of alkyltrimethylammonium salts with 8, 12 and 16 carbons in alkyl tails (C8, C12 and C16) for various degrees of side chain grafting densities. Strong incompatibility between the polyelectrolyte backbone (PMA-trimethyl ammonium, PMA-TMA) and alkyl chain results in a comb-like block with strongly amphiphilic monomer units.

As an example we have presented a phase map of these coil-amphiphilic comb block copolymers (Figure 2) based on a PS-*b*-PMAA block copolymer with $\Phi_{PMAA} = 0.15$

A number of effects are observed: 1) microphase separation at two length scales are realized in most of the data points presented in phase map on Figure 2, 2) phase boundaries have shifted considerably to low values of $\Phi_{AmphComb}$, 3) a new regime has emerged (l), in which small length scale microphase separation dominates the self-assembly behavior.

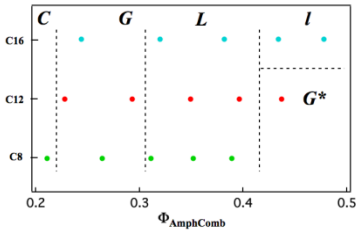

Figure 26: C: normal hexagonally packed cylinders, G: normal gyroid phase, G*: reverse gyroid phase L: large scale lamella, l: small length scale lamella with no large scale microphase separation

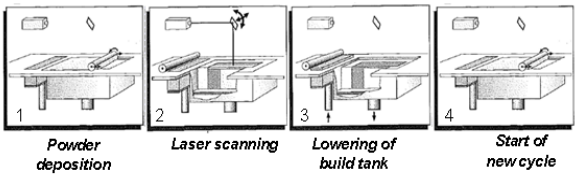
Introduction

The selective laser sintering (SLS) process is an additive manufacturing technology. It consists in 4 stages:

- a roller or blade system spreads a layer of polymer powder in the build chamber (1)
- a laser beam scans the area that corresponds to a "slice" of the object to be built (2)
- the platform in the building chamber moves downwards by a layer thickness (about 100µm) (3)
- another powder layer is spread and steps 1-4 are repeated (4).



Principles of selective laser sintering (SLS)

This results in building the object layer by layer in the vertical direction.

It is well known that such objects have low mechanical properties compared to injection moulded parts. Therefore, the improvement of mechanical properties (notably elongation at break) is a major technological issue for this process.

To reach this objective, fundamental scientific issues have to be overcome. Indeed, very complex physical phenomena occur during sintering (heat transfers, partial melting, coalescence and densification, ageing), which have to be understood more deeply than in the current state of the art. During sintering, many process parameters play crucial roles, like the temperature of the build chamber, the laser power or the scan spacing. Furthermore, powder particle size, size distribution and polymer rheological features, have also a key influence on the densification of the sintered material, especially during the coalescence process.

Consequently, the aims of this study are:

- to emphasize and explain the role of polymer features and process parameters on the microstructure and properties of sintered parts
- to correlate these properties to a unique energy criterion call "supplied energy density" (SED) enclosing the main process parameters [1].

Material and methods

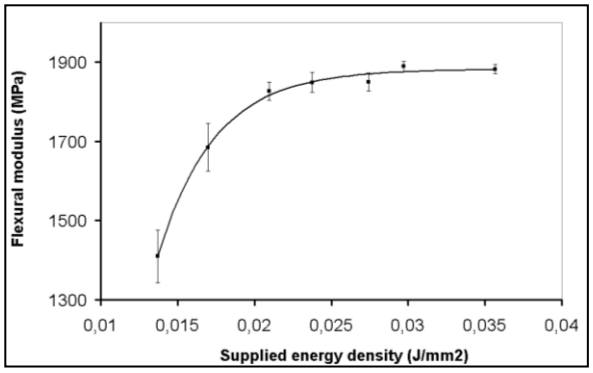
Polyamide12 is widely used in selective laser sintering because of its thermal properties [2]. During this study we used two types of polyamide 12 materials: DuraformPA obtained from 3D systems and InnovPA obtained from Exceltec.

Samples have been sintered with different SED by varying laser power and scan spacing.

Powder morphology was studied by scanning electron microscopy. The characterisation of the thermal properties and the degree of cristallinity was carried out by DSC. Porosity was measured by weighing. Microstructural investigations of the final parts were made by optical and electron microscopies on microtomed sections and by 3D X-ray tomography. Finally, tensile, flexural and impact properties were measured on the sintered parts.

Results and discussion

In our investigation we have shown that the SED and polymer characteristics (molecular weight, thermal properties) have a great effect on the microstructure by influencing the degree of porosity and the remaining fraction of nascent polymer in the sintered parts. Because of this microstructure, the elongation at break reduces strongly compared to injection moulded parts. However, the rigidity increases due to higher degree of crystallinity in sintered parts.



Evolution of flexural modulus versus supplied energy density for polyamide 12 sintered parts

Conclusion

As a conclusion, this study enables a better understanding of the complex relations between process parameters, polymer characteristics and final part properties.

Key Issues in Re-Processing Aged Polyamide-12 Powders by Selective Laser Sintering : Influence of Polymer Features Evolution on Part Properties

Claire Barrès, Stéphane Dupin, Amir Msakni, Olivier Lame, Jean-Yves Charmeau*

Université de Lyon, F-69361 Lyon, France; CNRS, UMR 5223, Ingénierie des Matériaux Polymères, Villeurbanne, France; *CNRS, UMR 5510, MATEIS, F-69621, Villeurbanne, France ;INSA-Lyon, Villeurbanne, France
claire.barres@insa-lyon.fr

Introduction

The selective laser sintering (SLS) process is an additive (layer by layer) manufacturing technology. Using a CAD file in which the object to be built is numerically "sliced" into successive sections in the vertical direction, the polymer processing consists in spreading layers of powder and scanning areas that correspond to "slices" of the object with a laser beam. This causes local melting and fuses the particles with their neighbours and with the previous layer. This cycle is repeated until the part is completed in the vertical direction. SLS has been used up to now to make prototype parts from PA12 mostly. Its potential for "rapid manufacturing" of custom-designed or small to mid-size series of parts is very attractive since no tool nor mold are needed [1].

However, since only ca. 20% of the powder is actually melted and sintered, the re-use of the remaining powder is a real issue, in order to improve the economic and environmental balances of such technologies. Moreover, the whole building tank is maintained for hours 30 to 10°C below the melting temperature of the polymer, which degrades powder features and limit its re-processability. Our purpose is therefore to contribute to process optimization by understanding in which manner the evolution of the powder physico-chemical properties upon ageing affects its processability and, ultimately, the sintered part properties.

Materials and Methods

Commercial PA12 powders were used and re-used in 5 successive manufacturing batches in an SLS machine (3D Systems, USA). Both sintered parts and remaining powder samples from each batch were collected for further analysis. In parallel, the powders were also aged in controlled conditions in a laboratory oven, at 170°C for 3 to 120 hours, for comparison purposes.

Powder morphology was studied by scanning electronic microscopy (SEM). The evolution of molecular mass was followed by intrinsic viscosity measurements in a phenol-1,2-dichlorobenzene mixture and by rheological measurements in the melt. The characterisation of the thermal properties was made by differential scanning calorimetry (DSC). Nanostructure modification was evidenced by X ray diffraction (SAXS). 3D Xray tomography, porosity measurements, and mechanical testing completed the characterizations of sintered parts.

Results and Discussion

Morphological analysis reveals a strong aggregation of fine particles upon ageing. This phenomenon is partly responsible for the degradation of powder flowability. Flowability is crucial to achieve the spreading of even, about 100 µm-thick powder layers.

Then, intrinsic viscosity measurements have shown a strong increase of the molecular weight during ageing, due to post-condensation of PA12. This phenomenon has been confirmed by rheological measurements in the melt. This increase of molecular weight has a great impact on the properties of final parts. Indeed, molecular weight governs the melt viscosity which is a key parameter of the coalescence, as show models such as Frenkel's [2]. An increase of the melt viscosity induces an increase of the coalescence time. The exposition time of the powder grains to the laser radiation is very short (some milliseconds). Therefore an increase of coalescence time greatly impacts the properties of final parts by promoting porosity due to incomplete coalescence of the particles.

The characterisation of thermal properties by DSC has shown an increase of the PA12 melting point upon ageing, which is a consequence of crystallites growth. Moreover a decrease of the crystallisation temperature with ageing is also observed. This modification can be explained by the increase of the molecular weight.

Finally, tensile, flexural and impact properties of parts made with new and used powder were measured. Some of these properties improved with used powder (e.g. elongation at break). More generally, they display a complex dependence on the number of re-using cycles, which results from simultaneous degradation processes: postcondensation and degradation of the polymer chains, alteration of particle shape, increase of viscosity and then of porosity, evolution of the ratio between re-crystallized and nascent crystalline fractions.

Conclusions

Although promising, selective sintering technologies presently still have their industrial development hindered by different factors, among which the difficulties met in reusing the un-sintered powder. Thus, we have undertaken a scientific approach aimed at showing how PA12 ageing affects both the powder processability and the final microstructure of sintered parts. The large range of characterization methods implemented here is original in the field of SLS studies. By improving the scientific knowledge in the field, this work will contribute to a better control of the process.

Introduction

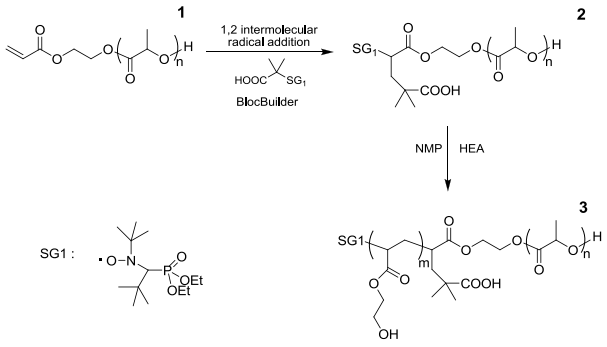
The use of synthetic polymer materials as guide scaffolds for nerve repair is a promising approach as alternative to natural ones, such as collagen, that present several drawbacks (reproducibility between samples, cost, possible contamination with pathogen agents,…). Among synthetic polymers, poly(2-hydroxyethyl (meth)acrylate) (PHE(M)A) polymers are attractive for nerve repair,[1] due to their hydrophilic and hydrogel-like properties. Aliphatic polyesters such as polylactide (PLA) are also choice candidates due to their biodegradability.[2] We aimed at combining the properties of these both kinds of polymers in a single homogeneous material. This can be achieved through the use of block copolymers of PLA and PHEA. Their synthesis through the combination of ring-opening polymerization (ROP) and nitroxide mediated polymerization (NMP) and their properties by means of degradation and Schwann cell adhesion are here described.

Materials and Methods

The ROP of D,L-lactide (Purac) was performed in toluene at 100°C using tin (II) 2-ethylhexanoate ($Sn(Oct)_2$) as catalyst and 2-hydroxyethyl acrylate (HEA) as initiator. The intermolecular radical 1,2-addition (IRA) of the BlocBuilder® (10 eq.) on the obtained acrylate end-capped PLA was performed in THF at 100°C. The NMP of HEA from the PLA macro-alkoxyamine was carried out in bulk at 120°C in presence of free SG1. The block copolymers were characterized by ^{1}H NMR and size exclusion chromatography (SEC). *In vitro* and *in vivo* degradation studies were performed on samples obtained by solvent casting from THF, in phosphate buffer pH 7.4 at 37°C and in rats by subcutaneous implantation, respectively. Schwann cell adhesion was studied on spin-coated polymer films from THF.

Results and Discussion

Our approach to obtain the targeted block copolymers relies on the preparation of SG1-terminated PLA macro-alkoxyamine for further initiation of the NMP of HEA (Scheme 1). For this, an acrylate end-capped PLA (**1**) of M_n~15000 g.mol^{-1} was first prepared by ROP of the D,L-lactide using HEA as initiator and $Sn(Oct)_2$ as catalyst. This PLA was further involved in the IRA with the BlocBuilder®, leading to the PLA-SG1 macro-alkoxyamine (**2**) with a high functionalization yield (~95%). The NMP of HEA from this macro-alkoxyamine led to the block copolymers (**3**) in a controlled manner.



Scheme 1. Synthesis pathway for PLA-b-PHEA.

In vitro / *in vivo* (rat) degradation properties of the PLA-*b*-PHEA block copolymers were then investigated and compared to those of parent PLA homopolymer. Over 12 weeks, we observed mass loss and molecular weight decrease. *In vitro* and *in vivo* findings were very similar for each polymer tested. When a short PHEA block was used (PLA-*b*-PHEA 15000-3000 g.mol^{-1}, 85/15 wt%), the degradation process was found to be very similar to that of homo-PLA, and was typical of a bulk erosion mechanism, with no mass loss observed until week 7 and continuous decrease of molar mass within this time frame. For a longer PHEA block length within the block copolymer (PLA-*b*-PHEA 15000-7000 g.mol^{-1}, 65/35 wt%), the degradation mechanism was modified, with a significant mass loss observed at early times and only a slight decrease in molar mass. The latter finding is related to the pronounced hydrophilicity and softness of the material induced by the PHEA block, which allow easy diffusion and rapid escape of the degradation residues from the material towards the aqueous medium. Schwann cells were found to better adhere on spin coated films of PLA-b-PHEA (85/15 wt%) than on PLA ones.

Conclusion

These results show the potential of such hydrophilized PLA-based copolymers for use in peripheral nerve repair.

A New Building Block Concept for Polymers Based on Multifunctional Coupling Agents

Frank Böhme, Lothar Jakisch

Leibnitz Institute of Polymer Research Dresden, Germany

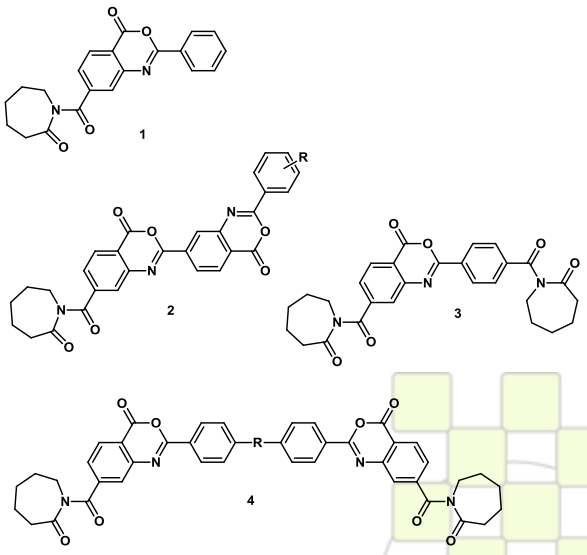
Boehme@ipfdd.de

Introduction:

Reactive compatibilization is a frequently used principle in polymer blending. Reactions between the blend components result in the formation of block or graft copolymers during processing which stabilize blend structures and improve mechanical performance. Usually, such reactions occur mainly in the interface and comprise only a small part of the whole mixture whereas most of the polymer chains remain unreacted. Because of these incomplete conversions, it is difficult to obtain pure block or graft copolymers with defined structures by reactive blending.

To overcome this problem, we developed new coupling agents containing at least two different reactive groups such as oxazinone, oxazoline, or lactamate groups [1-3]. It could be shown that these groups react under certain conditions very selectively in high yields with amino, carboxylic, and hydroxy groups, respectively. The reactivity of these groups is high enough so that the conversions could be performed under the conditions of reactive extrusion. Provided stoichiometry of the reacting groups is warranted, mixing of two oligomers containing different reactive terminal groups with respective multifunctional coupling agents allows obtaining block and graft copolymers with defined block lengths.

In this paper we introduce a new building block concept based on bi-, tri-, and tetrafunctional coupling agents containing oxazinone and lactamate groups. Consecutive conversion of the coupling agents with amino and hydroxy functionalized oligomers allows tailoring the polymer structure in a wide range. Besides alternating polymers, graft and starlike polymers are available.



Materials

Coupling agents **1-4** were synthesized according to the procedures described in reference [3].

As oligomers, amino terminated PA12 and hydroxy terminated polycaprolactones (PCL) were used.

The conversion of the oligomers with the coupling agents was preferably done in melt using glass flasks equipped with stirrers or in a mini-melt-mixer.

Results

Coupling agents **1-4** possess different numbers of oxazinone and lactamate groups. It could be shown that the hydroxy groups of PCL oligomers reacted preferably with the lactamate groups. After complete conversion of the lactamate groups, the reaction of the amino terminated PA12 with oxazinone group was performed. Using mono and bifunctionalized oligomers, different structures were available.

As an example, a series of PA12/PCL block copolymers with different block length was synthesized with coupling agent **1**. The mechanical properties are presented in Figure 1.

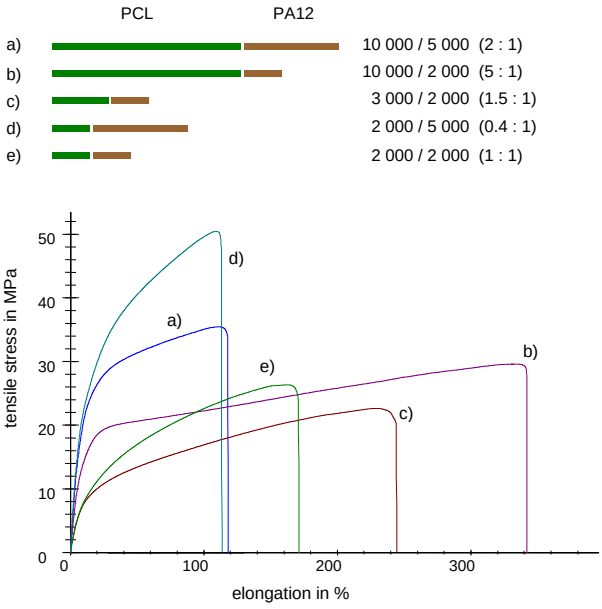


Figure 1 Tensile test curves of PA12/PCL block copolymers with different block length

Amorphous silica obtained from rice husk: Study of the enhanced surface area use as reinforcement of rubber

D. Mosca[1] *C. Mantero*[2] *P. Raimonda*[3]

[1, 2, 3] Instituto de Ensayo de Materiales, Facultad de Ingeniería, UDELAR

praimonda@fing.edu.uy

With a production of approximately a million tons of rice,[1] its husk, obteined during the process of production of grain, with a high silica content, is a real problem for Uruguay; a South American country with a surface area of 176,215 Km^2. Silica, is a filler often used in the rubber industry and notes that worldwide demand for this product is increasing, with a production that fails to satisfy the same and therefore with a tendency for prices to rise. In order to find a solution of the problem of environmental pollution, in a previous study, we evaluated the use of the ash with a composition of around of 90% in silica obtained from the controlled calcination of the husk as a filler in rubber compound.

The aims of this paper is to study how the husk acid treatment does increase the surface area of the ash, obtained by controlled burning, in order to maximize it´s effects and compare the results with commercial products.

RESULTS AND DISCUSSION

It was observed that the boil rice husk treatment with hydrochloric acid solutions at 10% was the best option for increasing the surface area of the structure of the silica from the ash and that this increase was achieved through the removal of sodium, potassium and calcium ions in it. In fact, we verified that we can extract 6 more times calcium, and 1.5 more times potassium in acid solutions at 10% than the same treatment with distilled water without affecting the silicon content of ash. Table I summarizes the results of the increased surface area of the structure of silica ash as a function of the concentration of hydrochloric acid.

Tabla I: Resumen de los datos obtenidos del área superficial de la ceniza de cáscara de arroz en función del % de HCl

HCl %	Sup. area in m^2/g
2	188
5	198
10	208
20	208

We studied, using a base formulation, how varied the mechanical properties of a compound based on SBR rubber wich was aded ash as a fill, whose specific surface area was increased by chemical pretreatment of extraction of alkali earth ion of the rice hulls. Controlled burning shell was performed at 600 °C, in order to obtain a residue of silica with amorphous structure, otherwise the product obtained with a crystalline structure is ineffective for the intended application. The results were compared with the values of the compound without charge, with ash obtained without treatment to increase surface area, and amorphous precipitated silica for industrial use. Characterization tests are summarized in Table II and were conducted under ASTM standards, with the exception of abrasion, which was conducted by the DIN ones.

Tabla II. Resumen de los ensayos de caracterización realizados sobre probetas.

10	560	27.2	70	132	1.346	11.1	2.7

. Notes: Firt line, test specimen witout fill.
Second line, test specimen with rice husk.
Third line, test specimens with ash without tratment.
Fouth line, test specimens with comercial Silica. Refrence
Fifth line, test specimens with ash husk treated with HCl

CONCLUSIONS

In summary we concluded that with the acid treatment of the rice husk was possible to increase the silica content in the ash, and in turn, improve significantly the specific surface area of the structure of the silica particles obtained by extracting the metal ions present in the husk. However we not achieved the expected results in the values of the mechanical properties of the formulated compound.

Recycling of Poly(ethylene terephthalate) Bottle Waste with Modified Styrene Butadiene Rubber Through Reactive Mixing

O.Moini Jazani[1], A.Ghaemi[2], A.Ebrahimi Jahromi[3]*

1. Polymer Engineering Department, Islamic Azad University omidieh Branch, Omidieh, Iran
2. Polymer Engineering Department, Amir Kabir University of Technology, Tehran, Iran
3. Polymer Engineering Department, Islamic Azad University South Tehran Branch, Tehran, Iran

*Corresponding author : o_moini@yahoo.com

Abstract

Styrene butadiene rubber (SBR) was modified by the grafting reaction of maleic anhydride (MAH) in the presence of the initiator benzoyl peroxide (BPO). This modified elastomer was then blended with poly(ethylene terephthalate) (PET) bottle waste, and the mechanical and morphological properties of the resulting blends were studied. The amount of grafted MAH was determined by chemical titration. The results revealed that the concentrations of MAH and BPO strongly affected the grafting process. The morphology of the dispersed phase for blends of PET waste and SBR-*g*-MAH was quite different from that of a simple blend of PET waste and SBR. The enhanced compatibility resulted in better impact properties. The better compatibility was concluded to result from bond formation between the carbonyl group of SBR-*g*-MAH and the hydroxyl or carboxyl end groups of PET

Introduction :

Magnetic nanohybrids based on inorganic cores encapsulated by a biocompatible polymeric corona have been widely studied due to their broad range of potential applications in ferrofluids[1], drug delivery[2] and biological cell labeling and bioseparation[3]. For these last applications, poly(ethyleneglycol methyl ether) (mPEG) is an ideal material with biocompatible properties (nonimmunogenic, nonantigenic and protein-resistant)[4]. Poly(ethylglyoxylate) (PEtG) or polymethylglyoxylate (PMG) are a family of new biodegradable and biocompatible polymers[5,6]. Recently, the synthesis of poly (mPEG-co-PEtG) as a new pH-sensitive material was described[7]. The purpose of this work is to synthesize by a "grafting to process", new core-shell structured nanohybrid materials composed of a maghemite γ-Fe_2O_3 core and a biodegradable block copolymer mPEG-co-PEtG shell.

Synthesis of the nanohybrides:

The maghemite nanoparticles were first synthesized by precipitation of magnetite from iron (II) and (III) chlorides (according to the procedure developed by Mornet) followed by oxidization of magnetite into maghemite using nitric acid[8]. Then, copolymers synthesis were carried out by anionic polymerization of ethyl glyoxylate (EtG) starting from methoxy-PEG with $\overline{Mn}$ = 2000 g.mol^{-1} . Ethyl glyoxylate was previously purified by distillation under vacuum over phosphorus pentaoxide (100 °C, 70mbar). Polymerizations proceed at room temperature in THF solutions, using triethylamine (NEt_3) as initiator, followed by functionnalization with IPTS. Grafting of silanated mPEG-co-PEtG onto nanoparticles was conducted in THF at 80 °C under N_2 flow with a polymer/nanoparticle ratio equal to 10.

Results and discussion :

The presence of maghemite was evidenced by FTIR spectrum showing three peaks around 631, 573 and 438 cm^{-1}. The particles exhibit a diameter of 14 ± 2 nm which was established by XRD patterns from measurement of the half-height width of the strongest reflection planes. The synthesis of copolymer mPEG-co-PEtG was performed according to the mechanism presented in Figure 1.

SEC characterization was used to investigate the average molar mass of obtained copolymers. Average molar masses are comprised between 2250g/mol and 5600g/mol instead of 2000 g.mol^{-1} for the starting mPEG. FTIR spectra of pure maghemite nanoparticles and nanohybrids obtained after different grafting time revealed the presence of the copolymer at the surface of the nanoparticles. The grafted amount of biodegradable copolymer was estimated by TGA (figure 2).

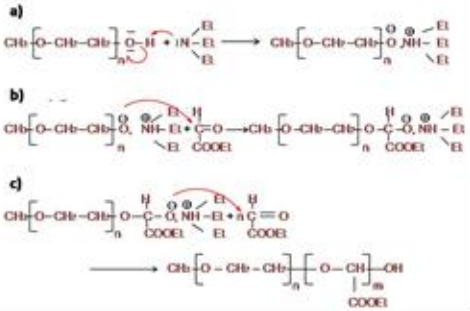

Figure 1 : Synthesis of mPEG-co-PEtG: (a) acido-basic reaction, (b) initiation and (c) propagation.

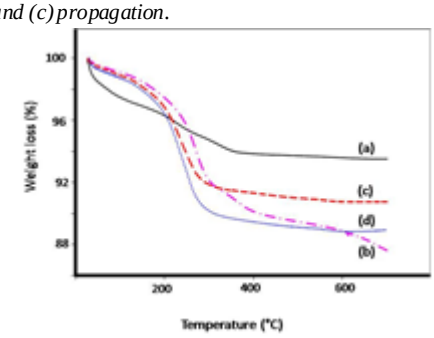

Figure 2 : TGA curves of pure maghemite nanoparticles (a) and nanohybrids obtained after different grafting time: 1h (b), 2h (c) and 5h (d).

The weight loss of grafted copolymer on the nanoparticles, is about 5 % (*w*/*w*) after 1h, 3 % (*w*/*w*) after 2h and 5 % (*w*/*w*) after 5h. Even if the weight loss are rather low these results revealed the aibility of mPEG-co-PEtG be grafted onto maghemite nanoparticles.

Conclusion :

This study is a first exploration of the grafting of a copolymer based on mPEG and PEtG onto maghemite nanoparticles. These preliminary results are quite encouraging and further work is still needed in order to improve the grafting rate of the nanoparticles.

Introduction

Rotational Molding (RM)[1] is a suitable process which allows fabricating hollow plastic parts. In the Reactive Rotational Molding (RRM)[2] process, synthesis is taking place during the molding. The initial viscosity of the epoxy/amine reactive mixture (DGEBA/DETDA) at the processing temperature (120-160°C) is very low (<0.001Pa.s) and it increases until gel point. A complete rehokinetic study was realized in a previous work [3]. In order to predict the flow of the reactive mixture at the starting steps of the process, we tried to simulate it using a meshless method. In this paper we study the simulation of reactive rotational moulding (RRM) of complex geometry mould using Smoothed Particle Hydrodynamics (SPH) method[4] .

After testing our code in the case of breaking dam problem, the free flow surface inside horizontally rotating mold is considered as a modelling of the process. More complex geometry of a turbine blade mold was also used.

Method

The Smoothed Particle Hydrodynamics is a meshless lagrangian numeric method. In this method the reactive fluid is represented by discrete particles. In the SPH method, the dynamic pressure p as a function of the density ρ is computed by the equation of state (1):

$$p = \frac{c_s^2 \rho_0}{\gamma}\left[\left(\frac{\rho}{\rho_0}\right)^{\gamma} - 1\right] \qquad (1)$$

To compute the momentum we used the following expression[5]:

$$\frac{dv_j}{dt} = -\sum_i m_i \left[\left(\frac{p_i}{\rho_i^2} + \frac{p_j}{\rho_j^2}\right) - \frac{\xi}{\rho_i \rho_j}\frac{4\eta_i\eta_j}{(\eta_i+\eta_j)}\frac{v_{ji}.r_{ji}}{r_{ji}^2+\varepsilon^2}\right]\nabla_j W_{ji} + g \qquad (2)$$

The density was calculated via the commonly used SPH expression for continuity equation:

$$\frac{d\rho_j}{dt} = \sum_i m_i (v_j - v_i)\nabla_j W_{ji} \qquad (3)$$

To assure the adherence of liquid resin to the internal walls of the mold we applied the non-penetration boundary condition. Time integration was done using Euler scheme

Results and Discussion

We compared between experimental and SPH code results for water dam breaking case (Fig.1).

The method was applied for horizontal rotating cylinder and to more complex geometry like the 2D turbine blade mold (Fig.2).

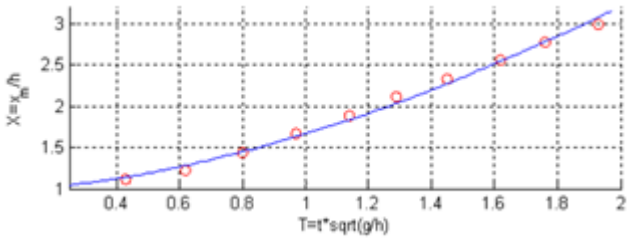

Fig.1 .Front location in broken dam problem, experimental results (o) and SPH (-)

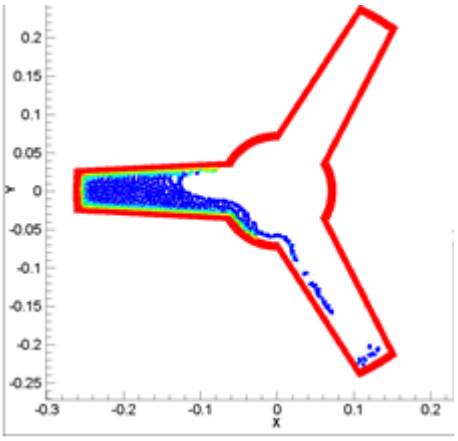

Fig.2. Flow of reactive fluid after 1s inside a turbine mold during the RRM process.

Conclusions

We simulated the free surface flow of a reactive liquid polymer during the first steps of the rotational molding. The Smoothed Particle Hydrodynamics numeric method was applied to simulate the flow. Free surface variation was tracked and easily obtained.

The first results were promising and we are working to optimize the different interactions aspects of the flow such as chemical crosslinking kinetics[3] and thermal transfer.

Introduction

Plastic bags are very controversial goods due to their apparent environmental impact. To minimize impact, solutions like biodegradable bags from polycaprolactone (PCL), Mater-bi or starch-polyethylene blends have been proposed. In general, economic reasons have been responsible of low market success. Recycled low density polyethylene is commonly used in a large variety of items with low requirements, one of them rubbish plastic bags which have a very low lifetime. Recycled LDPE is very cheap; it is easy molded and also can be obtained sustainably from bioethanol. However it is not compostable or biodegradable like PCL, starch or Poly(Lactic Acid) (PLA).

It is known that recycled polyolefins are slightly degraded due to a little amount of oxidative reactions that reduce their properties compared with virgin materials. In addition, more chemical or biological reactions can be produced due to the presence of new functional groups like hydroxyls, carbonyls or double bonds.

In this study we have prepared different blends from used LDPE and PCL, as biodegradable polymer that could induce degradation of LDPE. In spite of PCL and LDPE are not compatible, blends with both plastics can be made with reasonable properties [1]. These blends (as thin film) have been treated in a compost plant up to 15 weeks and characterized by weight loss, IR spectroscopy, DSC and mechanical properties. The objective of this study is to determine if blends of recycled LDPE and PCL have been biologically degraded, as blown-extruded film. Potential application as biodegradable plastic bags is the motivation of this project.

Materials and methods

LDPE from own plastic bag plant (blue colored with copper phtalocyanine) was our raw material (MFI = 0.5 g/10 min). PCL was obtained from Union Carbide, TONE 787 grade (MFI = 0.5 g/10 min) which is specially designed for film blow molding applications. Blends containing from 0 % to 50 % of PCL were prepared in a pilot plant extruder and blow molded. For every composition was necessary to adjust processing conditions (BUR), in order to obtain to 20 micron thickness films. These films could be easy characterized by FT-IR (Perkin Elmer 1000) and mechanically with a Polymer Laboratories Minimat testing machine for very little samples (50 mm long). Films were 500x500 mm cut and introduced in a homemade rigid iron rack, as container to be inserted in compost piles. Aerating static piles composting were developed in an urban plant in Torrelles (Barcelona – Spain), that works with organic urban waste. Every 4 weeks, a sample iron rack was retired and characterized. The composting process was completed in 15 weeks.

Results

Up to five blends were produced (0, 10, 20, 30, 40, 50 % PCL by weight). Sample with no PCL showed a very little absorption at 1720 cm^{-1}, in infrared spectrum, that indicates some extent in oxidative degradation of polyethylene. After 4 weeks of composting only 40 and 50 % PCL showed visually changes; little weight loss is detected. After 8 weeks 30 % PCL blend began to degrade, according to mechanical properties (break strain). After 15 weeks only 30, 40 and 50 % PCL clearly showed symptoms of degradation. Other samples did not display changes. IR spectra did not show significant changes at any of degraded films, due to PCL degradation mechanism does not modify its chemical structure [2]. After complete composting process, between 15 and 3 % weight loss in 50, 40 and 30 % PCL films were observed. Only strongly degraded samples (50 and 40 % PCL) lost completely their integrity after 12 weeks. These samples after 8 weeks reached elongations at break not more than 9 %. The 30 % PCL sample showed a constant decrease in mechanical properties; at 15 weeks of composting break strain were 11 %. Young modulus was around 1500 MPa and it did not vary notably during biodegradation process for undegraded blends.

The morphological study of these blends is currently being carried out.

Conclusion

Film samples obtained from blow molding of blends of PCL and recycled LDPE were produced and biodegraded by composting. Blends with high content of PCL degrade easily. A blend formulated with 30 % of PCL can be considered as potential material to be used as environmental friendly plastic bag, in spite of LDPE does not biodegrade.

Thermoplastic elastomer/organoclay nanocomposites: morphology, thermal and mechanical properties

Anna Szymczyk[1], Sandra Paszkiewicz[2], Zbigniew Rosłaniec[2]

[1]Institute of Physics, [2]Institute of Materials Science and Engineering, Faculty of Mechanical Engineering and Mechatronics, West Pomeranian University of Technology, Piastów Av. 17,70-310 Szczecin, Poland

Abstract

Resent interest on polymer matrix based nanocomposites has attracted much attention due to the interesting observations involving polymer composites with exfoliated clay and more recent studies nanocomposites with carbon nanofibers, carbon nanotubes, exfoliated graphite and metal nanoparticles [1-2]. These nanocomposites have shown that at low loading nanofillers can be used as reinforcing agents to improve the physico-mechanical properties of many polymers.

In this study our objectives is to established the possibility of the improvement of the tensile properties of semicrystalline thermoplastic elastomers. Nanofil 32 was used as nanofiller and poly(trimethylene terephthalate)-*block*-poly(tetramethylene oxide) (PTT-PTMO) segmented block copolymer was used as elastomeric matrix. The morphology of this copolymer consisted of semicrystalline PTT domains dispersed in the soft matrix of amorphous non-crystalizable PTMO.

The nanocomposites containing from 0.5 to 3 wt% of nanoclay (Nanofil 32, Rockwood Additives) were prepared *in situ* by introducing the filler into a reaction mixture for synthesis of PTT-PTMO segmented copolymer by polycondensation in the molten state [3-4]. In order to obtain nanocomposites with well exfolited nanoclay, Nanofil 32 was sonicated and mechanicallly stired in liqiud monomer (1,3- propanediol) and then introdced to the reaxtion mixture.

The properties of polymer-clay nanocomposites depend strongly on the dispersion of the clay layers and the interaction between the polymer chains and their surface. Therefore, the effect of the presence of the nanoclay on the phase separated structure and mechanical properties of the net PTT-PTMO copolymer and nanocomposites were studied by DSC, DMTA and tensile testing.

Structure and morphology evolution during tensile deformation of the net copolymer and nanocomposites were investigated by using synchrotron wide and small-angle X-ray scattering (WAXS, SAXS). The obtained nanocomposites form an exfoliated structure which can be observed by TEM. The DSC results have shown that glass transition and melting behaviour of PTT-PTMO copolymer was not significantly affected by the presence of nanoclay, but increase of crystallization rate and the decrease of supercooling degree required for crystallizing nucleation. Modulus and strength of the PTT-TMO elastomer was improved significantly in the presence of nanoclay attributed to the stiffness, rigidity, reinforcing effects and exfoliation of nanocaly. Besides, the elastic modulus increases without any worsening of the elongation at break. It was established that optimal concentration of Nanofil 32 in PTT-PTMO matrix is 0.5 wt%.

A comparison in dispersion of Carbon Nanotubes in aqueous media

Ghamgosar khorshidi V., Bakhshandeh G.R., Salimi A., Naderi Gh*

Iran Polymer and Petrochemical Institute, P. O. Box: 14965/115, Tehran, Iran

a.salimi@ippi.ac.ir

Introduction

Due to their unique properties, Carbon Nanotubes (CNTs) have been attracted much attentions in modern polymer nanocomposites [1]. In polymeric aqueous media, the effective surfactant must be loaded to achieve a good degree of CNT dispersion [1, 2]. The purpose of this work is to study and evaluate the ability of surfactants in CNT dispersion in aqueous media. The work was performed using two individual surfactants in non-functionalized and functionalized multi walled carbon nanotubes (MWNTs) dispersion.

Materials and Methods

The OH functionalized and non-functionalized MWNTs (diameter 10-30 nm, length 10 µm, purity 95%) were supplied by Institute of Petroleum Industry (Tehran, Iran). The surfactant sodium dodecylbenzene sulfonate (SDBS) from Fluka and sodium lauryl sulfate (SLS) from Merck was used as received. All dispersions were prepared in deionized water at surfactant concentration of 0.075 g/L and constant 1wt% of functionalized and non-functionalized MWNT. The samples were ultrasonicated for 5 minutes using (Bandelin HD 3200, Germany) and then filtered after centrifuging at 3000 rpm for 20 min. The dispersion of CNTs was characterized using UV-vis spectrophotometer model UV-1650 PC (SHIMADZU, Japan) [3].

Results and Discussions

Fig 1 shows the UV spectra of dispersions of non-functionalized and functionalized MWNTs using SDBS and SLS, individually. The functionalized CNTs showed higher absorption comparing with non-functionalized CNTs. The higher absorption in wavelength of 250-400 nm indicates for higher dispersion in functionalized CNTs in both SDBS and SLS containing dispersions [2, 3]. The functionalized CNT provides hydrogen bonding between the –OH group and the hydrophilic group of each surfactant and hence greater attractions to CNTs surface [3].

In comparison between two surfactants, the increase in absorption is more pronounced using SDBS for the same level of surfactant loading, i.e. 0.075 g/L. This behavior was observed in both functionalized and also non-functionalized MWNTs. Due to the existing benzene ring in SDBS structure, higher attraction to CNTs surface and hence better dispersion can be obtained [3]. The existing OH group in CNTs and also the benzenering of surfactants provide the highest degree of disperion for the SDBS-functinalizes MWNTs.

Conclusions

The existing functional group in CNTs and also the structure of surfactants are two main factors playing influence on dispersion of MWNTs. The disersion was better in functionalized CNTs due to hydrogen bonding and in SDBS containg disperion due to the benzene ring. These two parameters provides the highest degree of disperion for the SDBS-functinalizes MWNTs.

Introduction

It is well known that the crystallization behaviour of semi-crystalline polymeric materials is strongly affected by the thermo-mechanical history during processing. For instance, the wide range of cooling rates (from few to hundreds of degrees per second) employed in industry for polymer processing results in strong differences on the morphology development. For many polymers, fast cooling implies structuring at extreme undercoolings, with the possibility to develop kinetically driven metastable structures. In particular, on quenching, polypropylene develops a mesomorphic structure with a degree of order intermediate between that of the monoclinic -phase and of the amorphous supercooled liquid.[1] Its formation and transformation have been extensively investigated.[2] However, the role of molecular features in the development of this polymorph is not fully assessed yet. For example, the effect of stero-defects on mesophase formation is controversial,[3] while the role of constitutional defects (i.e. random copolymers) has been reported only in a few papers and the results are still not exhaustive.[4] Recently a Continuous-Cooling-Curves (CCC) approach has been applied to investigate the development of the mesomorphic structure in propene/ethylene random copolymers.[5]

Results and Discussion

The present work reports recent results on structure development of iPP and its copolymers with ethylene during fast cooling as obtained by coupling on-line thermal analysis with ultra-fast in-situ synchrotron radiation wide-angle X-ray scattering (WAXS).[6] Fast cooling was performed using an home-built quenching device, which enables controlled heating and rapid cooling of thin polymer samples by blowing compressed air on its surface. Simultaneous collection of WAXS patterns and sample temperature (i.e. CCC curves) was carried out with perfect synchronization. Thanks to novel photon counting Pilatus 300K detector, high quality WAXS patterns were collected, allowing to quantitatively describe the kinetics of mesophase and -phase development during ultrafast cooling, which last only a fraction of a second.As an example, Figure 1a shows the mesophase formation during fast cooling of a propene/ethylene copolymer thin film with 7.3 mol% of comonomer at 160 ºC/s. The evolution of the calculated mesophase fraction formed during cooling for two propene/ethylene copolymers (3.4 and 7.3 mol%) is shown in Figure 1 b.

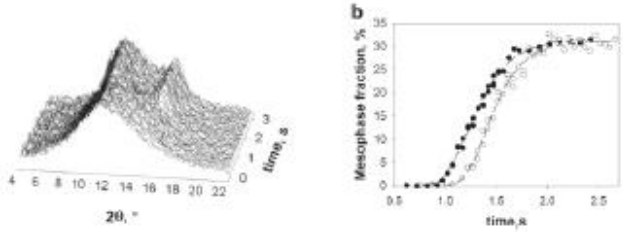

Figure 1 a (left) WAXS time evolution during cooling 160 °C/s for random propene/ethylene copolymers 7.3 mol % of ethylene; Figure b (right) Time evolution of mesophase fraction during cooling at 160 °C/s for random propene/ethylene copolymers with 3.4 (•) and 7.3 (○) mol % of ethylene.

Thus, the evolution of the mesophase fraction can be calculated in real-time for different cooling rates and different copolymer composition. In this manner, the coupling of X-ray with CCC data allows us to obtain quantitative diagrams indicating at what temperature the phase transition takes place as well as the content of the different phases.

A general concept can be stated on basis of our results: anything that negatively affects the crystallization kinetic of the α-phase (including regio-, stereo- and constitutional defects) decreases the minimum cooling rate required to obtain a prevailing mesomorphic sample. On the other hand, when the crystallization kinetics of the monoclinic structure is promoted (e.g. by nucleating additives) the formation of the mesophase can only take place at cooling rates which are practically inaccessible.

Introduction

From our last, partly already published, works we would like to show the results we obtained in studies of the influence of inorganic nano-filler on the morphology and mechanical properties of polypropylene (PP) fibres and what behavior is different in comparison with testing of bulky plastics material. Since, the fibers is a material containing oriented crystallites and macromolecules, the aim was to follow the influence of degree of orientation of PP fibres (what is attained with different drawing ratios at the spinning of PP composite) on the efficiency of nano-filler reinforcement, and also influence of the spinning process of the PP/filler nano-composite on the morphology of the fibres was investigated.

Materials and Methods

For preparation of PP/nano-composite, various kind and types of nano-filler based on clay or boehmite at our experiments were used. Silicate nanofiller: SOMASIF, Co.Chemical Yapan, modified with talcum and Na_2SiF_6. Boehmite: Disperal 40 and 60 (Sasol, Hamburg). Polypropylene: PP-HPF Slovnaft, a.s. Bratislava.

Laboratory spinning apparatus – VUCHV, a.s. Svit. TEM – Frieburg Material Forschung. Mechanical properties - Instron 1122.

Results and Discussion

An example, where the influence of the Nanofil type on some mechanical properties of PP nano-composite fibres is indicated, shows the Table 1. At these experiments also a compatibilizer AR 504 (based on grafted PP with maleic anhydride) was used. It seems to be interesting, that the maximal tenacity of fibres was obtained already at about 1 wt. % of Nanofil, and at higher content of filler the tenacity decreases up to the tenacity of neat PP fibres (till 3 wt. % of filler) and then also to more lower values [1]. The maximal tenacity of the PP nano-composite fibres at used conditions in Table 1, increases with drawing ratio of nano-composite fibres, but the quotient of the effect of the filler on their tenacity with respect to tenacity of the neat PP fibres decreases.

The influence of filler Nanofil on the elongation of the PP nano-composite fibres is very different. At low content of filler about 1 wt. %, the elongation of fibres decreased relatively considerably in comparison with neat PP fibres, but with further increase of filler, a slightly decreases of elongation was observed. For example: elongation ε of neat PP fibres achieved 109.8 % and but at 1 wt. % of filler ε decreased to 93.3 and then at 2 and 3 wt. % increases to 110 and 114 % resp. [2].

Table 1 The influence of filler Nanofil and compatibilizer AR 504 on tenacity (σ), of PP fibres at different drawing ratios (λ)

Nanofil wt. %	AR 504 wt. %	cN/dtex		
		λ = 2	λ = 3	λ = 4
0	0	1.49	2.19	3.86
1	2.8	1.85	2.81	4.22
2	5.6	1.61	2.65	4.15
3	8.4	1.47	2.46	3.97
4	11.2	1.48	2.20	3.48

The knowledge about the influence of filler on the viscosity of PP melt we have used at spinning the syndio-tactic (sPP) [3]. The laboratory spinning apparatus did not allowed to spine the neat sPP. Using sPP compounded with a silicate filler M-ODA the obtained sPP polymer composite was spinned. TEM micrographs of the sPP M-ODA fibres prepared at presence and without a compatibilizer showed the difference in exfoliation of filler particles. Without the compatibilizer the M-ODA particles were only partly exfoliated and some of them were seen on "fibre-skin" surface. Also a boehmite nano-filler Disperal compounded with iPP was spinned without use of compatibilizer and obtained fibres were tested. The original filler Disperal contained aggregated crystalline particles of size several hundred microns were dispersed without compatibilizer to nano-particles less than 200.

Conclusion

At these conditions prepared PP fibres containing Disperal 40 and Disperal 60 or silicate nanofiller showed some positive mechanical properties applicable for practical use. The observed properties of PP nano-composite fibres will be discussed.

Synthesis and Characterization of Natural Oil Based Alkyd–Acrylic Copolymers

Pirita Rämänen and Sirkka Liisa Maunu

University of Helsinki, Laboratory of Polymer Chemistry
P.O. Box 55, FIN-00014 Helsinki, Finland

pirita.ramanen@helsinki.fi

Introduction

Alkyd-acrylic copolymers have been widely studied as coating materials due to their attractive properties. By copolymerization it is possible to combine the positive properties of both: auto-oxidative drying and high gloss of alkyd resin and fast drying of acrylates. The aim of this study is to develop new environmentally friendly copolymers with special properties to be focused, for example, on various coating applications. The challenge and the novelty of this research is to utilize abundant renewable raw materials, such as tall oil fatty acids and rapeseed oil.

Materials and Methods

In this study acrylate monomers were polymerized in the presence of natural oil based alkyd resin, when acrylic macroradicals were grafted to the double bonds of the unsaturated fatty acid chains in the alkyd resin [1]. The polymerization was done via miniemulsion method due to the smaller particle size achieved and more stable emulsion created when compared to conventional emulsion polymerization. Films of these copolymers were prepared by drying the copolymer dispersions at ambient conditions and the effect of the product composition on the film properties was studied, e.g. the mechanical properties of films were studied with dynamic mechanical analysis (DMA). In addition solid state NMR spectra and IR spectra of copolymers and copolymer films were measured.

Results and Discussion

Solid state NMR studies showed that the drying of copolymer films occurred, in addition to physical drying via water evaporation, also chemically via double bond oxidation, which can be seen in NMR spectra as a diminution of the double bond peaks at 125 – 135 ppm (Fig. 1). From liquid state NMR studies it was observed that copolymerization between alkyd resin and acrylic monomers was occurred based on the decreased amount of double bonds.

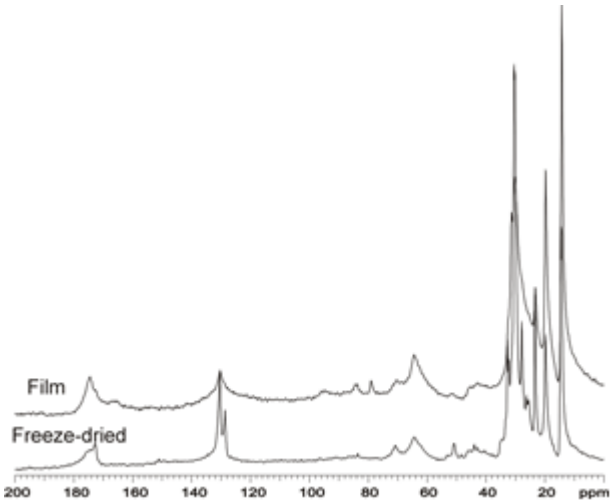

Figure 1. Solid state NMR spectra of freeze-dried copolymer and copolymer film.

The mechanical properties of films were studied with DMA. The stress-strain measurements prove that increased the alkyd content makes the films harder and more brittle.

Conclusions

The results show that copolymerization occurs and alkyd resin and acrylate monomers form copolymers and the prepared dispersions are stable for several months. Besides physical drying, drying of copolymer films was noticed to take place autoxidatively as with pure alkyd resins. It was observed that varying alkyd-acrylate ratio, alkyd resin type and acrylate monomer combination affect the copolymer and copolymer film properties.

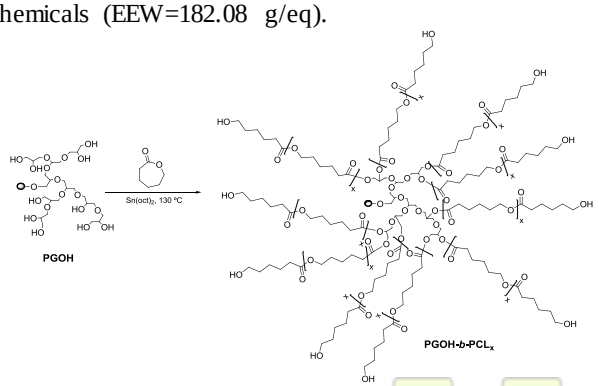
Introduction

The main objectives of our research on epoxy based materials are the control of shrinkage and the enhancement of toughness especially required in many applications. Employing reactive modifiers such as hyperbranched polymers (HBPs) a significant improvement of these properties was observed without affecting the thermomechanical characteristics due to the high free volume of the HBP and its chemical incorporation into the epoxy network [1,2].

In the present work, we propose the use of star polymers capable to improve not only the mechanical properties of the resulting thermosets but even the processability of the reactive mixtures. Until now the use of multiarm star copolymers based on poly(glycidol)-*b*-poly(ε-caprolactone) (PGOH-*b*-PCL_x) of different arm lengths as chemical modifiers of DGEBA (diglycidylether of bisphenol A) has not been reported. Our aim is to investigate the influence of this new polymer topology and of the arm length variation on the rheological behaviour, curing and gelation processes and on the final properties of the resulting PGOH-*b*-PCL_x/DGEBA thermosets.

Materials and Methods

Poly(glycidol) (PGOH, $\overline{M}_n$=12.200 g/mol, PDI:1.31) was synthetized according to [3]. ε-caprolactone (ε-CL) was dried over CaH_2 and distilled. Tin (II) 2-ethylhexanoate ($Sn(oct)_2$) and 1-methylimidazole (1MI) were used without further purification. Diglycidylether of bisphenol A (DGEBA) Epikote Resin 827 was provided by Shell Chemicals (EEW=182.08 g/eq).



Scheme 1. Synthetic route to PGOH-*b*-PCL_x, where x is the average degree of polymerization of ε-CL (x = 10 or 30).

Varying the monomer/initiator ratio (ε-CL:OH), two star copolymers with 165 arms/molecule and 1.000 g/mol or 3.000 g/mol of arm length were obtained by cationic ring-opening polymerization of ε-CL from poly(glycidol) employing $Sn(oct)_2$ as catalyst (**Scheme 1**). Both stars were used in a proportion of 5 wt% and 10 wt% to modify DGEBA. The curing kinetics was studied by DSC. The complex viscosity (η*) and the gelation process were evaluated by rheometry and DSC. Thermal characteristics were studied by DSC, DMTA and TGA. Curing shrinkage was evaluated by density measurements. Cryofractured samples were observed by ESEM.

Results and Discussion

The addition of PGOH-*b*-PCL_x to DGEBA retards the curing process, when 5 phr of 1MI was used as initiator. In comparison with pure DGEBA, the modified formulations reach the gelation at longer times and higher epoxy conversion which permits a better processabilitiy of the thermoset and the reduction of internal stresses.

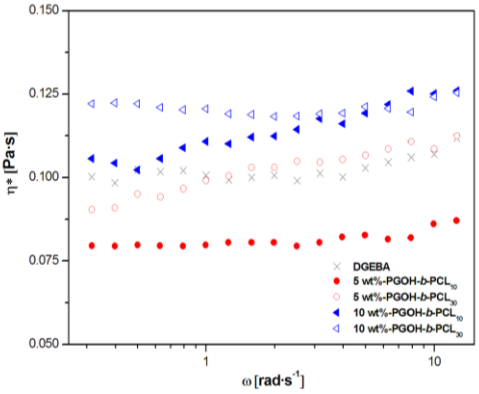


Figure 1. Complex viscosity (η*) versus angular frequency (ω) of reactive mixtures at 30 ºC.

In **Figure 1** it is observed that the incorporation of 5 wt% of PGOH-*b*-PCL_{10} diminishes the η* of the mixture, but increasing the arm length of the star, the viscosity rises significantly. The shrinkage during curing is reduced for all the formulations but using 10 wt% of PGOH-*b*-PCL_{30} the highest reduction is obtained. From all the studies done, we can conclude that the better coating improvements are obtained when a short arm length star copolymer is used.

marherna@ictp.csic.es

Introduction

Natural rubber (NR) is a well studied elastomer. Of particular interest is the ability of NR to crystallize, specifically the strain-induced crystallization that takes place whilst the material is stretched. Moreover, in many elastomer applications, network chain dynamics under external stress/strain are critical for determining ultimate performance[1]. Thus, a study on how the strain-induced crystallization affects the dynamics of a rubbery material is of outmost importance. This research studies the effect of orientation on the segmental dynamics as a function of the draw ratio, focusing on the relationship between the network structure and the strain-induced crystallization behavior of NR using Broad-band dielectric spectroscopy.

Materials and Methods

NR was kindly supplied by Malaysian Rubber (Berhad, Malaysia) under the trade name CV 60 (Mooney viscosity: ML(1 + 4) 100 ºC = 60). The curing system employed expressed as parts per hundred parts of rubber (phr) was: sulphur (2.5), zinc oxide (5), stearic acid (1) and MBTS (benzothyazyl disulfide) (1).

The uniaxial deformation measurements were carried out in a dynamometer (INSTRON, model 3366) at 25 ºC, and at a cross-head speed of 500 mmmin^{-1}. Stretching ratios from 250 to 750% were performed.

Broad-band dielectric relaxation spectroscopy (BDS) measurements were performed on an ALPHA□□ high resolution dielectric analyzer (Novocontrol Technologies GmbH, Hundsangen, Germany). The complex permittivity ($\varepsilon^* = \varepsilon' - i\varepsilon''$) of the stretched NR compounds was measured over a frequency window of $10^{-1} < F/Hz < 10^{7}$ in the temperature range from -60 to 25 ºC in 5 ºC steps. The dielectric relaxations were empirically described in terms of the Havriliak-Negami (HN)function[2]:

$$\varepsilon^*(\omega) = \varepsilon_\infty + \frac{\varepsilon_S - \varepsilon_\infty}{\left[1 + \left(i\omega\tau_{HN}\right)^b\right]^c}$$

Results and Discussion

After 300% strain, a noticeable upturn in stress is observed while stretching proceeds, as expected (see Figure 1a). This outstanding property of NR is believed to be due to the increased crystallization by stretching of the rubber causing molecular alignment in the stretching direction. This peculiarity gives NR a self-reinforcement character, since the strain-induced crystallites form an additional physical cross-linking network, carrying most of the applied load.

Concerning dielectric behavior, the α-relaxation, attributed to the segmental mode, manifests itself as a maximum in ε''(F); this maximum shifts to lower frequencies while stretching proceeds, slowing down the segmental motion of NR chains. Figure 1b shows an important rise in ε'' for the strained samples compared to unstretched NR, which can be associated with the increase in density as a consequence of the orientation suffered by chains. Also, from 300% strain on, a decrease in the intensity of ε''_{max} is observed. This behavior can be associated to a decrease with the drawing process in the total number of dipole groups in the crystalline regions, which can move easily in the external field[3].

From these results we can infer that the emergence of rubber crystals starts after 300% extension. In consequence, as the tie molecules in the crystalline-amorphous interphase become part of the crystalline regions, the degree of crystallinity increases since the orderly arrangement of molecules in the crystalline structure limits the chain mobility (see Figure 1c).

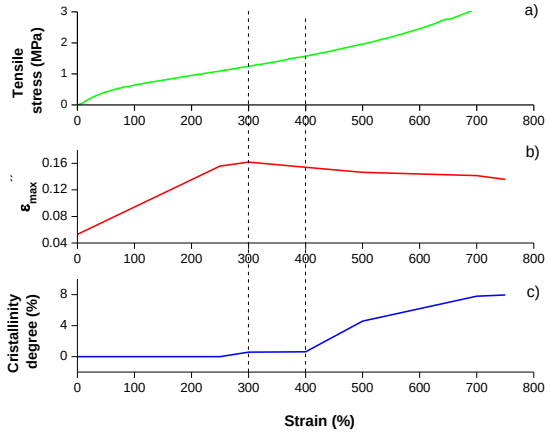

Figure 1. a) Tensile stress, b) dielectric loss maxima ε'', and c) crystallinity degree for stretched NR samples at different extension ratios.

Conclusions

Segmental dynamics of NR seem to be affected by uniaxial stretching since a slowing down of the α-relaxation is achieved. Also, the results presented herein are evidence of an amorphous/semi-crystalline transition between 300% and 400% strain: below this transition, molecular chains show orientation, but no crystallization takes place and dielectric strength increases dramatically; while above this transition, the crystalline structure formed limits the segmental dynamics of NR.

Adhesion Properties of Polycaprolactones and Polycaprolactone Based Polyurethane Prepolymers

Monica Garcia Ruiz, Juan L. Valentin, A. Marcos-Fernandez

Instituto de Ciencia y Tecnología de Polímeros (C.S.I.C.)

mgarciarui@repsol.com

Introduction

Polycaprolactones are a type of aliphatic crystalline polyesters with very good mechanical properties.

Although polycaprolactones (PCLs) are widely used in several applications, including polyurethane adhesives, there are not many bibliographic references about their adhesive properties.

On the other hand, poyurethanes are a very versatile family of polymers with properties spanning from soft to very rigid materials used in many applications including adhesives.

For adhesives, one of the major applications is in the footwear field, more specifically, in the adhesion of shoe soles to instep materials. Current trends lead towards the use of 100% solids adhesives, avoiding the use of solvents and water. For a 100% solids adhesive, the main properties it must fulfil are: good wettability of the substrate, good adhesion properties and good processability. The aim of this work is to evaluate the adhesion properties of PCLs and of PCL based polyurethane prepolymers (isocyanate capped) and correlate the results with their molecular weight and their chemical structure respectively.

Materials and Methods

Materials

Polycaprolactones were kindly provided by Perstop. In the following table, nominal Mn for high molecular weight polycaprolactones is indicated.

PCL	Mn
CAPA® 6250	25000
CAPA® 6400	40000
CAPA® 6430	43000
CAPA® 6500	65000
CAPA® 6800	80000

Isocyanate-terminated prepolymers were synthesized in bulk at 120ºC using MDI as diisocyanate and PCL diols kindly provided by Perstop. A series of prepolymers with different molecular weight of the PCL diol and different molecular weight of the resulting prepolymer were prepared, as listed in the following table:

Mn PCL diol	Mn prepolymer	%NCO
2000	25000	0.34
	50000	0.17
	100000	0.08
4000	25000	0.34
	50000	0.17
	100000	0.08
8000	25000	0.34
	50000	0.17
	100000	0.08

Methods

Thin films of PCLs and prepolymers were applied from the MEK solutions onto PVC strips, used as substrate for the adhesion tests, and solvent removed at ambient temperature. The covered PVC strips were heated at 80ºC in an oven until adhesive was melted, pressed for 15 seconds and stored at room temperature for 72 hours before performing the T-peel test.

Results and Discussion

For PCLs, a critical value of molecular weight was found to reach high adhesion values. Crystallinity was measured, and rheology and low-field RMN experiments for the melted PCLs was performed in order to correlate with the adhesion values.

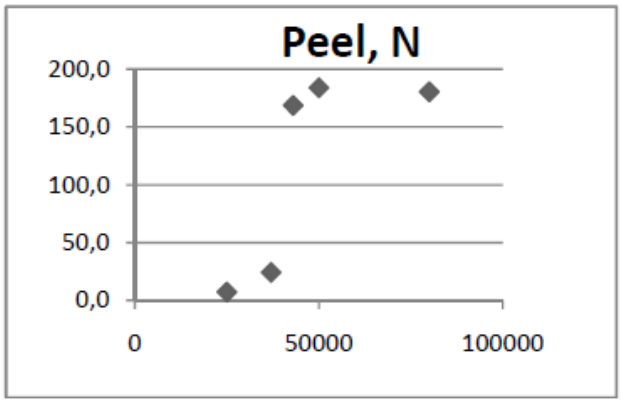

Figure 1. Adhesion results for PCLs

High adhesion values for isocyanate terminated prepolymers were obtained for PCL 4000 and 8000, with high PCL crystallinity. For short PCL diol, with lower crystallinity, only at high isocyanate contents adhesion values approached the values for the others. Isocyanate content also influenced the adhesion values, increasing adhesion when isocyanate content increased.

Conclusions

PCL has very good adhesion properties to PVC when molecular weight exceeds 40000 Da. This limiting value is not related to crystallinity, and do not correlate with mechanical properties. Adhesion properties of prepolymers were dependent on the crystallinity of PCL and isocyanate content, higher at longer PCL and higher isocyanate content.

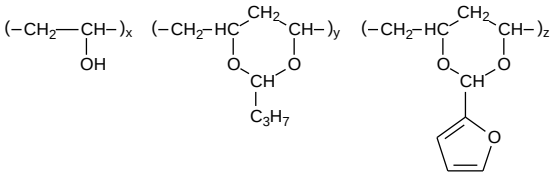
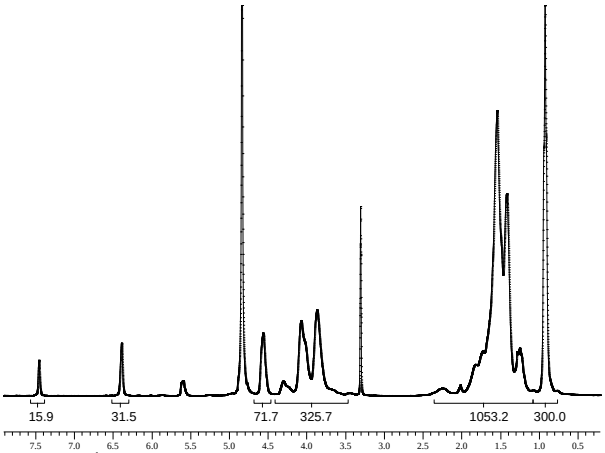
Polyvinyl butyral furfural (PVBF) is a mixed acetal of polyvinyl alcohol of general formula



having high adhesion, cohesion and heat resistance, which allows to use it as a component of construction, heat-resistant adhesives and thermosetting laminated plastics.

The present work is concerned with developing of methods and analysis of PVBF molecular structure, as well as determining their thermomechanical properties.

We have developed NMR technique for determining of PVBF chemical and stereoisomeric composition.



PVBF ^{1}H NMR spectrum at 400 MHz in CD_3OD. Under the spectrum regions of integration and the integral intensities of different group signals are shown.

Transmissive to Black Electrochromic Aramids Based on Electroactive Tetraphenylbenzidine Units

*Hung-Ju Yen, Kun-Ying Lin, and Guey-Sheng Liou**

Functional Polymeric Materials Laboratory, Institute of Polymer Science and Engineering, National Taiwan University, 1 Roosevelt Road, 4th Sec., Taipei 10617, Taiwan

E-mail: d96549005@ntu.edu.tw (Yen, H.-J.) and gsliou@ntu.edu.tw (Liou, G.-S.)

Electrochromic materials exhibit a reversible optical change in absorption or transmittance upon electrochemically oxidized or reduced, such as transition-metal oxides, inorganic coordination complexes, organic molecules, and conjugated polymers.[1]

According to Robin and Day,[2] the *N*, *N*,*N*',*N*'-tetraphenyl-*p*-phenylenediamine (TPPA) cation radical have been reported as a symmetrical delocalized class III structure with a strong electronic coupling while *N*,*N*,*N*',*N*'-tetraphenylbenzidine (TPB) cation radical was demonstrated as a class II structure with a weakly electronic coupling, both leading intervalence charge transfer (IV-CT) absorption bands in the NIR region.[3] These result made aryldiamine-containing molecule a interesting anodic electrochromic system for NIR applications.

our strategy is to design and synthesize TPB-based ECPs with a longer distance between two electroactive nitrogen centers and higher absorption wavelength than the TPPA-based ones.[3b] Furthermore, by the copolymerization of these two series ECPs, the absorbing bands and reflected coloration could be merged and offer the potential for the preparation of ECPs possessing either highly saturated or darker colors.

In this contribution, we synthesized the TPB-based diamine monomer, *N*,*N*'-bis(4-aminophenyl)-*N*,*N*'-di(4-methoxyphenyl)-4,4'-biphenyldiamine, and its derived aromatic polyamides containing *para*-substituted methoxy groups which could not only enhance the solubility by a high steric hindrance for close packing but also greatly prevent the electrochemical coupling reactions by affording stable cationic radicals. The result TPB-based polyamides are expected to reveal a slightly bathochromic shift when compared with the reported TPPA-based ones in the oxidized stages due to the longer conjugating length between two electroactive nitrogen atoms. In addition, by random copolymerization of TPB and TPPA-based diamine monomers, the resulting copolymer **IIb** could exhibit extensive absorption ranging of 400-750 nm required for a black electrochromism. To the best of our knowledge, copolymer **IIb** is the first transmissive to black ECP absorbing virtually the whole visible spectrum in the oxidized state.

Transmissive to Black Electrochromic Aramids Based on Electroactive Tetraphenylbenzidine Units

Charge-transporting polymers and glasses forming molecular materials for optoelectronic applications

J.V. Grazulevicius

Kaunas University of Technology

juozas.grazulevicius@ktu.lt

Introduction. Charge-transporting polymers and molecular glasses are widely used in (opto)electronic devices, such as electrophotographic photoreceptors of copying machines and laser printers, light-emitting diodes, solar cells, organic thin film transistors [1]. In this presentation the resent results of the work on the synthesis and properties of charge-transporting polymers and molecular glasses performed in the author's laboratories are reviewed.

Materials and Methods. Carbazole was used as the main building block in the design and synthesis of charge-transporting polymers and molecular glasses [2]. We used electron photoemission technique for estimation of ionization potentials and xerographic time of flight technique for the investigation of charge-transporting properties of the materials. Thermal transitions of the materials were estimated by thermogravimetric anlyis and differential scanning calorimetry

Results and Discussion. We prepared soluble charge-transporting polymers and oligomers by chain growth (photo)polymerization of oxiranes, oxetanes, thiiranes, vinyl ethers bearing different electroactive groups [3] also by polycondensation and polyaddition of bifunctional electroactive monomers [4]. We use cationic and radical photocross-linking of bifunctional monomers bearing electroactive moieties for the preparation of insoluble charge-transporting layers [5]. Such layers are useful in the fabrication of multi-layer optoelectronic devices if they are prepared by the solution casting techniques.

We also synthesized hole-transporting glass-forming molecular materials belonging to the families of condensed aromatic amines [6], hydrazones [7], enamines [8], ethynylenes, stilbenes and electron-transporting materials belonging to the families of thioxanthenes and aromatic imides [9]. The ionization potentials of hole-transporting materials range from 4.80 to 5.80 eV. Time-of-flight hole drift mobilities in the amorphous films of 2,7-substituted derivatives of carbazole [10] and carbazole-based enamines [8] exceed 10^{-2} cm^2/V. Electron mobilities in the layers of the newly synthesized perylene diimide derivatives exceed 10^{-3} cm^2 V^{-1} s^{-1} at high electric fields. for disordered organic solids these are state-of-the-art charge mobilities. Glass-forming stable free radicals have appeared to be very effective ambipolar organic semiconductors [11]. Well defined carbazole oligomers have appeared to be effective host materials for blue organic electrophosphorescent devices [12]. The triplet energies of these materials approach 3.0 eV. Using these host materials, blue phosphorescent OLEDs having efficiencies of up to 15 %, 31 cdA^{-1}, and 28 lmW^{-1} were demonstrated [13]. Some of the recently synthesized high-triplet-energy glass-forming hosts have appeared to be effective ambipolar semiconductors. They were successfully used for the development of single layer organic light emitting diodes.

Conclusions. We have prepared and studied charge-transporting monomers, polymers and glass-forming molecular materials, with the wide range of ionization potentials and high charge mobilities. The selected materials were successfully used in organic light emitting diodes.

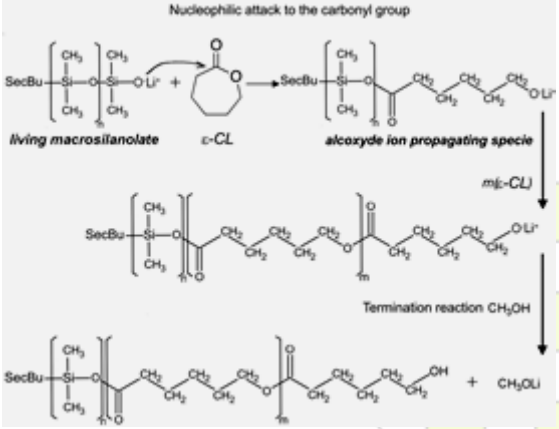
e-mail: valles@plapiqui.edu.ar, mvillar@plapiqui.edu.ar, aciolino@plapiqui.edu.ar

Introduction: Poly(ε-caprolactone) (PCL) is a biodegradable polyester which can be used as drug carrier because of its excellent drug permeability. Poly(dimethylsiloxane) (PDMS) is a biocompatible hydrophobic polymer with good properties as surface modifier. This combination makes PDMS-based copolymers excellent candidates for several biomedical applications. Thus, many synthetic strategies have been developed in order to synthesize block copolymers of siloxane/ε–caprolactone for specific applications [1-4]. In this work, we report the synthesis of these block copolymers under different reaction conditions by using anionic polymerization. We explored the use of PDMS macroinitiators to promote the anionic ring opening polymerization (AROP) of ε-caprolactone (ε-CL).

Experimental: The controlled synthesis of poy(dimethylsiloxane–*b*–ε-caprolactone) copolymers (PDMS-*b*-PCL) was studied by employing hexamethyl-cyclo(trisiloxane) (D_3) and ε-caprolactone monomers, a mixture of benzene/tetra-hydrofuran, and sec-Bu^-Li^+ as initiator. The reactions were carried out in whole-sealed glass reactors according to standards procedures for anionic polymerization (high-vacuum techniques). The molar mass, molar mass distribution, and composition of the resulting copolymers were obtained by Size Exclusion Chromatography (SEC), ^{1}H-Nuclear Magnetic Resonance (^{1}H-RMN), and Fourier Transform Infrared Spectroscopy (FTIR).

Results and Discussion: The synthesis of (PDMS-*b*-PCL) copolymers was carried out in two steps by using sequential addition of monomers. In the first step, D_3 polymerization was promoted by adding THF [5]. Under these circumstances, the living macrosilanolate initiators were obtained. Then, the ε-CL monomer was added to the reaction media in order to promote its co-polymerization. To achieve this, we hypothesized a nucleophilic attack of the PDMS macroinitiator already formed to the carbonylic carbon of the ε-CL monomer:



The results obtained are shown in Table 1. ε-CL incorporation seems to be temperature-dependant. At 50 ºC, the incorporation of ε-CL is close to the theoretical amounts expected by stoichiometry. At 40 ºC, there is lower incorporation, whereas at room temperature (RT) no incorporation is detected. These results suggest that temperature reaction is a fundamental parameter to promote higher ε-CL incorporation in the resulting PDMS-*b*-PCL copolymer.

Table 1: Synthesis of PDMS-*b*-PCL copolymers

Copolymer	T (ºC)	$x_{\varepsilon\text{-CL}\ t}$ a)	$x_{\varepsilon\text{-CL}\ e}$ b)	Mn (g/mol) c)	PD d)
PDMS-*b*-PCL 82	50	0.82	0.86	140,800	1.25
PDMS-*b*-PCL 67	50	0.67	0.61	94,500	1.25
	RT		0.00	-	-
PDMS-*b*-PCL 47	50	0.47	0.55	22,400	1.12
	40	0.47	0.10	17,900	1.15

a) Theoretical ε-CL molar fraction according to the initial monomer content, **b)** Experimental ε-CL molar fraction obtained by ^{1}H-NMR, **c)** Experimental Mn of copolymers from SEC and ^{1}H-NMR, and **d)** Polydispersity Index of copolymers according to SEC.

Conclusion: PDMS-*b*-PCl copolymers with different monomer compositions were obtained by AROP of the ε-caprolactone ring using PDMS macroinitiators, sequential addition of monomers, and anionic polymerization (high-vacuum techniques). The reaction is temperature-dependant: at 50 ºC, the ε-CL incorporation in the resulting copolymer is close to the theoretical amounts expected by stoichiometry; at 40 ºC, there is lower ε-caprolactone incorporation; and at room temperature no incorporation is detected.

The reaction will also be tested using (trimethylsilyl-methyl)lithium initiator with other siloxane monomer tetravinyl, tetramethyl, cyclo(tetrasiloxane) (V_4).

ACKNOWLEDGMENTS

We express our gratitude to CONICET, the Agencia Nacional de Promoción Científica y Tecnológica (ANPCyT), and the UNS for their financial support to this study, and Drs. Gabriel Radivoy and Cristian Vitale (INQUISUR) for their helpful advise.

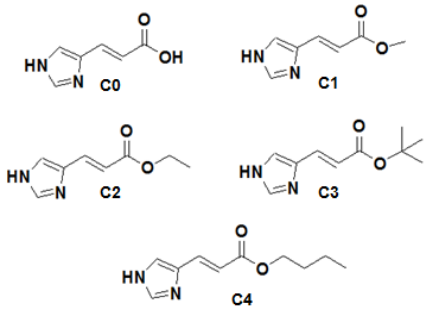
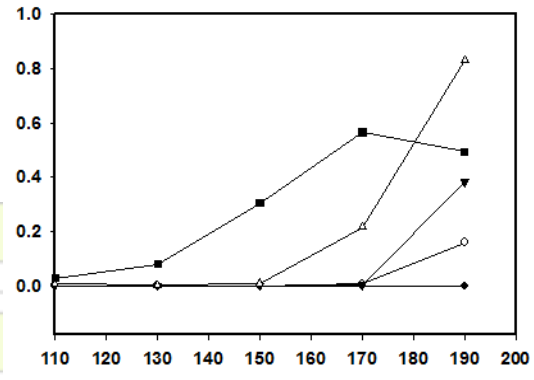
Nafion® membrane is a commercial membrane for PEMFC; however, the operation of Nafion® membrane at high temperature is limited due to an evaporation of water cluster resulting in decreasing of proton conductivity.[1, 2] Heterocyclic compounds such as imidazole, pyrazole, benzimidazoles are accepted as the compounds for proton transfer. The mechanism is suspected to relate to the hydrogen bond and structural reorientation through the resonance N-HN without the need of water molecules.[3,4] The proton conductivities of those heterocycles are about 10^{-4} S/cm[5] at intermediate temperature which still needs an improvement to compete with that of Nafion® membrane (10^{-2} S/cm at below 80 °C).[1,2] In order to develop the conductivity efficiency, here, we propose a synergistic effect between H-bond and chain mobility to enhance the proton transfer from a heterocycle to another. The present work focuses on a model case by using urocanic acid backbone with different alkyl chain length (**Scheme**) to satisfy the conditions related to the hydrogen bond and chain mobility.

Scheme



The number of methylene groups was varied from **C1** to **C4**. FTIR spectra of all derivatives showed an ester peak at 1710 cm^{-1}. The structural characterization identified by ^{1}H NMR confirmed imidazole ring at 9.18 ppm (1H, s) and 8.04 ppm (1H, s) with CH=CH at 7.59 ppm (1H, d) and 6.84 ppm (1H, d).



The proton conductivities of **C0**-**C4** in neat solid form were measured by using electrochemical impedance spectrometer (**Figure**). The fact that **C3** shows the significant proton conductivity for 0.8 mS/cm at 190 °C whereas urocanic acid did not perform the conductivity, this clearly informs us how the chain mobility plays an important role in proton transfer. The presentation will cover the temperature dependence FTIR, T_1 relaxation time, and thermal properties to clarify the plausible mechanism related to the proton transfer on the chain mobility under hydrogen bond network.

Figure Proton conductivities of **C0** to **C4** in neat compounds.

The authors would like to acknowledge the Thailand Research Fund (the Royal Golden Jubilee (RGJ) program) for the Ph.D. scholarship.

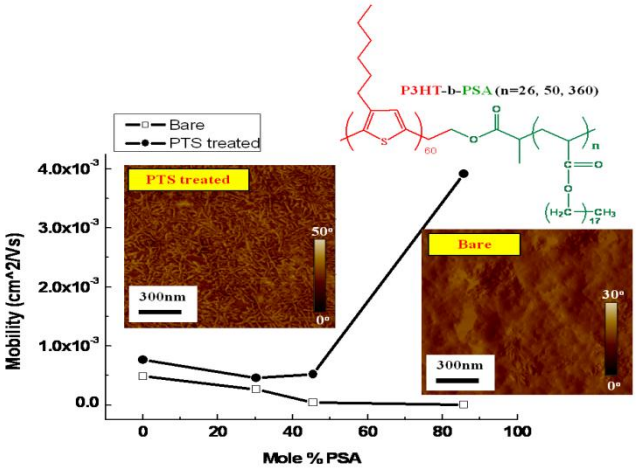
SABIC Innovative Plastics has recently launched the Synthesis, morphology and charge transport of new crystalline-crystalline diblock copolymers, poly(3-hexylthiophene-b-steryl acrylate) (P3HT-b-PSA), with various PSA segment lengths are reported in this study. The hole mobilities of P3HT-b-PSA diblock copolymers were investigated by field-effect transistors on both bare SiO_2- and phenyltrichlorosilane (PTS)-treated dielectric surfaces. On the bare SiO_2-surface, the mobility of the copolymers was decreased with the increased PSA contents. On the contrast, the mobility of the diblock copolymers on the PTS-treated substrates was enhanced to be $3.92*10^{-3}$ $cm^2V^{-1}S^{-1}$ as the PSA content was increased to be 85.7 mol%. The hydrophobic PTS-surface facilitated the orientation and the fiber-like self-assemblied structure of P3HT segments. Nevertheless, the mobility was reduced after the thermal treatment at a high temperature. It might be due to the thermally enhanced aggregation of P3HT nanofibers, which increased the amount of boundaries and led to the reduced mobility. This study indicated the significance of the P3HT/PSA ratio, surface modification, and thermal treatment on the morphology and charge-transporting characteristics of conjugated crystalline-crystalline block copolymers for high-performance organic electronics.



Nanocomposite Functional Membranes for Biomedical Applications

Ana Maria Popa, Francisco Teixeira, Stefanie Zuber, René M. Rossi

EMPA, Swiss Federal Laboratories for Materials Science and Technology, Laboratory for Protection and Physiology

ana-maria.popa@empa.ch

Introduction

Thermo-responsive polymers have been extensively studied in the last years, due to their potential applications in the biomedical field (e.g. controlled drug delivery). Their low mechanical stability however limits their application range. In this work we have investigated a novel class of thermo-responsive copolymers based on oligoethylene methacrylate (OEGMA) and vinyl caprolactam. These copolymers display tunable LCSTs in the physiological range which makes them extremely interesting for biomedical applications. We have explored different techniques for immobilizing these materials onto novel supports, as to extend their range of applications in the field of medical textiles, namely as active gating systems for moisture management in wounds or immobilized drug-delivery reservoirs.

Results and discussion

The random copolymers based solely on OEGMA monomers were grafted on functionalised track-etched polymeric membranes by controlled radical polymerization techniques (ATRP) as to obtain polymer-polymer nanocomposite membranes. The temperature-dependent permeation of caffeine molecules through the functionalized membranes has been demonstrated.

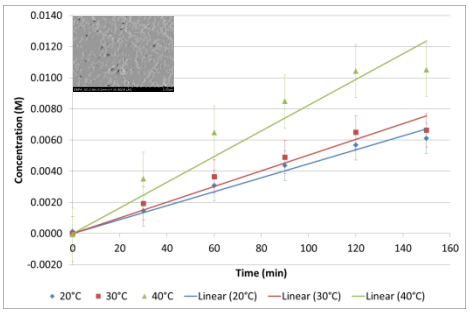


Figure 1. Temperature responsive permeation of caffeine through an OEGMA-functionalised track-etched membrane. Insert shows an SEM image of the modified membrane.

Additionally we have demonstrated a temperature-responsive permeation of water vapors through the functional pores, an effect which could be exploited for medical textiles where moisture management is necessary.
A second direction explored the synthesis of novel VCL-OEGMA copolymers. We demonstrated that minute amount of OEGMA can be incorporated into PVCL chains by simple free radical polymerization techniques and the LCST of these systems can be tuned in the physiological range.

Since their mechanical resistance is low, these polymers have been processed into microporous membranes by electrospinning together with poly(lactic acid), a biopolymer with superior tensile properties. The temperature responsiveness of these membranes has also been demonstrated.

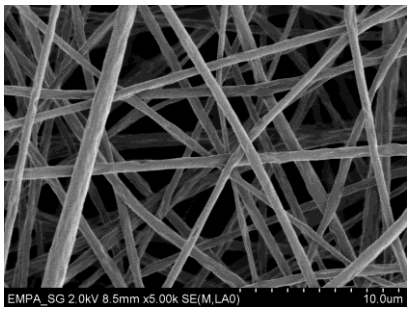

Figure 2. PLA-PVCL Composite microporous membrane obtained by electrospinning

Conclusions

We have presented two straight-forward processes for taking advantage of the very interesting properties of OEGMA and VCL based copolymers – biocompatibility and temperature-dependent behavior – by incorporating them in easy-to-handle materials with increased stability, such as microporous membranes and non-wovens. These new polymer/polymer nanocomposites open the perspective for numerous applications in the biomedical field, ranging from sensing to drug delivery.

Foamed Nanocomposites: A System in which Nanofillers Play a Multifunctional Role

M.A. Rodriguez-Perez, C. Saiz-Arroyo, J.A. de Saja

Cellular Materials Laboratory (CellMat), Condesed Matter Physics Department, University of Valladolid, 47011 Valladolid, Spain

e-mail: marrod@fmc.uva.es

Foamed nanocomposites constitute a novel class of materials combining the advantages of nanocomposites and cellular materials. Although the potential of these materials is very high the research and technology of these new materials is still at an embryonic stage[1,2].

Merging two types of materials and processing technologies poses new challenges compared to generic materials. It has been concluded that nanofillers enhance nucleation efficiency in the foaming process[2], but it is not clarified what is the mechanical reinforcement efficiency of nanofillers embedded within a cellular structure and how these two property attributes interact for giving required property values at macro-scale. When considering the main challenges to developers of foamed nanocompoites questions regarding the foaming behaviour and underlying physics; interaction at gas/polymer/nanofiller interfaces; homogeneity of cell sizes and fillers dispersions; and physical mechanisms responsible for local deformation pattern at nano / microscale resulting in a macroscopic mechanical response, cannot simply be answered by looking at the properties of the nanocomposites on the one hand and cellular materials on the other. *Strong interactions between these two groups of materials are to be expected in a final cellular nanocomposite material.*

During the last years our group has been studying different foamed nanocomposite systems proving that with a proper selection of the matrix and the nanoparticles, the nanoaditive can play a multifunctional role acting in very different ways:

1. Acting as nucleating agent for the cells, which allows reducing cell size and narrowing the cell size distribution which in turns also affect the physical properties.
2. Acting as nucleating agent for the polymer crystals, modifying the morphology of the base polymer.
3. Improving the polymer rheology, increasing the melt strength and as a consequence improving the stability of the molten foam.
4. Improving the foamability due to gas barrier effects
5. Improving the thermal and mechanical properties of the base polymer and as a consequence enhancing the physical properties of the foams.

To show the previous concepts this paper presents some examples regarding the fabrication of foamed low density polyethylene silica nanocomposites. Foams with cell sizes well below 100 microns and very homogeneous structure have been produced [3] (figure 1). It was found that the nanoparticles modified both the cellular structure and polymer morphology, acting as nucleating agent of the cells and polymer crystals. It was also found a strong improvement of the physical properties, much bigger in the cellular materials than in solid nanocomposites with similar compositions (figure 2), indicating the strong interaction (synergetic effect) between the nanoparticles and the cellular structure.

Poly(meth)acrylates obtained by Cascade Reaction

Helmut Keul, Dragos Popescu, Emin Hrsic, Martin Möller

Institute of Technical and Macromolecular Chemistry, RWTH Aachen and DWI an der RWTH *Aachen e.V.*

keul@dwi.rwth-aachen.de

Introduction

Preparation, purification and stabilization of functional (meth)acrylates with a high dipole moment are complex, laborious and expensive processes. In order to avoid purification and stabilization of the highly reactive functional monomers, a concept of cascade reactions was developed comprising enzymatic monomer synthesis and radical polymerization. Transacylation of methyl acrylate (MA) and methyl methacrylate (MMA) with different functional alcohols, diols and triols (1,2,6-hexanetriol and glycerol) in the presence of Novozyme 435 led to functional (meth)acrylates. After the removal of the enzyme by means of filtration, removal of excess (meth)acrylate and/or addition of a new monomer, e.g. 2-hydroxyethyl (meth)acrylate the (co)polymerization via free radical (FRP) or nitroxide mediated radical polymerization (NMP) resulted in poly[(meth)acrylate]s with predefined functionalities. Hydrophilic, hydrophobic as well as ionic repeating units were assembled within the copolymer. The transacylation of MA and MMA with diols and triols carried out under mild conditions is an easy and rapid in process and is suitable for the preparation of sensitive monomers.

Materials and Methods

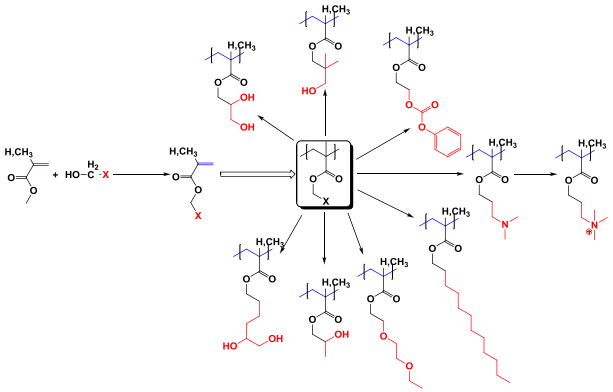
Methyl methacrylate (MMA), methyl acrylate (MA), functional alcohols, diols and triols were used without further purification. All solvents were used as received. A commercial lipase, Novozyme 435 (Lipase B from Candida antarctica immobilized onto a macroporous acrylic resin, 10 000 U/g) was dried in vacuum at room temperature for 24 h and stored under nitrogen before it was used as a biocatalyst for the transacylation reactions. All reactions were carried out in nitrogen atmosphere. All reaction products were analized via ^{1}H NMR spectroscopy and size exclusion chromatography.

Lipase-catalyzed transacylation reactions: Methyl methacrylate or methyl acrylate, a functional alcohol, and Novozyme 435 were stirred for 24 h at 70°C. The reaction was quenched by cooling the mixture to ambient temperature and the enzyme was filtered off. The molar ratio of (meth)acrylates was determined via ^{1}H NMR spectroscopy. Excess MMA or MA was removed by distillation and new monomers were eventually added before polymerization.

Copolymerization of monomers obtained by trans-acylation reaction: (i) Free radical polymerization. To a mixture of monomers obtained by transacylation reaction was added AIBN and reacted at 90°C for 24 h. The reaction was quenched by cooling the mixture to room temperature. The polymer was isolated by precipitation in a suitable solvent and dried in vacuo. *(ii) Nitroxide mediated polymerization:* To a mixture of monomers obtained by transacylation was added Blocbuilder™ initiator and SG-1 free nitroxide and immersed into an oil bath, preheated to 110°C. After 8 hours polymerization time, the reaction mixture was cooled to room temperature. The polymer was isolated by precipitation or dialysis and analysed by NMR and SEC.

Results and Discussion

Different functional polyacrylates were prepared by free radical polymerization as well as by nitroxide mediated polymerization of functional monomers prepared by in situ lipase-catalyzed transacylation. After the enzymatic transacylation of MA with different diols and triols a mixture of mono- and bisacrylates is obtained. We have shown that by free radical polymerization of the monomer solution directly obtained from the enzymatic catalyzed transacylation, a concentration up to 6 mol% bisacrylate is tolerated in order to get non cross linked polymers. Starting with 7 mol% bisacrylate significant polymer coupling was observed, while a concentration of 10 to 12 mol% bisacrylate leads to gel formation. Functional poly(meth)acrylates showing bacteriostatic or thermoresponsive properties were prepared.



Scheme 1. Cascade reaction for the preparation of functional Poly(acrylates) and poly(methacrylates)

Conclusions

The cascade reaction comprising an enzymatic transacylation and a nitroxide mediated polymerization or free radical polymerization represents a mild, easy and rapid process for functional polyacrylates and polymethacrylates. Well defined functional poly(meth)acrylates were prepared suitable for various application.

Solution processed conjugated molecules enable to manufacture low-cost a variety of opto/electronic devices by unconventional patterning methods, such as inkjet, screen, or gravure printing, with high throughput. The charge carrier mobility of state-of-the-art conjugated polymer semiconductors are comparable with a-Si so that it is expected that many applications will be replaced by cost-effective solution-processed organic field-effect transistors (OFETs) in near future. To realize advanced printed integrated complementary circuits, those p- or n-channel conjugated molecules must be patterned. Novel patterning methods have researched so far, but among those novel patterning methods, inkjet have a variety of advantages, such as removal of need for masks, which lead to cost-savings, efficient use of materials and waste elimination, non-contact deposition method [1].

Here we demonstrate high performance inkjet-printed p- and n-channel top-gate/bottom-contact polymer FETs, and applications to complementary inverter and ring oscillator circuits [2]. The various semiconducting polymers, such as p-channel [poly(3-hexylthiophene) (P3HT) and Polyera ActivInk P2100] and n-channel [poly{[N,N'-bis(2-octyldodecyl)- naphthalene-1,4,5,8-bis(dicarboximide)-2,6-diyl]-alt-5,5'-(2,2'-dithiophene)} (P(NDI2OD-T2))] were inkjet-printed using 50 μm diameter Microfab single nozzle in air. After formation of the stable inkjet droplets, p- and n-type organic semiconductors were directly patterned on glass or plastic substrate. Uniform printed lines on substrate can be obtained, which verified using optical microscope image.

Inkjet-printed P3HT FET devices showed good p-type characteristics, whose hole mobility was as high as 0.1 cm^2/Vs. Moreover, P3HT FET devices showed high on/off ratio more than 10^6, very low gate leakage current, little contact resistance, and no significant bias hysteresis. Moreover, newly developed ActivInk P2100 showed excellent p-channel OFET characteristics with very high hole mobility as high as 1.0 cm^2/Vs. For development of the polymeric complementary inverter circuits, where the combination of p- and n-channel transistors results in far greater circuit speeds, lower power dissipation and more stable operation, high performance and easily printable both p- and n-channel polymer semiconductors must be developed. We can obtain high electron mobility as high as 0.3 - 0.4 cm^2/Vs using P(NDI2OD-T2) and conventional PMMA gate dielectrics with proper selection of orthogonal solvents. Similar with those of P3HT FETs, P(NDI2OD-T2) transistors also showed high on/off ration, low threshold voltage, very low gate leakage current, little contact resistance and no significant bias hysteresis.

It is noted that n-type polymer, P(NDI2OD-T2), OFET characteristics are critically affected by selection of the gate dielectric and orthogonal solvent. Because of the very large solubility of P(NDI2OD-T2) (~60 g/L) and the location of the lowest unoccupied molecular orbital (LUMO) level at ~4.0 eV [3], an hydroxyl-free polymer dielectric and a perfectly orthogonal solvent are needed to prevent electron trapping and semiconductor surface roughness via swelling/dissolution of the underlying conjugated polymer. A poly(methyl methacrylate) (PMMA) dielectric solution in 2-ethoxyethanol (2E) was found to optimize the performance of both transistor type, which is essential for CMOS circuit fabrication.

By appropriate combination of p-channel and n-channel polymer FETs, we can demonstrate top-gated and inkjet-printed polymeric complementary inverter and ring oscillators. The inverter circuits were well operated at low operation voltage range as low as 5 V with a high voltage gain more than 30. Maximum and typical operation frequency of our printed ring oscillators is as high as 50 KHz and 1 – 50 KHz.

In conclusion, the first inkjet-printed high-performance polymeric complementary devices have been demonstrated. We believe that the operating frequency can be further improved by fine-tuning of the device architecture and optimization of the p-channel semiconductor processing. Based on a rough estimation, f_{OSC} >10 MHz are possible for a ActivInk P2100 and P(NDI2OD-T2)-based ring oscillator by reducing the FET channel lengths to ~1 μm and by minimizing the overlap capacitance (0.2–0.6 pF/mm) via self-aligned gate printing method.

email: chenwc@ntu.edu.tw

The memory characteristics of rod-rod diblock all-conjugated copolymers, poly(3-hexylthiophene) -*block*-poly(3-phenoxymethylthiophene) (**P3HT**-*b*-**P3PT**), and Its blends with PCBM were investigated. The field-effect transistors prepared from **P3HT**-*b*-**P3HT** showed a significant hysteresis between forward and backward gate-bias scans in the transfer curve, indicating the occurrence of the charge trapping. The charge trapping may be due to the amorphous P3PT moieties, reducing charge transport and trapping charge. **$P3HT_{102}$**-*b*-**$P3PT_{37}$** exhibited the dynamic random access memory (DRAM) behaviors in the sandwich configuration of ITO/**P3HT**-*b*-**P3PT**/Al. On the other hand, **P3HT** only showed the semiconductor characteristics, suggesting that the electrical switching behavior could be tuned through the **P3HT**/**P3PT** ratio. By blending a small amount (5-10%) of PCBM into **$P3HT_{102}$**-*b*-**$P3PT_{37}$** and **$P3HT_{89}$**-*b*-**$P3PT_{23}$**, based memory devices showed a write-once-read-many times (WORM) behavior with the switching voltages of -2.5∼-3.1 V and high ON/OFF ratios (10^5 -10^6). The mechanism associated with the memory characteristics was the charge transfer from the donor the polymers to acceptor PCBM, which stabilized the charge separated state and retained the high conductance state for a long time. The ON state of the **$P3HT_{102}$**-*b*-**$P3PT_{37}$**/PCBM device could remain more than 30 min after the power was turned off, whereas the pure **$P3HT_{102}$**-*b*-**$P3PT_{37}$** device relaxed from the on state to the off state quickly after removing the applied voltages. These experimental results provide the new strategies of designing block copolymers for tuning the memory characteristics for advanced flexible electronic devices.

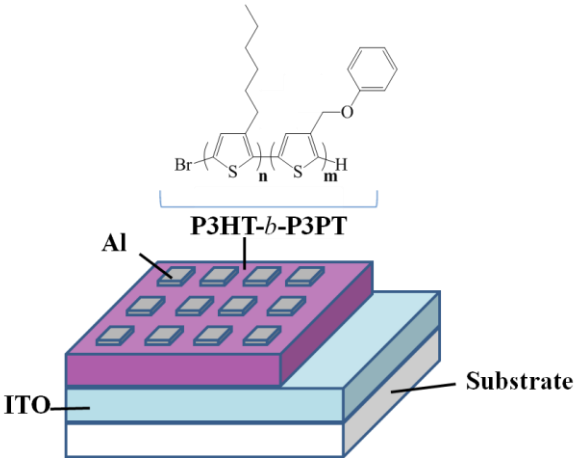

Figure 1. A schematic diagram of the memory device consisting of **P3HT**-*b*-**P3PT** thin film sandwiched between an ITO bottom electrode and an Al top electrode.

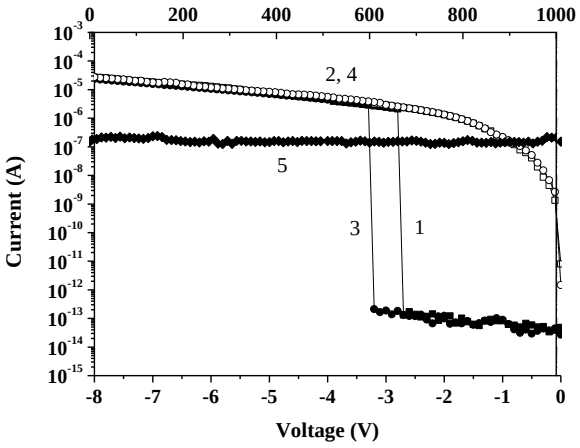

Figure 2. Current-voltage (I-V) characteristics of **$P3HT_{102}$**-*b*-**$P3PT_{37}$** memory device.

Effect of Composition on the Properties of Sulfonated Poly(indene)/Poly(vinyl alcohol) Membranes

Neiva Löser, Bruna dos Santos, Ricardo Cavalheiro, Maria Madalena Camargo Forte

Federal University of Rio Grande do Sul/Engineering School/Department of Materials – Porto Alegre/Brazil

mmcforte@ufrgs.br

Studies[1-5] has been carried out on exploring the possibilities of hydrocarbon-based membranes as potential candidate for polymer electrolyte fuel cells (PEMFC). The transport of charges across the membrane occurs by the migration of hydrogen's sulfonic groups, as well established for the DuPont trademark Nafion®[3], a perfluorinated membrane. On the other hand, sulfonation of molecular chains[4,5] can establish this feature to some appropriate hydrocarbon polymers, in which the sulfonic groups $-SO_3H$ is attacked in the macromolecule. Sulfonated aromatic polymers, inorganic composites, and polymer blends[2,7] electrolyte membranes have been explored and heterocyclic-based polymers have attracted special interest. In this work, membranes of sulfonated poly(indene) (SPInd) and poly(vinyl alcohol) (PVA) were investigated according to their composition.

The membranes SPInd/PVA were prepared as semi-interpenetrating polymer network (semi-IPN) by crosslinking PVA with a crosslinking agent (CA) glutaraldehyde (GA) or sulfosuccinic acid (SA). The membranes were evaluated by termogravimetry (TGA), dynamic-mechanic analyses (DMA), Water uptake (WU), Ion exchange capacity (IEC), and electrochemical impedance spectroscopy (EIS) under anhydrous conditions. The SPInd was obtained according to Makowsky[8] using acetyl sulfate. The SPInd/PVA membranes (**Table 1**) (0.8 ± 0.4mm) were obtained by mixing water solutions of SPInd (M_W=1,15x10^{6}g/mol and SD=56±2% (mol/molInd), produced in the lab, and of PVA (VETEC HD=99%; M_W=10^{5}g/mol), followed by the CA addition (5% w/w) at 60ºC. To avoid bubble formation, the solutions were prepared in an ultrasonic bath, and cast into plastic dishes (r = 8 cm) maintained at 60ºC for 48 h in an oven. The water uptake was calculated by correlating weight differences of the wet and dry membrane, after this be soaked 24h at R.T. and oven dried at 45°C until constant weight. The membrane IEC (meq/g) was determined by acid–base titration method.

Table 1. Designation and composition of the membranes

Designation	Ratio (wt%)	SPInd x10^{3}mol	PVA x10^{3}mol	CA mol
SPInd/PVA2-GA	80/20	5.17	3.41	7.5x10^{-5a}
SPInd/PVA3-GA	70/30	4.52	5.11	1.1x10^{-5a}
SPInd/PVA4-GA	60/40	3.88	6.81	1.5x10^{-4a}
SPInd/PVA2-SA	80/20	5.17	3.41	3.7x10^{5b}
SPInd/PVA3-SA	70/30	4.52	5.11	5.6x10^{5b}
SPInd/PVA4-SA	60/40	3.88	6.81	7.5x10^{5b}

[a]glutaraldehyde (GA); [b]sulfosuccinic acid (SA)

The SPInd has higher thermal stability than the non-sulfonate PInd, since at 1000ºC both presented residue of 0.3 and 16.7%, respectively. In the former ring condensation must occur due to a high interaction between the polymer chains caused by the $-SO_3H$ groups. The loss of $-SO_3H$ groups have occurred in a broad temperature range from 160 to 400 ºC. On the other hand, higher amount of PVA in the membrane did not depress the thermal stability of the SPInd since the mass loss occurs at the same temperatures as can be seen in **Figure 1**.

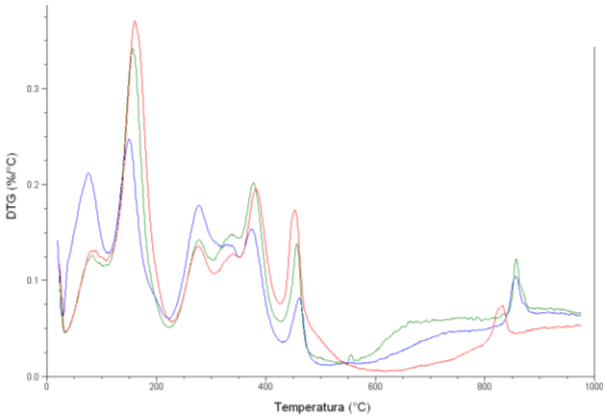

Figure 1. DTG curve of the SPInd/PVA-GA (5%) membranes with 20 (blue), 30 (green) and 40% (red) of PVA.

Table 2 shows the water up take, ion exchange capacity, resistance and conductivity of the SPInd/PVA-CA membranes. The type of CA affected the chain crosslinking and membrane characteristics. The membrane IEC depends on the $-SO_3H$ access to the ion sodium during the titration. The GA attaches to four –OH groups the PVA chains while the SA attaches only to two groups. Thus the number of –OH solvated by water in the former is lower than in the last. On the other hand, as higher the PVA content in the membrane higher the occurrence of intermolecular crosslink, that hindered the membrane swelling and water up take. Decreasing in the WU was observed for the membranes with SA. Although the membranes with SA have more $-SO_3H$ groups, the resistance in these membranes was higher and consequently lowers the conductivity.

Table 2. Ion exchange capacity (IEC) and water uptake (WU) of the SPInd/PVA-CA membranes

Membranes	IEC (meq/mol)	WU (%)	R (Ω)	δ(S.cm^{-1})
SPInd/PVA2-GA	3.36	444	5.88x10^6	1.97x10^{-7}
SPInd/PVA3-GA	3.31	811	7.32x10^5	1.59x10^{-6}
SPInd/PVA4-GA	2.78	570	1.76x10^7	6.17x10^{-8}
SPInd/PVA2-SA	2.75	1449	3.01x10^8	2.73x10^{-9}
SPInd/PVA3-SA	2.30	1201	1.07x10^8	1.51x10^{-8}
SPInd/PVA4-SA	2.35	981	1.77x10^6	6.61x10^{-7}

The composition affected the SPInd/PVA-CA membrane performance and the these with sulfosuccinic acid presented higher water uptake since it has more –OH sulfonic groups. The crosslinking agents were not so effective in hindering the membrane swelling.

Introduction

The design of functional soft nanoparticles is of current interest for several traditional (*e.g.* polymer processing industry) and emerging (*e.g.* nanomedicine) fields due to the interesting and sometimes unique properties displayed by such nano-objects. For instance, potential applications for unimolecular nanoparticles cover from processing additives to artificial enzymes, photostable bio-imaging agents and *in vivo* drug / siRNA-delivery systems.

In recent years, the irreversible intramolecular collapse of individual polymer chains to unimolecular nanoparticles in the sub-20 nm size range has become an efficient avenue to functional soft nano-objects free from emulsifiers/steric stabilizers.

In this communication we review the main chemical routes to unimolecular polymeric nanoparticles, with special emphasis on emerging, highly-efficient "Click" chemistry methodologies. Additionally, some examples of new nanoscale effects induced by unimolecular polymeric nanoparticles are illustrated.

Conventional Routes to Unimolecular Nanoparticles

Classical routes to well-defined, unimolecular nanoparticles in the sub-20 nm size range include, among others, the use of functional polymers containing pendant vinyl functional groups across the linear polymer chain.[1]

Under appropriate dilute conditions, selective intramolecular cross-linking of the vinyl functionality allows the synthesis of unimolecular nanoparticles with size < 20 nm.

Photo-cross-linking of cinnamoyl units[2] and the use of low-molecular homobifunctional cross-linking compounds are other related, well established techniques.[3]

"Click" Chemistry Routes to Unimolecular Nanoparticles

Significant progress in the field of unimolecular nanoparticle synthesis was made by the introduction of latent Diels-Alder functionalities and a continuous addition technique, even when harsh reaction conditions were required (250 ºC).[4]

A great breakthrough was the application of the intramolecular "Click" chemistry concept[5] to the efficient, room-temperature synthesis of functional unimolecular nanoparticles through intramolecular coupling of azide and alkyne functionalities resulting in permanent triazole cross-linking joints (see **Figure 1**).

This concept has been recently extended to the preparation of nanoparticles by intramolecular cross-linking of isocyanate functionalized copolymers.[6] Also, the formation of metastable polymeric nanoparticles has been demonstrated through a supramolecular approach.[7]

Current work by our Group involves the development of alternative, alkyne-homocoupling "click" chemistry procedures, as well as the introduction of innovative metal-free routes for the synthesis of multi-functional unimolecular nanoparticles.

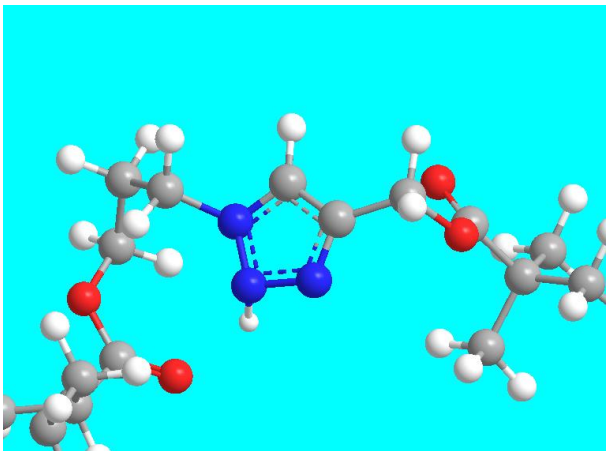

Figure 1. *Azide-alkyne "click" chemistry concept for the highly-efficient synthesis of biofunctional unimolecular nanoparticles at room temperature.*[5] *Intramolecular cross-linking joints result from the formation of conjugated triazole rings in the presence of copper(I) catalyst.*

Nanoscale effects

Illustrative examples of unimolecular-nanoparticle-induced nanoscale effects are: i) reduction of viscosity in thermoplastic and rubber melts,[8,9] ii) increase of quantum efficiency in organic, fluorescence-based nanoparticles,[10] and iii) arresting of phase-separation in polymer blends.[11]

Thermally Rearranged (TR) Poly(ether-benzoxazole) Membranes for Gas Separation

Mariola Calle and Young Moo Lee

WCU Department of Energy Engineering, College of Engineering, Hanyang University, Seoul 133-791, Republic of Korea

ymlee@hanyang.ac.kr

Thermally rearranged polybenzoxazole (TR-PBO) membranes have emerged as a new class of microporous organic materials showing extraordinarily fast molecular transport, as well as molecular sieving effect for small gas molecules.[1,2] Their microporous structure and size distribution results from thermally driven structural rearrangements in the solid state of precursor aromatic polyimides, containing *ortho*-hydroxy groups, into the highly rigid, ladder-like polybenzoxazole structure. Free volume elements and their size distribution can be tuned easily by varying the monomer structures of the precursor polyimides and by using different thermal treatment protocols. Thus, in our previous studies, the thermal conversion of a series of *o*-hydroxy polyimides prepared from diverse commercially available dianhydrides and bis(*o*-amino phenol)s was carried out and their gas transport behaviour was examined by varying the heat treatment protocol.[2-5] Most of these TR polymers showed outstanding gas separation performance, overcoming polymeric upper bounds for gas separation, but strongly dependent on the chemical structure of the precursor polyimides and also on the thermal rearrangement treatment. Thus, TR-PBO membranes containing six bulky fluorine groups, derived from 4,4'-(hexafluoroisopropilidene) diphthalic anhydride (6FDA) and 2,2'-bis (3-amino-4-hydroxy-phenyl) hexafluoropropane (bisAPAF) displayed the highest fractional free volumes and permeabilities among all the TR-PBO reported.[1,2] Moreover, as a rule, the gas permeability increased dramatically and the gas selectivity decreased slightly by increasing the heat treatment temperature.

As a continuation on the study and development of new high free volume polymer membrane materials using the thermal rearrangement concept, we have considered the possibility of tuning the formation of free volume elements in TR-PBO polymers, in terms of temperature and rate of conversion, by increasing the flexibility of the polybenzoxazole backbone. Hence, here we describe for the first time the synthesis and characterization of poly(ether-benzoxazole) membranes by thermal rearrangement of a novel fluorinated ether-containing poly(*o*-hydroxy imide) (**HPEI**).[6] The effect of increased chain flexibility on the physical and transport properties of the resultant TR polymer membranes for different thermal treatment protocols (e.g. final temperature and thermal dwell time), have been examined and will be presented in detail.

One Single Composite For Chemical Sensor Or Heating Purposes.

Myriam Bouhadid[1], Jacques Desbrières[1], Caroline Pillon[1], Nathalie Redon[2] and Stéphanie Reynaud[1]

[1]IPREM-EPCP, UMR 5254 (CNRS/UPPA), Hélioparc, 2 avenue du président Angot, 64053 Pau cedex 9, France ; [2]Ecole des Mines de Douai, 941 rue Charles Bourseul, BP 10838, 59508 Douai cedex, France

stephanie.reynaud@univ-pau.fr

The major target of intrinsic conducting polymer (ICP) development is to combine the electrical properties of these materials with the mechanical and processability properties of commodity bulk polymers. Among ICPs, polyaniline (PAni) received a great deal of attention because of its easy preparation with low costs and its stability under environmental atmosphere. Moreover, the electrical conductivity of PAni can be closely controlled over a wide range coming from 10^{-4} to 10 $S.cm^{-1}$ which makes PAni a good candidate for many applications[1-4] as antistatic films, electromagnetic shielding layers, sensors, technical packaging and anticorrosion.

The IPREM-EPCP group focused on the optimization of a simple way of synthesis to yield to a conducting composite in one-step[5-6]. The final aqueous dispersion contains composite particles mad of polymer matrix and polyaniline and is used without post formulation. Conducting films are obtained by spaying or automatic film applicator methods. The conductivity and the chemical composition of the final composite may be in line with the target application.

The same conducting composite was then successfully used as chemical sensor and heating surface. The whole process, *i.e.* from the synthesis to the film forming, remain as simple as possible and are carried out in soft experimental conditions, that is, without external acid or organic solvent.

After a brief presentation of the synthesis and the characterization of the conducting films, the performances of chemical sensors and heating surface will be discussed. The study of chemical sensor demonstrated the feasibility of whole polymer sensors to detect ammonia[7-9]. Moreover, all performances of this new chemical sensor are in line with the market needs in terms of response time, sensitivity, reproducibility. At last, these sensors introduce a breakthrough technology since their response is reversible with no need of servicing or calibration between two exposures (Figure 27). This feature is very interesting in terms of time-life and cost.

The same composite films have been successfully tested as heating surface. The temperature of the films is measured via an Infra-Red camcorder and the results are reported Figure 28. Its heating performances and its processability (soft final material, easy to cut and pattern) allow considering its development as heating devices suitable for low energy building (tunable size, thin film, easy to handle).

Synthesis and Applications of Copoly(*p*-phenylene)s Containing Bipolar Triphenylamine and 1,2,4-Triazole Groups

Chia-Shing Wu and Yun Chen

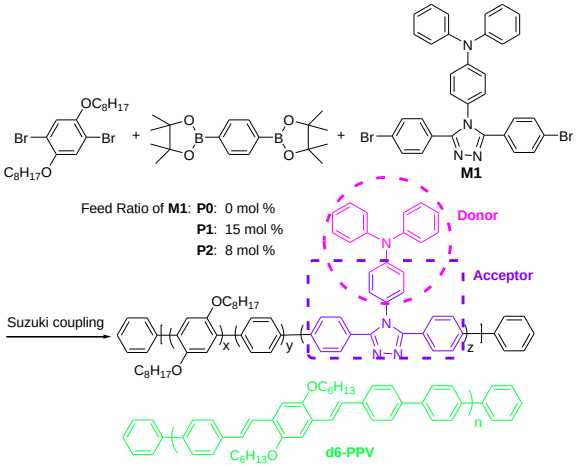
Department of Chemical Engineering, National Cheng Kung University, Tainan, Taiwan

n3895120@mail.ncku.edu.tw

Abstract: Two novel copoly(*p*-phenylene)s (**P1**-**P2**) containing bipolar groups (12.8 mol% and 6.8 mol%, respectively), directly linked hole-transporting triphenylamine and electron-transporting aromatic 1,2,4-triazole, was synthesized to enhance electroluminescence of poly(*p*-phenylene vinylene) (PPV) derivatives. The bipolar groups not only enhance thermal stability but also promote electron- and hole-affinity of the resulting copoly(*p*-phenylene). Blending the bipolar copoly(*p*-phenylene)s (**P1**-**P2**) with PPV derivatives (**d6-PPV**) as an emitting layer effectively improve the emission efficiency of its electroluminescent devices [ITO/PEDOT:PSS/polymer blend/Ca(50 nm)/Al(100 nm)]. The maximum luminance and maximum luminance efficiency were significantly enhanced from 310 cd/m^2 and 0.03 cd/A (**d6-PPV**-based device) to 1450 cd/m^2 and 0.20 cd/A (blend device with **d6-PPV**/**P1**=96/4 containing *ca.* 0.5 wt% of bipolar groups), respectively. Our results demonstrate the efficacy of the copoly(*p*-phenylene)s with bipolar groups in enhancing electroluminescence of PPV derivatives.

Keywords: bipolar; conjugated polymers; light-emitting diodes (LED); poly(*p*-phenylene) (PPP); triazole (TAZ); triphenylamine (TPA)

Introduction: Since the polymeric light-emitting diodes (PLEDs) using poly(*p*-phenylenevinylene) (PPV) as an emitting layer was first reported by Holmes *et al.* in 1990, PLEDs have attracted much research interest over the past two decades because of their potential applications in large-area display and solid-state lighting. An efficient PLED requires a balanced injection and transport between electrons and holes. Unfortunately, electron injection is usually more difficult than hole injection in conjugated polymers, such as PPV derivatives, leading to the imbalance between electron and hole injection and transport, which greatly reduces the luminescence efficiency of their PLEDs. In this study, to enhance both hole and electron transport/injection we synthesized two novel copoly(*p*-phenylene)s (**P1**-**P2**) containing 12.8 mol% and 6.8 mol% bipolar group, respectively. The copoly(*p*-phenylene)s exhibit not only good thermal stability but also enhanced hole and electron injection relative to homo-poly(*p*-phenylene) (**P0**) due to the presence of the bipolar units. Finally, the influence of bipolar contents on device performance is investigated, using blends of the bipolar copoly(*p*-phenylene) and **d6-PPV** as emitting layer. Both maximum luminance and maximum luminance efficiency of the blend devices are greatly enhanced.



Scheme. Synthesis of Copoly(*p*-phenylene)s (**P1**-**P2**), Poly(*p*-phenylene) (**P0**) and Chemical Structure of **d6-PPV**.

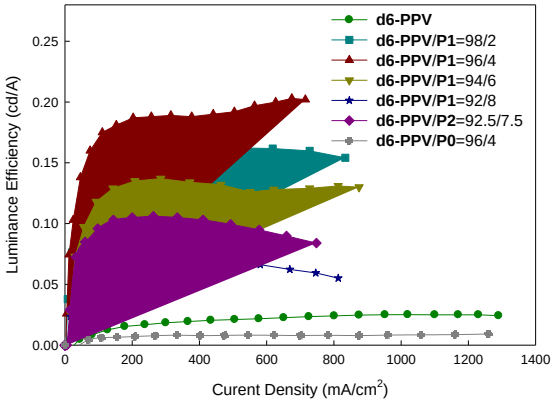


Figure. Luminance efficiency versus current density characteristics of PLEDs using blends of **d6-PPV** and **P1** (2~8 wt%), **P2** (7.5 wt%) or **P0** (4 wt%) as emitting layer. Device configuration: ITO/PEDOT:PSS/ **d6-PPV** + **P1**, **P2** or **P0** (80~100 nm)/Ca(50 nm)/Al(100 nm).

Conclusion: The function of the bipolar structure is to balance charges recombination in **d6-PPV**-based devices. Blending the copoly(*p*-phenylene)s containing bipolar moieties are promising additives to enhance device performance of **d6-PPV** due to improved carriers injection and transport.

Two-dimensional 4T-acceptor conjugated polymers have been shown to have excellent charge-transport characteristics and solar cell performances.[1] In this study, new two-dimensional conjugated homopolymer poly(5,5'''-di- (2-ethylhexyl)[2,3';5',2'';4'',2''']quarterthiophene) (P4T) and their copolymers, P4TT, P4TSe, P4TFT, P4TBDT, and P4TDTS, were synthesized by Stille coupling reactions under microwave heating. The effects of chemical structures on the electronic energy level, charge transport, and photovoltaic properties were explored systematically. Among these copolymers, P4TFT showed the highest
organic field effect transistor (OTFT) hole mobility of 0.12 $cm^2 V^{-1} s^{-1}$ due to its highly crystalline packing structure. The performances of bulk heterojunction polymer solar cells based on the blends of these 4T-based copolymers and 1-(3-methoxycarbonyl) propyl-1 - phenyl-[6,6]-C-71 ($PC_{71}BM$) were also characterized. P4TSe/ $PC_{71}BM$ based photovoltaic device showed the highest power conversion efficiency (PCE) of 2.6% under AM 1.5 illumination ($100mW/cm^2$). The above results exhibited that two-dimensional conjugated copolymers emerged as a promising candidate for organic electronics.

Introduction. Gels based of polyacrylamides (PAM) and modified-polyacrylamides (PAMs) and cross-linker(s) have been used in treatment of injection and productions wells to improve production of oils and gas [1]. Polyethyleneimine (PEI) is an organic cross-linker with a low toxicity that has been also used with PAM's and PAM derivatives for hydrogel systems. However, the mechanism of gelation of these systems is not yet well understood. This work evaluates the physicochemical properties of the polymer-crosslinker solution before, during and after the gel transition. Synthesized and well characterized: anionic poly(acrylamide-*co*-2-acrylamido-2-methyl-1-propane sulphonic acid) copolymer (PAM-*co*-AMPS) with 5, 10 and 20 mol-% of AMPS; hydrophobic poly(acrylamide-*co*-*tert*-butyl acrylate) (PAM-*co*-tBuA) with 1 and 5 mol-% of tBuA; and neutral PAM homopolymer were used. The presence of the co-monomers changes the charge density and chemical functionality of the PAM which can be conveniently used to modulate the gelation time [2]. The physicochemical mechanism of gelation was study by nuclear magnetic resonance (NMR), dynamic light scattering (DLS) and rheology. Also the viscoelastic properties of the gels were evaluated and the influence of crosslink density and polymer characteristics on the behavior of the gel was established.

Materials and Methods. Acrylamide (AM), 2-acrylamido-2-methyl-1-propanesulfonic acid sodium salt (AMPS) and hydrophobic *ter*-butyl acrylate (tBuA) were used as monomers. Sodium dodecyl sulfate (SDS), 2,2-azobis(2-methylpropionamidine) dihydrochloride, denoted VAZO56, were employ as surfactant and initiator, respectively. All these products were used without any further purification. Salt-free Milli-Q water (resistivity: 18.3 MΩ· cm) was used to prepare all brines for polymer dissolution. PAM and PAM-*co*-AMPS copolymers were synthesized via radical polymerization. PAM-*co*-PtBuA were synthesized via micellar copolymerization method [3]. The surfactant (SDS) was used at an excess value to ensure a number of hydrophobic units per block (assumed to be equal to the number of hydrophobic monomers) equal to 20 (N_H=20).

Results and Discussions. The mechanism of gelation and also the kinetics was found to be sensitive to the chemical structure of PAMs, besides the concentration of both polymer and crosslinker, and also temperature and pH. The mechanism of gelation was deeply studied using ^{13}C and ^{16}N RMN allowing to established the chemical groups responsible of the covalent links. Dynamic LS measurements performed at scattering angle of 90º allows to calculate the intensity time correlation function (TCF) $g_2(t)$ and the electric field TCF $g_1(t)$. The power-law behavior or not of $g_1(t)$ at the gel point was evaluated, as the behavior of the relaxation modes. Finally, the gelation process was monitoring recording by rheology the elastic (G') and viscous (G'') moduli during the in situ gelation of PAMs with the cross-linker PEI. Figure 1 illustrates the evolution of G' during gelation at constant temperature of 80 ºC, and a concentration of 0.5 wt% for both PAMs and PEI. From the G'(t) plot (Figure 1), three different periods in gelation process can be defined: (1) an initiation period where G` remains almost constant, (2) a sol-gel transition period where G` increases dramatically, and (3) an almost plateau regimen where G` slightly increases but did not reach a final equilibrium value before 24 h (results not shown). It is notorious from the Figure 1 that the gelation kinetic for the PAM-*co*-AMPS copolymers it is not the same from those of PAM and PAM-*co*-tBuA. The insert in Figure 1 shows the evolution of gel strength from ¨flowing¨ to ¨non-flowing gel¨ which revealed a behavior apparently not in accord with the formally gel definition. Different models and relationships between the different parameters were finally established.

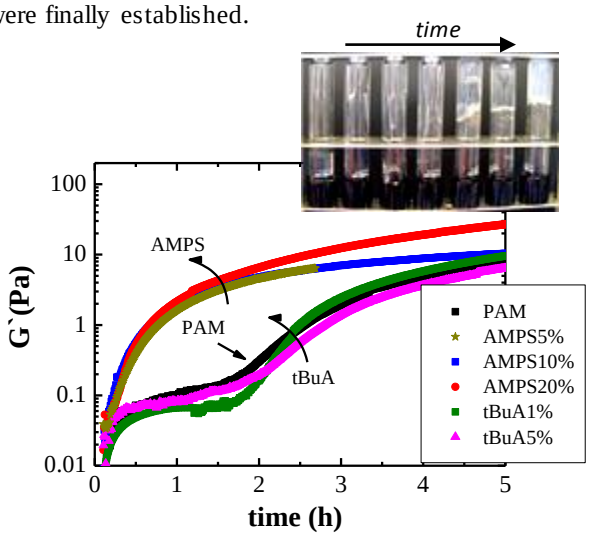

Figure 1. Variation of G' during gelation of PAM and PAM copolymers (0.5 wt%) with PEI (0.5 wt%) at 80 ºC under dynamis oscillations using ω = 1Hz and γº < 0.02. *Insert*: Gel evolution in time.

Viscoelastic and Generalized Newtonian Fluid Flows Simulation in Single Screw Extruder Using Computational Flow Dynamics

*Amirhosein Ahmadian, Yousef Tamsilian, Ahmad Ramazani S.A**

Sharif University of Technology Chemical, and Petroleum Engineering Department, Tehran, Iran.

*Email: ramazani@sharif.edu, Tel: +982166165431

This manuscript is presented to simulation of viscoelastic and generalized Newtonian fluid flows in an extruder considering that screw is turning instead of barrel turns which normally was considered in most simulation as assumption. A three dimensional finite-volume scheme is used to solve momentum and fluid equations. The real geometrical configuration of the channel is investigated to obtain best result and show effective profiles same as pressure, shear stress, velocity, and normal stress. The simulations concern incompressible fluids obeying different constitutive equations such as generalized Newtonian with shear-thinning properties (Carreau–Yasuda model), and viscoelastic differential model, the Phan–Thien/Tanner (PTT). The obtained results are shown in contour and vector form based on special position onto axial flow. Numerical results can demonstrate influence of boundary condition (fixed barrel and mobile barrel assumption) and rheological properties upon flow characteristics in considered geometry. The results show that screw moving as realistic conditions instead of mobile barrel assumption in single extruder has significant effects on pressure, stress, and velocity profiles comparing to results obtained from simulation with assumption of fixed barrel boundary that currently are used to model extruder flows. In other hand, in this study, we easily can observe two different behaviors of two different fluid models (viscoelastic and generalized Newtonian fluids) to compare the profiles

Ion exchange and Electron Exchange Properties of Polycalixresorcinarene

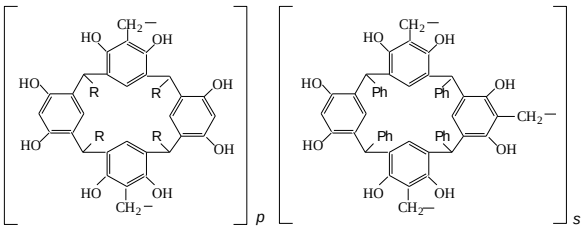
Altshuler H.N. and Ostapova E.V.

Institute of Coal Chemistry and Material Science, Siberian Branch of Russian Academy of Sciences

e-mail: ostapovaev@bk.ru

Introduction

Polycalixresorcinarenes as electrode materials for fuel elements of new generation was offered by us [1]. The oxidation-reduction processes with participation of hydrogen, oxygen and metals proceeding in polycalixresorcinarene matrix are investigated [1]. High electric conductivity of polycalixresorcinarenes equilibrated with aqueous solutions of electrolytes was established [2]. The goal of the present research was to study the ion exchange and electron exchange abilities of sulfonated polytetraphenylcalixresorcinarene



R= Ph-SO_3H .

Materials and Methods

The sulfonated polycalixresorcinarene was prepared by twice sulfonating of the network polymer synthesized by the resol polycondensation of tetraphenylcalixresorcinarene with formaldehyde following the procedure described in [3].

The dynamic ion exchange capacities of the polycalixresorcinarene were determined by passing the 0.1 M NaOH or 0.1 M NaCl through the polymers bed until the concentrations of H^+ in solutions at the inlet and outlet of the column became identical.

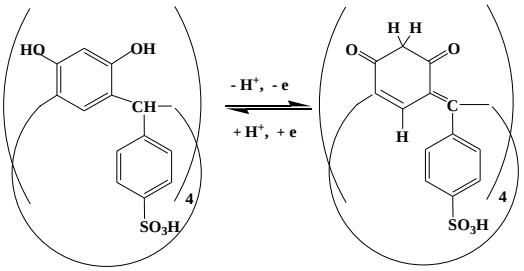
The dynamic electron exchange capacity of the polycalixresorcinarene was determined by passing the 0.01 M $Ce(SO_4)_2$ through the polymer bed until the concentrations of Ce^{4+} in solutions at the inlet and outlet of the column became identical. The value of the exchange capacity per kg of the H^+ form of the polymer dried at 105°C was calculated.

Electron exchange ability of polycalixresorcinarene were determined in the electrometric titration of polymer in 0.25 M H_2SO_4 with 0.01 M $Ce(SO_4)_2$ in 0.25 M H_2SO_4 using a bright platinum electrode referred to a saturated chlorine-silver electrode.

Results and Discussion

An analysis of the material balance indicates that the ion exchange from aqueous solutions involves protons of all sulfo groups and four protons of eight resorcinol OH groups (one per each resorcinol fragment) of repeating units of polycalixresorcinarene. The total ion exchange capacity of polymer (with respect to 0.1 M NaOH) is 5.65 moles per kg. The ion exchange capacity for polymer respect to the sorption of 0.1 M NaCl from neutral solutions corresponds to the concentration of sulfo groups in the polymer. It equals to 2.45 moles per kg.

It is revealed that the polymeric matrix of nanocomposite based on polycalixresorcinarene containing palladium participates in oxidation-reduction transformations according to the scheme



Thus after oxidation the resorcinol fragments of calixarene were transformed in quinoid structures. The analysis of FTIR-spectra of nanocomposite has shown that the basic fragments of macrocyclic structures of initial polymer are kept after treatment of nanocomposite by oxygen. The wide intensive strip in the rang of 3400 sm^{-1} corresponding to intramolecular hydrogen bonds in diols is observed in initial nanocomposite spectrum but the strip at 3400 sm^{-1} disappears in the spectrum of oxidized composite. In a spectrum of oxidized composite the intensity of strips at 2850 sm^{-1}, 2940 sm^{-1}, and 2920 sm^{-1} corresponding to asymmetric and symmetric valence vibrations of C-H bonds of methyl-methylene groups increases considerably.

The electron-exchange capacity of sulfonated polycalixresorcinarene equals to 3 electron moles per kg of polymer.

Conclusions

Polycalixresorcinarene is capable to exchange the protons by the cations from electrolyte solutions. The operating sorption pH interval of polymer ranges from 1 to 14.

Polycalixresorcinarene possess the electron-exchange ability caused by reversible oxidation of the resorcinol fragments.

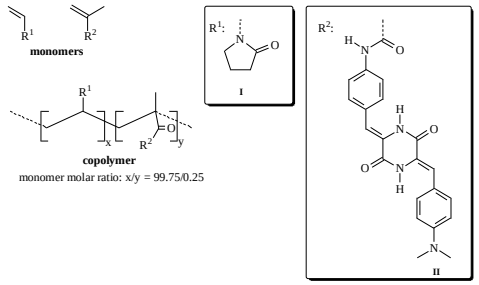
jmiguel@ubu.es

Introduction. Naturally, recognition in biological systems takes place in aqueous environments. The active sites, for example in an enzyme, have the shape needed to fit the guest molecule, or a part or the guest molecule, and the interaction relay on feeble bonds then takes place due to the hydrophobic microdomain in a hydrophilic general domain provided by the chemical and by the quaternary structure of a protein. In a very simplified manner, the competitiveness of the water molecules to establish these weak integrations is locally diminished or altered by the active site microsurroundings.

Mimicking nature, water insoluble receptors may be chemically anchored to a linear or crosslinked hydrophilic polymer, giving rise to water-soluble sensing polymers or to water-swelled sensing networks. The later approach permits easy control of swelling by means of increasing the crosslinking ratio. That is, the hydrophilic character of a polymer, derived from the chemical composition of the monomers, may be controlled not only by the monomer nature, but also by increasing the crosslinking monomer content of the network; thus, mechanically impairing the water uptake. Thus, an induced partially hydrophobic character may be addressed with an overall hydrophilic polymer associated with the mechanical stretching of the network upon swelling with water, as we have previously described.[1,2] Moreover, the polymers usually have good thermal and mechanical properties, can be easily transformed into end materials, such and films or coatings, to produce cheap sensing devices (e.g., user-friendly "naked-eye" film sensors). These polymers may also be incorporated as coating at the end of an optic fibre connected to a portable UV/Vis diode-array or fluorescence detector.[3]

Results and discussion. Thus, we prepared a methacrylamide monomer containing a piperazinedione derivative as the fluorogenic mercury sensing motif (**II**) and copolymerized them with a hydrophilic monomer (N-vinyl-2-pyrrolidone, **I**). The cross-linking agent, 1,2-ethanedioldimethacrylate, was used to obtain the dense, 100 μm thick polymer film or membrane (Scheme 1), with a water swelling percentage of 200 %. This membrane is optically transparent and demonstrates good mechanical properties, even after water or DMSO swelling. Upon soaking the film in aqueous solutions at physiological pH (pH= 7.4), the film exhibited selective fluorescence quenching behavior with increasing Hg(II) concentration, achieving a very low detection limit of 10 ppt (Fig. 1).

To test the fluorogenic anion and cation sensing selectivity of **II**, different anions and cations were tested. The addition of mercury cations resulted in a change in the gradual diminishing of the fluorescence intensity (F) of the 591 nm band. The fluorescent quenching was 8-fold when the relationship of **II** to Hg^{2+} was equimolar. In contrast, upon adding an equimolar amount of Cr^{6+} and Fe^{3+}, only a 1 and 0.5-fold fluorescence quenching was observed, respectively. The addition of a broad set of anions (sulfonate, chloroacetate, *p*-toluenesulfonate, oxalate, acetate, benzoate, cyanide, hydroxyl, nitrite, nitrate, carbonate, phosphate, fluoride, bromide, chloride), on the other hand, caused no effect.



Scheme 1. Chemical structure of monomers and copolymer

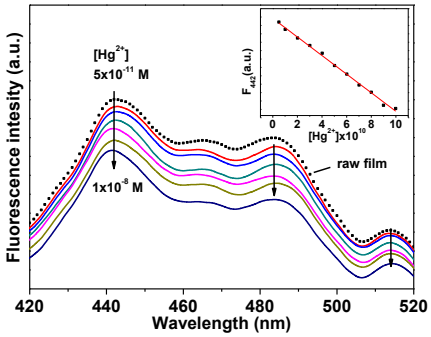


Figure 1. Selected titration curves of copolymer film with mercury cations in water at physiological pH (7.4) (inset: Hg^{2+} concentration vs. fluorescence intensity at 442 nm, F_{442})

Regarding biological molecules, the membrane showed a fluorogenic quenching upon adding increasing concentration of CoA, cysteine, and the tripeptide glutathione, with a lower detection limit of $1x10^{-6}$ M. Interestingly, and following the displacement-approach, the monomer in DMSO/water (90/10) solution, with the fluorescence quenched by an equimolar amount of Hg(II), recovered the fluorescence upon addition of the bimolecular mentioned above, improving the detection limit in one order of magnitude. The sensing performance of the hybrid organic/inorganic membrane is currently being carried out.

2: Institute of Polymer Science and Engineering, National Taiwan University, Taipei 106 Taiwan

E-mail: chenwc@ntu.edu.tw

High performance field effect transistors (FET) were fabricated by electrospun (ES) aligned nanofibers using two-dimensional regioregular polythiophene derivatives: poly[2',5''-5,5'''-di-(2-ethylhexyl),3';5',2'';4'',2''']-quaterthiophene-*alt*-3,6-dithien-2-yl-2,5-di(2-ethylhexyl)-pyrrolo[3,4-c]pyrrole-1,4-dione-5',5''-diyl] (**P4TDPP**), the molecular structure is shown in chart 1. The **P4TDPP** precursor solution was treated with gel-induced procedure to enhance crystallinity and further promoted FET mobility.

Figure 1 shows the normalized absorption spectra of polymer solution, thin film and nanofibers with different processing conditions. The intensity of **Solution-G** (polymer solution treated gel induced procedure) is increased evidently at 752 nm shoulder. It indicates the **P4TDPP** can self-organize to form crystallites through the gel-induced procedure. The maximum absorption wavelength of thin film (pristine procedure: **Spin-P**; gel induced procedure: **Spin-G**) and nanofibers (**ES-G**) is observed at 780 nm. It implies the three samples exhibit the identical π−π interaction of **P4TDPP**. The inset of Figure 1 shows that the absorption coefficient of **Spin-G** is 1.5 times larger than **Spin-P**, suggesting the crystallinity of **Spin-G** is higher than that of **Spin-P**.

The average FET mobility, on/off ratio and threshold voltage of nanofiber transistors are 0.305 $cm^2\ V^{-1}\ s^{-1}$, 1.30 × 10^5 and -1.25 V, respectively. It exhibited a higher mobility than those of thin film transistors (**Spin-P**: 0.029 $cm^2\ V^{-1}\ s^{-1}$; **Spin-G**: 0.152 $cm^2\ V^{-1}\ s^{-1}$). The high mobility is ascribed to order molecular stacking and regular orientation within aligned nanofibers discovered through synchrotron grazing incidence small angle X-ray scattering (GISAXS), as shown in Figure 2. Each layer consists of the parallel conjugated main chains stacked by π−π interaction. The (100) peak of all sample is displayed at q_z = 0.322 $Å^{-1}$ (plane spacing is 18.87 Å). Figure 2(c) and 2(d) show the 2D-GISAXS patterns of the incident beam vertical (**ES-G_V**) and horizontal (**ES-G_H**) to the long axis direction of aligned ES nanofibers collected onto ODTS modified SiO_2/Si wafer, respectively. The schematic representation of the polymer packaging is shown in Figure 2(e). Compared to the 2D-GISAXS patterns of **Spin-P** (Figure 2(a)), **Spin-G** (Figure 2(b)) and **ES-G_H** (Figure 2(d)), the **ES-G_H** exhibited stronger intensity of (100) peak (**ES-G_H** > **Spin-G** > **Spin-P**) and weaker intensity of (100) rings (**ES-G_H** < **Spin-G** < **Spin-P**). It suggests that **ES-G_H** has a higher crystallinity and more order packing structures with (100)-axis normal to the substrate. In contrast, the intensity of (100) peak of **ES-G_V** is lower 0.5 times than **ES-G_H**. It suggests that the (010)-axis (normal vector of π−π stacking plane) is parallel to long axis of nanofibers, as shown in Figure 2(e). The above result indicates that the ES **P4TDPP** nanofibers could form order stacking and high orientation lamella with high carrier mobility. The present study demonstrates that the combination of ES nanofibers and the gel-induced structure is a simple process to fabricate conjugated polymers for high performance FET.

Introduction

Conventional $scCO_2$ foaming, in which CO_2 is introduced into polymeric matrix and depressurized quickly to foam, normally produce microcellular foams with average cell sizes of about 10 μm and cell densities greater than 10^9 cells/cm^3 [1]. Polymer foams in nano or submicron cells with a well-defined open pore structure and tunable mass transport characteristics by CO_2 foaming have been brought into focus as their unique application (drug delivery devices and porous membrane materials) and the process non-polluting [2-3].In this work, we report a method to prepare open submicron cell structure by $scCO_2$ foaming of highly oriented iPP. Optical light microscopy (OM), differential scanning calorimetry (DSC), small-angle X-ray scattering (SAXS) and scanning electron microscopy (SEM) were employed to investigate the effect of the crystalline structure and the foaming conditions on the final cell morphologies.

Materials and Methods

A commodity iPP (RS 1684) with broad molecular weight and high melt strength, was purchased from Basell Co., America to obtain highly oriented iPP samples by injection molding. CO_2 (purity: 99.9% w/w) was purchased from Air Products Co., Shanghai, China. CO_2 foaming of the highly oriented iPP samples was performed in a high-pressure vessel placed in a homemade oil bath with a temperature controller and its accuracy was ±0.2 °C [4].

Results and Discussion

Figure 1a shows a typical skin-core structure of the injection molded iPP sample, and figure 1b indicates the presence of shish-kebab crystalline structure in the shear zone ("A" zone in figure 1a). The equatorial streak in SAXS pattern was attributed to the formation of oriented structure or shish, oriented parallel to the flow direction; meridional maxima were attributed to the layer-like oriented structure or kebab, oriented perpendicular to the flow direction [5].

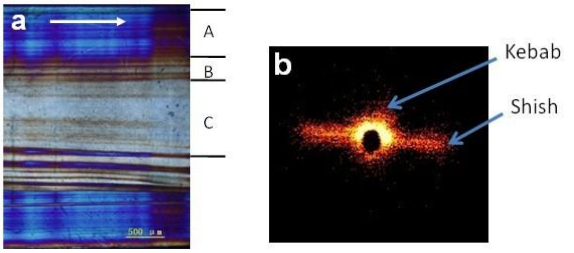

Fig. 1. (a) Optical micrographs of cross-sections of the injection molded iPP sample with a typical multiple layers distribution: (A) the 'shear layer'; (B) the 'intermediate layer' and (C) the 'isotropic core'. The white arrow indicates flow direction. (b) 2D SAXS image of the "A" zone in part (a).

It is generally accepted that crystallites are impenetrable for most non-reactive molecules including CO_2. In our previous work, we studied the effect of crystalline structure on the cell formation in an iPP during a solid-state foaming process, and found that the crystalline structure exerted a significant impact on the cell morphology of foamed iPP as cell nucleation and growth only occur in the amorphous regions where CO_2 dissolved [4].Therefore, with the restriction of the shish-kebab crystalline structure, the uniform nano or submicron size cell morphology must be obtained by CO_2 foaming under the certain foaming condition like figure 2 illustrated.

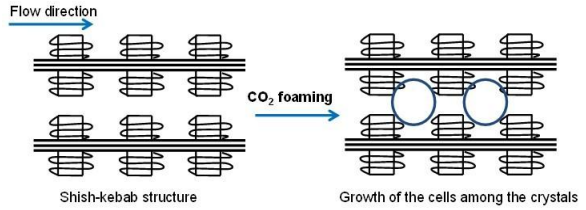

Fig. 2. Schematic of the restriction of cells growth in the amorphous and molten crystal regions of iPP.

To get the desirable cell morphology, we took the "A" zone in figure 1a to foam under CO_2 saturation pressure of 25 MPa and various temperatures. As shown in figure 3a, the un-foamed region still revealed the shish-kebab like structure when the foaming temperature was 140 °C. With the temperature increased, the open submicron cell structure was achieved (figure 3b) as more crystals, which restricted the growth of cells under the lower temperature, were molten.

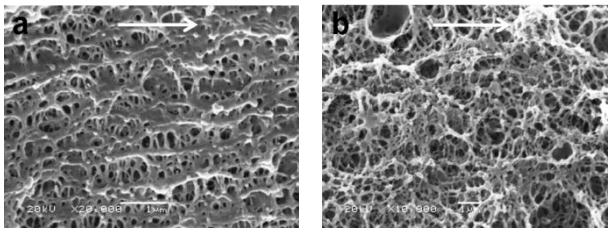

Fig. 3. SEM photographs of highly oriented iPP samples foamed at CO_2 saturation pressure of 25 MPa and (a) 140 °C, (b) 143 °C, respectively. The arrows indicate the flow direction, and the white bars in (a) and (b) are both 1 μm.

Conclusions

Open submicron cell structure was successfully achieved by $scCO_2$ foaming of highly oriented iPP. The crystalline structure and the foaming temperature have a significant impact on the final cell morphologies.

Design Rules for Fuel Cell Membranes

Gerhard Maier[1], *Markus Groß*[1], *Tim Fuller*[2], *Sean MacKinnon*[2], *Craig Gittleman*[2], *Cortney Mittelsteadt*[3]

g.maier@polymaterials.de

Introduction: Fuel cells are considered a potential alternative to batteries for portable electronics, internal combustion engines for cars, and even boilers and generators for stationary applications. Most technical problems solved now on the pathway to commercial success. However, depending on the specific application, there are still improvements desired concerning the proton conducting membranes in PMFCs. For automotive use, conductivity at low humidity and durability are most important.
Many different polyelectrolytes have been synthesized over the past decades for application as proton conducting membrane in fuel cells. While many of them (polymers as well as membranes) are well studied, it is often hard to identify the specific benefits and drawbacks of one chemical structure over another. Based on observations of the effects of certain chemical structures as well as the architecture of the polymer chains on membrane properties such as proton conductivity, water uptake, and durability, we have found some principles during the development of several series of ion conducting polymers that may serve as general guidelines for optimization.

Approach: Our approach to improve the proton conductivity of sulfonated hydrocarbon polymers at low humidity is to increase the "efficiency" of the proton transport, i.e. to reduce the amount of water required for proton transport.

Results and Discussion: Microphase separated polymers allow a very high local acid content (IEC) without excessive swelling of the membrane. The water that is present is located in hydrophilic domains, e.g. in segmented block copolymers. (Figures 1 and 2)
In addition, attaching sulfonic acid groups in side chains rather than the polymer main chain can enhance interaction of the ionic groups and improve phase separation.
Increasing the hydrophobicity of the non-sulfonated segments, especially avoiding groups that interact strongly with water by hydrogen bonding, further improves the water management by pushing most water from the hydrophobic domains into the hydrophilic domains, where it supports acid dissociation and proton transport. (Figure 3)
Another very important factor is the morphology of microphase separated block copolymers. Regular, ordered morphologies lead to better conductivity than when there is no phase separation. However, the highest conductivity can be achieved with microphase separated polymers with disordered morphologies, because in a disordered morphology the proton conducting domains are more interconnected than in a well ordered morphology with long range order [1].

The design of materials (especially micro-/nano-gels) that biodegrade and switch their physio-chemical properties in response to external stimuli constitutes a main research activity in controlled drug release. Biodegradation of the microgel matrix not only circumvents removal of the empty device but also can be used to modulate the release of loaded drugs for a long period of time. Dextran based polymers have been extensively studied for sustained release of protein drugs in recent years, because dextran is enzymatically degradable, hydrophilic and biocompatible. In particular, thermoresponsive polymers are a class of the environmentally switchable materials and poly(*N*-isopropyl acrylamide) (PNiPAAm) has been most intensively studied.

The structure and dynamics of such devices are characterized in terms of diffusive processes with time scales covering several decades. Scattering methods including small-angle neutron scattering (SANS), quasi elastic neutron scattering (QENS), small-angle x-ray scattering (SAXS), and dynamic light scattering (DLS) are well suited to investigate thoroughly the overall structure and the detailed architecture of the microgels.

Here we report a new simple method to obtain the dextran based microgels, DexM, with four different degrees of substitution using water-in-water microemulsion technique combined with ultrasonication. Size and size distribution of the microgels and degree of swelling were investigated as well. In order to evaluate the average pore size of the microgel network, we used confocal laser scanning microscopy (CLSM) combined with size exclusion experiments. The dynamics of confined water molecule in the microgel system was studied by using quasi elastic neutron scattering technique (QENS). Furthermore we have investigated the enzymatic degradation of DexM microgels.

In addition we have prepared novel dextran based "smart" microgels with nano/micro size using water-in-water microemulsion technique. In order to check the possiblity to use injectable device in controlled release, we have investigated the size, size distribution and thermoresponsivity of microgels. Furthermore we have investigated structural information using small angle neutron scattering (SANS).

Dextran microgels described in this contribution have an average diameter < 2 μm with relatively narrow size distribution (**Figure 1 (left)**). An increase of the degree of substitution (DS) of methacryloyl dextran polymers decreases the overall microgel size up to DS 25 % as well as the degree of swelling. Size exclusion/confocal microscopy experiments evidenced that the average pore size is < 3 nm.

A complex pattern characterizes the diffusion of water in DexM networks. The diffusion of bound water in the microgels showed a supercooling behaviour due to the hydrophilic character of dextran chains (**Figure 1 (right)**). Moreover, the dynamics of the associated water depends strongly on the pore size.

Finally, the biodegradation of microgels was investigated during the action of different hydrolytic enzymes, leading to the conclusion that the degradation is directly linked to the structural and interfacial features of the dextran based microgels.

In addition we have designed dextran based microgels modified with the incorporation of NiPAAm residues in network. Combining features such as dimensions in the micro/nano size domains and thermal responsivity in physiological conditions is the main characteristic of the microgels studied.

The structural details of "smart" microgels have been studied by SANS. At low Q values and above the volume phase transition temperature, VPTT, the scattered intensity vs. the scattering vector, Q, , approaches a Q^{-4} trend (Porod's behaviour) (**Figure 2**).

This leads to the conclusion that the microgels are characterized by a smooth surface at temperatures higher than VPTT. Below VPTT, the I(Q) shows a $\propto Q^{-2}$ trend indicating a higher roughness of the surface due to the presence of polymers chains projected toward the solvent. The analysis of the data at higher Q values allows the evaluation of a correlation length characterizing the average pore size across the volume phase transition.

vlebedev@pnpi.spb.ru

Self-organization of protonated star-shaped polymers composed of six polystyrene (PS) arms and six arms of polar polymer attached to common fullerene(C_{60})-centre have been studied by small-angle neutron scattering (SANS) in deuterated toluene at ambient temperature below the threshold of macromolecules' overlapping (concentration ~ 1 g/dl).

The samples of Li-polystyril (linear precursors) were synthesized by anionic polymerization of styrene in benzene. There was used oligopolystyrillithium (PSLi, polymerization degree 6-8). Star-shaped 6-arm PS with centre C_{60}, $(PS)_6C_{60}$, have been obtained by grafting fullerene C_{60} using living PS chains with lithium counterion in the mixture benzene-toluene at ambient temperature (the PSLi:C_{60} ratio was 6:1, Fig.1) [1].

The comparison of these data with properties of 6-arm PS-star has shown that the addition of six polar arms leads partially to the collapse of star when its polar arms become coiled in non-polar solvent (toluene). In solvent hetero-arm stars demonstrated the formation of supramolecular structures being clusters those size and density depend on chemical nature of polar arms.

Stars with PS and poly(2-vinylpyridine) are found weakly associated (average number of macromolecules in associate ~ 1.3) while hybrid polymers containing the arms of PS and poly(tert-butylmethacrylate) revealed a trend to be interpenetrated and associated into large-scale entities (diameter ~ 50 nm, ~ 12 macromolecules, Fig.2).

On the other hand, the hybrid stars with PS and diblock arms, poly(2-vinylpyridine)-poly(tert-butylmethacrylate), have exhibited a moderate self-assembly resulted in the formation of chain-like clusters (~ 4 particles, Fig.3). These SANS-results are discussed regarding to modern theories of polymers association.

a.nohales@ube.es; clara.gomez@uv.es

Introduction

Thermoplastic polyurethanes, due to the wide range of compositions available, have found extensive use in numerous commercial applications such as coatings, foams adhesives, sealants, synthetic leathers , membranes, elastomers as well as in many biomedical applications. Polyurethane elastomers are lineal segmented copolymers formed by thermodynamically incompatible segments named as the hard and the soft ones. The hard segments consist of a diisocyanate and a low molecular weight diol. The soft segments are high molecular weight polyols. In general, microphase separation between hard and soft domains is not complete and this conferee unique elastomeric properties at room temperature. Many factors such as type of polyol and diisocyanate, mass fraction, molecular mass, polydispersity of hard and soft segments, manufacturing conditions etc affect on morphological factors and define final properties, such as hardness, stiffness, tensile strength, and clarity of materials. A proper selection of the raw materials and molar composition becomes crucial as it provides the required properties that meet customers' needs. Commonly employed soft segments are derived from polyether or polyester polyol. However, nowadays, considerable attention have been devoted at the industrial level to new polycarbonate-based polyurethane elastomers due to their improved mechanical performance and their better anti-hydrolyzation and anti-oxidation properties compared to the traditional polyurethanes. The aliphatic polycarbonate based polyurethane can be used for industrial parts, building materials, sports goods, medical equipment, and even artificial tissues. New types of polycarbonate diols which are liquid at room temperature, such as the PH series used in the present work, are easy for handling, and show improved polyurethane flexibility and chemical resistance compared with the conventional commercially available (solid at laboratory conditions) polycarbonate diols, highly used since now. The aim of the present work was to synthesize thermoplastic polyurethanes based on aliphatic and liquid at room temperature polycarbonate diols (PCD). Two PCD molar masses (1000 and 2000) and three hard segment compositions (37, 48 and 62 wt%) have been selected to build up the polyurethane chains. Influence of the composition on the phase segregation and thermal stability has been investigated.

Experimental

The hard segment consists of 4,4'-diphenylmethane diisocyanate (MDI) and 1,4-butanediol (BD) as chain extender, both supplied by Aldrich. The soft segments are polyhexamethylene-pentamethylene carbonate diol of molar mass 1000 and 2000, and with trade name PH100 and PH200, both supplied by UBE Chem Eur.

Fourier Transform Infrared-Attenuated Total Reflection Spectroscopy (FTIR-ATR) were performed with a Thermo Nicolet Nexus FTIR spectrometer equipped with a multiple internal reflection accessory ATR single bounce.

Thermogravimetric analysis (TGA) experiments were performed using a Setaram Setsys 16/18 under oxygen atmosphere at 5ºC/min.

Differential scanning calorimetry (DSC) thermograms were carried out in a Mettler Toledo DSC821 Differential Scanning calorimeter at 10 ºC/min under dry nitrogen purge. The midpoint of the heat capacity change has been chosen to represent the glass transition temperature and melting point refers to the endotherm peak temperature.

Results and Discussion

FTIR spectroscopy was used to investigate the isocyanate conversion and hydrogen bond formation in polyurethanes. No isocyanate peak at ca. 2270 cm^{-1} was observed indicating full NCO conversion and absence of residual isocyanate groups. Also, it is observed the absence of the stretching vibration peak at 3640 cm^{-1} of free amidic NH groups not engaged in H-bonds. The only NH signal is a vibration peak of hydrogen-bridged amidic NH groups at 3326 cm^{-1}, which indicates that practically all NH groups participate in the formation of hydrogen bonds. To study the influence of the hard segment content on the formation of hydrogen bonds the "-C=O amide I" stretching region has been analyzed. The result of the deconvolution of the C=O stretching band in four Gaussian curves corresponding to free and bonded carbonate and urethane groups gives an idea of the degree of H-bonding. An increase in the hard segment content causes a decrease in the fraction of free to associated urethanes and a decrease in the fraction of free carbonate-carbonyl groups.

DSC analysis displays several transitions associated with the soft phase in the low temperature range and with the hard segment in the high temperature range. The glass transition temperature of the soft segments suffers a considerable increase when forms part of the polyurethane copolymer. This increase results from partial mixing between hard and soft segments, and restriction of the mobility of the polyurethane soft segment at the hard/soft segment junction.

Thermal decomposition of polyurethanes occurs as a result of a multitude of physical changes and is not dominated by a single process. TG/DTG curves show that up about 300 ºC the polymeric material is chemically stable. The first weight drop increases as the hard segment content decreases for both polycarbonate molar masses used.

Characterization of a Microbial Fucose-containing Polysaccharide Produced from Glycerol byproduct

Cristiana A. V. Torres [1], *Filomena Freitas* [1], *Maria A. M. Reis* [1], *Isabel de Sousa* [2], *Vítor D. Alves* [2]

[1]REQUIMTE/CQFB, Chemistry Department, FCT/Universidade Nova de Lisboa, 2829-516 Caparica, Portugal. [2]CEER-Biosystems Engineering, Institute of Agronomy, Technical University of Lisbon, Tapada da Ajuda, 1349-017 Lisbon, Portugal.

cristiana.torres@dq.fct.unl.pt

Microbial polysaccharides are environmental friendly and versatile polymeric materials with a wide range of distinct properties (e.g. thickening, emulsifying, flocculating and film-forming capacity) and industrial applications (e.g. food, pharmaceutical, cosmetics). When compared to plant and algae-derived polysaccharides, microbial production presents the advantage of being more productive and less resource intensive. Furthermore, microbial production processes are more amenable to control product composition, yield and productivity. Despite that, industrial microbial production is limited by the high cost of the carbon sources (e.g. sucrose, glucose, fructose) usually used. To overcome this limitation, those traditional substrates can be replaced by low cost carbon sources (agro or industrial residues/byproducts), such as glycerol byproduct from the biodiesel industry.

In this work, a fucose-containing EPS was produced by *Enterobacter* A47 DSM 23139 using glycerol byproduct from the biodiesel industry as substrate. The fucose-containing EPS is composed by neutral sugars, such as fucose, galactose and glucose and acyl groups substituents (acetate, pyruvate and succinate). Pyruvate and succinate confers to the polymer polyelectrolyte behaviour. It is a homogeneous polymer (PD = 1.3) with a high molecular weight (5.8×10^{6}).

The intrinsic viscosity of the fucose-containing EPS in 0.1 M NaCl was 8.03 ± 0.68 dL/g, with a Huggins coefficient (k_H) of 0.62 ± 0.21, suggesting some molecular aggregation. The EPS is a viscosity enhancer, forming viscous aqueous solutions which present a non-Newtonian shear thinning behaviour and a mechanical spectrum suggesting a viscous solution with entangled polymer chains. The EPS exhibits surface-active properties, showing potential to substitute current synthetic commercial products as emulsion forming and stabilizing agent. It might also be used in colloid and cell aggregation due to its high flocculating activity (comparable to $Al_2(SO_4)_3$). In addition, it is able to produce cohesive and flexible films. Beyond that, the presence of fucose (a bioactive component) envisages its application provides a great potential to be applied on pharmaceutical and cosmetic industries.

Considering all the characteristics presented the novel fucose-containing EPS has enormous potential to be used as viscosity enhancer on several industries, and in biomaterials, such as, scaffolds bioadhesives or drug delivery systems.

Block copolymers containing photocleavable side groups : Formation and disruption of micelles by light

Olivier Bertrand, Jean-Marc Schumers, Charles-André Fustin and Jean-François Gohy

Université chatholique de Louvain, Institut de la matière condensée et des nanoscience/Bio et Soft Matter

olivier.bertrand@uclouvain.be

Block copolymers are the focus of a sustained interest since they can be used for preparing micellar structures with various morphologies and functionalities when they are dissolved in a selective solvent for one of the blocks [1-2]. Moreover, the family of stimuli responsive block copolymers shows great potential for application in diverse fields due to their ability to change their properties when submitted to a stimulus (pH, temperature, light irradiation) [2]. Among all the existing stimuli light is particularly interesting [3] since it can be localized in time and space, it can be triggered from outside of the system, and it does not require particular reagents which limit byproducts. In this contribution, we combine the concepts of block copolymer micelles and light-sensitive polymers.

We report on block copolymers containing photocleavable side groups. The copolymer synthesis and the light induced formation or the disruption of micelles is discussed. The light induced micellization is studied with *o*-nitrobenzyl derivative. The block copolymers are composed of a polystyrene (PS) block and a poly(nitrobenzyl acrylate) or poly(dimethoxynitrobenzyl acrylate) block bearing photocleavable side-groups (PNBA-*b*-PS and PDMNBA-*b*-PS). The light induced disruption of micelles is studied with block copolymers containing p-methoxyphenacyl side groups. The block copolymer are composed of a poly(*p*-methoxypenacyl methacrylate) (PMPMA) block bearing photocleavable side-groups and a poly(oligoetheyleneglycol methacrylate) block (PMPMA-*b*-POEGMA).

Carbon Atom Volume as Indicator for Biodegradation Susceptibility in Highly Oxidized Species

Andrej Kržan, Janez Mavri

National Institute of Chemistry, Ljubljana Slovenia

andrej.krzan@ki.sI

Introduction

In general, biodegradation of organic substances occurs through oxidation or hydrolysis, however the oxidation level of the substrate is of great importance for the process since it defines the amount of energy a living organism can extract by aerobic digestion.

The oxidation level of the substrate can also be linked to the susceptibility of the substrate toward biodegradation: in inverse correlation to the energy content, un-oxidized hydrocarbons are less likely to biodegrade while more oxidized substrates are often good substrates for biodegradation. This empirical "rule" can be illustrated by polyethylene – a fully reduced hydrocarbon, which is not biodegradable (but can be made at least partially biodegradable by catalytic oxidation as in oxo-degradable technology), and the numerous natural polymers with medium oxidation levels: polysaccharides, proteins, polyesters, etc., which readily biodegrade. On the far end of this spectrum is the fully oxidized form of carbon - carbon dioxide, and it's unstable polymeric forms, which do not biodegrade due to their obvious lack of extractable energy content. These examples also points to a relation between stability and biodegradation: stable but reactive compounds of medium oxidative levels biodegrade best, while very stable or indeed very reactive species are not that likely to biodegrade.

In our earlier work we showed a stability/ biodegradability correlation.[1] We now quantified these observations through the analysis of carbon atom electronic structure[2] in a series of esters and related structures (Table 1) that were examined by the use of the Atoms in Molecules (AIM) quantum theory. This allows to divide the molecular physical space and electron density and assign them to individual atoms.[3] Through this method atomic charge and atomic volume can be derived directly from electron density.

Table 1. Structures studied. Formula: X-C(=Z)-Y

Compound /abrev.	X	Y	Z
Formic acid /fa	H	OH	O
Acetic acid /aa	CH_3	OH	O
Glycolic acid /ga	CH_2OH	OH	O
Oxalic acid /oa	COOH	OH	O
Urea /u	NH_2	NH_2	O
Thiourea /tu	NH_2	NH_2	S
Isobutene /ib	CH_3	CH_3	CH_2
Carbonic acid /ca	OH	OH	O
ca trimer /ca3	OCOOH	OCOOH	O
ca decamer /ca10	$O(COO)_4H$	$O(COO)_5H$	O
caNN	OH	OH	NH
caSS	OH	OH	S
caN	NH_2	OH	O
caS	SH	OH	O

Computational

All structures were geometry optimized in the Gaussian 2003 suite of programs. *Ab-initio* quantum chemical calculations were performed using the Hartree-Fock method in conjunction with the 6-31G(d) basis set. For some species, the calculations were also performed at the MP2/6-31++G(d,p) level. Wavefunction coefficients obtained from these calculations were then used as the input for AIM analysis performed using the AIMPAC software.

Results and Discussion:

AIM analysis of the examined structures surprisingly showed very little variation in the bond critical point (BCP, position on the bond path where neighboring atomic basins meet) position as well as the charges of atoms bound to the central carbon atom.

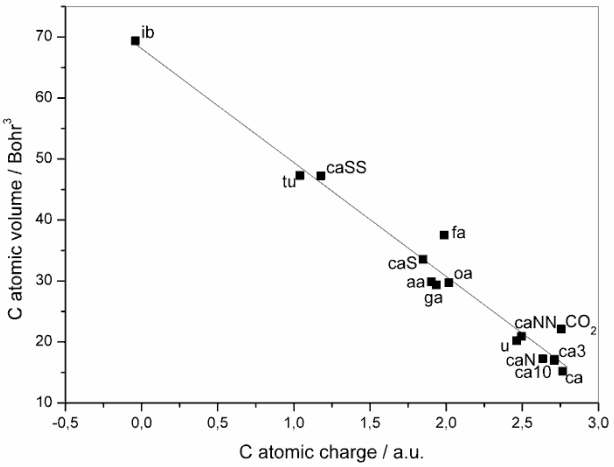

Figure 1. Carbon atom charge and volume obtained by Atoms in Molecules (AIM) quantum theory.

On the other hand the atomic charge and volume of the central carbon atom underwent a significant change and followed the electronegativity of its neighboring atoms and groups. High electron depletion due to electronegative neighbors is associated with small atomic volumes and unstable (unreal) structures, whereas medium depletion results in charge separation associated with reactive real molecules. The correlation is valid throughout the range from carbonic acid (ca) to isobutene (ib). Compounds in which carbon volume is below 18 bohr^3 appear to be unstable under normal conditions. Our approach is practical from the computational point of view since expensive calculation of the transition states associated with several mechanisms is avoided. The proposed application of the AIM approach is useful for design of novel biodegradable polymers.

Conclusions:

AIM calculated atomic volume of the central carbon atom is a sensitive descriptor for the electronic strain of oxidized carbons, which can be correlated to susceptibility towards biodegradation.

Introduction In the field of drug delivery, block copolymers are widely investigated because of their ability to form complex morphologies able to encapsulate drugs and release them in controlled way: micelles, nanoparticles,[1] and more recently polymersomes.[2] Considering the loading of hydrophilic compounds different approaches have been developed: direct dissolution, film rehydration or electroformation are mainly used but the encapsulation efficiency is low and purification procedures are systematically required. Recently, microfluidic ships have been used to create giant polymersomes and to encapsulate compounds using co-flow and flow focusing geometries.[3,4,5] We propose here a simple approach based on a co-flow geometry,in which polymersomes containing model hydrophilic molecules in a "one pot" process are elaborated *via* a double emulsion, controlled in the chip.[6]

Results.The chip proposed, (illustrated in Figure 1), thanks to the relative simplicity of the flow inside the capillaries allows a good control of the double emulsion (size of internal and external drop, number of water drop inside one organic drop...) Globally the morphology of the double emulsion can be predicted, knowing interfacial tensions (water/solvent –solvent/water) and the flow rates Q_1,Q_2,Q_3.

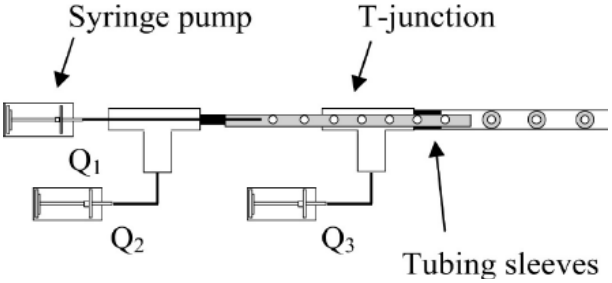

Figure 1:Picture of the device for the generation of double emulsion. Q_1 andQ_3: aqueous phases. Q_2: organic phase

The amphiphilic block copolymers stabilize the water/solvent interface (Figure 2), allowing the formation of polymersomes whose membrane consists of one or more bilayers of block copolymers after solvent evaporation.

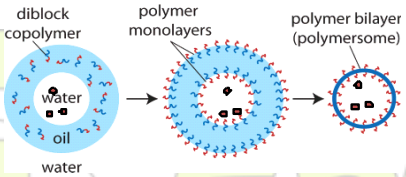

Figure 2: Solvent evaporation leading to the formation of polymersomes

Material and methods We have essentially worked on polybutadiene-block-poly(ethylene-oxide) solubilized in chloroform/cyclohexane mixtures and used an hydrophilic fluorescent probe (Fluorescein) as a model drug to evaluate the encapsulation efficiency of the process. In some cases Nile red has been solubilized in organic phase for better visualization.

Results and discussion We have obtained a good relationship between the morphologies of the resulting polymersomes and those of the double emulsion inside the microfluidic chip as illustrated in Figure 3.

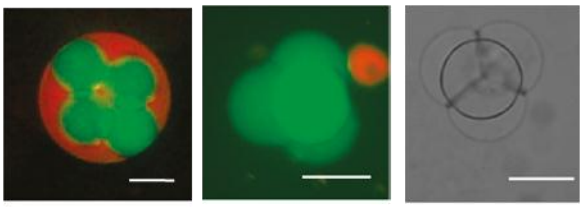

Figure 3: Multiple emulsion (four internal aqueous droplets) leading to tetrahedral polymersomes. (White bar=100µm)

Interestingly, the final size of the polymersomes corresponds to the size of the internal aqueous droplets, showing that the double emulsion created by the microfluidic device can be considered as atemplate for the microstructures obtained.In addition, Fluorescein used as a model drug in this study remains in majority in the aqueous internal compartment. Depending on the solvent mixture used, a "one pot" encapsulation can be reached with absolutely no leakage of the hydrophilic drug thus eliminating eventual purification steps.

Conclusion Using very simple microfluidic capillary device, we are able to prepare in a "one pot" process giant complex polymersomes structures in which model hydrophilic compound are encapsulated. This method is not only very interesting for application areas such as controlled release of drugs, but can be also considered for the construction of synthetic biomimetic structures, such as a cell or virus.

Click Chemistry to Fluorescent Hyperbranched Polymeric Sensors: Synthesis and Characterization

S. Medel, V. Abenza, P. Ramírez-López, M.C. de la Torre, C. Peinado, P. Bosch

Instituto de Ciencia y Tecnología de Polímeros (ICTP), CSIC

s.medel@ictp.csic.es

Introduction

Multifunctional sensors have exceptional sensitivity and specificity for analytes detection. A way to obtain them is functionalizing dendrimers[1], but this method has disadvantages, because precursors are expensive and only few different structures are available.

Hyperbranched polymers (HBP) are a special type of dendritic polymers that have attracted major attention because of their interesting properties resulting from the branched architecture as well as the high number of functional groups.[2] Many different structures are currently commercialized, being them much more available than dendrimers.

Cu-catalysed Huisgen 1,3-dipolar cycloaddition ("click reaction") between terminal alkynes and organic azides has recently been extensively used and found wide applications in polymer and materials science because of its high efficiency, versatility and excellent functional-group compatibility.[3]

In this work we present the functionalization of HBP through click chemistry for the fluorescent labeling of azide-functionalized hyperbranched polymers.

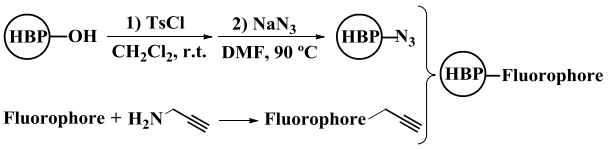
Materials and Methods

Hyperbranched polymers, Hybrane®, were kindly provided by DSM. All the other materials were from Aldrich and used as received. The polymers were characterized through conventional methods (^{1}H NMR and ^{13}C NMR, FTIR-ATR, SEC, UV-Vis spectroscopy and Fluorescence spectroscopy).

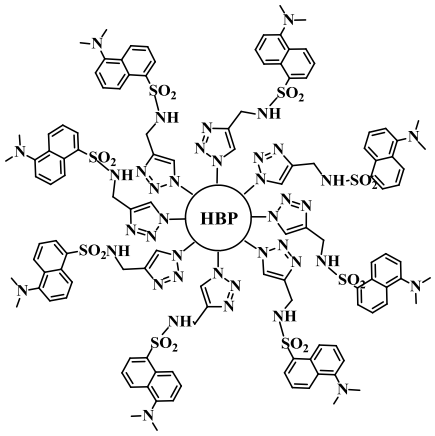
Results and Discussion

In our approach, we locate azide group onto the HBP skeleton and the alkyne function on the selected fluorophore. Azide-terminated polymers were preferred to those incorporating terminal alkynes.[4] Fluorophores like dansyl chloride, 9-chloroacridine and naphthalimide were chosen to prepare the fluorescent polymers. Scheme I describes the reactions of HBP and fluorophore functionalization. Final structure of the multifunctional HBP-sensors is illustrated in Scheme II.

The behaviour of the multifunctional HBP-sensors was studied by fluorescence response measurements towards both changes in polarity and addition of a strong organic acid. The fluorescence emissions of the different polymers were strongly affected by solvent polarity and they also showed fluorescent changes upon addition of protons.



Scheme I. Reactions of HBP and fluorophore functionalization.



Scheme II. Ideal structure of dansylated HBP-fluorescent multifunctional sensors.

Conclusions

A new series of fluorescent hyperbranched polymers have successfully been prepared by "click chemistry", introducing different fluorophores into the side-chain of HBP.

In addition, the fluorescence properties of these compounds appeared to be highly sensitive to the polarity and the pH.

Solid State Properties of Fluorinated Polyimides Containing Perylene and Oxadiazole Moieties

Mariana-Dana Damaceanu, Radu-Dan Rusu, Maria Bruma

"Petru Poni" Institute of Macromolecular Chemistry, Aleea Grigore Ghica Voda 41A, Iasi-700487, Romania

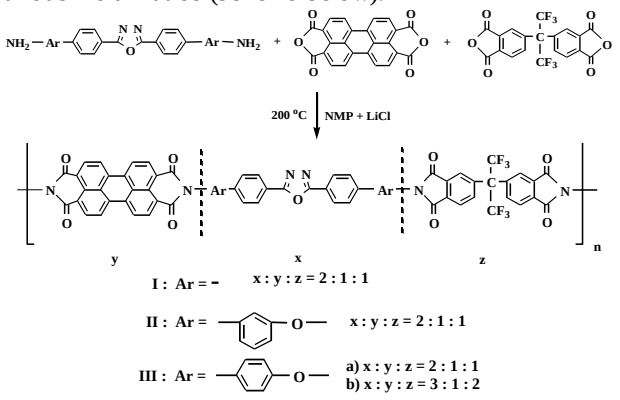
e-mail: damaceanu@icmpp.ro

Introduction

The increasing demand of advanced technologies for new materials offering high thermal, chemical and mechanical resistance and other special properties as electron-transporting ability, electroluminescence, optical and electrical conductivity stimulates the growing interest in aromatic polymers containing heterocyclic units [1,2]. The inclusion of imide rings together with other electron-rich rings, such as perylene, and with electron-withdrawing units, such as 1,3,4-oxadiazole, could be a good way to obtain polymers having a desired balance of properties [3]. However, the practical application of polyperyleneimides is very difficult due to their insolubility and lack of processability. In order to improve the solubility of perylene-containing polyimides, novel copolymers have been designed and synthesized by introducing flexible hexafluoroisopropylidene groups in the main chain. These polyimides based on aromatic diamines containing oxadiazole rings and a mixture of perylenetetracarboxylic dianhydride and hexafluoroisopropylidene-diphthalic dianhydride, dissolved in polar amidic solvents and gave flexible films, by casting their solutions onto glass plates. Here we present a study of these films by dynamo mechanical analysis (DMA), dielectric and X-ray photoelectron spectroscopy (XPS).

Materials and methods

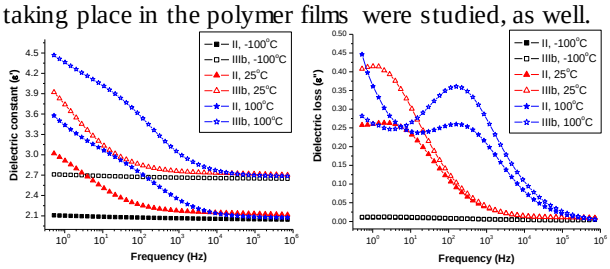
Copolyimides **I**, **II** and **III** were prepared by one-step polycondensation reaction of three different aromatic diamines containing oxadiazole ring with a mixture of perylenetetracarboxylic dianhydride and 4,4'-hexafluoroisopropylidene-diphthalic dianhydride taken in various molar ratios (scheme below).



The reactions were carried out in NMP with 3.5% LiCl, at a concentration of 7% total solids, under nitrogen stream, at high temperatures (200-210°C). For comparison, a related copolyimide, **IV**, based on 4,4'-oxydianiline and a mixture 1:1 of the same dianhydrides was synthesized. All these polymers possess film forming ability. The free-standing films having a thickness in the range of tens of micrometers were flexible, tough, and maintained their integrity after repeated bending, except for films prepared from polymer **IIIa**, which were brittle. The properties of these copolyimides such as solubility, thermal stability, glass transition, composition of the films, dielectric behaviour and subglass relaxations were investigated.

Results and discussion

The synthesized copoly(peryleneimide)s are soluble in a convenient aprotic amidic solvent which is NMP, at a concentration of 0.5-1%. The polymers are highly thermostable, with initial decomposition temperature being in the range of 465-475°C. The glass transition temperatures as evaluated by DMA using thin films, are above 300°C. The chemistry of the films was analyzed by XPS. The survey spectra for fluoropolymers **I-III** are dominated by C, O, N and F, with some minor components (Si, Cl, Li). Complex chemistry was observed in each film, and variations between the film samples were clear. It is likely that solvent, silicone and hydrocarbon contaminants are present, and perhaps water. Electrical insulating properties of the polymer films were evaluated on the basis of the dielectric constant, ε' and dielectric loss, ε'' and their variation with frequency and temperature. Figures below present the dependence of the real (a) and imaginary (b) part of the complex permittivity, on frequency, at low, moderate and high temperatures. The sub-glass relaxations taking place in the polymer films were studied, as well.



Conclusions

Thermostable polyimides containing oxadiazole and perylene units were prepared and thin films having a complex chemistry were made therefrom. The dielectric constant varies with frequency and temperature, taking low values even at high temperatures. The films displayed γ and δ relaxation processes connected with local movements of polymer chains.

Characterization, Melting and Crystalline Properties of Isotactic (4,2)-Enchained Poly(1-Butene)

Carolina Ruiz-Orta, Rufina G. Alamo

FAMU-FSU College of Engineering, Chemical and Biomedical Engineering Department, 2525 Pottsdamer St., Tallahassee, FL 32310

Alamo@eng.fsu.edu, Carolina@eng.fsu.edu

Introduction. The availability of new crystalline polyolefins by control of catalyst "chain-walking" offers the opportunity to study crystalline properties of new polymer structures similar to the most common polyolefin commodities. Living polymerization of 1-butene with an α-diimine Ni(II) catalyst generates new crystalline polybutenes with unique chain microstructures.[1] A normal (1,2) insertion followed by a subsequent chain-walking to the fourth carbon results in a (4,2) addition. Conversely, a regio (2,1) inversion followed by chain-walking produces (4,1) linkages leading to a sequence of four consecutive methylenes in the backbone chain. In addition, when high selectivity for (4,2)-enchainment is exhibited a (4,2)-enchained poly(1-butene) is obtained. This polybutene is isostructural with poly(*trans*-2-butene). In this work we study crystalline properties of the novel polybutenes with a similar content of (4,2) and (4,1) additions and different content of stereo defects.

Materials and Methods. The molecular characteristics of the two polybutene samples studied are as follows. From ^{13}C NMR, (4,2) additions (~96 mol%), stereo errors (9 or 16 mol%); (4,1) additions (~ 4 mol%), and zero (1,2) additions in both samples. The combined (4,2) and stereo defects are 12, (4,2PB12) and 21 mol% (4,2PB21) for the most and the least crystalline samples studied. From GPC, Mw = 54,000 Dalton, Mw/Mn = 1.5.

The melting peaks, T_m, heat of fusion, ΔH, and overall crystallization kinetics were followed by DSC (Perkin Elmer DSC7). Wide and small angle x-ray diffractograms (SAXS, WAXD) were obtained at ambient temperature on samples that were previously isothermally crystallized either in the DSC or in thermostated baths. The degree of crystallinity derived by WAXD, X_c, was determined from the x-ray powder diffraction profiles of samples isothermally crystallized at different temperatures, T_c. The WAXS pattern of molten 4,2PB was used as amorphous halo. Crystal and interlamellar thicknesses were obtained from SAXS profiles via one-dimensional correlation function analysis. Spherulitic morphology and linear growth rates were analyzed by polarized optical microscopy and a Linkam hot stage, and lamellar morphology by AFM in non-contact AC mode. The densities were measured at room temperature in a water/isopropanol density gradient column calibrated with standards glass floats.

Results and Discussion. *Crystalline Structure*. In spite of a relatively low tacticity (mm <0.8), and a significant content of (4,1) defects, WAXD patterns exhibit two relatively sharp crystallographic reflections at 2θ = 16.9 and 19.7 degrees, consistent with high order chain-packing symmetry. Unlike *i*PP and poly(1-butene) that display polymorphism with increasing stereo defects or increasing crystallization temperature, the crystallographic phase of 4,2PB is maintained with increasing T_c or defects. The WAXD-derived degree of crystallinity (X_c) is low (<30 %) in 4,2PB21, and exhibits a modest 37 to 52 % increase in a large T_c range in the sample with 12 mol% defects.

Under isothermal crystallization, 4,2PB12 develops relatively thick lamellar crystallites (~ 95 Å thick by AFM) that aggregate in highly ordered spherulites. This feature and the relatively high crystallinity content for a copolymer with a high content of structural defects suggests co-crystallization of the stereo defects, similarly to the inclusion of stereo defects in *i*PP crystallites. With increasing chain defects the structural irregularities break down the spherulitic and lamellar habits.

Thermodynamic Parameters. Degrees of crystallinity of isothermally crystallized specimens were combined with density measurements, heat of fusion, and lamellar thicknesses to estimate the densities of the crystalline and amorphous phases, ρ_c = 0.9494 g/cm^3 and ρ_a = 0.8698 g/cm^3, respectively, and the heat of fusion per mole of crystalline unit (ΔH° = 132.6 J/g). Accounting for a re-structuring of crystallites during melting, the crystallites thicknesses and melting temperatures were analyzed with the simplified Gibbs-Thompson equation to extract values of the equilibrium melting temperature and the basal surface free energy of the crystallites. The value of T_m° = 135 ± 4°C. The defects reduce the T_m° value of 4,2PB in reference to expectations for the defect free chain and values. At a 12 mol% defect level, the T_m° is similar to the value for form I of *i*poly(1- butene), and significantly lower than for *i*PP and *s*PP. However, the heat of fusion per mole of crystalline units (8670 J/mol) is similar to the values of *i*PP and *s*PP in spite of a larger repeat unit. From the Gibbs-Thompson relation, the interfacial free energy is σ_e = 77 erg/cm^2. This value is supported by a basically identical σ_e value obtained from an analysis of lamellar growth rates according to secondary nucleation theory. The σ_e value of 4,2PB is similar to values obtained for polyethylene and *i*PP homopolymers (~ 70 erg/cm^2), and lower than for *i*PP copolymers with about the same content of defects. This feature suggests a relatively flexible conformation that favours chain folding in the novel poly(butenes).

Conclusion. The thermodynamic and structural properties of 4,2PB synthesized with a α-diimine Ni(II) catalyst have been analyzed. Stereo and (4,1) regio are defects that hinder the crystallization, as given by the decreasing rates, decreased levels of crystallinity and lowered melting temperatures with increasing defect content.

SU8 – Carbon Nanotubes: Preparation, Characterization and Patterning

Marijana Mionić,[1] Richard Gaál,[1] László Forró,[1] Sébastien Jiguet,[2] Moshe Judelewicz[2] and Arnaud Magrez[1]

1) Ecole Polytechnique Fédérale de Lausanne (EPFL), Switzerland
2) Gersteltec SARL

arnaud.magrez@epfl.ch

Introduction: SU8 polymer consists of rigid epoxy oligomers allowing the micro-fabrication of structures with vertical walls and with high aspect ratio (>50). [1] Thanks to its photo-patterning abilities, SU8 is widely used in nano-engineering for MEMS, sensors, batteries, flat panel displays, fluidic and packaging applications.

However, SU8 is an insulating polymer and is brittle with high internal stress although it has high Young's modulus (Ey) as compared to other polymers.

Consequently, the synthesis of conducting SU8 composites with improved mechanical properties is highly demanded but remains very challenging.

Materials and Methods: Multiwalled carbon nanotubes (MWCNTs) were synthesized by CCVD of acetylene over Fe–Co catalyst supported by CaCO3.

Details of the supported catalyst preparation and MWCNTs synthesis procedure have been reported elsewhere [2, 3]. In brief, stoichiometric amount of metal salts corresponding to Fe2Co composition are dissolved in distilled water. CaCO3 and base are subsequently added inducing the precipitation of Fe and Co salts onto the CaCO3 support. The supported catalyst is subsequently dried by sublimation of water, and placed afterwards into a 80mm diameter CVD reactor for MWCNTs synthesis.

Composites precursors were prepared by first dispersing MWCNTs in gamma-butyrolactone (GBL). Long term stability is obtained by the addition of dispersing agent. SU8 powder is subsequently added to this mixture under vigorous stirring. The resulting solution with adjustable viscosity can be easily processed and patterned while polymerisation is can be achieved thermally or by photolithography.

Results and Discussion: Although we prepared successfully composites exhibiting exciting electrical and mechanical properties without surfactant [4,5], the appropriate use of surfactant results systematically in better CNTs distribution in the polymer matrix (figure 1). A percolating network of CNTs is formed above 0.2w% of CNTs at the end of the first step when GBL is fully evaporated. During crosslinking and polymerisation, composites shrink and the percolation threshold is reduced below 0.2w%. It has to be noted that the resistivity is reduced by 8 orders of magnitude as compared to pure SU8 with only 1w% of CNTs. This corroborates, together with SEM analysis (figure 1), the high quality of the CNTs produced in this project as well as the excellent dispersion of the CNTs within the polymer matrix by using surfactants.

Dip coating of glass substrates in the solution of composite precursor results in transparent coatings. Coatings can also be patterned by photolithography, screen or inkjet printing. Objects with complex structures can be easily produced. The mechanical and thermal properties of the composites are being characterized.

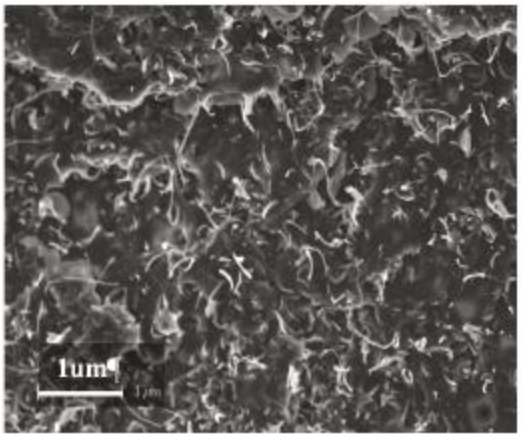

Figure 1: SEM analysis of analysis of the composites (3w%of CNTs after complete polymerisation) reveals a perfect dispersion of the carbon nanotubes in the SU8 matrix. Possible holes left by GBL evaporation are absent from the samples.

Conclusions: Here, we will present the synthesis,application and characterisation of conductive SU8-CNTs composites.

Introduction

The grafting of polymer brushes from metal oxide nanoparticles via surface-initiated controlled radical polymerization has been the subject of intense research these last years[1].

One of the key steps for obtaining stable hybrid metal oxide cores/polymer shells nanostructures relies on the grafting of an appropriate coupling agent between the nanoparticle surface and the polymer coating. Although many coupling agents have been explored to this end, the anchoring groups of the chelate type often fail on metal oxide surfaces in aqueous or protic media due to the hydrolytic instability of the surface attachment and/or the dynamic nature of the interaction. Therefore, the development of versatile and efficient surface modification strategies for obtaining strong and stable linkages in aqueous media, between the metal oxide NP surface and the polymer coating still remains challenging.

Results and discussion

In this talk, we address this issue by proposing a novel and facile methodology for the *in-situ* surface functionalization of Fe_3O_4 nanoparticles, based on the use of diazonium salts chemistry as coupling agents. Such unique chemistry has never been extended to the spontaneous functionalization of metal oxyde nanoparticles, probably due to the poor reducing character of this type of material inhibiting the generation of aryl radicals able to bind to the NP surface. We circumvented this difficulty by taking advantage of the transformation of diazonium species to diazoates in basic media which dediazonize spontaneously to give aryl radicals able to bind to the iron oxide surface through highly stable covalent linkages.

These aryl grafted groups were then used as macro-initiators for the growing of pH-sensitive poly(methacrylic acid) polymer chains (PMAA) from the NPs surface, by the iniferter method. This strategy provided individually dispersed, highly soluble and pH-sensitive PMAA-coated magnetic nanoparticles.

IR spectra after each treatment steps were made : a very intense band is seen at *ca.* 1715 cm^{-1} due to the C=O stretching mode. This feature, characteristic of poly(methacrylic acid), indicates that the polymerization step has been effective.

XPS confirmed the efficiency of the grafting procedure as well as the living caracter of the polymerization process. The magnetic properties of the functionalized Fe_3O_4 nanoparticles were then examined. The saturation magnetization of surface functionalized Fe_3O_4 nanoparticles appeared significantly reduced compared to pure Fe_3O_4 nanoparticles.

The stability of the NP-PMAA colloids in water was checked qualitatively. Fig. b reveals that the pH strongly influences the dispersion with flocculated NPs in deionized water (pH 5.5) while they appear highly stable in basic medium (pH 8).

Conclusion

Our approach offers several advantages over conventional methods: (i) ease and rapidity of the diazonium-based coupling agent grafting at the NP surface; (ii) presence of a covalent bonding between the polymer and the NP surface; (iii) opportunities offered by the living character of the polymerization process. We believe this synthetic approach will not only pave an additional way for the preparation of water-soluble and pH-sensitive PMAA-coated Fe_3O_4 nanocrystals but also provide a new general functionalization strategy for magnetic nanoparticles.

Introduction

Stimuli-responsive gels react on external stimuli with a drastic change of their degree of swelling. Such stimuli can be, e.g., temperature, pH, ionic strength, pH, salt concentration, composition of swelling agent. A unique feature of such hydrogels is that they serve as sensors and actuators at the same time. Therefore, responsive hydrogels are chemo-mechanical transducers converting chemical energy into mechanical energy and vice versa. A recent review on application of hydrogels as sensors and actuators is given in [1].

Magneto-resistive sensors have been proposed as detection components in biological devices such as biosensors and biochips. They directly provide an electrical signal that can evaluated with standard electronics. The change of a magnetic field can be followed by giant magneto-resistive (GMR) elements or sensors based on the Hall-effect.

Planar Hall sensors were applied in detection of magnetic micro-beads and nano-beads. Superpara-magnetic beads (diameter in µm-range) were coated with streptavidin and attached via bonding with biotin on a sensor-surface. The immobilization of the micro-beads on the sensor by biochemical interactions results in a change of the Hall voltage [2]. A biosensor plat-form combining on-chip integration of magnetic field generation with GMR sensors for magnetic label detection is described in [3]. Again, the signal is based on the immobilization of magnetic beads due to the high affinity between streptavidin and biotin. The magneto-resistive detection of magnetic particles by GMR sensor array is discussed on example of binding forces between magnetic micro-beads to a solid substrate [4].

A theoretical description of magnetic-hydrogel trans-duction principle based on GMR is given in [5].

Materials and Methods

The application of a stimuli-responsive hydrogel as a sensor layer in combination with a Hall-effect sensor was firstly demonstrated in our groups on example of monitoring the swelling/deswelling of a hydroxypropyl cellulose (HPC) foil decorated with magnetic particles [6]. The distance between magnetic particles and the Hall sensor depends on the degree of swelling. The Hall voltage measures the degree of swelling and therefore the properties of the liquid environment.

Now, we demonstrate the application of the GMR-effect as a transduction principle in hydrogel-based sensors.

Magnetic particles are fixed in a sensitive hydrogel. The measuring signals represent the response of the sensor signals to a relative change of the thickness of the filled hydrogel. The thickness is proportional to the degree of swelling, which depends, e.g., on an analyte concen-tration (composition sensitive hydrogel), or pH (polyelectrolyte gel).

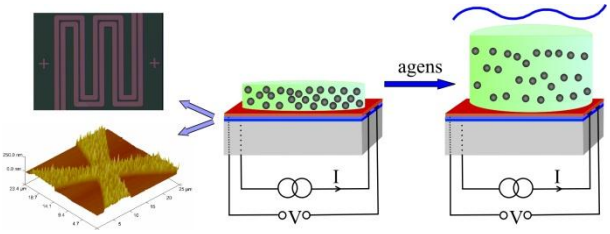

Fig. 1: Scheme of hydrogel-based magneto-resistive senor (left: GMR-meander and planar Hall sensor)

Results and Discussions

The presented paper describes our design of a magneto-resistive device based on a GMR platform (Figure1). GMR and a responsive polymer are coupled in different geometries (planar, tube, reaction vessel). The used stimuli-sensitive polymers (cross-linked HPC and PNIPAAm) are filled with different magnetic particles. The functionality of the designs is demonstrated on different tasks: Following the swelling/deswelling curve (Figure 2), monitoring the change of an analyte concentration, and counting of gel containers in a flow stream. On example of the used test arrangements the main properties of a GMR-based sensor are discussed, even in comparison with the Hall-based principle.

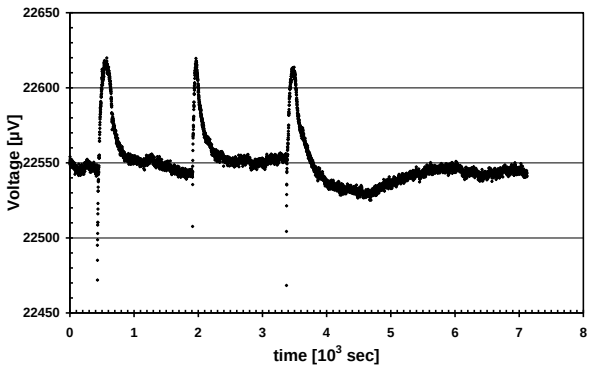

Fig 2: Swelling of HPC in water (298K); deswelling in air

The work was financed by DFG (Ar 193/11-2; Mo 887/1-2).

Introduction:

Controlled/''living''radical polymerisation techniques (C/LRP) enables the synthesis of many polymers using ATRP or similar methods.[1] By combining hydrophobic and hydrophilic moieties[2] amphiphilic block copolymers can be obtained. Those bearing polymerisable functionalities can be used as reactive surfactants in emulsion, dispersion and suspension techniques to obtain particles.[3] In this study, we present the synthesis of well-defined ionic and non-ionic amphiphilic block copolymers of P(MMA/HEMA)-*b*-PDMAEMA and PEG-*b*-P(MMA/HEMA) synthesised via ATRP, further modified to active surfactants in order to prepare core-shell microcapsules using soap-free emulsion polymerisation.

Materials and methods

Methyl methacrylate and butyl methacrylate were purified by passing through activated basic alumina prior to use. 2-(Dimethylamino)ethyl methacrylate, 2-hydroxyethyl methacrylate and toluene were degassed for 30 minutes prior to use. The ethyl-2-bromo isobutyrate (EBIB) was used as supplied. *N*-Propyl and *N*-octyl-2-pyridylmethanimine (PrMI, OcMI)[4] and the poly(ethylene glycol methyl ether) macroinitiators[5] were prepared as described previously. All reactions were carried out with standard Schlenk techniques under a dry nitrogen atmosphere using Cu(I)Br and all Schlenk solutions were degassed by three freeze-pump-thaw cycles. Molar mass distributions were measured using size exclusion chromatography (SEC) with differential refractive index detection on two PL-gel 5 µm mixed C columns and a PL-gel 5 µm guard column used with THF/TEA (95:5, vol/vol) at 1.0 mL/min as the eluent. NMR data were obtained on a Bruker DPX400 and cryogenic scanning electron microscopy was performed on ZEISS SUPRA 55-VP equipped with cold stage and sample preparation chamber.

Results and discussion

Copolymers with various amount of MMA and HEMA were synthesised at 75°C in toluene using EBIB and methoxy poly(ethylene) glycol (PEG, D_p113) as initiators. All polymers were targeted to have a low DP (~20). For all polymerisations M_n increased linearly with conversion and PDi remained low, 1.17 to 1.26 and from 1.20 to 1.23 (for the EBIB and the PEG initiated block copolymers) as expected for a LRP process. The statistical copolymers synthesised from EBIB were further used as macroinitiators in the synthesis of amphiphilic block copolymers P(MMA/HEMA)-*b*-PDMAEMA. All reactions were conducted at 100°C in toluene with a target DP ~ 50. All SEC chromatograms showed a monomodal peak and narrow PDi indicating the amphiphilic copolymers were obtained in controlled manner (Fig 1). Target degrees of quaternization (10, 25 and 50%) were readily achieved by adjusting the molar ratio of methyl iodide to PDMAEMA and integration from ^{1}H NMR analysis confirm degrees of 13.8%, 28.4% and 47.7% leading to ionic amphiphilic polymers. These ionic diblock copolymers (P(MMA/HEMA)-*b*-PDMAEMA) where then transformed into ionic surfmers reacting the hydroxyl group of HEMA part with methacrylic anhydride.

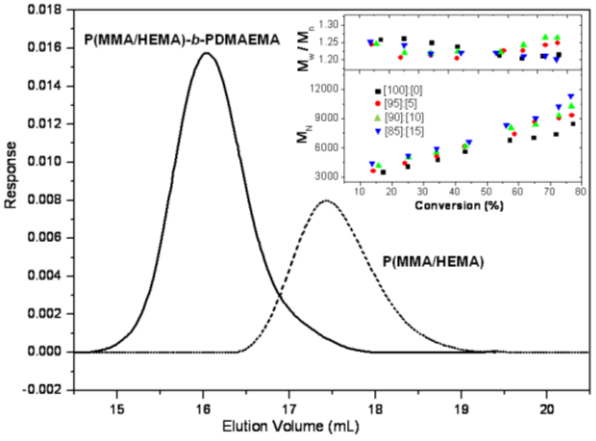

Figure 1: SEC traces of P(MMA/HEMA) macroinitiator and P(MMA/HEMA)-*b*-PDMAEMA diblock and evolution of M_n and M_w/M_n with time for the polymerisation of DMAEMA with various P(MMA/HEMA) macroinitiators.

Polymeric BMA microparticles were synthesised using ionic surfmers (25% quaternized) via emulsion polymerisation in which hexadecane was encapsulated. Up to 33% of hexadecane could be incorporate to the oil phase to obtain colloidal stable systems. Cryo-scanning electron microscope confirmed the core-shell morphology of the particles and differentiated between shell and core material.

Conclusions and References

A range of well defined ionic and non-ionic block copolymers were used as active surfactants to prepare particles with soap-free emulsion polymerisation technique.

Introduction: The development of nanocomposites based on polyamidoimides and nanotubes (NT) of different morphology and size is the perspective direction for obtaining new materials for the membrane application. In previous investigation it was shown that the introduction of inorganic tubular nanoparticles in to the matrix of poly(diphenyloxideamino-N-phenylphthalimide) leads to the formation of nanocomposite with improved mechanical properties permeable to a greater extent than the pure polymer in the process of pervaporation of polar liquids, in particular of water and alcohol [1]. In this paper the nonporous composite films based on aromatic polyamidoimides differing by the structure of diamine component, containing equal amount of silicate nanotubes $Mg_3Si_2O_5(OH)_4$ were obtained and their structure, morphology, thermal, transport properties were investigated.

Materials and Methods: The polyamidoimides as the matrices for nanocomposite were synthesized by the low-temperature polycondensation of dicarboxyphenyl-phtalimide dichloride with 4,4'-diaminodiphenyl ether (PAI-1,M 68000), or, 3,5-diaminobenzoic acid (PAI-2, M 57000) in solution [1]. As inorganic filler were used nanotubes $Mg_3Si_2O_5(OH)_4$ with chrysotile structure, synthesized under hydrothermal condition [1].

Results and Discussion: The transport properties both PAI-1, PAI-2 and their nanocomposites were tested at the pervaporation (Fig.1,2) in relation to a wide range of penetrating substances (water, methanol, cyclohexane, methyl-tert-butyl ether).

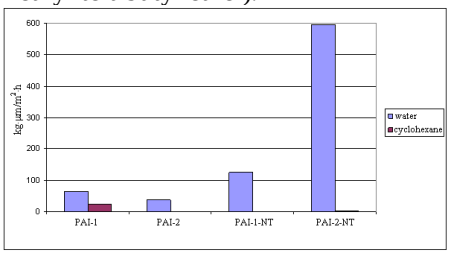

Fig.1 Separation of (a)methanol-methyl *tert*-butyl ether mixtureat 40°C;(b)methanol-water at 20°C on PAI1-NT

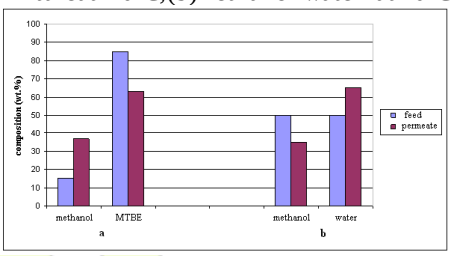

Fig.2 Permeability by water and cyclohexane of non-porous membranes PAI-1,PAI-2, PAI-1-NT, PAI-2-NT.

Polymer PAI-2 (more hydrophilic polymer than PAI-1) is twice more permeable by water than PAI-1, like in the case of PAI-1-NT compared to PAI-1. The introduction of nanotubes in the PAI-2 enhances the ability of the composite membrane to pass the water more than 4-fold, which makes the material 5-fold more permeable for water than PAI-1-NT.

Nanotubes were not found on both surfaces of nanocomposite films when content of NT in polymer matrix does not exceed 2wt%. The NT's fragment on the film surface can be recognized by AFM when the content of nanofillers attains 5wt% (Fig.3). In this case adhesion between Nts and PAI is broken (Fig.3b)

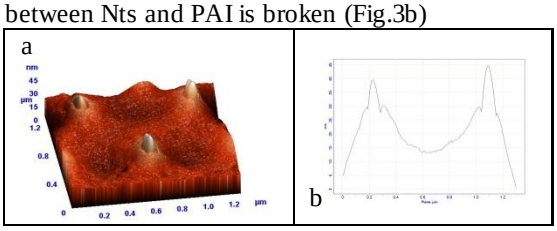

Fig.3. 3D image (a) and line profile (b) for composite PAI–NT-1 (5wt% of NT).

It was found by SEM and AFM that NTs combine into aggregates which regularly distributed in the inner layers of polymer. In the PAI-2-NT the aggregates are observed of 2-3 nanotubes whereas the number of NT's in agglomerate in PAI-1-NT increase up to 10-15.

Thermal properties of PAI-1, PAI-2 and their nanocompositis were also investigated. For the PAI-1-NTs composite, two steps of the mass loss have been registered. First step extends to 260°C, thus indicating a slower solvent evaporation as compared with the PAI-1. The second step related to the PAI-NT degradation is shifted to higher temperature, compared to pure PAI-1 (420°C and 360°C correspondingly).Thus, thermal stability of the PAI-1-NT composite increases in comparison with that for the PAI matrix.

Nt's introduction into polymer matrix leads to increasing of glass transition temperature for PAI-1-NT and PAI-2-NT in comparison with pure polymers.

Conclusions: New polymer-inorganic composites with improved thermalphisic properties (thermal stability and glass transition) are developed. Nanotubes in the composite form the aggregates in spite of the NT's content in polymer matrix. Dimension of aggregates is dependent from chemical structure of PAI.

Introduction into polymer matrix of $Mg_3Si_2O_5(OH)_4$ nanotubes leads to increase flow of water and lower aliphatic alcohols through the corresponding membrane film, which may be interest of practical application.

Study of Diffusion of Jeffamines into Reactive "Surface-attached" Polymer Networks

R. Navarro, M. Pérez Perrino, O. Prucker, J. Rühe

University of Freiburg – IMTEK. Department of Microsystems Engineering
Laboratory for Chemistry & Physics of Interfaces. Georges-Köhler-Allee 103 D-79110 Freiburg Germany

Introduction

The diffusion of linear polymer molecules into confined space scaffolds is an important topic of practical importance about which there is little fundamental understanding[1]. From a practical point of view, the study of the diffusion of macromolecules into the networks plays an important role if "surface-attached" networks or coatings are to be modified or functionalized. The diffusion of free polymer chains depends on the shape of the concentration profile at an interface between the incoming macromolecules and polymer network. In the present study the influence of copolymer composition regarding to PEGylation of these scaffolds has been studied. The penetration depth of free H_2N-PEGs into the reactive networks and the molecular weight dependence on the modification degree have also been determined.

Materials and Methods

A series of copolymers with "active ester" (AE) units and benzophenone (BP) moieties has been prepared. Their chemical structures were confirmed by conventional techniques, such as ^{1}H-NMR, ^{13}C-NMR, FTIR and GPC. The preparation of surface-attached networks was carried out by UV-light illumination of a thin polymer layer deposited on modified silicon wafer. The photocrosslinking reaction takes places by non-specific insertion of benzophenone units into C-H bonds. The modification reaction was carried out introducing PEG-NH_2 to these scaffolds using Et_3N as a catalytic agent. In this way the PEG chains were selectively grafted to reactive points (active esters moieties). The diffusion of H_2N-PEGs and the reactivity of these monomers are schematically shown in figure 1.

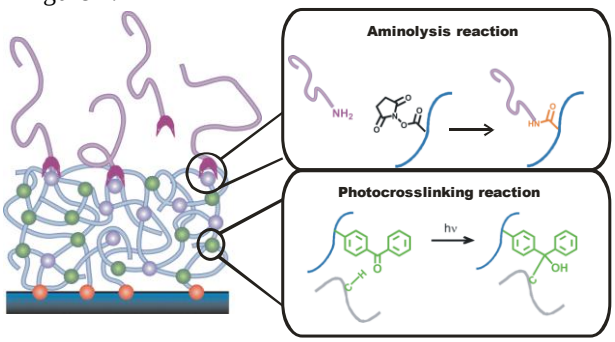

Figure 1: Schematic representations of diffusion of PEG-NH_2, aminolysis and photocrosslinking reaction.

In order to determine the degree of modification, the layer thickness has been measured by ellipsometry before and after PEGylation reaction. The modified polymeric networks were characterized by contact angle, XPS and SPR.

Results and Discussion

The functionalization of the surface-attached networks has been studied as a function of important reaction parameters, such as crosslinking density, reactive group content (AE content) and PEG-NH_2 molecular weight. Results are shown in figure 2.

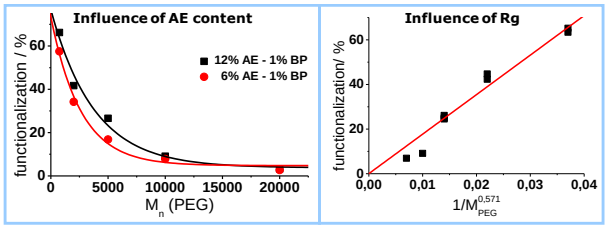

Figure 2: Variation of functionalization degree respect to Active ester (2a) and Radius of Gyration (2b).

The functionalization exponentially decreases from 65% for PEG750 to 5% for PEG20000, which indicates a strong influence of the molecular weight of free PEG chains. The penetration into the surface-attached networks depends on the radius of gyration (Rg) of the incoming macromolecules, which is according to the literature $Rg \sim M^{0.571}$ within the investigated molecular weight region[2]. This relation is clearly evident from the result plotted in figure 2b.

Under selective hydrolysis of most external AE units, the corresponding variation of funtionalization degree indicates that the PEG chains are able to diffuse into deeper layers and react with inner AE moieties. However under this reactive zone, there are still more reactive points, which are not accessible for free PEG-NH_2 (even for the lowest Mw) due to the shape of the concentration profile of surface-attached network and the *entropic shielding*. This entropic reason is related with the adopted conformation of these polymer networks during the modification reaction. Therefore, it was also possible to measure the depth of this interpenetration zone and our measurements estimate it to about 20 nm approximately.

Conclusions

The experiments described in this contribution show surface-attached polymer networks are systems that are barely penetrable for other large molecules. Typically functionalization degrees stay well below 10% if the Mw increases to as far thousand g/mol. These systems are therefore rather interesting candidates as layers to repel large molecules

Abstract :
Targets for fusion preparation on the French high power laser LMJ (Laser Mega Joule) require low density organic foam shells. These foam shells are composed of C, H and O, with a 2 mm diameter, 100 µm thickness and 250 mg.cm^{-3} density. The TMPTMA foam shells are synthesized by a microencapsulation technique giving a double emulsion water-in-oil-in-water. The foam shells have to fulfill severe specifications: diameter ranging from 1.7 to 2.3 mm, 100 µm thickness, 250 mg.cm^{-3} density, sphericity > 99.9% and non-concentricity < 1%. The diameter, density and thickness criteria are reached by using a droplet generator, whereas the shell shape (sphericity and non-concentricity) depends on several parameters of the process such as density, kinetics of polymerization, deformations of the shells, interfacial tensions and viscosity. The influence of the kinetics of polymerization upon the non-concentricity (NC) of the foam shells obtained is being studied here.

Introduction :
Water-in-oil-in-water (W/O/W) double emulsions are complex systems where a water droplet is entrapped within an oil droplet that in turn is dispersed in a continuous water phase [1]. Double emulsions can be produced using either a two steps drop break-up method with a mere succession of two T junctions [2], [3], or a single step process with parallel co-flowing streams [4], [5]. The monomer oil phase can later be polymerized either by a thermal or a UV process in order to fix the shell's shape (non concentricity and sphericity). In this work, a double emulsion W/O/W is obtained by using a droplet generator with parallel co-flowing streams. Once the shell's shape is set the organic phase is polymerized at 60°C with a thermal initiator. This process leads to a gelation time of 23 minutes. In the microfluidic area, the UV-polymerization is used to polymerized beads within a few minutes [4]-[7]. We thought that a faster polymerization kinetics may lead to better results of shells NC. Thus, a photo-polymerization process was investigated focusing on the effects of the incident light intensity and the amount of photo-initiator used on the shells NC.

Materials and Methods :
The external water phase of the double emulsion is a solution of 5% polyvinyl alcohol in water. The organic solution is composed of a monomer (trimethylolpropane trimethacrylate, TMPTMA), a mixture of two solvents (dibutyl phthalate and ethylbenzene), a surfactant (Span® 80) and a photo-initiator (2,2-dimethoxy-2-phenylacetophenone). The internal water phase solution is a mixture of water and deuterated water. The shells are produced by a microencapsulation technique using a triple orifice generator. The shells generated are then collected into an agitated horizontal flask. This flask is placed into a heated water bath at 60°C and under a nitrogen flow of 60 mL.min^{-1}. The shells are then photo-polymerized by illumination with a UV light (λ = 365 nm).

Results and discussion :
The UV-polymerization was performed with different amount of photo-initiator (5, 10 and 15%) and two incident light intensities. The results obtained are summarized in the table below.

incident light intensity (mW.cm^{-2})	% of photo-initiator	average NC (%)	% of shells with NC < 8 %
2	5	23	8
	10	21	9
	15	23	6
2,3	5	23	9
	10	17	29
	15	22	9

The best results of NC are obtained with 10% of photo-initiator for both incident light intensities. The highest light intensity seems to give better results of NC than the lowest light intensity.

Conclusion :
From the results of the experiments, we can conclude that the better results of NC are obtained with 10% of photo-initiator and a light intensity of 2.3 mW.cm^{-2}. However, these results of NC are really low compared to the results obtained with a thermal polymerization process (average NC: 98%). Thus, the UV- polymerization process still has to be improved to get results as good as with the thermal polymerization process.

Self-assembling of polyelectrolyte multilayers

Eduardo Guzmán[1], Raquel Chulia[1], Jesica Cavallo[2], Francisco Ortega[1], Ramón G. Rubio[1], Miriam Strumia[2], Cesar Gómez[2].
[1]Universidad Complutense de Madrid, Departamento de Química Física I, 28040-Madrid, Spain
[2] Universidad Nacional de Córdoba, Departamento de Química Orgánica, CP-5000 Córdoba, Argentina

After the seminal works of Decher and co-workers using polyelectrolytes with charges of opposite sign, [1, 2], the sequential electrostatic self-assembling of oppositely charged materials has attracted considerable attention as a simple and versatile method for constructing nanostructured materials. The reason of this interest is the existence of a large amount of promising applications in different fields as sensors, functional coatings, selective membranes and drug delivery [3]. Even though much has been advanced in the understanding or self-assembled multilayers of polyelectrolytes [4], less effort has been dedicated to the study of the adsorption kinetics, and to the desorption of drugs adsorbed within the multilayer.

In this work we have carried out a multi-technique experimental study of the adsorption kinetics of multilayers formed by Chitosan and Poly(acrylic acid) -PAA- as a function of the number of layers at different pH's, and of the same system including Propanolol. The main techniques used were a dissipative quartz microbalance (D-QCM) and ellipsometry. The combination of the results obtained using D-QCM and ellipsometry have allowed calculating the water content of the films as a function of number of layers [5].

The results show that the polymer adsorption is an almost irreversible process. In our studies, we have observed a very important effect of pH on the thickness and the water content of the films. The strongly non-linear dependence of the film thickness on the number of layers is due to the polymer diffusion within the film, which leads to high roughness and to a homogeneous chemical structure within the multilayer. The pH modifies the charge densities of the polymers, thus modifying their interactions and their mutual diffusion. Fig. 1 shows a set of representative results obtained by D-QCM. It can be observed that, in general, the addition of a chitosan layer leads to a lower increase on the thickness than the addition of a PAA layer. Additionally, the increase on the thickness of chitosan layers is almost the same for all the pH conditions studied, whereas the PAA layers changes very significantly. The thickness obtained by D-QCM for a given number of layers and for a pH is higher than that obtained by ellipsometry. This is a consequence of the fact that D-QCM is sensitive not only to the amount of polyelectrolyte adsorbed, but also to the water content of the multilayer.

In a second series of experiments, Propanolol, as a third component, has been adsorbed after each PAA layer. As expected the increase of thickness after each propanolol layer is much smaller than for each polymer layers. We have studied desorption kinetics studies in water using 22-layers films using the QCM technique, which point out that the desorption of Propanolol (remember that the adsorption of polymers is irreversible) lasts for at least six days, although some of the Propanolol remains adsorbed in the multilayer.

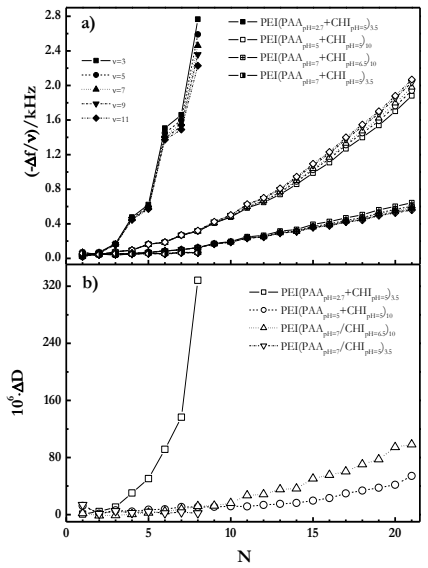

Fig.1 Multilayers PEI(PAA+CHI)$_n$ built using different pH combinations for the assembling of layers of PAA and CHI. Aggregation and Chain Dynamics in Supramolecular Polymers by Dynamic Rheology: Cluster Formation and Self-Aggregation

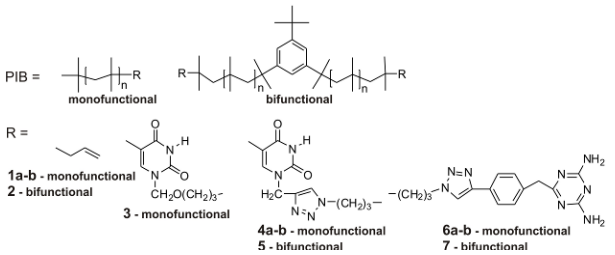
Florian Herbst, Klaus Schröter, Ilja Gunkel, Stefan Gröger, Thomas Thurn-Albrecht, Jochen Balbach and Wolfgang H. Binder

Martin-Luther-University Halle-Wittenberg – Institute of Chemistry and Institute of Physics

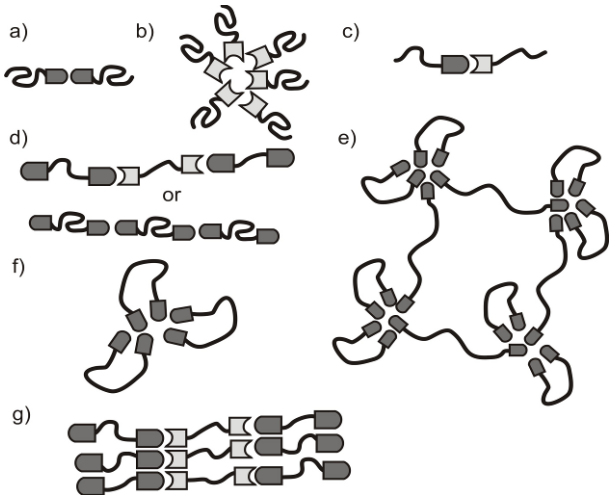
Wolfgang.Binder@chemie.uni-halle.de

Supramolecular polymers are of great interest in material science, since they exhibit remarkable properties including self-assembly and self-healing. The introduction of supramolecular motifs into the main-chain or at the chain-end of different polymers has been reviewed extensively, highlighting the wide scope of structural and dynamic features.[1]

Aim of this investigation was the synthesis of mono- and bivalent telechelic polyisobutylenes (PIBs) (**3-7**) bearing polar functional groups at their chain ends, which are capable to undergo self-assembly via hydrogen bonds. Melt rheology and SAXS measurements of the supramolecular polymers/mixtures were performed in order to become a deeper insight in the dynamics of the hydrogen bonds. Thereby the formation of clusters was observed.[2]



As used hydrogen bonding motif, the thymine/2,6-diaminotriazine interaction was applied. Since the mechanism of the living carbocationic polymerization of isobutylene does not permit the direct introduction of hydrogen bonding units, they were affixed onto the polyisobutylene chain via azide/alkyne "click"-reactions starting from azido-telechelic polyisobutylenes.[3] The resulting polymers were obtained in high purity and characterized by means of ^{1}H- and ^{13}C-NMR spectroscopy, as well as MALDI-TOF measurements, indicating completely telechelic PIB-polymers. Mixtures of the functionalized PIBs were made in order to achieve supramolecular A-B or $(\text{-A-B-})_n$ pseudo BCP's.[3] The dynamic-mechanical behavior of the resulting supramolecular blockcopolymers was investigated via bulk-rheology measurements (frequency sweep). It was shown that a equimolar mixture of monovalent thymine-telechelic PIB (**3**) and monovalent 2,6-diaminotriazine-telechelic PIB (**6a**) (both M_n ~ 3500 g/mol) exhibits a 40-times higher viscosity when compared to a non-functionalized PIB (**1a**) (allyl-telechlic species) with a similar molecular weight at room temperature. Furthermore, the supramolecular mixture shows strong temperature dependence in the range of 20 to 80 °C, explainable by the dynamics of the hydrogen bonds, due to a decrease of the virtual molecular weight.



It is noteworthy that the pure functionalized PIBs (**3-7**) show a strong increase of the viscosity, indicating an undefined clustering of the functional groups, as confirmed by additional SAXS-measurements. Possible modes of clusters/aggregates are displayed above (**a-g**). Monofunctional PIBs with a higher molecular weight (10000 g/mol) were investigated revealing a similar behavior. While all monofunctional PIBs flow at small angular frequencies, their bifunctional analogues (**5, 7, 5+7**) were rubber-like materials. The observed plateau modulus (~10^7 Pa) was higher than reported for a linear high molecular weight PIB (~10^5), indicating a serious amount of supramolecular cross-links between the polymer chains (**e**). By increasing the temperature to 60 °C the materials (**5, 7, 5+7**) start to flow, indicating a cleavage of the supramolecular cross-links. All the materials completely recover their properties at 20 °C after being heated at 80 °C within 20 minutes even after repeated heating-cooling cycles. Therefore the bifunctional (rubber-like) samples can be treated as a low molecular weight polymer melt at high temperatures and used as a strong rubber at room temperature which also exhibits self-healing properties.

Université catholique de Louvain, Place L. Pasteur, 1, Louvain-la-Neuve, Belgium.

jean-marc.schumers@uclouvain.be

Block copolymers have become nowadays powerful tools for the preparation of nanostructured materials.[1-3] They are indeed able to self-assemble at the nanoscale into well-ordered structures that can be used, among other things, for the preparation of nanoporous materials by selectively removing the minor phase. These materials exhibit the pore topology and the pore size of their parent structures and can be further used as separation membranes or templates for other nanomaterials.[1-7]

Most methods reported up to now for the creation of nanopores rely on the degradation of the sacrificial minor block. This degradation is often performed under harsh conditions and offers thus a rather poor control over the chemical functionality inside the pores.

This presentation will present an alternative and milder strategy based on the introduction of a photocleavable junction ($h\nu$) between the blocks of a polystyrene-*block*-poly(ethylene oxide) diblock copolymer (PS-$h\nu$-PEO).[8]

This diblock was synthesized by a one-pot simoultaneous ATRP–CuAAC ‘‘click’’ reaction process.[9] After its synthesis, the diblock was self-assembled into thin films displaying perpendicular PEO cylinders in a PS matrix. The films were then irradiated with UV light in order to cleave the junctions between the blocks. The nanoporosity was then generated by a simple soaking of the film in a water/methalol mixture, enabling the selective removal of the PEO minor phase.

INTRODUCTION

New photovoltaic technologies as organic and copper-indium-selenium (CIS and CIGS) allows thinner and more flexible modules. To growth the market shares of these flexible technologies, it needs to reach sufficient lifetimes by limiting considerably the insertion of water and oxygen in the device. High barrier materials, which are optically transparent in the visible domain, flexible, and low cost have to be developed. Furthermore these materials must have a good stability under exposure to solar light [1].

To obtain high barrier encapsulating foils, stacks alternating dense inorganic layers (such as SiOx, ≈ 300 nm) and organic layers (≈ 1µm) are deposited on a thick polymeric substrate [2]. The organic layers have to be as barrier as possible. Insertion of nanoclays in the organic layer brings improvement on the barrier properties [3], but nanoclays could decrease the photostability of the polymer [4]. The goal is to prepare barrier, transparent and flexible nanocomposite films which are photostable when inserted in the multilayer encapsulation. The nanocomposites are based on polyvinylalcohol (PVA) as the polymeric matrix and two different clays, natural and synthetic.

MATERIALS AND METHODS

PVA $(-CH_2-CH(OH)-)_n$ was 98% hydrolyzed with molecular weight ≈16,000 $g.mol^{-1}$. Clays were either natural clay such as sodium montmorillonite (Cloisite® Na+) or synthetic clay (Laponite). The nanocomposite films at different clay concentrations (up to 10 wt %) were characterized by several analytical techniques: UV-visible and infrared spectroscopies, XRD, TEM, DSC and permeability measurements. UV-light irradiations ($\lambda > 300$ nm, 60°C) were carried out in a SEPAP 12/24 unit [5], under accelerated artificial conditions in order to simulate natural ageing..

RESULTS & DISCUSSION

Characterizations of PVA/clay nanocomposites

Figure 1 shows the IR spectra of PVA/clay nanocomposites with various contents of Cloisite®Na^+. One observes a linear increase of absorbance at 1050 cm^{-1} (ν_{Si-O}) as a function of clay content, which clearly indicates the good distribution of the clay in PVA..

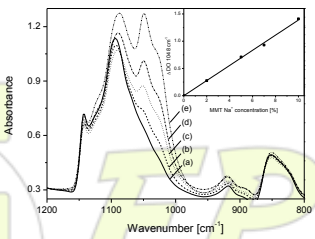

Figure 1 : FTIR spectra of PVA (a) and PVA/Cloisite®**Na^+** nanocomposites (b-e) with different clay content: (b) 2 wt%, (c) 5 wt%, (d) 7 wt%, (e) 10 wt%. Insert: ΔOD at 1050 cm^{-1} as a function of clay content.

DRX and TEM characterizations (Figure 2) reveal coexistence of silicate layers in intercalated and exfoliated states.

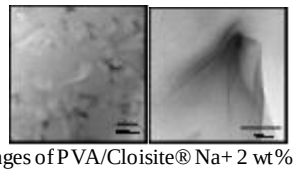

Figure 2: TEM images of PVA/Cloisite® Na+ 2 wt% at (a) low magnification and (b) high magnification.

Gas permeability of the nanocomposites decreases with increasing clay content up to 5%. This effect can be attributed to tortuosity effect of the clay platelets. However, the barrier properties are better in the case of Cloisite® Na+ than in the case of Laponite, which comes from the higher aspect ratio of Cloisite® Na^+ platelets.

Photostability of PVA/clay nanocomposites

In presence of both clays, the same photoproducts of PVA are formed, but a discrepancy on the photooxidation rate of PVA is observed depending on the clay: Cloisite® Na^+ displays a prodegradant effect whereas Laponite has no influence on the oxidation rate of PVA (figure 3). However, in the absence of oxygen, PVA nanocomposites are photostable and no modification of their chemical structure and morphologies are observed. This can be achieved when the nanocomposite layer is protected by an inorganic one, which is the case in the multilayer material.

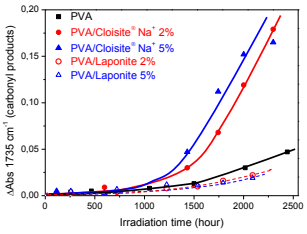

Figure 3: Photooxidation rate of PVA, PVA/Cloisite® Na+ and PVA/Laponite nanocomposite films as a function of irradiation time.

CONCLUSIONS

Cloisite® Na^+ and Laponite/PVA nanocomposites with intercaled/exfoliated silicate layers of clay homogeneously dispersed in the polymeric matrix have been developed. The best gas barrier properties were obtained in the case of Cloisite® Na^+. In multilayer encapsulant coating alternating inorganic and nanocomposite layers, these nanocomposites are photostable.

Abstract : The novel near-infrared (NIR) electrochromic polynorbornenes, poly(NBDTPA) and poly(HNBDTPA), containing electroactive chromophores were prepared, respectively, via ring opening metathesis polymerization from a new norbornene derivative (NBDTPA) using different Grubbs' catalysts, and followed hydrogen reduction. The glass transition temperatures (Tg) of poly(NBDTPA) and hydrogenated poly(HNBDTPA) were 141 ^{o}C and 91 ^{o}C, respectively. The 10% weight-loss temperatures of hydrogenated poly(HNBDTPA) and poly(NBDTPA) were up to 440 ^{o}C and 397 ^{o}C, respectively. Poly(NBDTPA) and poly(HNBDTPA) were highly soluble in common organic solvents such as toluene, xylene, chlorobenzene, 1,2-dichlorobenzene, tetrahydrofuran and benzene at room temperature. Hydrogenated poly(HNBDTPA) film showed excellent transparency (up to 91%). Poly(HNBDTPA) film exhibited three reversible oxidation redox couples at 0.63, 0.82 and 1.23 V v.s. Ag/Ag+ in acetonitrile solution. Poly(HNBDTPA) showed excellent stability and reversibility, with multi-staged color changes from its colorless neutral form to green, light-blue and dark-blue as applying potentials from 0 to 1.75 V. The color switching time and bleaching time of the poly(HNBDTPA) were 7.1 s and 4.2 s in near-infrared region (1230 nm) and 7.4 s and 4.5 s in UV-Vis region (420 nm), respectively.

Introduction: Electrochromism has been reported in redox-active inorganics, organic small molecules as well as in polymer materials such as conjugated polymers.[1-8] polyamides[5] and polyimides.[6] The colored polymers are disliked as electrochromic materials, and the native color is one of disadvantages for practical uses in optical devices.[9] It is well-known that hydrogenated polynorbornene derivatives are colorless, amorphous and readily solution-processed polymers with high thermal stability, optical transparency. Ring-opening metathesis polymerization (ROMP) offers an effective way in polymerization of norbornene monomers with different side chain substitutes. Grubbs' ruthenium (Ru) carbene complexes efficiently catalyzed ROMP under ambient conditions, with high tolerance toward polar functional groups. Thus, ROMP using Ru-based catalyst is a promising route to prepare polynorbornenes and hydrogenated polynorbornenes which has colorless, transparent and easily solution-processed properties.

Conclusion: The novel near-infrared (NIR) electrochromic polynorbornenes, poly(NBDTPA) and poly(HNBDTPA), were successfully prepared via ring opening metathesis polymerization from electroactive chromophore-containing monomer, NBDTPA, and followed hydrogenation, respectively. Poly(NBDTPA) and hydrogenated poly(HNBDTPA) exhibited similar electrochemical and electrochromic behaviors with high contrast and electrochromic reversibility. Thus, these characteristics suggest that the prepared colorless polynorborenes are good candidates for the electrochromic materials.

Introduction

Photoactive semi-conducting polymers have shown to be interesting candidates for organic photovoltaics due to their high absorption coefficient, easy processibility, mechanical flexibility and low costs [1-3]. At present, polymer-based systems reached already 6% to 8% in photovoltaic efficiency. However, despite promising efficiencies a detailed understanding is still limited.

In a typical organic solar cell the active layer contains two components, namely an electron-donor and an electron acceptor, to enhance exciton separation. It was found that besides fitting in electronic properties the inner film morphology of the two components is crucial for the photovoltaic performance [4]. In contrary to conventional layered systems, with a relative small interface, in the bulk heterojunction concept a donor and an acceptor material are blended which results in a much higher interfacial area [5-7]. Consequently, more excitons reach the interface between both and are separated. Besides, the high interfacial area also the structural length scales, which have to fit the small exciton diffusion length in organic materials (in the order of 10 nm), and percolation paths to the electrodes are of utmost importance. As the bulk heterojunction concept is commonly based on simple blending of two components, the structure develops in a self assembly process. Therefore the morphology of the active layer can only be controlled indirectly by several parameters such as the chemical composition, the solvent used and post production treatments.

Materials and Methods

In this investigation we probe the influence of the used solvent on the morphology formation of polymer-based bulk heterojunction systems for photovoltaic applications. Films are spin coated from different solvents. We chose the bulk heterojunction system consisting of the conjugated polymer P3HT (poly(3-hexylthiophene-2,5-diyl)) and the methano fullerene PCBM ([6,6]-phenyl-C61 butyric acid methyl ester). Both components fit very well concerning their electronic behaviors and this combination is probably the best investigated system in organic photovoltaics so far. Besides imaging methods such as atomic force microscopy (AFM), the advanced scattering techniques X-ray reflectivity and grazing incidence small and wide angle X-ray scattering (GISAXS and GIWAXS) reveal a full understanding of the inner film structure on molecular to mesoscopic length scales. Spectral characterization, such as absorption and photoluminescence, and optical microscope investigations complete this study.

Results and Discussion

In combination with topography imaging we are able to reconstruct schematic morphologies from the scattering experiments for the films made from the different solvents. Depending on the solvent, enrichment layers at the interfaces as well as varying structural length scales inside the active layer are found. As an example, **figure 1** summarizes the structures detected in this investigation in case of annealed P3HT:PCBM films made from the solvent chlorobenzene in a schematic morphology. Black areas illustrate pure PCBM and white areas pure P3HT phases. Possible phases containing portions of both components, P3HT and PCBM, are neglected in this presentation for clarity.

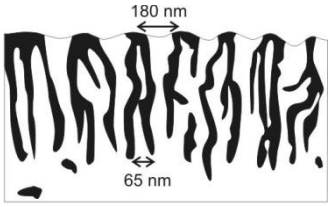

Figure 1. Black-and-white schematic morphology of annealed P3HT:PCBM film

Conclusion

It is found that the choice of solvent has direct influence on the lateral and vertical material arrangement and therefore on the device performance [8].

Convenient Method for Functional Biocompatible Hyperbranched Polymers

J.A.Loontjens, F. Xiang, L. Asri, J. Yin, S. Roest

University of Groningen, Nijenborgh 4 9747AG, Groningen, The Netehrlands

J.A.Loontjens@RUG.nl

Introduction

Due to aging of the world populations the need for polymeric auxiliaries for biomedical devices is rapidly growing. Tissue engineering, antibacterial coatings, micelles for drug delivery and the like attract therefore in the last two decades much attention. However, the body is extremely complex and therefore the requirements for biomedical polymers are highly demanding. Most of the studies tackle only one biomedical property, but we are deemed to cope with a number of requirements. The aim of our research is to make hyperbranched polyurethanes with multiple functional groups as depicted in Figure 1.

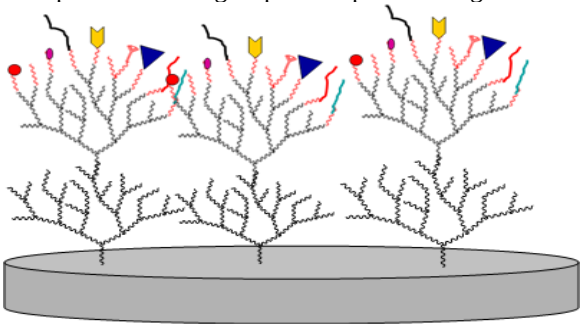

Figure 1: Schematic presentation of multifunctional hyperbranched coating.

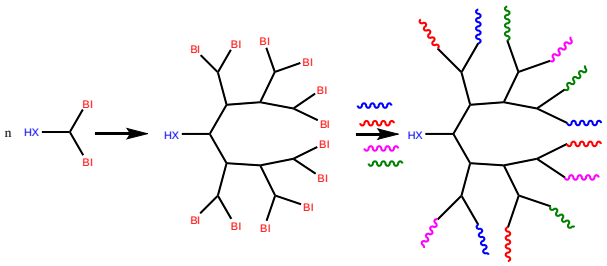
Materials and Methods

The key element of this research is our discovery of the extremely high selective reaction between primary amines and carbonyl biscaprolactam (CBC). In toluene at 80 °C compounds comprising primary and secondary amines form in 6 hours quantitatively caprolactam blocked isocyanates. By this approach AB_2 monomers were prepared in a one step reactions starting for example from bishexamethylene triamine. The consecutive polymerization of the AB_2 monomers, as well as the successive functionalization, is done at 145 °C in bulk or in DMF.

Results and discussion

Primary amines react with carbonyl biscaprolactam (CBC) quantitatively yielding blocked isocyanates [1, 2, 3]. More remarkably, when a polyamine comprises primary and secondary amines (or esters) exclusively primary amines react. Hence this methodology offers the possibility to make in one step blocked isocyanates comprising secondary amino groups (or esters), as depicted in scheme 1. Triamines, such as bishexamethylene triamine, comprise two primary and one secondary amino groups. Through the reaction with CBC the primary amino groups are converted into blocked isocyanates (B-groups), whereas the secondary amino group remains unaffected (A-group) below 100 °C. On heating at 145 °C the polymerization starts by the substitution of caprolactam of the B-group by the secondary amine (A-group).



Scheme 1: The synthesis of AB_2 monomers, the corresponding hyperbranched polymers and the corresponding modified hyperbranched polymers (BI = blocked isocyanate, X = O or NH).

We purposely designed the AB_2 monomer in such a way that the B-groups are the blocked isocyanates. To this end, the HB polymers comprise numerous blocked isocyanates (up to more than 30), which can be functionalized. Indeed every compound comprising hydroxyl or amino groups can be coupled onto the end of each polymer chain. Obviously, various compounds can be used, as each polymer chain comprises an abundant amount of BI's.

The conversion of lysine into the corresponding blocked isocyanate proceeds as well quantitatively, although it takes more time for complete conversion. The ester side group is used to introducing functional groups. The modified lysine blocked isocyanates yielded functional polyurethanes when heated with polyols.

Conclusions

We have developed a feasible novel method to make in one step in quantitative yield AB_2 monomers or functionalized amino acids (lysine). The polymerization of the AB_2 monomers starts simply on heating, yielding hyperbranched polymers furnished with blocked isocyanate end groups. The blocked isocyanate groups enabled us to tether hydroxyl of amino functional compounds provide with special properties. The polymerization of lysine blocked isocyanates yield linear polymers with functional side groups.

Introduction

Huisgen 1,3-dipolar cycloaddition of azides and alkynes is the reaction most commonly associated with 'click'-chemistry, a term coined by K. Barry Sharpless 0 in 2001. The Cu^{I}-catalyzed cycloaddition affords 1,2,3-triazoles 0 and can be performed in an aqueous system across a wide range of temperatures and pH, and thus is compatible with chemically and hydrolytically sensitive thin film composite membranes. Click functionalization is insensitive to acid and amine functional groups on the membrane surface, and can be complementary to other functionalization strategies that target these groups (e.g. with epoxy-functional polymers). Click chemistry is a versatile technique for the functionalization of thin film composite reverse osmosis membranes to reduce biofouling.

Experimental

TFC polyamide membranes were prepared from *m*-phenylene diamine (MPD) and trimesoyl chloride (TMC) via interfacial polymerization. Azide-functionalized membranes were fabricated of azide-functionalized acidchloride monomer analog, 5-(azidomethyl)isophthaloyl dichloride (AMID), which was prepared from commercially available starting material diethyl 5-(hydroxylmethyl) isophthalate in three steps [3,4]. Alkyne-functionalized polymers were prepared by esterification of polyethylenglycol (PEG) with 5-hexynoic acid or by aminolysis of trithiocarbonate-functionaled pNIPAM, obtained from reversible addition fragmentation chain transfer (RAFT) polymerization, and *in situ* Michael addition to propargyl acrylate. The procedure for click-grafting was adapted from a previously published procedure 0.

Results and Discussion

The new azide-functionalized TFC polyamide membranes were prepared by interfacial polymerization on ultrafiltration polysulfon and polyethersulfon membranes supports, using an aqueous solution of MPD and a mixture of TMC and AMID in decane.

Different amounts of AMID were used for the membrane preparation ranging from 0-50%. The TFC polyamide membranes were characterized via FTIR-ATR spectroscopy and the presence of azide functions on the surface of the membranes confirmed by the presence of the azide band located at 2105 cm^{-1}.

Different cycloaddition conditions for the PEG-alkyne grafting were tested. Best results were obtained at 60°C in 11% K_2SO_4 (cloud point conditions). Under these conditions, nearly complete disappearance of the azide absorption in the IR spectrum was obtained after 1 h.

The performance of the surface-modified membranes was evaluated in a dead-end cell and flux and salt rejections typically in the range of 20-50 LMH and 95-100% were determined, respectively, for AMID contents up to 25%.

Model PEG and pNIPAM brush surfaces were prepared by click reaction of alkyne-functionalized polymer with azide-functional surfaces. The azide-functional model surfaces were prepared by plasma polymerization of allyl glycidyl ether on polyethersulfone substrate, followed by reaction with sodium azide to introduce surface epoxide groups. Surfaces were characterized by XPS to follow the introduction of azide groups and their reaction under click conditions.

The model surfaces showed no measurable fouling on exposure to solutions of human serum albumen. By contrast, unmodified polyethersulfone showed significant adsorption of HSA under the same conditions.

When PEG and PNIPAM-modified surfaces were exposed to *S. epidermidis* bacteria, very limited attachment of isolated bacteria was observed after 6h. This may be associated with defects in the polymer brush. By contrast, untreated polyethersulfone samples showed significant colonization and biofilm formation after exposure to *S. epidermidis* for 6h under the same conditions.

Conclusion

The technology comprises a method of synthesising azide-functional reverse osmosis membranes, which can be functionalized with alkyne-functional polymers to impart antifouling properties to the membrane. Membranes prepared with up to 25% AMID content exhibit >95% salt rejection in dead end cell testing. The membranes have been successfully grafted with alkyne-functionalized polymers, which are readily prepared from commercially-available end-functionalized polymers or polymers which contain RAFT endgroups. Model polyethersulfone surfaces which have been grafted with the alkyne-functionalized polymers exhibit significantly improved antifouling behaviour compared to unmodified polyethersulfone surfaces.

Poly(high internal phase emulsion) material utilizes high volume fraction of an internal phase of an emulsion to template highly porous polymeric material. Pores are created due to the droplets of internal phase and additionally due to the shrinkage of the polymeric material produced from the polymerisation of the continuous phase of the emulsion. Result is a highly porous polymer with large pores in place of the droplets of the internal phase and smaller interconnecting pores between them. Such material, termed polyHIPE[1] (see Figure 1 for morphology) is permeable due to the interconnected porous structure and can be used in monolithic form as columns for synthesis facilitation[2], chromatography[3], reactive filtration[4], etc. However, because of the large diameters of pores (usually in the micrometer range), the surface area of such materials is rather low. In order to address this issue, we have introduced a second generation of pores to the polyHIPE material, utilizing a post polymerisation hypercrosslinking method. In this manner, much smaller pores can be generated by creating additional crosslinks in the material by a chemical method. Poly (4-vynilbenzyl chloride) polyHIPE material was prepared and a Friedel-Crafts method was applied in order to connect neighbouring chloromethyl groups with benzene rings. This resulted in a material with a much higher surface area, in the range of 1000 m^2/g (ranging 20 m^2/g prior to procedure) and controlled kinetics enabled tailored properties of the material. We have applied the material for the immobilisation of an organocatalyst[5] and for the immobilisation of piperazine for the removal of atrazine from water.

Introduction

Nanocomposites based on semiconducting polymers and metal or inorganic semiconductor nanofillers have gained recently an increasing interest due to their promising application in nonvolatile rewritable memories, optical sensors, SERS probes and phototovoltaic devices; the applications based on a resonance excitation of surface plasmons or charge transfer at the polymer/inorganic semiconductor interface. A well controlled nanostructuring of the inorganic phase as well as its immediate contact with the semiconducting polymer is desirable for achieving high efficiency of photonic or electronic processes. It was shown recently, that conjugated polymers comprising ionic or ionizable groups, i.e. semiconducting polyelectrolytes, are easily adsorbed to oppositely charged inorganic surfaces and by careful mixing the polymer with inorganic nanoparticles a desirable nanostructures can be obtained. For example, by mixing Ag nanoparticles (NPs) hydrosols with polyelectrolytes solutions nanocomposites can be easily prepared, which show very strong surface enhanced Raman (SERS) signals.

Materials

Regioregular *poly{3-[6-(1-methylimidazolium-3-yl)-hexyl]thiophene-2,5-diyl bromide}*, PMHT-Br, and *poly [(thiophene-3-yl)acetic acid]*, PTAA, shown in Fig. 1 were used as soluble π–conjugated polymers bearing cationic and anionic groups, respectively.

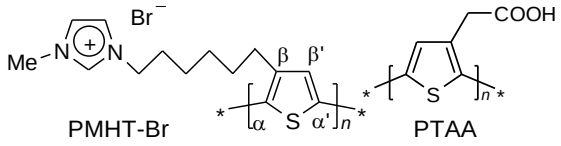

Figure 29: Ionic polythiophenes used in the study

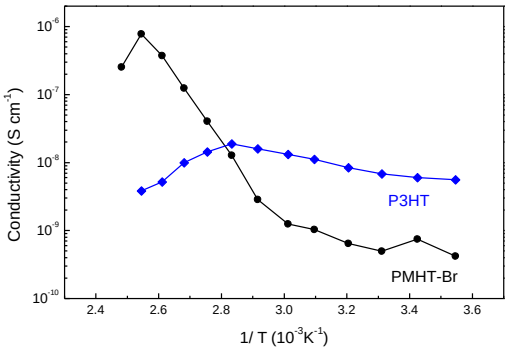
PMHT-Br was synthesized using recently developed two step procedure.[1] The resulting cationic polythiophene is soluble in water, common polar solvents like dimethyl sulfoxide, dimethylformamide and some alcohols. Silver and gold NPs were prepared by the reduction of a proper metal salt with sodium borohydride or citrate. Mesoporous TiO_2 layers prepared according recently published procedure[2] were used as received.

Results and Discussion

The measured electrical conductivity of the pure cationic PMHT-Br in vacuum was found to be $3x10^{-10}$ S/cm while the nanocomposites with Au NPs showed higher conductivity depending on the concentration of the Au NPs. The conductivity of composites and of the pure polymer showed a linear dependence on reciprocal temperature up to 80 °C with the average activation energy 0.32 eV (see Fig. 2 also compared with P3HT).

Mixed ionic and electron conductivity was detected with a steep increase of the ionic mobility at higher temperatures due to the increased segmental motion of the polymer confirmed by impedance spectroscopy. The I-V characteristics showed a nonlinear behavior and electrical bistability in forward and reversed directions.

Figure 30: Dependence of the electrical conductivity on reciprocal temperature. ● - PMHT-Br, ♦ - P3HT



When Ag or Au NPs and PMHT-Br are mixed in components ratios providing the charge balance between Ag-NPs and cationic polythiophene, NPs aggregated with interparticle distances enabling marked interparticle plasmon interactions, demonstrated by a red shift of optical absorption and strong SERS signals. The SERS activity of such NPs assemblies was preserved when the sol was cast on a substrate forming a thin solid film. The electrostatic interactions were successfully utilized also for the preparation of multilayered structures of alternating PMHT-Br, Au NPs and PTAA using layer–by–layer deposition technique on charged surfaces, even inside the mesoporous TiO_2. The surface plasmon resonance of metal nanoparticles contributed markedly to the overall extinction of the composite showing a red shift of optical absorption with increasing number of layers due to an increased electronic coupling of plasmons in the multilayer structure.

Conclusions

The electrostatic interactions between ionic polythiophenes, metal NPs and TiO_2 nanostructured surface were exploited for building aggregated or multilayered systems as a new materials with strong plasmonic effects and mixed ionic and hole conductivity.

Supramolecular Poly(3-hexylthiophene)s for Solar Cells: Synthesis and Electronic Properties

CLAUDIA ENDERS , ALI SHAYGAN NIA, WOLFGANG H. BINDER

Martin-Luther-University Halle-Wittenberg, Faculty of Natural Sciences II (Chemistry and Physics), Institute of Chemistry/Division Technical and Macromolecular Chemistry, Von- Danckelmann-Platz 4, 06120 Halle (Saale) (Germany)

claudia.enders@chemie.uni-halle.de

The sun is the largest supplier of carbon-neutral energy. Although there are a variety of inorganic solar cells for harvesting efficiently solar energy, the costs of processing are too high to be economically viable. Therefore a major motivation is the development of organic photovoltaic (OPV) materials and devices which are envisioned to exhibit advantages such as low cost, flexibility and unlimited availability. The state-of-the-art organic solar cell is built from a bulk heterojunction (BHJ) composed of electron-donating semiconducting polymers and electron-withdrawing fullerides or perylenes. Significant progress has been made on the structural enlightenment of these materials to increase the power conversion efficiencies over 7% up to now. However, many factors limit the performance of BHJ solar cells. Especially the morphology of the active composite layer plays an important role. Hence, we have combined the knowledge about microphase separated oligomers and polymers (well-known as supramolecular pseudo-block copolymers), which we have already gained[1], with the composition of BHJ solar cell materials.

Thus we have synthesized active layer materials based on postfunctionalized poly(3-hexyltiophene)s (P3HT) bearing hydrogen bonding moieties on the end groups and perylene derivates with the corresponding equivalent for attractive supramolecular interactions (see figure 1). Via these postfunctionalization reactions we synthesized telechelic P3HTs bearing trimethyl-silylacetylene moieties by microwave supported Sonogashira reactions.

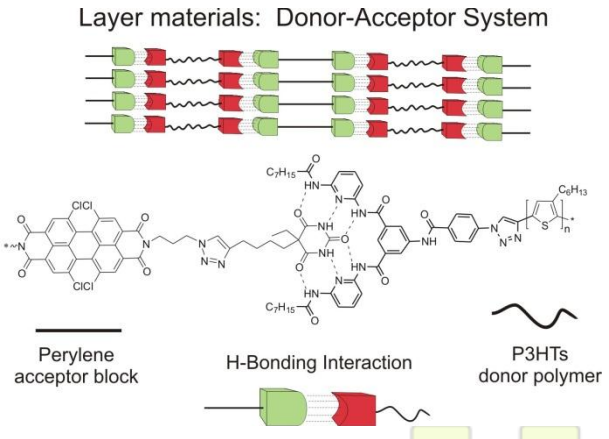

Fig.1 Selfassembly of postfunctionalized P3HT and perylene units to active layer material (D-A system)

After deprotection of the acetylene group we introduced hydrogen bonding units onto the polymer chain ends via the azide/alkyne "click" reaction (see figure 2). The defined end group structure analysis is therefore essential and was realized via LC-ESI-TOF mass spectrometry[2]. Beside this we investigated the electrochemical properties of all telechelic P3HTs, perylenes and their blends via cyclic voltammetry (CV), UV-vis and fluorescence spectroscopy to determine the electronic and optical band gap.

In a single active-layer organic solar cell the power conversion efficiency (PCE) will be measured. These results give us knowledge about the interface interaction between electron acceptor and conjugated polymer which are crucial for the photophysical performance in organic photovoltaic devices.

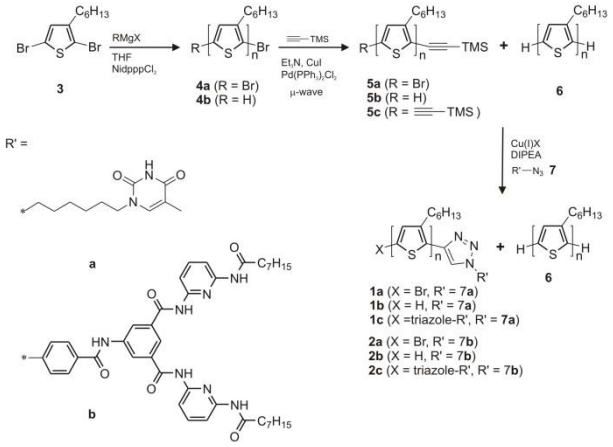

Fig.2 Postfunctionalization of poly(3-hexylthiophene)s via Sonogashira and azide/alkyne "click" reaction

s.destri@ismac.cnr.it

Efficient white electroluminescence can be obtained from a fully miscible blend of core-type polyfluorene-based copolymers prepared by using Suzuki coupling reaction between a properly functionalized fluorene prepolymer coming on its turn from a Suzuki polycondensation and the di-bromide derivative of either a green or a red dye.[**1]**

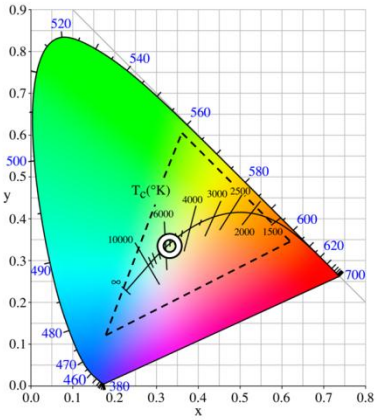

Fig.1 CIE 1931 chromaticity space, also showing Planckian locus

The chemical composition of the materials is a key factor to tune the emission colour, particularly the white shade (correlated colour temperature see Figure 1) which dramatically depends on the percentage of the three polymers constituting the blend. A deep molecular characterization of three polyfluorenes (PF) has been carried out combining different techniques such as (^{1}H- and ^{13}C)-NMR, and MALDI-TOF MS. Their exact molar mass distributions were calculated applying the absolute calibration curves builds by SEC-MALDI TOF MS analysis of selected SEC fractions of opportune choice PF samples. More than ten clusters of homologous peaks separated by about 1039.2÷1039.6 Da which correspond the mass of the PF repeating units (1039.4 Da), were envisaged in the prepolymer samples, each cluster has been assigned to linear PF chains bearing different end groups corroborating NMR observations. Reactive boronate linear chains are present together with unprofitable bromide terminated ones and un-reactive chains ending with phenyl or hydroxylic or hydrogen groups. Even more families are present in the final core PF. The identification of macromolecules terminated with hydrogen, hydroxyl and phenyl groups suggests that, in accordance to the literature[2], side reaction occur during the Suzuki polycondensation reaction between dibromide and diboronate monomers. The formations of PF chains terminated with bis(boronic pinacol) diester in the prepolymer samples suggests that this group, in the Suzuki polycondensation, is more stable with respect to the bis(boronic 1,3-propanediol) diester end groups.

Moreover, by applying a gel permeation cromatography to separate the samples as a function of the chains molecular weight we were able to discriminate among the different situations obtaining in the high molecular weight range only the polymeric chains which contain in a core or end position the dye (red or green emitting depending on the chosen sample).

Photophysical characterization (absorption and photoluminescence) has been carried out on diluted solution of the different fractions to investigate intramolecular energy transfer mechanism as a function of both the molecular weight and the acceptor dye position within the polymer chain (core or end-type copolymers), and its effect on the overall photoluminescence quantum efficiency.

Introduction. Long chain branched (LCB) polymers have value in processing techniques which demand high melt strength, including thermoforming, film blowing, extrusion coating, and blow molding processes. Due to the difficulties in the synthesis of branched polypropylenes, there hasbeen an increased interest in the chemical modification of polypropylene (PP).Among the most successful processes, reactive extrusion[1,2]is the most used, which degrades the polypropylene in a controlled fashion to create branches.

The rheological importance of these types of materials is the effect of long chainbranches on the extensional flow of the polymers. Linear and branched polypropylenes have been examined in a similar manner[3,4]. Polypropylene containing long chain branches strain-hardened while a linear polypropylene did not. Thesedifferences in rheology make branched polymers beneficial forsome polymer processing operations, such as blow molding andfilm blowing.

Experimental. Homopolypropylene HG009 fromValtec (MFI = 7.0, 230°C, 2.16 Kg and Mw: 232,400 g/mol) from Indelpro SA de CV. (México), was modified by a reactive-extrusion process with the addition of a small amounts of cyclic peroxide and a multifunctional co-agent. The peroxide was Diethyl ketone Triperoxide (DEKTP) synthetized in our laboratories and multifunctional co-agents were Trimethylolpropanetriacrylate (TM), Trimethylolpropanepropoxylate (TMPPTA), Pentaerythritoltetraacrylate (PETA) and N'N'-1,3-Phenylene dimaleimida (FDM) were supplied by Aldrich Chemical Co. (Fig.1)

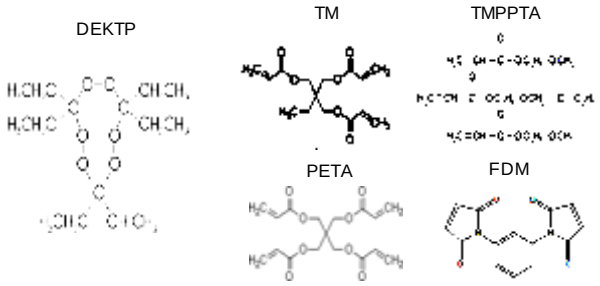

Figure 2.Initiator and co-agents used in PP modification

The PP melt modification was performed in an internal mixer Brabenderat 60 rpm, 180°Cfor 30min. Before 6 min of mixing,the co-agent was added and at 8 min the peroxide was added. The total reaction time was 30 min.The molar rate concentrations of the multifunctional co-agents/ peroxide were 10/1 (0.25/025 and 0.50/0.05).

In order to characterize the modified PP's, MFI, Mw, and gel content were measured. The chemical groups present in modified PP's were analysed by FTIR.

Results and discussion. Fig.2presents the evolution of the torque as a function of time for the system co-agent/peroxide = 0.5/.05 where all thesystems show a decrease of the torque with time except for TM and PETA, where the final torque is slightly increased.

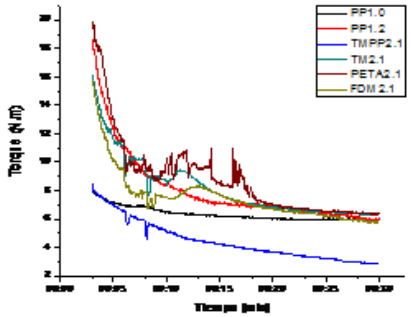

Figure 2. Evolution of the torque as a function of reaction time for the different evaluated systems

The results of MF, Mw, Mn and polydispersityindex (IP = Mw/Mn) are shown in the Table below.

System	[TPDEC] % mol	[Coagent] % mol	MFI (g/10 min)	MW (g/mol)	Mn (g/mol)	IP
PP1.0			7.31	223 331	53 843	4.14
PP1.1	0.025		7.42	210 143	56 043	3.74
PP1.2	0.050		15.285	206 294	49 542	4.16
TMPP1.1	0.025	0.25	15.266	217 285	51 715	4.20
TMPP2.1	0.050	0.50	31.33	181 489	63 236	3.69
TM1.1	0.025	0.25	12.537	214 538	54 050	3.96
TM2.1	0.050	0.50	9.89	289 399	71 430	5.25
PETA1.1	0.025	0.25	8.716	234 870	88 336	2.65
PETA 2.1	0.050	0.50	9.748	259 115	79 959	2.73
FDM2.1	0.025	0.25	14.66	188 846	52 014	3.63
FDM1.1	0.050	0.50	14.057	188 048	65 711	3.24

In all cases the MFI is higher than the pristine PP due to themacromolecular break up in the presence ofthe formed from the peroxide, attack the β hydrogen of PP. In the presence of the co-agents TM and PETA,the Mw increases with respect virgin PP. In these casesthe increase in MFI is related to the IP, since the low molecular chains gives a lubricant effect to the melt flow ofthe modified materials.A more extended discussion will be presented through the analysis of theglobal results in the extended paper.

Conclusions. It could be demonstrate that with theuse of the studied co-agents and in the presenceof the polyfunctionalperoxide DEKTP, the polypropylene radical functionalization can be achieved to obtain LCB PP.

Aggregates of Constant Size in Dilute Solutions of Associating Polyelectrolyte

Korchagina Evgeniya, Philippova Olga

Physics Department, Moscow State University, Moscow 119991, Russia

e-mail: phil@polly.phys.msu.ru

Introduction. Study of the self-assembly of associating polyelectrolytes in dilute solutions is quite important for the preparation of new functional polymeric systems. For instance, multichain aggregates of nontoxic, biocompatible and biodegradable polymers are very promising for various applications in pharmacy, biotechnology, cosmetics etc. In particular, it concerns aggregates formed by chitosan and its hydrophobic derivatives. In most of the papers the effect of the content of hydrophobes on the size of multichain aggregates of hydrophobically modified (HM) chitosan was studied. At the same time, the impact of such an important parameter as the main chain length of polymer on the dimensions of aggregates is not yet understood. Also, little is known about the aggregation numbers of multichain aggregates.

The aim of the present paper is to study the effect of the chain length of chitosan and HM chitosan macromolecules on the size and on the aggregation numbers of multichain aggregates formed in dilute aqueous solutions of these polymers.

Materials. Solutions of **c**hitosan and HM chitosan (containing 4 mol% of n-dodecyl side groups) with molecular weights of 55 000, 70 000 and 125 000 g/mol in 0.3M acetic acid and 0.05M sodium acetate.

Methods. Light scattering was used to determine the size of the aggregates, transmission electron microscopy (TEM) was used to visualize the aggregates.

Results and Discussion. In the dilute regime the solutions of chitosan were investigated by light scattering. For all the samples under study the correlation functions $g^{(1)}(q,t)$ of polymer concentration fluctuations show a bimodal relaxation behavior with fast and slow relaxation modes, which are due to the translational diffusion of unimers and aggregates, respectively.

It was observed that the hydrodynamic radius $R_{h\ agg}$ of aggregates does not depend on the length of individual chitosan chains. The same behavior is observed for the gyration radius $R_{g\ agg}$ of aggregates obtained from static light scattering data. To the best of our knowledge, this is the first observation of aggregates keeping a constant size independently of the length of individual chains in any associating polyelectrolyte solution. Such behavior is due to the presence of unscreened charges on the polymer chains. For dilute solutions of associating polyelectrolytes the equilibrium mean-field theory developed by Potemkin et al. predicts[1] that the size of aggregates is determined only by the content of associating groups and charged units as well as by the fraction of counterions escaped from the aggregate. At the same time, the size of aggregates should be independent of the chain length of individual macromolecules.[1] This result follows from the electrostatic nature of stabilization of the aggregates and is related to the classical Rayleigh problem of the charged droplet: a spherical droplet whose charge exceeds some critical value disintegrates into a set of smaller droplets of a certain size carrying charge lower than the critical one.

At the same time, the aggregation numbers of the multichain aggregates drop with increasing length of individual polymer chains,[2] which is also in perfect agreement with the theoretical predictions.[1] This result can be explained as follows. The energy of association is determined by the number of attracting groups. As shorter polymer chains have smaller amount of associating groups, their aggregates should include more chains in order to get a necessary gain in the energy of association.

The aggregation behavior for chitosan and HM chitosan is rather similar, but the size and the aggregation numbers of aggregates in HM chitosan are much larger than in its unmodified precursor, i.e. the incorporation of alkyl moieties into chitosan promotes the aggregation.[2]

The R_g/R_h ratio observed in aggregates of HM chitosan (0.58-0.59) lies within the range 0.3-0.6 characteristic for microgels that have a surface layer with much lower density than the core. Such structure of aggregates is confirmed by TEM data.[2]

Conclusions. Intermolecular association in dilute aqueous solutions of chitosan and HM chitosan of different molecular weights was studied by light scattering. It was observed that with increasing length of individual chains the aggregates keep constant size and almost constant number of hydrophobic and charged units; simultaneously, the content of polymeric chains in one aggregate decreases. When comparing the association phenomena in chitosan and HM chitosan, one can conclude that the introduction of hydrophobic substituents leads to larger and denser aggregates with higher content of polymeric chains. Analysis of light scattering and TEM data suggests that both in chitosan and HM chitosan the aggregates can be regarded as highly swollen nanogels with more dense core and loose shell with some dangling chains on the surface. Unique combination of properties of chitosan (biocompatibility, biodegradability, positive charge, nontoxicity, and bioadhesiveness) makes such aggregates very promising for the use as nanosize drug carriers.

jfferan@ugr.es

Introduction

Molecular imprinting is a method of inducing molecular recognition properties in synthetic polymers in response to the presence of a template species during formation of its three-dimensional structure. The show a lot of advantages, however the application of MIPs for optical sensors was only successful in a few cases due to the difficulty of its implementation in optical devices.

The incorporation of magnetic properties allows the *in situ* formation of sensor spots by magnetic separation and, consequently, optical readout from the outside.[1] Several magnetic MIPs have been synthesized and characterized, highlighting that both the amount and distribution of magnetite are essential for producing a good material;[2] evidencing that well-organized structures are needed to design magnetic-MIP which can be used as optical sensors. Thus, in this work we propose a novel strategy to design well-organized, highly magnetic MIP particles to be used as optical sensors.

Materials and Methods

For the synthesis of Magnetic hybrid nanoparticles encapsulated by EDMA/MMA (EDMA/MMA-Fe_3O_4-OA), 2 g of magnetite coated with oleic acid (Fe_3O_4-OA) were dispersed in 5 mL of n-heptane and added to 400 mL of milli-Q water containing 250 mg of SDS. The ice-cooled mixture was sonicated for 20 min in a high energy sonifier. The resulting miniemulsion was transferred slowly to a double-necked flask containing 1.5 mL of 40 wt% MMA and 60 wt% EDMA. The mixture was stirred during 2 hours at room temperature. Then, 180 mg of KPS was added to start the polymerization and the reaction system was heated to 65 ºC under a gentle stream of nitrogen.

Magnetic-MIPs were synthesized by solution polymerization (sMIP), emulsion polymerization (eMIP) and precipitation polymerization (pMIP) using 4-VP as functional monomer, DVB as crosslinker, pyrene as template, AIBN as radical initiator and EDMA/MMA-Fe_3O_4-OA as magnetic seeds.

Results and Discussion

The first experiment consisted in the study of the effect of amount and distribution of magnetite over the optical recognition of pyrene. Thus, mag-MIPs with different amounts of Fe_3O_4-OA (1, 2 and 5 wt%) were prepared by solution polymerization (sMIP) and emulsion polymerization (eMIP). We determined that 1) at least 5 wt% Fe_3O_4-OA are necessary; 2) Magnetite had to be homogeneously distributed among the single particles and phase separation had to be avoided; and 3) Fe_3O_4-OA had to be isolated from the MIP in order to avoid filter effects and self-absorption of luminescence emission.

Therefore, we proposed the synthesis of new magnetic microparticles of MIPs in which the magnetite is located inside the particle and the MIP is covering these magnetic cores. It allows the use of a higher amount of magnetite and the isolation between magnetite and sensing material. They were prepared in two steps: 1) magnetic nanoparticles of Fe_3O_4-OA were encapsulated in a crosslinked polymer (EDMA/MMA) by a miniemulsion polymerization; 2) Then, these magnetic particles were embedded into the structure of a MIP which was prepared by precipitation polymerization (see Fig. 1). The preparation of these particles is simple and provides a sensing material which is highly magnetic (approximately 5 wt%) and sensitive (detection limit of 7 ng mL^{-1} of pyrene in water). In addition, this material shows a very high affinity characteristic (MIP/NIP ratio of 2.41) and very high selectivity; none of the tested luminescent PAHs (ACE, FLU, ANT, BaP and BaA) interfered with the determination of pyrene.

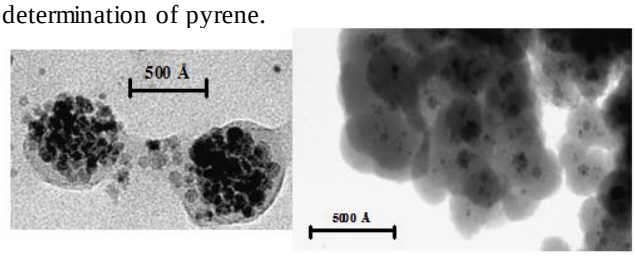

Fig. 1. HREM images of EDMA/MMA-Fe_3O_4-OA and mag-MIP produced by their encapsulation.

Conclusions

In this work we introduce a new synthetic route to a well-controlled magnetic imprinted material based on a two-step process: Firstly, the incorporation of the magnetite into a matrix which does not negatively influence the molecular imprinting phenomenon, and secondly, the embedding of these magnetic nano precursors in the MIP structure which can be used for optical sensing. To the best of our knowledge, this is the first time that a magnetic MIP can be used as optical sensor.

Introduction: Carbon nanoparticles are thought to be very interesting objects as fillers for polymer composites. It is caused by their high mechanical characteristics, electrical and thermal conductivity. In this term it is important to consider these particles as fillers for large-scale polymers such as polypropylene. As the most of polymer goods manufacturers prefer using masterbatch as the input material it is interesting to analyze the effect of masterbatch dilution on the properties of carbon nanocomposite that plays a key role in further commercial application. The goal of this work is to investigate the effect of dilution on the structure, mechanical and thermal properties of the result composites depending on particle shape, size and volume loading.

Materials: Two types of carbon nanofillers (multiwall carbon nanotubes – MWNT and exfoliated graphite nanoplatelets of different lengths – xGnP™ with fiber-like and plate-like particle shape respectively) have been explored. Polypropylene was used as matrix.

Methods: Nanocomposites were fabricated by melt mixing on two-roller mixing chamber. Materials with maximum filler volume loading about 10% were obtained as a masterbatch and then were diluted to 0,5, 2,5 and 5 vol.%.

Results and Discussion: It was found that dilution of composites based on carbon nanotubes leads to shortening of the nanotube length that crucially effects on the mechanical properties of these composites. Reinforcing effect of MWNT in diluted composite with filler loading 5 vol.% is ~8% lower than in straight-mixed one. Relative tensile moduli of masterbatch-derived materials based on xGnP(5) with less length well correlate with those of straight-mixed composites. However Young's modulus of composites with xGnP(10) slightly increases after dilution that can indicate the increasing of particle quantity. In dynamic conditions, the relative storage modulus of masterbatch-derived composites based on both graphite nanoplatelets and carbon nanotubes rise up with temperature to 50-60°C and then slightly decrease. In case of xGnP(5), the masterbatch dilution is accompanied by the glass temperature shift in the higher temperature area caused by decreasing of polymer chains mobility.

This work concerns the recent development and characterisation of a new polysiloxane material, which is used in the application of the integration of optical interconnections on printed circuit boards. To produce optical interconnects, two-photon photopolymerisation, induced by a femto-second laser is utilised in the fabrication of three-dimensional optical waveguides, embedded in a silanol terminated polysiloxane matrix material. The high photon density obtained in the focus of the laser results in the polymerisation of acrylate functional groups, which are attached to a polysiloxane backbone, causing an increase in the refractive index. A silanol terminated polysiloxane, cured by condensation reaction at room temperature in the presence of a Sn catalyst, has been investigated for this application. The material needs to fulfill a number of requirements to be a suitable candidate in this field. This includes having a low curing temperature, a high refractive index contrast between the matrix cladding material and the written waveguide core and the material must have sufficient flexibility and high thermal stability to withstand harsh processing conditions. High chemical and long-term stability is also required. The material currently being investigated has been characterised by FTIR spectroscopy, simultaneous thermal analysis and the refractive index of the cladding and core material was determined by ellipsometry measurements. Two Photon Absorption (TPA) material testing has been carried out on thin films to produce 3D waveguide structures with cross sections of up to 40 µm. The waveguides are characterised by phase contrast microscopy and cut back investigations to determine the optical losses. Optical interconnects have also been fabricated on specially designed printed circuit boards, with waveguide structures aligned correctly between optoelectronic components resulting in high photocurrents at the photo diodes. Recently produced demonstrators, consisting of optical interconnects mounted on fully flexible substrates, show low optical losses, which remain stable even at elevated temperatures and during long term storage. Room temperature curing enables fast and straightforward material processing, with the matrix material also being compatible with a specific two photon photoinitiator. This recently developed flexible polymeric material is highly suitable for applications in two photon processing of three dimensional optical waveguides

Bioinspired Polymeric Foam-Lattice Composite Combining Stochastic and Periodic Systems at two Different Length Scales: Lightweight Materials for Absorption Applications

rrinaldi@engineering.ucsb.edu

Abstract: Many systems found in nature are hierarchical multi-scale materials in which periodicity and porosity are prominent features [(1)]. Such hierarchy suggests that different mechanisms are operative at distinct length-scales, potentially enhancing mechanical performance beyond that which could be obtained in simpler systems. Inspired by examples provided by nature, we aim to develop, characterize and understand hierarchical composites combining periodic lattices with stochastic foams.

The system of present interest combines a periodic polymer lattice at the mm scale with a stochastic foam at the μm scale, yielding a hierarchical co-continuous composite. Stochastic systems (*i.e.* foams) are well-known for exhibiting enhanced absorption performance whereas periodic lattices are mostly designed to improve strength resistance [(2)]. The system developed here aims to combine those advantageous effects in designing lightweight materials with enhanced mechanical properties.

The lattice is produced via a self-propagating polymerization process [(3)] and is then filled with polyurethane foam. The final composite and its constituents are illustrated in the figure1 below:

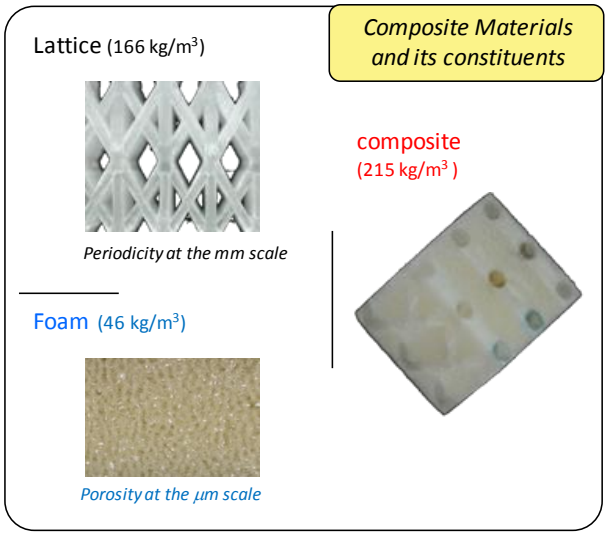

Figure 31: the composite designed consists of a lattice which interstices are filled with low density polyurethane foam.

The study focuses specifically on the efficacy of this composite structure on energy absorption capability. To this end, experimental measurements have been made of the compressive stress-strain response and parametric numerical studies using finite element analysis have been instrumental in clarifying the key design parameters of the lattice and in guiding the optimization process. Special cautions are devoted to the intrinsic mechanical response of the polymeric constituents: mainly, the strain rate sensitivity of both constituents [(4)] and its effect on the composite performance are under investigation.

In recent years, the interest in dye-functionalized responsive polymers, which respond to changes in the environmental conditions, strongly increased. Such 'smart' polymers are used for the development of new sensory materials for a wide range of applications in various fields, such as biomedical or optical sensing.[1] The approach allows simple and fast detection of, e.g. the temperature by measuring the absorbance or fluorescence of the solution. The high sensitivities arise from the incorporated solvatochromic dye molecules, which respond to minor local environmental changes that occur upon the temperature induced polymer phase transition. This phase transition is called lower critical solution temperature (LCST) behavior when the polymer precipitates upon heating. Recently, it was reported by our group that combining a solvatochromic dye with a temperature-responsive polymer leads to a color change upon changing the temperature, which can be used for optical sensing.[2]
Here, we present the synthesis of well-defined di(ethylene glycol) methyl ether methacrylate (DEGMA) based responsive copolymers by the reversible addition fragmentation chain transfer (RAFT) polymerization method. In this copolymerization we introduced a dye-functionalized monomer into the polymer backbone. The dye-functionalized monomer is based on 4-hydroxythiazoles, with a non classical chromophore structure similar to the luciferin dye of glowworms.[3] The obtained polymers revealed PDI values below 1.3 and were fully characterized and will be discussed in detail in the present contribution. Furthermore, the polymeric sensor was studied with temperature controlled UV/Vis and fluorescence spectroscopy and the effect of the polymer chain collapse upon passing the LCST transition on the attached dye emission and absorption behavior will be discussed in detail.
These non-classical chromophores show interesting photophysical properties and may open avenues for the construction of new multifunctional polymers.

jlarias@ugr.es

Introduction. The efficacy and safety of anticancer therapy is conditioned by the very high drug doses needed to obtain an efficient therapeutic activity, the poor pharmacokinetics of chemotherapy molecules, and the frequent multi-drug resistance of tumor cells. The application of nanotechnology strategies in oncology (nano-oncology) has revolutionized the transport of drugs to cancer, allowing the appearance of new treatments with improved specificity [1]. For instance, magnetic nanoparticles (NPs) have shown their capability to assure a controlled and efficient accumulation of anticancer drugs into the tumor mass. As well, these nanoplatforms can also result in a triggered drug release into the targeted site [2].
In this work, we describe the formulation of magnetic core/shell NPs made of magnetic nuclei (magnetite, Fe_3O_4) and a polymeric shell (chitosan). An extensive physicochemical characterization of this magnetic nanoplatform has been done. More interestingly, we have further carried out an *in vivo* proof of concept on the possibilities in controlling the biological fate of the magnetic NPs by the use of an external magnetic field (accumulation at the tumor periphery investigated by Prussian blue staining).

Materials and Methods. Superparamagnetic Fe_3O_4 NPs (size ≈ 10 nm) were prepared by chemical co-precipitation [3]. The formulation of magnetically responsive Fe_3O_4/chitosan nanocomposites was based on the coacervation method for the synthesis of chitosan NPs [4]. Briefly, chitosan (1 %, w/v) was dissolved in an aqueous solution of acetic acid (2 %, v/v) containing 1 % (w/v) pluronic® F-68, and 0.75 % (w/v) Fe_3O_4. 12.5 mL of a solution of Na_2SO_4 (20 %, w/v) were added dropwise to the chitosan solution under mechanical stirring. Stirring was continued for 1 hr to obtain the aqueous suspension of core/shell NPs. The suspension was then subjected to a cleaning procedure by magnetic separation. Mean particle size was determined in triplicate by PCS. To confirm the size measurements, the nanocomposites were checked by HRTEM. The magnetic properties of the Fe_3O_4/chitosan NPs were determined by using a vibrating magnetometer.
Animal experiments were done according to the French and European Community guidelines for the care and use of experimental animals. DBA/2 mice (4 weeks old) weighing ≈ 15 g were used for this study. L1210 *wt* murine subcutaneous tumor model was developed by subcutaneous injection of the exponentially growing L1210 *wt* leukemia cells in suspension containing 30 % growth factor reduced Matrigel™. When mice developed palpable tumors, they were randomly divided into 3 groups of 6 each, i.e. untreated, treated with magnetic NPs, and treated with magnetic NPs under the influence of a 400 mT extracorporeal magnetic field. The accumulation of the NPs was qualitatively evaluated in terms of iron content using Prussian blue staining technique [5].

Results and Discussion. The coacervation method allowed the formation of well-stabilized Fe_3O_4/chitosan nanocomposites with an average diameter of 190 ± 30 nm and a narrow size distribution (polydispersity index: 0.071). HRTEM microphotographs of the magnetic composites proved that the iron oxide nuclei were covered by a polymeric shell. No presence of aggregates or bulky sediments was observed. In addition, no appreciable change in the size of the magnetic colloid was detected after 2 weeks of storage at 4.0 ± 0.5 ºC in water.
The very good magnetic responsiveness of Fe_3O_4/chitosan nanocomposites was quantitatively investigated by the hysteresis cycle, and qualitatively confirmed by direct observation and microscope visualization of the performance of nanocomposite suspensions under exposure to a 400 mT permanent magnet.
Tumor sections of the mice treated with Fe_3O_4/chitosan NPs without exposure to magnetic field revealed a negligible presence of the iron content as indicated by faible staining. On the contrary, tumor sections of mice treated with the magnetically-guided Fe_3O_4/chitosan NPs showed significant accumulation of iron, mainly deposited at the tumor periphery, where the external magnet was placed.

Conclusions. We have demonstrated that it is possible to reproducibly coat Fe_3O_4 NPs with a shell of chitosan. Prussian blue staining investigation of the tumor biopsies clearly evidenced their accumulation at the tumor site. The very important magnetic responsiveness of Fe_3O_4/chitosan (core/shell) NPs opens promising possibilities to improve drug delivery to cancer.

Introduction

Since the 60's, polyurethanes have been playing a key role in the development of biomedical devices due to their versatility, mechanical properties and excellent tissue compatibility. Polyurethanes have been extensively studied as biodegradable and/or injectable materials and have found several applications. Polyurethane networks (PUN) are synthesized by incorporating at least one reactant with functionality higher than 2, and depending on their composition PUN can be hydrophilic/hydrophobic, elastomeric/rigid and degradable/non-degradable.

Although linear segmented polyurethanes and multiblock copolymers with controlled hydrophilicity have been extensively studied, investigation on hydrophilic crosslinked polyurethanes is limited.

PUN composed of hydrophilic and hydrophobic segments can provide controlled swelling and allow homogeneous dispersion of drugs. For this reason, the characteristics of PUN are ideal for the design of controlled drug release systems. However, the use of polyurethanes in this field remains largely unexplored.

In this work, a series of crosslinked poly(ester-ether urethane)s with a range of hydrophilic character were synthesized. The effect of composition-morphology on the PUN swelling behavior and their application as drug-delivery vehicles has been investigated.

Materials and methods

Initiated by glycerol, poly(ε-caprolactone)s (PCL triol) were synthesized by ring-opening polymerization of ε-caprolactone. Molecular weight (M_n=1060 and 3130Da) were determined by titration of hydroxyl groups. Commercial PCL triol (M_n≈900Da), polyethylene glycol (M_n≈400Da), 1,6-hexamethylene diisocyanate (HDI) and DMAc were purchased from Aldrich. Prior to reaction, all polyols were exhaustively dried under vacuum. DMAc was dried over molecular sieves and distilled under reduced pressure. Dibutyltin dilaurate was used as catalyst in PUN synthesis.

Preparation of PUN: Predetermined amounts of PCL triol, PEG and catalyst were dissolved in DMAc. After adding HDI the reactive mixture was vigorously mixed and degassed under reduced pressure. Films were prepared by casting from the degassed colorless mixtures and allowed to cure at 60ºC for 24 h. Although the composition of PUN was changed, they all comply with the following molar ratio: $([OH]_{PCL\ triol} + [OH]_{PEG}) \times 1.05 = [NCO]_{HDI}$. The polyol component contained 10, 30, 50, 70, 90 and 100 % by weight of PCL triol. Samples were coded as P*X*-*Y*, where *X* and *Y* correspond to PCL triol and PEG mass percentages, respectively.

Results and discussion

Three series of PUN (PUN_{900}, PUN_{1060} and PUN_{3130}) with different PCL and PEG content were successfully synthesized. Infrared analysis confirmed the complete reaction of isocyanate groups. In all cases, sol content in PUN increased with the increase of PEG. Networks having PEG content higher than 70% underwent partial dissolution during extraction.

The DSC analysis revealed the presence of a single T_g, indicating that PUN consisted in a non-segmented polymeric network. The absence of a long chain macrodiol avoided the formation of hard/soft microphases. In all series, PUN exhibited T_g values higher than the starting PCL triol with T_g increasing with PEG content.

PUN_{1060} P100-0 displayed a small melting endotherm, whereas the other samples of this series were amorphous. PUN_{3130} series presented lower T_g values due to its semicrystalline character. Both series displayed the same T_g value for P10-90 samples, indicating that networks with low PCL content had a thermal behavior not dependent of PCL chain length. In PUN_{900} series all the samples were amorphous, showing T_g values almost constant with composition.

All the PUN series exhibited close equilibrium swelling values for the same PEG content. Equilibrium was achieved in approximately 1 h. The water uptake, as expected, was controlled by the content of hydrophilic monomer and it was not dependent on the chain length or crystallinity of the hydrophobic monomer. For PUN_{1060} P30-70 hydrolytic degradation was observed after 3 h.

Finally drug release capacity was studied by loading some PUNs with paracetamol. Drug release profiles showed paracetamol was released progressively within 8-12 days depending on PUN formulation.

Conclusions

Polyurethane networks having non-segmented structure and different hydrophilic-to-hydrophobic ratio were synthesized. Water uptake was controlled by the PEG content, with star-shaped PCL chain length not affecting the swelling degree. Based on experimental results, PUN with varying degrees of hydrophilicities have considerable interest as non-toxic controlled drug delivery devices in the form of implants (i.e. depot systems for localized drug delivery), and antimicrobial coatings. Profiles of paracetamol release have shown promising results.

Double Hydrophilic Copolymer Poly(ethylene oxide)-*block*-poly(2-ethyl oxazoline) as a Carrier of Cobalt bis(dicarbollide) Conjugates Designed as HIV Protease Inhibitors

Introduction: It has been recently discovered that cobalt bis(dicarbolide) and its derivatives act as potent inhibitors of HIV protease.[1] Since the metallacarborane conjugates are sparingly soluble in water, suitable drug delivery carriers are needed. We can take advantage from the fact that cobalt bis(dicarbollides) interact with water soluble polymer poly(ethylene oxide), PEO, via unusual dihydrogen bonds and insoluble nanocomposite forms as a result.[2] In order to prepare stable polymeric nanoparticles with embedded metallacarboranes, we chose biocompatible double-hydrophilic diblock copolymer poly(ethylene oxide)-*block*-poly(2-ethyl oxazoline), PEO-PEOX.

Materials: Sodium salt of metallacarborane anion [3-cobalt(III) bis(1,2-dicarbollide)](-1) was a kind gift of Dr. Bohumír Grüner and Dr. Jaromír Plešek (Institute of Inorganic Chemistry, ASCR, Řež near Prague). Poly(ethylene oxide) was purchased from Fluka (M_w is 41.5×10^3 and PDI 1.10). Poly(2-ethyl-2-oxazoline) was purchased from Aldrich (M_w is 50.0×10^3). Poly(ethylene oxide)-*block*-poly(2-ethyl oxazoline) was purchased from Polymer source, Inc. (Dorval, Quebec, Canada), (M_w of PEO and PEOX: 5.0×10^3 and 6.5×10^3, respectively, PDI 1.10).

Results and Discussion: First we studied nanoparticles based on interaction of PEO-PEOX with parent sodium cobalt bis(dicarbollide) to elucidate their mutual interaction. In NaCl solutions with sufficiently high metallacarborane content, we observed stable spherical nanoparticles with radius 69 nm. Their structure was studied by means of light scattering, AFM, cryo-TEM and 1H NMR (the cryo-TEM micrograph is shown in Figure 1). Thermodynamics during their formation was studied by ITC.

As the second step, we mixed PEO-PEOX solutions differing in NaCl concentrations with several metallacarborane-based HIV protease inhibitors, which are almost insoluble in water. The increase in their solubility was estimated spectrophotometricaly. The nanoparticles were characterized by means of light scattering and AFM.

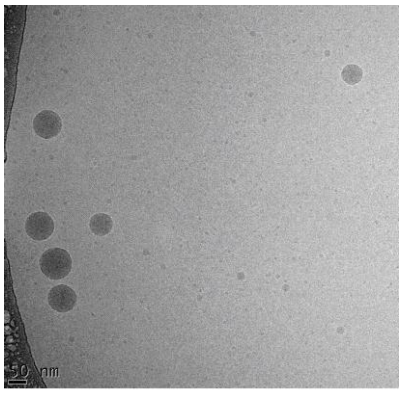

Figure 1: PEO-PEOX/metallacarborane nanoparticles imaged by cryo-TEM technique.

Polyesters and Polyesterimides Containing Phosphaphenanthrene Bulky Groups for High Performance Applications

Diana Serbezeanu, Tăchiţă Vlad-Bubulac, Corneliu Hamciuc, Magda Aflori

"Petru Poni" Institute of Macromolecular Chemistry, Aleea Gr. Ghica Voda 41A, Iasi-700487, Romania

e-mail: diana.serbezeanu@icmpp.ro

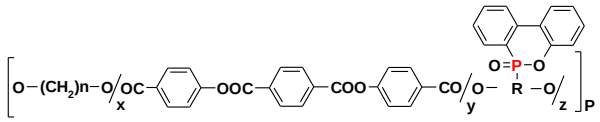
Introduction: Thermotropic liquid-crystalline polymers (LCPs) have generated much interest in material science in recent years because of their various industrial and commercial applications, such us optical devices and engineering plastics [1]. The main chain wholly aromatic thermotropic polyesters and polyesterimides have received considerable interest for technological applications because of their good thermal stability, excellent chemical resistance, high glass transition temperatures, in addition to good processing and mechanical properties. In order to design aromatic polymers with lowered melting transitions, which allows appearance of the liquid crystalline phases below the temperatures corresponding to the thermal degradation or isotropization, several approaches have been taken into consideration: copolymerization, insertion of flexible spacer, use of laterally attached bulky groups, introduction of bent or crankshaft sequences etc. [2]. Introduction of lateral bulky groups to *p*-oriented monomers has also been applied to lower the melting points of LCPs. The incorporation of phosphaphenanthrene bulky structure (9,10-dihydro-9-oxa-10-phosphaphenanthrene-10-oxide (DOPO)) into polymers resulted in polymers with good solubility, resonable thermal stability, good adhesion, low birefringence etc. [3,4]. In addition, phosphorus-containing polymers meet the requirements of low toxicity and low smoke during burning for environmental and health considerations. In the present work we describe the results of the polycondensation of different aromatic bisphenols containing phosphaphenanthrene groups with a diacid chloride containing two preformed ester groups and various aliphatic diols.

Materials and Methods:

Terephthaloyl-bis-(4-oxybenzoyl-chloride), 2-(6-oxido-6H-dibenz<c,e><1,2>oxaphosphorin-6-yl)-1,4-naphthalene diol, 2-(6-oxido-6H-dibenz<c,e><1,2>oxaphosphorin-6-yl)-1,4-benzene diol and 1,4-bis[N-4-hydroxyphenyl)phthalimidyl-5-carboxylate]-2-(6-oxido-6H-dibenz<c,e><1,2>oxaphosphorin-6-yl)-naphtalene were synthesized in our lab. The aliphatic diols, 1,3-propanediol, 1,4-butanediol, 1,5-pentanediol, 1,6-hexanediol and 1,12-dodecanediol, were purchased from commercial sources. The molar ratio of aromatic bisphenol to aliphatic diol was varied to generate copolyesters and copolyesterimides with tailored physicochemical properties, structure-properties relationships being established.

Results and Discussion:

The polymers were synthesized by polycondensation reaction at high temperature. Their structure was confirmed by FT-IR, ^{1}H NMR, ^{31}P NMR spectroscopy and elemental analyses. The general structure of the polymers is depicted in following image.



The thermo-oxidative stability of the polymers was evaluated by TGA in air at a heating rate of 10 °C min^{-1}. TGA revealed that the polymers were stable up to 350°C. The effect of the phosphorus content on the thermal properties and the flame retardancy was evaluated by means of thermogravimetric analysis (TGA), TGA-FTIR, and scanning electron microscopy. The char yield at high temperature increased by increased the content of phosphorus-containing bisphenol. The effect of the aliphatic content on the liquid crystalline behavior was investigated by polarized light microscopy, differential scanning calorimetry, and X-ray diffraction. The influence of the content of the aliphatic unit on the phase behavior of the polymers has been examined. It has been found that the transition temperatures become smaller by increasing the aliphatic content. Smectic phases were observed from polymers with a higher content of aliphatic moieties when polymers were heated upon their mesomorphic transition. Broad mesophase temperature ranges were observed for these polymers, making them interesting from practical point of view. The degree of crystallinity increased upon increasing the content of aliphatic moieties.

Conclusions:

A comprehensive study on the synthesis and on the relationship between the aliphatic/aromatic ratio, polymer liquid crystalline phase structure and thermo-oxidative stability of thermotropic liquid crystalline aromatic-aliphatic polymers derived from various ratios of phosphaphenanthrene-containing bisphenols, various aliphatic diols, and terephthaloyl bis-(4-oxybenzoyl-chloride) is presented.

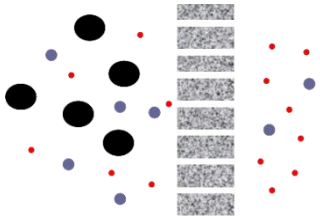
From Polymers to Well-Patterned Membranes by Mimicking the Nature

Annarosa Gugliuzza

Institute on Membrane Technology-National Research Council (ITM-CNR),
Via P. Bucci, Cubo 17/C, I-87030 Rende (CS), Italy

a.gugliuzza@itm.cnr.it

Introduction: The membranes are well-structured films with associated separation, catalysis, controlled storage, (bio)conversion, sensing, and (bio)mimetic properties.

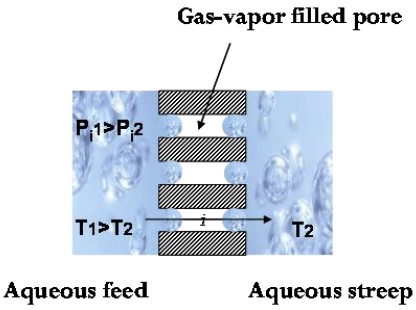


Representative scheme of a permselective porous membrane

Despite many efforts have been done over the years, the building up of complex and sophisticated polymeric structures at the nanometer scale remains a current challenge for many membranologists.
The ambitious target is to decide on nanoscale any desired macroscopic interplayed membrane properties such as transport and surface functions.
To select ideas and principles directly from nature and apply them to the membrane design takes advantage over conventional manufacturing procedures, because controlled chemical composition and tight placement of various components are attractively allowed at the nanometer and micrometer length scales, yielding programmable properties.
Materials: Poly(ethersulphone) (*PSU, Solvay-Solexis, USA*) and modified poly(etherketone)s (*PEEK-WCs, Department of Chemistry, IFM, University of Turin, Italy and Chang Chung Institute, Cina*)
Results and Discussion: Here, we propose an advanced bio-inspired procedure to build-up high-definition polymeric membranes according to a bottom-up approach. Water droplets are used as natural building blocks to template polymeric patterns through self-assembly events. Droplets are caused to arrange in semi-crystalline lattices by thermocapillary and Marangoni forces, yielding interfaces that challenge lithographic precision.
Depending on the operating conditions, the dynamics of the water droplets can be controlled and directed towards the formation of polymeric patterned architectures that exhibit well-defined packed pore geometry, uniform pore size and spatial distribution.

Representative scheme of membrane pore formation

The singular topology of the polymeric films causes very high interfacial area and surface roughness, which efficiently affect the final transport and surface properties of the membranes.
These new polymeric interfaces well meet the requirements of an advanced branch of the membrane science: the membrane contactor technology. When equipping a contactor device, these 3D well-ordered membranes exhibit ability to establish long-term stable interfaces between two aqueous phases at the entrance of each single pore, causing transfer of large amount of water vapour from one phase to the other.



Scheme of a membrane contactor

Higher performance has been observed for these polymeric interfaces than commercial membranes. The reason is the highest surface porosity enabling simultaneous events to occur in all region of the membrane surface.
The surface porosity causes also high surface roughness responsible for enhanced hydrophobicity, yielding controlled mutual liquid-membrane interactions at the entrance of the pores. The intrusion of liquid inside the channels is prevented, resulting in long term stability of the interface and long operational time.
Conclusions: Regular polymeric membranes with structural features and surface properties have been realised by a bio-inspired approach. High-definition architectures have been constructed by exploiting the ability of water droplets to template liquid films through spontaneous rearrangement in ordered arrays. Macroscopic properties including transport and water repellence have been programmed through the control of structural features on nanoscale. Ideal interfaces for advanced membrane unit contactors have been realised.

Preserving Cytokines' Stability and Activity: A Novel Controlled Release Polymeric Drug Delivery Approach

Husam M Younes[1,2] *& Mohamed Shaker*[2]

[1]Pharmaceutics & Polymeric Drug Delivery Research Laboratory, Department of Pharmaceutical Sciences, College of Pharmacy, Qatar University, Doha, Qatar. Email: husamy@qu.edu.qa

[2]School of Pharmacy, Memorial University of Newfoundland, Health Sciences Center, St. John's, NL, Canada

Introduction: The application of therapeutic proteins and cytokines like Interleukin-2 (IL-2) for long-term, localized delivery has been hindered by a lack of a delivery device that releases active protein at a concentration within their therapeutic window [1]. The purpose of this oral presentation is to report on the osmotic-driven controlled-release from novel visible-light photocrosslinked biodegradable elastomeric devices recently designed in an attempt to overcome this limitation.

Materials and Methods: All chemicals were purchased from Sigma-Aldrich and used as received. Novel biodegradable and biocompatible poly (decane-co-tricarballylate) [PDET] elastomers were synthesized by polycondensation reaction between tricarballylic acid and alkylene diols, followed by acrylation and photo-curing (Figure 1A) [2-3]. IL-2 loaded micro-cylinder and disk-shaped elastomeric devices were prepared by intimately mixing IL-2 lyophilized powder with the acrylated prepolymer prior to photocrosslinking (Figure 1 B) [4]. IL-2 release was analysed through using IL-2 ELISA system and the *in vitro* bioactivity of released IL-2 was assessed using C57BL/6 mouse cytotoxic T lymphocyte. The influence of various parameters such as the elastomer crosslinking density, the volumetric drug loading percentage and the incorporation of osmotic excipients like trehalose on the release kinetics of the drug was also examined.

Results and discussion: The disk-shaped specimens showed faster IL-2 release profiles than microcylinders, with drug release proceeding via typical zero-order release kinetics. The increase in the device's surface area and the incorporation of trehalose in the loaded lyophilized mix increased the IL-2 release rate. As well, it was shown that the decrease in the degree of prepolymer acrylation of the prepared devices increased the IL-2 release rate. Cell based bioactivity assays showed that IL-2 released over a period of 28 days, retained more than 94% of its initial activity. These bioactivity results represent a highly significant improvement over the other previously published data provided with a quantitative analysis of the actual percentage of bioactive IL-2 released during the period of the release study.

Conclusion: The novel PDET elastomeric drug delivery systems demonstrated to be promising as protein drug delivery vehicles for localized and sustained IL-2 immunotherapy.

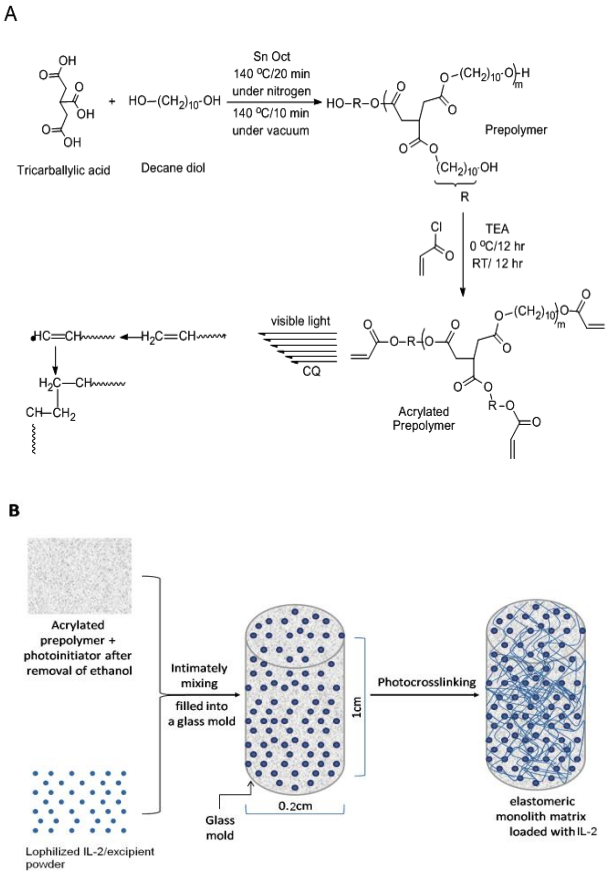

Figure 1. A schematic representation of the synthesis, acrylation and photo-crosslinking of the PDET elastomers. The step-reaction polymerization of tricarballylic acid and decane diol was catalyzed by stannous 2-ethylhexanoate. The acrylation process was done by reacting with acryloyl chloride in the presence of triethylamine. To photo-crosslink, acrylated prepolymer was mixed with the photoinitiator, poured into a sealed glass mold and crosslinked under visible light (40mW/cm2).

Phase-Morphology and Structure of Model Fullerene - Polymer Materials

Bucknall@gatech.edu

Introduction Organic or polymer based photovoltaic devices promise solar technologies that are inexpensive enough to be widely exploited and therefore provide a significant fraction of the Nation's future energy needs. Nanoscale heterojunction systems consisting of fullerenes dispersed in conjugated block copolymers are promising materials candidates for achieving high performance devices. The fullerenes can be functionalized to change their electronic properties or to alter their interactions with the different components of the block copolymer. The block copolymer ratio or composition may be varied to produce different microphase morphologies and these morphologies may be further altered or oriented by the choice of processing conditions or substrates. This versatility is also a challenge to the rational exploration of these materials because the number and types of possible variations are far too large to investigate without predictive models or well-established data and guidelines to expected behavior.

Approach In order to guide the use of electron acceptor fullerenes in these systems we are using multi-scale molecular modeling coupled with neutron and X-ray scattering to determine the structure behavior of model polymer-fullerene mixtures. Neutron scattering is particularly useful for these types of studies since the fullerene generally have a high scattering contrast with respect to most polymers. This natural contrast, enhanced in some cases by careful selective deuteration allows us to carefully probe the atomic and molecular interactions in these complex systems.

Results and Discussion An initial model system we investigated was vinyl polymer and C_{60} blends. This system allowed us to probe the molecular interactions between fullerenes and polymers. We used scattering methods to determine miscibility as well as computational density functional theory (DFT) methods to evaluate binding energies. These studies have shown the role of π-π interactions in controlling interactions between the polymer and the fullerene. We recently we have been studying the phase behavior in model conjugated polymer-fullerene blends. This paper will describe the latest results in predicting miscibility and ultimately the phase behavior in such blends. The influence of processing conditions on the phase behavior and molecular structure in blends of, for instance P3HT and PCBM, is known to directly affect electronic performance, such as photovoltaic efficiency. In our studies we are exploring a number of approaches to control phase domain structure and orientation, using for instance block copolymers, and control of surface interactions.

Our neutron reflectivity measurements have shown that processing time scales of thin film spinning from dilute solutions can affect the through thickness thin film composition of polymer-fullerene blends (see Figure 1). These data show that segregation and selective absorption to the substrate from the polymer-fullerene solution is time dependent and can dominate the composition profile.

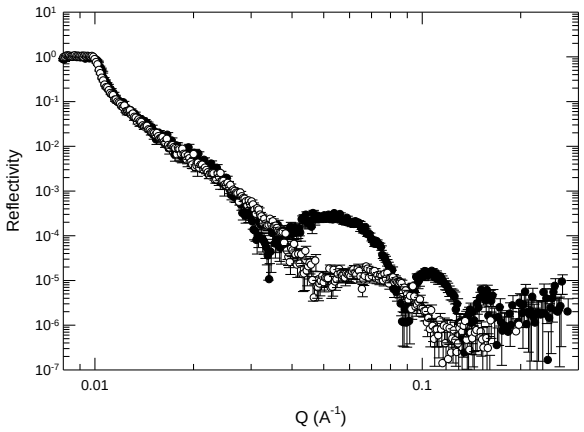

Figure 1: *NR plots of films of PS-C_{60} blends spun immediately after (open circles) and 5 minutes after solution deposition (filled circles).*

We are also examining processing conditions such as casting solvent, thermal gradient zone annealing and substrate surface energy on film structure. As example, we are developing a top down soft contact method using UVO treated PDMS for orientation control of block copolymers thin films. The flexibility of PDMS ensures conformal contact with the top surface of the BCP film, whereas its surface energy was tuned by controlled UVO exposure. The PDMS film was delaminated from the BCP surface after annealing and the BCP film structure characterized (see Figure 2).

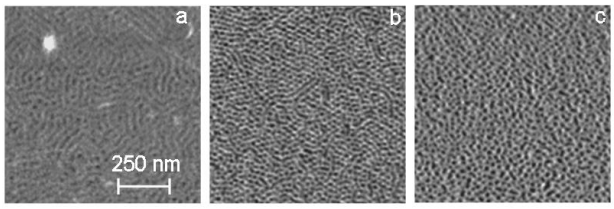

Figure 2: *Tapping mode AFM Phase images of the micro-phase separated cylindrical PS-PMMA BCP films (a) annealed without PDMS film cover and top surface covered by (b) partially hydrophilic PDMS films exposed to UVO and (c) hydrophobic PDMS films (unexposed to UVO).*

Conclusions A comprehensive effort involving theoretical methods as well as experimental studies of polymeric-nanoparticle donor-acceptor (D-A) thin films has been launched. Key objectives are to examine the correlation between polymer –nanoparticle system processing parameters vs. film morphology vs. OPV properties. We examine a wide range of nanostructures offered by block copolymer systems for this purpose.

Liquid Crystal Homo and Alternating (Co)polymers Based on π-Conjugated Backbone for Organic Electronics

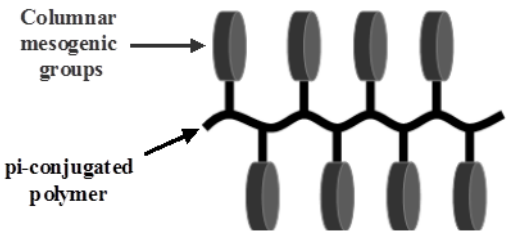
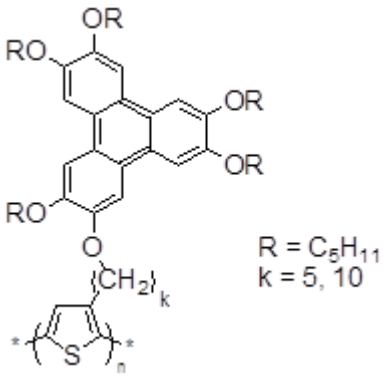
fabrice.mathevet@upmc.fr

The self-organization of π-conjugated organic materials forming highly ordered supramolecular architectures has been extensively investigated in the last two decades in view of optoelectronic applications.[1] Indeed, the control of both the mesoscopic and nanoscale organization within thin semiconducting films is the key issue for the improvement of charge transport properties and achievement of high charge carrier mobilities. These well-ordered materials are currently either self-organized semiconducting polymers[2] or liquid crystals.[3] Indeed, on the one hand previous studies have shown that well-defined polymer architectures such as a regioregular poly(3-alkylthiophenes)[4] promote self-organizations in a two-dimensional sheet-like lamellar structures due to the high planarity of the polymer chains. More recently it has been reported that a semiconducting main-chain liquid-crystalline thieno[3,2-b]thiophene polymer exhibited enhanced charge-carrier mobility, when crystallized from the mesophase, due to the formation of large, well organized lamellar domains.[5] On the other hand, it has been demonstrated that discotic mesogens self-assembling into columns can exhibit high charge carrier mobilities due to the efficient one-dimensional anisotropic charge transport along the columnar axis.[6] However the supramolecular architecture resulting from the phase separation at the nanoscale of two covalently linked π-conjugated systems able to self-assemble individually in a lamellar and a columnar nanostructure respectively, has never been investigated to the best of our knowledge.
In this context, we endeavored to investigate the self-organization of a side-chain liquid crystal (SCLC) semiconducting polymer where (i) the backbone is a π-conjugated polymer and (ii) the side groups are π-conjugated discotic mesogens.



Here we describe the design and synthesis of columnar side-chain liquid crystal homo and alternating (co)polymers with triphenylene mesogens as side groups, and well-defined regioregular polythiophene as backbone.



These different kinds of architectures prepared following the Grignard methathesis (GRIM),[7] allow the control of the triphenylene side group ratio along of the polymer chains, and lead to tunable electronic properties and nanostructures.
In this work, we will give the details on the synthesis and structural characterization studied by Polarized-light Optical Microscopy (POM), Differential Scanning Calorimetry (DSC) and Temperature-dependent, small-angle X-ray diffraction. Moreover, their photophysical properties and the preliminary charge transport results will also be depicted in view of applications for organic optoelectronics.

Fibres forming the extracellular matrix (ECM) of a live tissue have a specific orientation and structure that heavily influences its response and therefore its function. Apart from this anisotropy, biomimetic scaffolds try to emulate the natural ECM with structure architectures having geometries, pore sizes and surface textures that favors the cell adhesion, proliferation, transport of nutrients and residues and the formation of a vascularate. Photopolymerization is a suitable technique for the preparation of complex artificial structures since allow a good spatial control of the polymerization reaction so it is a very convenient technique for the production of polymeric microstructures with well defined features of interest in tissue engineering applications.

Acrylate based systems have been widely studied for the preparation of scaffolds. Usually they comprise biodegradable segments functionalized with acrylate reactive end groups. The chain growth polymerization mechanism of acrylates results in nondegradable hydrocarbon polymeric chains that may be difficult to eliminate by the body after in vivo degradation leading sometimes to side effects in the patient.[1] Anseth and coworkers have investigated thiol-ene biodegradable photopolymers that result in a controlled homogeneous network architecture generated via a step-growth mechanism obtaining as a result an improved control of the degradation-elimination process.[2] Only very recently the thiol-yne reaction has been proposed to be used in photopolymerizable systems that result also in homogeneous network architectures[3] however the thiol-yne reaction has not been tested as a biomaterial.

In the present communication we demonstrate the use of the thyol-yne reaction to produce microstructured biomaterials which can be used as a versatile platform for cell culture. Our material is based in a hyperbranched polyester functionalized with alkyne groups, a multifunctionalized thiol and a UV photoinitiator Citotoxity and cell viability essays have shown that the material is biocompatible. We have also created two dimensional structures with controlled geometries using direct laser writing followed by a solvent etching step. We have studied the cell growth and proliferation in bidimensional relief structures with different geometric parameters. The influence of the polymeric structure geometry on cell morphology will be discussed.

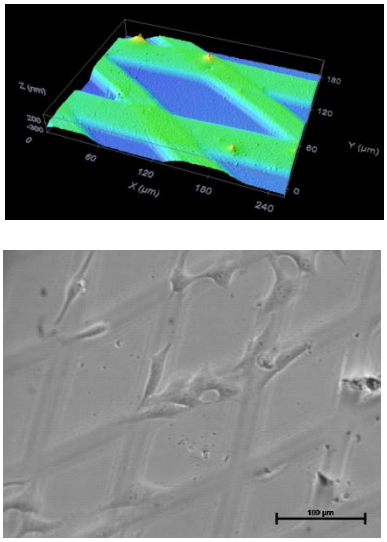

Figure 1. (a) Topography image, obtained using a confocal microscope, of a two dimensional structure generated by direct laser writing onto a casted film followed by subsequent solvent etching step (two sets of parallel stripes arranged at an oblique angle). (b) Phase contrast microscope images of HeLa cells cultured onto patterned polymeric structures.

j.steinke@imperial.ac.uk

There is a wide variety of dielectric materials, which include polymers, SAMs, inorganic compounds and hybrids. With the increasing interest in the study and fabrication of OTFTs there is a need for new dielectrics that can be easily printed. These polymer dielectric films need to be thin and robust. It is also favourable, when gravure printing the films, to be able to adjust the molecular weight and thus the viscosity of the polymer blends. PHEMA and crosslinked PHEMA (XL-PHEMA) has already been gravure printed and used as a dielectric in organic electronic devices. XL-PHEMA has been shown to be robust, easy to process and high performing in gravure printed OTFTs (Figure 1).[1]

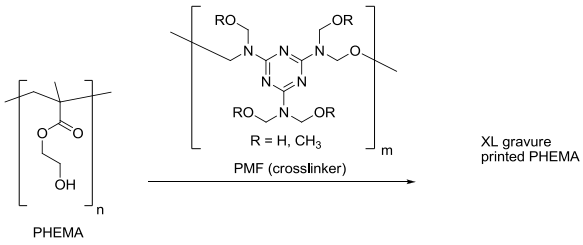

Fig 1. PHEMA as a low temperature crosslinkable dielectric for gravure printing.

In order to retain the advantageous properties of PHEMA while being able to produce much thinner gravure printed films, we have begun to develop PHEMA-based copolymers to improve the deposition characteristics of PHEMA.[1,2]

ATRP is the preferred controlled polymerisation method (over RAFT and NMP) as it has been shown to polymerise a wide variety of methacrylates with good control over molecular weight and gives narrow polydispersity (typically $M_w/M_n < 1.3$).[3,4] ATRP can also give access to obtain well-defined copolymers such as block-polymers and gradient polymers (Fig 2) to further tune the physical and chemical properties.[2,5]

Specific functionality has to be introduced to the PHEMA "base" dielectric to improve the performance. Therefore, co-monomers providing specific interactions to enhance adherence of the dielectric to the substrate, and in our case to gold electrodes, have been synthetically introduced to achieve thinner films and a more controlled ink transfer during gravure printing.

One such functional inclusion is the introduction of thiol groups into the dielectric to enhance the affinity to the gold electrodes. (Fig 2)

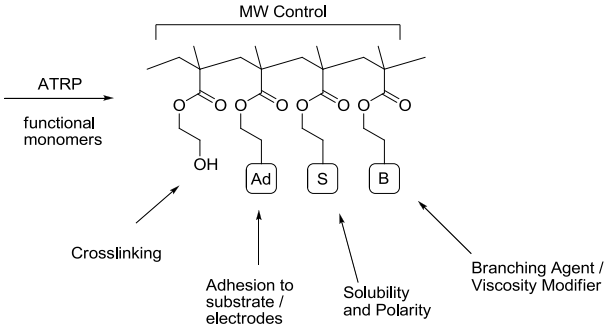

Fig 2. Synthesis of PHEMA copolymers for the introduction of specific functionalities.

Films of PHEMA copolymers containing thiol group as adhesion promoters have been both thermally- and UV-cured using a variety of crosslinkers. We will show data comparing spin coated and gravure printed PHEMA films both thermally- and UV-cured and their performance as dielectrics for OTFTs.

Introduction

Multifunctional materials have received widespread attention their ability to perform simultaneously two or more functions make them attractive materials for applications from biomedical to aerospace encompassing many disciplines [1]. Energy storage is one of the areas where the introduction of multifunctional materials is expected to save weight and volume by combining the features of structural materials with those responsible for the electrochemical performance.

Our focus in this area is on supercapacitors where the main components are the electrodes, separator and electrolyte. We have opted to combine epoxy resin with liquid electrolyte to provide a resin which retains its desirable mechanical performance while exhibiting sufficient levels of ionic conductivity. Despite these contradicting requirements, it was shown earlier [2] that it is possible to cure epoxy resins in the presence of ionic liquid. However authors found that ionic liquid content significantly affects both mechanical performance and ionic conductivity and samples which were ionically conducting had low Young's Modulus.

Results and discussion

A commercially-available epoxy resins was studied. It was found that at only 30 wt.% of resin monolithic tough plaques with a thickness of 2-3 mm could be made which showed ionic conductivities of 1 mS/cm (measured at 25 °C) and Young's Modulus 0f 200 MPa. A clear correlation was found between resin content and performance of the cured product. An overall trend similar to that found by Endo [2] was observed. Figure 1 gives an indication of the morphology encountered in one of these multifunctional resins. At the meeting we will provide details on the effect of additives on the curing kinetics, phase separation, ionic conductivity and morphology of the resultant resin. We consider these initial results as an important step towards the materials developments required for structural supercapacitors.

Introduction

Stimuli-responsive hydrogels are a group of materials which reveal relatively large and abrupt change in the properties in response to even small modification in environmental conditions [1, 2]. Because of such properties going together with their good biocompatibility and biodegradability, they are expected to be perfect materials in various biomedical and pharmaceutical applications. The biggest disadvantage of these amazing materials preventing them from commercialisation is their insufficiently quick response to an applied stimulus. Hence, many studies have been performed lately to improve response kinetics of hydrogels. The most important factor that slows down the squeezing rate of a hydrogel is the formation of a dense skin layer which is impenetrable by water molecules and slows down further diffusion processes. One of the most promising strategies of solving this issue is introducing hydrophilic dangling chains into a polymer network. Their role is to prevent to some extent aggregation of hydrophobic chains and maintain channels for water diffusion. The additional advantage should be caring out such modification with use of atom transfer radical polymerisation (ATRP) which allows to control well the architecture of synthesised polymer [3].
The analytical problem to solve is finding a proper methodology to analyze kinetics of thermo-stimulated volume phase transition, and control of potential skin formation.

Experimental

Thermo-responsive hydrogels both “mother gel” and “daughter gel” based on 2-(2-methoxyethoxy)ethyl methacrylate (MEO2MA) were prepared by ATRP method with crosslinking agent (EGDMA; ethylene glycol dimethacrylate) concentration 1:100. Mother gel does not contain any dangling chains and daughter gel contains dangling chains (MEO2MA) with degree of polymerization of 65 [4].Relaxations of polymer chains during volume phase transition (VPT) were analyzed with use of Novocontrol Alpha Analyser Concept 80 apparatus. In order to keep good contact between hydrogel sample and electrodes and to avoid flowing of water out of a cell the measurements were performed using the Novocontrol Liquid Sample Cells BDS 1308.

Water-molecular interactions during volume phase transition were studied with Bruker FT-Raman spectrometer combined with confocal microscope Ramanscope.

Results

Broadband dielectric spectroscopy results revealed that α-process (related to segmental relaxation of the polymer) accelerates ca. 1.5 decade (from 5x104 Hz to 1.3x106 Hz) after heating of the hydrogels above VPT (temperature of ca. 20C). After cooling down below this temperature it slows down again. Such behaviour is probably related to the facts that polymer chains in their hydrated state (hydrogel in equilibrium swelling degree) are stretched and after desorption of water they relax and change their conformation. Analysis of shifts of bands related to particular hydrophilic centres at polymer chain during VPT shows that various centres release water at different stages of the transition. For example, desorption of water from the $–OCH_3$ groups ends just in the initial stage of the hole process.

Introduction

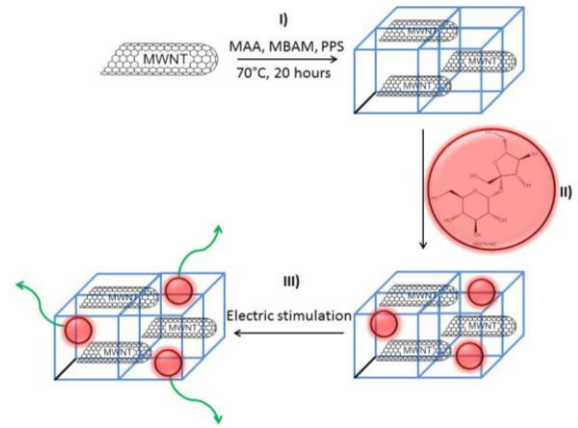
The development of controlled drug delivery systems offers the possibility to deliver drugs at predefined periods of time and at predetermined rates. This provides an alternative to the shortcomings of conventional drug delivery formulations[1].Hydrogels have been extensively used in the development of 'smart' controlled delivery systems[2] for their ability to swell and de-swell in response to external stimuli. Electro-responsive drug delivery systems have been developed using polyelectrolyte hydrogels based on poly(methacrylic acid) PMAA matrices[3]. The mechanism of such controlled drug delivery system is based on the chemo-mechanical changes of the gel matrix, such as shrinkage and contraction upon application of an electrical field[4]. Although previously reported systems offer interesting responses regarding pulsatile drug release with ON/OFF electrical field application, the maximum percentage of drug released of 35% after one hour.
Multi-walled carbon nanotubes (MWNTs) have attracted a lot of interest in biomedical applications due to their unique mechanical, thermal, and electrical properties. In this work, we present the development of an electro-responsive PMAA-MWNT hydrogel composite for the generation of 'smart' controlled drug delivery systems.

Materials and Methods

MWNT-PMAA hybrid gels were prepared by *in-situ*radical polymerization (at 70°C for 20 hours) in the presence of pristine MWNTs. Methacrylic acid (MAA),N,N'-methylene bisacrylamide (BIS) and potassium persulfate were used as backbone monomer, cross-linker and initiator, respectively. The incorporation of individualised MWNTs into the polymeric network was characterized by SEM and Raman spectroscopy.

Results and discussion

Homogeneous PMAA-MWNT hydrogel composites with different MWNT concentrations were successfully fabricated.The response of the gels to electrical stimulation was studied by measuring matrix de-swelling as a result of water release upon application of an electrical field. Introduction of MWNTs into the gel matrix decreased the bulk resistivity of the gels and led to an enhanced gel response to electrical stimulation. ^{14}C-sucrose was selected as model hydrophilic drug and drug release was monitored over time while applying ON/OFF electrical field at 15 min exposure interval every one hour. Drug release up to 50% was reached after an hour, in a pulsatile manner for the hybrid gel synthesized with the highest MWNT concentration. The presence of MWNTs seemed to enhance gel damage after exposure to the electrical field as confirmed by SEM.



Scheme 1: Synthesis protocol of the MWNT-PMAA hydrogel hybrids

Conclusion

The incorporation of MWNTs into the gel polymeric network has enhanced the electrical responsiveness of the gel and led to significant improvement in drug release, using the model drug ^{14}C-sucrose, up to 50% after an hour of ON/OFF electrical field application, in a pulsatile manner. This offers a great alternative for the development of more efficient controlled drug delivery systems.

Exploiting Adsorption to Taylor the Behavior of Polymers at the Nanoscale

Simone Napolitano, Cinzia Rotella, Michael Wübbenhorst

Department of Physics and Astronomy, KULeuven

simone.napolitano@fys.kuleuven.be

Presence of free surfaces and attractive interfaces might dramatically alter the behavior of polymer chains: deviations from bulk behavior are observed already at hundreds of nanometers, a length scale which cannot be explained in terms of finite size effects.

A large number of experimental works highlighted how properties of ultrathin polymer films (<200 nm) depend on the annealing conditions used during their preparation [for a review see Reiter and Napolitano, Journal of Polymer Science, part B: Physics, **48** (2010), 2544-2547]. We show clear evidence that the changes ultrathin films undergo during annealing are strongly correlated to the amount of chains irreversibly adsorbed at the interface.

A careful analysis of the time evolution of the dielectric function during annealing steps above T_g revealed three different regimes: at short times (in comparison to the adsorption time) the thickness of the adsorbed layer is constant and the interface mimics the effect of a free surface (packing frustration, see Napolitano et al. ACSNano, **4** (2010). 841-848); upon increase of surface coverage, the films undergo a series of metastable states characterized by the largest changes in the deviations from bulk behavior; finally the system approach a new equilibrium whose properties are fixed by the new interfacial configurations.

Our picture is confirmed by further investigation of the impact of annealing on tracer diffusivity and on the crystallization kinetics, as well as on the determination of the distribution of glass transition temperature and dielectric relaxation strength at different distances from the adsorbing interface. Measurements of the local dielectric properties were achieved by selectively placing layers of dye-labeled polystyrene at different depth inside films of neat polystyrene (Rotella, Napolitano et al., Macromolecules, **43** (2010), 8686-8691).

Finally, we show that during annealing ultrathin films evolve towards a steady state whose properties might still differ from bulk. In particular, for polystyrene, the lack of specific interactions with the substrate results in slow adsorption kinetics, keeping the deviations from bulk behavior in steady states with an extremely long lifetime.

New insights in the synthesis of rod-like polyamides. Dependence of molecular weight on the synthetic method

Guiomar Hernández, Cristina Álvarez, José G. de la Campa, Javier de Abajo. Ángel E. Lozano

Instituto de Ciencia y Tecnología de Polímeros, CSIC., Madrid, Spain.

lozano@ictp.csic.es

Introduction

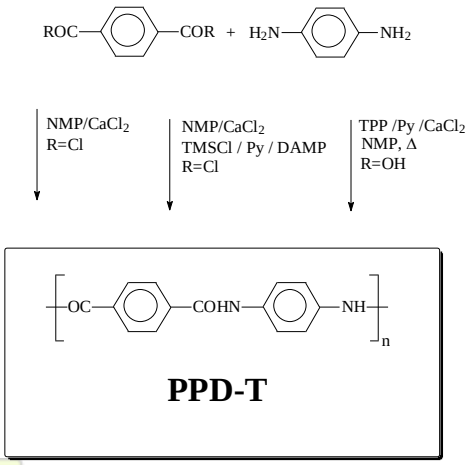
In order to attain materials with improved properties for advanced applications, polymers with the highest possible molecular weight should be synthesized. During the development of the macromolecular chemistry, many synthetic methods have been refined to obtain total conversion of reactive groups, use of mild conditions to limit the hazard of side secondary reactions, easiness of operation and a long so forth.

With regard to aromatic polyamidation, the most common method both in the industry and academia consists of the reaction between diacid chlorides and aromatic diamines in aprotic polar solvents. However, it is necessary to add Ia and/or IIa salts when seeking to obtain wholly rod-like aromatic polyamides (aramids) [1-4].

A milestone in the synthesis of aromatic polyamides was the use of silylated diamines from the 1980s. These monomers are more reactive and produce higher molecular weight (MW) polyamides. It is noteworthy that Imai [5] realized that gelation point for aramids, such as poly(*p*-phenylene terephthalamide), **PPD-T,** was achieved at longer times than when the reaction was made using the classical conditions. This result seems to point out to a different mechanism.

Afterwards, our group developed a new synthetic method by using *in situ* formed silylated diamines, obtaining aramids with higher Mw values than ever reported [6].

This communication deals with the synthesis and characterization of polyamide **PPD-T** synthesized using three methods, as shown in the following scheme:



Both classical and in situ silylation polyamidation were performed. The activated reaction using phosphorous compounds was also made for comparison purposes [7]. The target was finding a method which rendered very high Mw PPD-T.

Materials and Methods

Terephthaloyl chloride (TCl, Aldrich) was recrystallized from hexane and subsequently sublimed at high vacuum just prior to use. 1,4-Phenylene diamine (PPD, high- purity Aldrich) was sublimed before being used. Terephthalic acid (TA, Amoco) was used after drying under vacuum at 100°C. Calcium and lithium chloride (Scharlau) were dried at 250°C overnight and kept in a desiccator with phosphorous pentoxide under vacuum. Other materials and solvents were commercially available and used as received

A typical polymerization reaction is as follows: a double-walled glass flask was charged with diamine and polar aprotic solvent under a blanket of nitrogen. After diamine dissolved, the stirred solution was cooled to 0ºC and diacid chloride was added. The mixture was allowed to react under nitrogen for 1h at 5ºC, and then for 12h at 20ºC. Polymers were thoroughly washed with hot water and ethanol and finally dried at 100°C under vacuum. Yields were quantitative for all samples of PPD-T. The *in situ* silylation reaction conditions reported in [6] were used.

Results and Discussion

Samples of PPD-T obtained in 5 batches under different reaction conditions of in situ silylation, were compared with those prepared by the classical polyamidation and the phosphorous assisted reaction. The inherent viscosity data permitted to assert that much higher molecular weight were obtained by the silylated promoted method.

The time to reach the gel point was also determined. The critical point of PPD-T via *in situ* polyamidation was attained at longer times than those obtained with other methods. This fact was explained by pressuming that the amide groups formed during the reaction were being silylated. A tertiary base (pyridine and a mix of pyridine and N,N-dimethylamino pyridine) was used in order to favor the -silyl amide moieties and then it was possible to confirm this assumption. A model NMR study and molecular modeling has justified this assumption. Finally, optimization of the method has produced a polymer with very high viscosity.

Heterocomplementary H-Bonding RAFT Agents: New Tools for the Preparation of Tailor-made Supramolecular Block Copolymers

Senbin Chen, Arthur Bertrand, Pierre Alcouffe, Catherine Ladavière, Jean-François Gérard, Frédéric Lortie and Julien Bernard

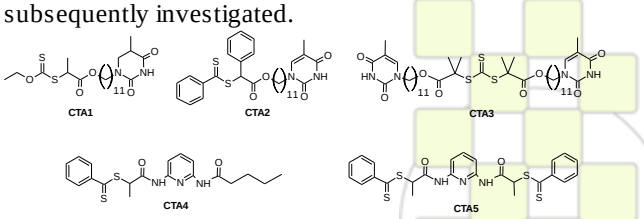
Université de Lyon, INSA-Lyon, Université Claude Bernard Lyon 1, IMP, F-69621, Villeurbanne Cedex (France)

e-mail: julien.bernard@insa-lyon.fr

Introduction-Despite the increasing attention paid to the construction of supramolecular edifices, the development of block copolymers from self-assembly of tailor-made H-bonding macromolecules remains in its infancy in comparison with covalent analogues. Strategies affording the incorporation of H-bonding units at a specific region of a polymer backbone (chain ends, centre of the chain) are indeed rather limited. Introduction of such motifs can be achieved through postpolymerization functionalization.[1] However, this approach suffers from incomplete transformation of the macromolecules. Surprisingly, the alternative approach consisting in incorporating H-bonding units during the polymerization by using functionalized initiators, chain transfer agents (CTA) or chain terminators in order to optimize the chain functionalization has been scarcely explored so far.[2] Herein, we report a new straightforward approach to the preparation of well-defined sticker-functionalized polymers by RAFT polymerization from original CTAs bearing heterocomplementary H-bonding motifs and the generation of supramolecular block copolymers thereof.[3]

Materials and methods-All reagents were purchased from Aldrich. Monomers were filtered prior to use by passing through a column of basic aluminium oxide. H-bonding CTAs were synthesized as previously described.[3] NMR spectra were recorded on a Bruker AVANCE400 spectrometer using $CDCl_3$. Polymers were analyzed with a SEC apparatus running in THF at 25°C (1mL.min^{-1}) and equipped with a Viscotek VE1121 automatic injector, three columns (Waters HR2, HR1 and HR0.5), and a differential RI detector (Viscotek VE3580). Molar masses were derived from a calibration curve based on a series of PS standards. TEM was performed on a Philips CM120 microscope.

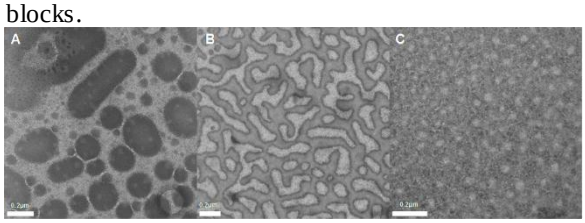
Results and discussion-Aiming at generating a library of well-defined H-bonding polymers, a series of monofunctional and difunctional CTAs bearing either thymine (T) or 2,6-diamidopyridine (D) heterocomplementary recognition units have been prepared (Scheme 1). The capability of the heterocomplementary CTAs to associate through H-bonding interactions was first evidenced by ^{1}H NMR (K_{ass}= 110-140 M^{-1} in $CDCl_3$ at 20°C). Radical polymerizations of vinyl acetate (CTA1), methyl methacrylate (CTA2), isoprene (CTA3), *n*-butyl acrylate (CTAs 3-5) or styrene (CTAs 3-5) were subsequently investigated.



Scheme 1: T and D-functionalized CTAs.

All CTAs were proven to effect a good control of the polymerizations. Sticker-functionalized polymers grew linearly with conversion and polydispersity indices remained narrow (PDI<1.5 excepting for PI samples). Experimental molar masses (1.5-22K) were in good agreement with those expected and polymerizations proceeded with pseudo-first order kinetics indicative of a constant number of propagating centers. ^{1}H NMR/MALDI-TOF analyses demonstrated the incorporation of T/D units on the polymer chains and molar masses evaluated from relative integration of polymer backbone protons and T/D motifs protons were in excellent agreement with theoretical values.

The formation of supramolecular block copolymers and miktoarm stars was demonstrated by ^{1}H NMR with a significant downfield shift of the NH thymine proton ($\Delta\delta$=0.7-0.8 ppm; [T]=[D]=3 × 10^{-3} mol.L^{-1} in $CDCl_3$ at 20°C) observed after adding an equivalent of D-functionalized chains to T-functionalized chains. K_{ass} for the T-D association between H-bonding PS, PBuA, PVAc, PI or PMMA were comparable (80-90M^{-1}) suggesting that the chemical nature of the polymer does not interfere with the recognition process. Supramolecular block copolymer formation in the bulk was further confirmed by TEM (Scheme 2). Indeed whereas blends of unfunctionalized PVAc and PS-D-PS exhibited poorly dispersed domains, macrophase separation was prevented for H-bonding polymer blends owing to supramolecular assembly of the blocks.



Scheme 2: TEM pictures of PVAc/PS-D-PS 1/1 blend (A), 0.5/0.5/1 PVAc/T-PVAc/PS-D-PS blend (B) and T-PVAc/PS-D-PS 1/1 blend (C).

Conclusions- we have designed a series of original heterocomplementary H-bonding CTAs allowing the generation of well-defined H-bonding macromolecules. The self-assembly of these polymer chains afforded the straightforward generation of synthetically challenging supramolecular miktoarm stars and block copolymers.

Copolymers of Trimethylene Carbonate and Glycolide: Synthesis and Relationship between Microstructure and Properties

E. Díaz-Celorio, L. Franco, A. Rodríguez-Galán, J. Puiggalí

Departament d'Enginyeria Química, Universitat Politècnica de Catalunya, ETSEIB, 08028-Barcelona

Jordi.Puiggali@upc.edu

Great efforts are nowadays focused on developing polymers for specialized uses (e.g. surgical sutures, scaffolds for tissue engineering or controlled drug delivery systems). In general, polymers that should be employed in the biomedical field must accomplish strict requirements and consequently an improvement of properties appears necessary to extend their application range.

Glycolide and its copolymers with different lactones and/or cyclic carbonates are widely employed due to their biodegradability, biocompatibility and physical properties. In particular, the copolymerization of glycolide and trimethylene carbonate is interesting since may provide materials with controlled properties. Thus, the stiffness of polyglycolide can be compensated by the elastomeric characteristics of poly(trimethylene carbonate). Despite the commercial uses of some glycolide/trimethylene carbonate copolymers, it is clear that they have been designed to accomplish specific requirements. Thus, a complete understanding of the influence of composition and microstructure on properties is still necessary.

Copolymers with different architectures (i.e. random, blocky and segmented) were synthesized under a nitrogen atmosphere in a stainless steel jacketed batch reactor with a capacity of 250 mL at 0.2 MPa and temperatures that ranged between 180 and 220 ºC. Synthesis followed a two step strategy where firstly a soft segment with a theoretically random distribution was prepared by reaction of the two monomers, and then two hard segments were incorporated at each end of the middle soft segment by a subsequent polymerization of glycolide. Block copolymers were obtained from a soft segment constituted only by trimethylene carbonate units whereas random copolymers corresponded to those attained after the first polymerization step.

Analysis of polymer microstructure (Figure 1) and occurrence of transesterification reactions (Figure 2) were evaluated by means of NMR spectroscopy. Mechanical properties were measured from fibers and rectangular shaped samples prepared by using a small-scale melt spinning apparatus and by melt pressing, respectively. Thermal properties were determined by DSC and related to the hard segment content (Figure 3). All the studied copolymers showed similar thermal degradation behaviour although the stability of the corresponding homopolymers was significantly different. Hydrolytic degradation rate in pH 7.4 phosphate buffer was dependent on the microstructure and specifically of the crystallinity of the samples. Influence of the soft segment content and composition on the crystallization process was evaluated by optical microscopy and synchrotron radiation experiments.

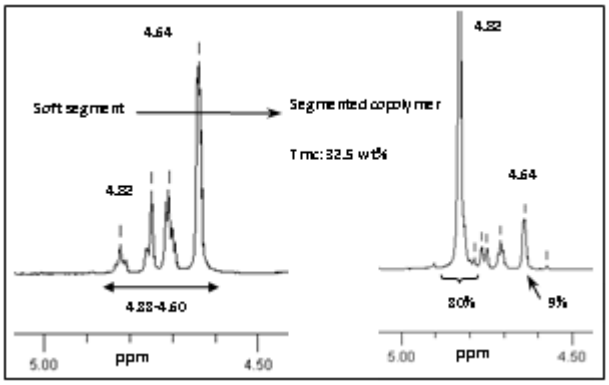

Figure 1. ^{1}H-NMR spectra of representative samples showing glycolide signals of different sequences.

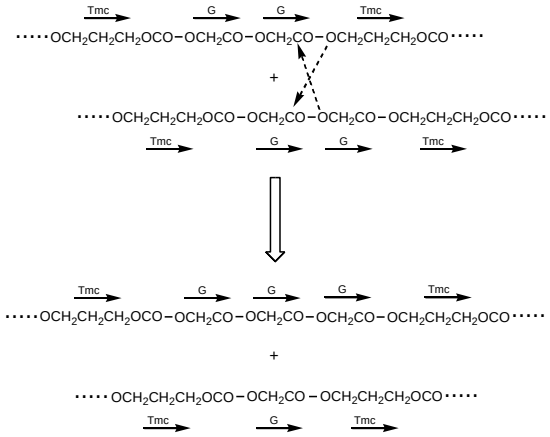

Figure 2. Transesterification reactions that lead to new TmcGTmc sequences.

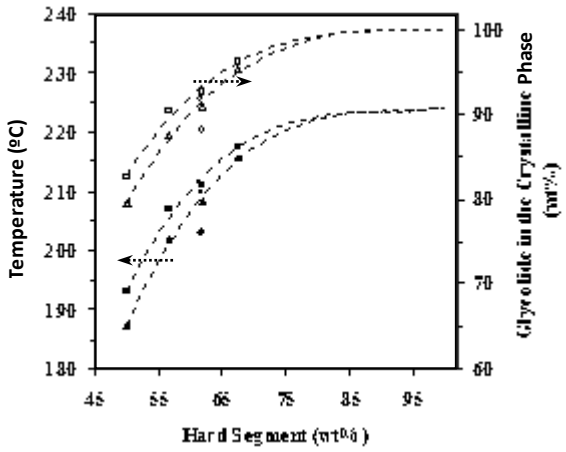

Figure 3. Dependence of the melting temperature with the hard segment content.

Innovative Polyelectrolytes For Advanced Applications

David Mecerreyes, Ana Pascual, Ali Aboudzadeh

Institute for Polymer Materials, POLYMAT, University of the Basque Country, Joxe Mari Korta Center, Avda. Tolosa 72; 20018 Donostia-San Sebastian, Spain

e-mail: david.mecerreyes@ehu.es

The properties and classical applications of polyelectrolytes are being outspreading in the last years by the introduction of new ionic moieties (cations and anions) into the polymeric backbone [1]. These new ionic moieties are being developed due to the scientific and technological interest in the field of ionic liquids and for this reason, some of the new polyelectrolytes are being named polymeric ionic liquids (PILs). Examples are found in the figure including polycations and polyanions having i.e. new cations; imidazolium, pyridinium, guanidinium, pyrrolidonium and anions including tetrafluoroborates, hexafluorophosphates, triflates, amidotriflates, and carboxylates. In the last few years, those innovative polyelectrolytes have been finding a wide range of applications in different technological fields such as polymer electrolytes for batteries, electrochromic devices, biosensors, solar cells, gas membranes, anion sensitive block copolymer micelles, smart surfaces and nanocomposites [3-4].

In this presentation, we will review the recent developments in the synthesis and application of innovative polyelectrolytes by introducing the author's work and his perspectives for the field.

Introduction

Nowadays, the environmental impact of fossil fuels is undergoing an important attention due to the CO_2 emissions associated with their combustion, which are strongly believed to be contributing to global warming [1]. According to the EU directive 2002/91/EC, close to 40 % of the final energy consumption and also the 36% of CO_2 emissions in the Europe Community in 2002 were due to the residential and tertiary sectors [2] and the new EU directive 2010/31/UE [3] establishes in a 20% the reduction in the green house gases emissions. In the USA, where the energy consumption in buildings is the 30% of the total consumption, the situation is quite similar [4]. The energy demand in the residential sector can be reduced by using the solar energy that reaches the buildings surface. Phase Change Materials (PCMs) can be used to storage the solar energy and release it when external temperature goes down. On the other hand, rigid polyurethane foams (RPU foams) are widely used as insulating materials in buildings due to their low thermal conductivity and high mechanical and chemical stability [5]. However, the thermoregulating properties of the RPU foams can be improved by incorporating PCMs in them [6,7]. Therefore, in this work polyurethane foams have been incorporated with different contents of microencapsulated PCMs and their thermal and mechanical properties have been studied. A special experimental set up has been designed for measuring their thermal behavior and thermal energy storage (TES) capacity.

Materials and Methods

Polyol used was Alcupol R-458 from Repsol YPF S.A. As isocyanate, diphenylmethane-4,4'-diisocyanate (MDI) supplied by Merck Group was used. Catalyst Tegoamin 33 and surfactant Tegostab B8404 were supplied by Evonik Degussa International AG. Deionized water was used as blowing agent. Spherical microcapsules containing Rubitherm® RT27 with a particle size between 1 to 5 μm were obtained following the method described in the Patent EP2119498 [8]

RPU foams were synthesized by weighting and mixing the polyol, silicone, water, amine and the microcapsules and stirring the mixture during 1 min. Then, the isocyanate was added and the solution was stirred for 5 seconds, curing the foams at room temperature.

The foams rising process was measured by an ultrasonic system sqs-01. The microcapsules distribution in the foam was studied by DSC analysis. Cellular structure was depicted by SEM and the cellular size distribution was determined by the program Image Plus. Foam densities were calculated by weighting and measuring the volume of the samples. Uniaxial compression tests were performed according to ASTM D1621 by using using the Model 5584 of an INSTRON universal testing instrument. The thermal behavior and the thermal energy storage (TES) capacity of the foams were studied by measuring the inlet and outlet heat flux to a foam slab subjected to an external heat source.

Results and Discussion

The RPU foams rises properly even when they are incorporated with a 21wt% of microcapsules. However, the higher the microcapsules content, the lower the rising rate and the final height of the foam. The rising process was successfully fitted by a model of reaction curve of 4 tank-in-series. The decrease in the height promoted an increase in the foam density. It can be pointed out that all the synthesized foams satisfied the Spanish regulations for the use of foams in buildings (UNE 92120) that demands a minimum density of 30 kg/m^3. SEM analyses showed that the higher the microcapsules content, the lower the cell size. However, for the higher studied concentrations 18 and 21wt%, microcapsules agglomerate and promote the rupture of struts, giving place to some big cells. On the other hand, the TES capacity increases with the microcapsules content, observing an enhancement of 16.5 kJ/kg in this property when a 21 wt% of microcapsules have been incorporated. Finally, the mechanical tests indicated that, synthesized foams exhibited mechanical properties similar to those reported in literature.

Conclusions

RPU foams with thermo-regulating properties can be developed by incorporating microcapsules containing PCMs. The characterization analyses of these foams allowed to select 18 wt% as the microcapsule content to synthesize foams with a high TES capacity and a good structure and mechanical resistance. According to the experimental results, this foam is able to storage an amount of energy of 12.1 kJ/kg or 23.6kJ/m^2.

Acknowledgments

A fellowship from the Spanish Ministry of Science and Innovation is acknowledged.

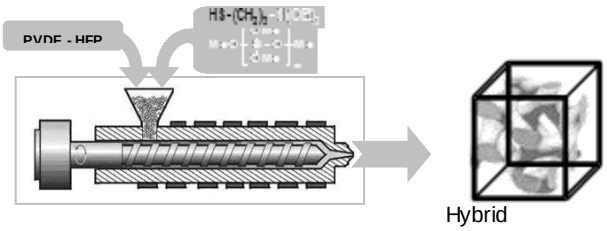
bounor@univ-lyon1.fr

Hybrid organic-inorganic materials based on a fluorinated polymer matrix have a large interest as several functionalities could be combined such as enhancement of mechanical properties, electrical and thermal conductivities, use for photovoltaics, antibacterial properties, etc. In addition, numerous papers describe the design of materials based on a polymer matrix and a phase which allows a ionic migration for purification, electrochromic devices, batteries, or fuel cells. The conventional approaches consist in the introduction of already pre-formed nanoparticles such as layered silicates, carbon nanotubes, or nanoclusters whereas the sol-gel chemistry allows to synthesize *in-situ* a nanoscale and hierarchical inorganic phase within the organic polymer medium from the hydrolysis and condensation of metal alkoxides.

This paper proposes a description of the design of hybrid O/I materials based on a fluorinated polymer (polyvinylidene fluoride PVDF) and silicon alkoxides precursors including organofunctional ones (fluorinated, thiol) via an extrusion process.



In fact, this approach allows to generate *in situ* in molten PVDF a silicon-rich phase at high contents of eq. SiO_2 (up to 25 wt. %) and tailored interfaces without the introduction of organic solvents which are conventionally used, i.e. enabling the direct processing of O/I films. The influence of the nature of the silicon alkoxide precursors and their degree of pre-condensation, as well as the extrusion process conditions, on the resulting morphologies of the O/I hybrids are detailed.

Synthesis of Phenylphosphine Oxide Containing Urethane Acrylates and Their Applications

Introduction

Polyurethanes gives excellent performance properties such as toughness, flexibility, elongation, low Tg, low modulus, etc. Because of these inherently good qualities, it made sense to use urethane backbone by adapting as ultraviolet (UV)-curing format. The isocyanates are reacted with diols and polyols to form NCO terminated prepolymers. Then these prepolymers reacted with small acrylated monomers (hydroxyethyl acrylate and methacrylate, etc.), it was shown that the active NCO group of the polymer was replaced by a terminal acrylate functionality.[1,2]

Polyurethane acrylates constitute a class of materials widely used in UV-curable formulations to produce flexible and abrasion resistant coatings.[2] The advantages offered by the UV-curing process; including high speeds of curing that lead to high productivity, lower energy consumption, generation of polymer materials without emission of volatile organic compounds, pollution reduction, cost-effectiveness. and industrial applications such as adhesives, printing inks, photoresist, biomaterials, protective coatings.[2-5]

Curing based on UV radiation allows fast, almost istant, transformation of wet coating composition into a solid material by polymerization at ambient temperature without emission of volatile compound.[6]

The electron pair of the phosphine structure has been donated to an oxygen atom, the phosphine oxide group is unreactive, although it is very polar and subject to strong hydrogen bonding.[7] Phosphine oxide moiety is known to be very good in enhancing thermal and mechanical properties.[8-10]

Materials and Methods

In this study bis[(4-β-hydroxyethoxy)phenyl] phenylphosphine oxide (BHEPPO) was synthesized as mentioned in the literature.[6,11] Different polyols (polyester polyol, polyetherpolyol, and polycarbonate diol) and a diol (BHEPPO) as the soft segment, isophorone diisocyanate (IPDI) and toluene diisocyanate (TDI) as hard segment, hydroxyethyl methacrylate (HEMA) as the blocking agent were used to synthesize reactive urethane acrylate. Coating performance of the polyurethane acrylates on plexiglass substrates was determined by the analysis technique, such as contact angle, pendulum hardness, pencil hardness, gloss. Water absorption, gel content, solvent and chemical resistance values are observed. Also stress-strain test were enhanced.

Results and Discussion

The gloss values of the synthesized polyurethane acrylates (PUA) increased with the increasing BHEPPO content. The pendulum hardness, pencil hardness, tensile strength and e-modulus values increased with increasing BHEPPO content. The value of elongation at break decreased with increasing BHEPPO content. This is totally related with the rigid phenylphosphine oxide groups in the main backbone of PUA's. The contact angle values which were tested with water, decreased by increasing the BHEPPO content. This is related with the hydrophilicity of the phenylphosphine oxide groups.

The chemical and solvent resistance was tested by using hydrochloric acid 10%, Acetic acid 10%, sodium hydroxide 10%, chloroform, xylene, and methanol. The appearance of the samples was good except chloroform treated samples.

Conclusions

Different types of PUA's have been synthesized. The effects of soft segment types (different polyols and BHEPPO) on their physical and thermal properties have been investigated.

The excellent mechanical properties such as pendulum hardness, pencil hardness, tensile strength, e-modulus of the PUA's could be observed by the incorporation of BHEPPO into the PUA's backbone with increasing the content of BHEPPO. The gloss values of all the PUA films were good.

Introduction

Nanoscale particles are used or been evaluated for use in many fields. Because of large surface area and high surface reactivity nanoscale particles provide cost effective solutions to many challenging environmental remediation problems. However there are more concerns rising about toxicity of manufactured nanoparticles for microbes, plants and mammals and the impact of free nanoparticles release to the environment. Embedding the nanoparticles into polymer or other substrates however significantly reduces the environmental risk, while retaining the bulk of the particle reactivity.

In this work novel hybrid material with iron oxide nanoparticles imbedded into a macroporous polymer structure were produced, and their efficiency for removal of heavy metals from aqueous media was tested.

Results and conclusions

Hybrid macroporous hydrogels containing iron oxide nanoparticles were prepared in the form of monoliths by polymerization of 2-hydroxyethyl methacrylate and acrylamide in semi-frozen conditions. Nanoparticle distribution was improved by adding nanoclays to polymer solution. The effect of nanoclays on the structure and physical properties of multicomponent hybrid hydrogels were studied. The material has unique structure of large interconnected pores which provide high permeability (*ca*. 3 * 10^{-3} m s^{-1}). Fe_2O_3 and Fe_3O_4 nanoparticles were physically embedded within the macroporous polymer preventing their release into the environment.

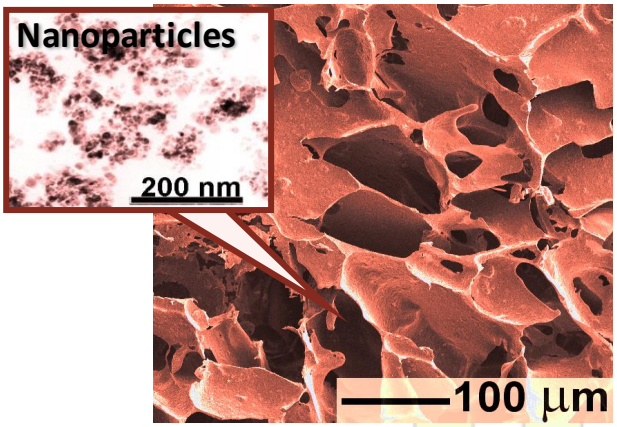

Figure 1. TEM image of a transverse section through the hydrogel with the iron oxide nanoparticles randomly distributed inside the polymer wall (top) and SEM image of the hydrogel cross-section (bottom).

Adding of nanoclays improve the mechanical properties of hydrogel and distribution of iron oxide in the matrix. The hybrid macroporous hydrogel showed promising results for the removal of trace concentrations of As(III), Pb, Cu and Ni from solution. The leaching of iron was minimal and the device could operate at a pH range 3.0 – 9.0.

Hybrid hydrogel can be produced in different configurations that can be adapted to specific applications: monolithic blocks, polymer sheets, discs or columns for through-flow (or flow-over) applications (Figure 2).

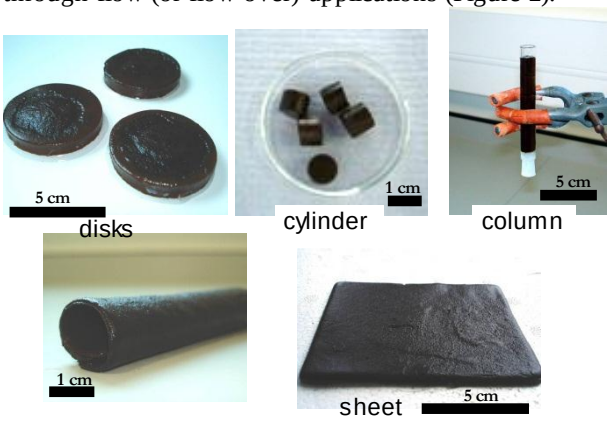

Figure 2. Hybrid macroporous hydrogel in different configurations

The interconnected large pores, mechanical stability and low flow resistance of hybrid macroporous hydrogels make them promising materials to be used as a support for nanoparticles in developing absorption/filtration devices for the clean-up ground water, surface waters and drinking water.

Introduction

Microspheres largely used in coatings, adhesives or inks have been recently employed for other purposes such as medical and biological applications. However, the final use of particles for a targeted purpose is conditioned by different parameters such as suitable and uniform sizes, colloidal stability, but requires also control over the nature and density of the surface functional groups. The preparation of systems able to respond and adequate their properties depending on the environmental conditions is a current center of interest. Systems that exhibit such behavior needs necessarily to incorporate in its structure either responsive polymers or different functional groups (multifunctional interfaces). In particular, the development of multifunctional materials that may adapt their surface properties by orientation of one or other functionality depending on the environmental conditions appears to be an interesting approach. To the best of our knowledge there are only few examples of multifunctional particles. In these cases the authors generally prepared microspheres enveloped with a second polymer shell or modified them chemically to introduce the multifunctional groups: single functional groups or polymer chains.

We describe an approach to prepare environmentally responsive multifunctional particles with hydrophobic (fluorinated moieties) and hydrophilic functional groups (carboxylic acid) able to modify their surface functionality depending on the environment of exposure.

Materials and methods

The particles employed throughout this study were prepared by precipitation copolymerization of divinylbenzene and 2,3,4,5,6-pentafluorostyrene (DVB/5FS 55/45 v/v) with AIBN as initiator (Fig. 1) and using a Acetonitrile/Toluene (95/5 v/v) mixture as solvent. To this mixture and prior to the initiation step, an amphiphilic block copolymer, i.e. polystyrene-block-polyacrylic acid (PS_{31}-b-PAA_{21}) was added. The reaction was carried out during 4 h at 85°C.

Results and Discussion

The presence of the appropriated surface functionality was verified by XPS analysis of the microspheres. XPS analysis revealed that whereas the O1S signal was missing upon annealing to air at 90°C during 3 days, a further annealing to water (80°C, 2 days) increases the oxygen content at the surface as evidenced by the presence of a signal at ~532 eV. Since the oxygen comes exclusively from the PAA segment of the diblock copolymer, annealing to water enhances the migration of the diblock copolymer towards the interface. On the opposite, the F1S signal (~ 687 eV) is larger when the particles are annealed in air. In contact to air the hydrophilic diblock copolymer tends to migrate beneath the surface, so that the surface is now enriched in the fluorinated groups provided by the monomer 2,3,4,5,6-pentafluorostyrene employed for the polymerization.

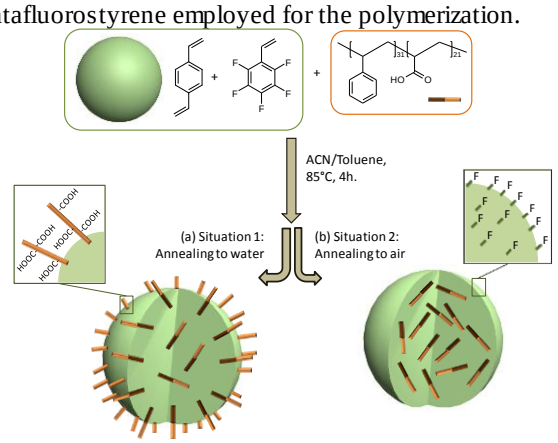

Fig 1. Approach for the preparation of the environmentally responsive particles by combining hydrophobic moieties (fluorinated monomer) and hydrophilic functional groups (carboxylic acid groups present in the poly(acrylic acid) block).

We employed the particles annealed to air to obtain superhydrophobic surfaces and the particles annealed to water to both disperse the fluorinated microspheres in aqueous solution and analyze their response to pH. The elaboration of films from particles annealed to air by solvent casting lead to the formation of superhydrophobic surfaces with contact angles of 165±1.6°. A completely different wettability is observed when the particles are annealed to water under stirring at 80°C during 2 days. Under these conditions, the contact angle of the particle films decreases below 30±1.9°.

Conclusions

We present a new and versatile methodology for the fabrication of switchable (super)hydrophobic /hydrophilic smart surfaces prepared from multifunctional particles containing both hydrophobic (fluorinated) and hydrophilic moieties.

Novel Functional Chromatographic Supports: from Preparation to Application

Alexandros Lamprou[1], *Agni Faviola Mika Gavriilidou*[2,1], *Giuseppe Storti*[1], *Massimo Morbidelli*[1]

[2] Department of Chemical Engineering, Aristotle University of Thessaloniki, Greece
alexandros.lamprou@chem.ethz.ch

Intoduction: The most widespread method for downstream purification of therapeutic proteins, like monoclonal antibodies, is chromatography. Our work's objective is the introduction of novel functional polymeric stationary phases, with advantageous mass transport properties, in order to address different chromatographic modes and solutes after proper surface modification.

Materials and Methods: Initially, primary latex hard core-dual soft shell nanoparticles, surface-modified with an ATRP initiator, are produced by a 3-step semi-batch miniemulsion polymerization. Subsequently they are aggregated in a controlled fashion by gradient salt addition under shear, in combination with the "reactive gelation"[1] technique.

The resulting microparticles are used to pack a conventional HPLC column and consequently their pores are functionalized in situ with polyelectrolytic or environmentally responsive chains, grafted from the pore surface by continuous ATRP. The growth of polymer brushes bearing ionic units and their respective application performance is currently under optimization. Nevertheless, apart from the possibility to carry out conventional ion-exchange protein separations, temperature-controlled purification emerges as an attractive alternative.

Results and Discussion: The microclusters produced are irregularly shaped, yet monodisperse, macroporous (N_2 & Hg porosimetry) and mechanically rigid (SEM), with compact internal structure (DLS). The packed column exhibits exceptionally high total porosity (Inverse Size Exclusion Chromatography) and pressure drop comparable to commercial chromatographic supports. Moreover, due to the large pore size there are no diffusion limitations (Van Deemter analysis), which is ideal for purification of large biomolecules.

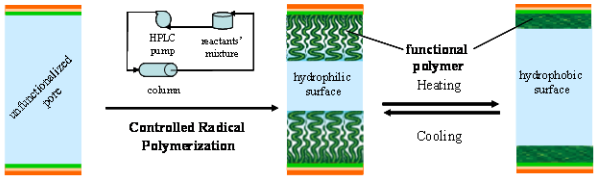

Figure 1: Pore functionalization scheme.

ATRP allows for sufficient functionalization tuning; the degree of polymerization is quantified and correlated with the column's hydraulics and on-line separation performance. For the environmentally responsive functionality, the effect of grafting density, as well as eluent salinity and polarity on the retention of a range of small hydrophobic pharmaceuticals was investigated.

Conclusions: Our results confirm the ability of this novel functional environmentally responsive support to perform analytical separations based on hydrophobic interactions, by responding to temperature cycles. Commonly employed salt of solvent control gradients could thus be substituted by mere temperature changes.

New Developments on Hybrid Colloidal Materials for Applications in Magnetic Hyperthermia

Rebeca Hernández, Coro Echeverría, Vanessa Zamora, Carmen Mijangos

Instituto de Ciencia y Tecnología de Polímeros

rhernandez@ictp.csic.es

Introduction

Magnetically mediated hyperthermia (MMH) consists of the localization of magnetic nanoparticles (NPs) within tumour tissue followed by exposure to an externally applied alternating magnetic field to cause them to heat to temperatures around 40-43 0C. For MMH, superparamagnetic and ferrimagnetic iron oxides have been explored extensively. The encapsulation of these particles on polymer nanogels, crosslinked particles whose dimensions are in the nanoscopic range, allows the intracellular delivery of entrapped drugs combined with magnetic hyperthermia and protects the biological tissue from the contact with the inorganic particles [1].

In this communication, we will present new methods implemented in our group for the synthesis of polymer gels containing magnetic NPs and their response to remote heating by applying a magnetic field [2,3]. In addition, recent results on the encapsulation of magnetic nanoparticles on polymer nanogels [4], will also be presented with emphasis on the relation between viscoelastic and structural organization of these systems. This systematic study is essential for the development of applications.

Materials and Methods

Polymer nanogels with dimensions around 400-500 nm with encapsulated 10 nm magnetic iron oxide nanoparticles prepared from synthetic polymers such as poly (acrylamide-co-acrylic acid) (PAAm-AA) and biopolymers such as chitosan will be considered. Specific power absorption measurements were performed using a homemade ac applicator working at 260 kHz and field amplitudes up to 16 mT and equipped with an adiabatic sample space (0.5 mL) for measurements in liquid phase. Rheological studies were carried out using the AR-G2 TA Instruments stress-controlled oscillatory rheometer. To visualize the morphology and distribution of magnetic nanoparticles, transmission electron microscopy (TEM) at 300 kV was used.

Results and discussion

Figure 1a shows a TEM image where it can be observed that 10 nm iron oxide nanoparticles are encapsulated within a polymer nanogel and that they are not aggregated. Likewise, in situ formation of iron oxide nanoparticles inside polymer gels (figure 1b) allows the homogeneous dispersion of iron oxide nanoparticles and, in addition, the polymer matrix controls the NPs polydispersity

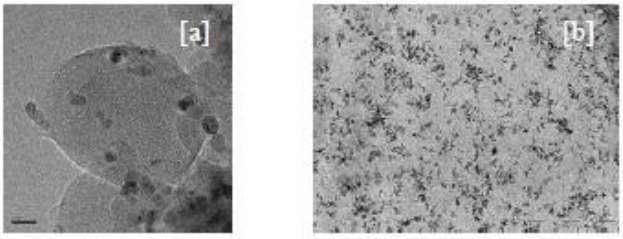

Figure 1. TEM microscopy corresponding to (a) PAAm-AAc nanogel with a 5 wt% Fe3O4 nanoparticles. (b) Fe3O4 nanoparticles synthesized inside a polymer hydrogel derived from alginate.

Interestingly, rheological measurements have shown that for both systems, the elastic modulus is independent of the frequency and that the elastic component (G′) is higher than the viscous one (G″) which is characteristic of gel behavior. In both cases, the introduction of iron oxide nanoparticles causes a reinforcement of the system as demonstrated through the increase of the elastic modulus with the iron oxide NPs concentration. The heating response is also dependent on the iron oxide NPs concentration as shown in remote heating experiments.

Conclusions

Hybrid polymer nanogels and gels have been obtained through two different methods: encapsulation and in situ synthesis of iron oxide nanoparticles. Both methods have proven useful to obtain systems with response to magnetic fields and hence for the development of applications in magnetic hyperthermia.

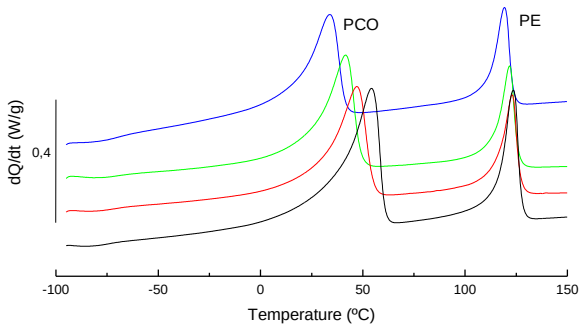
cuevas@gaiker.es

Introduction: Smart materials start playing a fundamental role in materials engineering due to their capability to respond actively to external stimulus. In particular, shape memory polymers (SMPs) are stimuli-responsive materials able to adaptively store a temporary shape and recover a 'memorized' permanent shape under specific changes in heat, light, moisture or magnetic fields, among others.
In contrast to most common dual-SMPs able to move from one shape to another, increasing attention is focused on recent thermo-responsive SMPs with multi-shape memory effect upon heating. These exciting discoveries enable further applications in, e.g. deployable structures, biomedicine, adaptive optical devices, smart fasteners and intelligent textiles.
In this work, covalently crosslinked semi-crystalline polymeric blends with thermally-induced triple-shape actuation capabilities, characterized by programmable recovery process from one temporary shape to an intermediate shape before returning to the permanent shape, were developed. The concept was based on forming two segregated crystalline domains, each having its own transition temperature, by combining semi-crystalline polymers, with adjusted respective melting temperatures and elasticity through controlled density of covalent knots. Consequently, applying two-step programming process it was able to create multiple subsequent intermediate shapes, which were not necessarily unidirectional.

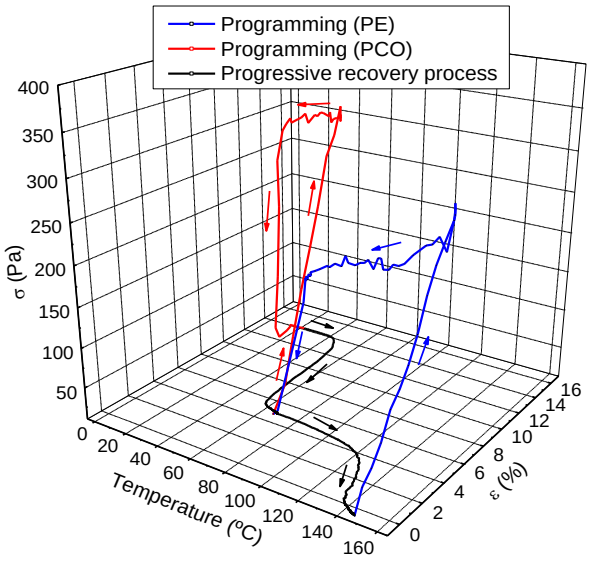
Materials and methods: Thermo-responsive crosslinked semi-crystalline polymeric blends were manufactured by melt-compounding and free-radical crosslinking process of double bond containing low broad molecular weight *trans*-polyoctenamer (PCO) and linear medium-density polyethylene (PE).
Thermogravimetric analysis (TGA), differential scanning calorimetry (DSC) and dynamical-mechanical-thermal analysis (DMTA) were used to characterize the formulations, as well as shape memory features like multiple shape fixities (R_{f1} and R_{f2}), shape recoveries (R_{r2} and R_{r1}) and actuation temperatures were evaluated by thermo-mechanical bending experiments.

Results and discussion: Apart from high thermal stability (main thermal decomposition above 430ºC for all developed formulations), evaluation of thermal and thermo-mechanical properties allowed demonstrating two different crystalline domains from both segregated components. Furthermore, corresponding melting temperatures, considered the respective transition temperatures ($T_{trans-1}$ and $T_{trans-2}$) of shape memory features for multiple shape effect, were adjusted by controlling the crosslinking density.



DSC thermograms demonstrating two crystalline domains.

Original permanent shape, thus, was defined by covalent knots along polymeric network, whereas multiple intermediate temporary shapes could be determined by the semi-crystalline domains from PE and PCO, respectively, by two-step thermo-mechanical programming process.



Triple-shape memory capabilities (thermo-mechanical cycling test).

Conclusions: Polymers with multi-shape functionality demonstrate promising applications in temperature sensing/actuating elements. The described approach, thus, allowed developing a series of thermo-responsive triple shape memory polymers with adjustable individual activation temperatures and progressive recovery ratios close to 95-100% for programmable temporary and original shapes.

Multi-armed, biodegradable polyphosphazenes and their use as macromolecular anti-cancer drug carriers

S. Wilfert, I. Teasdale, I. Nischang, O. Brüggemann.*

Institute of Polymer Chemistry (ICP), Johannes Kepler University Linz

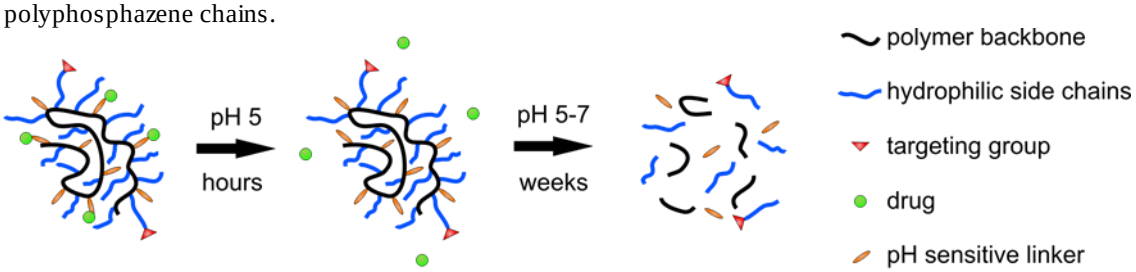
Sandra.wilfert@googlemail.com

Biocompatible, biodegradable polymers have gained increasing interest for their role in the development of drug delivery systems. Due to their structural variability, hydrolytic degradability and non-toxic degradation products, polyphosphazenes offer tremendous potential for drug delivery applications. Since the hydrodynamic volume plays a crucial role in the pharmacokinetics and biodistribution of polymeric drug carriers, the synthesis of polymers with well-defined architectures and controlled molecular weights is essential.

In this work we present the synthesis of novel multi-armed polyphosphazenes with controlled architectures and narrow molecular weight distributions. For this purpose, various end-capped phosphoranimines were polymerized with chlorophosphoranimine in a living cationic polymerization. The functionality, solubility and biodegradability of the polymers were adjusted via the side substituents of the polyphosphazene chains.

The ability to carefully control and tailor molecular weight and architecture via the polyphosphazene backbone is important for the design of macromolecular carriers.

To illustrate the versatility of the synthetic procedure to prepare polyphosphazene-drug conjugates, we also synthesized branched, hydrophilic polyphosphazenes carrying tumor-targeting ligands and anthracycline antibiotics attached to the polyphosphazene backbone via a cleavable hydrazone linkage. The conjugates showed a controlled release of the anti-cancer drug in a pH-triggered response. Furthermore, the rate of degradation of the polyphosphazenes could be controlled through careful selection of substituents. These biodegradable, multi-functional polyphosphazenes represent extremely promising candidates for the use as polymeric carriers for the tumor-targeted delivery of anti-cancer drugs.



Anti-cancer drug-loaded polyphosphazenes prepared by living cationic polymerization. Drug release via a pH response is followed by degradation of the macromolecular carrier.

Effects of Parameters on Emittance of Thermal Control Coatings Based on Polyurethane and Titanium Dioxide

Navarchian@eng.ui.ac.ir

1. Introduction:

Polyurethanes (PUs) are widely used in different industries such as aerospace [1]. The coatings that are used for coating of satellites surfaces should have specific optical properties including maximum total emittance (ε) to maintain the thermal balance of spacecraft and so to protect it against the extreme temperature variations. Because of this characteristic these kinds of coatings are called "Thermal Control Coatings: TCCs". The aim of this work is to develop a coating on aluminum surface based on PU binder and TiO_2 pigment having maximum total emittance. The influences of polyol molecular weight, diisocyanate type, surface pretreatment, NCO/OH ratio and pigment volume concentration (PVC), on total emittance of PU coatings have been statistically investigated.

2. Experimental:

To synthesize the prepolymer, 40 g of PTMG (MW = 1000 or 2000) was reacted with diisocyanate (Hexamethylene diisocyanate (HDI), isophorone diisocyanate (IPDI)) according to specified NCO/OH ratio (1.4, 1.6 or 1.8). The reactions were carried out at 80°C for 6 hrs in a three-necked flask. The prepared resin was dissolved in solvent (xylene /n-butyl acetate: 50/50, v/v) and the specified amount of TiO_2 was added to the mixture. TiO_2 pigments (particle size 10μm) were dispersed in resin with a pearl mill apparatus at 800 rpm [2]. Chemical (using alcoholic phosphoric acid cleaner) and anodic (sulfuric acid anodic) methods were used for surface pretreatment. A L_{16} Taguchi array was employed for experimental design, using S/N response.

3. Result and discussion

3.1. Analysis of variance

Table 1 shows the ANOVA statistical terms for total emittance of PU/TiO_2 coatings. The critical F-ratios for two and three-level factors at confidence level of 95% are 5.33 and 4.46, respectively [3]. It is clear from Tables 1 that the important contributors to variability of the results are pigment volume concentration (E), NCO/OH ratio (D), polyol molecular weight (A), and diisocyanate type (B), respectively. In the present study, factor C (surface pretreatment) represents the lowest F-ratio in the ANOVA tables which implies that both surface pretreatment methods have a same effect on the response.

Table 1. ANOVA table for total emittance (ε)

Factor	DOF	Sum of squares	Variance	F-ratio	Contribution%
A	1	0.0291	0.0297	262.13	12.11
B	1	0.0122	0.0122	109.78	5.04
C	1	0.0026	0.0026	23.62	1.05
D	2	0.0436	0.0218	196.15	18.09
E	2	0. 1513	0.0756	680.21	62.99
Other/error	8	0.0009	0.0001		.071
Total	**15**	**0.239**			**100**

3.2. Influence of operating variables on ε

The effects of factors on ε are shown in Fig. 1. TiO_2 particles strongly reflect the rays within infrared wavelength range, so that TiO_2 can be assumed as a non-absorbing pigment [4]. On the other hand PU resin containing C=O and N-H functional groups absorb and then emit rays in infrared wavelength range [5]. Therefore increasing PVC% or decreasing polymeric phase results in decreasing ε [4]. The use of polyol with higher MW for synthesis of PU resin results in less C=O and N-H absorptive bonds in unit mass, and thus reduction in ε. A same reason justifies also the effect of NCO/OH ratio on the response. IPDI indicates a greater emissivity due to its cyclic structure [4,5].

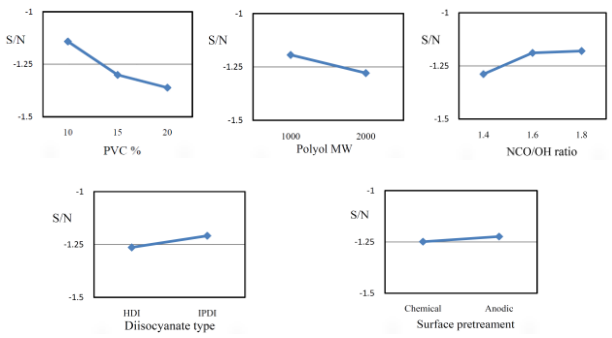

Fig. 1. The effect of factors on total emittance of PU/TiO_2 coating

3.3. Optimum conditions

The optimum conditions to attain a PU/TiO_2 coating with maximum emittance can be determined from maximum points in main effect plots (Fig.1). The predicted value for ε at optimum conditions was therefore obtained as 0.891. In order to verify the validity of the recommended optimum conditions, a new sample was prepared according to proposed optimum factor levels. The predicted value for ε in optimum conditions (0.891) was found reasonably in agreement with the experimental data (0.887).

4. Conclusion

The ε of PU/TiO_2 coating strongly depends on the PVC% and the best performance is obtained at high pigment content. The NCO/OH ratio, polyol MW and diisocyanate type, have also intermediate effects, so that the higher ε is obtained with NCO/OH ratio = 1.8, and with IPDI reacted with high MW polyol. The surface treatment method does not affect ε, and thus the chemical method can be chosen for pretreatment in order to decrease the costs and energy consumption.

Introduction

Glycopolymers, typically, containing cyclic saccharides are used in biomolecular recognition processes. In contrast, polymers with an open-chain sugar structure seem to be more efficient on enhancing the hydrophilicity of the polymer surface than those containing cyclic saccharides. To this respect, glycopolymers containing the sugar groups in the open-chain form, such as lactone, can be used to modify polymeric materials surface to prevent the undesirable adhesion of protein, cell, or other molecules.

In this work, we report the synthesis of statistical glycopolymers by conventional radical polymerization and their posterior employment as stabilizers in the emulsion polymerizations of methyl acrylate. This is an easy method to prepare particles bearing saccharides by using only classical radical polymerization.[1]

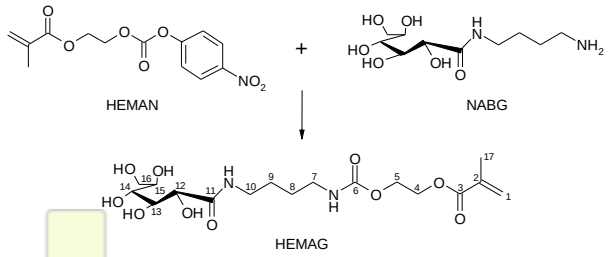
Experimental part

Materials

2-Hydroxyethyl methacrylate, HEMA, and methyl acrylate, MA, were purified by conventional methods. 2,2'-Azobisisobutyronitrile, AIBN, was purified by successive crystallizations from methanol. *p*-Nitrophenyl chloroformate, glucono-1,5 lactone and 1,4-diaminobutane were used without further purification. Sodium persulfate and thiosulfate were used as received. Dimethyl sulfoxide, DMSO, and triethylamine were previously distilled; methanol, ether dioxide and ethanol were used as received.

Synthesis of Glycomonomer, HEMAG

The aminosaccharide, N-(4-aminobutyl)-D-gluconamide, NABG, and activated HEMA with p-nitrophenyl chloroformate, HEMAN were prepared by following the literature. The glycomonomer, 2-[({[4-(D-gluconamid-N-yl) butyl]amino}carbonyl)oxy] ethyl methacrylate, HEMAG, was prepared according to the following Scheme.



Copolymerization Reaction

The HEMAG and MA monomers were polymerized with AIBN as an initiator ($3 \cdot 10^{-2}$ mol/L) and with DMSO as a solvent (1 mol/L) at 70 ºC. The copolymerization was monitored in-situ by proton NMR using tube sealed under argon atmosphere.

Emulsion Polymerization

Water-soluble glycopolymers obtained at very high conversion ($f_{HEMAG} \cong F_{HEMAG} \geq 0.5$) were used as surfactants in the emulsion polymerization of MA. All the reactions were carried out in batch, in a three-neck reactor with a reflux condenser, an argon inlet, and a mechanical stirrer. At different reaction times, samples were withdrawn by syringe under an argon flow. Hydroquinone was added to quench the polymerization, and the monomer conversion was determined by gravimetry.

Results and discussion

A series of amphiphilic statistical glycopolymers were synthesized by conventional radical polymerization of methyl acrylate and a synthesized glycomonomer with the glucose groups in the open-chain form, HEMAG. The monomer reactivity ratios were calculated from the cumulative feed and copolymer molar fraction data obtained during the reaction. The HEMAGl-MA system is fairly described by the Mayo-Lewis terminal model. The thermal properties of the obtained glycopolymers such as their glass transition and thermal stability temperatures, which resulting to be dependent on the carbohydrate composition, were studied to evaluate their operability for the application of these materials as antifouling coating. The incorporation of NABG into HEMA could leads to a considerable decrease in Tg due to the diaminobutyl flexible spacer. However, the inter- and intramolecular hydrogen bonds between carbohydrate hydroxyl groups compensate this diminishment.

The water soluble statistical glycopolymers, i.e. those with compositions higher than 0.5 in glycomonomer, were used as polymeric surfactants in the MA emulsion polymerization. In this sense, increasing the molar fraction of MA in the copolymer improves the performance of the glycopolymers as surfactants, and smaller and more monodisperse particles are obtained, varying their size in the range of 200 nm and 1 μm.

Abstract:

The control of macromolecular structure has recently become an important facet of polymer science from both an academic and an industrial point of view.

Indeed, free-radical crosslinking of Polydimethyl-vinylmethyl-siloxane (vinyl-PDMS) rubber by organic peroxide suffers from premature crosslinking at high temperatures, which is called scorching. Consequently, the basic aim of the investigations described in this work is to widen and explore the network topology-crosslinking kinetics relationships and find a novel way to control free-radical crosslinking chemistry and topological parameters of final PDMS networks. The work is primarily focused on the extensive study of the crosslinking control of PDMS rubber at high temperatures. A novel composition using 2,2,6,6-tetramethylpiperidinyloxyl (TEMPO) and dicumyl peroxide (DCP) for scorch delay and control of the final network topology of the PDMS has been proposed. The work specified in this investigation is therefore directed to find a proper [TEMPO]/[DCP] ratio provided the development of a new biphasic material such as PA12/PDMS blend type Super-TPV (Super Thermoplastic Vulcanizated). For this purpose a new method based on the relationship between the kinetics of the macro-radicals coupling [Rcc(t)] was derived from a fundamental kinetic model and the viscoelastic changes of the complex shear modulus (G'(t)ω and G''(t)ω). The kinetic model takes into account the initiator (DCP) decomposition and the trapped PDMS macro-radicals in the presence of a radical scavenger such as TEMPO. As a main result, the rheological modelling shows that this new method accurately predicts the time variation of complex shear modulus at any temperature and [TEMPO]/[DCP] ratio (Figure 1). Interestingly, addition of TEMPO to the TPV novel composition provided the PA12/PDMS blend compatibilization in the dynamic process and gives a new material having a controlled structure and morphology. A better insight in understanding the blend composition and the morphology development relationships is aimed at.

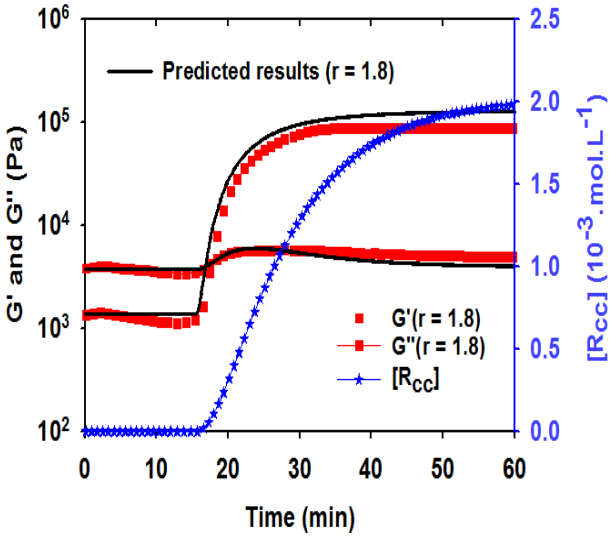

Figure 1: Rheological modelling of the free-radical crosslinking of PDMS rubber in presence of TEMPO nitroxide.

stefan.koestler@joanneum.at

Introduction:

Polyaldehydes are a very special class of polymeric materials. Their most distinguishing property is that many of them have ceiling temperatures close to or below room temperature. Therefore they can be depolymerized following a well defined unzipping reaction and are converted back into the monomers at moderate temperatures. Although this type of unzipping reaction has been recognized long ago [1] and such polymers were used as self-developing photoresists [2], the responsive properties of polyaldehydes were so far not explored for other applications. This interesting class of materials remains to be rediscovered for the preparation of smart functional materials. Recently it could be shown that polyaldehydes allow for the preparation of amphiphilic block copolymers [3] and the construction of chemoresponsive materials [4]. In this contribution we report on the preparation and characterization of poly(phthalaldehyde) and poly (glyoxylate) and amphiphilic block-copolymers. We also show applications of these thermoresponsive materials as dispersants, in the preparation of organic nanoparticles [5], or for inkjet formulations. Moreover the potential for further applications such as the synthesis of organic/inorganic hybrid materials will be discussed.

Materials and Methods:

Polyaldehydes from phthalalehyde and ethylglyoxylate were prepared by ionic polymerization. Block copolymers were obtained by coupling of preformed telechelic blocks. Molar mass and polymer composition were characterized by dual-detection size exclusion chromatography among other techniques. The thermal behaviour and depolymerisation reactions were investigated using scanning thermal analysis coupled with mass spectroscopy. Colloidal and self-assembly properties of amphiphilic polymers were investigated using dynamic light scattering, fluorescence probe techniques and by use for nanoparticle stabilization. Polyaldehyde homopolymers were investigated for the formulation of conductive inkjet printing inks. Inks were evaluated using rheology and printing tests using a piezoelectric drop-on-demand materials printer.

Results and Discussion:

Homopolymers of phthalaldehyde were polymerized with cationic and anionic initiators and their properties were compared. In order to prevent immediate depolymerisation the polymer endgroups were blocked using isocyanate capping reagents. For the preparation of block copolymers, poly(phthalaldehyde) blocks were endcapped with bifunctional reagents in order to obtain telechels. Telechelic polyaldehyde blocks having isothiocyanate endgroups can be isolated and subsequently coupled to amino-terminated poly (alkyleneoxide) to form amphiphilic block-copolymers. The poly(phthalaldehyde) blocks can selectively be depolymerized at moderate temperature (Fig. 1). These blockcopolymers were shown to be able to form micellar aggregates in solution. Consequently they were found to be effective dispersants. They were for example successfully applied for in-situ stabilization of organic nanoparticles during direct condensation synthesis.

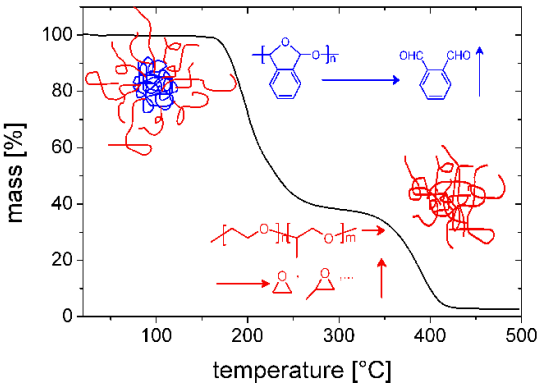

Figure 1: Thermogravimetry of poly(phthalaldehyde) – poly(alkyleneoxide) block-copolymer showing well defined depolymerisation/decomposition steps.

Different aldehyde polymers were also investigated as key components in the formulation of inkjet inks for printing of electrically conductive metal structures. Depending on their molecular structure and chemical composition, polyaldehydes can contribute various functionalities to the ink formulation. After printing, they can be easily and almost completely removed from the printed pattern by a simple heating step at moderate temperature. Such functional ink formulations are expected to have a major impact in fields like plastic and printed electronics, sensors and photonics.

Conclusions:

Due to their special thermodynamic properties, poly-aldehydes show a huge potential for the design of smart, stimuli-responsive materials. A few first examples could be demonstrated so far but many others can be expected for the future.

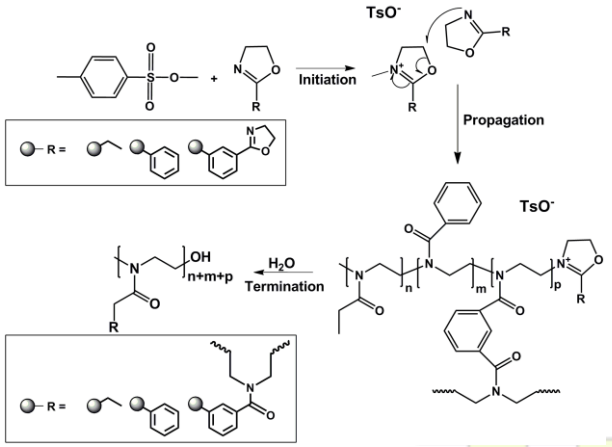
e-mail: f.wiesbrock@tugraz.at

Introduction: As the population of the world ages, new and more effective means of medical care will invariably have to be developed, integrating many fields of science. The diverse nature of polymer materials and the degree of specification which can be engineered via various functionalities allows for use in applications such as drug delivery, where stealth characteristics and biocompatibility of polymers allow for effective and safe use within the body,[1] surgical procedures such as suturing, bone grafting and tissue adhesion,[2] and in the growing field of tissue engineering and its reliance upon materials more biocompatible and functional than existing artificial implants.[3]

Materials and Methods: 2-Ethyl- and 2-phenyl-2-oxazoline were chosen as monofunctional oxazolines because of the food&drug administration FDA approval of the corresponding homopolymers.[4] Crosslinking of the propagating chains during copolymerization was provided by phenylene-1,3-bis-oxazoline. Hydrogel syntheses were performed in solvent-free one-pot routines under microwave irradiation benefiting from the acceleration of reaction speed under autoclave conditions.[5-6] The cationic ring-opening polymerization of 2-oxazolines was initiated by methyl tosylate (Scheme 1) and completed within reaction times of 1 h or shorter. Yields were 95% or higher (determined after repeated swelling/drying cycles). Organic compounds present in the polymerization mixtures were trapped in the polymer networks and not released during swelling.



Scheme 1: Hydrogel syntheses from the cationic ring-opening copolymerization of 2-ethyl-, 2-phenyl-2-oxazoline, and phenylene-1,3-bis-oxazoline.

Results and Discussion: Benefiting from the different hydrophilic/lipohilic characters of poly(2-ethyl-2-oxazoline) and poly(2-phenyl-2-oxazoline),[5] a 32-membered library of hydro-, lipo- and amphigels was prepared. Swelling degrees could be fine-tuned by careful balance of the three 2-oxazoline monomers (Figure 1). Representative hydrogels composed of all three monomers did not show any cytotoxicity effects according to ISO 10993-5, -12. Hydrogels with cross-linking degrees of 1:25 or lower quantitatively trapped organic compounds eventually present during polymerization in the polymer network. Degradation of the polymer networks by amide bond cleavage and concomitant release of the trapped compounds like pharmaceuticals was found to be triggered by acidic environments as they are characteristic in cancer cells.

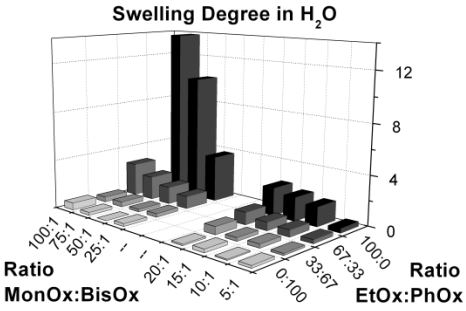


Figure 1: Maximum swelling degrees of the hydrogels in aqueous environments.

Conclusions: The rapid and facile synthesis of tailor-made oxazoline-based hydrogels with applicability in medicinal fields, in particular for pH-mediated drug delivery is reported.

Magnetic Properties of Neutral Substituted Poly(thiophenes)s

Steven Vandeleene, André Stesmans, Margriet Van Bael, Thierry Verbiest, Guy Koeckelberghs

Laboratory of Molecular Electronics and Photonics, Katholieke Universiteit Leuven, Celestijnenlaan 200F, B-3001 Heverlee, Belgium

guy.koeckelberghs@chem.kuleuven.be

Introduction:

Research on conjugated polymers has shown a great evolution since it became a topic of interest a few decades ago. While conjugated polymers were initially recognized as potential plastic electrical conductors, they are nowadays mainly investigated for applications based on their optical and electronic properties, such as field-effect transistors, light-emitting diodes and solar cells. The magnetic properties of materials based on conjugated polymers have also been investigated, but in these materials spins were deliberately introduced by oxidation (formation of polarons) or by the incorporation of spin-carrying moieties, such as radicals or carbenes. Here, we investigated the magnetic properties of neutral, substituted poly(thiophene)s.

Materials and methods:

The poly(thiophene)s studied (Figure 1) differ in the nature of the substituent (alkyl, alkoxy, thioalkyl) and regioregularity, the substitution pattern (head-to-tail (HT) versus HH-TT) and the molar mass. The poly(thiophenes)s were prepared using methodologies which result in defect-free structures and were thoroughly purified. Prior to the measurements, the polymers were treated with hydrazine. The measurements were carried out under inert atmosphere to avoid any oxidation.

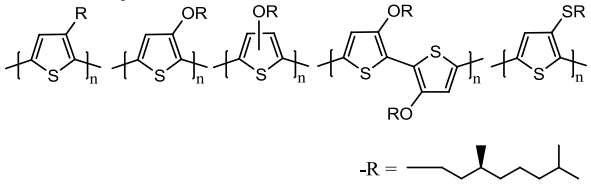

Figure 1. *Structure of the poly(thiophene)s studied.*

Results and discussion[1]:

The powders were subjected to ESR spectroscopy and SQUID magnetometry. ESR spectroscopy reveals the presence of unpaired electrons in all samples. The spin density is independent on the substitution pattern or regioregularity, but depends on the nature of the substituent. Slight oxidation of the samples (by exposure to ambient air) increases the spin density. The spins give rise to a paramagnetic behavior, demonstrating that no interactions occur, which is in line with S = ½. SQUID magnetometry reveals the presence of a second spin system. The amount of Bohr magnetons measured by SQUID is typical much higher than the amount of electron spins, measured by ESR. Moreover, they give rise to a superparamagnetic behaviour and the magnetization curves are not affected by oxidation. These results demonstrate that (at least) two systems are present: electron spin, sensed by ESR and a second spin systems, which is different from electron spins and ESR-inactive.

At low temperature (5K), most poly(thiophene)s show a ferromagnetic behavior. The coercivity does not depend on the amount of Bohr magnetons, but a clear correlation is present with the presence and strength of a absorption band, arising from stacked polymer chains which interact via π-interactions. This hypothesis was further investigated by measuring samples of HT-poly(3-alkylthiophene)s of different molar mass and by applying different annealing conditions. In both series, the degree of crystallinity is varied. In addition, annealing can also result in a different stacking. While the amount of Bohr magnetons is clearly affected by an increase of the crystalline fraction, the coercivity is not. Therefore, it must be concluded that the coercivity depends on the strength of the π-interactions.

Conclusions:

The magnetic properties of neutral, substituted poly(thiophene)s were studied. Two spin systems were identified. One is the electron spins, which gives rise to paramagnetism. A second spin system results in superparamagnetism at room temperature and ferromagnetism at low temperature. The number of Bohr magnetons depends on the fraction of lamellar stacked polymer chains, while the coercivity is governed by the strength of the π-interactions between the stacked chains.

Optimization of multilayer heat sealing

E. Planes[1*], *L. Flandin*[1]

[1]LMOPS UMR CNRS 5041 – Université de Savoie, Campus Scientifique, Bat. IUT F-73376 Le Bourget-du-Lac Cedex, France

Introduction.

Polymer-metal multilayer have been widely used for decades in packaging industry and more recently in building, as the envelope of vacuum insulation panels (VIP). The use of multilayer structures enables to have good level of barrier to gas combine with sufficient mechanical properties. In both cases the seal corresponds to the weakest zone. Even if the optimization of the heat sealing parameters of single layer films have been the subject of many investigations [1, 2], the heat sealing of multilayer has been less studied [3, 4]. Thus the aim of this study is to investigate the heat sealing properties of multilayer film, and to compare them to that of a single layer.

Materials and Methods

Materials The multilayer films are composed of one polyethylene (PE) layer and one (PETM) or three (F1Bis) polyethylene terephtalate coated or not with aluminum [5]. The low density polyethylene (LDPE) was employed as the sealing material: a control film was sealed and characterized for comparison.

Methods

Sealing Heat-seals were performed in the laboratory using Medsealer 460 MSID (K) heat sealer (Francopack). The pressure was fixed at 240 kPa and different experimental conditions were tested, varying dwell times: from 1 to 90s and sealing temperatures from 110 to 180°C.

T-peel test Strips of 25 mm wide were used for T-peel test at 90°. The samples were peeled at room temperature in an Instron mechanical testing machine, using a 2kN load cell. The constant rate of loading 100 $mm.min^{-1}$ was chosen and the force F (N) and displacement (mm) were recorded during the test. In this report, the raw data shows the force divided by the width (F/W) as a function of the displacement. The maximum force (F_{max}) divided by the nominal width (W) and the thickness (e) of the film is commonly employed to quantify the quality of the seals and defined as apparent seal strength SS. In addition, the failure modes of each test were carefully examined and will be described later.

Results and Discussion

As shown previously in the literature for monolith film, the most influencing heat-sealing parameter is the temperature and this is also valid for multilayer films. In addition the sole observation of failure modes enables to estimate the set of parameters to optimize the mechanical strength of the seal. In fact, the "peeling and tearing mode" (named (C)) corresponds to the maximal seal strength of the seal. This is confirmed by the evolution of the seal strength versus sealing temperature or dwell time.

Even if the study of multilayer sealing presents some similarities with one of simple film: the range of optimal heat sealing parameters, which was included within that of LDPE film, some differences were evidenced. A reduction of the optimal time-temperature range was observed: this latter becomes much smaller with an increasing number of PET layers. A very interesting advantage of multilayer was highlighted in this study: it concerns the influence of stiffer layers (*i.e.* PET), compared to flexible sealant layer (*i.e.* LDPE), on the mechanical behavior of the seal, since its maximal strength increases with the number of PET layers.

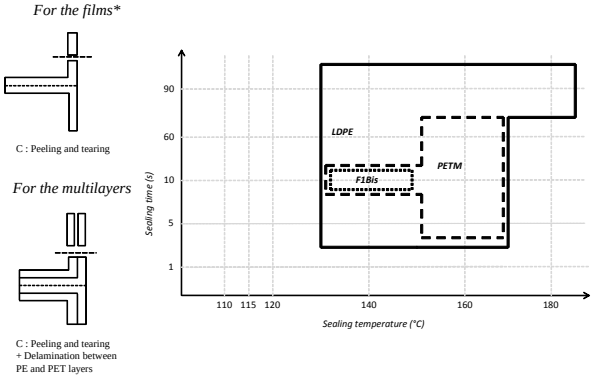

Figure 32: (left) Schematic illustration of failure mode (C) observed for monolith and multilayer films, (right) Range of optimal heat sealing parameters for three studied films

Conclusions and References

In this study, a method of optimization of heat sealing parameters was developed based on the observation of failure modes after peeling tests.

This work has allowed highlighting the interest of multilayer for sealing: an overlap of the range the optimal heat sealing parameters with the one of the sole sealant material and a more elevated mechanical strength of seal in the case of multilayer.

It would now be interesting to study other sealant materials in multilayer and more particularly the influence of the number, the nature (in chemical and mechanical terms) of the different layers of the multilayer.

tijana.ristic@tosama.si

Trends in developing new high-quality medical and healthcare textiles are in surface functionalization of textiles with intention to introduce bioactive properties with emphasis on antimicrobial activity. Due to the fact that consumers are becoming more and more concerned and watchful of their health and well-being, there is a significant interest in cellulose materials' functionalization using natural biodegradable and non-toxic reagents – as, for example, less employed polysaccharides and their derivates possessing antimicrobial properties From among the various polysaccharide products, amino-functional polysaccharides has recently gained considerable attention for use in pharmaceutical and medical applications.

One of the most promising amino polysaccharide is chitosan, a chitin derivative, obtained by alkaline deacetylation. Chitosan is a natural, renewable resource; a polycationic biopolymer that possesses a well-documented and wide-spectrum of biological activity, including antibacterial and antifungal activities. Therefore, chitosan's incorporation into the cellulose matrix offers many advantages over traditional treatments of cellulose fibres because of its non -toxicity, biodegradability, and biocompatibility. Several techniques are available for introducing chitosan onto cellulose fibres. These methods have been mainly limited to the treatment of cellulose fibres with cross-linking agents, the soaking of cotton fibres into chitosan solutions or impregnation by chitosan solutions, etc. The adsorption of chitosan and its interactions with cellulose material are not only affected by the surface physicochemical characteristics of the cellulosic substrates but may also be strongly influenced by the chitosan aggregate's nature. The introduced amounts of amino groups onto cellulose fibres and, consequently the fibre antimicrobial activity, may increase with the attachment of polysaccharides in colloidal form, in comparison with attaching a totally-soluble form of chitosan, such as chitosan acidic solution.

Thus, the aim of this work was to compare the adsorption of fully soluble chitosan (acidic solution) with the adsorption of precipitated chitosan particles, onto cellulose viscose fibres. The content of amino groups in the functionalized cellulose fibres was studied using potentiometric titration, and a conventional spectrophotometric method C.I. Acid Orange 7. Surface modification and adsorption of chitosan were, in addition, monitored by using XPS analysis. The antimicrobial activity of the functionalized cellulose fibres was examined against common pathogenic bacteria and fungus.

Modification of Surface Properties of Organically Modified Clay Particles for Preparation of Nanocomposite Hydrogels

Various types of montmorillonite (MMT) and closely related minerals are the most important and widely used phillosilicate fillers in polymer composites, due to their large active surface area (MMT: 700-800 m^2/g) and ability to swell remarkably in water. On the other hand, organically modified clay particles are known for their adsorption capacity for heavy metals, organic dyes and pollutants. This property makes them a very attractive component to be introduced into polymer matrices, but their intrinsic hydrophobic nature presents a challenge when inclusion into hydrogels is required.

Aim of our study was to modify surface of organically-modified clay particles in order to ensure a sufficiently stable aqueous dispersions, which would be later on used in the preparation of polymer hydrogels. We have used a non-ionic polysaccharide-based surfactant system – Inutec SP1 (based on chicory inulin) for the improvement of wettability of clay particles and consequently, enhancement of their dispersion ability in water-based systems. Different concentrations of surfactants were tested. Properties of the particulate surfactant-stabilized aqueous colloidal system were determined by zeta potential, electrophoretic mobility and dynamic light scattering measurements. Determination of contact angles gave us insight into the particles' surface interaction ability with water and non-polar solvents. Structure of dried particles in powdered form was investigated by small-angle X-ray scattering. Combination of electrokinetic and scattering data and established hydrophobic/hydrophilic character with analysis of particles sedimentation behaviour, allows us to use these findings to plan and predict the influence of such modified MMT particles on the formation of hydrogels and their subsequent properties. By modifying surface properties of clay particles with non-ionic surfactant, we have managed to reduce the size of particles and consequently achieved better incorporation of clay particles in hydrogel matrix. Increased surface area due to the reduction of particle size results in more active functional sites.

An elegant and facile single-step UV-curing approach to self-assembled Metallopolymer Capacitors

Introduction

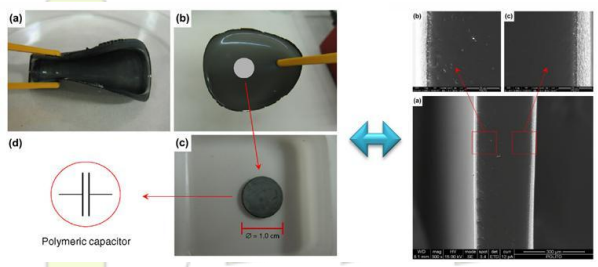
The current widespread interest in silver-metalized polymeric materials is driven largely by their potential applications in printed circuit boards, contact devices in microelectronics, flexible polymer electronics, catalysis, space applications etc. Silver-polymer nanocomposites have also been studied with the purpose of enhancing the dielectric constant for applications in embedded capacitors[1].

Free-radical photopolymerization (UV-curing) is a well established polymerization technique that takes place under UV light to obtain a highly cross-linked polymeric thermoset matrix. The process is well-known for being fast and environmentally friendly[2].

Here we report the first example of dual surface nanosilvering of a methacrylate polymer film by a simple UV-curing process. During the process the metalized film is directly developed from a single homogeneous solution that contains both the native metal precursor (i.e., Ag^+) and the desired reactive precursors of the final polymeric network. That is, the sample is obtained in a single stage and no subsequent distinct metallization stage is involved. To the best of our knowledge, such an approach has not been reported so far. This kind of polymeric film metalized on both sides is conceptually a capacitor, well-suited for flexible and/or nonplanar electronics.

Materials and Methods

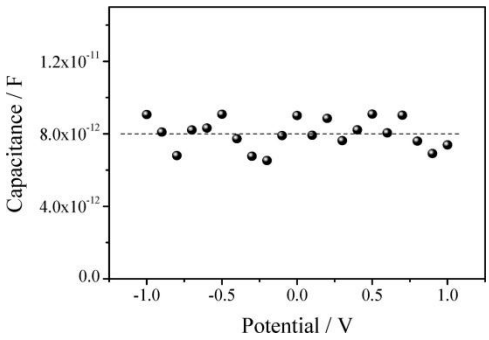
The reactive formulations were prepared as follows: $AgNO_3$ was dissolved in 50% (v/v) CH_3OH + H_2O mixture. To this solution, BEMA, pyrrole and initiator were added subsequently and mixed thoroughly. A molar ratio of 2:1 or higher for pyrrole to silver nitrate was maintained to ensure complete reduction of Ag(I). The mixtures were then poured into Petri dishes and exposed to UV-radiation for 3 min on each side. The photochemical curing was performed by using a medium vapor pressure Hg UV lamp (Helios Italquartz, Italy), with a radiation intensity on the surface of the sample of 30 mW cm^{-2}. For this process, the samples were held under a pure N_2 atmosphere in small sealed boxes equipped with a quartz window. These conditions ensure maximum curing. Free films were easily detached from the dishes (see the figure below).



Results and Discussion

Current-voltage (*I-V*) curves were recorded for the surfaces of the samples to know how conductive they are. The I-V curves obtained for the top surface of sample were perfectly linear, suggested an ohmic behavior. Moreover, the overlapping of the multiple curves recorded over different points on the surface indicates a highly homogeneous distribution of Ag nanoparticles and polypyrrole on the surface.

Circular discs of 1.0 cm in diameter were cut out from the master film and tested for capacitive properties. The figure below shows the capacitance vs. potential curve for a sample at a frequency of 100 Hz.



It is similar to the curve obtained by Liu et al.[3] for a polymeric capacitor prepared by inkjet printing with polyimide in the center and poly(3,4-ethylenedioxythiophene) on the surfaces, and the capacitance value is also similar, i.e., in the picofarad range.

Conclusion

In summary, we have successfully introduced a novel, simple but efficient method that allows excellent dual surface metallization of a methacrylic-based polymer network, in a single step. The formation of two conducting layers on either sides of an insulating polymer in a single step opens up possibilities of rapid production of highly flexible polymeric capacitors, which until now are made by time-consuming multiple steps procedures. The whole process is remarkably convenient, with short reaction time, "environmentally friendly", and no need for any complex equipment or manipulation.

**e-mail: lara.perrin@univ-savoie.fr*

Introduction:

The performance of organic photovoltaic solar cells depends on the active layer morphology, especially the arrangement of the donor and acceptor materials. A common way to improve the performance of organic solar cells would be to increase the amount of donor / acceptor interfaces. Different ways have already been explored[1]. A new approach could consist in developing nano-multilayers of donor and acceptor polymers by forced assembly.

Materials and Methods:

Poly(3-octylthiophene) P3OT was chosen as the donor polymer and Poly(styrene-co-NC_{60}-methylstyrene) $PSNC_{60}MS$ as the acceptor polymer. The first part of the work focused on synthesis and characterization of various acceptor polymers with different amounts of C_{60}. To determine the optimal composition of the fullerene C_{60} in polystyrene matrix the electrical (charges mobility and conductivity), optical (absorption, optical gap energy) and photovoltaic properties (tests in bi-layer and bulk-heterojonction photovoltaic solar cells using P3OT as donor polymer and $PSNC_{60}MS$ as acceptor polymer) have been measured. Finally, the rheological behaviour and characteristic temperatures of both polymers were studied to confirm their plausible processability by extrusion.

Results and Discussion:

The work presented here is part of a broader project, which will consist in using a new solvent-free process[2] to produce nano-multilayers organic solar cells, with alternating donor and acceptor. Two polymers were designed and synthesized taking into account several criteria, like special processing conditions and photovoltaic properties.

The polythiophene family is well known in the field of solar cells. A good compromise between photovoltaic and processing properties[3] is easy to find using the commercial P3OT with an octyl side chain.

The $PSNC_{60}MS$ combines photovoltaic properties (good acceptor characteristic) of the fullerene C_{60} and processing properties of polystyrene. A large range of polystyrene grafted by a various percentage of C_{60} was synthesized in the laboratory, by a three steps method[1b].

Both physicochemical and photovoltaic properties were characterized as a function of C_{60} percentage. This enables us to determine the lowest amount of C_{60} required for an application in solar cell.

A percolation threshold of 4.4%vol (7.1%wt) was identified for both conductivity and mobility measurements (Figure 1).

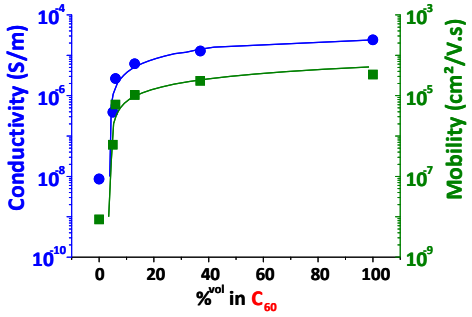

Figure 1: *Conductivity and Mobility values obtained for $PSNC_{60}MS$*

Then, the 'extrudability' of both selected polymers (donor and acceptor) was estimated using TGA and DSC in order to detect the possible range of processing temperature (180-300°C). In addition, the rheological behaviour (Figure 2) was qualified with a plan-plan rheometer to estimate possible processing conditions[2].

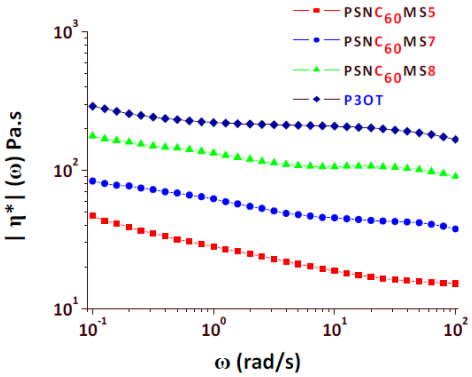

Figure 2: *Comparison of rheological behaviour of P3OT and $PSNC_{60}MS$ with different C_{60} percentages.*

Conclusions and References:

As a conclusion, the study summarized here confirms both chosen polymers are compatible with the aimed application, and suitable for coextrusion process.

Next steps of the study will be a large scale production of these polymers, in order to do the first processing of solar cells active layer by nano-multilayers forced assembly.

Among the most interesting new phenomena arising from the nanosizing of materials are those derived from specific interactions between electromagnetic radiation and nanoparticles, as for instance optical properties. Selected metals (typically Au, Ag and Cu) present the so called, **Surface Plasmon Resonance** (SPR),[1] a property which can be recognized by naked eye, as such metal nanoparticles present vivid colorations. Although this phenomenon requires a full quantum dynamic formulation for its complete description, it classically manifests itself as an absorption band in the visible spectrum, originated by large electronic movements due to a notable increase of the local electric field at the metal/matrix interface.

The main interest of this effect is that the local field enhancement allows observing several non-linear processes with conventional illumination sources. However, to take full advantage from SPR-derived physical processes it is in many cases mandatory to embed the nanoparticles into a homogeneous and transparent matrix which enables the handling of the material. The embedding process poses two main problems, first how to integrate the particles in the matrix without aggregating them and second, how far do the properties stay the same when the particles change their environment. Matrixes for embedding can be inorganic, like glasses or porous silica, though integrating the nanoparticles in polymeric matrixes has many practical advantages, mainly related to the light weight and mechanical properties of these materials.

Two main strategies have been used to prepare **metal-polymer nanocomposites**: (i) *ex situ* methods based on the dispersion of metal nanoparticles in polymer solutions or in monomer mixtures to be afterwards polymerized[2] or (ii) *in situ* methods in which metal nanoparticles are generated in the midst of the polymer matrix by the spontaneous or induced reduction of the metallic precursor.[3] Both methods fail to offer a simple way to prepare well dispersed nanocomposites in a varied range of polymer matrixes.

The alternative presented in this work is based on a **multiscale** approach in which metallic nanoparticles are supported on an inorganic carrier, **sepiolite**. Sepiolite is a magnesium silicate which presents a needle-like structure that can be relatively easy to disperse in polymers by conventional processing techniques.[4] To embed Ag and Au nanoparticles in the fibers, sepiolite was subjected to acid and thermal treatments previously reported.[5] The as-obtained *metallic sepiolites* were afterwards dispersed in the polymer matrixes: low density polyethylene (LDPE) and polystyrene (PS) by melt compounding in a lab extruder. The inorganic content ranged from 2 to 40%.

The resulting materials were macroscopically homogeneous as a consequence of an optimal dispersion of the metallic sepiolite as checked by microscopy techniques (SEM and TEM). Sepiolite has a similar refractive index as those of the polymer matrix avoiding light scattering and, thus, the materials show an excellent optical transparency. The multiscale composites exhibit plasmon bands at all loading coatings regardless of the film thickness. Plasmon maxima for Ag and Au-sepiolite composites are located at 445-426 nm and 530-537 nm, respectively, depending on the polymer matrix. In addition, the composites not only behave as plastic materials, but also they are mechanically reinforced and thermally stabilized by the addition of the sepiolite fibers.

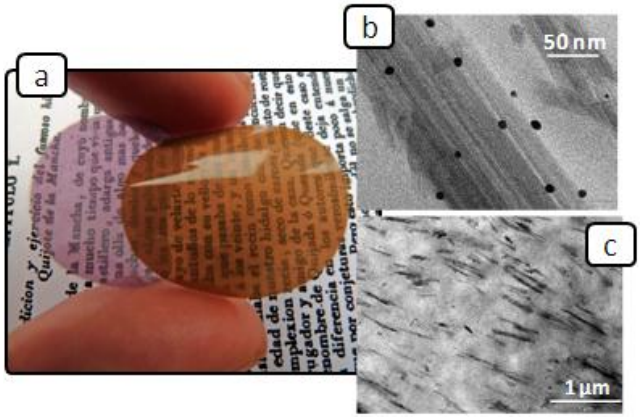

Figure. a) Visual appearance of films (50-µm width) prepared from the multiscale gold and silver nanocomposites. b) and c) TEM micrographs showing the metallic nanoparticles (Au) supported on the sepiolite carrier and the sepiolite dispersed in the polymer matrix (LDPE), respectively.

Introduction

Magnetic nanoparticles (NPs) are used in life sciences as contrast agents for imaging applications as well as heating sources for hyperthermia.[1] However, their lack of stability in *in vivo* conditions, their potential toxicity and their poor targetability must be improved through chemical modifications of their surface. Herein, we report on a new method to modify the surface of magnetic NPs by adsorption of a double hydrophilic poly(ethylene oxide)-*block*-poly(L-lysine) (PEO-*b*-PLL) copolymer end-functionalized by a targeting peptide and/or fluorescent probe. The physical entrapment of anticancer drug (doxorubicin) within the adsorbed polymer layer was achieved to combine both imaging and therapeutic capabilities in a single system. In addition, the co-adsorption of PEO-*b*-PLL copolymer with thermoresponsive copolymers was explored from a fundamental point of view at first and then as a mean to trigger the drug release by applying an alternative magnetic field.

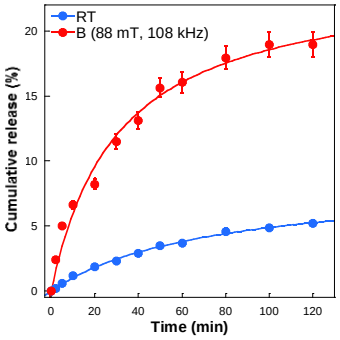
Materials and Methods

Silica coated perovskite nanoparticles, PEO-*b*-PLL and Jeffamine-*b*-PLL (thermosensitive) copolymers were synthesized and characterized according to previous reported protocols.[2,3] The functionalization of the copolymers with fluorescent probes and targeting peptide was achieved through thiol/maleimide coupling reaction. Block copolymer adsorption onto nanoparticle surface was performed in 10 mM phosphate buffer pH 7.4. Doxorubicin was physically entrapped in the polymer layer during this adsorption step as well.

Results and discussion

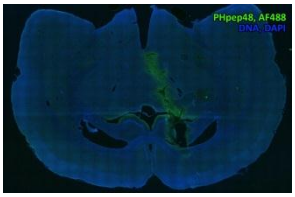
Magnetic nanoparticles used in this study are based on manganite perovskite nanoparticles (Tcurie = 43°C) of 60 nm in diameter surrounded by a 5 nm thick silica shell. The silica layer confers to the particles a strong negative charge at physiological pH. A series of PEO-*b*-PLL copolymers with different block lengths were physically adsorbed onto modified magnetic NPs. The gradual addition of silica particles to an excess of PEO-*b*-PLL copolymer solution was the preferred method for particle coating as it favoured equilibrium conditions where the copolymer layer has good stabilizing properties against flocculation. A combination of analytical techniques such as dynamic light scattering (DLS) and isothermal titration calorimetry (ITC) evidenced the higher affinity of PLL blocks with silica surface over PEG blocks. Indeed, we showed that PLL interacts with silica surface through both electrostatic interactions with SiO^- groups and hydrogen bonding with silanols. PEO_{113}-*b*-PLL_{10} was found to be the most interesting copolymer composition since it affords high colloidal stability in time and in protein rich media. Actually, such physico-chemical properties are related to the conformation of the PEO block at the particle surface. Interestingly, we showed that this conformation is set by the length of the anchoring block (PLL), short or large PLL blocks favouring a brush-like or mushroom conformation of the PEO blocks, respectively. Jeffamine-*b*-PLL copolymers where jeffamine is a random copolymer of ethylene oxide and propylene oxide with a LCST of 70°C was co-adsorbed with PEO-*b*-PLL copolymers to confer thermosensitivity to the polymer layer. High doxorubicin loading contents of 30 and 70% were achieved by incubating NPs with doxorubicin at room temperature and 50°C, respectively. This underlines the higher hydrophobicity of the mixed copolymer layer when temperature increased. In a similar manner we showed that the doxorubicin release was fastened when the temperature increased.

As expected, we demonstrated that the hyperthermia induced heat could enhance the bioavailability of doxorubicin entrapped within the thermosensitive polymeric shell. (see opposite figure)



Lastly, the NPs were functionalized by AlexaFluor 488 and a cyclic targeting peptide. A brain inflammation was induced in rat by inoculation of a proinflammatory cytokine (IL-1β/LPS). NPs were intravenously injected in the caudal vein.

Fluorescence imaging of brain slices showed a preferential accumulation of NPs along endothelial cells close to the inflammation site. (see opposite image)



This result was also confirmed by magnetic resonance imaging (MRI) where a negative contrast was observed at the inflamed site.

Conclusion

We reported the synthesis of multifunctional magnetic NPs affording targeting, hyperthermia and therapeutic properties. Preliminary biological evaluations have confirmed their potential use for brain diseases.

Effect of Polymer Structure of Acrylic Pressure-Sensitive Adhesives on Light Leakage Phenomenon in TFT-LCD Panel

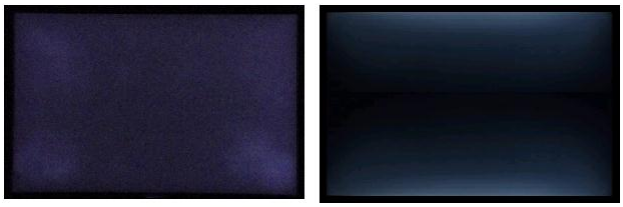
Irina Nam, Kyoungjin Ha, Kilsung Lee, Lee June Kim, Changmin Lee, Misun Kim, Tuwon Chang

Polymer Synthesis and Dispersion Group, Manufacturing Materials R&D Center, Electronic Chemical Materials Business Unit, Cheil Industries Inc., Samsung

nam.irina@samsung.com

Introduction.

Thin film transistor liquid crystal display (TFT-LCD) are widely used in desktop computer monitors, laptop computers, mobile phones, digital cameras, navigation systems, video game systems, etc. With continuously increasing consumer demands, manufactures pay lots of efforts in perfection of their products. Nowadays, one of the main problems in TFT-LCD panels is a phenomenon called "light leakage", seriously affecting black-white contrast and color brightness (Figure 1).



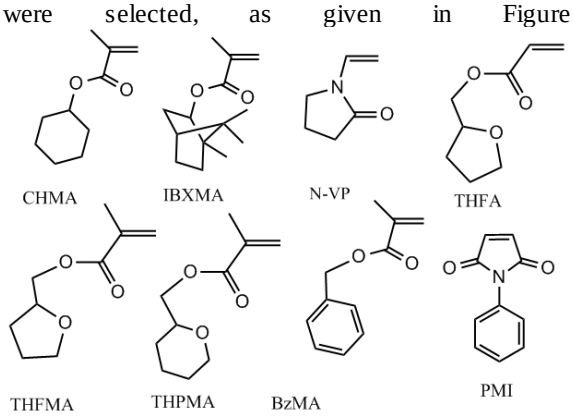
a) corner light leakage at AV mode b) edge light leakage at TN mode

Figure 1. Examples of light leakage in LCD in a) vertical alignment and b) twist nematic modes.

It occurs due to thermal stress in the polarizing film, one of the main parts of TFT-LCD panel, caused by a heat from the back light unit [1]. A pressure-sensitive adhesive (PSA) used for assembling of the polarizing film is believed to provide stress relaxation to the polarizing film and prevent its thermo-induced shrinkage, and thus minimize the light leakage [2,3].

Results and discussion.

In this paper, we supposed that introduction of acrylic/methacrylic monomers having an aliphatic or aromatic cycle in ester radical position will result in improved heat-resistant and visco-elastic properties of the PSA. As such, eight commercially available monomers were selected, as given in Figure 2.



Figiure 2. Structure of the monomers.

Effect of the polymer structure and glass transition temperature on light leakage performance was investigated in complex with other two important characteristics of PSA system, as creep and peel strength. It was found that the polymers with the lowest and the highest glass transition temperatures (Tg) were excellent in prevention of light leakage. Zero light leakage was achieved through synergy of two mechanisms: resistance to thermo-induced shrinkage and stress relaxation. We also succeeded in making our PSA suitable for universal application in TFT-LCDs from 2.5 to 19 inch with obvious technological and economical benefit.

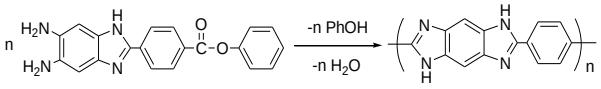
E-mail: polykim@cc.okayama-u.ac.jp

Introduction

Aromatic polybenzimidazoles possess the outstanding performances, and they have been paid much attention from both the academic and industrial aspects.[1,2] Materials down-sized to the nanometer scale can show very different properties, enabling unique applications, and hence polybenzimidazole nanofibers will become more indispensable in high-technology field. Reaction-induced phase separation during isothermal solution polymerization is a very useful method for the morphology control of poor processable polymers, and we studied the morphology control of poly[2,6-(1,4-phenylene)-benzobisimidazole] (PPBI) during the polymerization of 1,2,4,5-tetraaminobenezene and diphenyl terephthalate. [3] PPBI crystals obtained by this method exhibited very unique brush-like morphology, whereas the nanofibers could not be prepared so far. This study aims to prepare the PPBI nanofibers by the self-polymerization of 2-(1,4-carbophenoxyphenyl)-5,6-diaminobenzimidazole (CPAB).



CPAB PPBI

Experimental

CPAB was synthesized according to previously reported procedures. [14] Liquid paraffin (LPF) from Nacalai Tesque and a mixture of structural isomers of dibenzyltoluene (DBT) from Matsumura Oil (Barrel Therm 400) were purified by vacuum distillation.

Polymerization in DBT was described as an example. DBT was placed into a cylindrical flask and heated up to 350°C under slow stream of nitrogen. When the temperature reached to 350°C, CPAB was added under stirring. The mixture was stirred to dissolve CPAB entirely, and then polymerization was carried out for 6 h at 350°C without stirring. Polymerization concentration was 1 wt%. Precipitated polymers were isolated by filtration at 350°C, and then washed with acetone. PPBI crystals were obtained with the yield of 85%.

Results and Discussion

Table presents polymerization results. Spheres with smooth surface and those with short needles on the surface were formed in LPF with the yield of 75 %. The diameter of the spheres with smooth surface ranged from 0.4 to 0.8 μm. The polymerization in DBT/LPF (DBT content: 50 wt%) afforded brush-like crystals with the yield of 65 %. The brush-like crystals were comprised of plate-like crystals and needles. Small needles, of which the length and width were averagely 80 and 20 nm, grew on the surface of the plate-like crystals. The polymerization in DBT gave the nanofibers successfully with the yield of 85 % as shown in Fig. The width of the fibers ranged from 30 to 110 nm and the fibers fused each other, resulting in the formation of three-dimensional network structure like nonwoven fabrics. The length is longer than 1 μm between the fused points. IR spectrum of the nanofiber network is identical with that of PPBI. The inherent viscosity (η_{inh}) of the nanofiber network was 0.65 $dL \cdot g^{-1}$ and it is the highest value among the PPBIs prepared in other solvents. The nanofiber network possesses the highest crystallinity. In order to evaluate the molecular orientation, the nanofiber network and the brush-like crystal were observed in details on a TEM. Fig. shows morphologies and SAED patterns. Sharp reflection spots were clearly observed in SAED of the nanofiber and the fiber identity period 1.06 nm was correspond to the length of one repeating unit 1.26 nm, suggesting that the molecules might align along the long axis of nanofibers. Oligomers left in DBT at 350°C were analyzed by MALDI-TOF mass spectrometry. Oligoimidazoles up to tetramers were detected and those larger than pentamers must crystallize to form the nanofibers. The molecular weight increased by the polymerization in the precipitated crystals.

Table Polymerization of CPAB in three kinds of solvent

Solvent	Yield (%)	η_{inh} [a] ($dL \cdot g^{-1}$)	Morphology	$T_{5\%}$ [b] (°C)
LPF	75	0.59	sphere, SN [c]	413
DBT/LPF-50	65	0.60	brush	422
DBT	85	0.65	fiber	457

[a] η_{inh} was measured in 97% sulfuric acid at a concentration of 0.2 $g \cdot dL^{-1}$ at 30°C. [b] Temperature of 5% weight loss measured on a TGA at a heating rate of 20°C·min^{-1} in N_2. [c] SN stands for spheres with needles on surface.

Thermal stability of these products was measured by TGA in N_2 and temperatures of 5 % weight loss are in the range of 413 - 457°C. The nanofiber network possesses the highest thermal stability due to high molecular weight and high crystallinity.

Conclusions

The nanofiber networks were formed by the polymerization of CPAB in DBT. The width of the nanofiber ranged from 30 to 110 nm. Molecules were aligned along the long axis of nanofibers. The nanofiber networks exhibit the highest thermal stability.

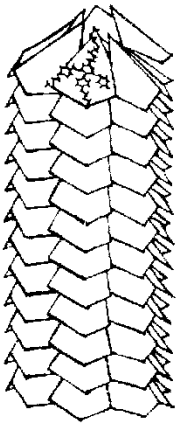
Supramolecular chemistry and molecular technology are among the most claimed fields of modern materials science. Attention of researchers is concentrated on fundamental principles of self-assembling, embracing molecular recognition of exo- and endoreceptors, as well as on the possibilities for manipulating the nanosystem structure by moderate changes of environment conditions and of outer fields of different nature (including geometrical confinement). Self-assembling is a co-operative process, giving substantial benefits for manufacture rates. Moreover, it is a “bottom-up” process, in which molecules of particular compound form supramolecular aggregates to be used as building blocks of the macroscopic system. Thus, the use of self-assembly process allows for much more accurate manipulation by the material structure and for the design of neat, precise structures.



We have carried out comparative analysis of the structure of supramolecular aggregates formed by tapered and conical dendrons, ordered by different driving forces: van-der-Vaals (compounds on the basis of gallic acid), ionic (symmetric and asymmetric benzene-sulfonates of alkaline metals), fluorophobic effect etc. It was shown that at room temperature tapered dendrons form usually ordered 2-d hexagonal phase. Internal structure of cylinders is determined by a complex of different factors, such as the type of focal group, length and chemical structure of aliphatic chains. With increasing temperature compounds studied undergo a transition to the disordered columnar phase, followed by isotropization. It was shown that ϕ_{bh} - ϕ_h transition is a co-operative process of consecutive "melting" of alkyl tails and mesogen groups. In benzene-sulfonates this effect has a very important consequence. In ordered state, cylinders formed by such compounds, have an axial channel, its diameter being a function of the metal counter-ion. During transition to disordered columnar phase, increasing mobility of mesogens causes channels to close, thus giving the way to design of membranes with temperature controlled ion transmission.

Further heating of disordered columnar phase results in significant decrease of column diameter, with negative thermal coefficient $\beta=-(1\div2)\times10^{-3}$ K^{-1}. Such behavior can be explained by polymer chain unwinding in the column upon heating. In several cases we also observed high-temperature cubic micellar or bicontinuous phases. Although isotropization strongly depends of the chemical structure of tails, it takes place at the same critical column diameter due to the Rayleigh instability of the cylinder because of the increased fluctuations of its diameter with increasing temperature. Intensity of these fluctuations is a function of interactions between mesogenic groups and aliphatic matrix. For the cylinders with rigid cores, ordering of high-temperature fluctuations may lead to the development of 3D ordered structures. This effect was found upon heating of monomers with partially fluorinated alkyl tales: bicontinuous gyroid phase develops near the temperature of isotropization. Its structure was thoroughly studied by the reconstruction of electron density maps (see Figure on the right).

We studied self-assembling structures, formed by tapered dendrons (including chiral molecules on the basis of gallic acid and dipeptides) in bulk and in solutions. It was found that in the solution dendrons form elongated aggregates similar to those in bulk.

ricarda.wagner@infu.tu-dortmund.de

Introduction

The need for materials allowing rapid testing is constantly growing. Being cheap and robust, molecularly imprinted polymers (MIPs) based on responsive host monomers may be employed as sensing materials, e.g. in handheld devices or fibre-optic sensors operating with miniaturised optical equipment and a chromo- and/or fluorogenic-sensing matrix.[1-3]

Materials

We previously reported on the use of urea-based monomers for imprinting oxyanion templates.[4]

We present here a compilation of novel urea-based monomers designed for imprinting various molecules of biological and environmental importance such as amino-acids, peptides and proteins. The monomers are designed to have the dual ability to specifically bind a target molecule and to report the binding in the form of quenching or enhancement of their fluorescence emission or shifts in their UV-visible spectra.

Fig 1.: Induced colour changes of solutions of a urea-based monomer in the presence of increasing concentration of guest TBA-Benzoate (0 – 10 eq) in DMSO.

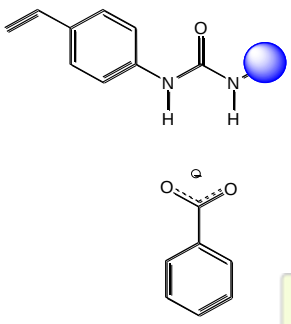

Fig. 2: Proposed complexation mode of Urea-based monomers with Benzoate

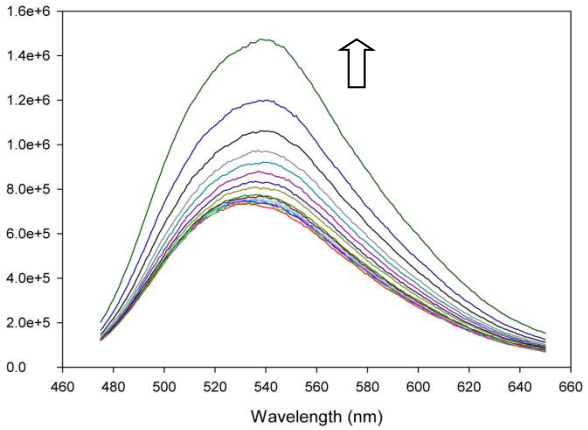

Fig. 3: Induced change in fluorescence emission intensity of urea-based monomer upon addition of increasing concentration of guest molecule TBA-Benzoate (0 – 40 eq) in DMSO.

The most promising of the novel urea-based monomers were successfully employed as building blocks in the synthesis of molecularly imprinted polymers.

Monolithic as well as nano- and hierarchically structured bead formats were applied for a variety of targets, including small- molecule anions such as amino acids up to antibiotics and proteins.

The monolithic polymers were evaluated chromato-graphically to test their molecular recognition behaviour, whereas their chromogenic and fluorogenic properties were investigated in response to various targets in different solvents for comparison with the behaviour of the soluble host monomer alone.

Conformational Behavior of Conjugated Polymers with Oligo(PhenyleneVinylene) Side Chains

Helmuth Peeters, Wouter Vanormelingen, Thierry Verbiest, Guy Koeckelberghs

Laboratory of Molecular Electronics and Photonics, Katholieke Universiteit Leuven, Celesijnenlaan 200F, B-3001 Heverlee, Belgium

helmuth.peeters@chem.kuleuven.be

Introduction:

During the last decades there has been a great interest in conjugated polymers, as they are implemented in polymeric photovoltaic cells, field-effect transistors and light-emitting diodes. In most cases the electric and optical properties solely arise from the polymer main chain. The function of the side chain, very often an aliphatic chain, is limited to ensure good solubility and to stabilize the supramolecular organisation. Preceding research[(1)], that focused on a system with oligo(phenylenevinylene) (OPV) side chains implemented on a dithienopyrrole polymer main chain, demonstrated that the side chain is also of critical importance for the conformation of the polymer. More specifically, substitution of the β position of the OPV side chain has a crucial influence. The bulkiness of the latter determines the conformation of the polymer, i.e. – short chains will favour a helical conformation, while bulky chains force the polymer in a lamellar supramolecular structure.

Materials and methods:

The polymers are synthesized using a Stille polycondensation of a dibromo OPV derivative and a distannate, for instance a distannylated thienothiophene. These polymers all have the same molecular structure - the same polymer main chain and the same OPV side chain, except the bulkyness of the R' alkyl group differs. the polymers were investigated with UV-Vis, CD and emission spectroscopy

Results and discussion:

Given the fact that the nature of the polymer backbone and OPV side chain is the same, possible differences in the optical and electronic properties must originate from a different conformation or supramolecular structure. The polymers will adopt a coil like structure with identical UV-Vis spectra for the polymers, regardless the length of the R' substituent. It is also important to note that no CD signal will be expected in a good solvent. In a poor solvent on the contrary, a polymer with a short R' chain, will preferably adopt a (one handed) helical conformation due the space filling substituted gallic moiety (Figure 1).

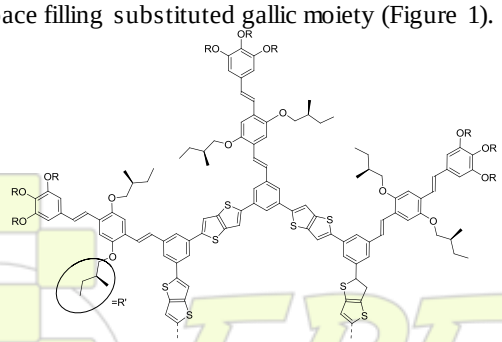

Figure 1: Preferred helical conformation for a polymer with a short R' chain (-R = -C_8H_{17}).

When substituting the polymer with a long R' chain, the polymer will be sterically unable to adopt a helical conformation in a poor solvent (Figure 2A). A planar, zig-zag conformation on the other hand is allowed and this will result a lamellar, supramolecular structure (Figure 2 B).

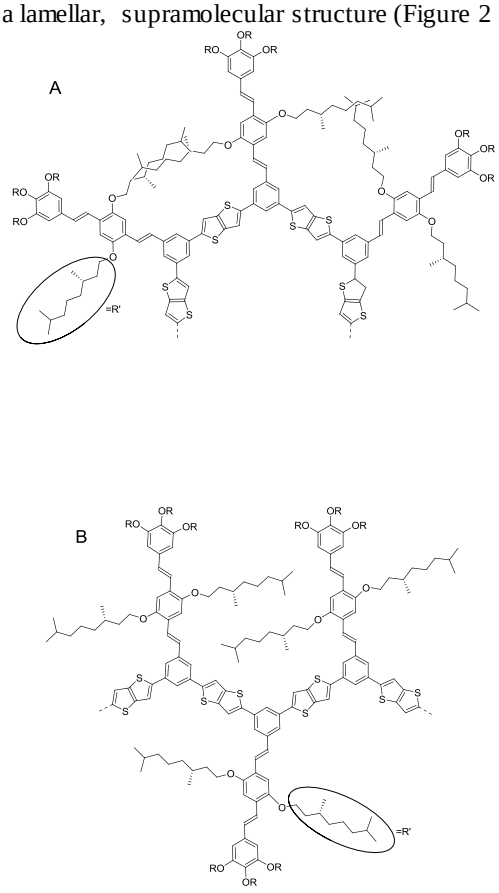

Figure 2A: The long R' chains prevent a helix conformation and B: the lamellar zig zag conformation of the polymer with long R' chains(-R = -C_8H_{17}).

Conclusions:

Small alterations in structure of the polymer, i.e. a change in length of the R' chain, has a tremendous influence on the conformation of the polymer. Applying this on polymers with another main chain, the conformation can easily be altered from a helical conformation to a supramolecular structure, by just tuning the length of the R' group.

Nanocomposites: dispersion quality and percolation threshold

Nick Watzeels, Hans E Miltner, Christophe Block, Guy Van Assche, Bruno Van Mele, Hubert Rahier

Vrije Universiteit Brussel (VUB), Physical Chemistry and Polymer Science (FYSC), Pleinlaan 2, B-1050 Brussels, Belgium

Email: nick.watzeels@vub.ac.be

Introduction

The last two decades a lot of research was spent on nanocomposite. The key factor in attaining the superior properties of these novel hybrid materials is the achievement of high levels of nanofiller dispersion of the incorporated low amounts of nanosized filler particles, resulting in a vast amount of polymer/filler interphase. [1]

Materials and Methods

The nanocomposites used in this work were prepared by melt mixing techniques, using Poly(ε-caprolactone) (PCL) or Poly(propylene) (PP) as polymer matrix. As nanofiller particles we used silicates based on natural montmorillonite (exchanged with quaternary alkyl ammonium ions), multi walled carbon nanotubes (MWNTs) and cellulose nanocrystals.

The nanocomposites of this work were prepared by melt mixing

Morphological information was obtained from atomic force microscopy (AFM), Transmission electron microscopy (TEM) and Wide-angle X-ray scattering (WAXS). Small angle oscillatory shear rheometry ('dynamic rheometry') experiments were carried out using a cone-and-plate geometry. Thermal characterization was performed using Modulated Temperature Differential Scanning Calorimetry (MTDSC). The mechanical properties of the various materials were assessed by determining their secant modulus (3-point bending mode).

A simulation program called Macropac (Version 6.1) (Intelligensys Ltd) was used to model the packing of objects into a simulation container.

Results and discussion

A comprehensive overview of available methods for assessing nanofiller dispersion is presented for a wide range of layered silicate-based nanocomposites, carbon nanotube-based nanocomposites and nanocomposites containing cellulose nanocrystals. [2]

Focusing on their respective strengths and weaknesses, rheological, mechanical and thermal characterization approaches are evaluated in direct relation to morphological information. [3] An advanced thermal analysis methodology (using MTDSC) is employed for the characterization of the PCL and PP nanocomposites. During quasi-isothermal crystallization, the presence of high aspect ratio nanofillers strongly affects the amount of crystalline-amorphous interface, thus increasing the recorded excess heat capacity (Cpexcess). This increase is in direct relation to the nanofiller dispersion quality. [4]

In a second part of the work, the minimum loading of nanofiller particles needed to obtain a physical network (percolation network) was studied using a simulation program called Macropac (Intelligensys Ltd). [5] Macropac uses a Monte Carlo approach to place particles at random in a simulation box (see Figure 1).

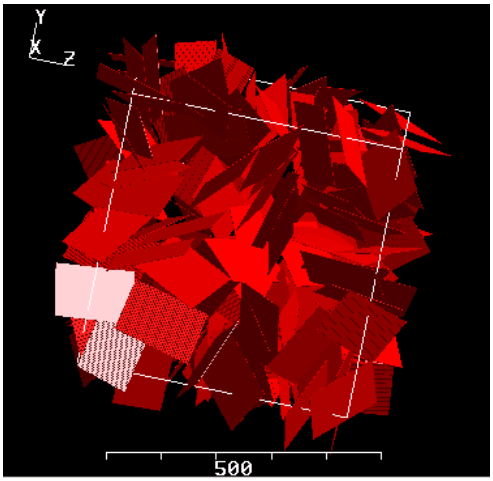

Figure 1: 3-D visualization of a packing of plate-like structures, mimicking silicate platelets, obtained using Macropac simulation software.

Conclusions

It is observed that the degree of filler dispersion is strongly influenced by the specific matrix/filler interactions and the processing conditions.

It is concluded that each techniques used to study the nanofiller dispersion in nanocomposites provides information on a different level of the quality of the dispersion. In other words, a combination of different techniques is needed to make a qualitative assessment of the nanofiller dispersion.

Amphiphilic block copolymers, comprised at least two incompatible homopolymers covalently connecting at their ends lead to a fascinating class of self-assembling materials and present unique properties in selective solvents. Copolymers containing poly(ethylene oxide) (PEO) as hydrophilic segment and polystyrene (PS) as hydrophobic segments in PS-*b*-PEO diblock or PS-*b*-PEO-*b*-PS triblock copolymers were widely studied in the literature. The only way, which allows synthesizing block copolymers with well-defined structure, is the living/controlled polymerization techniques, namely ionic polymerization and radical controlled polymerization (CRP). Contrary to the PS-*b*-PEO diblock copolymers, the PS-*b*-PEO-*b*-PS triblock copolymer cannot be prepared directly by anionic polymerization. There were relatively few studies, which have exploited CRP for the synthesis of PS-*b*-PEO-*b*-PS copolymers. In this work, we describe the synthesis of PS-*b*-PEO-*b*-PS and PSAN-*b*-PEO-*b*-PSAN (PSAN for poly(styrene-*co*-acrylonitrile)) triblock copolymers using a new method: nitroxide mediated polymerization of styrene with a difunctional PEO macroalkoxyamine.

Difunctional PEO macroalkoxyamines were characterized by ^{1}H, ^{31}P NMR and mass spectroscopy (EIS-MS and MALDI-Tof),[1] whereas a series of block copolymers with different molar masses and compositions were characterized by ^{1}H NMR, size exclusion chromatography and 2D chromatography.[2] The character self-assembling in ordered structure of obtained PS-*b*-PEO-*b*-PS triblock copolymers was studied by AFM and different morphologies (spherical, hexagonally packed cylindrical and lamellar) were observed according to the copolymer compositions.

A rational synthesis of mesoporous silicas with ultralarge accessible pores by using PS-*b*-PEO-*b*-PS copolymer as templates was studied. Mesoporous silicas have a uniform large pores size of up to 38 nm and high BET surface area of ~ 500 m^2/g. This study demonstrated that the pore diameter of obtained silica increases linearly with the M_n values of the PS block.[3]

3D construction of nanomaterials from the assembly of PSAN-*b*-PEO-*b*-PSAN triblock copolymer micelles was studied. We demonstrated that by playing with the solvent system, spherical or worm-like micelles are formed in situ during the spin coating of copolymer solution and assembled into two different nanomaterials, the nanoparticle (Fig. 1) and the "spider web" films (Fig. 2).[4] These materials are nanoporous materials with pore size controlled by the interspaces between particles or by the superposition of "spider web" layers. Their use in membrane technology is also undertaken.

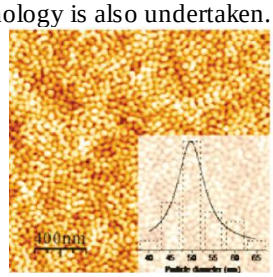

Figure 1: AFM image of the self-standing nanoparticle superlattice film prepared from a DMF/toluene (50/50, v/v) copolymer solution.

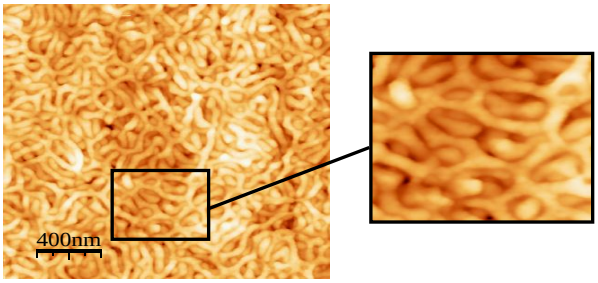

Figure 2: AFM image of the Self-standing "spider web" superlattice film obtained from a DMF/toluene (25/75, v/v) copolymer solution.

Synthesis and characterization of biodegradable polyurethane sealants containing rosin resin

Pilar Carbonell-Blasco, José Miguel Martín-Martínez

Adhesion & Adhesives Laboratory. University of Alicante. 03080 Alicante (Spain)

pilar.carbonell@ua.es, jm.martin@ua.es

Introduction

Polyurethanes are proposed as potential sealants for disc defects in spine in the FP7 European project DISC REGENERATION. One of the properties absent in these sealants is their biodegradability. One strategy to impart biodegradability to polyurethane sealants is the modification of their structure by incorporating natural biodegradable moieties. In this study, different amounts of rosin resin were incorporated as part of the chain extender during polyurethane synthesis. Because of the existence of one carboxylic moiety in the rosin resin structure, the reaction with the isocyanate end groups in the prepolymer is feasible, anchoring the rosin resin molecules at the extreme of the polyurethane chains. Furthermore, an additional drawback of the polyurethane sealants is their lack of sufficiently strong initial adhesion, i.e. the polyurethane needs some time to allow the immobilization in their application site. Rosin resin is a natural tackifier obtained from pine exudates and it is added in adhesive formulations to impart high initial strength. Therefore, the objective of this study was to increase the initial adhesion of polyurethane sealants in disc defects imparting potential biodegradability at the same time.

Materials and Methods

The polyurethane sealants were obtained by using the prepolymer method and different mixtures of rosin resin and 1,4 butane diol were used as chain extenders. The polyurethanes were characterized by ATR-IR spectroscopy, plate-plate rheometry, Differential Scanning Calorimetry (DSC), Dynamic Mechanical Thermal Analysis (DMTA), Thermal Gravimetric Analysis (TGA), ºShore A hardness, contact angle measurements, and Laser Confocal Microscopy. The adhesion properties of the polyurethane sealants were tested by T-peel test of plasticized PVC/polyurethane sealant/plasticized PVC and leather/polyurethane sealant/leather joints, and single lap-shear tests of aluminum/polyurethane sealant joints.

Results and Discussion

Polyurethanes with different mixtures of rosin resin and polyadipate of 1,4 butane diol in the chain extender were prepared (Table 1).

Table 1. Nomenclature of the polyurethanes with different content of rosin resin in the chain extender.

Polyurethane	*Amount of rosin resin (wt%)*
100BD	0
75BD+25RR	25
50BD+50RR	50
25BD+75RR	75
100RR	100

Figure 1 shows that the addition of the rosin resin in the chain extender changes the rheological properties of the polyurethanes, imparting higher storage modulus (i.e. higher cohesion), particularly at higher temperature. The higher the amount of rosin resin in the chain extender, the higher the increase in storage modulus (the mixture 25 eq% butane diol+75 eq% rosin resin is an exception).

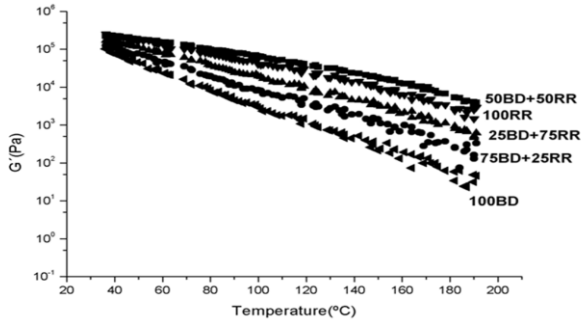

Figure1: Variation of the storage (G´) modulus as a function of the temperature of the polyurethanes.

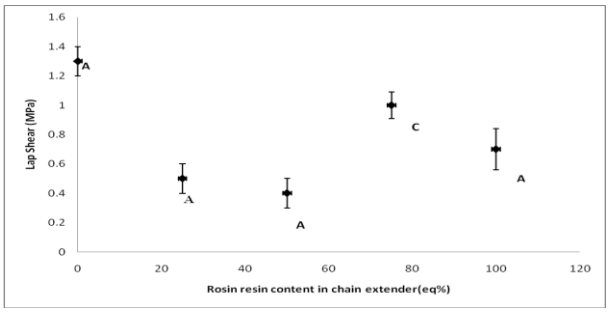

Figure 2: Lap shear values of aluminum/polyurethane adhesive/ aluminum joints as a function of the rosin resin content. Values tested 72h after joint formation. Locus of failure: A= Adhesion failure; C= Cohesive failure in the adhesive.

The single lap shear values of aluminum/polyurethane adhesive joints were relatively high and shows an adhesion failure (Figure 2), except for the mixture of 25eq% of 1,4 butane diol and 75eq% of rosin resin (cohesive failure in the polyurethane is produced).

Conclusions

The addition of rosin resin in the chain extender modifies the viscoelastic properties of the polyurethane sealants. The use of the mixture of 50 eq% of 1,4 butane diol and 50 eq% of rosin resin as chain extender imparted improved the properties to the polyurethane. Furthermore, the adhesion properties are reasonable.

lukas.scherer@empa.ch

In recent years, there has been a rapidly increasing interest in membranes with switchable properties. As a result, the diffusion process of gases, liquids and dissolved molecules can be controlled. The working principle of switchable gate membranes mostly relies on membrane pores, which are coated with stimuli-responsive molecules or polymers. Stimuli responsive polymers are the most important building blocks for such smart membranes in the design of novel functional macromolecular systems with applications for instance in drug release systems. Stimuli can include changes in pH, temperature, light and others.
Alumina or silica based membranes are mostly used. However, nanoporous alumina or silica membranes are very brittle, so it is difficult to manufacture an actual device. In contrast, many polymeric materials have superior flexibility and are therefore investigated as an alternative.
The basic condition for the accomplishment of photoregulative release of drugs is to design a polymer membrane with chromophores capable of transforming light energy into a change in conformation and/or a change in surface polarity. This condition can be achieved by incorporating the photoisomerizable chromophores into the side or main chains of the polymer by covalent bonds. For porous membranes, tailored grafted functional polymer layers on the pore walls can be used to reversibly change the permeability and/or selectivity of the membrane. Switching of material properties with light is of particular interest because this stimulus can be addressed locally, very fast and with high selectivity. Especially for biological applications, the use of light offers unique opportunities, as light fluxes are easier to control temporally than most other stimuli and can be adjusted not to perturb delicate biological structures.
Spirobenzopyrans are well-characterized molecules and exhibit both thermo- and photochromic responses that reversibly transform a colourless, non-polar closed form into a strongly coloured, polar merocyanine opened form through rupture of the spiro carbonoxygen (C–O) bond (Figure 1).

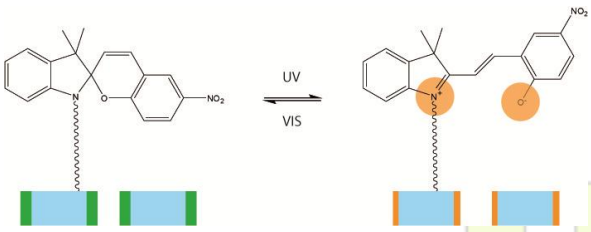

Figure 1: Photochromic spirobenzo-pyran molecule (left, uncharged), immobilized on a porous membrane surface (blue) converts into its merocyanine form (charged, orange) when irradiated with UV light (365 nm). The back reaction is induced by visible light (450-550 nm).

The increased conjugation of the merocyanine form shifts the absorption to longer wavelengths, thus giving rise to visible colour. The merocyanines can return either thermally or with visible light to the colourless spirobenzopyran.
Photochromism is accompanied by a large change in the structure and in the dipole moment. These changes suggest that such molecules are useful in light controlled, "smart surface" applications.

Different surface modification methods of several porous organic membranes were studied like dip-coating, plasma-coating and grafting from the surface. The most promising results were obtained with membranes with plasma inducedpolymerization (Figure 2). Starting from those radicals, co-polymerization of either hydroxyethyl acrylate (HEA) or hydroxyethyl methacrylate (HEMA) with an acrylate decorated spirobenzopyran provided a membrane systemwhich had switchable transport velocities of studied molecules in aqueous medium.

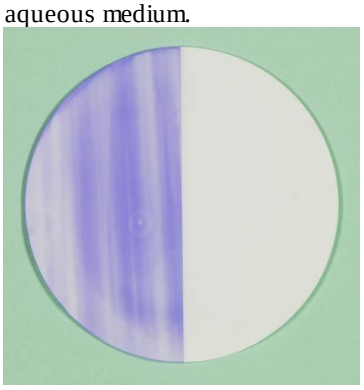

Figure 2: Surface modified PVDF membrane. The right half of the membrane was covered during irradiation of the membrane with 360nm.

Due to this switchability of the membrane resistance, it was possible to change and control the diffusion rate of several molecules across the membrane.
By choosing an appropriate matrix material, specific pore size, the right surface modification conditions and the optimal photochromic molecule, the system was fine-tuned for the diffusion of different specific molecules.

Polyesterification Catalyzed by Hydrotalcite Modiefied Nanoparticles

INTRODUCTION

Polyesterification of dimethyl terephthalate (DMT) with neopentyl diol (NPG) has been studied in melt reaction system using a variety modified hydrotalcite (MHT) nano particles as catalyst and nano-filler.

Hydrotalcite (HT), a magnesium-aluminum hydroxy-carbonate, is a naturally occurring mineral of chemical composition $Mg_6Al_2(OH)_{16}[CO_3]4H_2O$ exhibiting a layered crystal structure. The carbonate ion in the interlayer can be exchanged with other anions, and the thickness of the layer is determined by the ionic radius of the anion. The introduction of various guest substances into the gallery and leads to the material with permanent microporosity across the range of molecular size. This process being known as PILSs (pillared interlayers clays) since the calcinated anions acts as pillars. The convenient method, commonly applied for this purpose, is the replacement of alkaline metal cations in clay gallery with organic ions by ion exchange. The modified Mg/Al, Zn/Al and Sn/Al hydrotalcite-type clay compositions containing large, pillaring organic anions were synthesised by ion exchange and used as catalysts and nano-filler in polycondensation reaction.

EXPERIMENTAL

1.*The preparation of modified anionic clays (MHT)*

The pillared Mg/Al hydrotalcites (PILSMHTs) were obtained by co-precipitation at pH=10 with respective salts of the following organicer then acids: p-dodecyl-benzenesulphonic acid (DDS), terephthalic acid (TPA) and aminolauric acids (ALA):

DDS TPA ALA

In the similar way wwere obtained zinc/aluminum hydrotalcite (HT-ZnAl) and tin/aluminum hydrotalcite pillared with terephtalic acid (HT-SnAlTPA)

2. *Polyesterification*

Polyesters were obtained by melt condensation from dimethyl terephthalate (DMT) and neopentyl glycol (NPG) in the presence (0.5% w/w) of modified HT (HT DDS, HT-TPA and ALA-HT, respectively) as catalyst at temperature range 185-195ºC. The progress of reactions was monitored by measuring of amount of condensed methanol and the acids number of polyesters.

RESULTS and DISCUSSION

The MHTs structures were characterized by elemental analysis, FTIR, DTG and XRD. XRD spectra shown that pillaring of HT with organic anion contained long aliphatic chain caused the exfoliation of HT layers from 0.8 nm to 3 nm. The DTG analysis shown that the most thermal stable is hydrotalcite modified with DDS which has decomposition temperature range 659-687ºC (Table 1).

Table 1: Differential Thermal Gravimetry (DTG) analysis of MHT

MHT	$T_{10\%}$ (°C)	Max.temp. range of decomposition (°C)	DTG_{max}(°C)	Weight loss at 700°C(%)
DDS-HT	209	659-687	308,460, 687	74.9
TPA-HT	189	562-582	361,369	66.5
ALA-HT	189	444-525	375,457,490	71.0

The catalytic activity of Mg/Al hydrotalcite pillared with DDS, TPA or ALA are higher then non modified Mg/Al hydrotalcite and increased as the acid strength of pillaring agent increased. The highest catalytical activity shown Zn/Al hydrotalcite (HT-ZnAl) and Sn/Al hydrotalcite pillared with terephthalic acid (HT SnAL TPA). All modiefied hydrotalcite have higher catalytic activity than Fascat 4100 $[C_4H_9SnO(OH)]$.(Fig. 1)

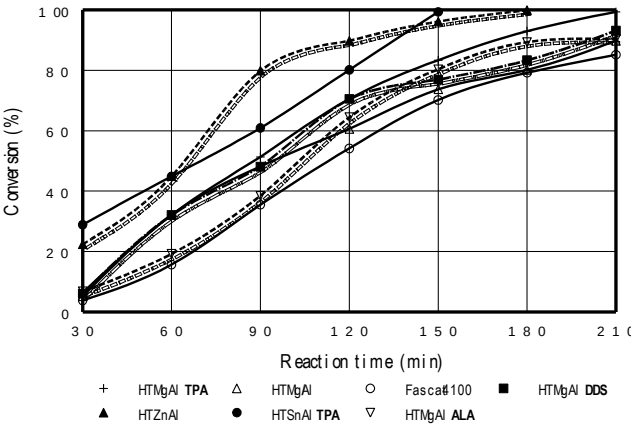

Fig.*1 The catalytical activity of modiefied hydrotalcite obtained by calcination of Mg/Al hydrotalcite precursor*

CONCLUSION

- The modified Mg/Al, Zn/AL and Sn/Al hydrotalcite-type clay compositions containing pillaring organic anions DDS, TPA and ALA are attractive catalyst in polycondnesation reaction.
- All modified hydrotalcite have higher catalytic activity than Fascat 4100 $[C_4H_9SnO(OH)]$.
- The modified hydrotalcites act as nano filler to increase softening point and Tg and thermal degradation of polyester resins.

Epitaxial Growth from the Crystalline Cores of Cylindrical Polyferrocenylsilane (PFS) Block Copolymer Micelles

Siti F. Mohd Yusoff, Joe B. Gilroy, Ian Manners

School of Chemistry, University of Bristol, United Kingdom

chzsf@bris.ac.uk

The introduction of metal centers can introduce a wide range of additional functionality to polymeric and supramolecular materials. Block copolymers consist of two or more chemically distinct polymer segments, or blocks, connected by a covalent link. PFS block copolymers with a short crystalline PFS block form core-corona cylindrical micelles in selective solvent for the longer block. The terminii of these micelles are found to be active towards further addition of new PFS block copolymer, a process reminiscent of a living covalent polymerization and can therefore be regarded as living supramolecular polymerization.[1-3] We demonstrate that living polymerizations driven by the epitaxial crystallization of a core-forming metalloblock represent a synthetic tool that can be used to generate complex and hierarchical micelle architectures from diblock copolymers. Using this novel concept, homoepitaxial growth using the addition PFS homopolymers and PFS diblock copolymer to the cylincrical micelles seeds can be studied. This talk presents living supramolecular for the formation of complex micelle architectures including block co-micelles and network-like structure.

Abstract: The crystallization of highly isotactic polypropylene (iPP) confined to self-ordered nanoporous alumina has been studied by differential scanning calorimetry. The pore size ranges from 25nm to 400nm with a pore depth of 80-100μm. A transformation from predominantly heterogeneous to predominantly homogeneous nucleation takes place if the pore diameter becomes smaller than 65 nm. The dependence of the heat of fusion on the pore diameter was determined. The pore diameter below which crystallization is completely suppressed was derived. The predicted suppression of crystallization in nanopores having diameters below 20 nm indicates the critical nucleus size.

Introduction: Polypropylene is a thermoplastic of outstanding commercial importance. Thus, it has attracted many researchers around the globe. Understanding the development of the crystalline phase during solidification of semicrystalline polymers is important in setting-up optimum processing conditions as well as predicting properties of final products[1]. The mechanical performance and optical properties of polymeric materials are significantly influenced by crystallinity and crystal morphology, which varies with the thermal history during processing[2]. Generally, the crystallization of bulk iPP is initiated by heterogeneous, athermal nucleation followed by a 3D spherulitic crystal growth.[3] Controlling crystallization of semicrystalline polymers by geometric confinement has attracted considerable interest as it has been shown that confinement can affect crystal nucleation, crystal growth and crystal orientation.[4, 5].

Nanoporous anodic aluminum oxide (AAO) has been widely used a an inorganic model matrix as it contains arrays of straight, cylindrical nanopores uniform in length and diameter that can easily be infiltrated with polymeric melts[6]. It is already known that segmental dynamics of polymers is altered in the presence of the hard pore walls of AAO.[7] With respect to polymer crystallization, some authors have reported heterogeneous surface nucleation of polyethylene confined to AAO nanopores small enough to neglect the presence of other types of heterogeneous nuclei.[8] This finding leads to several open questions about the type of nucleation under hard confinement typical for AAO: Is the crystallization process always heterogeneous within the small AAO nanopores? Can hard confinement completely suppress polymer crystallization and if so, what is the required size? In this research study, we explore these issues using iPP confined within the nanopores of self-ordered AAO.

Materials and Methods: AAO was prepared according to literature:[9] The iPP (PSS, Mainz) had a number-average molecular weight M_n=32500 g/mol and a polydispersity index M_w/M_n=3.32. Infiltration of the iPP was performed by placing neat iPP on the surface of the self-ordered AAO at 473 K for 20h. Thermal analysis was carried out using a Mettler Toledo Star differential scanning calorimeter.

Results and Discussion: The Figure shows the total enthalpy of crystallization and relative crystallization change as a function of pore diameter. The heat of fusion strongly decreases as the pore diameter decreases. Linear extrapolation reveals that iPP infiltrated into AAO with pore diameters below about 20 nm would be unable to crystallize. The predicted complete suppression of crystallization within the 1D hard confinement of AAO contrasts with results reported for 2D crystallization of poly(ethylene oxide) and iPP in multi-layer nano-assemblies. These experiments revealed that these polymers could still crystallize as single lamellae with large aspect ratios.

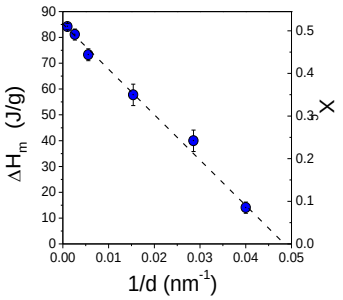

Figure. Heat of fusion and degree of crystallinity of iPP plotted as a function of inverse self-ordered AAO pore diameter.

griselda.barrera@ufrgs.br

Introduction

Polymeric nanocomposites are hybrid materials formed by an organic polymeric matrix in which the inorganic fillers are dispersed in nanometric dimensions[1]. The nanometric fillers normally used are: clay, alumina, carbon nanotubes, gold, silver and graphite[2]. The polymer/graphite nanocomposites are interesting due to the potential conductive properties. Graphite is chemically similar to carbon nanotubes and structurally analogous to layered silicate and hence is a potential nanofiller to improve the properties of neat polymer. Graphite can be introduced into the polymeric matrix to form nanocomposites through fusion of the polymeric matrix, intercalation in solution and *in situ* polymerization. There are some works in the literature related with the synthesis of polymer/graphite nanocomposites using *in situ* polymerization but the monomers used have been methylmethacrylate[3], aniline[4] and styrene.[5-7] The use of graphite and polyolefins as starting materials is convenient because both are inexpensives and with very different properties, one is conductive and the other is insulating, the formation of a nanocomposite of them will extend the applicability of both materials.

This work describes the synthesis of polyethylene/graphene nanocomposites through *in situ* polymerization of ethylene in the presence of graphene nanosheets, using the catalytic system Cp_2ZrCl_2/MAO ((bis(cyclopentadienyl)zirconium(IV)dichloride/methylalu minoxane). The main objective of this work is to prepare graphite nanoparticles with a well defined structure, and to grow polyethylene within the pores and galleries of this laminated material to obtain a well dispersed nanocomposite to evaluate the thermal, mechanical and electrical properties this new material.

Materials and Methods

Graphene nanosheets (GNS) previously treated with methylaluminoxane (15wt%), were added into the reactor as filler at percentages from 1 to 14 % (wt.%). The polymerization reactions were carried in a 100 mL PARR reactor. Toluene was used as solvent, MAO as cocatalyst (Al/Zr=1000) and Cp_2ZrCl_2 as catalyst (2.10^{-6} mol). The reactions were done at 70ºC, using an ethylene pressure of 2.8 bar during 30 min. The characterization of the GNS and the PE/GNS nanocomposites were done by SEM, TEM, AFM and XRD. The nanocomposites properties were studied by TGA, DSC and DMA. The mechanical and conductivity properties were also investigated.

Results and Discussion

XRD and TEM analysis of GNS showed that the chemical and thermal treatments of graphite produced graphene sheets of about 10 graphenes. Polyethylene/graphene nanocomposites, with graphene amounts of 1.2, 2.8, 5.6 and 14.3 wt%, were obtained by *in situ* polymerization, with good catalytic activity. XRD and TEM analysis showed that the GNS were further exfoliated by the ethylene polymerization, giving graphite crystals with smaller number of graphene layers than the exfoliated graphite initially added. TEM micrographs of the nanocomposites showed the presence of regions where the graphite maintained an organized structure (intercalated graphite) and others where it was more disorganized (exfoliated graphite).

The onset degradation temperature increased by 30°C in the nanocomposites with 2.8 and 5.6 wt.% of GNS. All the nanocomposites presented higher storage modulus than neat polyethylene. This indicates that the GNS have a reinforcing effect on the polyethylene matrix. The impedance measurements showed an increase of electrical conductivity of the nanocomposites. This enhancement is related to an increase in mobility in the network and in the density of the potential charge carriers.

Conclusions

Polyethylene/Graphene nanosheets nanocomposites were successfully obtained by *in situ* polymerization of ethylene using a metallocene catalyst. Nanocomposites showed higher thermal stability, rigidity and conductivity than the polymeric matrix.

Introduction

The outstanding properties of carbon nanotubes (high tensile modulus [1], high electric conductivity [2], and high aspect ratio) make them ideal candidates for use in nanocomposites, and particularly in those based on rubber matrix [3]. However, to obtain an improvement of the properties, a good degree of dispersion of the CNT in the matrix is crucial. It was shown that the grafting of blocks copolymer onto nanotubes surface [4, 5] or their encapsulation by a copolymer [6] improved this individualization. Nevertheless, an approach of the CNT surface modification or a polymerization in the presence of the NTC (polymerization in situ) [7] seems two ways which are very difficult to be transposed in the industry.

The CNT dispersion in an EPM rubber is investigated here by using a statistical copolymer as dispersing agent. An association between the EPM and the ethylene-*co*-vinyl acetate (EVA) being very current in the rubber industry, and we chose to investigate this way because EVA exhibits a good affinity with the CNT and improve their dispersion [8].

Materials and methods

We studied more exactly the influence of various parameters (EPM/EVA ratio, matrix viscosity) on the CNT dispersion and prepared an EPM-EVA master batch loaded with 20% of CNT. We dilute this master batch on an EPDM matrix and we compared the influence of carbon nanotubes, carbon black or the blend of both on the rubber properties.

We work with the classic methods used for rubber mixing, like an internal mixer and an open two roll mill, which are soft mixing techniques.

Results and discussion

Firstly, we demonstrate that matrix viscosity and EPM-EVA ration influence the CNT dispersion. We observe a better CNT dispersion with a low matrix viscosity. We obtain EPM-EVA composites with very good conductive properties (fig 1). The master batch loaded at 20wt% has a surface conductivity equal to 2,6S/cm.

We will present the influence of fillers and their possible synergy on the rheological and electrical properties of an EPDM rubber. In particular, we will compare the rheological and electrical percolation thresholds in the presence of fillers and will quantify their impact on the vulcanization kinetics of elastomers. We will demonstrate that the dilution of the master batch allows to obtain a rubber filled with a constant Mooney viscosity.

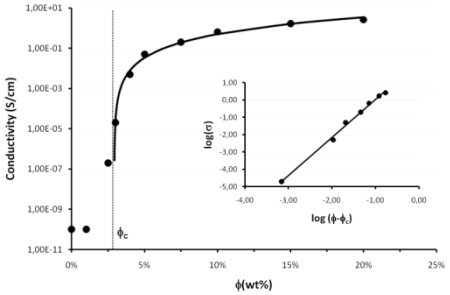

Fig. 1: Effect of CNT content on surface conductivity. The inset shows the variation of logs versus log (ϕ–ϕ_c) with ϕ_c =2,93wt% and t = 2,20

The synergistic effect between carbon black and carbon nanotubes will be shown on the mechanicals properties but not on the electrical properties [9].

Conclusion

We demonstrated that it is possible to prepare a rubber, with industrial techniques, which exhibits very good electrical properties. The synergy between carbon black and CNT was only demonstrated on mechanical properties.

Introduction

More than 30 years ago it was proposed by Armand that the helical structure of polyether chains, like polyethylene oxide (PEO), might provide a framework for ion transport in crystals of these polymers. This suggestion was considered not feasible in view of the mounting evidence that long-range transport of lithium ions is inhibited in crystalline phases of the host materials and that ionic mobility in such systems is intimately connected with the segmental motions of the host. By contrast, our experimental data on thin-film stretched polymer electrolytes (PE) obtained more than 10 years ago and aimed at longitudinal alignment of PEO helices unambiguously showed that ordering of polymer electrolytes enhances both intrachain cation motion and its interchain hopping. This finding was supported by other researchers and mathematical models. It was shown that the less tangled the channel, the lower the activation energy required to overcome the potential barriers of the hopping from site to site, created in the PEO by structural loops.

In addition, we recently presented a procedure for the perpendicular orientation of the helical PEO segments by casting the PEs under a magnetic field. This enhances the ionic conductivity (σ) in the Z direction (perpendicular to the film plane) by about one order of magnitude. The magnetic-field effect is even more pronounced in polymer electrolytes with incorporated diamagnetic and ferromagnetic nano-fillers.

Results and Discussion

In this work we have found that casting, under a gradient magnetic field, of PEs comprising only 1% of aromatic dipeptide nanotubes coated with ferrofluid (FF-PNT) increased the total PE conductivity at room temperature by a factor of about eight, as compared to the PE with 14% content of hematite and by 2 orders of magnitude, as compared to pristine PEs. The FF-PNT-modified PE cast under MF is thermally stable. Even after 1 month of storage at 70°C it retains conductivity values that are very close to that of the freshly-cast film. As opposed to other fillers tested so far, the incorporation of FF-PNT to the pristine typically-cast PE, eliminates formation of large spherulites. A highly–homogeneous, fine-grained morphology with well-defined round-shaped crystallites develops in this composite PE under an applied MF (Fig.1). The XRD patterns make it clear that the applied magnetic field influences the crystallinity of the PE containing FF-PNTs more strongly than it does that of pristine films.

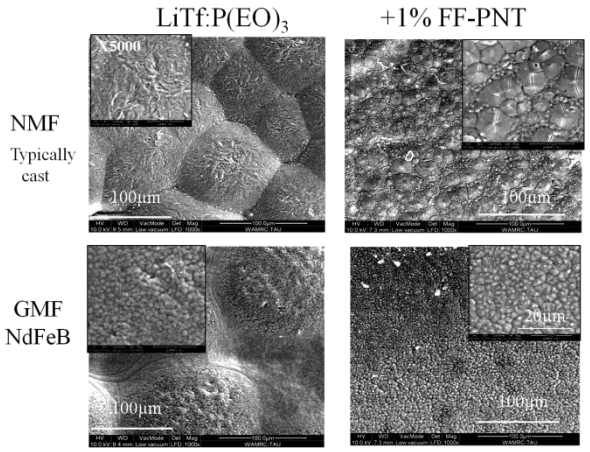

Fig.1 ESEM images of typically-cast pristine and composite polymer electrolytes

Finally we present the original approach to promote orthogonal orientation of PEO helices by the attachment of gold-coated maghemite nanoparticles to the thiol- or amine-end groups of the polymer chain. The "bridging" properties of mercaptoundecanoic acid (MUA) enabled preparation of -γFe_2O_3 particles covered by the nano-seeds of Au. The core-shell structure of the nanoparticles was verified by XRD, XPS and TEM-EDS analysis. The Au-maghemite nanoparticles have been incorporated into the PE by two-step procedure and cast under a gradient magnetic field. The conductivity values of these electrolytes are close to those of PE with FF-PNTs.

Introduction

The increase of gas and vapour barrier coatings is one of the most important issues in packaging applications. The packaging of carbonated drinks, food requiring modified atmosphere, preservation of aromas or biscuits friability usually need complex multilayer structures. Many efforts are done for the obtainment of packaging characterized by high barrier properties to water vapour or gases and simple production.

In the last years very interesting results were obtained by using organically modified silicate layers. In this case the modification of the polymer is usually obtained by melt blending the polymer with these nanoclays; however actually no clear indications on the risk of the contact of the nanocomposite materials obtained by using organically modified nanoclays are available and EU regulation still does not regulate nanocomposites for food contact use.

One of the most interesting alternative ways to increase gas barrier properties of polymers is the development of silica barrier coatings. Transparency, microwave compatibility and chemical inertness are the most important characteristics of SiOx-based film. The use of plasma enhanced chemical vapour deposition technique (PECVD) for the obtainment of barrier coatings onto different substrates is nowadays well established[1,2]. Layers like SiNx and SiOx, usually obtained by PECVD, can decrease the gas permeation through polymer substrates by several orders of magnitude.

Nevertheless, the known costs of vacuum systems in terms of technological reason and on-line processing limits have generated increasing interest to develop atmospheric condition alternatives. For these reasons atmospheric pressure plasma deposition represents an interesting solution in order to reduce equipment costs and to increase the on-line processing capability, which is a fundamental parameter for continuous productions, as in the case of traditional packaging production.

Next to traditional, low pressure techniques, normal pressure plasmas have been employed successfully for surface treatment. The use of an atmospheric pressure plasma jet (APPJ), compared to other non-equilibrium, normal pressure plasmas, is advantageous in particular for local film deposition or for the coating of 3D forms e.g. inner walls of wells, trenches or cavities. The jet geometry offers the advantage that the surfaces to be treated are not placed between electrodes thus allowing better flexibility in terms of substrate distance and electrical field[3].

In this work we present the application of this technology for the obtainment of silica barrier coatings onto different polymer substrates, ranging from poly(propylene), which is one of the most used polymers in flexible packaging applications, to poly(lactic acid), which is receiving more and more attentions for packaging applications, but which most important drawback is the very low thermal stability.

Different silica precursor were evaluated and results on adhesion, mechanical properties, carbon content, and gas transmission rate are presented together with thickness information and coating morphology.

Introduction: Well defined model surfaces of polymeric materials are important tools to study adsorption, wettability, adhesion or other interfacial phenomena. Model substrates of cellulose, the most abundant biopolymer, are of interest because this polymer can contribute significantly to a sustainable and renewable way in the utilization of natural resources. Several methods and film preparation techniques for cellulose model films are know from literature [1]. Besides their characterization cellulose model films were utilized for principle investigations like polymer adsorption studies or enzymatic degradation of cellulose [2]. Usually, cellulose model films are prepared from trimethylsilyl cellulose (TMSC), a derivative that is soluble in organic solvents and can be regenerated to pure cellulose under hydrochloric acid vapors [3]. A scheme of this desilylation reaction is depicted in figure 1.

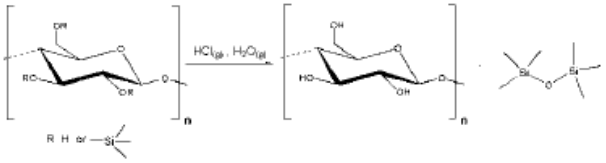

Figure 1: Reaction scheme for the desilylation of trimethylsilylcellulose (TMSC) to pure cellulose

Even though this kind of model film is used widely, little is known about the time dependent desilylation of TMSC to cellulose. In this work we therefore investigated the preparation and surface properties ofcellulose model films that were regenerated from TMSC for different regeneration times. Furthermore we showed a practical example how these model films can be structured by soft-lithography and how model films in general can be used to study interfacial phenomena at cellulose surfaces.

Materials and Methods: TMSC dissolved in toluene was spin coated on silicon wafers. The time dependent regeneration to cellulose was studied by contact angle measurements, X-ray photoelectron spectroscopy (XPS), infrared spectroscopy and optical thickness measurements (Sarfus). Atomic force microscopy was applied for morphological investigations. Selected cellulose surfaces derived in this way were structured by a new soft-lithographic method applying enzymes and polydimethylsiloxane (PDMS) moulds.

Results and Discussion: The time dependent regeneration of TMSC to cellulose allowed the targeted manufacturing of cellulose model films with different degrees of desilylation. The degree of desilylation can be followed easily by contact angle measurements and

XPS analysis. It is assumed that during the course of desilylation volatile silicon species tend to adsorb on the cellulose model films. These species can be removed under reduced pressure. Atomic force microscopy showed that the surface morphology of the films is not immediately influenced during the desilylation even though morphology changes are observable after drying or vacuum treatment.
In addition pure cellulose model surfaces regenerated from TMSC with a thickness in the nanometer range can be structured using an enzymatic treatment in combination with a soft-lithographic mould. A typical structured cellulose film is shown in figure 2, where separated cellulose lines with 50µm spaces and a thickness of 40 nm are depicted.

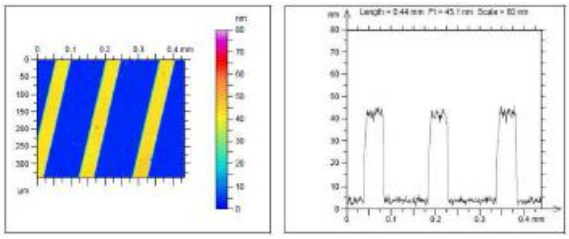

Figure 1: Soft-lithographically structured cellulose films on a silicon substrate. The left image shows a top view of a Sarfus-image whereas the right image depicts the cross-section of the structured film.

Conclusion: In this work we could show how the time dependent regeneration of cellulose model films from TMSC is reflected in the wettability and elemental composition of the surfaces. Furthermore a new oftlithographic technique was introduced to structure a biopolymeric thin film with the aid of enzymatic degradation. The research leading to these results has received funding from the European Union Seventh Framework Programme (FP7/2007-2013) under grant agreement n° 214653.

New "bottom-up" fabrication techniques are now effectively explored for the production of nanostructured functional materials. Specifically, controlling the spatial organization of nanoparticles in a material would allow taking full advantage of the nanoparticles specific properties. For example, interesting optical properties in the visible range are foreseen when assembling plasmonic nanoparticles. Such spatial control can be obtained by template-assisted self-assembly, using matrices presenting a spontaneous molecular organization. Among the promising self-assembled systems are the diblock copolymers made of two molecular chains of distinct chemical nature linked together, which present solid state spontaneous structures with long-range order and tunable characteristic sizes between 10 and 100 nm. In particular, alternating lamellar and hexagonally-ordered cylindrical structures are described in many diblock copolymers systems. Such copolymers have proven useful templates for ordering nanoparticles with long-range order.

In this presentation, we will describe an original methodology for the preparation of ordered nanocomposites of block copolymers and nanoparticles, using the specific swelling properties of amphiphilic diblock copolymers, as well as the study of the prepared materials.
Poly(styrene)-block-poly(acrylic acid) amphiphilic copolymers form hexagonal and lamellar phases in the melt state, depending on their molecular structure.

These ordered phases can be swollen in water while preserving their morphology and long range order,

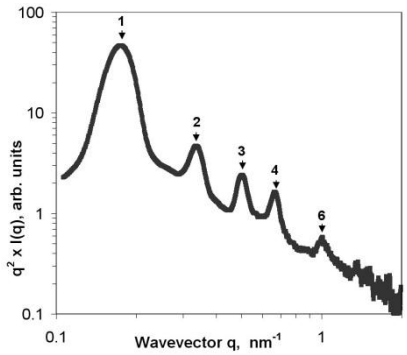

Figure 1: Small-angle X-ray scattering curve of the solid lamellar phase of a symmetric PS-b-PAA copolymer, plotted as $q^2I(q)$. The structure factor peaks, indicated by arrows and numbers corresponding to the peak order, are characteristic of the lamellar symmetry of the lattice. The position of the first order peak gives access to the lattice parameter, here d=36.4 nm.

thanks to the glassy nature of the poly(styrene) core. The stability of the swollen phases, and their behavior in dispersion, are linked to the properties of the poly(acrylic acid) polyelectrolyte brushes and can be monitored via the pH or ionic strength of the dispersion.

We use these properties to propose a original methodology for introducing solid nanoparticles, which present two advantageous specificities. First, it is possible to reach high densities of introduced particles. Second, aqueous sols of nanoparticles can be used. The copolymer ordered phases are indeed swollen with the aqueous sol instead of water, and the nanoparticles can penetrate within the copolymer dispersions. Provided an attractive interaction is tuned between the nanoparticles and the hydrophilic block of the copolymers, which can be done in this case by playing on the pH of the dispersions,and depending on the particle sizes, the nanoparticles can be trapped within the structure upon drying. We will present our study of the incorporation of 15-nm diameter silica nanoparticles, 7-nm diameter cerium oxyde nanoparticles and 10-nm diameter gold nanoparticles in the 18-nm thick poly(acrylic acid) layers of the ordered lamellar phase of a poly(styrene)-*block*-poly(acrylic acid) copolymer. Volume fraction of nanoparticles was varied in both thin films on silicon wafer and bulk samples. We will show how small-angle scattering and reflectivity of X-rays, ellipsometry, atomic force and electron microscopies were used to get a detailled structural description of the nanostructured composites and validate the control of the density and organization of the nanoparticles. We will finally discuss first results of optical measurements with the gold nanocomposites.

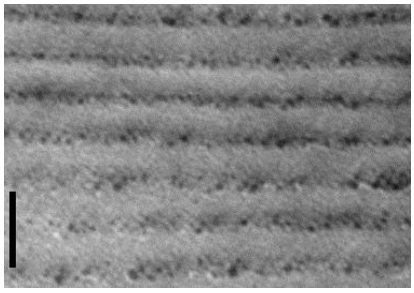

Figure 2: Transmission electron micrograph (side view) of an ordered lamellar composite film of gold nanoparticles and poly(styrene)-b-poly(acrylic acid) copolymer. Bar = 50 nm.

Nanostructures from tunable self-assembly of a simple diblock copolymer

Alberto Bianchi, Michele Mauri and Roberto Simonutti

Department of Materials Science, Università di Milano-Bicocca, Via R. Cozzi 53 20125 Milano (Italy)

roberto.simonutti@mater.unimib.it

Introduction:
Amphiphilic block copolymers with low polidispersity (D) are thermodynamically driven to auto-assemble forming regular nanosized morphologies when dissolved in selective solvents [1]. We focused on producing controllable structures from commonplace monomers like styrene or dimethylacrylamide (DMA). The assembly was tuned by chemical nature of the solvent, providing several different structures that can be the basis for the preparation of materials.

Materials and Methods: RAFT synthesis was performed based on literature [2] using an optimized transfer agent. The PS block was synthesized first in bulk with 3-(benzylsulfanylthiocarbonylsulfanyl) propionic acid as RAFT agent, with M_{nNMR} = 11000, M_{nGPC} = 11920, and D = 1.06 measured by GPC. After copolymerization of the PDMA block, quantitative NMR was used to establish the polymer as $PS_{105}PDMA_{817}$. T_g was measured by DSC at about 84°C for the PS block and 120 °C for the final copolymer.
^{1}H NMR was performed on a Bruker Avance III 500 MHz instrument.

Results and Discussion: the polymer was diluted in different solvents at room temperature using several tens of mg per mL. $CDCl_3$ provides a clear solution indicating solvatation of both blocks. D_2O and toluene formed colloids with a cloudy appearance, indicating presence of structures in the tens to hundreds of nm size range.

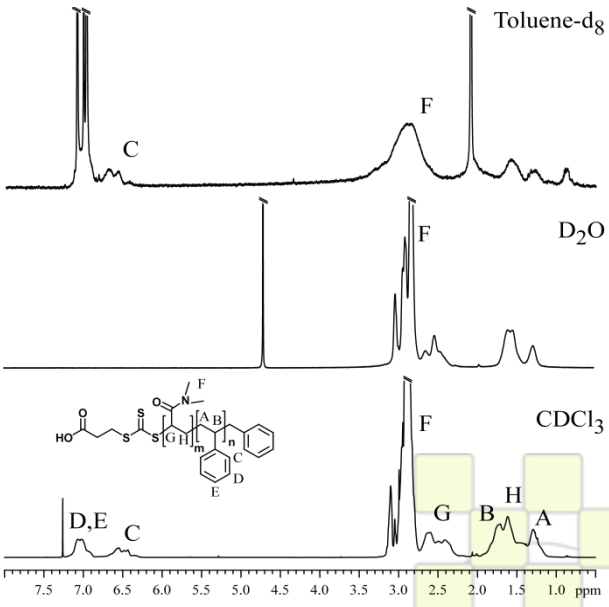

Figure 1: ^{1}H NMR spectra of PS-b-PDMA in different solvents. C and F peaks are fingerprints of PS and PDMA respectively.

Dynamic Light Scattering of the aqueous colloid confirmed the presence of particles with average diameter of 120 nm and sharp distribution.
^{1}H NMR spectra are shown in Figure 1. Each block has specific signals, namely from 6.5 to 7 ppm for PS while PDMA is around 2.8 ppm.
Solution NMR is optimized for fast moving molecules and does not detect solid-like fractions because of extremely low T_2 relaxation time [3]. The presence or absence of peaks in the spectra can be interpreted as a function of mobility. The spectrum in $CDCl_3$ contains peaks relative to all protons in the sample. The peaks of the styrenic block disappear in water, meaning the hydrophobic block is behaving as a rigid solid. In toluene, the styrenic block is solvated and provides full signal intensity, while the PDMA is also visible but with a significant line broadening corresponding to reduced but not solid like mobility.
A direct investigation of the nanostructures was performed by TEM. As seen in figure 2, the sample deposed from aqueous solution contains small circular objects arranged in a pseudohexagonal layer. In toluene, the polymer chains arrange in worm-like shapes, that aggregate in interconnected structures.

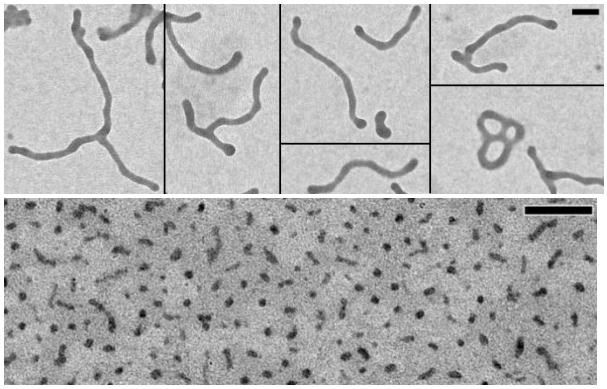

Figure 2: TEM images of PS-b-PDMA deposed from toluene (above, selection of worm-like shapes) and water (below). All scale bars are 200 nm.

Conclusions: Despite the simple starting monomers, PS-b-PDMA copolymer has not been studied extensively but has a rich capability to form different sharp nanostructures that we show here for the first time. Self-assembly provided hard, stable, core shell particles in water and less defined worm-like micelles in toluene. Work is under way to verify if such structures can then be assembled in the solid state.

The melting and non-isothermal crystallization behaviors of polypropylene/montmorillonite (MMT) nanocomposites under high pressure CO_2

Jie Chen, Tao Liu, Ling Zhao and Wei-kang Yuan*

State Key Laboratory of Chemical Engineering, East China University of Science and Technology, Shanghai 200237, P. R. China.

email: chenjie851127@gmail.com, zhaoling@ecust.edu.cn

Introduction:

Due to their enhanced mechanical properties, polypropylene(PP)/montmorillonite(MMT) nanocomposites foams have attracted increasing interest as an alternative for pure PP foamed counterparts[1]. The crystallization behavior of semicrystalline polymer composites under high pressure CO_2 plays a critical role in the CO_2 foaming process. In the industrial foaming process, such as extrusion and injection foaming, semicrystalline materials experience a nonisothermal process due to the cooling. Numerous research work have been done on both isothermal and nonisothermal crystallization kinetics of PP composites[2,3]. Several authors have studied the effect of CO_2 on isothermal crystallization behavior of PP[4-6], while limited research data is available on nonisothermal crystallization under CO_2[7]. To the authors' best knowledge, no detailed research work has been reported on nonisothermal crystallization kinetics of PP/MMT nanocomposites under CO_2. In this work, non-isothermal crystallization behaviors PP/MMT nanocomposites under CO_2 were carefully studied and the nonisothermal crystallization kinetics was also analyzed from the DSC data.

Materials and Methods

PP/MMT nanocomposites containing 1%, 2% and 4% MMT were prepared by melting blending of commercial PP and nano MMT in a Haake Minilab system (Thermo Electron). Neat PP was also prepared by the same process.

Nonisothermal crystallization measurements of both PP and PP composites were conducted in a high-pressure DSC at constant rates of 5, 2, 1, and 0.2 K/min under ambient N_2 and 5, 20, 40 and 60 bar CO_2.

Results and Discussion

In this work, both the melting and non-isothermal crystallization behaviors of polypropylene (PP) and PP/montmorillonite (MMT) nanocomposites under atmospheric N_2 and high pressure CO_2 were studied using high-pressure differential scanning calorimeter (DSC). High pressure CO_2 had strong plasticization effect on both PP and PP composites, and depressed their T_m and T_c. Due to the heterogeneous nucleation effect of MMT, PP composites showed a lower melting peak temperature (T_m) and a higher crystallization peak temperature (T_c) in comparison with PP at the same atmospheric condition, as shown in Fig. 1.

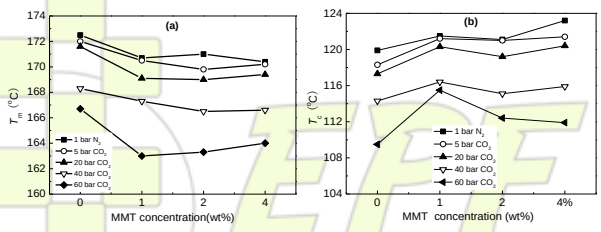

Fig.1. Effect of MMT on T_m and T_c of PP/MMT composites under CO_2

Jeziorny modified Avrima method and Mo's method were applied to analyze the non-isothermal crystallization kinetics of PP and PP/MMT composites under high pressure CO_2. Mo's approach demonstrated a success for all the system investigated. *F(t)* obtained from mo's method showed that the crystallization rates of both PP and PP composites first decreased with increasing CO_2 pressure, reached a minimum, and then increased. This trend was flattened after introducing nano-MMT into PP.

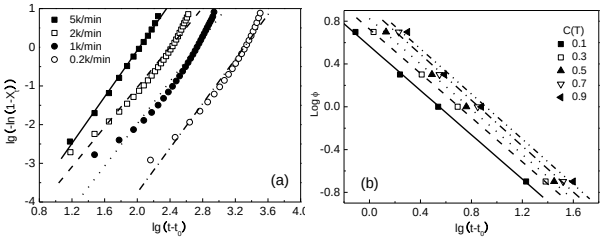

Fig.2 Fitting results for the non-isothermalcrystallization of PP/1%MMTin the presence of CO_2 at 20 bar (a) Jeziorny modified Avrima method, (b) Mo's method

The activation energy, ΔEa, for the non-isothermal crystallization kinetics of PP and PP/MMT composites was also evaluated by Kissinger method. ΔEa increased in the presence of nona-MMT. However, the overall crystallization rate characterized by half crystallization time, $t_{1/2}$, showed an increase in PP/MMT nanocomposites, indicating that the heterogeneous nucleation effect of fillers still played a critical role to enhance the overall crystallization rate although nano-MMT inhabited the transport of the polymer chains to the growing surface.

Table 1 The activation energy based on Kissinger method

	ΔEa(KJ/mol)				
	N_2	CO_2			
	0.1MPa	0.5MPa	2MPa	4MPa	6MPa
PP	291.4	287.5	278.3	283.5	231.2
PP-1%	301.3	301.3	295.7	295.5	348.9
PP-2%	316.2	321.5	298.9	305.6	309.0
PP-4%	351.0	320.6	311.9	352.2	285.0

Mechanical properties of PA66/PA6/multi-walled carbon nanotube ternary nanocomposite prepared by melt mixing method

Maryam Hadizadeh[a], *Akbar Shojaei*[a], *and Reza Bagheri*[b]

a. Department of Chemical and Petroleum Engineering, Sharif University of Technology, P. O. Box 11155-9465, Tehran, Iran, akbar.shojaei@sharif.edu.

b. Department of Materials Science and Engineering, Sharif University of Technology, Tehran, Iran.

Abstract

In this investigation, the blends of polyamide 66 (PA66)/polyamide 6 (PA6) were prepared by internal melt mixing method in a full range of PA6 concentrations, from 0 up 100 wt%, with an interval of 25 wt%. Additionally, the corresponding nanocomposites for the blends were prepared by the same mixing method via the incorporation of 1 wt% of multi-walled carbon nanotube (MWCNT). All the blends and the corresponding nanocomposites were characterized by tensile testing, dynamic mechanical thermal analyzer (DMTA), impact strength and differential scanning calorimeters (DSC). The result indicated that the PA66/PA6 blend is a miscible system in all concentrations of PA6, as was expected. Additionally, it was found that incorporation of MWCNT into PA66, improves the mechanical properties, however, the addition of PA6 into PA66/MWCNT, improves the effectiveness of MWCNT much higher.

Introduction

Carbon nanotubes (CNTs) have found great attraction in recent literature for producing polymer nanocomposites due to its superior multifunctional properties such as excellent mechanical, electrical and thermal properties as well as unique geometry, i.e. tubular shape with very high aspect ratio. However, incorporation of CNTs into the polymeric matrix is a challenging task, particularly through the melt mixing method. This is originated from the significant interaction between the CNTs bundles and the entanglement of CNT bundles, restricting their efficient dispersion in the polymeric matrix. Literature shows diversity in the enhancement of mechanical properties of PA6 with incorporation of CNTs. Some authors reported a significant enhancement in the mechanical properties of PA with CNTs[1], while others reported a low or moderate improvement[2] . Recently, the dispersion state of MWCNT in both PA6 and PA66 in the melt mixing method was compared[3]. It was found that the dispersion state of MWCNT in PA6 is better than that of PA66.

In this work, the effect of incorporation of PA6 on the mechanical performance of PA66/MWCNT was well investigated. To do this, the mechanical performance of PA66/PA6 blends was compared to that of PA66/PA6/MWCNT at the same PA66/PA6 loadings.

Materials and procedures

PA66, PA6 were purchased from Radici Group and Hyosung, respectively, and MWCNT (TNMC3, COOH content of 2 wt%) was procured from Timesnano, china. PA66/PA6 blend and PA66/PA6/MWCNT were prepared by a Brabender 350E internal melt mixer with a cavity size of 370 cm^3. The ternary nanocomposites always included 1 wt% MWCNT. The compounds were injection molded into dumbbell shaped and notched impact bars. Tensile properties, DMTA, DSC and impact strength of the samples were determined according to the related standards.

Results

Fig. 1 exhibits the elastic moduli of PA66/PA6 and PA66/PA6/MWCNT, obtained by static tensile testing and DMTA, versus the content of PA6. As can be seen the elastic modulus of PA66/PA6 decreases by increasing the PA6 content linearly justifying the miscibility of this blend. The miscibility was also corroborated by DSC and DMTA analysis. By incorporation of MWCNT, the elastic modulus shows an increase, however, the extent of enhancement with respect to unfilled blend, increases by increasing the PA6 content.

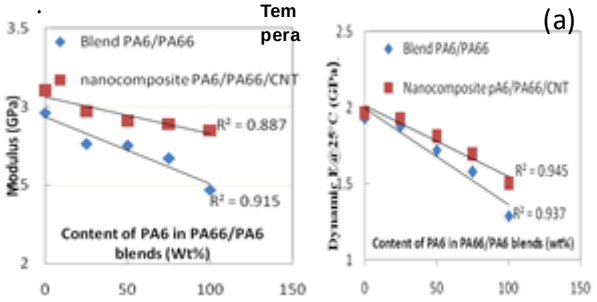

Fig. 1. Elastic modulus of PA66/PA6 blends and their nanocomposites with 1 wt% MWCNT (a) tensile modulus and (b) Dynamic elastic modulus.

Conclusion

It was found that the effectiveness of MWCNT on the mechanical performance of PA66 was improved by incorporation of PA6 in the nanocomposite. This could be explained by the improvement of dispersion of MWCNT in the matrix and enhancement of crystallinity of the matrix by incorporation of PA6.

Nanocomposites based on carbonaceous nanoestructures oxidized by solar energy

M López, M Blanco, E Aranzabe, A Marcaide

Fundación Tekniker, Av Otaola 20, 20600 Eibar Gipuzkoa (Spain)

mblanco@tekniker.es

Introduction: Carbon nanotubes (CNTs) have attracted much interest during the recent years due to their inherent extraordinary electrical, thermal, structural and mechanical properties [1]. Nowadays, the incorporation of nanotubes into ceramic and polymeric matrices is a vast area of study and research However, the pure CNTs are generally insoluble in common solvents and polymers, and they usually form stabilized bundles due to van der Waals force. So, it is extremely difficult to align and disperse the CNTs in a polymer matrix.[2]. One of the routes to increase the interaction between matrix and reinforcement is submitting CNTs to functionalization by aggressive chemical processes that insert functional groups on the sidewall of CNTs. The main disadvantage of these treatments is that CNT structure can be damaged during the process thus affecting CNT properties. Moreover, the high consume of solvents and energy required for these treatments point out the necessity of more environmentally friendly processes.
In the present work, an alternative method based on photoFenton treatment assisted by solar radiation to oxidize CNT is proved that overcomes main problems associated to conventional processes. The Fenton process consists on the generation of hydroxyl radicals, which have a high oxidation potential, using H_2O_2 as source of OH• radicals and Fe^{2+} salt as catalyser in an aqueous medium (pH=2.7) [3]. When the process rate is enhanced by UV radiation, it is call photoFenton process. The process conditions such as reactive concentration, reactant ratio and time of reaction have been optimized using a parabolic collector to concentrate solar radiation. In the figure 1 an scheme of the overall process of photoFenton modified nanotubes is observed.

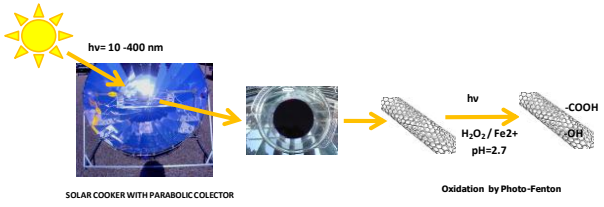

Figure 1. Scheme of the overall process of photoFenton modified nanotubes.

Results and Discussion: The PhotoPhenton process promotes the generation of carboxylic (-COOH), carbonylic (C=O) and/or hydroxylic (-OH) groups onto CNT surfaces without affecting their structural integrity as was shown by Fourier transform infrared (FTIR) spectroscopy and thermogravimetric analysis (TGA) in Figure 2 and by scanning electron microscopy (SEM). The photoFenton process achieves an increase in the oxidation degree in comparison with a usual oxidation method using HNO_3 concentrated acid.

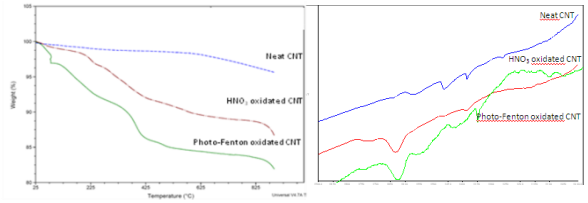

Figure 2. TGA thermograms and FTIR spectra of MWCNT pristine and oxidized with HNO3 and photoFenton treatment

PhotoFenton modified and oxidized by HNO_3 carbon nanotubes were incorporated into a thermoplastic matrix, polyamide 6 (PA 6) using a twin screw corrotating microextruder. SEM micrographs show that a homogeneous CNT dispersion into the matrix was obtained with the applied processing conditions for the three types of CNT, as it is shown in Figure 3.

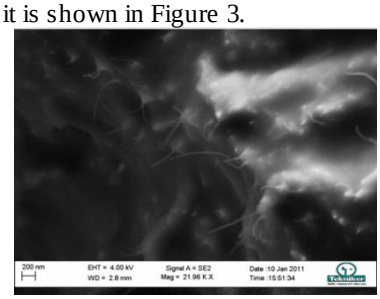

Figure 3. SEM micrograph of photoFenton oxidized CNT in PA 6 matrix

The effect of CNT content and CNT oxidation treatment in thermal and mechanical behavior of nanocomposites were analyzed by dynamic mechanical analyzer (DMA), differential scanning calorimetry (DSC) and TGA. The obtained results show a similar performance of nanocomposites based on CNT oxidized by both methods.

Conclusions: In summary, CNT oxidation by the photoFenton process assisted by solar energy is proved a suitable alternative environmentally friendlier and less costly to conventional chemical oxidation processes. Composites obtained by the incorporation of CNT oxidized with the photoFenton process into polyamide 6 show a similar behaviour than the obtained by the incorporation of CNT oxidized with common chemical methods.

Introduction

Polysaccharides (PS) are cheap, stable, renewable, biodegradable, natural polymers comprising a huge chemical and structural variability. PS are used for the preparation and modification of many different nanoparticle systems [1,2]. The applicability of such PS NPs is often limited by their hydrophilicity, which does not allow the entrapment of active hydrophobic substances (i.e. drugs or fluorescent dyes) into the NP core. Hydrophobic PS NPs can be generated from cellulose acetate [3]. Their applicability for i.e. pharmaceutical purposes or surface modifications is limited by the hydrophobic nature of the NP surface which lacks reactive functional groups. A suitable way to generate hydrophobic core / hydrophilic shell PS NPs is the self assembly of amphiphilic PS based copolymers [1,4]. The main drawback of this method is the time consuming chemical synthesis of PS based copolymers. We present here a new way to generate CA NPs with tailored designed functional hydrophilic PS surfaces (CA/hPS NPs).

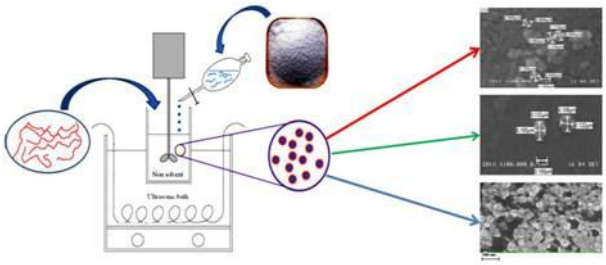

Figure 1: Preparation of in situ functionalized CA NPs

Experimental

CA/hPS NPs were prepared in one step analogous to a recently published nanoprecipitation method [5]. Briefly, CA was dispersed in an aqueous hPS solution under continuous stirring and sonication (Figure 1). CA/hPS NPs were characterized by dynamic and electrophoretic light scattering, charge titration and scanning electron microscopy and fluorescence spectroscopy.

Results/Discussion

Using amino cellulose (AC), low molecular weight chitosan (CHI) carboxymethyl cellulose (CMC) and hydroxyethyl cellulose (HEC), we generated CA NPs with shells carrying different functional groups and surface charges (Figure 2a). Hence, varying the hydrophilic PS allows the tailored design of the CA NP surface for designated applications. The pH dependent zeta potential (Figure 2a) and charge titration experiments showed clearly the successful functionalization of the NP surface.

In addition we demonstrated that CA/hPS NPs can be utilized for the entrapment of hydrophobic substances like drugs or dyes (Figure 2b) and the design of nanostructured, functional surfaces (Figure 3).

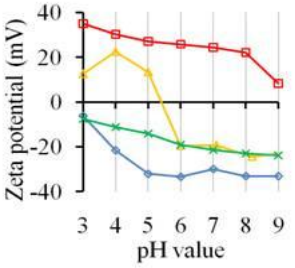

Figure 2a: pH dependent Zeta potential. □CA/AC, △CA/CHI, ×CA/HEC, and ◇CA/CMC NPs

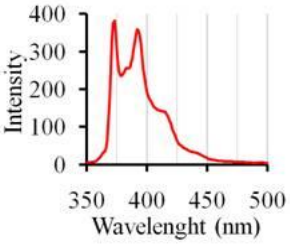

Figure 2b: Fluorescence spectra of pyrene encapsulated into CA/CMC NPs

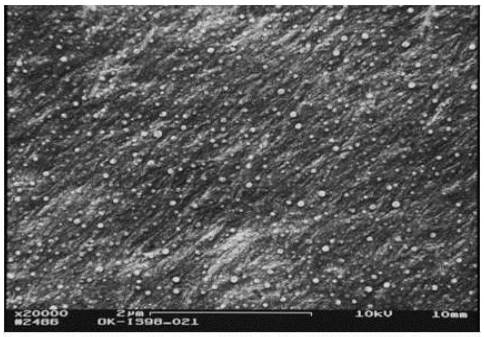

Figure 3: Chitosan surface modified with CA/CMC NPs

Conclusion

We successfully generated functional CA NPs with tailored designed PS surfaces. Future possible applications for CA/hPS NPs are the development of targeted drug delivery systems, and the design of nanostructured surfaces i.e. for the immobilization of active biomolecules.

Preparation and characterization of nitrile butadiene rubber-nanoclay composites with maleic acid anhydride as compatibilizer- Part I: Rheometric and swelling characteristics

E.M. Sadek *[1], *D.E. El-Nashar* [2]

E-mail address: elham_sadek@hotmail.com

Nitrile butadiene rubber (NBR)-nanoclay composites have been prepared in an open two-roll mixing mill and vulcanized using a conventional sulphuric system. Some sort of compatibilizer like maleic acid anhydride (MAH) can be utilized safely to improve the distribution of the nanoclay in the rubber matrix . Maleic acid anhydride-treated organoclay (MOC) was successfully synthesized. The synthesis method involves two possible reaction routes: (1) intercalation of ammonium cations of cetyl trimethyl ammonium bromide (CTAB) inside the untreated sodium bentonite clay galleries in order to obtain organoclay with average particle size = ~ 4nm as observed by transmission electron microscope (TEM). A higher basal spacing was obtained as indicated by X-ray diffraction (XRD). (2) Maleic acid anhydride dissolved in water was mixed with the prepared organically modified clay to give (MOC). The prepared clay structures were analyzed by Fourier transform infrared (FTIR) spectroscopy. Also, FTIR investigation confirmed the incorporation of (MOC) in NBR matrix, XRD analysis indicated that an exfoliated structure was obtained, and scanning electron microscope (SEM) images displayed the good interaction between the MOC and the rubber matrix. The influence of the MOC content (i.e. 1,3,5,10,20 phr) relative to the micrometer clay (i.e. 10, 20phr) on the NBR compounds was analyzed through rheometric and swelling characteristics. Rheometric study demonstrated an increase in minimum and maximum torques, delayed scorch time and optimum cure time for the MOC (3phr) incorporated NBR compound compared to pure NBR. The cure rate index followed the same trend. In addition, these particular compounds showed decreased equilibrium swelling in toluene solvent, increased cross linking density, more volume fraction and bound rubber content compared to the corresponding rubber filled with micrometer clay

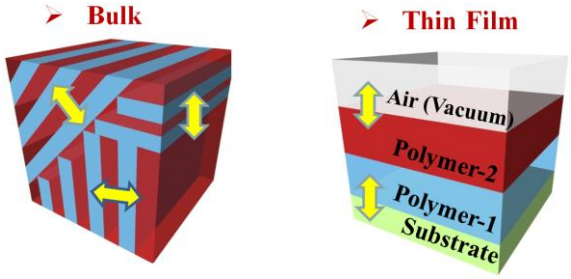
Transition Behavior of Block Copolymer Films on Controlled Interaction

Du Yeol Ryu, Eunhye Kim, Hyungju Ahn, and Jinsam Gong*

Department of Chemical and Biological Engineering, Yonsei University, Seoul, Korea

dyryu@yonsei.ac.kr

Block copolymer (BCP) self-assembly in thin films has recently been the focus of increased research interest due to their potential use as templates and scaffolds for the fabrication of nanostructured materials [1-2]. These potential applications have stimulated numerous studies on the influence of controlled interfacial interactions, confinement structure, and morphology of BCPs in thin films. The Flory-Huggins interaction parameter (χ) between the two block components is inversely proportional to temperature (χ decreases with increasing temperature) and the order-to-disorder transition (ODT) is governed by the product of $\chi \cdot N$, where N is the overall number of segments. Hence, a phase-mixed or disordered state can be observed when $\chi \cdot N < 10.495$ in the weak segregation regime. In addition, the phase behavior in a thin film geometry that confines polymer chains to the interfaces will be influenced by the interfacial interactions at substrate/polymer and polymer/air and the commensurability between the equilibrium period (L_0) of the BCP and the total film thickness.



Generally, the microdomains in BCP films orient normal to the film surface when the interfacial interactions are balanced (or neutral towards the two block components) and film thickness is commensurate with L_0[3-5]. In contrast, the preferential interactions of one block component with an interface and/or the difference of surface tension between two block components will lead to an orientation of the BCP microdomains parallel to the film surface. In developing neutral surfaces, random copolymer (A-*r*-B) approaches to balancing interfacial interactions have been successfully developed for surface modification using either a chemical grafting or cross-linking strategy, enabling the microdomains of block copolymer (A-*b*-B) to orient normal to the film surface [3-5].

In this presentation, we investigated the phase transitions for the films of block copolymers (BCPs) on the modified surface, like the order-to-disorder transition (ODT) by in-situ grazing incidence small angle x-ray scattering (GISAXS) and transmission electron microscopy (TEM). The selective interactions on the surface by a PS-grafted substrate provide the preferential interactions with the PS component of the block, while a random copolymer (PS-*r*-PMMA) grafted substrate do the balanced interfacial interactions on the surface. The thickness dependence of transition temperatures for PS-*b*-PMMA films on preferential surfaces in terms of the temperature dependence of χ between two block components will be discussed in comparison to that for PS-*b*-PI films on the PS-grafted substrate.

Interestingly, with decreasing film thickness, typical behavior of the BCP films on the preferential interactions indicates an increase of transition temperature. This behavior is in quite contrast to a decrease of transition temperature for the films on the balanced interfacial interactions because the random copolymer grafted substrate provide a surface-induced compatibilization toward two block components.[6-8]

An originality of the present work is that α,ω-aminopropyl polydimethylsiloxane (PDMS) and thermoplastic polyurethane (TPU) have been reacted in bulk at high temperature. Generally, PDMS/TPU copolymers are obtained via a reaction involving TPU precursors and functional PDMS oligomers and most often the reaction is done in solution at moderate temperature. Here, the elevated temperature allowed observing specific behaviour detailed below.

Experimental. Different α,ω-aminopropyl and α,ω-hydroxyethyl PDMS oligomers have been mixed with a thermoplastic polyurethane in the molten state at 200°C. Samples have been collected at different mixing/reaction times and analysed by HNMR spectroscopy and size exclusion chromatography (SEC). The morphology of the material has been characterised by scanning (SEM) and transmission electron microscopy (TEM).

Results. At 200°C the splitting of the urethane group of the TPU is releasing hydroxyl and isocyanate terminated TPU chains. It has been demonstrated that the splitting was followed by the fast reaction of the amino-siloxane with the released isocyanate. This reaction formed aryl-alkyl ureas and promoted the insertion of PDMS units inside the TPU chains, forming TPU-co-PDMS copolymer with a very fine morphology. An example of such morphology is depicted in figure 1 A). The visual aspect of the sample which was highly transparent is shown in figure 1 B). The transparency is linked to the very small size of the PDMS phase (~20nm). However, the morphology was not stable and coarsening was observed for longer reaction times. In figure 1 C) and D), the morphology and visual aspect of a sample reacted during 27 minutes is depicted. The PDMS phase size is between 50 and 150nm diameter and the material is totally opaque. This morphology evolution was unexpected and had to be explained. The following interpretation was proposed.

After the formation of the aryl-alkyl ureas several reactions can proceed. One possibility is the cleavage of unsymmetrical aryl-alkyl urea groups into alkyl isocyanate and primary aromatic amine. The reaction of the former with primary alkyl amine borne by the siloxane leads to alkyl-alkyl urea as was shown by Lu et al. on small model molecules [1].

In terms of macromolecular structure, the formation of alkyl-alkyl ureas has one important consequence: it implies that two siloxane units are now consecutive in the copolymer chain (figure 2).

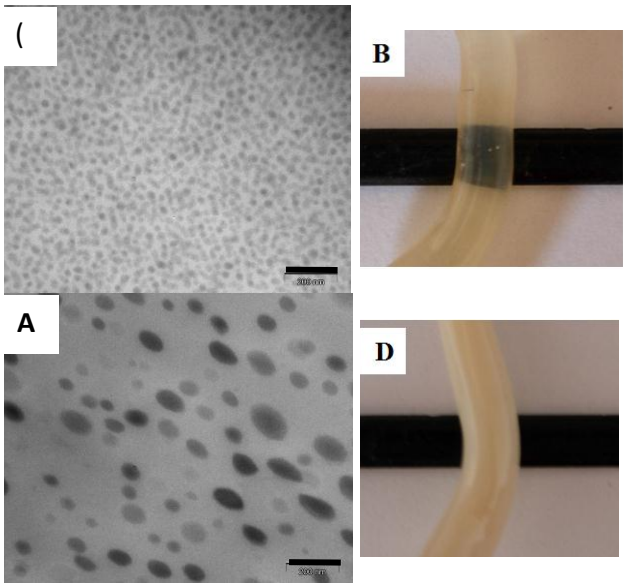

Figure 1. Transmission electron micrographs and corresponding macroscopic views of the reactive blend TPU/amino-PDMS 90/10 wt%
A) and B) after 3 minutes mixing. The blend is transparent. C) and D) after 27 minutes mixing time the morphology coarsens, the blend is opaque.
The silicone appears in dark grey. The scale bar is equal to 200 nm.

Thus, the formation of alkyl-alkyl urea leads to an increase in the average length of the siloxane segments that can then segregate in the shape of larger domains (about 100 nm or more) depending on the composition of the material.

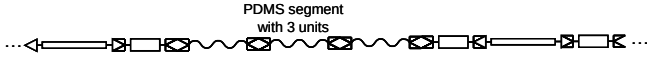

Figure 2. Scheme of the proposed structure of the TPU/PDMS when more and more aryl-alkyl ureas are replaced by alkyl-alkyl ureas formed later in the reactive process.

Effect of clay/polymeric modifier combination on structure and properties of epoxy nanocomposite

Ivan Kelnar, Jakub Rotrekl, Ludmila Kaprálková

Institute of Macromolecular Chemistry AS CR, v.v.i. Heyrovského sq. 2, 162 06 Prague, Czech Republic
kelnar@imc.cas.cz

Introduction

Inorganic nanofiller exhibit not only enhancement of most material parameters, but also significantly affect phase structure of multiphase polymer systems. In the case of epoxy containing polymeric modifiers dissolved in uncured epoxy affecting of reaction induced phase separation (RIPS) come into account. At the same time, formation of various complex structures (both in thermoplastics and epoxy) may lead to the synergy between these components and thus enhanced and/or better balanced mechanical behaviour. This study deals with the effect of nanofiller content, type and modification and/or functionality on structure and properties of polymer-modified epoxy. The effect of simple combination is compared with modifier/clay adduct obtained by ionic exchange.

Materials and Methods

Epoxy was DGEBA (Epilox A 19-02) with cycloaliphatic amine hardener (Laromin C 260)

Clay/polymer adducts were prepared by ionic exchange of Na+ ions of montmorillonite (MMT) by protonated aminated polymers.

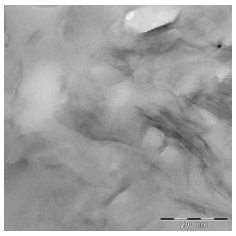
In the case of aminated polyoxypropylene (APOP), water was applied as reaction medium whereas for aminated butadiene-acrylonitrile rubber (ATBN) and aminated polybutadiene (LBA) THF/water mixture was used.

Results and Discussion

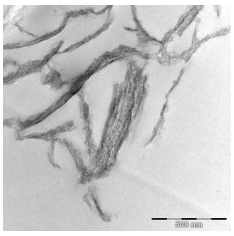
In the case of simultaneous clay and liquid rubber addition, the increasing clay content influences size of RIPS generated particles. Both enlargement and diminishing occurred. E. g., with epoxy/APOP no remarkable affecting at ambient curing temperature is accompanied by significant decrease at 70°C whereas with epoxy/POP enlargement over 2.5% Cloisite 30B content was found.

The interplay between clay-affecing of viscosity, curing kinetics and nucleating effect of clay (together with possible influencing of miscibility) was evaluated by simultaneous (chemo)rheological and cloud point measurements. Results obtained with several liquid elastomers with different structure, molecular weight and functionalities combined with layered silicates, layered double hydroxides and TiO_2-based nanotubes are discussed. With most of systems studied, addition of clay to rubber modified epoxy leads to improved balance of mechanical behaviour. The synergy between dispersed components occurred at different clay content ranges and was most significant in the case of blended inclusions formation (Fig. 1a)

Very interesting results were obtained with modifier/clay adduct prepared mostly by ionic exchange, especially in comparison with single combination of these components. This modification promotes self assembly leading in some cases to nanolayered structure of polymer embedded platelets, which was most significant for LBA/MMT adduct (Fig. 1b), i.e., for polymeric component with low affinity to epoxy. In this way, very fair balance of mechanical properties (exceeding simple combination of components) can be achieved. At the same time, unusually significant dependence on concentration, adduct composition and polymer chain length indicate some new kind of influencing mechanical behaviour of epoxy. This fact is confirmed also by the significant deteriorative effect of a low adduct content on properties, not found for simultaneous addition of separated components. Effect of adduct on structure of polymer-modified epoxy is also evaluated. Though its effect on phase structure is comparable with commercial clay, significant difference in mechanical properties between epoxy/APOP and epoxy/POP systems further confirm different effect of adduct on epoxy systems behaviour.



a)



b)

Fig 1a) TEM of blended inclusions of epoxy/APOP/Cloisite 30B 90/5/5 system b) TEM picture of epoxy containing 6% of LBA-MMT adduct

Conclusions

Combination of clay and low-molecular-weight rubbers is a tool for improving balance in mechanical behaviour of epoxy nanocomposite.

Best mechanical behaviour was found when adduct of aminated rubbers with MMT was used. This is caused by the formation of elastically embedded nanosized planar arrays of elastomer-modified clay and an increase in T_g of epoxy network, leading to a new effective way of affecting the mechanical behaviour of epoxy.

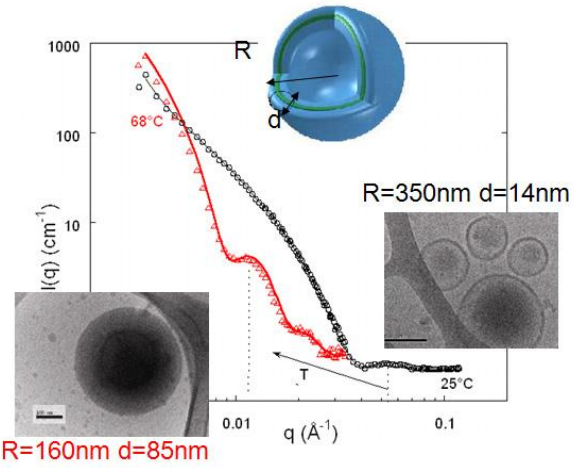
The supramolecular organization of amphiphilic block copolymers in water is an interesting strategy to design smart nanoparticles for applications such as drug delivery or nanoreactors. A challenging requirement for these applications is the ability in response to external stimuli to destabilize these supramolecular organization so as to release the encapsulated substances.

To address this goal, polymer vesicles, commonly called polymersomes, have been developed in which a specific stimulus destabilizes the vesicle structure.[1] We thus study a new class of polymersomes, in which the hydrophobic part is a liquid crystal polymer (LCP).[2] Recently, we have shown that light inducing by using the isomerization from *trans* to *cis* configuration of the azobenzene group in the LCP, could destabilize asymmetric azobenzene-containing liquid crystal polymersomes.[3] It is also well-known that certain LCP can undergo conformational changes, from a rod to a coil shape at the nematic-isotropic transition upon temperature variation.[4] On the other hand, aromatic LCP can change orientation under magnetic field. Therefore, the temperature changes and the magnetic field may be used as physical stimuli to induce modification of the structures of vesicles membrane.

We have studied two series of amphiphilic block copolymers in which the hydrophobic block was a side-on nematic LCP, poly((4''-acryloxybutyl) 2,5-di(4'-butyloxybenzoyloxy) benzoate) (PA444) or poly(4-butyloxy-2'-(4''-methacryloyloxybutyloxy)-4-(4-butyloxybenzoyloxy) azobenzene) (PMAazo444), and the hydrophilic block was polyethyleneglycol (PEG).[2] By combining both Small Angle Neutron Scattering (SANS) measurements under *in situ* temperature change and magnetic field application and cryo- transmission electron microscopy (cryo-TEM), we have studied the thermo- and magneto-responses of LCP vesicles.[6]

Large changes in membrane thickness, vesicle size and interior compartment volume are observed for both LCP–*b*-PEG vesicles. At room temperature, block copolymers self-assemble and form vesicles with a radius of 450-500 nm and a bilayer membrane thickness of 10-15 nm. Upon heating, the membrane thickness, d, started to increase dramatically from a temperature (~55°C) above T_g but below T_{NI} of the LC polymer block, and reached up to 120 nm at $T > T_{NI}$. The thickness of the membrane was inconsistent with a bilayer structure. The vesicles were transformed into thick-walled capsules, which surprisingly remained stable even for temperatures above T_{NI}.
The PEG chains should partially dehydrate when increasing temperature, but this cannot explain a so huge increasing of membrane thickness. We propose that the membrane reorganized into a structure consisting of microphase separated LC and PEG domains.



Changes upon temperature of SANS curves (25°C, 68°C) and of Cryo TEM images (20°C (right) and 90°C (left); scale bar is 100nm) of PEG-b-PMAazo444 vesicles. The vesicle radius is reducing while the membrane thickness increases.

This structure would account for the large membrane thickness and the domains would be very similar to those of LC block copolymers in pure state, except that the PEG domains would be partially hydrated in the capsule membrane. Such structural transition is not reversible and the polydomain membrane remains even when the sample is cooled back down to room temperature. The system is thus very different from other thermo-responsive systems with LCST polymer block, which formed larger hydrophobic spherical particles when increasing the temperature. Analysis of changes in structural parameters such as the internal aqueous volume and the polymer membrane volume suggest that capsule scission and fusion also occurred during the transition.

Finally, these polymersomes were also sensitive to applied magnetic field, but in a limited temperature range: application of a magnetic field of 1.4Tesla substantially increased the membrane thickness due to the induced mesogen alignment.

Preparation of Fluoroalkyl End-Capped Oligomers Possessing Nonflammable and Flammable Characteristics in Silica Gel Matrices

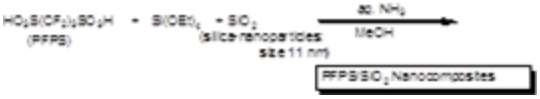
Hideo Sawada

Department of Frontier Materials Chemistry,
Graduate School of Science and Technology, Hirosaki University
Hirosaki 036-8561, Japan

e-mail: hideosaw@cc.hirosaki-u.ac.jp

From the developmental viewpoints of a higher thermally stable fluorinated polymeric materials, it is in particular interest to study the hybridization of fluorinated polymers with inorganic materials such as silica gels. For example, Lee et al. reported that PTFE [poly(tetrafluoroethylene)]/SiO_2 organic-inorgnic hybrids can be prepared through a sol-gel process with tetraethoxysilane.[1] Kim et al. have very recently reported the preparation of perfluoroalkyl methacrylate polymer/silica organic/inorganic hybrids in supercritical carbon dioxide.[2] However, these fluorinated polymers/silica hybrids exhibit a clear weight loss behavior corresponding to the contents of parent fluorinated polymers in the hybrids around 600 ~ 700 °C or 400 ~ 600 °C, respectively.[1, 2] In a variety of fluorinated polymers, especially, fluoroalkyl end-capped oligomers are attractive materials, because they exhibit various unique properties such as high solubility, surface active properties, and nanometer size-controlled molecular aggregates which cannot be achieved by the corresponding non-fluorinated and randomly fluoroalkylated ones.[3]

Here, we have succeeded in applying these fluoroalkyl end-capped oligomers to nonflammable fluorinated polymeric materials through the sol-gel reactions with silica nanoparticles under alkaline conditions. Especially, in these fluorinated oligomers, fluoroalkyl end-capped N-(1,1-dimethyl-3-oxobutyl)acrylamide oligomer [R_F-$(DOBAA)_n$-R_F]/silica nanocomposites have been verified to exhibit a nonflammable characteristic even after calcination at 800 °C through the formation of hexafluorosilicate anion during the nanocomposite reactions; although the parent fluoroalkyl end-capped oligomer can decompose completely around 500 °C. In contrast, no formation of hexafluorosilicate anion during the composite reaction affords a usually flammable behavior for fluoroalkyl end-capped acrylic acid oligomer [R_F-



$(ACA)_n$-R_F]/silica nanocomposites.

In addition, we have found that not only R_F-$(DOBAA)_n$-R_F oligomer but also perfluoro-1,3-propanedisulfonic acid (PFPS) are applicable to nonflammable fluorinated materials through the sol-gel reactions with silica nanoparticles under alkaline conditions as shown in the following Scheme.

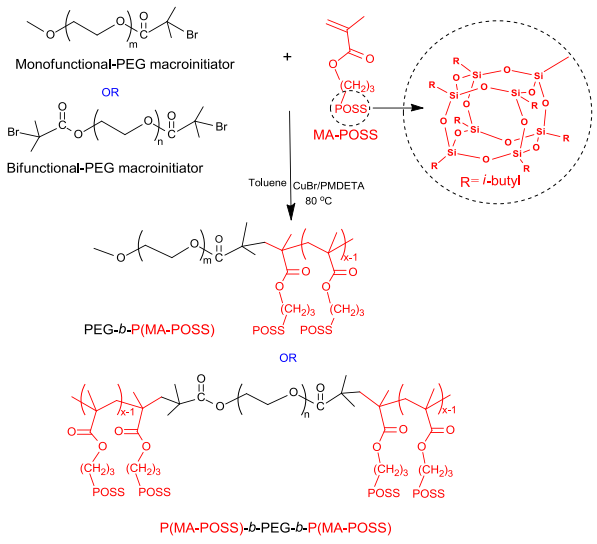
Abstract

Amphiphilic block copolymers combine characteristic features of the constituent blocks in a unique way creating hybrid materials that have the ability to self-assemble forming well-defined nanostructures of various morphologies in solution and thin film. The current work focuses on the synthesis, self-assembly and gelation in aqueous medium, of well-defined amphiphilic hybrid block copolymers with poly(ethylene glycol) (PEG) and poly(methacrylisobutyl polyhedral oligomeric silsesquioxane) P(MA-POSS) as the hydrophilic and hydrophobic blocks respectively.

The synthesis was carried out via a living radical polymerization technique; namely atom transfer radical polymerization (ATRP), employing PEG as the macroinitiator. Two types of block copolymers; diblock copolymers (PEG_{5k}-*b*-P(MA-POSS)) and triblock copolymers (P(MA-POSS)-*b*-PEG_{10k}-*b*-P(MA-POSS)) were prepared.

Synthesis Scheme



The hybrid amphiphilic block copolymers could self-assemble into nanoparticles-micelles in aqueous solution. Using the dynamic light scattering (DLS) technique, the hydrodynamic particle radii, R_h was calculated and found to be varying with the degree of polymerization (DP) of P(MA-POSS), for example, for diblock copolymer; PEG_{5k}-*b*-P(MA-POSS), it increased from R_h ~ 13.3 ± 1.1 nm to ~ 17.5 ± 1.4 nm with change in the DP of P(MA-POSS) from 4 to 6. The micellar structures formed by the P(MA-POSS)-*b*-PEG_{10k}-*b*-P(MA-POSS) triblocks were 'flower-like', where the PEG middle block assumed a loop conformation in the corona. Larger aggregates formed by P(MA-POSS)-*b*-PEG_{10k}-*b*-P(MA-POSS) were also detected in solution, whuich were interpreted as a contribution from some PEG chains adopting an extended conformation with one end dangling in solution, causing gelation at higher concentrations via intermicellar interactions. The gel formation at relatively lower copolymer concentrations (< 9 wt. %) and their rheological behavior was investigated.

The influence of hydrophobic POSS nanoparticles (Octavinyl-POSS), added to block copolymer solutions, was also investigated on their micelle formation, gelation, and rheological performance. Thus, the hydrodynamic size of the particles, formed by PEG_{5k}-*b*-$P(MA\text{-}POSS)_{3.6}$, increased more than four times to 56.9 ± 3.7 from 13.6 ± 1.0, with the addition of 0.1 wt% POSS nanoparticles. In case of P(MA-POSS)-*b*-PEG_{10k}-*b*-P(MA-POSS) triblock copolymers, which is associative in character, addition of POSS nanoparticles resulted hydrogel, with a significantly higher storage modulus, G', yield strengths, σ_y, and lower critical gelation concentration, c_g as compared with the pure triblock copolymer. Furthermore, gelation was induced in aqueous solutions of diblock copolymer by introducing P(MA-POSS)-*b*-PEG_{10k}-*b*-P(MA-POSS) triblock copolymer chains and the rheological performance was investigated.

Thermoset Nanosphere Formation: A Model Case from SEBS and Benzoxazine Molecular Assembly System

Suwabun Chirachanchai[1,2] *and Wonchalerm Rungswang*[1]

[1]The Petroleum and Petrochemical College, Chulalongkorn University, Soi Chula 12, Phyathai Road, Pathumwan, Bangkok, Thailand 10330.

Polymeric nanospheresaremainly referred to thermoplastic material due to the ease of controlling morphology and variety of materials. However, the preparations are complicated involving multi-step synthesis whereas. The most of nanospheres areloosely bound via secondary forces which maintain their structures only in specific conditions. In the case of thermoset nanospheres, the ease of handling is the advantage but the difficulty in controlling morphology during curing is the short-coming.

The present work, developsa novel approach to formthermoset nanospherevia molecularassembly mechanism through a study case of polystyrene-b-poly(ethylene-co-1-butene)-b-polystyrene triblock copolymer (SEBS)and benzoxazine monomer (BZ).

By simply blending BZin SEBS followed by thermal curing, well-defined nanometer sized thermoset particles were easily obtained. For example, the ratio of SEBS:BZ / 75:25 (S75BZ25) gave polybenzoxazine (polyBZ)nanospheres after thermally curing about 170 ± 43 nm (Figure, A). The less content of BZ brought the small nanospherical size. The proposed mechanism is related to the molecular interaction between BZ and PS segments in SEBS under π-π stacking. The molecular interactionmight lead to a pocket-like structure where the BZ starts crosslinking in a confined space.

To clarify the proposed mechanism, a series of thermoplastics, such as PS, polycarbonate (PC) and chlorinated polyethylene (CPE) which may form molecular interaction with BZ in different manner were selected. The resultsshowed that only PS gives the spherical polyBZ for all blending ratios but in micrometer sizes of 10 ± 3 μm for PS25BZ75 (Figure, B).The molecular interaction between two benzene rings belonging to BZ and SEBS, or BZ and PS via π-π stacking was also confirmed by using nuclear magnetic resonance (NMR) technique based onspin-lattice relaxation (T_1) and Nuclear Overhauser effect spectroscopy (NOESY).

When the confined space becomes as small as micrometer sized fibers, the thermoset nanospheres also reduces their sizes significantly. The electrospun fibers obtained from the blends of BZ and SEBS with the size about 6±0.8 μm gives the polyBZnanospheres with the size of 87± 14 nm.

In conclusion, the present work, for the first time, shows that we can simply develop thermoset nanospheres when the molecular interaction between polymer matrices and thermoset monomer is effective and at that time the factors to control the size is the content of thermoset monomer as well as the confined space of the matrices.

The authors would like to acknowledge the Royal Golden Jubilee Program (the Thailand Research Fund (PHD/0058/2550)) for the financial support.

Introduction

Addition of carbon nanotubes (CNT) to polyimide (PI) is an attractive alternative to tailor PI properties, since CNTs can improve, for instance, elastic modulus or electrical conductivity [1, 2]. In order to modify PI properties, good CNT dispersion is necessary. CNT agglomeration makes CNT dispersion especially difficult. Several techniques can be used for CNT dispersion in PI, such as high and low energy sonication [3], chemical modification of CNTs [4] and use of surfactants [5].

PI-CNT nanocomposites have been synthesized and characterized in order to determine the effect of CNT concentration on PI thermo-mechanical properties. As shown in Figure 1, composites with CNT concentrations ranging from 0.1 to 1%wt were synthesized via modified diester-diamine route [6]. The dispersion of carboxyl functionalized multi-walled carbon nanotubes (MWCNT-COOH) was achieved by combination of surfactants and *in-situ* polymerization under sonication.

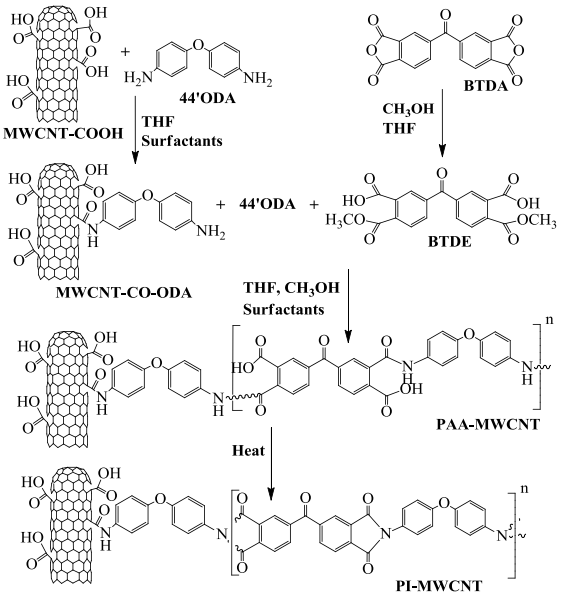

Fig. 1. Modified diester-diamine route for synthesis of PI-CNT composites

Materials and Methods

MWCNT-COOH were bath and horn sonicated in tetrahydrofuran (THF) with Sodiumdodecylbenzene sulfonate and 4,4'-oxydianiline (4,4'ODA). Methanol was reacted at 70°C with 3,3',4,4'-benzophenone tetracarboxylic dianhydride (BTDA) to produce diester. The diester solution was added to CNT-44'ODA solution and reacted under bath sonication at 65°C. After solvent volatilization, PI-CNT composites were obtained by thermal imidization at 300°C.

Results and Discussion

PI glass transition temperature (Tg) increased with CNT concentration from 287 to 335°C for the nanocomposite containing 0.3%wt CNTs and decreased for nanotube concentrations greater than 0.3%wt (Figure 2). Maximum increase in elastic modulus was also achieved for the 0.3%wt CNT nanocomposite.

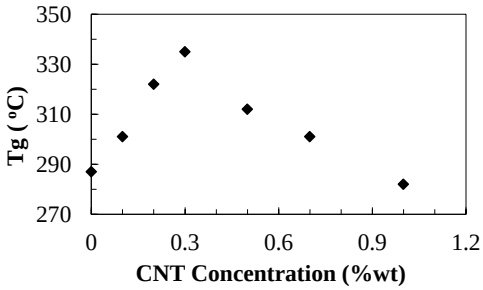

Fig. 2. Tg of PI-CNT composites (Measured by DSC)

Reduction of CNT dispersion quality as nanotube concentration increases is proposed as an explanation for the maximization of property improvement in the 0.3%w nanocomposite. Different CNT dispersion methods are studied in order to verify this hypothesis. The effect of monomer ratio (molecular weight) and crosslink agents in thermo-mechanical properties of polyimides is also investigated as a potential root cause for maximization of property modification at a particular CNT concentration.

Conclusions

Addition of CNTs to PI matrices can improve their thermo-mechanical properties, such as glass transition temperature. For this improvement to take effect, appropriate CNT dispersion is necessary: if CNT dispersion is not adequate, no significant property improvement is observed.

larraza@ictp.csic.es

Introduction.

Polycaprolactone (PCL) is a semicrystalline, biodegradable and biocompatible polymer. Due to its slow degradation rate, its application in the tissue engineering field has importantly increased [1, 2]. In this work, PCL nanocomposites containing organomodified montmorillonite (MMT), that simultaneously act as a substrate for cellular growth and prevent infections by microorganisms were prepared. The clay was modified with a block copolymer (PCL-b-DEAEMA) synthesized by ATRP. The different blocks contain PCL and quaternary ammonium species that attach to the clay surface and also act as cationic antiseptics [3]. The effect of the clay on the mechanical and superficial properties along with the thermal stability and its biodegradation rate was studied. The thermooxidative degradation process was monitored by the analysis of chemiluminescence emission [4]. Bacterial biodegradation was studied by determination of CO_2 using indirect impedance measurement.

Materials and Methods.

PCL with different proportions of clay were prepared. In order to compare the effect of the clay in the matrix, nanocomposites with neat clay were prepared too. All the samples were prepared by melt processing in a Haake MiniLab mixer. Nanocomposites morphology was characterized by XRD and TEM. The mechanical analysis was carried out by tensile testing and the superficial properties were analyzed by contact angle measurements. Thermooxidative stability was studied by TGA and chemiluminescence emission analysis. The biodegradation of the samples by *B.subtilis* and *P.Putida* was carried out at 30ºC and evaluated by measurement of the carbon dioxide produced using a Bac-Trac 4300 (SY-LAB Geräte GmbH, Neupurkerdorf, Austria).

Discussion

The modification of the clay produced an increase in the interlayer space and in the compatibility with the polymer leading to an intercalated/exfoliated morphology. The nanocomposites prepared with organomodified clay MMT-(PCL-b-DEAEMA) present an improvement on the mechanical properties with the clay content. The presence of the block copolymer in the clay/polymer interphase modifies the hydrophobic nature of the nanocomposites and an increase on the contact angle with water was observed. TGA analysis showed a higher thermal stability of the nanocomposites regarding to the neat PCL, this effect is due to the good barrier properties of the clay and was improved in the case of those samples with organomodified clay. The better stability of nanocomposites was confirmed by chemiluminescence (QL) emission analysis, which is related to the amount of oxidation species (hydroperoxides) generated during the thermooxidative degradation process, Figure 1A. PCL showed a higher QL intensity than the samples with clay. And for a given clay amount, those with modified clay showed a lower intensity. By CO_2 determination, it was observed that the presence of the quaternary ammonium species in the clay, decreases the biodegradation with respect to the materials with natural MMT mirroring the bactericide effect of the organomodified clay. Figure 1B shows the biodegradation by *B.Subtilis* in a period of 70 days.

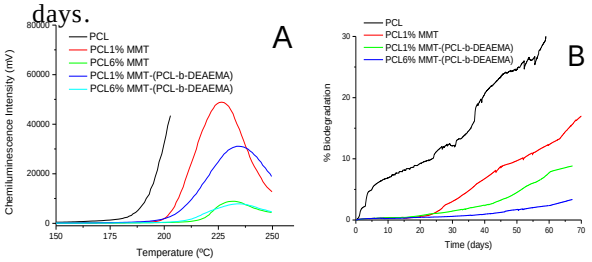

Figure 1. Chemiluminescence emission of PCL and nanocomposites *vs* temperature under O_2 (A). Biodegradation rate during a period of 70 days in the presence of *B. subtilis* (B).

Conclusions

The modification of the clay led to an improvement of the compatibility and dispersion of the filler in the matrix, showing better mechanical properties and higher thermal stability with respect to the neat PCL and the materials prepared with natural MMT. Contact angle measurements showed the effect of the organic surfactant by increasing the contact angle values in the materials prepared with MMT-(**PCL-b-DEAEMA)**. The presence of the ammonium cations of the block copolymer in the interphase matrix/filler, delays the biodegradation of the nanocomposites with respect to the materials with natural MMT and neat PCL, in presence of *B. subtilis y P. putida*, evidencing the biocide effect of the presented nanoclay.

Introduction

A model of the temperature and electric field dependence of the mobility of polarons and bipolarons in conjugated polymers in terms of an Hückel and stochastic approach is presented. Polarons and Bipolarons are self-localized, charged quasi-particles associated with characteristic distortions of the polymer backbone and with quantum states in the energy gap due to strong electron-lattice coupling[1]. The mobility is shown to have a strong dependence on the electric field, with two distinct regimes of temperature dependence. Lattice thermal oscillations enhance polaron mean velocity for electric fields of 1 mV/Angs or higher. In contrast, its mobility is damped by thermal oscillations under weaker electric fields.

The electroluminescence in conjugated polymers has a great impact in optoelectronic devices such as organic light emitting diodes (OLED's). The microscopic description of the temperature dependence of the charge carriers mobility in these materials is of fundamental importance. Our results are in good agreement with experimental data.

Methods

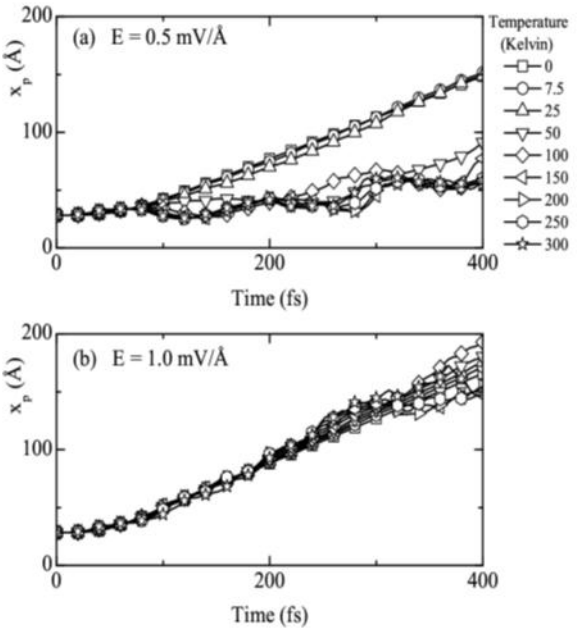
The essential physics of the mobility is contained in an Hückel model Hamiltonian with the hopping integral between neighboring carbon atoms explicitly dependent on the carbon-carbon distance,[2] and the Langevin approach to treat the sites motion where a random force term acts on each site simulating a thermally excited lattice. The electric field E is included in terms of a time dependent vector potential, A, by a Peierls substitution.[3] We obtain the wave functions, site positions and velocities at time t by numerical integration of the Schrödinger equation and the Langevin lattice equation of motion.

The effects of the external electric field and the thermal bath on the mobility are obtained by varying systematically E and T. The electric field takes the values from zero to 3.25 mV/Angs. The temperature values vary from zero to 300 K. The dynamics of the system is followed during 400 fs (time step t=0.004 fs). We have considered polymeric chains with N=200 sites with periodic bound conditions and containing initially one single positively charged polaron or bipolaron.

Results and Discussion

We considered the charge carrier trajectories and their velocities. When T=0 K, and after 100 fs, these trajectories are smooth and linear so, the velocity is constant. When E=0 mv/Angs, the bipolarons and polarons execute a brownian motion around the initial position and their averaged velocity are zero. We can see that the polaron kinetic energy is a linear function of temperature as it should be expected.

Two specific cases where the polaron mobility changes considerably with E and T are shown in the figure. In (a) we show polaron trajectories for E=0.5 meV/Angs. For this value of the electric field the polaron velocity is damped by thermal oscillations



when T > 25 K. In (b) E=1.0 meV/Angs, in this case the thermal bath enhances the polaron velocity[4].

Conclusions

We solved the time-dependent Schrödinger equation for the pi-electrons and the equations of motion for the lattice displacements with temperature and electric field effects. This electric field-temperature-dependent model clearly presents two regimes for charge carrier mobility for field values used in physical devices like OLED's and OFET's. The presence of two different regimes for the temperature dependence of the mobility is shown to be consistent with the large mobility differences reported for conjugated polymers. It is shown that the temperature could enhance or damp the carrier mobility depending on the external electric field strength. For electric fields of about 1 mV/Ang or higher, the temperature works to increase the mobility of the charge carriers with a presented mechanism, that is distinct from the conventional semiconductor mechanism.

Abstract

Conducting polymers have been investigated intensively over the last thirty years or so and the reason for this seems to be the fact that although they are organic material, their conductivity can achieve values that are comparable to semiconductors and metals. Moreover, their conductivity, electrochemical and optical proprieties make these materials excellent candidates to the development of high technological devices such as batteries, gas separating membranes, sensors, microelectronic devices, corrosion protection, electrochromic display devices and all-optical devices.
Amongst the most studied CP, polyaniline (PAni) is the preferred conducting polymer since it offers several advantages over the inherently conducting polymer family. Although its conductivity is not as high as other conducting polymers, its conductivity does not degrade upon exposure to environmental conditions.

Usually, PAni can be synthesized by a chemical, electrochemical, or photopolymerization process. Each one of these methods of synthesis provides an as made conducting polymer material with slightly different morphologies, and consequently, slightly different physical and chemical properties. Amongst these methods, the photopolymerization process has come to be more in evidence nowadays after our pioneering work, which used Ag^{+}, assisted by UV light to promote the polymerization of aniline monomer, which results in a composite material consisting of PAni and Ag^{0}. As a consequence of this research work, we also developed a new method for storing optical information and drawing patterns of conducting polymers that can be used for the development of all electronic device applications that use polymers.

In this work we extend the energy range of the light using x-ray and gamma ray and also use another non conventional source, the ultrasound waves to induce the conducting monomer polymerization.
Polyaniline (PANI) and polyaniline/silver nanocomposites composite were obtained through sonication of an aqueous solution of aniline and silver nitrate at room temperature and by the interaction of the x-ray and γ ray with the aqueous monomer solution. Also we propose a mechanisms to explain the formation of these products which is based on the fact that both methods produce hydroxyl radical •OH and hydrogen radical •H, which acts as an oxidizing agent for the polymerization of aniline monomer and as reducing agent for silver ions, respectively. Spectroscopic, X-ray and scanning electron microscope (SEM) measures showed that polyaniline and silver nanoparticles of 40nm of average diameter are obtained when ultrasonic technique is used whereas silver nanoparticles of 60nm average, and highly fibrillar polyaniline network with diameter of 60 nm is obtained when γ radiation is used.
Comparing the morphology of the chemical synthesized polyaniline with polyanianile obtained by x-ray and γ radiation, we observe that the morphology somehow seems to be correlated with the energy of the ionization radiation. The morphology for the chemical synthesis is globular whereas it is Fibril like for the gamma radiation, one the other hand for the x-ray synthesis it's appear to be a medium term, the fiber seems to be formed by the fusion of several globules.

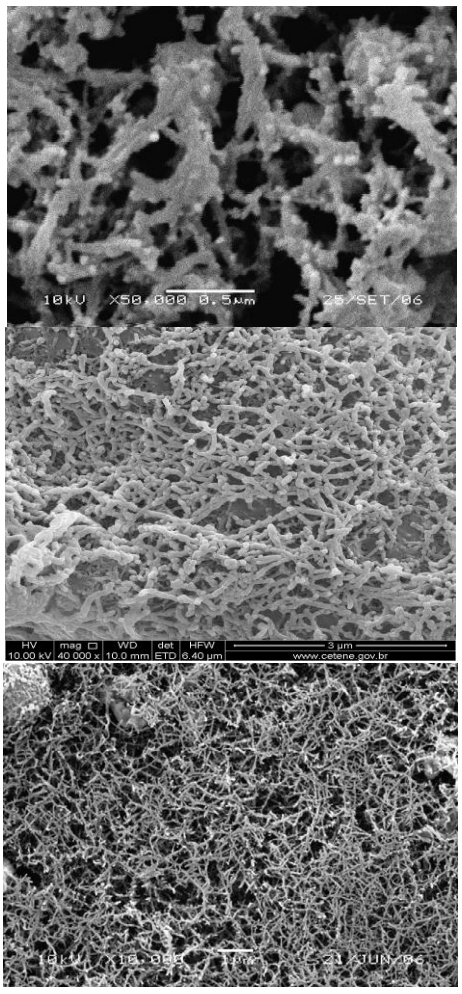

Fig. 1. Scanning electron microscopy images of polyaniline/silver nanocomposite grown from a solution of aniline nitrate and silver nitrate (a) under ultrasonic irradiation for 2 h, (b) under x-ray dose of 5 kGy and (c) under γ ray dose of 10 kGy

Concentration and temperature influence on the rheological behavior of a filled polymer

aimerino@uma.es

Introduction

Over the years many products have been invented and tried in order to improve body armour. Shear thickening fluids are very much appreciated for protective applications in ballistics and stab. The shear thickening fluid (STF) is a combination of hard metal oxide particles suspended in a liquid polymer. This mixture of flow and hard components at a particular composition, results in a material with remarkable properties [1]. The shear thickening trend can take place in concentrated colloidal suspensions that have been shown to exhibit reversible shear thickening resulting in large, sometimes discontinuous, increases in viscosity above a critical shear rate, after a shear thinning behaviour at low shear rate and followed by a shear thinning region at high shear rate. In order to fit this phenomenon with a mathematic model, several attempts have been made [2]. But they use different equations to fit each region. In this work, we propose a function which fit all the experimental results.

Materials and Methods

The fumed silica used was Aerosil R-816 (Degussa Corporation). This is a hydrophobic silica, with a specific surface area of 190 m_2/g and a primary spherical particle size of 12 nm. Fumed silica primary particles are irreversibly fused into larger structures called aggregates whose particle size is under 100 nm. The continuous phase in our studies is a polyetylene glycol having an average molecular weight of 400 (PPG400) (Aldricch Chemicals). Each suspension was prepared by adding the liquid to the silica in a blender and mixing for approximately 60 minutes at 15 s^{-1}. Steady-shear viscosity has been measured using a parallel plate geometry on a stress-controlled rheometer (Haake Rheo-Stress RS600). The diameter of plates was 20 mm.

Discussion and results

Viscosity curves have been used to study the dependence of the rheological behavior of a polar polymer filled with hydrophobic silica fumed nanoparticles with particle concentration and temperature variation. At room temperature, shear-thickening behavior has been observed in between two shear-thinning regions when solid concentration is higher than 5% v/v. When temperature increases to 35-40ºC, this behavior is observed when solid concentration is higher than 11% v/v [3]. A new apparent viscosity function has been used to fit the experimental results [4]. Fig 1 shows the experimental results. As can be seen, this model fit the experimental results fairly well, specially at temperatures close to the room temperature (in between 15-25ºC).

As a very low shear rate Newtonian behavior was observed, Krieger-Dougherty equation was used to fit shear zero viscosity/solid concentration curves.

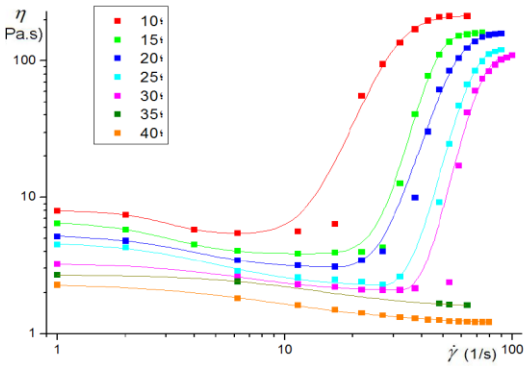

Figure 1. Apparent viscosity curves of silica in PPG 400 suspensions at 0.110137 v/v, at different temperatures.

The intrinsic viscosity calculated from the fitting process is much higher than 2.5 (hard spheres model) and the maximum packing fraction is much lower than 0.7, which is interpreted as the manifestation of the formation of aggregates of aggregates. This result leads us to justify the shear-thickening behavior here observed on the basis of "hydroclusters" formation, which are being generated by the action of hydrodynamic forces on silica aggregates.

Conclusions

Fumed silica suspensions in polypropylene glycol (PPG400) exhibit shear-thickening under steady flow. The shear-thickening behavior can be explained through a clustering mechanism, which attributes the thickening phenomena to the presence of temporary, flow-induced clusters. The calculated intrinsic viscosity value, which is a measure of the solute contribution to the suspension viscosity, is 23, and the maximum packing fraction is 0.22. These values are far away from those obtained for the hard sphere model, supporting the cluster theory.
The mathematic model here developed is able to fit the experimental results in the two regions observed in this STF fluid.

Properties of thin films of amphiphilic block copolymers based on Nvinylpyrrolidone and 2,2,3,3-tetrafluorpropylmethacrylate

Deniskina I.V, Zamyshlyayeva O.G., Batenkin M.A., Shandruk G.A.

Amphiphilic block copolymers have attracted much research interest because of the unusual properties associated with the processes of surface segregation and selforganization in solution and in films.

The study of surface morphology, physical and mechanical properties and thermo-mechanical characteristics of thin films of amphiphilic block copolymers can provide useful information for their application as gas separation membranes, photoresist in nanolithography processes, emulsifiers and stabilizers for emulsions and dispersions, compabilizators, nanocontainers [1-3].

Objects of study in this work are films of amphiphilic diblock copolymers based on the linear structure of the hydrophilic poly-N-vinylpyrrolidone (PVP) and hydrophobic poly-2,2,3,3-tetrafluorprorylmethacrylate (PFMA) previously obtained by radical polymerization of the first in the presence of the transmitter chain bis-(pentafluorophenyl)-germane to follow postpolimerization in the monomer FMA [4]. The method investigated AFM surface morphology of hybrid diblock copolymers, the individual PVP and PFMA, as well as a mechanical mixture of homopolymers in a weight ratio of 10% PVP and 90% of the PFMA. Patterns of regular granular relief spherical particles 0.78 microns and mesh size of about 2 microns.

Determined contact angles for films of block copolymers, the individual PFMA and the mechanical mixture of PVP and PFMA. The values of surface tension and its components.

Defined glass transition temperature for a given number of polymers using the method of DSC. Shows the shift of glass transition temperatures of block copolymers to a temperature of individual PFMA.

Films of copolymers, PVP, and the mechanical mixture were tested for tensile strength. The tests were conducted on tensile testing machine Zwick / Roel Z005 in the mode of uniaxial tension. Shown improvement in strength of the hybrid copolymers as compared to the fragile film PFMA.

Hierarchically structured polymeric films used as a model substrate for the investigation of adhesion and wettability

P. Escale, M. Save, C. Derail, L. Billon and L. Rubatat

IPREM / EPCP, UMR 5254, Université de Pau et des Pays de l'Adour, FRANCE

laurent.rubatat@univ-pau.fr

This work concerns the elaboration and the study of hierarchically structured films made of block copolymers in the aim of investigating the wettability and adhesion properties. The first level of structuring is a micrometer honeycomb morphology (left and center figures) obtained by a controlled solvent evaporation method under humid atmosphere. The second level of structuring is achieved via the self-assembly of diblock copolymers at the nanometer length scale (center & right figures). The challenge of the present study relies on the design of appropriate block copolymers that will spontaneously arrange into honeycomb films and concomitantly form the nanostructures during the fast solvent evaporation, i.e. less than a minute.

The selected block copolymers are poly(*n*-butylacrylate-*b*-styrene) and poly(*ter*-butylacrylate-*b*-styrene) synthesized via nitroxide-mediated polymerization, NMP. Two series of copolymers with different block ratio were synthesized in order to reach the regular copolymer morphologies (lamellar, cylindrical, etc.). The choice of the copolymers allowed us to investigate the effect of the polymer glass transition and of the Flory interaction parameter on the structures. The film morphology characterization, done by optical microscopy (left figure), atomic force microscopy (AFM, center figure) and small angle neutron scattering (SANS, right figure), revealed the nanostructuration of the acrylate-based coil-coil diblock copolymer within the walls of the highly ordered microporous polymer films. Preliminary contact angle measurements as well as tack and peeling experiments using the honeycomb films as a model substrate will be discussed.

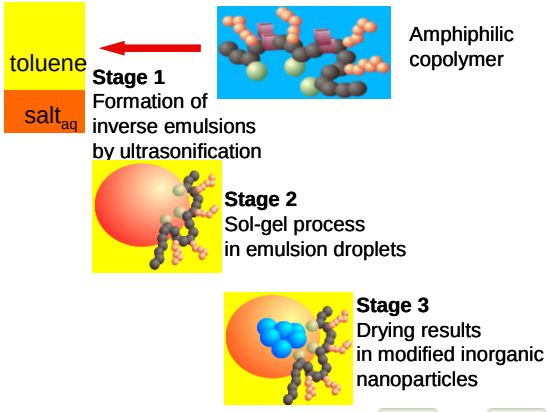
Introduction

The controlled synthesis of inorganic nanocrystals or hybrid inorganic-organic materials with specific size is a rapidly developing field in science since physical and chemical properties, such as composite transparency and catalytic activity, are strongly influenced by the shape and morphology of the nanoparticles. For example, zinc oxide has been used in solar cells, sensors, as activator for organic accelerators and as co-accelerator in the vulcanization process. For these applications the fabrication of morphologically distinct nanostructures is required. Most of the nanoparticles are used in nanocomposites. In this case, compatibility between the inorganic and the organic components is normally achieved by hydrophobization with an organic shell in an additional step.

Results and Discussion

A universal approach for the preparation of functionalized inorganic nanoparticles through the inverse emulsion technique (**Figure 1**) has been developed.[1,2] In this method, the formation and hydrophobization was achieved in one step. The emulsions were stabilized by a statistical amphiphilic copolymer. In the micelles of the inverse emulsion, the inorganic nanoparticles were formed from a precursor salt by adding a precipitation agent. Various types of hydrophobized inorganic nanoparticles like metal oxides, sulfides and metals were accessible, which could be generated by sol-gel reaction or precipitation process. More complex structures were also available, like perovskites and zinc oxide particles coated with a silica shell, dedicated for UV protection.[3,4]



This inverse emulsion process has been extended to produce *in-situ* hydrophobized, shape-anisotropic, inorganic nanoparticles in a single step.[5] In a first approach, the stabilizing as well as the hydrophobizing property of the copolymers was combined with the ability to control the crystallization in one polymer (structure directing emulsifier - SDE). In a second approach, a mixture of two polymers was applied: an amphiphilic copolymer for hydrophobizing/stabilizing the inorganic nanoparticles and a polar or double hydrophilic polymer that induced the anisotropic growth of the inorganic nanocrystals (structure directing agents - SDA). Homopolymers and block copolymers, consisting of phosphonic acid, polyethylene oxide and propylene oxide groups, were used as SDAs. The suitability of this process has been demonstrated by the fabrication of zinc oxide nanorods, shape-anisotropic cadmium sulfide nanoparticles and porous anatase nanoparticles (**Figure 2**). The homogeneous incorporation of such particles into a composite could be easily achieved as the emulsifiers could be adopted to any polymeric matrix by varying the hydrophobic monomer in the amphiphilic copolymer. Consequently, new types of hybrid materials based on shape-anisotropic inorganic nanoparticles are now accessible.

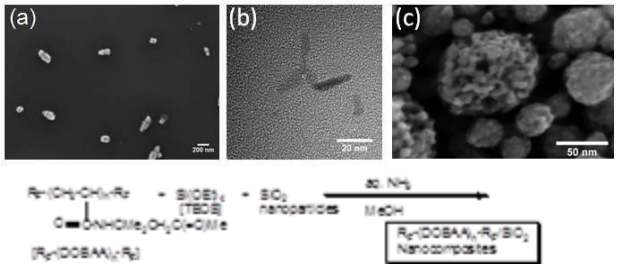


Figure 2. SEM and TEM images of hydrophobized, shape-anisotropic ZnO (a), CdS

Conclusion

The presented approach offers a fast and efficient method for obtaining a broad variety of *in-situ* hydrophobized inorganic nanoparticles of different shapes and morphologies. This technique is based on the precipitation of the particles in inverse emulsions in the presence of specially designed (co)polymers. By the choice of structure-directing polymers not only the shape and morphology of the inorganic nanoparticles obtained but also the size can be controlled. The avoidance of a complex polymer synthesis makes the process attractive for industrial applications, especially when focusing on other systems such as nanocomposites.

The polymer brush is among the best studied systems in polymer science. Brushes, formed by long polymer chains densely grafted to a solid-liquid or to a liquid-liquid interfaces, received ample attention from both theoretical and experimental perspectives. In the meantime, advanced synthetic approaches now allow the making of macromolecules with a virtually arbitrary complex and well-controlled branched architecture (stars, combs, dendrons). Moreover, the technology to attach these to surfaces becomes available. It is believed that brushes from branched architectures may introduce novel desired features, such as enhanced stimuli responsiveness, outstanding nanomechanical properties, and tuned biointeractivity. From a physical point of view, brushes of branched macromolecules are challenging because the distribution of the elastic tension and the fluctuations of the individual molecules is far from trivial as these properties will differ from the behavior of the same molecules in solution.

In the present work, equilibrium structural properties of polymer brushes formed by dendritic polymer chains (dendrons), Figure 1, are studied by means of Scheutjens-Fleer self-consistent field (SF-SCF) modeling and scaling analysis.

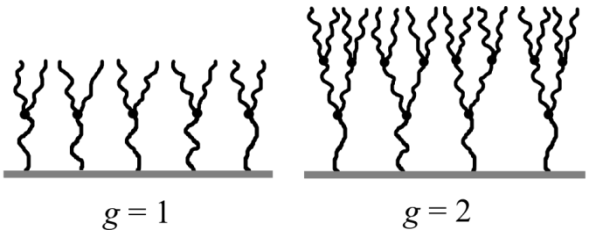

Figure 1. Schematic illustration for polymer dendritic brush. In this example, the branching functionality q =2, and g=1 and 2 is the number of generations on the left and right, respectively

Limiting cases of minimal and maximal possible losses of conformational entropy corresponding to different assumptions concerning distribution of elastic tension in the end-grafted dendrons are analyzed on the basis of the Flory-type scaling approach. The numerical SCF modeling indicates that the effective exponent of the power-law dependence for the height of dendritic brush on the grafting density differs from that derived within the Flory-type approximation. This is explained by changing of the intramolecular elastic tension distribution upon an increase in grafting density.

The distributions of end and branching points are wide and exhibit multiple maxima, pointing to a broad distribution in the chain stretching, Figure 2. This distribution leads to monotonically decreasing overall density profiles.

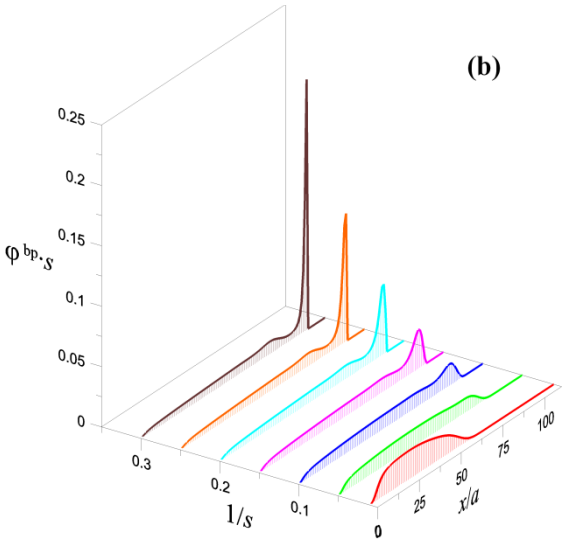

Figure 2. Number distribution of the branching points, scbp(z), for a firstgeneration dendritic brush with g=1 and branching point functionality q=3 for different grafting densities 1/s as indicated.

This implies an intrabrush segregation of dendrons having contributions that belong to different subpopulations. For the brushes formed by the first generation dendrons we made a detailed analysis of this phenomenon. Near the surface the brush is enriched by dendrons that have only weakly extended spacers. The second population of the dendrons are characterized by a strongly, at high grafting density almost completely, stretched root spacer and are predominantly found in the periphery of the brush. In brushes formed by dendrons of higher generations, multimodal distributions were found both for the terminal segments and for the branching points. These correspond to multiple populations which are stratified throughout the brush.

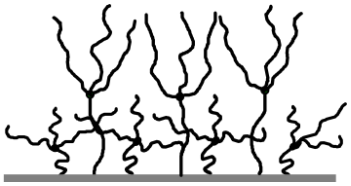

Figure 3. Schematic illustration of the occurrence of two populations of conformations of dendrons in a g=1 dendritic brush.

Solutions of Amphiphilic Polyelectrolytes: Effect of Electrostatic Interactions on Self-Organization

Sergey V. Venev and Igor I. Potemkin

Physics Department, Moscow State University, Leninskie Gory 1-2, Moscow 119991, Russian Federation
Institute of Polymer Science, University of Ulm, Albert-Einstein-Allee 47, Ulm 89069, Germany

e-mail: igor@polly.phys.msu.ru

Amphiphilic block copolymers are known to form micelles in selective solvents: insoluble blocks form the core of the micelle and the soluble (polyelectrolyte) blocks form the corona. Local violation of electric neutrality in polymer systems due to entropy-driven escape of counterions can induce long-range electrostatic forces which together with mobility of counterions play very important role in micellization. Therefore, one can expect that (i) the local violation of electric neutrality in micellar solutions and (ii) the composition of the block copolymer are responsible for the size of the micelles and their morphology. To the best of our knowledge, the simultaneous effect of these two factors on the morphology of the micelles in solutions of diblock copolymer with neutral (insoluble)
and charged block has not been studied yet.

In the present paper, we develop a mean-field theory of micelle formation in salt-free solution of diblock copolymers with a soluble polyelectrolyte block and an insoluble neutral block [1]. The so-called three-zone model is used which is a simplified alternative of the Poisson-Boltzmann approximation. This model allows analyzing an inhomogeneous distribution of counterions outside the corona (an analogue of Gouy-Chapman layer and Manning condensation). We study both dilute and concentrated solutions. Conventional spherical, cylindrical and planar morphologies of "direct" (soluble) micelles are considered in the crew-cut regime (short soluble blocks). We also analyze the stability of inverse (insoluble) spherical and cylindrical micelles, which form a dense phase. In this phase, the soluble blocks with the solvent form spherical (cylindrical) cores which are embedded in a matrix of the insoluble blocks. Phase diagrams of the solution are constructed on the basis of conditions of the true equilibrium, i.e., they include one- and two-phase stability regions as well as triple points, Fig. 1.

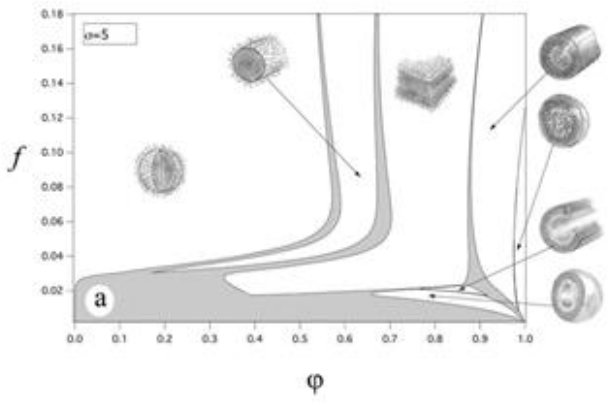

Fig. 1. Phase diagram of diblock polyelectrolyte in a selective solvent in variables: polymer volume fraction *f* and the fraction of the soluble block in the copolymer *f*. The fraction of charged groups 1/s=0.2. Grey areas correspond to the phase coexistence regions.

We demonstrate that the presence of charged groups practically does not change the phase behavior of the solution at high polymer concentrations. In this regime, the main factor governing the swelling of the coronae is the polymer concentration. On the other hand, the role of the charged groups at low polymer concentrations is very important. The Rayleigh instability prevents formation of nonspherical micelles at low polymer concentrations. The charged groups promote stability of the spherical micelles: they remain stable at conditions when the neutral spherical micelles change morphology or precipitate.

Mesoscale Simulation of Network Formation and Structure, Combining Molecular Dynamics and Kinetic Monte Carlo Approaches

Anatoly V. Berezkin, P. Ulrich Biedermann, Alexander A. Auer

Max-Planck Institut für Eisenforschung GmbH,
Max-Planck-Straße 1, 40237 Düsseldorf, Germany

a.berezkin@mpie.de

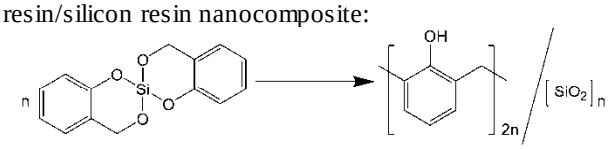
Introduction

Structure and physical properties strongly depend on the network topology. As opposed to linear polymers, prediction of this topology is not so straightforward, and usually requires sophisticated theoretical approaches: random graph theory, diagram techniques, field theory etc. In case of multiple competing chemical reactions, substitution effects, topological confinements, and polymerization-induced phase transitions theoretical treatment becomes too complicated or impossible, especially at high monomer conversions. Due to this a direct molecular simulation of curing is a simple, but powerful alternative to analytical theory. Since the time scale accessible in such simulations is limited, mesoscale models, parameterized on the basis of phenomenological kinetics or quantum-mechanical calculations, seem to be more preferable here than the atomistic molecular dynamics exploiting reax force fields.

Methods and Results

In this work application of a hybrid scheme, combining mesoscale or coarse-grained molecular dynamics, and stochastic kinetics (Monte Carlo) is illustrated by two simulations: 1) mesoscale simulation of organic-inorganic nanocomposite formation by twin-polymerization of a spirocyclyc monomer, and 2) coarse-grained simulation of polyurethane network formation. While segregation forces in these polymers are relatively weak, nanostructure formation is a chemically-controlled process strongly dependent on the reaction mechanisms.

Cationic ring-opening twin polymerization[1] starts from a spirocyclic compound and yields phenolic resin/silicon resin nanocomposite:



Cleavage of four unequal bridging units (-O-, and –CH_2-O-) and formation of new bonds leads to two chemically connected and topologically entangled networks. This process was simulated using dissipative particle dynamics modified to allow for multiple competing chemical reactions. These reactions "proceed" with probabilities derived from DFT *ab initio* calculations.[2] Diverse competing reactions of different mechanisms were described with a specially developed script language.[3]

The influence of catalysis, relative rates of reactions in phenol resin, and siloxane network, as well as incompatibility of components on the nanocomposite structure was studied systematically. It was shown, that polycondensation typically begins with phenolic resin formation, simultaneously yielding silanol groups. These groups initiate subsequent formation and growth of SiO_2 domains in the cross-linked organic matrix. Limited mobility and small size of inorganic fragments suppress physical segregation of chemically-different molecular fragments, resulting in a fine inorganic network with domain diameter about 2 nm. Even weak segregation disperses this network into small siloxane nanoparticles. Morphology and dimensions of the domain structure are in a good agreement with experiment.

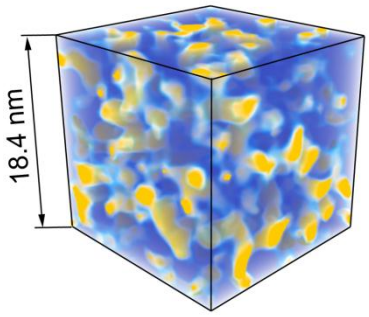


Figure. Simulated nanocomposite structure. Phenol resin is shown with blue, and siloxane net with yellow colors.

Coarse-gained molecular dynamics followed by reinsertion of atomistic details is highly promising, when influence of crystallization, glass transition, or growing viscosity has to be addressed, or time evolution of mechanical and relaxation properties is of interest. Different aspects of such chemically-oriented coarse-graining are considered for the case of polyurethane network formation from standard industrial formulations. The coarse-grained character of "reacting" beads requires correction of reaction probabilities to accurately reproduce phenomenological kinetics, observed in experiment. First steps in this direction will also be presented.

Introduction

The synthesis and immobilization of stable and well defined silver nanoparticles (AgNPs) is a rapidly expanding field in nano-sciences. Especially their size-dependent electronic, optical, and chemical properties make them attractive targets for the synthesis of new materials.[1-2] Like colloidal silver[3], AgNPs are known for antibacterial and antimicrobial properties.[4] AgNPs are currently used in various applications such as catheters, scaffolds and wound dressings[5]. Beside their medical applications they are also applied in textile finishing [6]. Generally, the immobilization of AgNP on (renewable) polymer surfaces offers a promising new way to extend the application and use of these polymers. Furthermore a combination of the well known properties of AgNPs with the biocompatibility and antithrombogenicity of a polysaccharide, namely sulfated chitosan, allows the manufacturing of particles that are functionalized on their surface fAgNPs.[7] Particles modified in this way can be used for surface modifications of polymeric materials. For the immobilization of fAgNPs on polymer surfaces several strategies can be followed. In this work we compare two of these strategies namely the electrostatic adsorption and the covalent binding of fAgNPs that are functionalized with sulfated chitosan. The immobilization was followed via contact angle measurements and atomic force microscopy (AFM). Additionally, the antimicrobial properties of different immobilization methods were compared.

Materials and Methods

fAgNPs were synthesized using the functional, water soluble, polysaccharide sulfonated chitosan (S-Chi) as stabilizing and reducing agent. The synthesized fAgNP were immobilized on different polymeric surfaces namely poly(methylmethacrylate-acrylicacid-copolymer (PMMA-Co-AA), poly(methylmethacrylate) (PMMA), and regenerated cellulose. Electrostatic immobilization which was achieved using a polyethyleneimine (PEI) pre-coating was compared with covalent binding via 1-ethyl-3-(3-dimethylaminopropyl)-carbodiimide (EDC) over the activation of carboxylic groups. The PMMA surface was hydrolyzed under alkaline conditions to create carboxylic groups on the surface which are needed for the covalent immobilization using EDC. The immobilizations steps and their stability were followed by contact angle measurements and AFM. Furthermore the antibacterial properties of the surfaces were examined and compared with respect to the immobilization method.

Results and Discussion

All mentioned polymeric surfaces were successfully modified with fAgNPs. As can be seen in Figure 1 a denser surface packing is obtained with electrostatic adsorption as shown on Fig 1 with PMMA-Co-AA surfaces. Even if a less dense coverage is obtained using covalently immobilized fAgNP, it shows a much better stability then the electrostatic bound ones. Long term experiments showed that covalently immobilized particles retain their stability and wettability on modified polymer surfaces.

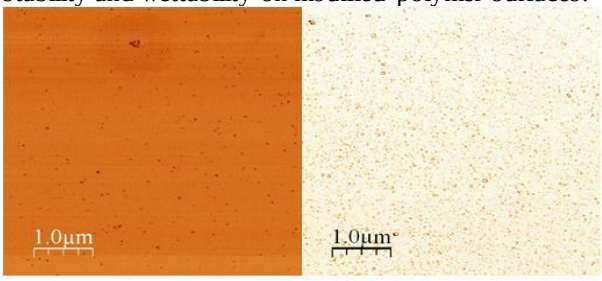

Figure 1: AFM images of S-Chi stabilized fAgNPs electrostatic immobilized (right) and covalently bound (left)

Conclusions

In summary, two methods for the immobilization of functionalized silver nanoparticles on different polymeric materials could be demonstrated. On the one hand the electrostatic adsorption is shown which leads to a dense surface coverage. On the other hand we successfully could show covalent immobilization with EDC. This technique leads to better immobilization stability of the particles.

Diffusional limitations during polymerization determine the reaction kinetics, as well as the properties of the final polymer (molecular mass, polydispersity index, etc.). An understanding of the fundamental processes influencing diffusion and dynamics in polymers and polymer solutions is therefore of great interest. **Single-molecule spectroscopy and microscopy (SMS/SMM)** have already proved to be suitable techniques for this purpose.[1,2] Unlike 'ensemble' measurements on polymerizing samples, which only yield data averaged over a large number of molecules, measurements on individual molecules provide information about distributions and the time dependence of the parameters studied. In particular, SM techniques allow to examine **heterogeneity** in systems on a molecular level.

SMS/SMM techniques have recently been used for the first time to follow the free radical polymerization (FRP) of styrene.[3,4] Investigation of the polymerization reaction over the entire conversion range is possible by combining *fluorescence correlation spectroscopy (FCS)* and *wide-field microscopy (WFM)* to follow diffusion of **individual, fluorescent probe molecules** (present in a concentration of ~ 10^{-9} M). In FCS, confocal excitation of the dye molecules is applied, and the fluorescence signal is recorded with an avalanche photodiode (APD) point detector. In WFM, on the other hand, a 24 × 24 μm^2 sample area is illuminated at once (wide-field excitation), and movies are recorded by means of a CCD camera, which has a limited time resolution. Both SM techniques complement each other, since FCS is a powerful method to follow diffusion processes that are characterized by a diffusion constant $D >$ ~ 10^{-13} m^2 s^{-1}, whereas WFM is a suitable technique to track slowly moving molecules with $D <$ ~ 10^{-12} m^2 s^{-1}. Because the viscosity of a polymerizing reaction mixture gradually increases, the average velocity of diffusing reporter dye molecules decreases; the first stage of the polymerization reaction ('low' viscosity) can be followed by FCS, but from a certain conversion onwards ('high' viscosity) one needs to switch to WFM. The experimentally obtained, time-dependent diffusion constant(s) of the reporter dye molecules can give direct, fundamental information about the polymerization process.

We are applying this methodology to the study of **thiol-ene 'click' chemistry reactions** and ***controlled* radical polymerization (CRP) processes**. Both reaction types allow, in principle, to obtain highly homogeneous networks. This is in contrast to free radical polymerizations, for which a high degree of heterogeneity is observed during network formation: at moderate conversion, local nanogel clusters act as dye traps that slow down/immobilize some dye molecules, while others can still move *quasi* freely in the regions where no network has been formed yet.[3] One of the main questions is how the 'bulk' homogeneity observed for CRP and 'click' chemistry is reflected on a molecular level, and whether genuinely no heterogeneity at all can be found on this length scale. The results are compared with the FRP of the same monomers. Furthermore, differences between linear (or possibly star-shaped) and cross-linked polymers are investigated (to elucidate differences between temporary and permanent cross-links), as well as the influence of the probe size. Both ATRP (more specifically, ARGET and ICAR ATRP) and NMP have been selected as CRP processes.

We will also present a new experimental setup that is dedicated to the study of polymerizing samples. The **single-molecule fluorescence microscopy setup** consists of (i) an FCS part; (ii) a WFM part; and (iii) a Raman part. It allows to investigate a polymerizing reaction mixture over the entire monomer conversion range while monitoring conversion by Raman spectroscopy measurements, all of this completely *in situ* on the microscope. Home-made sample holders allow to keep the mixture under an inert atmosphere, and to heat the sample – if required. Raman spectroscopy was validated as a suitable technique to determine the conversion of different monomers in a multi-component mixture. For the Raman measurements, either a high-boiling solvent is used as an internal standard, or a calibration is performed by reference measurements on polymer standards.

The sharp thermal transition of the diblock copolymers methoxy-poly(ethylene glycol)-block-poly(N-isopropylacrylamide) (PNIPAAM-b-MPEG). A combined analytical-ultracentrifugation and dynamic-light-scattering study.

Álvaro Ortega, Ramón Pamies, and José García de la Torre

Departamento de Química Física, Facultad de Química, Universidad de Murcia, Spain

jgt@um.es

Introduction:

Poly(N-isopropylacrylamide) (PNIPAAM) is one of the most extensively investigated thermoresponsive polymers due to its interesting and novel properties and applications. One of the most interesting aspects of PNIPAAM is its thermoresponsive sensitivity, which gives the possibility of a local and temporal release by changing the temperature of the environment slightly above the low critical solution temperature (LCST), which can be tuned with the molecular weight of both blocks. Below this critical temperature, the polymer stays soluble in water but above LCST the hydrophobicity of the molecules is increased and the system exhibits a macroscopic phase separation. The characterization of PNIPAAM and PNIPAAM-based copolymers and their self-assembled structures is usually done by means of scattering and microscopy techniques but Analytical Ultracentrifugation (AUC) has been scarcely used for these purposes [1].

In the present work, diblock copolymers containing a constant length of a PNIPAAM block but with different lengths of the hydrophilic block monomethoxy-capped poly(ethylene glycol) (MPEG), were synthesized by utilizing atom transfer radical polymerization (ATRP). The prepared product is methoxy-poly(ethylene glycol)-block-poly(N-isopropylacrylamide) with the composition: $MPEG_n$-*b*-$NIPAAM_{71}$, where *n* adpots values of 0, 12, 23 and 114. We have performed experiments with AUC at different temperatures to evaluate the thermoresponsive behavior of the single chains and the self-assembled aggregates of these diblock copolymers. An evaluation of the influence of the length of the MPEG block at different concentrations and temperatures has been carried out.

Materials and Methods:

All the chemicals used for the synthesis of the block copolymers were purchased from Aldrich and Fluka. The polymers were synthesized by means of atom transfer radical polymerization (ATRP) as reported in a previous work [2]. AUC experiments were performed on a Beckman Optima XL-I ultracentrifuge (Beckman coulter, Palo Alto, CA), using for detection the Rayleigh interference optics. Sedimentation velocity experiments were performed in a range of temperatures from 5 to 35ºC at 40000 rpm.

Results and Discussion:

Firstly, we carried out the determination of the specific volume ($\bar{V}$) by means of the sedimentation coefficients in H_2O and D_2O. Although the composition changes significantly, the $\bar{V}$ value was 0.84 cm^3/g for all the polymers.

After the determination of $\bar{V}$ values, we have obtained the sedimentation (s) and the diffusion coefficients (D_t) of the copolymers at several temperatures by means of a velocity study at 40000 rpm at 0.1, 0.5 and 1wt% concentrations. Therefore, we were able to extrapolate these values to ideal conditions (c=0). By means of Stoke-Einstein equation, from D_t^o we determined the values of hydrodynamic radii (R_h), depicted in the figure, with good agreement with Dynamic Light Scattering (DLS) data [2].

In order to study the self-assembly of these copolymers, we attempted experiments at 3wt% concentration. All the experiments for the evaluation of the aggregated species at temperatures over 30ºC were conducted at 5000 rpm, to be able to appreciate larger species which would sediment too fast to be detected at 40000 rpm. Interestingly, even at this slow rotor speed an enormous aggregate can be observed that sediments in less than 2 minutes, forming a band at the bottom of the sedimentation cell that exceeds the linearity in the interference detection system, making it impossible to determine the concentration at this area. We conclude that at this temperature, and after the sedimentation process the high local concentration existing at the bottom of the cell can reach a condition where a phase separation is clearly visible, even by direct eye observation of the centrifuge cell, indicating the formation of a gel phase or even a precipitate.

Conclusions.

The determination of the unimeric chains is possible by AUC with good agreement with DLS data. Presence of oligomers was detected at high. Specific volume of the polymers can be calculated by AUC.

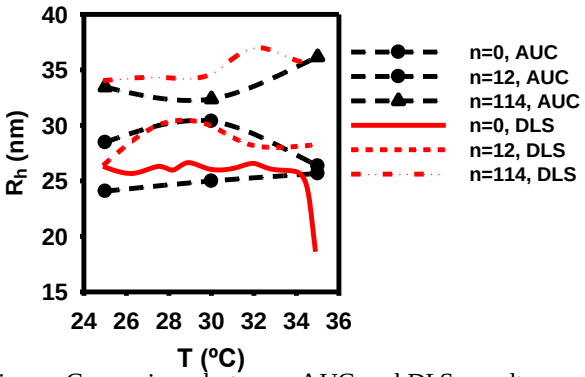

Figure. Comparison between AUC and DLS results.

Introduction

The ability to create regularly shaped nanoscale objects which serve as the building block is an extremely important goal in materials science. One of the key issues is to design and create new polymer materials with unprecedented improvements in their physical properties. Different self-assembly pathways are described to lead to hierarchical structures formed from heterogeneous chemical species, like organic molecules, polymers, organic-inorganic nanobuilding blocks [1]. Ionic liquids (ILs), which are organic salts with a melting point below 100 °C, with unique properties such as their chemical stability, excellent thermal stability, inflammability, low vapor pressure and high ionic conductivity have become more attractive in material science. This work reports for the first time the achievement of a nanoscale structuration from ILs into a polymer matrix. This structuration can be tuned by a wide choice of cation-anion combinations including pyridinium, imidazolium, and phosphonium as cation associated to iodide, bromide, or fluorinated anions. The preparation of IL nanostructured films from a fluorinated polymer solution could open many applications in energy and materials fields.

Materials and Methods

A general and simple method for the synthesis of a serie of organic halide and fluorinated salts is reported based on i) Iodide (I^-), bromide (Br^-) and hexafluorophosphate (PF_6^-) combined phosphonium cations with one long alkyl chain denoted $C_{18}P\ I^-$, $C_{18}P\ Br^-$, $C_{18}P\ PF_6^-$, respectively. ii) Iodide associated imidazolium cation with two long alkyl chains denoted $C_{18}C_{18}Im\ I^-$. iii) Iodide combined pyridinium salt denoted $C_{18}Py\ I^-$ [2]. The chemical structure of ILs combined to iodide anion is described in Figure 1.

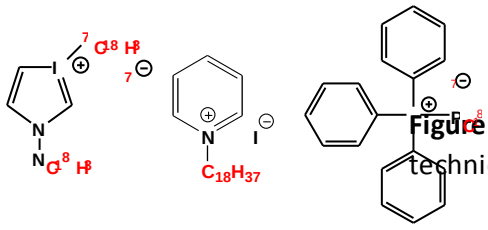

Figure 1. Chemical structure of synthesized ionic liquids

To prepare supramolecular ionic networks, the three functional ionic liquids have been introduced in very low quantities (1 wt%) in a aqueous suspension of polytetrafluoroethylene (PTFE) under stirring. Then the suspension was spread on stainless steel plates to get 50 µm-thick wet layer. A thermal treatment at 400 °C for 10 minutes was applied to obtain the final polymer film.

Results and Discussion

The hydrophobic nature of polytetrafluoroethylene and the strong interactions between the ionic domains and the PTFE matrix generate a phase-separated morphology. It is the balance of interactions between polymer medium and anion-cation pairs that leads to different morphologies [3]. TEM micrographs reveal different types of structuration which are tuned by the chemical nature of cation and of anion as well. For example, by using the same phosphonium cation combined with different anions, Figure 2 shows final morphologies varying between an agregated one with the fluorinated or bromide anion and a fine structuration at nanoscale with the iodide conteranion. The morphologies characterized by SAXS and XPS analysis are comparable to those observed in ionomers [4].

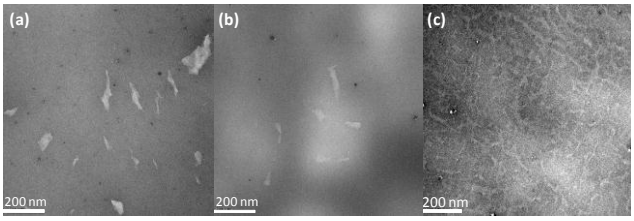

Figure 2. TEM micrographs of the nanocomposites (a) PTFE/$C_{18}P\ PF_6^-$, (b) PTFE/$C_{18}P\ Br^-$, (c) PTFE/$C_{18}P\ I^-$

The distribution of ionic liquids in the polymer matrix plays a key role on the elongation at break of films. We have highlighted that the 'spider web' structuration leads to a dramatic increase of 190% of the elongation at break as shown in Figure 3. Thus, the formation of this network can play a retardant role against the beginning of catastrophic cracking.

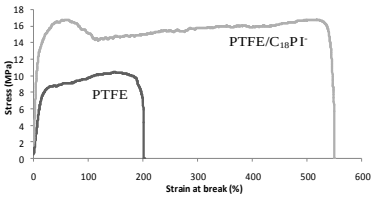

Figure.3 Effect of the phosphonium ionic liquid (1wt%) on the mechanical properties determined by uniaxial tensile tests at room temperature and 0.004 s^{-1}

Figure 1. Scheme of the applied inverse emulsion technique.

Conclusions

The use of ionic liquids as functional building blocks based on pyridinium, imidazolium and phosphonium cations to achieve materials combining a structuration at nanoscale with the dramatic mechanical properties of the resulting ionomers has been successfully demonstrated for the first time in a fluorinated matrix.

Dynamic Dielectric Spectroscopy and Thermo Stimulated Current for identification of gene mutation in plant model

Frédéric Roig[1], Eric Dantras[1], Jacqueline Grima-Pettenati[2], Colette Lacabanne[1]

[1]Physique des Polymères, Institut Carnot CIRIMAT, UMR CNRS 5085

[2]Surfaces cellulaires et signalisation chez les végétaux, Pôle de Biotechnologies Végétales, UMR 5546 CNRS Université Paul Sabatier, 31062 Toulouse Cedex 09, France

Abstract: The Arabidopsis Thaliana is considered by geneticists as a model plant because of its rapid growth, ease of laboratory culture and complete sequencing of its genome. The strategy of geneticists is to focus research on a plant genome with the smallest possible in order to analyze it, and then use information acquired to begin the exploration of more complex genomes. However, the biochemical analysis did not differentiate at the molecular level mutants and natural plant.

Dynamic Dielectric Spectroscopy (DDS) and Thermo Stimulated Current (TSC) have been applied to the investigation of such complex systems. The combination of dielectric techniques by accessing a wide frequency and temperature range can probe the molecular mobility of delocalized to localized molecular mobility of the composite plant. The majority of structural components of plant cell walls are cellulose and lignin. First, the molecular mobility of the two major components has been characterized. Then the composite plant is studied in its natural state and finally in its mutant state. DDS shows that the same relaxation modes are observed in both states. Contrarily, TSC exhibits differences in their fine structure.

Analysis of TSC data allows us to define the macromolecular dynamic by the activation enthalpy and entropy that are plotted on compensation diagrams, respectively for natural Arabidopsis Thaliana (Figure 1) and its mutant CAD C / D (Figure 2). We observe three segments showing discrete compensation phenomena corresponding to three relaxation modes.

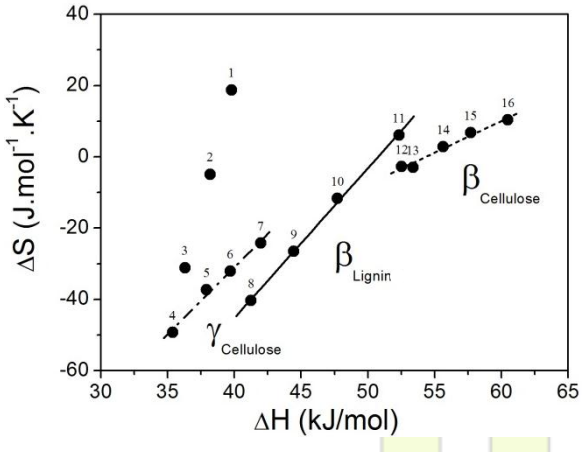

Figure 1: Compensation diagram of Arabidopsis Thaliana

The relaxation mode in the lowest enthalpy ($\gamma_{cellulose}$) is characteristic of the polar groups of cellulose, (-CH_2OH and -OH) [1,2]. The β_{Lignin} mode is associated with the molecular mobility of polar groups (-OH) of lignin and $\beta_{cellulose}$ mode corresponds to the molecular mobility of the cycles of glucose via glycosidic linkages. In Figure 2, we observe only two modes $\gamma_{cellulose}$ and β_{Lignin} with comparable slopes in contrast to Figure 1.

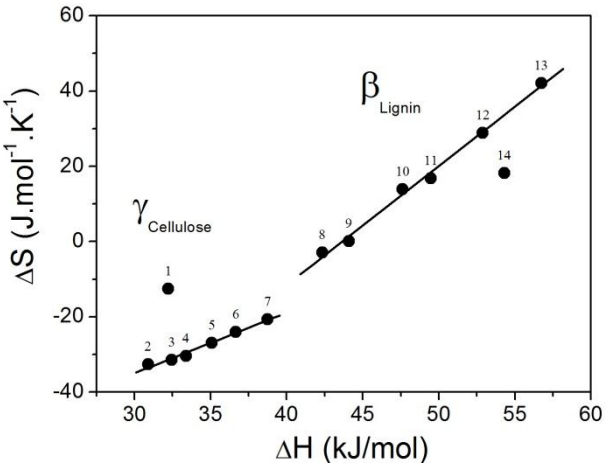

Figure 2: Compensation diagram of Mutant CAD C/D

Similar behaviour is observed between the two modes due to a common origin of these two modes. Indeed in this mutant plant, the genetic modification changes the chemical structure of lignin by increasing the proportion of alcohol function [3,4].

Thermo Stimulated Current coupled with Dynamic Dielectric Spectroscopy proves to be a suitable set of methods to identify the influence of gene mutation on the dynamic structure of the natural plant. The evolution of nanometric mobility is clearly exhibited by the compensation diagrams.

Introduction. In the last time ionic liquids (ILs) strongly attract interest of researchers because it was found out that these substances possess some unique and very useful properties. ILs are solely composed of anions and cations. Nevertheless they are liquid at around room temperature. Main advantageous peculiarity of ILs is the fact that they are very good as solvents and reaction media. This is because ILs are almost nonvolatile and at the same time they can dissolve a wide range of both organic and inorganic substances. For example, an important achievement related to the high solvent power of ILs is the invention of the novel effective and environment friendly cellulose processing technique.

Properties of an individual IL are explained by its chemical structure. At the same time, it is evident that the useful properties of ILs are somehow generally inherent to ILs nature, i.e. there are some laws which are valid for all ILs as a *whole class* of substances. The goal of our research is to reveal the laws. It is evident that general properties of ILs are somehow related to the main basic feature of ILs: they are composed of ions only. We show that because of it ILs can have a unique dual nature that can explain some of their interesting unusual for common liquids properties. The reason is that the properties of an IL's cations can strongly differ from the properties of the IL's anions. The contradictious properties of the two types of particles would immediately make them segregate if (just hypothetically!) the electrostatic interactions vanished. But the coulomb attraction makes these "incompatible" particles stay together in an intermixed state and compose thus a substance (the IL) having the unusual dual nature.

Method. We use the dual nature concept together with a Flory-Huggins like lattice model in which it is supposed that each elementary cell is occupied by one particle, and each ion of an IL is treated as an individual independently moving particle, noncoulombic interactions of two particles are described by the Flory-Huggins parameters. With the help of this method we have explained the high solvent power of ILs[2], the micpophase separation in a IL/nonionic liquid (nIL) mixture[3,4] and predicted that a polymer microgel swelling ratio can depend on the amount of polymer the gel consists of if the solvent is an IL[5]. In the present part of the work[1] we analyze the properties of the system consisting of an IL and of two types of nonionic molecules, **A** and **B**. We suppose that the duality of the IL shows up in different affinities of the IL's cations and the IL's anions to **A** and to **B**: the cations are attracted stronger to **A** than to **B** and anions vise versa are stronger attracted to **B** than to **A**.

We consider a two phase system in which the two phases are formed because the nonionic components **A** and **B** are incompatible with each other (they can't form a homogeneous mixture). We investigate how the ions of the IL are distributed near the phase boundary and how the IL contributes to the value of the phase boundary surface tension. We consider for that the two-phase system as a sequence of flat elementary layers parallel to the phase boundary. Each of them is composed of elementary cubic cells and it is one cell thick. We find the concentrations of the components and the electrostatic potential in each if the layers by means of the free energy minimization. Our method allows to calculate concentrations profiles near the phase boundary and the surface tension of the phase boundary at any concentration of ions in the bulk of the phases (i.e. in the case of an IL when ions volume fraction is of order unity and in the case of low concentrations of ions as well). The method is applicable both for systems that are far from the crtitical point or close to it.

Results. We have shown that a double electrostatic layer is formed at the phase boundary. The width of the double layer increases as the concentration of ions approaches either zero or the value corresponding to the critical point. The ratio of the maximal cations (anions) concentration in the layer to their concentration in the bulk far from the boundary is the larger the lower is the concentration of IL and the higher is the difference in the affinities of the cations and the anions to **A** and to **B**.

We have also shown that the surface tension of the phase boundary is the smaller the higher is the difference of the affinities and the higher is the concentration of the IL. The surface tension can even reach zero at a concentration of IL lower than the one corresponding to the critical point, what means that at the corresponding values of the parameters characterizing the system the mixture is to be microheterogeneous. One can say that an amphiphilic IL behaves as a surfactant, but instead of a monomolecular layer it forms at the phase boundary a double electrostatic layer which can be up to several hundred molecules thick.

Thermal and Electronic Conduction in Conjugated Polymers

Luiz F. Roncaratti, Pedro H. de Oliveira Neto, Wiliam F. da Cunha, Ricardo Gargano, Geraldo Magela e Silva

Instituto de Física, Universidade de Brasília, Brasil

lz@fis.unb.br

Introduction

The synthesis and applications of semiconducting organic polymers has created a demand for scientific understanding of thermal and electronic transport in nanomaterials [1,2].
The macroscopic description of the thermal and electronic conduction in conjugated polymers is obtained from a microscopic model of an one-dimensional lattice of coupled atoms, the first and the last of which interact also with a quantum thermal bath.

Methods

Our system is defined by a model Hamiltonian containing an interaction potential that depend on relative atomic coordinates [3], plus a Tight-Binding term as approximation for the π electrons-phonons interaction [4]. The last term includes also a modified hopping term to take into account an external electric field [5]. Each boundary atom is also coupled to a set of reservoir oscillators representing two independent thermal baths.
To time evolve the system, we prepare a stationary state fully self-consistent with the degrees of freedom of electrons and phonons. To perform the dynamics we solve the Schrödinger one-particle equations coupled with the Euler-Lagrange equations to treat the lattice. Since our main objective is to characterize the dynamics under a temperature regime we eliminate the reservoir degrees of freedom in the usual way and obtain a quantum Langevin equation [6] for the boundary atoms. These equations are defined by an exponential correlated noise and its respective memory kernel [7]. The set of equation of motion was integrated numerically [8] using a fourth-order Runge–Kutta method.

Results and Conclusion

In our model thermal conductivity can be directly calculated through the temperature gradient along the chain. This value can be tuned to fit experimental data adjusting few parameters of the model. Topological defects over the conjugated pattern (solitons, polarons, exitons…) allowed by our model Hamiltonian are responsible for the electronic conduction. We also found that the behavior and intrinsical properties of theses quasi-particles are defined by the temperature effects. These results and their analysis shed new light on several experimental controversies [9,10,11,12].

Introduction

In recent years Reverse Addition Fragmentation Chain Transfer (RAFT) polymerisation has emerged as an attractive method for polymer synthesis, providing control of molecular weight and molecular weight distributions with narrow polydispersity indexes [1]. There has also been a unique twist in fingerprint research which has involved the implementation of nanotechnology into the function of novel fluorescent fingerprint reagents, based on Quantum Dots (QDs) [2]. QDs are semi-conducting nanostructures that possess unique intrinsic luminescent properties that are size dependent at the nanoscale [3]. Here we combine advantages of RAFT polymerisation with nanotechnology using QDS in the synthesis of fluorescent nanocomposites for fingerprint detection. The polymeric surface modifications provide stability and solubility of the QDs. QDs investigated in this study were Cadmium Sulphide (CdS) and Oxidised Carbon QDs in various polymers, in particular, polydimethylacrylamide (PDMA). The polymers also play a role in the adherence to latent fingerprints (produced by sweat excretions on the palmer of the hand).

Materials and Methods

Size tuneable CdS QDs capped with 2-mercaptoethanol were first synthesised, with the appropriate amounts of sodium sulphide and cadmium chloride in DMF. The 2-mercaptoethanol on the surface of CdS was coupled, with an ester link, to a C12-carboxyl-terminated RAFT agent. From then RAFT polymerisation of a chosen monomer was performed via a grafting-from mechanism. Similar chemistry was applied to Oxidised Carbon QDs; synthesised via acid treatment of activated carbon and dialysis membrane filtration.

Fingerprint subjects were prepared by depositing fingerprints onto non-porous surfaces such as glass, and aluminum foil. Aqueous solutions of each nanocomposite (CdS/Polymer and Oxidised Carbon QDs/Polymer) were spotted onto the fingerprint substrate, followed by washing with water. Fluorescently developed fingerprints by these nanocomposites were visualised and photographed under UV light.

Results and Discussion

QD size was determined by computational methods with UV-Vis spectrophotometry. The band gap energy ($E_{g(QD)}$) was determined from the QDs absorbance, and the hyperbolic band model (equation 1) was used to estimate the nanostructure diameter (r) ($E_{g(bulk)}$= Band gap energy of the bulk, m*= effective electron mass, $\hbar$ =The Dirac Constant) [4].

Equation 1: $$E_{g(QD)} = \sqrt{\frac{E_{g(Bulk)}^2 + 2\hbar^2 E_{g(Bulk)}(\pi/r)^2}{m^*}}$$

Fluorescence spectrophotometry showed how the QDs fluorescence was retained after each step of synthesis of the nanocomposite. Broad fluorescence allowed the developed fingerprints to be visualised as two different colours. Filters were used with photography to capture this property (Figure 1).

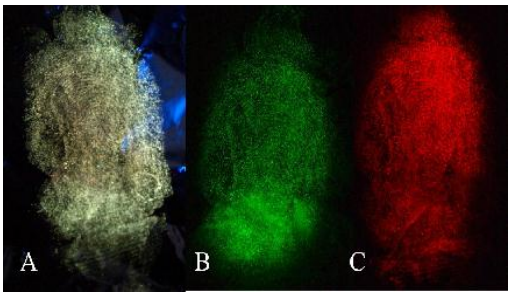

Figure 1. Fingerprints detected on aluminum foil (A) no filter (B) 525 ± 40 nm filter (C) > 555 nm filter.

Research with the Oxidized Carbon QDs showed similar results with respect to fingerprint detection on non-porous surfaces.

^{1}H NMR, FTIR and GPC was utilised to monitor the RAFT polymerisation of the chosen polymers, and to verify their successful synthesis.

Conclusions

CdS and Oxidised Carbon QDs were synthesised and functionalized with a RAFT agent. RAFT polymerisation of desired monomers from the surface of these QDs was performed. The resulting fluorescent nanocomposites were used to detect latent fingerprints deposited on non-porous surfaces. The photographs taken of fingerprints developed with the QD/polymer nanocomposites under UV light prove these fluorescent properties.

Introduction: Macromolecules of star geometry are of substantial interest because of their unique properties and possible applications. The branched topology defines the shape and physicochemical properties of a single macromolecule in the solution and together with the presence of large number of functional groups and the cavities created in star interiors offers interesting perspectives to applications as nanoscale materials for encapsulation and release of active compounds and as polymer-drug conjugated delivery vehicles [1-3].
Here, we report the synthesis of core-shell star polymers with the hyperbranched cores and polyacrylic or polymethacrylic acid arms. Stars obtained via atom transfer polymerization of *tert*-butyl acrylate and methacrylate were subjected to acidic hydrolysis to obtain structures with poly(acid) arms. The applicability of the star polymers as anticancer drug *cis*-diammine-dichloroplatinum (II) carrier was explored addressing two challenging aspects: achieving high drug payload, and evaluating the therapeuticactivity of the *cis*-platin-star polymer conjugates in vitro towards different cancer cell lines.

Materials and Methods: *tert*-Butyl acrylate and *tert*-butyl methacrylate were distilled over CaH_2 prior to use. CuBr, PMDETA, $CuBr_2$ and trifluoroacetic acid (TFA) were used as received. Anisole, dichloromethane, 1,4-dioxane were purified by distillation prior to use. The syntheses of hyperbranched macroinitiators were carried out as described in our previous reports [4, 5] yielding poly(arylene oxindole) of M_n=20 000 g/mol and poly[p-(iodomethyl)styrene] of M_n=2400 g/mol.
The polymers were characterized by NMR (Bruker Ultrashield 600) and FTIR (Nicolet FTIR 6700) spectroscopy. The molar mass and the dispersity of star poly(meth)acrylates was determined by GPC with multiangle light scattering detector (DAWN EOS,Wyatt Technologies). Light scattering (Brookhaven) experiments were performed to provide information about the size and shape of macromolecules in solution.

Results and Discussion: Synthesis of new star polymers of controlled structure, shape and charge was performed using controlled radical polymerization (ATRP) of *tert*-butyl acrylic and methacrylic monomers onto hyperbranched polymeric cores. The synthetic route involved the "core first" method and consisted of two main steps: the synthesis of the star macromolecules with active ester functionalities followed by their conversion to carboxylic groups.
Such polymerization processes were reasonably well controlled and leaded to well-defined star polymers with the number of arms 10 and 28 and M_n up to 280 000 g/mol. The resultant star structures were characterized by GPC with triple detection. The evidenced much more compact structure of these polymers, as compared with their linear counterparts, supported the star formation. The hydrolysis of polyacrylate and polymethacrylate arms in the presence of TFA proceeded smoothly at the ambient temperature, yielding polymers with branched hydrophobic interior and poly(acrylic acid) external shell. The representative stars which differed considerably in the degrees of polymerization of the arms and, consequently, in total molar mass were selected for LS measurements to obtain the information about the size of particles formed in water by star copolymers with a change of pH. In the case of stars with 10 poly(acrylic acid) arms no aggregation upon the change of pH was observed, the size of nanoparticles was around 10 nm.
Key features for drug conjugation, such as hydrophilic shell of stars and high density of functional carboxylate groups were used for reversible exchange of ligands with *cis*-platin and therefore to regeneration the nanocarrier at physiological salt concentrations. A high drug payload (up to 85%) was achieved – higher than the one obtained with the linear alternating copolymers, or dendrimer macromolecules. The platinum (II) complexes were released in sustained manner without initial burst effect. In vitro studies revealed lower cytotoxicity of the conjugates consistent with the sustained release of the agent and slower cellular uptake of the conjugated drug compared to that of free *cis*-platin.

Conclusions: Core–shell type star poly(meth)acrylates were synthesized using controlled radical polymerization via "core-first" approach, followed by acidic hydrolysis to obtain structures with polyacid arms. Light scattering investigations were performed to provide information about the size of stars in solution. In some cases, preliminary studies on immobilization of anticancer drug, *cis*-platine, were performed.

Water-Soluble Polymer-*grafted* Platinum Nanoparticles for the Subsequent Binding of Enzyme: Synthesis and SANS study.

Géraldine Carrot, François Gal, Henri Perez

LLB-LFP CEA/CNRS
IRAMIS- CEA/Saclay

geraldine.carrot@cea.fr

The convergence of nanoscience and biotechnology has showed an extensive development in the recent few years, particularly due to the attractive use of nanoparticles as a platform for various biological applications.[1] The unique properties of metal nanoparticles (NPs) together with well-reproductible synthetic and functionnalization procedures (surface-capping ligands), lead to a wide range of elementary building units for the construction of such hybrid structures. On the other side, biomolecules are interesting with their unique recognition, transport and catalytic properties. Therefore, conjugation of NPs with biomolecules could provide electronic transduction of biological phenomena, particularly beneficial for the development of biosensors.[2] Functionalized platinum nanoparticles (PtNPs) possess catalytic properties which represent a great interest in the elaboration of electrochemical biosensors. To improve the understanding of phenomena involved in such systems, we designed platinum-polymer-enzyme model structures, according to a bottom-up approach. These structures have been elaborated from 2-nm platinum nanoparticles grafted with polymer.[3]
In previous work, we have particularly showed that Surface-Initiated ATRP (*SI*-ATRP) of *n*-butyl methacrylate from PtNPs leads to polymer-*grafted*-PtNPs with controlled chain lengths. We also showed that free initiator was not necessary to maintain a good control of the surface polymerization. The platinum core is small enough with a sufficiently high grafting density of the initiator at the surface to be considered as a usual macroinitiator.
We therefore used the same method to polymerize *ter*-butyl methacrylate (*t*BuMA) because the polymer could further be hydrolyzed to generate poly(methacrylic acid) chains. Poly(methacrylic acid) (PMAA) cannot be polymerized directly from ATRP due to the complexation of copper with carboxylic acid groups. Routine characterization of the objects has been performed via thermogravimetric analysis and ^{1}H-NMR. The structure of these objects, the molecular weight and the grafting density of polymer chains were principally elucidated by small-angle neutron scattering (SANS). This technique is particularly well-adapted for the characterization of such multi-components materials (Figure 1). By using index matching, it is possible to study either preferentially the inorganic core, or the polymer chains. We particularly showed, the strong complementarities of SANS and chemistry, and particularly, how SANS could detect deviation or lead to characteristic data that other routine techniques could not. The polymer corona signal has been particularly studied in deuterated dimethylacetamide (*d*-DMAC).

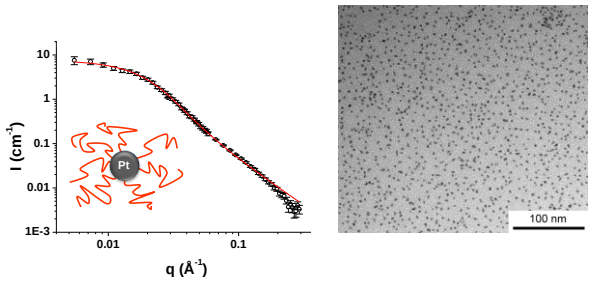

Figure 1. SANS spectrum of P(*t*BuMA)-*g*-PtNPs in *d*-DMAc and Transmission Electron micrograph of PtBuMA-*g*-PtNPs.

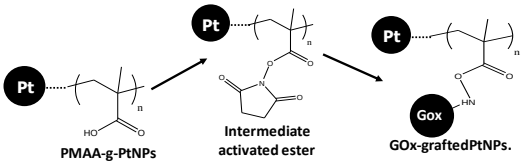
We therefore designed hybrid structures in solution through the modification of the poly (methacrylic acid)-*grafted* Pt nanoparticles (PMAA-*g*-PtNPs) to graft an enzyme via an activated ester reaction (Scheme 1).



Scheme 1. Activation of the PMAA-*g*-PtNPs with *N*-hydroxy-succinimide (NHS) and subsequent grafting onto the glucose oxydase.

Both UV spectroscopy, SANS and SEM (scanning electron microscopy) will be used to characterise the structure of the hybrid nanostructure, after checking the remaining activity of the grafted enzyme.
To study the electrochemical properties of protein/polymer-*grafted*-PtNPs, it is necessary to transfer these nano-objects onto electrodes. Using Langmuir-Blodgett (LB) technique, we also elaborated two different thin-film architectures (LB films and polymer brushes) where enzymes were subsequently grafted. The control of the homogeneity, thickness and roughness was attested by neutron reflectivity measurements and TEM. After the physical characterization of these systems, the study of their electrochemical behavior towards H_2O_2 and glucose revealed significant differences due to their structure and their composition.

Introduction

In this study, we explore further the role of nanoclay particles in the foaming of PP/clay nanocomposites.[1,2] The nanoclay particles were doing dual role as a nucleating agent for CO_2 gas or fluid and polypropylene molecules. We tried to figure out the relation between the cell generation and the processing variables.

Experimentals

Polypropylene terpolymer (poly(propylene-co- ethylene -co-1-butene), with a composition of 94.5wt% of polypropylene unit, 3wt% of ethylene unit, and 2.5wt% 1-butene unit, was obtained from Honam Petrochemicals Co. (Korea). Foamed terpolymer was prepared by injecting out the blowing-agent submerged terpolymer particle in an autoclave through a nozzle. In order to aid the compatibilization between PP terpolymer and the annoclay particles, small amount of maleic anhydride grafted polypropylene (MAPP) was added. Surface modified monmorillinite (Cloisite 20A, Southern Clay) was used. Terpolymer and premade master batch were mixed in a twin screw extruder (Prism) and extruded. Weight ratio between the matrix polymer and the master batch compound was controlled to set the clay amount s 0.2 wt% and 1wt%.

Results and Discussion

Small angle X-ray diffraction (SAXD) patterns for pristine organoclay 20A, two sc CO_2 foamed nanocomposites are illustrated in Figure 1 (0.2 wt% of clay)). Unfoamed samples show a diffraction peak of Cloisite 20A. The peak of unfoamed sample is shifted to lower angle compared to that of clay, which indicates that unfoamed samples have intercalated morphology. This expansion could be attributed to the diffusion of CO_2 and compatibilizer polymer chains into the clay galleries. SAXD patterns of all foamed samples show no peaks, which indicate full exfoliation of the nanoclay particles. The samples foamed under the subcritical condition show no peak at all. This means the foaming by CO_2 caused the exfoliation. The polymer chains are not in the fully melt state in this condition. This means that further smearing of polymer molecules into the gallery was not the cause of exfoliation or most of the exfoliation was done by the CO_2 molecules adsorption and growth by later pressure release.

Figure 2 shows the cell morphology of the foamed structure of PP and three composite samples. The pure PP foam has but smaller than composite foamed one. All the foaming temperatures were lower than the melting temperature of PP at the applied pressure, hence the crystal lamellae later split by the cell growth to form the walls of the cell. Nanocomposites show uniform cell size.

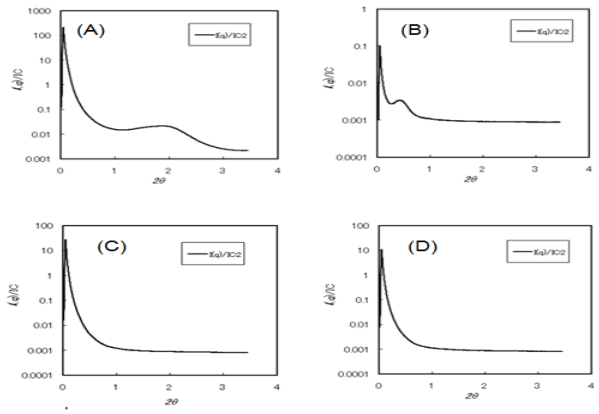

Figure 1. SAXS pattern for (A) Cloisite20A (B) Unfoamed (C) Subcritical CO_2 (D) Supercritical CO_2

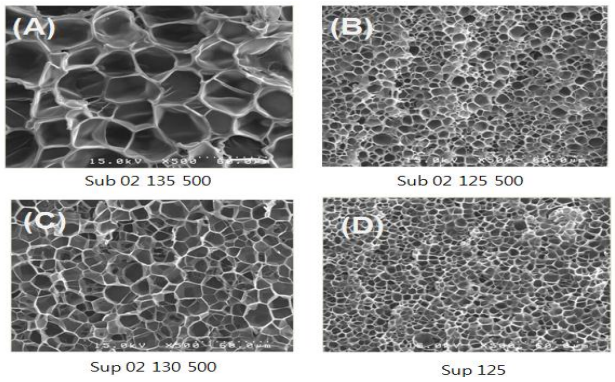

Figure 2. SEM photos of the fractured surfaces (A) Sub CO_2 (135°C foaming), (B)Sub CO_2 (125°C foaming), (C) Sup CO_2 (130°C foaming), (D) PP Sup CO_2 (125°C foaming).

Conclusions

The SAXD analyses showed that the foaming process facilitates dispersion of clay particles. Fully exfoliated structures were obtained for all foamed samples. Clay layers provide more heterogeneous nucleating sites for foaming. Nanocomposites of better dispersion of clay platelet produces more cells and more uniform structure. More details will be presented at the conference.

Introduction

For more than twenty-five years, random amphiphilic polyelectrolytes have been known to enhance the apparent water solubility of highly hydrophobic compounds[1,2]. Poly(dimethylmalic acid) (PDMMLA), a degradable polymer, polyanionic at neutral pH, can be easily obtained in a partially hydrophobized form through copolymerization of malolactones with different pendant aliphatic or aromatic groups[3,4].

In this work, we synthesized various malolactones to obtain a range of amphiphilic copolymers with varying hydrophobic substituent rate and chain length. The influence of these parameters, of pH and of the presence of sodium chloride upon the apparent solubility of pyrene and clofazimine in aqueous solutions of these polymers was studied.

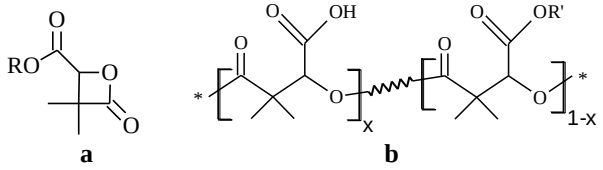
Materials and methods

The monomers and polymers were synthesized following the method described by Barbaud *et al.*[3,4] adapted to the ratios and side chains used in this work.

Molecular weight determinations were done by SEC analysis in THF, with PS as a standard.

Results and discussion

The monomers (fig.1a) were obtained from commercial diethyloxalpropionate in five steps with yields of 15-20%, in accordance with litterature.



a **b**

Figure 1 : PDMMLA monomers (a) and polymers (b)
R = benzyle, hexyle or decyle
R' = hexyle or decyle

Ring opening copolymerization of the benzylated and either hexylic or decylic lactones with defined ratios followed by hydrogenolysis yielded the desired random copolymers (fig.1b), with molecular weights ranging from 50,000 to 150,000 and polydispersity between 1.1 and 1.3. ^{1}H-NMR spectra confirmed that the hydrophilic-hydrophobic ratios corresponded to the initial ratios of the lactones.

As expected, solubility studies monitored by UV-visible spectroscopy showed that water solubility for both pyrene and clofazimine was improved by increasing the hydrophobicity of the polymer. However, the solubility in moles of hydrophobic compound per mole of monomeric unit was up to ten times higher for clofazimine than for pyrene. For the latter, solubilization is achieved solely by hydrophobic interactions with the polymer side groups, whereas for clofazimine, which is polar and protonable, there is a combination of both hydrophobic and electrostatic interactions with the negatively charged polymer.

The presence of sodium chloride increased the solubility of pyrene, but decreased the solubility of clofazimine (fig.2). In the case of pyrene, shielding the charge of the polymer allows the latter to coil more, and to form bigger hydrophobic domains where pyrene can solubilize. The charge on clofazimine is also shielded by the salt, thus resulting in a weaker interaction with the polymer and a poorer apparent solubility. This confirms the major role of charge interaction in the solubilization of clofazimine.

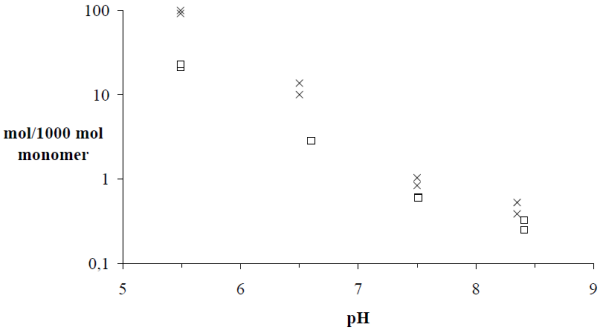


Figure 2 : Apparent solubility of clofazimine in a 1% solution of 30%-hexylated PDMMLA with (▫) or without (×) sodium chloride

Conclusion

Degradable PDMMLA derivatives improved the apparent water solubility of pyrene and clofazimine, with or without sodium chloride. However, it is still lower than with non-degradable poly(methyl vinyl ether-*alt*-maleic acid) derivatives[2].

Future work will aim at synthesizing more hydrophobic degradable copolymers with other side groups, in order to further increase the solubility of these compounds. Analyses are also under way to characterize the objects formed in solution, notably to determine if monomolecular or polymolecular micelles are involved.

Modification of the Electrical Properties of TPU by Modified Expanded Graphites

Jürgen Pionteck, Francesco Piana

Leibniz Institute of Polymer Research Dresden, Dept. Polymer Reactions and blends
Hohe Str. 6, 01069 Dresden Germany

pionteck@ipfdd.de

Introduction: For some applications it is necessary that polymers exhibit a certain degree of conductivity, which can be reached by mixing conventional isolating polymers with electrically conductive fillers. We analyzed the influence of the processing conditions of nano-composites based on thermoplastic polyurethanes (TPU) and expanded graphite (EG) or graphene oxide (GO) on their properties with focus on the electrical conductivity.

Materials and Methods: The TPUs used were commercial products from Elastolan varying in hart segment content, polarity and crystallinity, and self-made TPU based on diisocyanates (MDI, H12-MDI, or IPDI) and 1,4-butanediol (forming the hart segments) and PTHF as soft segment.
Melt mixing was done by means of a DSM 5 mL Microextruder in a one step process or in a two step process, preparing first a masterbatch from solution followed by diluting the masterbatch to the desired EG concentration by melt mixing with pure TPU. The composites were compression molded to 1.5 or 1 mm thick plates for testing electrical and mechanical properties, respectively. TPU composite powder mixtures were obtained by dissolution of TPU in an EG/DMAc dispersion followed by precipitation in ethanol. In-situ TPU/EG composites were obtained by dispersion of the graphites in the PTHF/BD mixture, which was then polymerized after addition of the diisocyanate. In all cases sonic treatment was used to improve the graphite dispersion.

Results and Discussion: When melt mixing, the TPU with the highest Shore hardness (C74D50) gave a conductivity of 1.3 10^{-5} S/cm already at 2 wt.% EG content, while the percolation concentration of the other TPU (1185A, S60A15) was between 6 and 4 wt% EG. Interestingly, at higher EG concentrations of up to 10 wt% the conductivity increased just slightly. Precipitated powder mixtures containing 10 wt.% EG exhibit higher conductivities than the extruded composites, in case of C74D50 as high as 0.07 S/cm. Using these composites as masterbatch for the preparation of composites containing 2 to 8 wt.% EG by melt mixing resulted in somewhat lower conductivities when compared to the directly melt mixed composites of the same composition (Fig. 1).
There is a strong influence of the melt-mixing conditions on the conductivity, as shown exemplary for composites in Fig. 2.

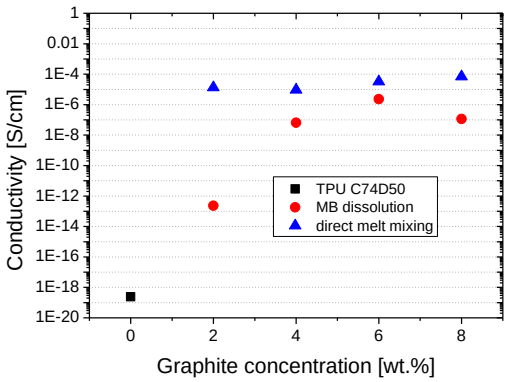

Figure 1: Conductivity versus filler content of TPU C74D50/EG composites prepared by direct melt mixing or by dissolution of the precipitated master batch

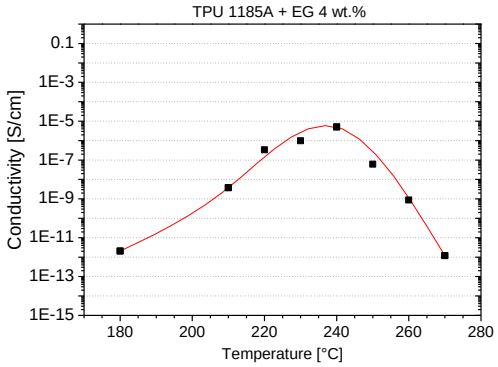

Figure 2: Dependence of conductivity of TPU 1185A containing 4 wt.% CNT on melt-temperature

The in-situ syntheses of TPU/EG composites resulted in materials with rather poor conductivities, widely independent of the used diisocyanates and composition. There seems to be no big influence of the aromaticity, polarity and crystallinity on the electrical behaviour of the composites. These effects and the use of oxidized graphites are still under investigation.

Acknowledgements: We are grateful for the support of the project by the Deutsche Forschungsgemeinschaft (DFG) and to SGL Carbon for providing the graphites.

Processing and Properties of Carbon Nanotube-Polymer Composite Fibers

In nanocomposite materials, the final properties are strongly related to the distribution of the carbon nanotubes (CNTs) inside the polymer matrix, adding new performances to the material. To a certain extent, the composite structure can be tuned during processing, through the control of the dispersion or interactions between the nanotubes and the polymer, and the spatial re-arrangement of the structure. Trying to aim these objectives, our team has been working for several years on dispersion and processing of CNTs into various composites, like films, coatings and fibers [1].

The presentation will be dedicated to the synthesis and properties of carbon nanotube fibers. We spin CNT fibers by a coagulation process which consists in injecting a CNT dispersion in a poly(vinyl) alcohol solution (PVA) [2]. The method has been scaled-up and a new pilot for continuous production has recently been set-up. Moreover, an original method has been developed in order to characterize the strength of the fiber during the process [3]. This in-situ characterization method can be extended to various fiber processes, as many synthetic or natural polymer fibers are produced via the transformation of a liquid solution into a solid filament.

The fibers we obtain via this wet-spinning process have a nanocomposite structure with a large fraction of oriented CNTs and polymer. They exhibit electrical conductivity and exceptional mechanical properties. With strain to failure up to 450%, the energy needed to break the fibers exceeds that of any other known materials. We will discuss the different routes we follow to increase the electrical, structural and mechanical properties of these fibers, leading to markedly improved energy absorption and new thermo-mechanical properties [4,5].

Phase Behavior and Structure Formation under Fast Cooling of Syndiotactic Poly(propylene) Nucleated with 1,3:2,4-bis(3,4-dimethylbenzylidene)sorbitol

A.M.J.T. Meijer-Vissers, J.G.P. Goossens

Eindhoven University of Technology, Department of Chemical Engineering and Chemistry, Laboratory of Polymer Technology, P.O. Box 513, 5600 MB Eindhoven, The Netherlands

A.M.J.T. Meijer-Vissers@tue.nl

Syndiotactic poly(propylene) (s-PP) has some interesting properties such as high ductility and high optical transparency. However, it is less commercially successful than isotactic poly(propylene) (i-PP). This is mainly a result of the fact that it is a slow-crystallizing polymer.[1]

One way to improve this is by adding nucleating agents. Nucleating agents are a family of additives which are used to speed up processing rates of polymers by providing more nucleation sites and therefore reducing the cycle time. In the case of i-PP, 1,3:2,4-bis(3,4-dimethylbenzylidene)sorbitol (DMDBS) is a very efficient nucleating agent and so-called clarifying agent. Since DMDBS is a polar molecule, and i-PP is fully apolar, this leads to a rich phase behavior when i-PP and DMDBS are mixed together. From the application point of view, the most interesting concentration regime extends from ~ 0.1 wt% to 1 wt% of DMDBS, where i-PP exhibits a high clarity and low haze. In this regime, the temperature at which gelation occurs depends on the concentration of the additive,[2] which also governs the mechanical properties.[3] Further, the main crystal modification found for i-PP/DMDBS systems is the α-modification.

Previous research showed that DMDBS can also nucleate s-PP.[4] In this study, we investigate the phase behavior of s-PP with DMDBS. The cooling rates that are generally employed are 5-20 °C/min. However, polymers solidify under actual processing conditions at cooling rates which can range from only a few to hundreds of degrees Celcius per second, which is far beyond those accessible by common laboratory instrumentation.

Fast cooling results in the development of structural order at extreme undercooling and, for some polymers, this leads to formation of metastable states. The development of the mesophase in i-PP based materials was recently studied by Cavallo et al. through continuous cooling curves (CCC) diagrams.[5] In a similar fashion, we constructed continuous cooling curves for several blends of s-PP and DMDBS during fast cooling with in-situ WAXD.

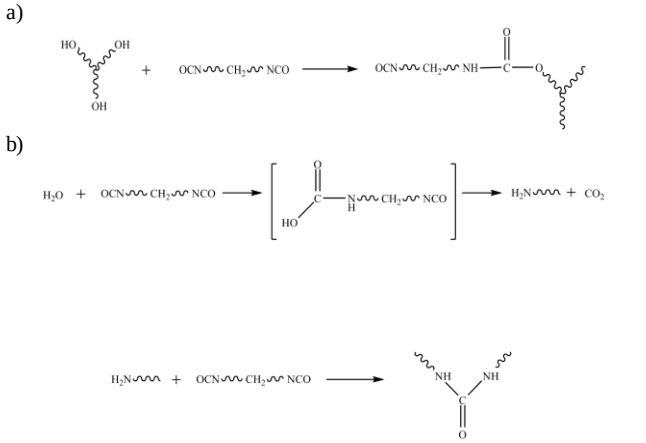
Introduction

The use of nano-sized fillers in polymer foams provides unique thermal, electrical and mechanical properties compared to conventional micro-sized fillers, which cannot be accommodated in the cellular structure of the foams.[1] Polymeric foams are important and versatile materials which account for 10% of the total volume of polymer market share. Foams have outstanding strength to weight ratio, resilience, electrical, thermal, and acoustic insulating properties, among other characteristics.[2]

Materials and Methods

Flexible polyurethane foams are produced by the exothermic reaction of a diisocyanate with polyether polyol (gelling reaction) and water (blowing reaction). These reactions form a segmented block copoly(urethane-urea) and carbon dioxide gas which is responsible for the foam formation.[3] Two series of PU foams were synthesised with 25% and 32.5% of hard segment (HS) by adjusting the water and isocyanate content.



Scheme 1. Chemistry of PU foams: a) Gelling reaction and b) Blowing reaction.

Carbon nanotubes (CNTs) were synthesised in-house by a chemical vapour deposition (CVD) process[4] from the decomposition of ferrocene-toluene vapour injected at 5ml/h under an inert atmosphere at 760ºC. Functionalisation of CNTs was carried out in a mixture of acids at 120ºC for 30 minutes and then filtered with distilled water until neutral pH. Functionalised graphene sheets (FGS) were produced from the adiabatic expansion at 1000ºC of graphite oxide under argon atmosphere[5]. Nanofillers were mixed in the polyol to achieve a good dispersion before adding the isocyanate.

A fixed concentration, 0.5 pphp in polyol, of carbon nanofillers was selected for comparison purposes.

Results and Discussion

Polymerisation kinetics as well as hydrogen bonding development were analysed by FT-IR in order to gain an understanding of the effect of carbon nanofillers on the rate of reaction and the structure development of the resultant PU foams. The reaction kinetics was strongly influenced by the HS content and the decrease in the rate and isocyanate conversion was ascribed to an increase in the viscosity of the systemand, hence, a restriction of the chain mobility due to the larger HS content. At equivalent HS content, the onset of microphase separation (MST) occurred at an earlier isocyanate conversion for foams filled with carbon nanofillers compared to the unfilled foams. From SAXS data we observed that the average distance in samples with 32.5% HS content was affected by the presence of carbon nanofillers while no differences were observed for samples at 25% HS content.

Conclusions

Carbon nanofillers with different morphology and functionality delayed the onset of microphase separation of flexible polyurethane foams without significantly changing the interdomain spacing. Hence, carbon nanofillers affected the reaction kinetics of the polymerisation reaction but not the final morphology of the nanocomposite foams. Thus, any changes on the mechanical properties of this type of system would be related to reinforcing effect of the fillers rather than a change of the microstructure.

Introduction: Polymer / layered silicate nano-composites constitute an interesting class of materials which allow the investigation of basic scientific problems and, at the same time, are utilized in many applications.[1] Mixing polymers with layered inorganic materials can lead to three types of structure, depending on the interactions between the two components: the phase separated, where the two components are immiscible, the intercalated, in which the polymer chains reside within the inorganic galleries forming thin polymer films, and the exfoliated one, where the interactions between the chains and the surfaces are very favorable so that the inorganic layered structure is destroyed resulting in dispersed platelets within the polymer matrix.[2] Despite the large number of studies in this area,[3,4] the influence of the addition and the state of dispersion of the nanofillers on chain conformation and/or crystallization has been largely overlooked. In this work, we aim to systematically study the effect of incorporation of inorganic material and/or elucidate the influence of the severe confinement on the structure and conformations of polymer chains in PEO / Na^+-MMT nanohybrids.[5]

Materials and Methods: Poly(ethylene oxide), PEO, with molecular weight M_w=100,000 gr/mol, glass transition temperature, T_g, -67°C and melting temperature, T_m, of 65°C, was utilized and mixed with a hydrophilic montmorillonite, Na^+-MMT (Southern Clay). The nanocomposites were prepared by direct melt intercalation; the two components were mixed in the appropriate amounts, grinded in a mortar to get a fine powder and annealed in a vacuum oven at 100°C for 2 days. A series of composites with PEO content that covers the whole regime from pure polymer to pure clay were prepared and were characterized by X-ray diffraction, XRD, and differential scanning calorimetry, DSC. Moreover, the conformations of the polymer chains in the crystal and in the amorphous state were investigated utilizing Raman and infrared spectroscopi.

Results and Discussion: XRD measurements reveal that for all hybrids, intercalated nanocomposites with mono- and bi-layers of PEO chains are obtained. Moreover, for nanohybrids with low polymer concentration, where all polymer chains are intercalated or in close proximity to the inorganic surfaces, the peaks that correspond to the crystalline structure of PEO can not be observed indicating that PEO is purely amorphous. It is only when there is plenty of excess polymer outside the completely filled galleries that polymer crystallization is observed. In agreement with XRD, DSC measurements show the melting and crystallization transitions only for hybrids with high polymer content. To investigate the conformations of the chains in the hybrid material in relation to that of pure PEO more quantitatively, Raman and IR spectroscopy have been applied.

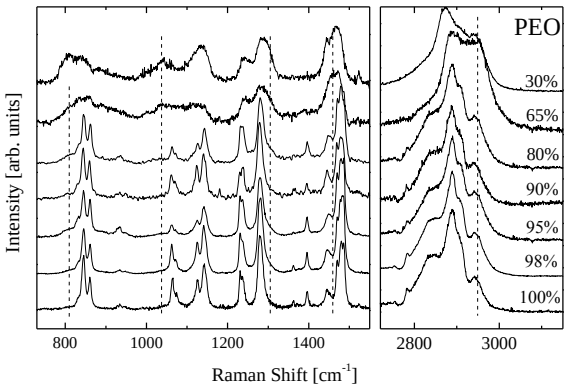

Figure 1: Raman spectra of PEO and of PEO / Na^+-MMT nanohybrids with different polymer content at 25°C.

Figure 1 shows Raman spectra of nanohybrids with different compositions, which show that, indeed, it is only at high polymer concentrations that the sharp peaks attributed to crystalline PEO are observed. Moreover, quantitative analysis reveals that the intercalated chains are more disordered and liquid-like than even the PEO melt measured at higher temperatures.

The preparation of organic/inorganic hybrid materials composed of organic polymers and inorganic components are described as a route to combine and even increase the advantageous properties of both classes of molecules in one material. A particularly attractive strategy to build nanostructured hybrid materials is based on the use of well-defined clusters that keep their molecular integrity and therefore their intrinsic properties during the assembly of superstructures. For example, a recent approach is based on the use of molecular titanium oxo-clusters, which constitute structurally well defined nanosized building blocks. These titanium oxo-clusters have well defined size and shape, and their surface can be chemically modified in order to bear functional ligands for further hybrid materials elaboration. In the case of $Ti_{16}O_{16}(OEt)_{32}$ cluster for example, the ethoxyde group present at the surface of the metallic oxo-core could be exchanged by transalcoholys reactions.[1] The present work will report the design of a hybrid star-like architecture by post-modification of a titanium oxo-cluster with polymer chains following the grafting onto and grafting from strategies.[2] In the second strategy, starting from a well-defined multifunctional titanium oxo-cluster initiator, a "grafting from" approach based on atom transfer radical polymerization (ATRP) has been develop. Conditions to prevent possible side reactions between monomer, polymer and titanium oxo-cluster ligands will be discussed. The kinetics of polymerization and the final structure will be carefully investigated. Rheological properties of the materials will be also described.[3]

Crystallization in Co-continuous Nanostructured Blends and Composites

Sylvie Tencé-Girault, Léa Gani, Thomas Périé, Ludwik Leibler

Matière Molle et Chimie (ESPCI-CNRS, UMR 7167), ESPCI ParisTech
10 rue Vauquelin 75005 Paris - France

sylvie.girault@espci.fr

Co-continuous thermodynamically stable nanostructured blends of functionalized polyolefin (FPE) and polyamide-6 (PA6) have been designed and synthesized by reactive blending[1,2]. The grafting reaction occurs between the PA6 amino end-group and maleic anhydride units randomly distributed along the backbone of FPE. Depending on the chemical structures of FPE and PA6, blends with various nanostructures are obtained. These blends exhibit both solvent resistance and outstanding mechanical properties at low and high temperatures.
First, the relationship between these attractive properties and the structure and crystallization at the nano and micro-scales is studied. Then, we show that these blends are particularly nice matrices for carbon nanotubes (CNT) composites.

Due to the high reactivity of the maleic anhydride / amino couple, a large amount of graft copolymers is created *in-situ* during the reactive extrusion. As the two components of this graft copolymer are incompatible, a nanostructure is formed. The polydispersity of the backbone and the grafts helps to stabilize a co-continuous disordered structure and facilitates the incorporation of the unreacted homopolymers in the nanostructure. While keeping the PA6 as minority phase, the co-continuous nanostructure is observed in a wide composition range (Figure 1).

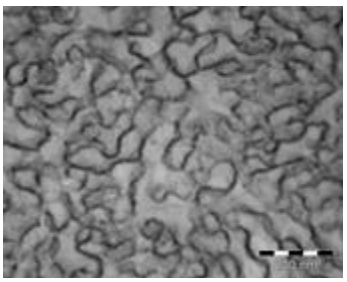

Figure 1: Morphology of a FPE/PA6 80/20 wt % blend observed by TEM (PA6 in black).

The blend is transparent and crystalline. Two melting temperatures are observed at 87°C and 216°C, attributed to the FPE and the PA6, respectively. The blend exhibits outstanding solvent resistance and thermo-mechanical properties. Indeed, with a low amount of PA6 (20 wt %) the blend does not flow at the melting temperature of the majority phase, FPE, but at 200°C. Morever, a storage modulus of 7MPa is measured between the two melting temperatures. These properties are due to the crystallization of the PA6. A crystallization study enables us to propose a model for the organization of graft copolymer and homopolymer chains in the co-continuous structure (Figure 2). PA6 crystallizes in a lamellar morphology inside the co-continuous nanostructure, it is confined in thin domains of 12 nm thickness. FPE crystallizes in this morphology as well.

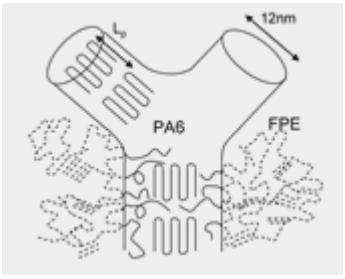

Figure 2: Schematic representation of the FPE and PA6 chains in the blend.

CNT are dispersed in these blends by melt blending in a micro compounder. On the TEM picture of the composite, we still observe the continuous PA6 phase (Figure 3). CNT are not confined in one phase, but they cross over the two phases FPE and PA6.

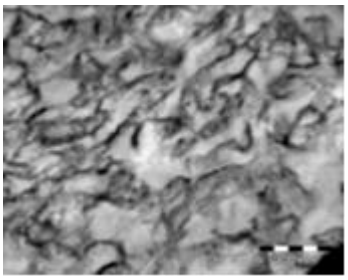

Figure 3: TEM image of the composite morphology (PA6 in black).

The mechanical and electrical properties of the composite are significantly enhanced by the CNT incorporation. This is due to a double interconnected network: a network of crystalline PA6 with high melting temperature and a conducting CNT network. The crystallinity of the blend is preserved and the formation of trans-crystalline lamellae of PA6 surrounding the nanotubes in confined domains is observed.

grillard@crpp-bordeaux.cnrs.fr

Because of their high aspect ratio and small size, carbon nanotubes (CNTs) are well-suited for the inclusion in textile polymer fibers. CNTs intrinsically exhibit remarkable mechanical properties [1,2] and are electrically conductive [3]. They are therefore promising candidates to develop new composite fibers with improved properties and novel functionalities potentially useful in several industrial textile applications. We investigated in this work the properties of melt spun CNTs/polymer composite fibers.

First, CNTs and polymer are mixed via an extrusion process at high temperature. Homogeneous mixing is critical in order to achievable spinnable materials. The melt spinning device is composed of a single-screw extruder, two winders separated by an oven and a wind-up roll to collect the fiber at the end of the process. Several parameters can be varied such as screw extruder speed, the extruder temperature, the winding apparatus speed or the post-drawing ratio (ratio between the second and the first winding apparatus speed). The fiber production and processing are associated to fiber elongation in strong extensional flow fields. Those physical mechanisms strongly affect the structure and properties of the fibers. In particular, electrical characterizations show a great increase of the resistivity with the fiber elongation rate. According to X-ray scattering measurements, this decrease is not dominated by the orientation of CNTs as observed in other nanocomposites [4,5,6]. We discuss other effects of structural changes and consider variations of inter-tube contact probabilities. We propose an analytical model that quantitatively accounts for the observed variations of resistivity. The progresses achieved in this work should allow a much better control of the properties of fibers and other CNT composites produced by extrusion processes.

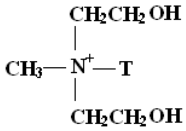
giovanna.colucci@polito.it

Introduction: The development of rubber-clay nanocomposites attracts great interest because layered silicates can be used as new ''white'' reinforcing agents to replace carbon black in rubber compounds [1-3]. These materials are currently prepared by solution blending, latex compounding, melt intercalation and in situ polymerization[1-3]. From an industrial point of view, melt intercalation is the most direct, cost effective and environmentally friendly technique to make nanocomposites. One of the most critical issue for their preparation is the dispersion of the clays inside a rubber matrix, due to their high hydrophilic nature.

Therefore, organophilic montmorillonites, made by cation exchange of onium salts, have been preferred; however, although the compatibility is good, they do not guarantee fully exfoliation of the clay in the rubber matrix[2-3].

In this paper we report the modification of Cloisite 30B by intercalation of low MW polybutadienes (LPBs) and their maleinized homologues (LPB-MAs) with the same maleic anhydride content. We describe the reaction between the pendant succinic rings of maleinized LPBs and the hydroxyl groups of the clay modifier; moreover, we study the effect of the modifications on the properties of the clays. Morphological and structural investigations of the SBR-based composites obtained by melt blending are described and structure-properties relationships deeply discussed.

Materials and Methods: The commercial organo-clay Cloisite 30B (C30B, Southern Clay Products, USA), was used as starting material (see below the formula of the onium cation).



T= (65% C_{18}, 30% C_{16}, 5% C_{14})

The clay modifiers were two LPBs, MW 5000 and 1500, and two homologues LPB-MAs, with the same maleic anhydride content of 7.5 wt.%. LPBs used as modifiers were kindly supplied by Synthomer Ltd. UK. The modification procedure was reported in an our previous published work [4].

A styrene-butadiene emulsion copolymer (SBR) trade name Europrene 1739 (24 wt.-% styrene content, extended with 35 phr of oil) was used as matrix for the preparation in internal batch mixer of the rubber-based nanocomposites.

Results and Discussion: In Table 1, data describing clays modified either with LPBs or with LPB-MAs are reported. A first evidence of the modification is given by the amount of organic matter estimated by TGA.

Upon modification, in all samples a clear increase of the organophilicity of the clay is achieved, testified by contact angle values around 100°. XRD analysis reveals a remarkable increase of the interlayer distance when C30B is modified with LPB-MAs, while using simple LPBs the interlayer distances remain the same or show a slight increase depending on LPB MW.

Table 1. Characterization of modified clays.

Sample	Contact Angle with H_2O (°)	d_{001} (nm)	Organic Content @800°C (%)
C30B	60	1.8	32
C30B +LPB-1500	97	1.9	64
C30B + LPB-MA-1500	107	7.0	71
C30B + LPB-5000	98	3.6	62
C30B + LPB-MA-5000	96	7.6	76

FT-IR analysis clearly shows that the succinic rings pendant from the LPB-MA chains effectively react with the OH groups of C30B.

TEM images of the SBR-based composites containing the modified clays show the influence of the nature of the polybutadiene modifier. Using the clay modified by LPB-MA (Fig.1a) a large number of particles are well dispersed and in the form of isolated lamellae; the modification of the clay with a not maleinized LPB results in a lower number of isolated lamellae and larger tactoids (Fig.1b).

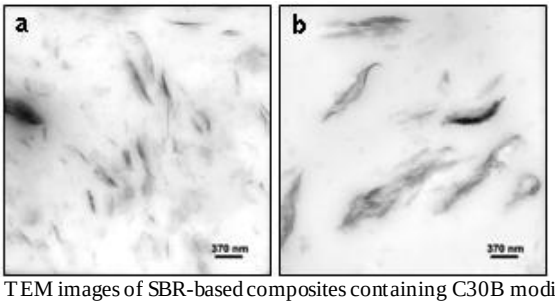


Fig.1 TEM images of SBR-based composites containing C30B modified with maleinized (a) and not maleinized (b) LPBs.

Conclusions: The succinic functional groups grafted onto the LPBs chains play a crucial role in modifying and increasing the interlayer distance to achieve a good dispersion of the new organo-clays within the rubber matrix. Rubber-based composites containing maleinized clays exhibit intercalated structures independently from the MW of maleinized LPBs.

Directing self assembly of RAFT polymers using end group functionalisation

Dr Helen Willcock[1], *Dr Rachel K. O'Reilly*[1]

[1]University of Warwick

h.willcock@warwick.ac.uk

It is well documented that amphiphilic block copolymers can be assembled into a range of nanostructures such as spherical micelles, vesicles, toroids and cylinders when placed in a selective solvent for one of the blocks, in order to reduce energetically unfavourable interactions between the none-soluble block and the solvent.[1-2] Although the morphology formed is dependent upon a number of factors, it is proposed that the volume ratio between the hydrophobic and hydrophilic blocks is the most important. Specific structures can be targeted by considering the inherent molecular curvature and how this affects the packing of the polymer chains. This is described by the dimensionless packing parameter, *p*, and is shown in Figure 1.[3]

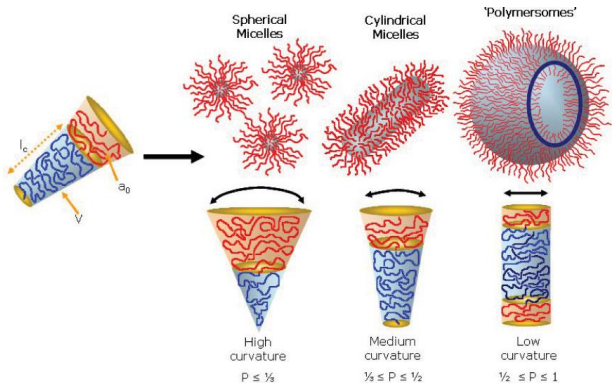

Figure 1 *Self-assembled structures formed by amphiphilic block copolymers in a block selective solvent.*

It has also been shown that secondary forces such as H-bonding or π-π interactions can aid the self-assembly process, and more recently the self-directed assembly of hydrophilic polymers with hydrophobic contents as low as 6 wt % have been described, and the work demonstrates that the presence of two spacially close rigid rings (such as in the pyrene end group) is a crucial structural requirement for vesicle formation. [4]

Reversible addition–fragmentation chain transfer (RAFT) polymerisation is one of the most versatile CRP techniques as it exhibits good tolerance to a diverse range of functional groups in monomers, solvents and initiators and offers control over a wide range of monomers through the use of different classes of chain transfer agents (CTAs).[5] As polymerisation occurs by insertion of monomer units into the C-S bond (at the α end), end-functionalised polymers can be easily achieved by incorporating the functional groups into the RAFT agent (groups R and Z) and by post-polymerisation reaction of the thiocarbonyl-thio group at the ω end (Figure 2).[6]

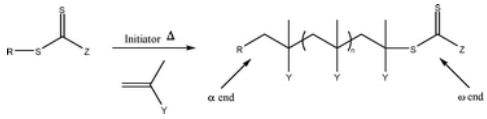

Figure 2 *Schematic representation of RAFT polymerisation showing α- and ω- ends of the resulting polymer.*

RAFT polymerisation has been used to synthesise polymers with both α and ω chain-end functionality by incorporating a hydrophilic, chargeable pyridine group into the R group of the RAFT chain transfer agent, followed by post-polymerisation introduction of a bulky, planar fluorescent group at the ω end. This was achieved by aminolysis of the trithiocarbonate end group, followed by Michael Addition of the resulting thiol to the activated alkene of hostasol acrylate. The successful incorporation of the fluorescent group has been confirmed by GPC using UV detection, and the effect of this bulky planar group on the self assembly properties of the homopolymers will be discussed.

Introduction

Water-borne polymerizations (emulsion and miniemulsion) are of great importance in industrial applications as they provide environmental-friendly processes, allow the removal of the reaction heat easily and assure the feasible handling of the final product that has a low viscosity. The final application of most polymer lattices is in the form of film (i.e. as paint or adhesive). The film formation process is the transformation of a polymer dispersion into a coherent polymer film. This process is usually divided in three stages: (i) evaporation of water and particle packing, (ii) deformation of particles and (iii) interdiffusion between particles and coalescence. All these stages have a great influence in the final film properties and the used emulsifier plays an important role in them. Low molecular weight ionic emulsifiers are commonly used to stabilize polymer particles in emulsion polymerization. However, they may create drawbacks in the final film applications as they usually migrate during the drying of the latexes, leading to poor adhesion of the polymer film to the substrate and introducing high water sensitivity. An alternative for overcoming these problems is the use of polymeric surfactants, especially amphiphilic block copolymers, as they absorb strongly on the particle surface. The hydrophobic part of the block copolymer is absorbed inside the particle whereas the hydrophilic part remains outside the particle forming a hairy layer.

In this work the effect of the acrylic acid (AA) hairy layer length on the film formation and final film properties has been studied. This requires the design of hairy layers of controlled lengths, which has also been part of this work.

Materials and Methods

Initially, different amphiphilic p(AA-*b*-BA) block copolymers containing different units of each monomer were synthesized by solution polymerization via RAFT process. Then, these copolymers were adsorbed on a clean latex, as shown in Figure 1

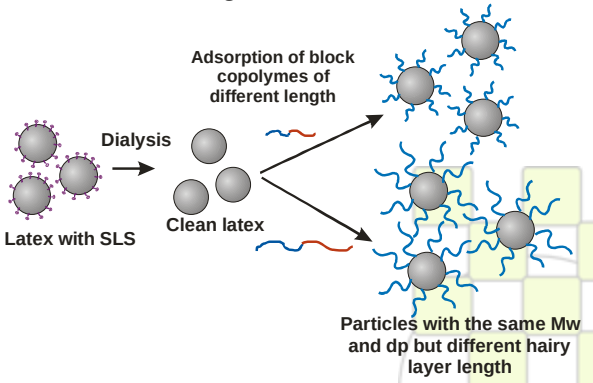

Figure 1. Steps followed to obtain polymer particles with hairy layers of different lengths.

So, a butyl acrylate (BA) /methyl methacrylate (MMA) (50/50 wt %) latex synthesized using a common anionic surfactant (sodium lauryl sulfate, SLS) was dialyzed against distilled water, in order to remove all the anionic emulsifier. Block copolymers of different lengths were added to different fractions of the clean latex. Thus, polymer particles with the same diameter and molecular weight but with different hairy layer length were obtained for comparison.

Films of the different latexes were formed and their properties such as tensile stress, static contact angle with water or water absorption were compared. Furthermore, the film formation step of each of them was studied by ESEM.

Results and Discussion

p(AA-*b*-BA) block copolymers containing different AA and BA units, with low Đ, were successfully synthesized by RAFT polymerization.

Concerning the film properties of the latexes with different hairy layer lengths, it was observed that although there were not significant differences in the contact angle values, the water absorption of the films was different. Films containing longer AA chain lengths absorbed more water. Tensile stress measurements demonstrated that the presence of AA chains on the particle surface decreased the final film properties. This effect is probably caused by the restricted interdiffusion between particles due to the high Tg of the AA (Figure 2).

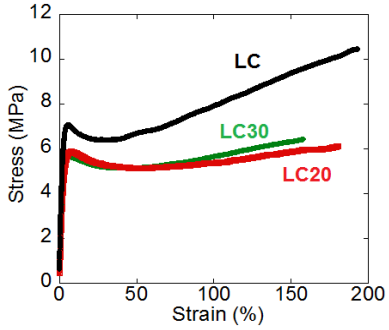

Figure 2. Stress-Strain curves for different films. LC corresponds to the clean latex and LC20 and LC30 to the clean latex stabilized by p(AA-*b*-BA) containing 20 and 30 units of each monomer respectively.

mercedes.fernandez@ehu.es

Introduction

The preparation of polymer/carbon nanotubes (CNT) nanocomposites with an improved electrical conductivity, implies, in general, a dispersion of the nanotubes in the polymer matrix and a subsequent solidification process. In the case of thermoplastic matrixes, dispersion is usually carried out in the molten state and then the temperature is decreased below the melting temperature or the glass transition temperature of the system. Notwithstanding this *modus operandi* is currently employed for basic studies and industrial purposes, few papers refer to a crucial aspect: The evolution of the electrical conductivity from the molten state to the solid state. Moreover, contradictory results have been found in the literature. According to Alig *et al*. [1] the effect of cooling polypropylene (PP)/ multiwalled carbon nanotubes (MWCNT) nanocomposite melts to temperatures below crystallization, is a significant decrease in the electrical conductivity. But, Lim *et al* [2] report an electrical conductivity enhancement in ethylene-co-vinylacetate (EVA)/MWCNT nanocomposites for samples cooled to the crystallization temperature.

Results and Discussion

In this contribution the electrical conductivity of dispersions of MWCNTs in a polycaprolactone based polyurethane (PUR) is investigated in the molten state, during crystallization and in the solid state. The study focuses on the effect of flow on both, electrical conductivity and dynamic viscoelastic results, establishing the percolation threshold within the framework of the "dynamic percolation" concept. The flow conditions affect the agglomeration and, eventually, the orientation of nanotubes, which gives rise to different values of the fitting parameters ϕc and t of the percolation equation $X=Xo\ (\phi-\phi c)^t$. Depending on the results obtained in the molten state, an electrical conductivity increase or a decrease is observed during crystallization process. Figure 1 shows the conductivity enhancement observed during crystallization for a PUR/2 wt % MWCNT nanocomposite.

The results are discussed considering different hypothesis, including the assumption of a distribution of the conductive particles in amorphous regions, around the crystalline regions.

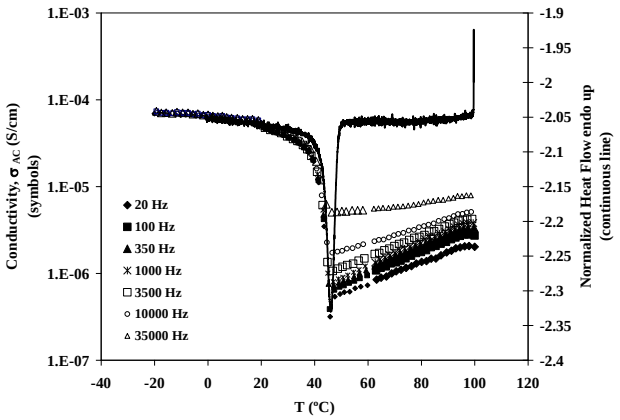

Figure 1. Temperature dependence of conductivity, σ_{AC} of the PUR/2% MWCNT nanocomposite recorded at the indicated frequencies during crystallization for 1ºC/min cooling rate (symbols). Heat Flow from DSC experiment at the same scanning rate (continuous line) is plotted for comparison purpose.

email: jasna@tmf.bg.ac.rs

Polymer hydrogels resemble natural living tissues more than any other class of synthetic biomaterials due to their high water content and soft consistency. However, their relatively low mechanical strength and low response rate, which mainly arise from restricted molecular motion of the chains caused by the high degree of crosslinking, affect their application. Fast responses, excellent mechanical properties, comparable to those found in living systems, are required for some specific applications, such as chemical sensors and artificial organs. The desired values of modulus and response rate of hydrogels could be achieved by molecular design. Recently, the new class of nanocomposite (NC) hydrogels based on poly(*N*-isopropylacrylamide) (PNIPA) with improved mechanical properties, high transparency and high deswelling rates has been designed.[1,2] Further improvements of properties of NC hydrogels were accomplished by addition of linear hydrophilic polymers to the networks, i.e., by forming semi-interpenetrating networks (SIPN).[3,4]

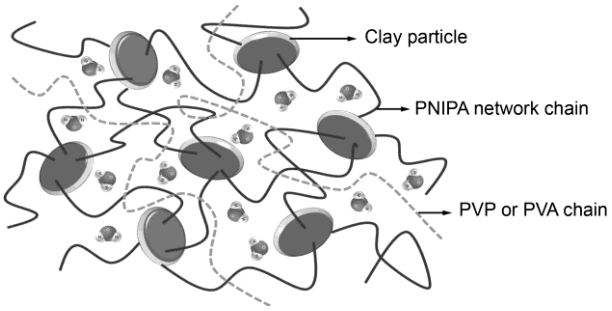

Figure 1. Schematic presentation of the structure of the PNIPA/clay network interpenetrated with linear PVP or PVA chains.

In this study, the SIPNs based on PNIPA physically crosslinked with inorganic clay and interpenetrated with linear hydrophilic poly(*N*-vinyl pyrrolidone) (PVP) or poly(vinyl alcohol) (PVA) polymers, are presented (Figure 1.). Linear PVP or PVA were used due to their high hydrophilicity and high molecular weight, which makes them capable to form entanglements and imparts some useful properties, such as good physiological inertia and biocompatibility. The hydrogels were crosslinked with 1-6 wt% of inorganic clay (hectorite, Laponite XLG). SIPN hydrogels contained linear interpenetrants in the range of 0.5 to 1.5 wt%. Hydrogels were prepared at 10 wt% of polymer in water (as-prepared state) and then swollen to equilibrium. The equilibrium degree of swelling at 25 °C, the dynamic shear modulus and the effective crosslinking density, tensile strength and elongation at the equilibrium swelling and in the "as-prepared" state are presented.

The mechanical properties and the gel structure of SIPN are compared to PNIPA hydrogels. Both hydrophilic linear polymers, PVP and PVA, modify the morphology of NC hydrogels by increasing pore size and contribute to the higher equilibrium swelling ratio and higher swelling - deswelling rates. The degree of swelling of SIPNs and PNIPA hydrogels was in the range 12 to 40 and deceased with the increasing content of clay. Kinetics of swelling and deswelling was used to estimate the responsiveness of the gels. A considerably faster deswelling and volume shrinkage of SIPN hydrogels was achieved by the addition of 1 wt% PVP and 1.5 wt% PVA. The volume phase transition temperature of hydrogels was determined by differential scanning calorimetry (DSC). The insertion of hydrophilic linear polymers slightly decreases the lower critical solution temperature, LCST, while the volume phase transition is broader as the content of clay increases. Scanning electron microscopy (SEM) was used to investigate the morphology of the PNIPA and SIPNs hydrogels. The tensile strength of the SIPNs reinforced with linear hydrophilic polymers was higher than that of the PNIPA/clay networks and was almost proportional to the clay content. The strongest hydrogels were those with 10 wt% PNIPA and 5 wt% of nano-clays, displaying tensile strengths of 85 kPa and elongation of 955 %. All properties at the equilibrium swollen state are lower than in the as-prepared state, due to the lower concentration of chains per unit volume, but the trends are maintained.

The hysteresis in the elongation-reversion curves of hydrogels observed in both as-prepared and swollen state, increased significantly with the clay content as well as with the presence of linear PVP, confirming their contribution to a slow relaxation of hydrogels. Hysteresis in the first cycle was large and it was significantly reduced in repeated cycles. It could be concluded that the elastic properties of hydrogels might be improved by pre-stretching. The SIPN and PNIPA NC hydrogels exhibited excellent elastic recovery even at high elongations.

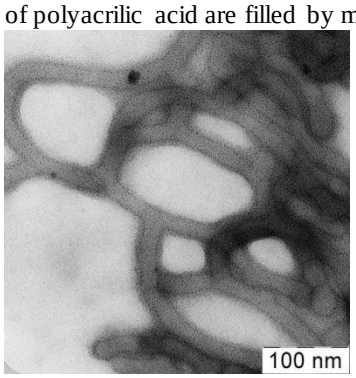
Introduction. Design of nanocomposite polymer materials with metal particles attracts growing interest due to their specific behaviour and prospects of application. Water-insoluble interpolyelectrolyte complexes may include a wide variety of metal ions with high sorption capacity (up to 30 %wt) and may be considered as promising systems for reduction of metal ions directly in polymer matrixes [1]. On the other hand it is possible to use the solutions of stars of polyacrilic acid or micellar solutions of amphiphilic block copolymers for preparation of nanomaterials inside macromolecules. Preparation of nanomaterials with adjusted structure in polyelectrolyte metal complexes by radiation-chemical reduction of metal ions is in focus of our research.

Materials and Methods. The solutions of polyelectrolyte metal complexes (stars of polyacrilic acid (PAA) or polystyrene - polyacrilic acid block copolymers with ions Cu^{2+}) and films of interpolyelectrolyte metal complexes (polyethyleneimine (PEI) - polyacrilic acid (PAA) with ions Cu^{2+}, Ni^{2+} or Ag^{+}) were used for study of peculiarities of formation of nanocomposites materials. The samples of complexes in aqueous alcohol environment were irradiated at 293 K using e-beams, ^{60}Co and X-ray irradiation in vacuum or inert atmosphere. The degree of ion reduction was controlled by EPR or optical spectroscopy. Small angle X-ray scattering (SAXS), electron microscopy and optical spectroscopy were used for characterization of the obtained nanocomposite polymer materials. The e-beam, X-ray and γ-irradiation were used for obtaining of metal nanoparticles

Results and Discussion: The SAXS data demonstrate formation of metal particles under irradiation of polymer systems. It is shown that the type of irradiation, the type of metal ion and composition of polymer system affect on formation of metal nanoparticles and structure of resulting metal polymer hybrid materials. The formation rate and localization of reducing agents generated by irradiation, their transport in polymer matrix are main factors, which determine size distribution and spatial ordering of nanoparticles in polymer matrix. The γ-irradiation results in formation of materials with relatively narrow distribution of nanoparticles (2-5nm), while the application of X-rays leads to ensembles of nanoparticles on the surface or in the bulk of polymer matrix. The type and content of metal ions in metal films affect the structure of nanocomposites. In the case of e-beams, the structure of resulting materials is defined by energy of accelerated electrons.

It was found that irradiation of solutions of polyelectrolyte complexes of star-like PAA macromolecules with copper ions resulted in effective reduction of metal ions and subsequent formation of nanoparticles. It should be noted that obtaining of nanoparticles in aqueous complexes of copper requires higher irradiation doses. The sizes of nanoparticles are determined by the presence of star-like macromolecules. The nanoparticles with sizes 2-4 nm were obtained after radiation induced reduction of copper ions in micellar solutions of polystyrene -polyacrilic acid block copolymers. In casting films of copolymers the microphase of polyacrilic acid are filled by metal nanoparticles (fig.1).



Conclusions: The high radiation-chemical yields of reduction of ions demonstrate good prospects for use of the polyelectrolyte metal complexes for the radiation-chemical synthesis of nanoparticles by this technique. The radiation-chemical approaches provide preparation of composites with uniform distribution of nanoparticles and materials with regular spatial distribution of nanoparticles including localization of metal structures in subsurface.
It was shown that complexes of macromolecules with metal ions in solutions may act as microcontainers for obtaining of nanoparticles. The approaches discussed in this paper make it possible to obtain provide wide opportunities for synthesis of nanocomposites with controlled content, size and spatial distribution of nanoparticles.

Introduction

Surfaces of inorganic materials can be tailored through the covalent attachment of monolayers of polymer chains [1-4]. Numerous synthetic approaches were developed to allow the preparation of such surface-attached monolayers. Different types of chain polymerization have been shown to be suitable for the creation of polymer monolayers. As far as step polymerization reactions are concerned, polycondensation reactions have also been used for the preparation of monolayers consisting of terminally anchored polymer chains. However, the layer thicknesses obtained from these polymers are usually limited for thermodynamic reasons. An alternative solution for the preparation of surface-attached high molecular weight polymer chains by condensation reactions is a discontinuous process in which A-A and B-B monomers are added sequentially to form the polymer chains in a monomer-by-monomer assembly. The advantage here is that in each step the substrate with the growing reactive site may be exposed to an excess of monomer pushing the equilibrium at each step towards a complete reaction.
In the present work we follow such an approach for the formation of step-by-step polyaramide monolayers and study multi-step condensation reactions for the formation of surface-attached high molecular weight polyaramide films.

Experimental

The substrate (silica wafers) is activated in a first step by a silanation reaction which creates functional organic groups on the surface. These OH- or NH2-functionalized wafers are then sequentially dipped in a freshly prepared 10^{-3} M solution of diacid chloride in toluene (one drop of pyridine added) and a 10^{-3} solution of diamine in DMF with intermediate rinsing steps with DMF (see Fig.1). Finally the samples are washed with a mixture of NMP/ Hexamethylphosphoramide in order to asure that no monomeric or oligomeric compounds remain absorbed to the surface.

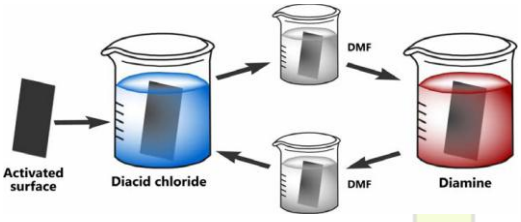

Figure1: experimental procedure for the preparation of molecularly controlled polyaramide layers

After every fifty reactions (i.e. attachment of 25 polyaramide units) an FTIR transmission spectrum of the wafer is recorded (figure 2).

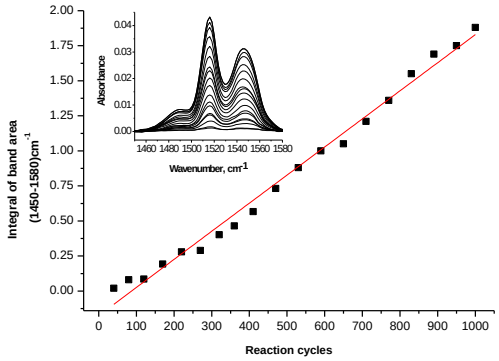

Figure 2: FTIR band area of surface-attached polyaramide monolayers in the region from 1580-1450 cm^{-1} as a function of the number of reaction cycles.

Results

It is found that polyaramide assemblies of well defined thickness and uniform topography can be synthesized by this step and repeat approach. IR, ellipsometry and AFM measurements demonstrate that the film thickness grows linearly with the number of dipping steps and that more than 1000 reaction cycles can be carried out without observing any decrease in film growth. This Merrifield-like approach of molecular assembly represents a very interesting mechanism of film growth as the layers consist of polymer chains in which the units are firmly attached to the surface and linked together either through covalent chemical links or through ionic interactions. This mechanism leads thus to a rather unusual form of formation of surface-atttached thin films. The described approach allows thus the preparation of molecularly designed assemblies of polyaramides with precisely controlled thicknesses. The synthetic effort required to generate these interesting systems is high, but might be lowered significantly through automatization of the dipping procedure.

erhasan@liverpool.ac.uk

We demonstrate the first example of the synthesis of core-branched ABC copolymer structures having incompatible functionalities such as tertiary amino and carboxylic acid groups.

The ABC branched copolymer was prepared using a one-pot ATRP approach. The ABC copolymer structure was composed of monomethoxy polyethylene glycol (PEG) as the A-block, poly(2-dimethylaminoethyl methacrylate) (PolyDMA) as the B-block, and the C-branched block was composed of poly (t-butyl methacrylate/ ethyleneglycoldimethacrylate)(Poly(t-BMA/EGDMA)) (Figure 1). The ABC linear block copolymer analogue was prepared in same approach in absence of ethyleneglycoldimethacrylate. The ABC copolymers were characterized using NMR and GPC.

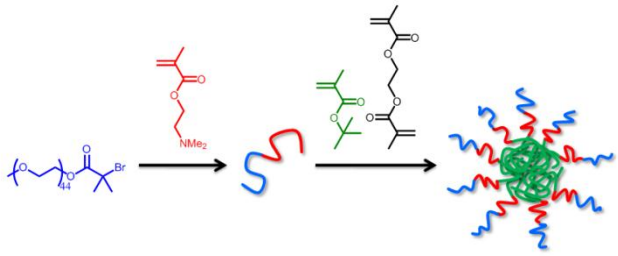

Figure 1

Both the linear and branched ABC copolymers were readily soluble in THF. DLS studies of the branched ABC structure in THF showed a well-defined single scattering mode with a radius of 12 nm, whereas the linear polymer in THF formed a poorly scattering system. Dialysis was used to form polymer nanoparticles with hydrophobic core and dual (inner/outer) shell. Both the linear and branched structures formed nanoparticles with spherical shape and hydrodynamic radius of 8 nm.

For the preparation of particles containing incompatible functional groups, hydrolysis of the poly(*tert*-butyl methacrylate) block of ABC copolymers to poly(methacrylic acid) was carried. In these ABC structures, there is the potential for interpolyelectrolytic complexation, depending on the degree of ionisation of the functional groups. The DMA group is known to have a pKa of about 7.0 while poly(methacrylic acid) is known to have a pKa of 4.9. To probe the differences in behaviour between the linear and the branched ABC polymers, the turbidity of solutions at different pH were measured.

Polyesteramide nanofibers – preparation and properties

Jiří Brožek[1], *Lenka Malinová*[1], *Václava Benešová*[1], *Daniela Lubasová*[2], *Lenka Martinová*[2], *Jan Roda*[1]

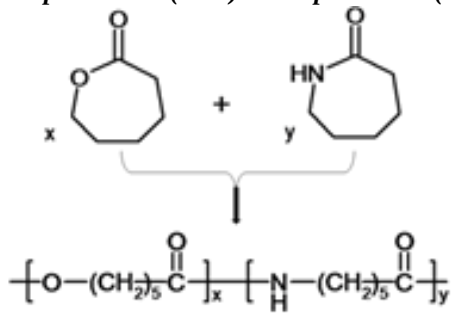
Jiri.Brozek@vscht.cz

Polyesteramides based on ε-caprolactam (CLA) and ε-caprolactone (CLO) – poly[(ε-caprolactam)-*co*-(ε-caprolactone)]s - seem to be very promising materials combining good mechanical properties of aliphatic polyamides with well-known degradability of aliphatic polyesters which makes them valuable candidates for biomaterials and environmentally friendly plastics. These polyesteramides can be prepared by an anionic[1-3] or a hydrolytic copolymerization[4] of CLA and CLO.

ε-caprolactone (CLO) ***ε-caprolactam (CLA)***



poly[(ε-caprolactam)-co-(ε-caprolactone)]

The application of ε-caprolactam magnesium bromide as an initiator of the ring-opening polymerization is rather exceptional[2,3] because it is possible to prepare copolymers containing equilibrium amount of unreacted monomers and low content of extractable portions. The copolymers thus prepared for further applications need no extraction. Glass transition temperature decreased monotonously with increasing content of lactone in the copolymer. It indicates that a random copolymer is formed. With increasing content of ester bonds in the copolymer, its impact strength and drawability increase, and modulus decreases.

Polyesteramides were subjected to biodegradation studies[5]. The hydrolyzability of PEAs increases with increasing fraction of ester bonds in macromolecules in accordance with the well-known higher sensitivity of ester bonds to hydrolysis compare to amide bonds. This was proved in both the composting tests as well as in abiotic hydrolysis test[5].

Polyesteramides prepared according to ref.[3] were used for the preparation of nanofiber sheets by electrospinning, i.e. a process for producing fibers the diameter of which is in the range below 1000 nm. In this process, fibers are formed by an action of electrostatic field from the surface of a polymer solution or melt and are put on a collector that acts as an anti-electrode. We have focused on solvent systems which allow one to prepare high aspect ratio nanofibers.

The solubility of the copolymer changes with its composition. With decreasing content of the CLO units, the polarity of the copolymer increases and the choice of the suitable solvents becomes narrower. The choice of the solvent plays an important role for electrospinning process. Polyesteramides containing from 10 to 40 mol.% of lactone structural units are soluble in polar solvents such as 1,1,1-trifluoroethanol, formic acid and formic/acetic acid mixed solvent system.

An example of very fine nanofibers prepared by electrospinning is shown in Figure for PEA with 30 mol.% CLO units.

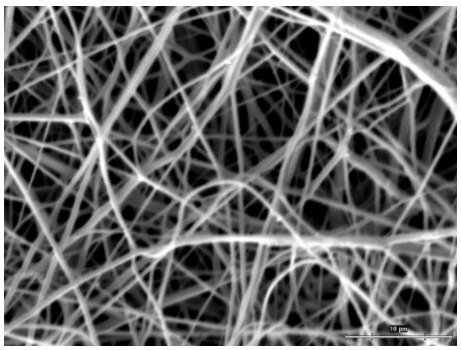


Figure: SEM image of nanofiber sheet prepared by electrospinning (polyesteramide containing 30 mol% lactone units, 10 wt.% solution, mixed solvent system formic/acetic acid 2/1)

The electrospinning process was influenced by system parameters such as solvent used, molar mass of the copolymer, its composition and solution properties.

Introduction

Acid polyurethane with COOH groups on its surface was functionalized with hydroxylapatite using a non-conventional synthesis route: hydrothermal method at high pressure (20-80 atm) and low temperature (60-100 ^{0}C). This technique allows formation of new phases and nanostructures and is frequently used for the preparation of inorganic nanomaterials which couldn't be obtained by solid-state fabrication route. Hydrothermal reactions take place in a sealed vessel, in aqueous medium and consist of dissolution-recrystallization of usually insoluble materials. In this study, hydrothermal reaction for hydroxylapatite (HAp) obtaining is accompanied by chemical reactions between newly formed HAp and water miscible polymer solution. In hydrothermal conditions, water and organic particles form a homogenous phase which represents an excellent reaction medium for the functionalization of inorganic nanostructures with organic polymers [1, 2].

Materials and Methods

Purity grade hydroxylapatite precursors, namely calcium nitrate tetrahydrate and ammonium dihydrogen phosphate were solubilized in water under a strict pH control, adding ammonium hydroxide as a mineralizing agent. The aqueous suspension thus obtained was further mixed with the polymer solution under vigorous stirring, followed by a hydrothermal treatment. Reactions were conducted in a closed system at low temperature (T < 100 ^{0}C) and high pressure (P > 20 atm) leading to nanostructured composite powders.

Results and discussion

The influence of pressure on the polyurethane (PU) and its bonding with hydroxylapatite has been of special interest in this study. Polymer structure is presented in figure 1.

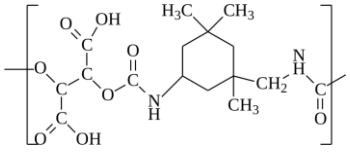

Fig. 1. Hard polyurethane-containing COOH groups.

Hybrid organic inorganic nanostructures have been prepared at various pressure values and characterized using chemical, structural and thermal methods. High-pressure synthesis could lead to structural and conformational changes of the materials, including a possible increase of H bond density in the polymer structure. The chemical structure was studied by FTIR spectroscopy and the results were corroborated with those obtained by physical characterization, *i. e.* XRD and HRTEM techniques. A representative HRTEM image is shown in figure 2.

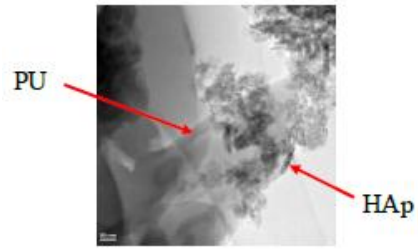

Fig. 2. HRTEM image of PU functionalized with HAp.

Thermal characterization (DSC) was used to investigate the morphostructural differences between hybrids prepared at different pressures. An example of DSC analysis at different heating rates is presented in fig. 3.

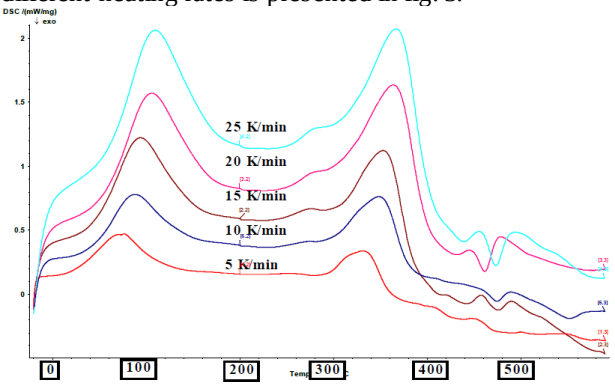

Fig. 3. DSC of PU-HAp composites at high pressures.

Conclusions

Nanostructured composites based on acid polyurethane and hydroxylapatite were prepared under hydrothermal conditions at low temperatures and high pressures. The organic/inorganic composites showed fine hydroxylapatite nano-whiskers incorporated into large polyurethane particles. Calorimetric analysis revealed the influence of pressure on chemical structure, conformation and morphology. A possible explanation could be that density of hydrogen bonds between macromolecular chains increase with pressure and in the same time the hard segmented polyurethane becomes more flexible, polar and able to interact with other molecules through carbonyl groups of the urethane structure (NH-CO-O).

Introduction

Fillers such as carbon black and silica are nanostructured: primary particles build up aggregates that can not be separated via thermomechanical mixing. Over the last years, new fillers have become available that can be dispersed in a matrix as individual particles having at least one dimension in the order of one or few nanometers. They are in fact known as nano-fillers and, among them, layered silicates[1] and carbon nanotubes[2] (CNT) are most investigated, both in the academic and industrial worlds, as a consequence of their outstanding properties.

This contribution is focused on CNT[3] and reports results from a research activity aimed at exploiting their huge potential in the frame of an easy large scale development.[4] A single nanotube is hundred times stronger than steel and has remarkable electrical and thermal conductivities. However, CNT are bundles, rather than single nanotubes, with a graphite inert surface. To disentangle them, developing an interaction with the matrix, for example with a polymer matrix, is still a main issue. In this work, morphology, dispersion and structure of CNT were investigated in thermoplastic and elastomeric polymer matrixes and in an aqueous dispersion medium. The synergy between CNT and a further filler was studied by using: (i) furnace carbon black in an elastomeric matrix, and (ii) an original polymeric filler polynorbornene (PN) nanoparticles in a thermoplastic matrix as well as in liquid dispersions. A poly-1.4-cis-isoprene was selected as the elastomer and an ethylene/1-octene copolymer as the thermoplastic polymer. Mixing energies and the known latex approach were primarily applied to improve the CNT dispersion, whereas hybrid filler networks, formed by CNT and the other filler, were studied as promoters of improved material properties. Dynamic-mechanical and electrical properties of the composite materials were determined, in particular assessing the percolation threshold of CNT and CNT/other filler systems. Investigations were performed with the help of transmission electron microscopy (TEM), tensile and dynamic-mechanical tests, measurements of square sheet resistance. Results are correlated with the filler structure: individual particles or aggregates or hybrid filler networks. This contribution proposes a comparative and comprehensive analysis of CNT features and behaviour in the most typical frames (thermoplastic and elastomeric matrixes and liquid dispersions) and, in particular, discusses the hybrid systems as a way to achieve an easier dispersion of CNT.

Materials and Methods

Multiwall CNT were Baytubes® C150 P from Bayer Material Science, with a chemical purity ≥ 95 wt.%, a length in the range 1-10 μm, a number of walls between 3 and 15 and outer and inner diameters of 1–16 nm and 4 nm, respectively. Synthetic cis-polyisoprene was from Nizhnekamskneftechim Export, with 70 Mooney Units (MU) as Mooney viscosity (ML(1+4)100°C). PN-based nanoparticles were obtained by freeze drying a SDS-stabilized latex prepared according to literature procedure.[5] Polymer composites were prepared via blending in an internal mixer.

Results and Discussions

CNTs were not homogeneously dispersed in a polymer matrix in the absence of a further filler; however, they were able to build up a network at a content (≅ 3 wt.%) much lower than that of a traditional filler. Mixing in a elastomeric matrix was found to favour dispersion and disentanglement of CNTs, that were also broken to shorter tubes. A further compatible filler, such as carbon black, brought to the formation of a hybrid filler network at a CNT level (≅ 1 wt.%) lower than that obtained for CNTs alone. Also the polymeric filler was observed to favour the formation of a CNT-based network. All these conclusions are based on both dynamic-mechanical and electrical measurements and are supported by TEM observations. A good correlation between formation of CNT-based networks and improvement of material properties, such as reinforcement and electrical conductivity, was found.

The latex approach was confirmed as a powerful tool to achieve nice CNTs dispersion: in particular, CNT pre-treatment with a surfactant, its dispersion/sonication and obtainment of a hybrid emulsion system with CNT and PN nanoparticles led to latexes that were either used to prepare coatings or, through liofilization, added to a thermoplastic polymer matrix. Correlation between CNT dispersion and material electrical conductivity, at a very low CNT level, are discussed.

Conclusions

Different approaches to achieve CNT dispersions, exploiting their unique properties were *vis a vis* investigated. In particular, the development of hybrid filler systems appears as a way to allow an easy development of CNT-based materials.

Abstract

This contribution presents several hybrid materials showing different properties based on cellulose nano whiskers and chitosan functionalized with different organofunctional silane compounds. The obtained materials were characterized concerning their surface composition and their interaction abilities (Contact angle, surface free energy) and also their morphology (Atomic Force Microscopy). It is shown that properties of these materials can be tailored over a wide range choosing different organofunctional silane compounds.

Introduction

For material scientists, the combination of organic and inorganic materials offers an enormous range of possibilities to combine the functional variety of organic chemistry with advantageous properties from inorganic compounds such as thermal stability. [1] The idea of creating hybrid materials on the basis of modified polysaccharides and organofunctional-silanes has been a fascinating topic of research [2][3], during the past decades and many applications have been described e.g. as precursors for enzyme immobilization [4], for encapsulation of biomolecules in silica gels [5], anti-adhesive and antibacterial multilayers [6], bifunctional catalyst [7].

Cellulose is the most abundant natural polymer in the world and consists of ß-1-4-linked D-Glucose units. Cellulose nanowhiskers can be prepared by controlled acid hydrolysis of cellulose fibers. The incorporation of those nano whiskers into nanocomposites is very attractive due to their nanoscale dimensions, high surface area, unique morphology, low density and mechanical strength. [8]

Chitin is a ß-1-4-aminoglucan and is after cellulose the second most abundant natural polymer in the world. Chitosan is the most important chitin-derivate. It is the only pseudo natural cationic polymer in the world and is used to prepare hydrogels, films and fibers and finds applications in the biomedical sector, whereas the biocompatibility is essential. [9][10]

Materials and Methods

Cellulose nano whiskers were prepared via sulphuric acid hydrolysis [8] Chitosan was dissolved in acetic acid. All organofunctional alkoxy-silanes were prehydrolyzed via acid hydrolysis with hydrochloric acid.

The hybrid materials were prepared via solution casting and spin coating on different substrates, whereas the amount of silane to polysaccharide was varied. The surface interaction abilities were characterized using contact angle measurements with three different liquids to calculate the surface energy with different models. The surface morphology was studied using AFM.

Results and Discussion

The contact angle measurements were performed using distilled water, diiodomethane and formamide. Different model approaches have been used to calculate the total surface energy and the polar and nonpolar surface contributions. According to the nature of the functional silane side-chains, the surface energy contributions are varying. By means of AFM, the root mean square roughness and the average roughness were calculated.

Conclusions

In summary, different kinds of functional hybrid materials were prepared and characterized. Depending on the silane to polysaccharide ratio, foils and composite materials could get obtained. The incorporation of silanes into the polysaccharide matrix enhances the mechanical properties of the materials as well as their thermal stability.

Nano-hybrid PDMA/silica hydrogels: from structure to mechanical properties

S. Rose, A. Marcellan, T. Narita, D. Hourdet

Physico-Chemistry of Polymers and Dispersed Media, UMR 7615, ESPCI

Severine.rose@espci.fr

Introduction

Hydrogels are cross-linked polymers forming a three-dimensional network highly swollen in aqueous environment. The low fracture toughness of these systems is a limiting factor for their potential applications molecular sieves, super absorbent polymers or contact lenses. Among the different reinforcement strategies of the mechanical properties of hydrogels, we chose to focus on the impact of inorganic nanoparticles in soft polymer networks. This concept came from Haraguchi in Japan who studied polymer/inorganic clay networks[1,2]. In our laboratory, we recently started to investigate the interactions between poly(N,N-dimethylacrylamide) and silica nanoparticles and their effects on the mechanical properties of PDMA/silica hydrogels[3,4].

Materials and methods

Hybrid hydrogels have been prepared at room temperature by free-radical polymerization in water of N,N-dimethylacrylamide (DMA) in the presence of silica nanoparticles (R=17 nm), using potassium persulfate (KPS) and N,N,N',N'-tetramethylethylenediamine (TEMED) as redox initiator. A chemical cross-linking agent was also used: N,N'-methylenebisacrylamide (MBA). Several weight ratios (silica/polymer and polymer/water) and several amounts of covalent cross-linking agent were tested, keeping constant the molar ratio DMA/KPS/TEMED.

Results and discussion

Swelling experiments, performed in water and salt solutions, show that the swelling ability of the network decreases with the amount of added particles (Figure 1). These results clearly indicate that silica beads really behave as physical crosslinkers by strongly interacting with PDMA chains.

The mechanical behaviour of hydrogels was characterized using monotonic tensile tests, loading-unloading cycles and stress relaxation.

The introduction of silica highly increases the stiffness of the network, in agreement with the strong interactions taking place between PDMA chains and silica surfaces. Non-linear behaviours were also pointed out with softening at small deformation and hardening at high strain related to finite chain extensibility (Fig. 1). All these effects have been shown to strongly depend on silica content. The analysis of hysteresis and residual strains induced by cycles, clearly indicate that contrary to chemical cross-linkers, hybrid interactions increase the dissipative process. Life-time PDMA-Silica interaction seems to be key-aspect in these mechanical properties. (Fig. 2)

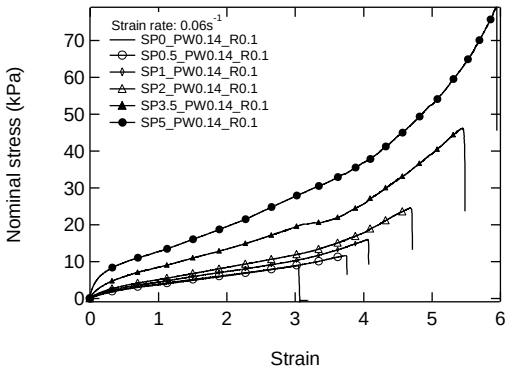

Fig. 1: Typical tensile stress-strain curves ($\dot{\varepsilon}$ ~0.06 s^{-1}) effect of filler content

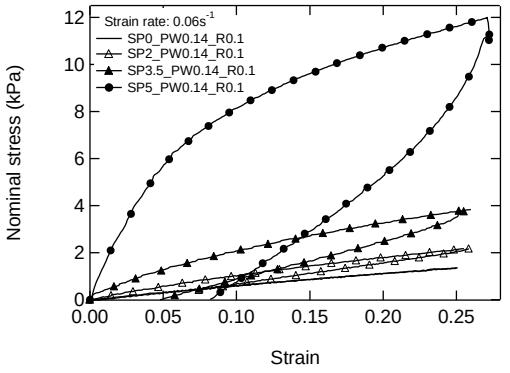

Fig. 2: First loading-unloading cycle, εmax=0.25 ($\dot{\varepsilon}$ ~0.06s^{-1})

Finally, the internal structure of hydrogels and the distribution of inorganic particles inside the organic matrix were also investigated by small angle neutron scattering. The dynamic properties at small lengths and short time scales of the networks were studied by dynamic light scattering.

Conclusion

We have successfully shown a strong and reversible interaction between PDMA and silica particles. We pointed out that silica nanoparticles greatly enhance the mechanical properties of hydrogels, keeping a high deformability.

Structure/highly electrical conductivity relationships of gold nanowires/P(VDF-TrFE) nanocomposites

Antoine Lonjon[1], Lydia Laffont[2], Philippe Demont[1], Eric Dantras[1], Colette Lacabanne[1]

[1] Physique des Polymères – Institut Carnot CIRIMAT Université Paul Sabatier, Toulouse, France
[2] Institut Carnot CIRIMAT, ENSIACET, Toulouse, France

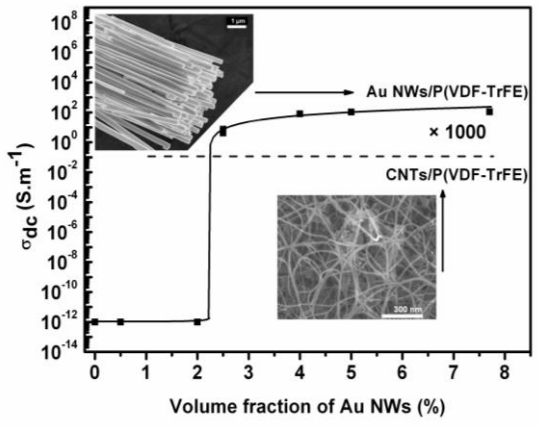
lonjon@cict.fr

A low content of conductive fillers can significantly improve the electrical properties of an insulating polymeric matrix. These improvements are achieved through conventional processing techniques without any negative effects on mechanical behavior of the matrix. Typical mixed fillers into polymer matrix are carbon black, CNTs and metal particles. These studies showed that electrical and mechanical properties of reinforced polymer composites depend on many factors; such as particles intrinsic properties, dispersion quality, orientation, interfacial adhesion, aspect ratio and filler content. The dispersion quality was especially well-known as one of the most important factors in electrical properties with specific difficulties to control it in nanocomposites. Experimental percolation threshold was known to be strongly dependent on the apparent aspect ratio of the filler and not on their nanometric size. Very low percolation threshold were obtained with introduction of CNTs with aspect ratio ζ higher than 100 and even 1000. The literature reaches a consensus: above the percolation threshold (<5 vol %), the conductivity value of CNTs composites levels off at an upper limit[1] of about 10^{-1} S.m^{-1}. Metal nanowires (NW) have attracted much attention because of their specific properties such as intrinsic electrical conductivity.

In order to obtain higher electrical conductivity, the introduction of metallic nanowires, with a good aspect ratio sounds pertinent[2]. In this study, gold nanowires were prepared in order to elaborate high conductive nanocomposites at low Au NW volume fractions to preserve the mechanical properties of the P(VDF-TrFE) matrix. Gold nanowires were synthesized by electrochemical way giving a uniform high aspect ratio ($\zeta \sim$ 200). AuNW polymer composites were elaborated by addition of AuNW in a PVDF-TrFE matrix[3].

The conductivity of melt-pressed nanocomposite films has been studied as a function of AuNW volume fraction and it shows a very low percolation threshold (p_c) near 2.2 vol%. At the percolation threshold p_c, the volume electrical conductivity of nanocomposites exhibits a critical behaviour from 10^{-12} S.m^{-1} to 10^{2} S.m^{-1}. The influence of process on the percolation threshold value was studied. It is crucial to emphasize that electrically percolated AuNW nanocomposites reach an electrical conductivity 10^3 times higher than the one of CNTs namocomposites independently of the process. Despite moderate aspect ratio regarding CNTs, metallic nanowires represent a very promising route for improvement of the electrical conduction in polymer matrix composites

The increase of Au nanowires volume fraction on the morphology and crystallization of P(VDF-TrFE) matrix was investigated by differential scanning calorimetry[4].



Moreover, the surface resistivity of spray coatings has been studied as a function of AuNW volume fraction and it shows the existence of a very low percolation threshold around 2 vol%. The surface resistivity above the percolation threshold reachs a low value near 4 Ω/□. This value is more than 1000 times lower than sprayed CNT coating.

Design of "All-supramolecular" nanocapsules made of low-molecular weight bis-ureas through interfacial reaction in miniemulsion

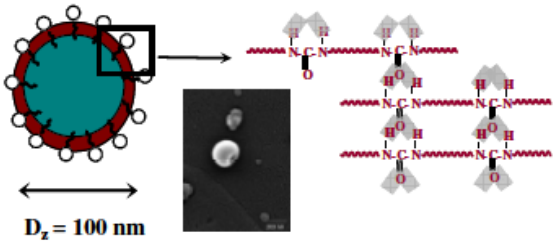
E. Groison, S. Adjili, A. Ferrand, F. Lortie, N. Sintes-Zydowicz and D. Portinha

Université de Lyon, INSA-Lyon, UCBL, CNRS, France

daniel.portinha@insa-lyon.fr@insa-lyon.fr

Introduction

The preparation of polymeric nanocapsules has attracted an intense interest in recent years due to their potential applications in fields such as controlled drug-delivery or contrast agents. In this frame, the miniemulsion process represents a well-suited strategy, due to its versatility making it possible to obtain oily or aqueous-core with different kind of polymers (vinylic, urethane, urea…) as the membrane [1-3] However, the major limitation of polymer-based nanocapsules is the lack of permeation pathway through a high molecular weight polymer membrane [4] This contribution presents a new strategy for preparing nanocapsules with a shell made of a supramolecular polymer which repeating units are held together by reversible interactions rather than covalent bonds [5]. These nanocapsules were prepared in classical miniemulsion through interfacial addition reaction of a diisocyanate (IPDI) and a monoamine (iBA), forming low-molecular weight bis-ureas moieties (M1) which are strong self-complementary interacting molecules through hydrogen-bonding. As a comparison, a diamine (DAB) was used to prepare oligo/polyurea-based nanocapsules (M2).



Materials and Methods

Chemicals were purchased from Aldrich and used as received. For preparing the miniemulsion, SDS (3wt% relative to the organic dispersed phase) was added to deionized water. A mixture of cyclohexane containing hexadecane (3wt%) and IPDI (10wt%) was added under magnetic stirring to the aqueous phase. The miniemulsion was then prepared by ultrasonifying the previous emulsion for 5 min. An aqueous solution of iBA was continuously added using a syringe pump operating at a flow rate of 1 ml/min, under magnetic stirring. The reaction mixture was then maintained under magnetic stirring at room temperature for 4 hours. SEM experiments were performed on a Hitachi S800. The size distribution of the nanocapsules was determined by DLS on a Malvern Nanosizer ZS. ^{1}H NMR analyses were recorded on a Bruker Avance II 250 spectrometer in d_6-DMSO at 298K. MALDI-TOF MS experiments were conducted using Voyager-DE PRO equipped with a N_2 laser (λ = 337 nm). The spectra were recorded in reflection mode.

Results and Discussion

Oily core low-molecular-weight urea-based nanocapsules were successfully obtained through interfacial reaction in direct miniemulsion between a diisocyanate and a monoamine. The control over the stability of the latex and the absence of any coagulum require a careful adjustment of the rate of addition of the amine to the miniemulsion. For the dimensions of the nanocapsules, measured by DLS, M1 nanocapsules present a D_z around 100 nm with a low PDI (0.11), while the M2 nanocapsules present a higher mean-diameter (150 nm) with a less well-defined distribution (PDI = 0.15). SEM pictures for M1 system show dented nanometric spherical objects attesting for their internal cavity, which dimensions are in the same order of magnitude than the values determined by DLS. Surprisingly, the nanocapsules from M2 could not be observed, as if the membrane was so brittle that it could not resist to the preparation of the SEM sample. Then the nanocapsules membranes were characterized by ^{1}H NMR and MALDI-TOF MS. The spectrum for M1 presents one main peak at m/z equal to 391.4 Da and some other peaks (at 587.4 and 783.6 Da) which global contribution is very small. The first peak corresponds to the cationized bis-urea molecule (MNa+), whereas the quite less intense peaks correspond to tris and tetra-urea resulting from the reaction between IPDI with isophorone diamine, the side-product of the IPDI total hydrolysis. Because of similar structures, the relative intensities of the peaks can be considered as indicative of the mixture composition. For M1, the membrane is composed of more than 95% of bis-urea molecules. In addition, the thorough examination of the ^{1}H NMR spectrum obtained for the M1 sample confirms that the membrane is mainly composed of bis-ureas, and hence asserts the MALDI-TOF MS results. For M2, MALDI-TOF spectrum of nanocapsules reveals many peaks between m/z 311.1 and 1884.4 Da, attesting that oligomers were formed: one set of peaks can be ascribed to the products of the polyaddition of the IPDI on the DAB (Δ(m/z) = 310 Da), with isocyanate and amine groups as chain ends. Another peak at m/z equal to 507.1 was also observed and assigned to a minor species.

Conclusions

This strategy opens the scope of a new type of nanomaterials exhibiting stimuli-responsiveness due to the reversible interaction linking the repeating units.

Introduction

Block copolymer materials have attracted a great deal of attention in the last decades due to their ability to self-assemble into different nanostructures[1-2]. While in polymer blends the constituting polymers separate at macroscopic scale ruled by enthalpic/entropic phenomena, in block copolymers the phase separation occurs in the nanometre range taking advantage of the covalent bonding between the constituting blocks. In fact, the immiscibility of the constituent blocks is responsible for this ability of block copolymers to self-assemble into well-defined ordered nanostructures with domain dimensions of 5-100 nm. The obvious interest in using these materials for patterning lays on their ability to self-assemble forming a dense array of nanostructures having dimensions and spacing which are difficult to obtain by other ways, or are prohibitively expensive to fabricate using conventional lithographic processes.

In this work di-block copolymers based on aliphatic polyesters such as polylactic acid (PLA) and poly(ε-caprolactone) (PCL) have been synthesized and characterized (PCL-b-PLA), based on the idea that both PLA and PCL are biodegradable and biocompatible polyesters[3-5] and promising materials in regenerative medicine as they degrade through hydrolytic scission of the ester group. Moreover, both of them present good processability, mechanical properties and shape memory effects.

Materials and Methods

PCL-b-PLA block copolymers have been synthesized by ring opening of the corresponding lactones using tin octoate as catalyst. After the polymerization of PCL with n-butanol as initiator to obtain different lengths, L-lactide has been added in different percentage. The copolymerization of the PCL-b-PLA block copolymers has been obtained at 180 ºC for 3 h.

Solution ^{1}H-NMR was recorded at room temperature for $CDCl_3$ on a Varian Unity Plus 300.

Matrix-assisted laser desorption ionization time-of-flight (MALDI-TOF) spectra were obtained by using a Voyager DE-PRO time-of-flight mass spectrometer (Applied Biomaterials) in the linear mode.

SAXS measurements were taken at beamline BM16 at the European Synchroton Radiation Facility (Grenoble, France).

Differential scanning Calorimetry (DSC) was performed in a Mettler Toledo 800. Samples were sealed in perforated aluminium pans. Two heating scans have been performed at 10 ºC/min.

Atomic Force Microscopy (AFM) analysis has been performed by Nanoscope IV of Digital System.

Results and Discussion

In order to make a deep analysis on the morphological changes and how the nanostructurable architectures of PCL-b-PLA block copolymers can be changed, different PCL-b-PLA block copolymers have been synthesized.

Taking into account that the self-assembled ability of block copolymer materials is influenced by their Flory-Huggins interaction parameter χ, their molecular weight, the volume fraction of the block Φ, and also by the conditions of preparation, the PCL-b-PLA block copolymers have been synthesized varying both the length of the blocks as well as the molecular weights of each block.

The chemical structure has been analysed by nuclear magnetic resonance spectroscopy, NMR and MALDI TOF experiments facilitating assignment of the block-length and the molecular weights of each synthesized PCL-b-PLA block copolymer.

The block nature of the synthesized copolymers has been demonstrated by NMR.

Morphological structure has been studied by Atomic Force Microscopy (AFM) and compared with the results obtained by Small Angle X-Ray (SAXS) experiments.

The influence of the nature of the block copolymer and the amount of each block in the amorphous and/or crystalline nature of the PCL-b-PLA block copolymers have been verified by DSC thermograms and SAXS experiments.

Finally, both the different amount such as the different length of the blocks influences the degree of crystallinity of the synthesized PCL-b-PLA block copolymers.

Conclusions

PCL-b-PLA block copolymers with different block lengths as well as different molecular weights have been synthesized. In general both Tc and Tm of PLLA blocks are affected by the presence of PCL. So, the degree of crystallinity of PLLA decreases by increasing PCL content. Moreover the amount and molecular weight of PCL influences the morphology as well as the crystallinity of PCL-b-PLA block copolymers.

Introduction. The sharp increase in electromagnetic pollution due to the fast development of gigahertz electronic systems and telecommunications justifies a very active quest for effective electromagnetic interference (EMI) shielding materials. Most of the time, metallic boxes are used as shielding materials, acting as EMI reflectors and not as absorbers[1]. As an alternative, polymers filled with carbon fillers[2] (e.g., carbon black, carbon fibers and carbon nanotubes) have been extensively investigated for EMI shielding purposes because of unique combination of electrical conductivity and polymer flexibility. The use of carbon nanotubes (CNT) offers substantial advantages over conventional carbon fillers because they can simultaneously enhance the electrical conductivity and reinforce the mechanical performances of the filled polymers.[3] A major drawback of CNT/polymer nanocomposites[4] is a high propensity to reflect EM radiations instead of absorbing. For the particular case of electronic device protection, the emitted wave does not cross the composite material, but EMI prevails in the inner volume as a result of multiple reflections from the walls, that may alter proper operation of the device (cf. fig. 1).[5]

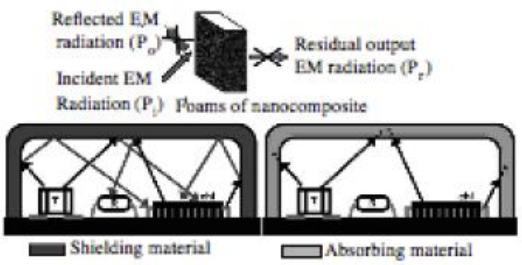

Fig. 1: a) Behavior of MWNT/polymeric foams under EMI radiation, b) schematic differences between an EMI shielding material which only reflects the wave and an EMI absorber in an electronic device.

For an EMI shielding material to absorb electromagnetic radiations, its dielectric constant must be as close to that of air as possible.[5] A straightforward approach to this highly desirable situation relies to foaming of CNT containing polymers. The relative volume of air in an open-cell foam is high, and therefore favorable for the matching of the wave impedances of the expanded material and the ambient atmosphere.

Results and Discussion. This communication reports on the preparation of novel nanocomposites foams that are efficient broadband microwave absorbers.[7] Multi-walled carbon nanotubes (MWNT) are first successfully dispersed into polymer matrix by melt-blending as confirmed by TEM microscopy and rheology. Then foaming of these nanocomposites[8] occurs under supercritical CO_2 conditions by a two-step process.[9] This physical foaming constitutes a green alternative to classical foaming agents.[10] Well-defined microcellular foams[11] were obtained with cell size around 10-50 µm and cellular density around 10^8 cells per cm3, the morphology of the foam was determined by SEM microscopy. The impact of several criteria on the morphology of the foam will be discussed. The EMI shielding efficiency of these materials are then evaluated and compared to the non-foamed nanocomposites. Finally, we will discuss about the design of the foam that is essential to optimize the performances of the EMI absorber.

Conclusions. New nanocomposite materials with high electromagnetic wave absorption effectiveness have been successfully prepared with the use of supercritical CO2 as the foaming agent. It was found that adding voids into the nanocomposite improved substantially the wave absorptive capacity, thus reducing greatly the signal reflection. The resulting material is also much lighter and more flexible than metallic counterparts currently used, making them very attractive from an industrial point of view.

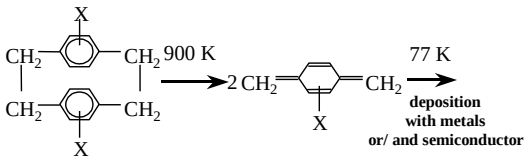
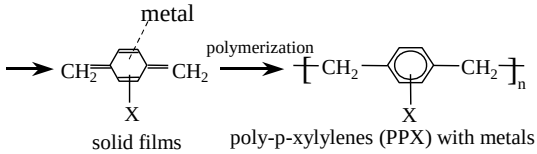
Hybrid polymer/metal(semiconductor) nanocomposites are of great interest recently. Low cost, the simplicity of preparation, the wide spectrum of stable properties are the critical points for possible applications of hybrid nanocomposites as photovoltaic solar cells, light emitting diodes, magnetic media storage capacity, chemical sensors and others. It is important that, the properties of hybrid nanocomposites depend not only on the Coulomb blockade phenomenon and on the quantum size dependent characteristics of low-dimensional metal and semiconductor nanoparticles or nanowires, but on the interaction in the assemble of clusters, its structure and on the nature of interface between the polymeric matrix and the nanoparticles. The new VDP-based method of synthesis of hybrid nanocomposites, their structure and their electronic, magnetic, photophysical and sensoric properties will be presented.

The vapors of monomer of p-cyclophanes and of the various metals or semiconductors were simultaneously deposited in the vacuum on the substrate cooled by liquid nitrogen. The active intermediate were prepared by pyrolysis of cyclophanes at 650-700°C (Gorham's method) the metal or semiconductors were evaporated thermally or by e-beam sputtering. The following heating of the prepared cocondensate is accompanied by the several simultaneous processes, such as the polymerization and crystallization of matrix and the aggregation on inorganic into nanoparticles or into nanowires. The schematic of process is presented in the figure.



p-cyclophanes (vapor) p-xylylenes (vapor) (PX)



solid films poly-p-xylylenes (PPX) with metals

The thin films containing the nanoparticles of metal (Ag) and semiconductor (PbS) were prepared.

The processes of polymerization and structural organization were studied by the complex of experimental methods including UV-spectroscopy, X-ray diffraction, DSC and AFM.

On X-Ray patterns of samples, containing less, than 10 % of silver, a wide diffuse maximum, corresponding to d-spacing d ~ 0.23 nm, was observed. With increasing metal concentration, reflections 111 and 200 of silver crystal lattice, become narrower to be resolved. Correspondingly, average crystallite size increases from 2.5 to 5.0 nm.

Crystal structure of PPX is presented by a mix of β- and α-modifications, the former one being dominant. Simultaneous co-condensation of polymer and inorganic component lead to the formation of composite material, characterized by dominance of α-form in PPX matrix. This can be explained by the influence of "hot" silver atoms on PPX polymerization process.

Small-angle X-Ray studies showed, that scattering curves of composite materials with silver content less than 4% or more, than 8%, are well described by compact particle scattering model of 4nm and 6nm in size correspondingly. High-temperature vacuum annealing of the samples (30 min at 150 ºC) lead to the recrystallization of polymer matrix and to the growth of silver particles.

The structural investigations of PbS/PPX nanocomposite films showed the presence of inorganic nanoparticles embedded in the polymer matrix. Five reflections (111, 200, 220, 311, 222) corresponding to crystal lattice of PbS along with intense reflection of PPX were observed. At low concentration the PPX is polymerized in β-form and at higher concentration it formes α-structure as in the case of silver nanoparticles. The average crystallite size of PbS estimated from halfwidth of reflection 220 is equal approximately to 4.5 nm.

The presence of crystalline reflections and amorphous halo of PPX on diffraction pattern points to the semicrystalline structure of polymeric matrix. Note that the lateral crystallite size of polymer lamellae exceeds 20 nm and is significantly larger than the crystal size of inorganic compound. The volume distribution is narrow with maximum at app. 4 nm; the main population of PbS crystallites has a size much less than 10 nm. The distribution curve for the nanocomposite containing 4.7 vol.% of PbS is well described by a lognormal distribution. For higher concentrations the distribution is bimodal and each mode is described by normal distribution. We can propose mechanism of inorganic particles formation based on the shape of size distribution. The lognormal distribution corresponds to the Brownian coagulation models and in the case of normal distribution the particles formation is due to particles diffusion during the polymerization and crystallization of the polymer matrix.

The slope of the tail part of SAXS curve of PbS/PPX equals to -4.8, which is typical for the dense three-dimensional particles with the interface on the boundary.

Relaxation Dynamics in Ultrathin Polymer Films Investigated at the Nanoscale

K. H. Nguyen[1]*, *D. Prevosto*[2], *M. Labardi*[2], *S. Capaccioli* [1,2], *M. Lucchesi*[1,2], *P.A. Rolla*[1,2]

*Email address: nguyen@df.unipi.it

Ultrathin polymer films with thicknesses of tens of nanometers have been used as an ideal sample geometry for studying the effects of one-dimensional confinement and polymer-substrate interactions on the morphology and dynamics of the polymeric materials. These effects on dynamic relaxation of ultrathin polymer films have been investigated effectively on macroscopic scale using a variety of techniques[1]. Some attempts to detect the local dielectric response have been recently performed by using electrostatic force microscopy technique. In this technique, one electrode is represented by the conductive substrate where the sample is deposited, and the second electrode is the conductive probe tip of an atomic force microscope (AFM). Most implementations until now have been exploited to measure dielectric constant of thin insulator films[2]. A possible approach to obtain highly local measurements of dynamics of ultrathin films is the local dielectric spectroscopy (LDS)[3,4].

LDS has been implemented by means of an atomic force microscope (AFM)-based method named frequency-modulated electrostatic force microscopy. In essence, an excitation voltage, $V(t) = V_{ac} \cos(\omega t)$, is applied to the conductive probe of the AFM, producing an electric field in the sample region close to the probe, which induces dielectric polarization. The force field due to interaction of the charged probe with the polarized sample induces a variation of the cantilever resonant frequency. This variation at the second harmonic, 2ω, which is related to the dielectric polarization of the sample, is measured in amplitude and phase. Information on the dielectric relaxation can be then obtained. We applied this technique to study the change in structural dynamics of poly(vinyl acetate) (PVAc) at different interfaces, such as in presence of silicate nanoparticles with high spatial resolution[4] and in ultrathin polymer films deposited on a metallic substrate.

In particular, ultrathin polymer films with a free upper surface have been studied for different values of thickness, temperature and over different substrates, in ambient pressure and controlled atmosphere (relative humidity less than 8%).

An increase in dynamics of PVAc films coated on gold has been detected when film thickness decreases down to 35 nm (Fig. 1). At smaller thicknesses the deviation respect to the bulk becomes even larger but not greater than a factor 2 for films of 18 nm thickness[5].

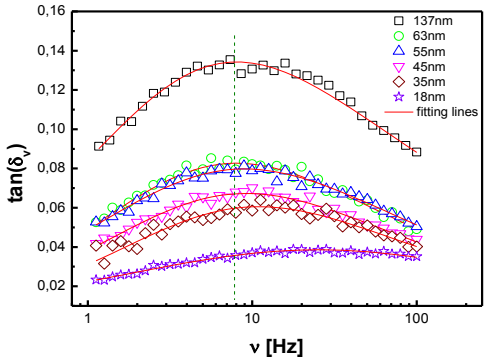

Fig. 1. Frequency dependence of the phase shift spectra ($\tan\delta_v$) on ultrathin PVAc films with different thicknesses, deposited on gold substrate, at the temperature of 324.6 K.

Tuning Thermomechanical Properties of Polystyrene/Polybutadiene-Based Thermoplastic Elastomers by Grafting Crystallizable Side Groups

Julie Prévost[1], *Minh Ngoc Nguyen*[1], *Ilias Iliopoulos*[1], *Ludwik Leibler*[1]

[1]Matière Molle et Chimie, ESPCI ParisTech (ESPCI-CNRS, UMR 7167), 10 rue Vauquelin, 75005 Paris (France)

julie.prevost@espci.fr

Thermoplastic elastomers are of the most successful examples of nanostructured polymeric materials with numerous applications (automotive, footwear, bitumen modifiers, adhesives…)[1]. Polystyrene-*b*-Polybutadiene-*b*-Polystyrene (SBS) triblock copolymer is the archetype in this category. Because of the incompatibility between the hard (PS) and soft (PB) components, microphase separation occurs, resulting in the dispersion of polystyrene domains in a polybutadiene matrix. We propose here an efficient and easy route to tune the properties and the temperature responsiveness of these processable elastomers by grafting crystallizable side groups on the PB block.

The thiol-ene coupling is used to attach crystallizable 1-octadecanethiol (C18) on SBS. The free-radical addition of C18 on the double bonds of the PB block proceeds in solution, in the presence of an initiator, and leads to high yields. Depending on the initial amount of thiol, the degree of functionalization can be modulated in the range from 4 to 30 mol% (referring to all monomer units).

By differential scanning calorimetry (DSC), we show that the thiol-ene coupling yields to graft copolymers with modulable crystallization temperatures by varying the graft content. Dynamic mechanical analysis (DMA) shows a large increase of the glass transition of the modified block and a sharp transition of the storage modulus around the melting temperature, upon grafting C18 (figure 1). While thermal and mechanical properties of the neat SBS are largely affected by grafting alkyl side chains, the cylindrical morphology of the neat SBS is preserved even with high degrees of grafting (figure 2).

In conclusion, the thiol-ene coupling is a simple and robust strategy to graft crystallizable alkyl side chains on SBS and therefore incorpore an additional thermal transition in a classical thermoplastic elastomer. We obtain nanostructured crystallizable graft copolymers with tunable thermomechanical properties by varying the graft content.

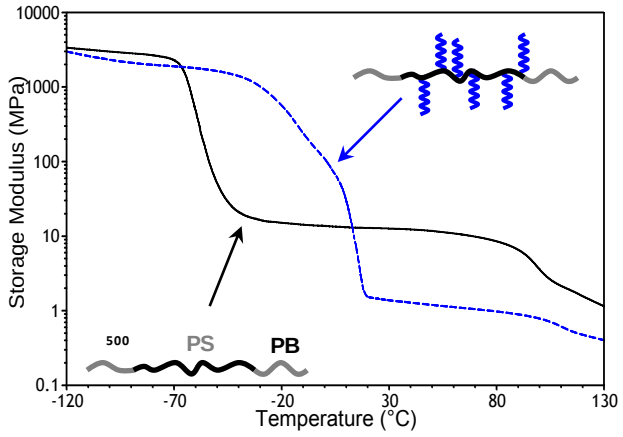

Figure 33: Storage modulus (E') as a function of temperature at 1Hz for the neat (full line) and graft SBS (50 wt % of C18) (dashed line).

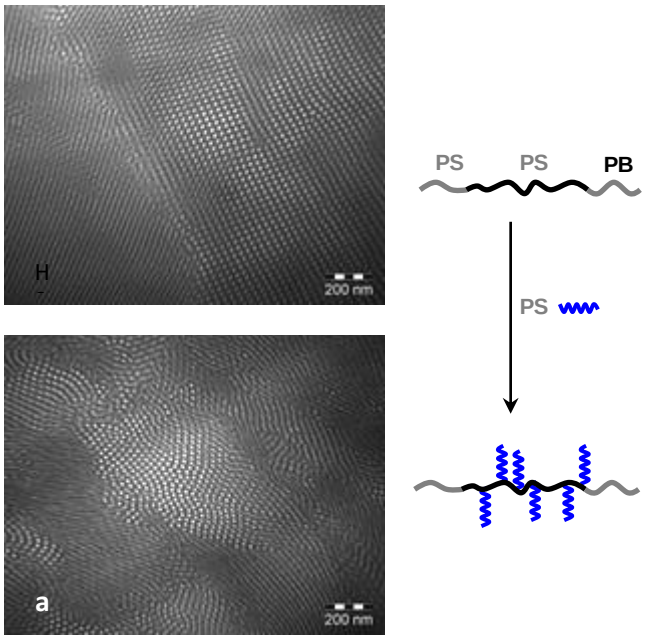

Figure 34: TEM micrographs of films prepared by solvent cast from toluene solutions followed by annealing at 180 °C for 48 h. Copolymers were stained by OsO_4. a) SBS, b) graft SBS (50 wt % of C18).

Introduction

The preparation of multi walled carbon nanotube (MWCNT) composites has received a substantial amount of attention during recent years. It is well known that functionalization of MWCNTs facilitates dispersion of the nanofiller in composite materials. However, there are few examples in the literature where the conductive properties of composites containing functionalized CNTs have been investigated. In these cases it has been shown that the functionalization has had a detrimental effect on the conductive properties of the composite.[1,2]

Here we present a method for functionalization of MWCNTs with poly(ethylene-co-butylene), which is a well known compatibilizer for polypropylene, though to our knowledge has not been used on MWCNTs.

The objective was to exploit the good properties of the compatibilizer to produce composites of functionalized MWCNTs with a relatively low degree of functionalization. The hypothesis was that good dispersion would still be obtainable due to the functionalization, while other properties such as conductive properties and potentially also mechanical improvements would not be substantially deteriorated or possibly even improved.

Methods and Materials

MWCNTs with an average diameter of 9.5 nm and average length of 1.5 µm were purchased from Nanocyl S. A. (Belgium). Poly(ethylene-*co*-butylene)-OH (M_n=7000 g/mol, Kraton Liquid Polymer L-1203) was acquired from Kuraray Co., Ltd. (Japan), all other chemicals were purchased from Sigma-Aldrich and used as received.

Results and Discussion

In the presented study a functionalization method based on nitrene chemistry, which is well known in functionalization of CNTs,[3] has been applied to obtain a low degree of functionalization of poly(ethylene-co-butylene) on an industrial grade MWCNT. For this purpose an azide functional poly(ethylene-co-butylene) was synthesized and coupled to the MWCNT as shown in Figure 1.

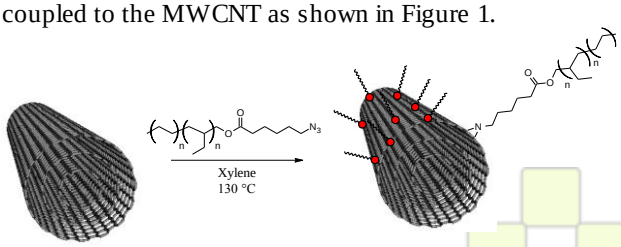

Figure 35: Preparation of Poly(ethylene-co-butylene) modified MWCNT (f-MWCNT).

The functionalization of the f-MWCNT was confirmed by both Raman spectroscopy as well as TGA. PP composites of both pristine as well as the f-MWCNT was prepared in a two step procedure, applying a new masterbatch procedure followed by extrusion on a miniextruder. The PP composites where prepared with a varied concentration of both pristine and f-MWCNT from 0.1 wt% to 1 wt%.

The composites were characterized by both rheology and dielectric resonance spectroscopy (DRS) to describe the extent of dispersion, effects of concentration as well as the conductive properties as shown in Figure 2 for DRS. The f-MWCNT/PP composite was found by DRS to have a percolation threshold below 0.3 wt%.

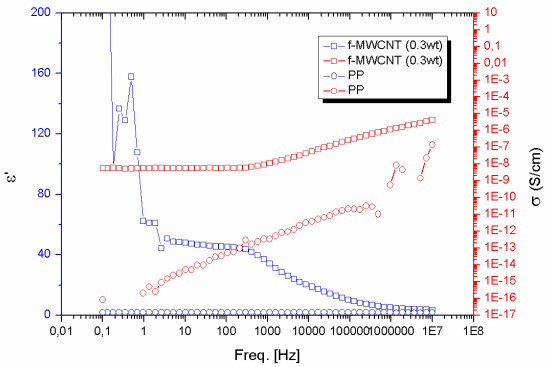

Figure 36: Dielectric resonance spectroscopy of f-MWCNT compared to PP.

Conclusions

A novel f-MWCNT/PP composite was prepared and investigated. Well dispersed materials were prepared through a masterbatch procedure. The f-MWCNT/PP composites were found to have conductivity comparable to the pristine MWCNT/PP. A low percolation threshold was identified for both the modified and unmodified materials.

Electrosynthesis study of poly (N-methyl aniline)/Ag nanocomposite

S.M.Seyed mohaghegh, *F.Ansari*, *B.Najafzadeh*

Iran Polymer & Petrochemical Institute (IPPI) PO Box 14965/115, Tehran, Iran

s.m.mohaghegh@ippi.ac.ir

Introduction

Au Conjugated polymers were first extensively studied for their electrical conductivity and valuable optical and electroluminescence properties [1]. Polyaniline (PANI) occupies a very significant place among these materials because of its high conductivity in the doped state. Recent developments have shown that PANI and its derivatives can also be used in the field of polymer-based light emitting diodes as an interface layer between the metal electrode and the emitting polymer layer to ease charge injection [2].

The composites of conducting polymers, such as polyaniline (PANI), with noble metals find applications in electrocatalysis [3], catalysis [4], design of fuel-cell electrodes, sensors, conducting printing inks, recovery of noble metals etc [5].

Silver has recently received considerable attention in this respect. The first method has only been used exceptionally for modifying silver nanoparticles with PANI or substituted PANI. Composites of silver and PANI have been prepared by the direct reduction of silver nitrate with PANI or PANI derivatives.

Experimental

The electropolymerisation of polyaniline (PANI) and polyaniline/Silver (PANI/Ag) and poly (N-metylaniline) (PNMA) and poly (N- metylaniline)/silver (PNMA/Ag) was carried out in a conventional three electrode electrochemical cell. Gold (Au) disc electrode was used as the working electrode (WE). An Ag/AgCl electrode and a Pt electrode as the reference electrode (RE) and counter electrodes (CE), respectively. The (PANi/Ag) and (PNMA/Ag) nanocomposite film was synthesized by the Cyclic voltammetry (CV) using cell from 0.01 M $AgNO_3$ + 0.4M aniline + 1.0M HNO_3 solution at room temperature.

Results and discussion

It is rather easy to polymerize PANI/Ag, while polymerization of PNMeANI/Ag is more difficult. It is well known that alkyl substituted anilines are oxidized at lower potentials than aniline because the alkyl substituents increase the electron density of the aromatic ring (electron-donating effect). The N-substituted PANI, PNMeANI, has a different electrochemistry from PANI and the other alkyl substituted PANIs due to N-substitution.

It is also known that N-substitution decreases the electrical conductivity of PNMeANI in comparison with PANI. In order to determine the electrochemical property of PANI/Ag and PNMAg nanocomposites film electrode, both PNMAg film and PANI/Ag nanocomposite film electrodes were investigated in 1.0MHNO3 aqueous solution by CV and the corresponding results are shown in Fig.1 and 2 (curve 1, PANI/Ag nanocomposite film; curve 2, PNM/Ag film). not only the anodic current peak but also the cathodic current peak of PANI/Ag nanocomposite film is higher than those of PNM/Ag film.

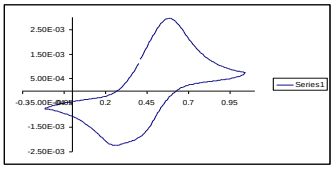

Fig.2 PNMA/Ag in HNO_3 1M

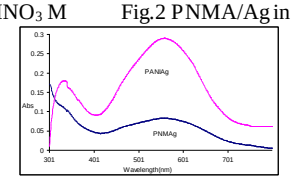

Fig.3 poly(N-alkylanilines)/Ag and PANI/Ag in NMP

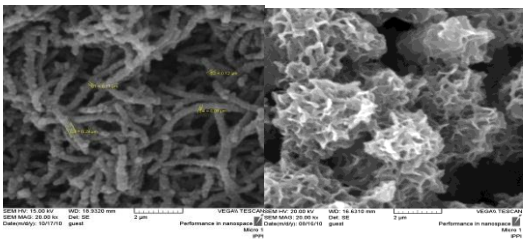

Fig.4 SEM PANIAg (a) and PNMAg(b)

The UV-VIS obtained spectra and SEM images and are given in Fig. 3, 4 respectively. The UV–vis spectra of all the synthesized poly (*N*alkylanilines)/Ag and polyaniline/Ag were in agreement with published patterns. The spectra of poly(*N*-alkylanilines) are composed of one absorption band with a maximum at λ = 325–333 nm assigned to the π–π* transition on the basis of the studies concerning polyaniline. As expected, the band in the region of λ = 560 nm was weak, due to the weak conjugation induced by the modification carried out on the nitrogen atom.

SEM images of the PANIAg (a) nanocomposite powders show non-agglomerated uniformly packed silver particles. The particles are of spherical and granular nature and seem to be nano sized, typically in the range of <50 nm (Fig. 4). SEM images of the PNMAg (b) nanocomposite powders show non-fiber uniformly packed silver particles.

Introduction

Experimental investigation of nanoscale processes in polymer aqueous solutions are of a great importance for development of nanomedicine, nanoelectronics as well as fundamental studies of physical chemistry of polymers. Nanoscale details of interpolymer reactions that yet are insufficiently studied may significantly affect structure and properties of resulting interpolymer complexes [1].

However, there are a limited number of instrumental techniques for direct observation of nanostructures only. Most of available devices such as atomic force and scanning electronic microscopes are designed primary for investigation of surfaces of solid bodies.

Therefore development of new methods for investigation of nanostructured polymer complexes in liquid phase with the same accuracy as it is for solids is of importance.

In this work we developed a construction of an instrument intended for measuring electric potential distribution within macromolecular coil per se in solution.

Concept and scheme of measurement of electric characteristics of macromolecular coil in solution

Proposed approach is based on measuring of a differential probe characteristic in solution – aqueous or organic. In case of non-charged macromolecules, a buffer electrolyte is used. The probe characteristic represents a dependence of a probe current on the probe potential; differential probe characteristic is the difference of such currents. It is determined, particularly, by contact difference of potentials probe – solution, depending on whole range of processes taking place on metal surface immersed into the electrolyte or polyelectrolyte solution.

It is shown that even short-term contact between a separate macromolecular coil and the probe results in changing the probe characteristic in correspondent time interval. Using of two closely situated probes allows register such changes by means of self-fluctuations inherent for polymer solution. Resolving power of this method is determined by distribution of electric lines between the edge points. It can be shown that main contribution is made by the macromolecules being in direct contact with the edge points.

Consequently, in the conditions when one edge point is being in contact with one macromolecule while another is not, a differential probe current appears. At chaotic movement of the macromolecules in solution, periodically occur conditions for emerging a differential signal. That signal can be measured directly with the help of differential amplifier that enables avoidance of uncontrolled factors.

The methodology worked-out in atomic-force microscopy is also applicable for fabrication probes with square as small as that of the edge point. Thus, investigation of the single macromolecule's characteristics becomes possible.

In this work we developed a new method for determination of characteristics of macromolecular coil based on measurement of radiofrequency spectrum of the probe signal. The scheme of this device is given in Figure 1.

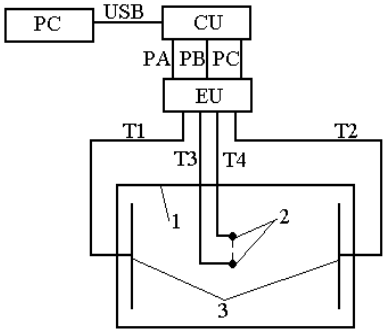

Fig.1. Scheme of the probe signal gauge; 1 – solution, 2 – wire probes coated by isolation, 3 – driving electrodes, EU, CU – controlling and measuring blocks, providing coupling with PC.

This scheme allows measurement of the differential currents up 10^{-6} A. The test measurements of the probe and differential probe characteristic of the aqueous solution of polyacrylic acid were performed. According to the results, the spectrum of the differential signal is in the range up to 5-7 MHz, which is in a good correlation with theoretical calculation. Along with the above said sensitivity, high resistance to vibrations is a considerable advantage of this scheme taking into account that the measurement is conducted in fluctuation regime.

Conclusions

A comparatively simple measurement method for investigation of characteristics of a single macromolecular coil was suggested. It allows obtaining quite accurate data without assembling expensive anti-vibration blocks.
