Conclusions: We report, for the first time, a higher prevalence of increased androgen sensitivity in patients with severe obesity compared with the general population. Moreover, both increased androgen sensitivity and, conversely, the presence of HH are independently associated with CVD, suggesting the involvement of distinct pathogenic mechanisms: on the one hand, higher androgens are a known risk factor for CVD; on the other, HH may reflect an underlying systemic inflammatory state capable of exerting deleterious effects on both the cardiovascular system and the central regulation of the hypothalamic-pituitary-gonadal axis.

P502 - LBA_ECE_1380 - Dual targeting of the HSP70–HSP90 chaperone axis in adrenocortical carcinoma: a novel inhibitor induces G1 arrest and multi-pathway collapse beyond mitotane

Adnan Batman[1], Ezgi Nurdan Yenilmez Tunoğlu[2], Irfan Koca[3], Merve Al[4] and Yusuf Tutar[5]
[1]*Endocrinology and Metabolism, Altunizade Acibadem Hospital, Istanbul, Türkiye;* [2]*Division of Medical Techniques and Services, Demiroglu Science University, Vocational School of Health Services, Şişli, Türkiye;* [3]*Department of Chemistry, Department of Chemistry, Bozok University, Yozgat, Türkiye;* [4]*Istanbul, Türkiye;* [5]*Department of Chemistry, Department of Basic Pharmaceutical Sciences, Recep Tayyip Erdogan University, Istanbul, Türkiye*

Background: Adrenocortical carcinoma (ACC) remains a highly aggressive malignancy with limited therapeutic options, and mitotane provides only modest benefit. Heat shock proteins HSP90 and HSP70 play a significant role in regulating oncogenic protein stability and resistance to apoptosis together. We hypothesised that by targeting the HSP70 and HSP90 chaperone axis simultaneously, the survival networks of tumours could be more fully disrupted compared to a single target strategy.

Materials and Methods: NCI-H295R cells were gradually treated with increasing mitotane and a dual HSP70/HSP90 inhibitor over 48 hours. To assess their viability, cell viability was measured using MTT analysis, and the IC50 value was determined. Apoptosis was measured using Annexin V-PE/7-AAD flow cytometry, and cell cycle distribution was analyzed using Muse™ assays. Gene expression changes were measured using qPCR, and pathway enrichment was analysed for this paper.

Results: The dual HSP70/HSP90 inhibitor showed much better cytotoxic activity than mitotane, resulting in a lower IC50 (3.21 ± 0.03 μM vs 6.96 ± 0.03 μM, $P < .001$). Later apoptosis was much more likely to occur and was of greater magnitude in mitotane treatment compared to that of the HSP70-HSP90 inhibitor. The single chaperone-targeted and inhibitor-targeting mechanism was explained by protein expression profiles at the molecular level, showing that HSP inhibition led to more upregulation of MAPK signaling (MAP2K1 and MAP2K3), cell cycle progression (CDC20, TBX2), GPD2 modulation, angiogenesis (ANGPT1, FOXC2 and SNAI1), and epithelial-mesenchymal transition for cells. The pathways were shown to have been significantly disrupted, specifically the PI3K-Akt and MAPK signalling networks, due to the global destabilization of the client proteins via the HSP70-HSP90 activation axis. This pattern is consistent with a multi-pathway regulatory role of HSP chaperone systems in ACC biology.

Conclusions: Dual inhibition of the HSP70–HSP90 chaperone axis exerts superior antitumor effects than mitotane by inducing multilayered disruption of survival signalling, cell cycle progression, and stress adaptation. This strategy represents a promising next-generation therapeutic approach in ACC and supports further translational development.

P503 - LBA_ECE_1463 - Anti-Müllerian hormone as a marker of gonadotropic–androgenic interaction during female development

Mariola Krzyścin[1], Anna Paczkowska[2] and Elżbieta Sowińska-Przepiera[1]
[1]*Szczecin, Poland;* [2]*Police, Poland*

Background: The interpretation of anti-Müllerian hormone (AMH) in paediatric and adolescent populations remains uncertain, as its clinical use is largely extrapolated from adult ovarian reserve models. This study aimed to define age-dependent endocrine correlates of AMH across female development, with particular focus on pubertal maturation.

Methods: A retrospective cross-sectional study included 238 females from late infancy to early adulthood undergoing routine

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

endocrine assessment. Participants were stratified by developmental stage. Associations between AMH and gonadotropins (LH, FSH, LH/FSH ratio), androgens, estradiol and selected endocrine parameters were analysed using Spearman correlation. In adolescents, receiver operating characteristic (ROC) analysis was performed using an AMH threshold of 30 pmol/L.

Results: AMH demonstrated stage-dependent associations with hormonal parameters. In early life, AMH was inversely correlated with FSH, most strongly in toddlerhood ($\rho = -0.70$, $P = .0001$) and early childhood ($\rho = -0.30$, $P = .04$), consistent with preserved ovarian–pituitary feedback. During adolescence, the association profile shifted, with positive correlations between AMH and LH ($\rho = 0.30$, $P = .03$) and androstenedione ($\rho = 0.50$, $P = .02$). Adolescents with AMH ≥30 pmol/L showed a higher LH/FSH ratio ($P = .004$) and increased androstenedione levels ($P = .01$), alongside lower total testosterone ($P = .009$). ROC analysis demonstrated the highest discriminatory performance for androstenedione (AUC = 0.78, $P < .01$), followed by LH/FSH ratio and total testosterone (both AUC = 0.70, $P < .05$).

Conclusions: AMH reflects distinct, age-dependent endocrine patterns in females. In adolescence, elevated AMH is associated with LH-dominant gonadotropic activity and increased androgen production, particularly androstenedione, supporting its interpretation as a marker of functional endocrine phenotype rather than ovarian reserve alone.

P504 - LBA_ECE_1079 - Evaluation of metabolic parameters and glucose dynamics before and after parathyroidectomy in patients with primary hyperparathyroidism

Ece Seçgin Demir[1,2], Müge Yılmaz[1], Büşra Kanbur[1], Mehmet Dönmez[1], Ziya Mithat Bıyıklı[1], Naile Gokkaya[1], Serhat Özçelik[1] and Kadriye Aydin[1]

[1]Department of Endocrinology and Metabolism, Kartal Dr. Lütfi Kırdar City Hospital, İstanbul, Türkiye; [2]Endocrinology and Metabolism, University of Health Sciences, Kartal Dr. Lütfi Kırdar City Hospital, İstanbul, Türkiye

Objective: Primary hyperparathyroidism (PHPT) is frequently accompanied by metabolic disturbances, including impaired glucose tolerance and dyslipidemia. The prevalence of diabetes mellitus in PHPT is approximately three times higher than in the general population, and nearly 40% of patients exhibit impaired glucose tolerance. Elevated intracellular calcium levels reduce insulin-stimulated glucose transport, thereby increasing insulin requirements. This study aimed to investigate the effects of parathyroidectomy on glucose metabolism, insulin dynamics, and lipid profile in patients with PHPT.

Methods: We retrospectively reviewed 45 PHPT patients who underwent parathyroidectomy between 2014 and 2024. All patients had normal renal and thyroid function and demonstrated normalized parathyroid function postoperatively. Preoperative and one-year postoperative levels of parathyroid hormone (PTH), calcium, phosphorus, 24-hour urinary calcium, 2-hour oral glucose tolerance test (OGTT), total cholesterol, triglycerides, HDL, LDL, HbA1c, and HOMA-IR were analyzed. Paired comparisons and correlation analyses were conducted to assess postoperative changes and their associations with biochemical parameters.

Results: Postoperatively, PTH, serum calcium, 24-hour urinary calcium, total cholesterol, and LDL levels significantly decreased, whereas phosphorus, HbA1c, and OGTT 60-minute glucose levels significantly increased. Other OGTT glucose values and the 90-minute insulin showed non-significant increases. Preoperative PTH were weakly positively correlated with changes in fasting insulin ($r_s = 0.352$, $P = .041$) and moderately positively correlated with fasting glucose changes ($r_s = 0.407$, $P = .017$). Greater reductions in PTH were moderately negatively correlated with increases in fasting glucose ($r_s = -0.424$, $P = .014$). Decreases in serum calcium were weakly negatively correlated with OGTT 30-minute glucose increases ($r_s = -0.352$, $P = .048$), whereas rises in phosphorus were weakly negatively correlated with OGTT 90-minute insulin ($r_s = -0.364$, $P = .041$) and moderately negatively correlated with HbA1c ($r_s = -0.460$, $P = .031$).

Conclusions: Parathyroidectomy may improve glucose tolerance and insulin dynamics in some PHPT patients, although this effect is not universal. Variability may relate to disease severity and diagnostic delay. Postoperative deterioration in postprandial glycemia may reflect these factors. Higher preoperative PTH is associated with more adverse postoperative glucose and insulin outcomes, whereas greater postoperative PTH reduction mitigates fasting glucose deterioration. Modifications in calcium and phosphorus levels may further support metabolic improvement. Early and effective surgical intervention may prevent worsening of glucose and insulin dynamics and improve lipid profiles. Patients with PHPT should undergo regular monitoring for impaired glucose tolerance, diabetes mellitus, and dyslipidemia.

Keywords diabetes mellitus, dyslipidemia, insulin resistance, parathyroidectomy, primary hyperparathyroidism

P506 - LBA_ECE_1262 - Circulating metabolic profiling in severe obesity represents a new potential biomarker to predict weight loss after bariatric surgery

Chiara Lepri[1], Valentina Balloni[2], Arianna Propato[1], Giorgio Crocetti[3], Giovanni Quartararo[3], Andrea Bernini[2], Michaela Luconi[1] and Giulia Cantini[1,4,5]

[1]Department of Experimental and Clinical Biomedical Sciences "Mario Serio", University of Florence, Florence, Italy; [2]Department of Biotechnology, Chemistry and Pharmacy, University of Siena, Siena, Italy; [3]Department of Surgery, General and Bariatric Surgery Unit, Santa Maria Nuova Hospital, Florence, Italy; [4]University of Florence, Florence, Italy; [5]University of Florence, Florence, Italy

The global prevalence of severe obesity is exponentially increasing worldwide, representing one of the most serious and rapidly growing health problems, alongside with its comorbidities such as type 2 diabetes (T2DM) and cardiovascular disease (CVD).

Bariatric surgery is the elective treatment for patients with body mass index (BMI) greater than 40 kg/m^2 or BMI of 35-40 kg/m^2 in combination with comorbidities, as it leads to a rapid and significant weight loss, resulting in a marked improvement of comorbidities and a reduction of long-term obesity-related mortality.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

However, bariatric surgery does not always result in the expected excess weight loss (EWL) in severely obese patients, making it necessary to identify new prognostic markers in order to predict weight regain and/or improvement in metabolic parameters.

In the present study, we applied untargeted metabolomic based on nuclear magnetic resonance (NMR) spectroscopy to compare the metabolic profiles in serum samples of twenty severely obese patients before and after bariatric surgery (BMI 45.0 ± 6.6 vs 29.6 ± 5.2, $P < .0001$, respectively) as well in paired subcutaneous (SAT) and visceral adipose tissue (VAT) biopsy.

Our analysis revealed that patients affected by severe obesity were characterized by a significant dysregulation of several metabolites associated with lipid metabolism, such as ketone bodies (acetone, 3-hydroxybutyrate, and acetate) and short chain fatty acids (SCFA), and a significant upregulation of metabolites associated with the purine salvage pathway (hypoxanthine and inosine) compared with healthy lean subjects (FC: 13.3 ± 7.4, $P < .0001$; FC: 10.0 ± 6.7, $P < .0001$, respectively).

Parallel RNASeq analysis of patients' SAT and VAT specimens taken before and after bariatric surgery identified the possible cellular pathways that support the NMR results.

Changes in the metabolic profile of circulating and adipose tissue-specific small molecules in patients with severe obesity after bariatric surgery could provide insights into the molecular mechanisms underlying systemic and regional metabolic dysregulations characterizing this pathology and allow prediction of response to bariatric surgery.

Understanding these pathways may offer novel targets to help non-responders patients achieve the EWL in order to prevent the development of comorbidities and their consequences.

P507 - LBA_ECE_1354 - Association between serum testosterone levels and calcium oxalate stone formation: a propensity score–matched case–control study

Suzy Park[1] and Junho Lee[2]
[1]Cardiff University, Cardiff, United Kingdom; [2]Seoul, South Korea

Introduction: Calcium oxalate (CaOx) stones constitute roughly 70-80% of urinary calculi and are twice as prevalent in men, implying an androgenic influence on lithogenesis. Laboratory data demonstrate that testosterone accelerates CaOx crystallisation, whereas anti-androgenic agents inhibit it, yet clinical confirmation remains limited. The objective of this study was to assess the association between serum testosterone and calcium oxalate stone formation, adjusting for metabolic factors.

Methods: We conducted a retrospective case–control study at a single teaching hospital. Cases were male patients who underwent surgical removal of proven CaOx stones between January 2024 and April 2025 ($n = 44$). Potential controls were 2925 men who, during health screening from 2010 to 2024, showed no renal stones on ultrasonography and had complete metabolic panels, including total testosterone. Propensity scores were calculated from age, body-mass index, systolic and diastolic blood pressure, serum triglycerides, low-density lipoprotein cholesterol (LDL-C), high-density lipoprotein cholesterol (HDL-C), and uric acid. A 1:5 nearest-neighbour match without replacement yielded 220 controls. Total testosterone was compared with the Mann-Whitney U test; biochemical hypogonadism (<3.5 nmol/L) was analysed with χ^2 tests and expressed as odds ratios (ORs, 95% CI).

Results: Among 44 men with confirmed CaOx stones and 2925 potential controls without stones, CaOx stone formers were significantly older and had significantly lower HDL-C and LDL-C than controls prior to propensity score matching. Median total testosterone level was significantly lower in stone formers (3.6 vs 4.7 nmol/L, $P < .001$), and biochemical hypogonadism ($T < 3.5$ nmol/L) was more common (47.7% vs 22.4%, $P < .001$). Propensity score matching based on demographic and metabolic factors yielded 220 matched controls (1:5 ratio), eliminating baseline differences, including age (58.5 vs 60.0 years, $P = .981$) and BMI (25.4 vs 24.8 kg/m^2, $P = .492$). After matching, testosterone level remained significantly lower in CaOx stone formers (3.6 vs 4.3 nmol/L, $P = .018$), and hypogonadism ($T < 3.5$ nmol/L) remained more prevalent (47.7% vs 25.0%, $P = .003$). The matched OR for hypogonadism in CaOx stone formers was 2.74 (95% CI 1.41-5.33).

Conclusions: After adjustment for confounders, men with CaOx stones displayed substantially lower serum testosterone and nearly a three-fold higher likelihood of biochemical hypogonadism. These findings link androgen deficiency to CaOx lithogenesis and support that hormonal modulation could become a preventive or adjunctive strategy in recurrent stone disease. Prospective longitudinal studies targeting androgen pathways are warranted to clarify causality and therapeutic potential.

P508 - LBA_ECE_1052 - Long term neuropsychological evaluation of adults' patients with craniopharyngioma

Julie Guillotin[1], Charlotte Planchon[1], Julien Engelhardt[1], Edouard Gimbert[1], Thomas Cuny[2], Antoine Tabarin[1] and Blandine Gatta-Cherifi[1]
[1]CHU de Bordeaux, Pessac, France; [2]APHM, Marseille, France

Introduction: Neurocognitive function has been studied primarily in children and in patients diagnosed during childhood after treatment of craniopharyngioma. Long-term data in adults are scarce. We report long term neurocognitive outcomes in adult patients treated for craniopharyngioma

Patients and Methods: The sample included adult patients with a history of craniopharyngioma treated at least 5 years earlier that had been invited for a neuropsychological evaluation. Comorbidities impairing cognitive function (eg stroke sequelae, Parkinson's disease), language barrier preventing neuropsychological testing, age >75 years were exclusion criteria.

All assessments were performed by the same neuropsychologist in the neurosurgery department. The battery included standardized tests.

Results: Twenty-two patients (14 women, mean age of 46 ± 12 years mean interval since the last treatment was 15 ± 7 years) went through neuropsychological evaluation. Six patients (27%) were diagnosed during childhood (<18 years) and 16 (73%) in adulthood.

In the whole group, sixteen patients (73%) reported excessive fatigue, including 10 with mild-to-moderate fatigue and 5 with severe fatigue. The Stroop Grefex test (cognitive inhibition) was

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

abnormal in 15 patients (68%) and borderline in 4 (18%). The Revised Commission test (organizational abilities) was abnormal in 15 patients (68%) and borderline in 2 (9%).

The Trail Making Test Part B (TMT-B) was impaired in 8 patients (36%), and Part A (TMT-A) in 6 (27%).

The results were very similar when we considered only patients with a craniopharyngioma diagnosed during adulthood.

These findings translated into a high need for supportive care, with half of the patients referred for additional interventions such as speech therapy or psychological counseling.

Discussion and Conclusions: The present study demonstrates that adult survivors face long-term neuropsychological sequelae, many years after treatment, that need specific care. Recent guidelines emphasize the need for systematic neuropsychological follow-up in craniopharyngioma and our findings strongly support this recommendation.

P509 - LBA_ECE_1035 - Protective effects of the GHRH agonist MR-409 in experimental models of amyotrophic lateral sclerosis

Francesca Pedrolli[1], Carola Torazza[2], Iacopo Gesmundo[1], Tiziana Bonifacino[2], Roberta Schellino[3], Federica La Rocca[3], Federica Bistolfi[1], Chiara Perotti[1], Wei Sha[4], Medhi Wangpaichitr[4], Marina Boido[3], Antonia Ratti[5], Andrew V. Schally[4], Marco Milanese[2] and Riccarda Granata[6]

[1]Department of Medical Sciences, University of Turin, Turin, Italy; [2]Department of Pharmacy (DIFAR), University of Genoa, Genoa, Italy; [3]Department of Neurosciences "Rita Levi Montalcini", University of Turin and Neuroscience Institute Cavalieri Ottolenghi, Turin, Italy; [4]Miami VA Healthcare System, Endocrine and Polypeptide Institute, Miami, FL, United States; [5]Department of Neuroscience, IRCCS Istituto Auxologico Italiano and Department of Medical Biotechnology and Translational Medicine, University of Milan, Milan, Italy; [6]Department of Molecular Biotechnology and Health Sciences, University of Turin, Turin, Italy

Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disorder characterized by progressive upper and lower motor neuron (MNs) loss, skeletal muscle atrophy, neuroinflammation, and mitochondrial dysfunction. Despite extensive research, effective disease-modifying therapies remain limited. Growth hormone-releasing hormone (GHRH), beyond its role in stimulating pituitary growth hormone (GH) secretion, exerts several peripheral actions, including promotion of cell survival and proliferation. Notably, both GHRH and its agonistic analog MR-409 have demonstrated neuroprotective and anti-inflammatory effects in experimental models of ischemic stroke, spinal muscular atrophy, and Alzheimer's disease. However, the role of GHRH in ALS has yet to be elucidated. Therefore, this study investigated the potential protective effects of GHRH and MR-409 in both *in vivo* and *in vitro* ALS models. Male and female wild-type (WT) and $SOD1^{G93A}$ transgenic ALS mice received daily subcutaneous treatment with MR-409 (0.8 mg/kg) or vehicle. For behavioral studies, a longitudinal cohort was treated from postnatal day 70 until sacrifice at the humane endpoint ($n = 8$ females, $n = 11$ males), whereas a separate cohort was treated from day 70 to day 100 for *ex vivo* molecular and histopathological analyses ($n = 5$ females, $n = 5$ males). In female $SOD1^{G93A}$ mice, MR-409 increased body weight, improved motor function, and showed a positive survival trend, with no effects in males. In the spinal cord, MR-409 counteracted MN loss and reduced IL-1β and GFAP mRNA levels in both sexes. In skeletal muscle, we observed attenuated atrophy in females accompanied by reduced expression of the atrophy-related markers MuRF1 and atrogin-1 in both sexes. *In vitro*, GHRH and MR-409 were tested in human SH-SY5Y neuroblastoma cells and iPSC-derived MNs from TARDBP-mutant ALS patients exposed to sodium arsenite to induce mild chronic oxidative stress. In SH-SY5Y cells, GHRH (5 μM) and MR-409 (1 μM) prevented sodium arsenite-induced UNC13A cryptic exon retention and reduced p62 accumulation. Consistently, preliminary results in iPSC-derived MNs showed that GHRH counteracted the sodium arsenite-induced reduction of UNC13A. Overall, these findings suggest a neuroprotective role for GHRH agonists in ALS.

EP1 - ECE_2238 - Severe orthostatic hypotension due to hyporeninemic hypoaldosteronism in a woman with diabetic autonomic neuropathy: challenges in management

Nehan Shakeel[1,2,3], Hafiz Sohail[3,4], Shakil Qamar[5] and Ma Pyeh Kyithar[5,6,7]

[1]Diabetes & Endocrinology Department, Midland Regional Hospital Portlaoise, Ireland; [2]Diabetes & Endocrinology, Portlaoise, Ireland; [3]College of Physicians and Surgeons Pakistan, Islamabad, Pakistan; [4]Portlaoise, Ireland; [5]Diabetes & Endocrinology Department, Midland Regional Hospital Portlaoise, Ireland Portlaoise, Ireland; [6]School of Medicine, Trinity College Dublin, Ireland; [7]Dublin, Ireland

Orthostatic hypotension is an under-recognized presentation of diabetic neuropathy. Hyporeninemic hypoaldosteronism, classically associated with diabetic nephropathy, may also occur in individuals with autonomic dysfunction and contribute to severe symptomatic orthostatic hypotension.

We report a case of a 39-year-old woman with a 5-year history of poorly controlled type 1 diabetes mellitus due to non-concurrence with insulin therapy (HbA1c 172 mmol/mol). She presented to Emergency Department with significant urinary retention. Further investigations with MRI lumbosacral spine, urology review and urodynamic studies showed neurogenic bladder secondary to diabetic autonomic neuropathy. Additionally, she was found to have severe, painful peripheral neuropathy. Three months following her first admission, the patient re-presented with a six-day history of progressive dizziness, lightheadedness, and near-syncope upon standing. Symptoms were most pronounced in the morning and improved when supine. Physical examination revealed a supine blood pressure of 125/80 mmHg, which decreased to 60/30 mmHg on standing, accompanied by an increase in heart rate from 89 to 119 bpm—findings consistent with severe orthostatic hypotension. Neurological and systemic examinations were otherwise unremarkable. Recent medication changes included initiation of ramipril (1.25 mg daily) and duloxetine (60 mg daily for peripheral neuropathic pain) two weeks before presentation.

Diagnostic work-up excluded adrenal insufficiency, as indicated by a morning cortisol level (344 nmol/L) and short synacthen test (0-minute cortisol: 462 nmol/L; 30-minute cortisol:

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

873 nmol/L). There was no evidence of diabetic nephropathy as urine ACR and renal function were normal and corticomedullary differentiation was intact on renal ultrasound. Further evaluation revealed a low renin level (2.0 pg/mL), undetectable aldosterone (<26 pg/mL) and a non-calculable aldosterone-to-renin ratio due to the absence of measurable aldosterone. In the context of suboptimal glycemic ranges with autonomic and peripheral neuropathies, hyporeninemic hypoaldosteronism was determined to be a key factor contributing to severe orthostatic hypotension.

Management included intravenous fluid administration and discontinuation of potentially exacerbating medications (ramipril and duloxetine). Midodrine was initiated and titrated up to 10 mg three times daily, with the addition of fludrocortisone. Peripheral neuropathic pain was managed with low-dose gabapentin and topical therapies. The patient demonstrated substantial clinical improvement with resolution of postural symptoms within three days.

This case highlights hyporeninemic hypoaldosteronism as a significant contributor to severe orthostatic hypotension in individuals with diabetic autonomic neuropathy. Pharmacological agents such as ACE inhibitors and SNRIs may exacerbate orthostatic hypotension in susceptible patients. Early recognition and tailored management of orthostatic symptoms with midodrine and fludrocortisone can lead to marked symptomatic improvement and enhanced quality of life.

EP2 - ECE_3553 - Hypokalemia metabolic alkalosis—could this be Cushing's syndrome?

Khurram Qayyum, Muhammad Masroor Amjad, Muhammad Haroon Riasat, Sega Pathmanathan, Rehmat Karim and Najeeb Shah
Hull University Teaching Hospitals NHS Trust, Hull, United Kingdom

Cushing's syndrome is a rare but serious endocrine disorder with a diverse clinical presentation, often posing diagnostic challenges, particularly in ACTH-dependent cases. Severe metabolic abnormalities such as hypokalaemia may provide important clues to an ectopic source, even when classical clinical features are absent or imaging findings are equivocal.

We present a case of a 64-year-old female with a background of hypothyroidism who presented with weakness, lethargy, difficulty climbing stairs, and intermittent blurred vision for 2 weeks. Clinically, she was hypertensive with proximal myopathy and easy bruising, without classical cushingoid features. Biochemistry revealed severe metabolic alkalosis (Ph 7.72 and bicarbonate 38.5 mmol/L) and persistent hypokalaemia (lowest, 2.1 mmol/L). Two 24-hour urinary free cortisol measurements were markedly elevated at 11 710 and 17 014 nmol (normal 0–165), and cortisol failed to suppress following 1 mg overnight dexamethasone suppression testing (>1650 nmol/L). ACTH was elevated at 64 ng/L, confirming ACTH-dependent Cushing's syndrome.

Although the ACTH levels were mildly elevated which would usually suggest a central source, the onset, severity of hypokalaemia and absence of cushingoid features suggested ectopic ACTH secretion. Pituitary MRI demonstrated a 4 mm are with slight enhancement, but this was considered equivocal. CT imaging of the thorax, abdomen, and pelvis revealed a small hyperattenuating right pericardial lesion and a non-specific pancreatic finding, with no definite tumour identified. Whole-body FDG-PET showed mild uptake in the para-mediastinal pleural lesion abutting the right heart border; however, octreotide scanning was negative. Neuroendocrine markers, including chromogranin A and urinary 5-HIAA, were normal.

Medical management with antihypertensives including spironolactone, and metyrapone was initiated to control hypercortisolaemia. Following multidisciplinary discussion (MDT) within endocrinology and the respiratory team, the para-mediastinal lesion was deemed to be the most likely ectopic source. The patient underwent bronchoscopy and right video-assisted thoracoscopic surgery. A lesion was identified in the right middle lobe which was excised. Histology confirmed a completely excised atypical carcinoid tumour (pT2 Nx) with Ki-67 of 10%. Pre-operatively, metyrapone was discontinued and hydrocortisone replacement commenced peri-operatively to prevent adrenal insufficiency on removal of the lesion.

Following surgery, the patient experienced significant symptomatic improvement with normalisation of her biochemistry. Hydrocortisone is being weaned off. She will be followed up closely to pick up recurrence in view of a high Ki-67 index. This case underscores the importance of integrating biochemical findings, clinical features, and MDT input in the evaluation of ACTH-dependent Cushing's syndrome, particularly when imaging results are inconclusive.

EP3 - ECE_3361 - Accuracy and clinical utility of founder mutation testing for familial hypercholesterolemia in Finnish population

Antti Jokiniitty and Saara Metso
Endocrinology, Tampere University Hospital, Tampere, Finland

Background: In Finland, due to a founder effect, seven pathogenic variants are estimated to account for approximately 80% of the genetic spectrum of Familial Hypercholesterolemia (FH). National current care guidelines recommend these founder variants be tested in patients with probable or definite FH according to the Dutch Lipid Clinic Network Criteria (DLCNC). If testing is negative but clinical suspicion remains high, broader genetic testing is advised. However, the clinical characteristics of patients referred for founder mutation testing and its diagnostic yield are not well defined. With the increasing availability of next-generation sequencing (NGS), the optimal testing strategy should be reassessed to improve variant detection and guide best practice.

Aims: To evaluate clinical characteristics, family history, and FH probability (based on DLCNC) of patients referred for FH founder mutation testing in the Pirkanmaa Health Services region, Finland (2000–2024); to assess the proportion of positive founder-mutation results; and to determine the proportion of patients with negative founder testing underwent broader genetic evaluation and were diagnosed with a pathogenic FH variant.

Methods and Results: We performed a retrospective analysis of 1126 patients referred for FH founder variant testing between 2000 and 2024. Clinical and genetic data were collected from electronic health records.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Testing was conducted as cascade screening in 37 patients with a known familial FH founder mutation and in 1089 unrelated patients. A positive FH variant was detected in 67.6% of those with a known familial mutation and 1.5% of those without.

Out of founder mutation–negative patients, 121 underwent extended genetic testing, revealing an FH variant in 9.9%.

Based on DLCNC clinical classification, FH variant prevalence was 64.3% in patients with definite FH, 10.7% in probable FH, 2.7% in possible FH, and 1.2% in unlikely FH categories.

Overall, 137 patients had premature atherosclerotic cardiovascular disease (ASCVD) and 989 did not; FH prevalence was similar in both groups (5.1% vs 4.8%).

Conclusions: Founder mutation testing remains an effective first-line genetic screening approach for patients with definite FH or family history of FH in Finland. However, its diagnostic yield is low among unrelated individuals without known familial variants. Broader genetic testing after a negative founder result identified additional FH cases in 10% of patients, highlighting the need to combine targeted founder screening with comprehensive sequencing for optimal FH detection.

EP4 - ECE_2923 - Primary bilateral macronodular adrenal hyperplasia associated with an ARMC5 variant: early detection in a presymptomatic carrier

Lina Panceraitė[1], Radvilė Matukaitienė[1,2], Lina Kievišienė[3] and Birutė Žilaitienė[1,2]

[1]*Department of Endocrinology, Lithuanian University of Health Sciences, Kaunas, Lithuania;* [2]*Institute of Endocrinology, Lithuanian University of Health Sciences, Kaunas, Lithuania;* [3]*Department of Genetics and Molecular Medicine, Lithuanian University of Health Sciences, Kaunas, Lithuania*

Primary bilateral macronodular adrenal hyperplasia (PBMAH) is a rare disease, accounting for <2% of cases of Cushing's syndrome (CS). Patients with PBMAH have varying levels of cortisol secretion and are often diagnosed with PBMAH due to incidental radiological findings of the adrenal glands, as in our case. During evaluation for angioedema, a CT scan in a 53-year-old woman revealed an incidental finding of nodular thickening up to ~11 mm in the left adrenal gland (most likely hyperplasia). Further abdominal MRI showed that the left adrenal gland is nodular, with a suspicious solid lesion measuring 1.2 × 0.9 cm with small fatty-density inclusions, based on MRI, a small pheochromocytoma was suspected; the right adrenal gland is structurally normal with no additional lesions. Further evaluation of this finding by an endocrinologist was carried out. An overnight dexamethasone suppression test was performed, and cortisol suppression was not achieved (56.24 nmol/L, $n < 50$). DXA showed normal BMD, and spinal X-ray revealed degenerative changes. Other laboratory findings included free metanephrines (metanephrine 0.08 nmol/L, *n* 0-0.507; normetanephrine 0.41 nmol/L, *n* 0-1.18), ACTH (2.1 pmol/L, *n* 1.63-14.15), TSH (2.03 mU/L, *n* 0.4-3.6), and a normal aldosterone-renin ratio (43). Whole-exome sequencing identified a heterozygous pathogenic variant in the ARMC5 gene NM_001105247.2:c.517C>T (p.Arg173Ter). This gene is associated with autosomal dominant PBMAH and has incomplete penetrance, as a second hit in the gene is required for PBMAH to develop. A repeat overnight dexamethasone suppression test again showed inadequate suppression (58 nmol/L, $n < 50$). A low-dose dexamethasone test was then performed, and suppression was achieved (40.6 nmol/L, $n < 50$); overall, the tests revealed mild autonomous cortisol hypersecretion. The patient case was discussed at a MDT on rare endocrine and adrenal diseases. Although the patient carries this variant, because adrenal hyperplasia is unilateral and she currently does not have typical clinical features of CS, she does not at present meet the criteria for PBMAH and can be considered a presymptomatic carrier of a genetic variant. In patients with pathogenic ARMC5 variants, PBMAH and CS most often present in the fifth or sixth decade of life, ie, with later onset compared with unilateral cortisol-producing adrenal adenomas. Therefore, the patient requires regular endocrinological follow-up, as there is a high likelihood of developing PBMAH and CS in the future. Monitoring facilitates early treatment initiation and helps prevent progression of CS-related complications such as cardiovascular, metabolic, and musculoskeletal disorders.

EP5 - ECE_3437 - Adrenocortical adenoma with ischemic necrosis

Athanasios Kasotas[1], Grigoris Effraimidis[2], Dionysios Vrachnis[1], Nektarios Adamopoulos[1], Maria Galani[1], Eleni Georgiou[1], Ioannis Gkountios[1], Anastasia-Konstantina Sakali[1], Maria Apostolopoulou[2] and Alexandra Bargiota[2]

[1]*Department of Endocrinology and Metabolic Diseases, University General Hospital of Larissa, Larissa, Greece;* [2]*Department of Endocrinology and Metabolic Diseases, Faculty of Medicine, School of Health Sciences, University of Thessaly, University General Hospital of Larissa, Larissa, Greece*

Introduction: Adrenocortical adenomas are by definition benign neoplasms and in most cases are discovered incidentally during imaging evaluation. Large adenomas (>4–5 cm) may very rarely develop ischemic necrosis with imaging features that mimic malignancy, making the differential diagnosis a significant challenge.

Case Presentation: A 74-year-old woman was referred for evaluation of a large right adrenal mass (7.4 × 7.5 cm), which was incidentally detected on magnetic resonance imaging (MRI) of the spine for spondyloarthritis.

The patient reported mild right-sided low back pain and had no clinical symptoms or signs of adrenal dysfunction or other pathological findings. Past medical history included type 2 diabetes mellitus, arterial hypertension, and dyslipidemia. Biochemical evaluation revealed mild autonomous cortisol secretion (MACS), with cortisol of 3.9 μg/dL after a 1-mg overnight dexamethasone suppression test (ODST), normal 24-hour urinary free cortisol, preserved circadian rhythm of salivary cortisol, and normal urine metanephrine and normetanephrine.

Computed tomography (CT) of the retroperitoneum demonstrated a 7.5 × 8.9 × 7.5 cm mass of mixed density, with well-defined margins, heterogeneous contrast enhancement, dystrophic calcifications, lipid components, extending to the upper pole of the right kidney and to the right hepatic lobe. Adrenal MRI confirmed the atypical imaging features (heterogeneity, calcifications, progressive heterogeneous enhancement, and extending to the kidney and liver).

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

The patient underwent laparoscopic surgical excision of the lesion. Histological and immunohistochemical examination was consistent with extensive ischemic necrosis of a benign adrenocortical adenoma, with rare mitoses, absence of cellular atypia, and preservation of architecture.

The patient remains free of recurrence 7 months post-surgery.

Conclusions: Large adrenal masses with extensive necrosis, despite of radiological findings that could not exclude malignancy, could be benign, underscoring the decisive role of histopathological evaluation and immunohistochemical confirmation.

EP6 - ECE_2007 - Genetic pleiotropy between primary aldosteronism and hypertension maps to adrenal cell states

Zhuolun Sun, Changying Jing and Tracy Ann Williams
Medizinische Klinik und Poliklinik IV, Ludwig-Maximilians-Universität (LMU) München, Klinikum der Universität München, München, Germany

Background: Primary aldosteronism (PA) is a major yet underdiagnosed cause of secondary hypertension. While genome-wide association studies (GWAS) have identified genetic variants associated with PA and blood pressure (BP) separately, their shared genetic basis across multiple biological levels remains undefined. We aimed to systematically characterise the shared genetic architecture between PA and BP regulation, from pleiotropic loci and genes to pathways, and to integrate these findings with single-cell and spatial transcriptomic profiling of adrenal tissue.

Methods: We analysed genetic overlap between PA and BP using two independent PA datasets (French COMETE Network and Million Veteran Program) and three BP phenotypes (systolic, diastolic, and pulse pressure). Our stepwise analytic strategy included measuring genome-wide and regional genetic correlations, identifying shared risk loci through cross-trait meta-analysis, and prioritising candidate genes influencing both conditions. Biological relevance was evaluated using functional annotation, tissue-specific expression, and integrated single-cell and spatial transcriptomic analyses.

Results: PA demonstrated significant positive genetic correlations with all BP traits, with six specific genomic regions showing strong shared signals. We identified 143 independent loci associated with both PA and BP, predominantly in regulatory regions influencing gene expression across adrenal, vascular, cardiac, adipose, and neuroendocrine tissues. Gene-based analyses prioritised 43 shared genes, implicating pathways related to vascular remodelling and extracellular matrix turnover. Single-cell and spatial analyses revealed that *SLC24A3* is highly expressed in aldosterone-producing adenoma cells and exhibits marked intratumoural heterogeneity. *SLC24A3*-positive regions corresponding to a functionally specialised, high secretory endocrine state, whereas *SLC24A3*-negative regions were characterised by a stress-adaptive, low-secretory state.

Conclusions: This study defines a shared genetic architecture linking PA and BP regulation. It demonstrates that their frequent clinical association arises not only from the direct haemodynamic effects of aldosterone but also from a substantial, pre-existing genetic predisposition that dysregulates common endocrine-vascular pathways.

EP7 - ECE_3227 - Diagnostic performance of an inflammation-based score for mild autonomous cortisol secretion in adrenal incidentalomas—data from a tertiary Romanian center

Beatrice Cristea[1], Vlad Radulescu[1], Roxana Fota[1], Ioana Maria Posea[1], Cristina Stancu[1,2], Anda Dumitrașcu[1], Monica Livia Gheorghiu[1,3] and Corin Badiu[1,3]
[1]Research Department, Endocrinology IV, C.I. Parhon National Institute of Endocrinology, București, Romania; [2]Laboratory of Molecular, Cellular and Structural Endocrinology Research, Endocrinology IV, C.I. Parhon National Institute of Endocrinology, București, Romania; [3]Endocrinology, Endocrinology IV, "C Davila" University of Medicine and Pharmacy, Bucharest, Romania

Background: Risk stratification and confirmation of autonomous cortisol secretion for adrenal incidentalomas remains challenging when relying on isolated hormonal or imaging markers. Low-grade systemic inflammation may contribute to metabolic risk in mild autonomous cortisol secretion (MACS). We aimed to develop and compare simple point-based scores integrating hormonal, imaging, and inflammatory markers for improved identification of MACS.

Methods: We retrospectively analyzed **321 patients** with adrenal incidentalomas (135 MACS, 186 non-functioning adenomas [NFA]). Inclusion criteria were age ≥18 years, available blood count and imaging results at the time of the diagnosis, before any intervention. Baseline ACTH, DHEAS, neutrophil-to-lymphocyte ratio (NLR), and maximal tumor diameter were assessed. Patients with known infections, haematological/autoimmune disease, other functional adrenal masses were excluded. ROC analysis determined optimal cut-offs. The score was constructed by assigning one point to each abnormal parameter. Therefore, we propose the **NLR-based score with four items**: a) ACTH ≤ 10.08 pg/mL, b) DHEAS ≤ 42.1 µg/dL, c) imaging by CT or MRI scan-largest diameter ≥24.5 mm, d) NLR ≥ 2.21 (0–4 points). Diagnostic performance was evaluated using ROC analysis of both the raw score and predicted probabilities from the logistic model.

Results: Individual parameters showed moderate discrimination: a) ACTH:AUC = 0.79, b) DHEAS: AUC = 0.72, c) tumor diameter AUC 0.70, d) NLR:AUC = 0.60 (all with $P < .001$). The **NLR-based score** demonstrated good diagnostic accuracy (AUC **0.817**, 95% CI 0.763–0.870), with each one-point increase associated with a **3.47-fold increase** in MACS odds (95% CI 2.49-4.81, $P < .001$). A threshold of ≥2 points yielded sensitivity **82.6%** and specificity **61.4%**, while ≥3 points achieved high specificity (**92.1%**).

Discussion: The NLR-based score provides valuable clinical support when standard 1 mg overnight dexamethasone suppression testing is inconclusive or unreliable. Its high specificity (92.1% at ≥3 points) is particularly useful for borderline cortisol results near diagnostic threshold, offering additional diagnostic confidence without further testing. The score also serves as a practical alternative when dexamethasone testing is compromised by drug interactions or unavailable in resource-limited settings.

However, the clinical applicability of this score is limited in patients with active inflammation, infections, or hematological

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

disorders, where elevated NLR values unrelated to autonomous cortisol secretion may generate false-positive results.

Conclusions: A multimodal clinical score incorporating systemic immune-inflammation improves the identification of MACS in adrenal incidentalomas. The score demonstrates robust diagnostic performance and offers flexible thresholds for both screening and confirmatory clinical use.

EP8 - ECE_3239 - Real-world application of the 2025 Endocrine Society Guideline on primary aldosteronism: a 10-year retrospective study in Hong Kong

Kelly Hiu Ching Wong, David Lui, Carol Ho Yi Fong, Alan Chun Hong Lee, Kathryn Choon-Beng Tan and Paul Chi-Ho Lee
The University of Hong Kong, Hong Kong, Hong Kong

Background: In the 2025 Endocrine Society guideline on primary aldosteronism (PA), aldosterone suppression testing is only recommended to individuals with a positive PA screen and intermediate probability of lateralizing PA. Mineralocorticoid receptor antagonists (MRA) should be tried among individuals who have low probability of lateralizing PA without confirmatory testing, and prescribed also among those who have intermediate probability of lateralizing PA even if their aldosterone suppression test was negative. Here, we evaluated the real-world application of this probabilistic framework using a 10-year retrospective cohort of patients who underwent aldosterone suppression testing in our institution.

Methods: All patients with a positive PA screen, defined as plasma aldosterone ≥200 pmol/L, plasma renin activity (PRA) <1 mg/mL/h and aldosterone-to-renin ratio (ARR) ≥400 in our institution, who underwent saline infusion test (SIT) between January 2015 and September 2025 at Queen Mary Hospital, were included.

Results: Among the 304 patients with positive PA screen and underwent SIT between 2015 and Sep 2025, 12 (3.9%), 259 (85.2%) and 33 (10.9%) patients were classified into the low, intermediate and high probability of lateralization PA, respectively. Positive SIT was found in 33%, 54.8% and 97% in the low, intermediate and high probability groups, respectively ($P < .001$). Consistently, 8.3%, 13.5% and 51.5% eventually underwent adrenalectomy in the three groups, respectively ($P < .001$). Among the 142 patients with positive SIT in the intermediate probability group, 35 (24.6%) underwent adrenalectomy. The probability of lateralizing PA was not influenced by most indications of ARR testing including young hypertension, hypokalaemic hypertension and obstructive sleep apnoea, except in the setting of adrenal incidentaloma (AI) ($P = .002$), where the majority of patients were in the intermediate probability group. Compared with patients without AI, those with AI were significantly older ($P = .033$), requiring less anti-hypertensive medications (1.48 vs 2.2, $P < .001$), and none of them had hypokalaemia. Patients with AI were also significantly less likely to be tested positive at SIT compared to those without (22.7% vs 64.6%, $P < .001$), and only 1 patient eventually underwent adrenalectomy in the AI group.

Conclusions: Our findings confirmed the limited clinical utility of aldosterone suppression testing among patients categorized as high probability for lateralizing PA. However, whether the recommendations of trial of MRA without confirmatory testing in low-probability groups, and prescribing MRA in intermediate-probability groups even with negative SIT, should be applied among individuals with AI, given their high prevalence and low-risk of true PA, require further larger studies for confirmation.

EP9 - ECE_3658 - Diagnostic performance of late-night plasma ACTH in Cushing's syndrome

Georgios Kostopoulos[1], Evangelia Makri[2] and Zoe Efstathiadou[2]
[1]Thessaloniki, Greece; [2]Endocrinology, Hippokration General Hospital, Thessaloniki, Greece

Background: Endogenous Cushing's syndrome (CS) is associated with substantial morbidity and mortality and remains a significant diagnostic challenge. Following biochemical confirmation of endogenous hypercortisolism, determination of adrenocorticotropic hormone (ACTH) dependency represents a critical step in the diagnostic algorithm. Current guidelines recommend measurement of morning plasma ACTH levels for disease classification; however, ACTH secretion follows a circadian rhythm with physiological late-night suppression that is frequently lost in ACTH-dependent CS.

Objective: To evaluate the diagnostic performance of late-night plasma ACTH for determining ACTH dependency in endogenous CS.

Methods: We conducted a retrospective cohort study including patients evaluated for CS at a tertiary endocrine center between January 1, 2010 and December 31,2025. Patients with biochemical evidence of endogenous CS and available morning and late-night plasma ACTH measurements were included. ACTH dependency was established based on final clinical diagnosis incorporating biochemical testing, imaging, dynamic testing, and pathology where applicable. Diagnostic performance was assessed using receiver operating characteristic (ROC) analysis. Area under the curve (AUC) with 95% confidence intervals (CI) was calculated using the DeLong method. The optimal cutoff was determined using Youden's index, and clinically relevant rule-out and rule-in thresholds were explored.

Results: Twenty-eight patients with CS were included (71.4% female, median age of diagnosis 53.5 years). Etiologies included adrenal adenoma ($n = 16$), corticotroph adenoma ($n = 10$), thymic carcinoid ($n = 1$), and adrenocortical carcinoma ($n = 1$). Median late-night ACTH was 46.8 pg/mL in ACTH-dependent disease and 8.6 pg/mL in ACTH-independent disease. Late-night ACTH demonstrated excellent discrimination between ACTH-dependent and independent CS (AUC 0.995, 95% CI 0.98–1.00). Lower thresholds (7.5 and 10 pg/mL) achieved maximal sensitivity, supporting a rule-out strategy, whereas higher thresholds (>20 pg/mL) provided near-complete specificity, consistent with a rule-in approach. Morning ACTH showed slightly lower diagnostic accuracy (AUC 0.984), with no statistically significant difference compared with late-night ACTH ($P = .48$).

Conclusions: Late-night plasma ACTH shows high diagnostic accuracy for determining CS etiology and may enhance decision-making, but external validation is warranted.

EP10 - ECE_2752 - Impaired glucocorticoid metabolism, rather than mineralocorticoid excess, is an independent predictor of cardiovascular risk in chronic kidney disease

Maria Tomkins[1,2], Darran Mc Donald[1,2], Fozia Shaheen[3], Angela Taylor[3], Olive McEnroe[4], Declan de Freitas[4], Carol Traynor[4], Amy Hudson[4], Ciara N. Magee[4], Peter Conlon[4], Colm Magee[4], Mark Denton[4], Conall O'seaghdha[4], Diarmuid Smith[2], Wiebke Arlt[3,5,6], Michael W. O'reilly[1,2] and Mark Sherlock[1,2]

[1]Department of Medicine, Royal College of Surgeons in Ireland, Dublin, Ireland; [2]Department of Endocrinology, Beaumont Hospital, Dublin, Ireland; [3]Institute of Metabolism and Systems Research, Birmingham, United Kingdom; [4]Department of Nephrology, Beaumont Hospital, Dublin, Ireland; [5]Medical Research Council Laboratory of Medical Sciences, London, United Kingdom; [6]Institute of Clinical Sciences, Imperial College London, London, United Kingdom

Introduction: Chronic kidney disease (CKD) is a prevalent chronic disease with associated increased mortality. Cardiovascular disease (CVD) is the predominant cause of death in CKD and risk of CVD is potentiated by mineralocorticoid receptor (MR) activation. Historically, aldosterone has been the primary corticosteroid of concern for driving excess CVD risk in CKD. Importantly, however, MR activation can occur from both mineralocorticoid and glucocorticoid binding. The enzyme 11β-hydroxysteroid dehydrogenase type 2 (11β-HSD2) converts active cortisol (F) to inactive cortisone (E) thereby protecting the MR from illicit glucocorticoid activation. 11β-HSD2 activity is impaired in CKD.

Methods: To investigate the contribution of disrupted adrenal steroid metabolism to renal disease and CVD risk in CKD we performed multi-steroid profiling via liquid chromatography–tandem mass spectrometry on paired serum and 24-hour urine samples from non-diabetic patients across the stages of CKD ($n = 103$) and age-, sex-, and BMI-matched healthy controls ($n = 39$) alongside detailed cardiometabolic phenotyping, including pulse wave velocity (PWV) and bioimpedance body composition analysis. Patients with recent or current use of MR antagonist, glucocorticoids or other interfering medications were excluded. Statistical analysis included Spearman correlation tests with multivariable regression analysis. Values were log-transformed, where appropriate.

Results: Despite elevated plasma aldosterone concentrations [357 pmol/L (157-564) vs 235 pmol/L (138-309), $P = .01$], patients with CKD had significantly lower urinary excretion of total mineralocorticoid metabolites [398 nmol/L (256-611) vs 882 nmol/L (613-1197), $P < .0001$] compared to controls, suggesting impaired renal clearance. 11β-HSD2 activity declined with worsening renal function evidenced by an elevated F/E ratio [11.1 (8.2-13.9) in CKD vs 5.7 (4.6-7.1) in controls, $P < .0001$]. Multivariable regression identified elevated serum aldosterone, lower total urinary mineralocorticoid metabolites and increased F/E ratio to be independently associated with lower eGFR when accounting for age, sex, antihypertensives, urine volume and urine creatinine concentration.

We also found an independent association of both the F/E ratio ($\beta = 0.1$, $P = .04$) and total urinary glucocorticoid metabolites ($\beta = 0.09$, $P = .007$) with arterial stiffness (PWV), controlling for age, sex, renal function, blood pressure, and antihypertensive use. Mineralocorticoid markers showed no independent associations with cardiometabolic outcomes.

Conclusions: This is the first study to interrogate the complete steroid metabolome in CKD providing an insight into renal determinants of steroid metabolism. Our findings highlight the important role of impaired 11β-HSD2 activity, reflected by an elevated F/E ratio, in driving glucocorticoid-mediated MR activation and arterial stiffness. Additionally, impaired glucocorticoid metabolism is a greater contributor to CVD risk than aldosterone and should be considered as a potential therapeutic target in CKD.

EP11 - ECE_1092 - Work loss and income before and after diagnosis of Addison's disease: a population-based longitudinal study

Stavros Stergianos[1,2], Åsa Hallqvist Everhov[3,4], Jonas Söderling[3], Jakob Skov[5,6] and Sophie Bensing[1,2]

[1]Department of Medicine, Solna, Experimental Endocrinology Division, Karolinska Institutet, Stockholm, Sweden; [2]Department of Endocrinology, Karolinska University Hospital, Stockholm, Sweden; [3]Department of Medicine, Solna, Clinical Epidemiology Division, Karolinska Institutet, Stockholm, Sweden; [4]Department of Clinical Science and Education, Karolinska Institutet, Södersjukhuset, Stockholm, Sweden; [5]Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden; [6]Region Värmland, Center for Clinical Research, Karlstad, Sweden

Background: The effects of autoimmune Addison's disease (AAD) on employment and income over time remain inadequately characterized.

Objective: To assess how a diagnosis of AAD influences work-loss days, taxable earnings and disposable income in the working-age population compared with matched controls from the general population.

Methods: We conducted a nationwide register-based cohort study in Sweden. By linking the Swedish Addison Register with national health and labour-market registers, we identified 716 individuals aged 20–62 years with incident AAD diagnosed between 2003-2019, and 3271 comparators from the general population matched on sex, age, county, calendar year and education level. We examined outcomes over a 10-year window around diagnosis: annual lost work-days (via linear regression) and median taxable earnings and disposable income (via quantile regression).

Results: Compared with matched comparators, patients with AAD had significantly greater work-loss from one year before to three years after diagnosis. The maximal difference occurred in the first year post-diagnosis (mean excess of 30.5 days; 95% CI 22.9–38.0; $P < .001$). At the median level, patients with AAD had lower taxable earnings by USD 1,107 (95% CI −2042 to −173; $P = .02$) one year before diagnosis, and by USD 1105 (95% CI −2166 to −43; $P = .04$) one year after diagnosis. Their disposable income was also reduced by USD 1084 (95% CI −1813 to −354; $P = .004$) one year post-diagnosis. Importantly, both work loss and income differences attenuated over time, returning close to comparator levels by approximately four years after diagnosis.

Conclusions: In this large national cohort, AAD was associated with a transient increase in work absence and reductions in

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

earnings and income, particularly concentrated around the time of diagnosis and peaking in the subsequent year. Encouragingly, both employment participation and income recovered to near-normal levels within about four years. These findings highlight the importance of supportive interventions around diagnosis to mitigate socioeconomic impact in individuals with AAD.

Abstract citation ID: lvag096.628

EP12 - ECE_1663 - Abiraterone acetate as a treatment option for canine Cushing's syndrome

Sara Galac[1,2,3], Nynke Deckers[4], Els Wouters[4], Patricia Peeters[4] and Hans S. Kooistra[5]
[1]*Faculty of Veterinary Medicine, Clincial Sciences, Utrecht, The Netherlands;* [2]*Faculty of Veterinary Medicine, Clinical Sciences, Utrecht, The Netherlands;* [3]*Faculty if Veterinary medicine, Clinical Sciencesnet, Utrecht, The Netherlands;* [4]*Regivet, Oirschot, The Netherlands;* [5]*Utrecht University, Utrecht, The Netherlands*

Introduction: Abiraterone acetate (ABA) is a selective and irreversible inhibitor of cytochrome P450 17A1 that profoundly suppresses cortisol synthesis, making it a promising candidate for the medical treatment of Cushing's syndrome (CS). Naturally occurring CS in dogs is approximately 1000 times more prevalent than in humans and closely resembles the human disease in terms of anatomy, pathophysiology, clinical presentation, and diagnostic and therapeutic approaches. This positions canine patients as a valuable translational model for the evaluation of novel therapeutic strategies for CS.

Objectives: To evaluate the clinical and hormonal effects of ABA in dogs with naturally occurring CS.

Methods: This prospective clinical study included ten dogs with CS, in which the diagnosis was confirmed by endocrine testing and diagnostic imaging. The starting dose of ABA was 1 mg/kg administered twice daily, with subsequent dose adjustments guided by clinical response and ACTH stimulation test results. Dogs were monitored at two- to three-week intervals until a stable dose—defined by well-controlled clinical signs and sufficient adrenocortical reserve—was achieved, followed by three-monthly evaluations for up to one year.

Results: Clinical improvement was observed in 8/10 dogs; however, polyuria resolved only after the addition of desmopressin acetate. In 3/8 clinically improved dogs, ABA therapy was discontinued after 1, 3, and 10 months, respectively, due to deterioration of the patient's condition. The remaining 5/8 dogs were followed for 16, 14, 10, 6, and 4 months.

Two dogs were excluded before reaching an optimal dose because of minimal clinical improvement and concurrent gastrointestinal signs, which were considered possible side effects of ABA treatment.

Hormonal evaluation demonstrated a decrease in urinary cortisol excretion to within the reference range, as assessed by the urinary cortisol-to-creatinine ratio, in all clinically improved dogs. Endogenous ACTH concentrations did not differ from baseline values at any follow-up time point, suggesting that ABA-treatment was not associated with hypocortisolism. Median serum aldosterone concentrations increased significantly ($P < .001$) during treatment, and hypokalemia was detected in 4/10 dogs. In one patient, mineralocorticoid excess syndrome was suspected, and concurrent treatment with spironolactone was initiated. ABA-treatment induced a significant increase in progesterone concentrations ($P < .001$), consistent with its mechanism of action.

Conclusions: ABA may represent an effective medical treatment option for dogs with CS; however, mineralocorticoid excess should be closely monitored. The canine model provides important translational insights into the efficacy, endocrine adaptations, and adverse effects associated with CYP17A1 inhibition.

EP14 - ECE_2531 - Predictive factors of hypertension remission in patients with medically and surgically treated primary aldosteronism: a single center study

Bogdan Baluta[1], Stéphanie Le Scouiller[2], Fabio Bioletto[3], Thierry Frouget[4], Caroline Dourmap[5], Juliette Hascoet[6], Benoit Peyronnet[6] and Patricia Vaduva[1]
[1]*Endocrinology, Diabetes, and Nutrition Department, Rennes University Hospital, Rennes, France;* [2]*Clinical Pharmacology Department–CIC Inserm 1414, Rennes University Hospital, Rennes, France;* [3]*Endocrinology Department, Torino University Hospital, Torino, Italy;* [4]*Nephrology Department, Rennes University Hospital, Rennes, France;* [5]*Cardiology Department, Rennes University Hospital, Rennes, France;* [6]*Urology Department, Rennes University Hospital, Rennes, France*

Introduction: Primary aldosteronism (PA) is the most frequent endocrine cause of secondary hypertension, characterized by aldosterone production independent of the renin-angiotensin-aldosterone system. Compared to essential hypertension, PA is associated with significantly higher cardiovascular (CV) morbidity and renal damage. This study aimed to identify predictors of hypertension remission and factors associated with the occurrence of cardiovascular and renal events in PA patients.

Methods: We conducted a retrospective single-center study at Rennes University Hospital, including 202 patients (aged ≥18 years) diagnosed with PA who underwent adrenal vein sampling (AVS) for lateralization assessment. Data were extracted from electronic medical records. Logistic regression models were used to identify independent factors associated with hypertension remission and the onset of CV or renal complications.

Results: The cohort had a mean age of 48.9 ± 11 years (63% male). At diagnosis, mean systolic blood pressure (SBP) was 152.4 ± 24.3 mmHg, mean diastolic blood pressure (SBP) was 92.38 ± 13.42 and the mean duration of hypertension was 7.6 ± 7.3 years. Comorbidities included type 2 diabetes in 19.8%, and hypercholesterolemia in 20.3% of the patients.

AVS identified lateralized PA in 44.5% (85/191) of patients, with a 37.7% (66/175) discordance rate between CT scans and AVS results. Medical therapy was the primary treatment for 61.5% (118/192) of the cohort.

Overall, hypertension remission was achieved in 45% (91/202) of patients. Multivariable analysis identified three significant predictors of remission: preoperative hypokalemia <3.4 mmol/L (OR 2.24; 95% CI 1.21–4.17; $P = .01$), lateralized PA on AVS (OR 3.69; 95% CI 2.02–6.73; $P < .001$) and surgical treatment (OR 4.08; 95% CI 2.19–7.61; $P < .001$).

At the end of follow-up, the absence of hypertension remission was significantly associated with an increased prevalence of left

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

ventricular hypertrophy, microalbuminuria, and coronary artery disease ($P < .05$).

Conclusions: In patients with PA, hypokalemia, lateralization on AVS, and adrenalectomy are strong predictors of hypertension remission. Notably, failure to achieve remission is linked to a higher burden of cardiovascular and renal complications, emphasizing the need for early diagnosis and optimized targeted therapy.

EP15 - ECE_2175 - Glucocorticoid actions in the liver at single-cell resolution

Ronja Mueller[1], Ronny Scheundel[1], Aliana Harris[1], Gizem Oeztuerk[2], Anke Kunstmann[1], Sabine Vettorazzi[2] and Franziska Greulich[1]

[1]*Metabolic Programming, Technical University of Munich/School of Life Sciences Weihenstephan, Freising, Germany;* [2]*Institute of Comparative Molecular Endocrinology and Physiology, University of Ulm, Ulm, Germany*

Glucocorticoids (GCs) are adrenal steroid hormones that play a central role in the regulation of energy homeostasis and immune function and are widely prescribed as anti-inflammatory agents. Their clinical use, however, is limited by significant adverse effects, including hepatic steatosis, osteoporosis, and hyperglycaemia. Sustained exposure to elevated endogenous or exogenous GCs, as observed in Cushing's syndrome or during long-term GC therapy, leads to profound metabolic dysregulation, yet the underlying tissue- and cell-type–specific mechanisms remain incompletely understood.

GCs exert their effects through the glucocorticoid receptor (GR), a ubiquitously expressed nuclear hormone receptor that translocates to the nucleus upon ligand binding. GC exposure induces rapid and highly tissue-specific transcriptional responses, driven in part by context-dependent GR binding to chromatin regions with distinct DNA accessibility landscapes. How these tissue-level responses are further resolved into cell-type–specific actions and integrated to generate metabolic phenotypes such as diabetes is largely unknown.

To address this, we performed single-cell multiome sequencing of liver tissue from wild-type and GR-deficient mice subjected to chronic synthetic GC treatment for two weeks. Cell-type resolved analyses revealed pronounced and distinct GC-responsive transcriptional programs across hepatic cell populations. Prolonged GC exposure reprogrammed hepatocyte metabolic pathways and was associated with a marked reduction in F4/80-positive hepatic macrophages, indicating coordinated molecular and cellular adaptation to sustained GR signalling. By integrating single-cell transcriptomic profiles with chromatin accessibility and GR binding data, we delineate the cell-type–specific contributions of GC action in the liver and construct a comprehensive cellular response network underlying hepatic adaptation to chronic glucocorticoid exposure.

Background: Pheochromocytoma is a rare neuroendocrine tumor, occurring in less than 0.2 percent of patients with hypertension and primary aldosteronism alone occurring in 5-10% of all hypertension patients, mixed pheochromocytoma and primary aldosteronism is very rare in those patients.

Case Presentation: In 2024 60 years old female patient presented with high blood pressure (T/A max 200/100 mmHg). She was taking combined medication—ace inhibitor/ calcium channel blocker for her high blood pressure. Past medical history: rheumatoid arthritis, she was taking corticosteroid, but she stopped taking them 4 months prior. Before endocrinologist she was consulted by a cardiologist and urologist. She had made Computed Tomography (CT) scan of the abdomen, where in the right adrenal gland area was seen a fluid filled dense mass with clear contours measuring 6.7 × 7.7 cm in cross-sectional and 7 cm in craniocaudal dimensions. Antihypertensive medications were changed to alpha-adrenergic blocker and calcium channel blocker, with all rules followed, the lab tests were performed: ACTH and urine cortisol were in normal ranges, Aldosterone 79.0 ng/L (reference range—11.7–236), Renin <1.0 ng/L (reference range 1.7–23.9), Aldosterone renin ratio >79 (reference range <20), Urine Metanephrine i.u (24 h) 6615 ug/24 h (reference range 43.4-260), Normetanephrines i.u. (24 h) 11515 ug/24 h (reference range—128-484), Dopamine i.u. (24 h)—2138 ug/24 h (reference range—59.7-403), electrolytes and blood glucose levels were in normal ranges. Primary aldoseronism and/or pheochromocytoma was suspected. Patient underwent laparoscopic unilateral (right) adrenalectomy. Postoperative histopathomorphology report: adrenal cortical adenoma and pheochromocytoma. After surgery mild hypertension persisted, she is taking calcium channel blocker. Although mild hypertension persisted in lab tests on follow up after surgery: aldosterone, renin, aldosterone renin ratio in blood were in normal ranges, also urine 24 h metanephrine, normetanephrine and dopamine were in normal ranges.

Conclusions: Most primary neoplasms of the adrenal gland arise either from adrenal cortical cells or adrenal medulla chromaffin cells. Mixed adrenal tumors composed of more than one cell type of adrenal gland is very rare. This case describes a single adrenal neoplasm composed of the cells of adrenal cortex and medulla.

EP17 - ECE_3324 - When the adrenal breaks the rules: ACTH-expressing adrenocortical carcinoma: a case report

Andreea-Alexandra Grosu[1], Ioana Claudia Dan[1], Cristina Stancu[1,2], Dumitru Ioachim[1] and Corin Badiu[1,3]

[1]*Adult Endocrinology, Endocrinology IV, National Institute of Endocrinology "C.I Parhon", Bucharest, Romania;* [2]*National Institute of Endocrinology, Bucharest, Romania;* [3]*Endocrinology, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania*

Adrenocortical carcinoma (ACC) is a rare and aggressive endocrine malignancy, most often causing adrenocorticotropic hormone (ACTH)—independent hypercortisolism. ACTH expression by ACC is extremely rare and represents a major diagnostic challenge.

This report presents the case of a 41-year-old female patient who was incidentally diagnosed in June 2025 with a large mass

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

involving the right adrenal gland (1.21/1.15/0.79 cm) by an abdominal magnetic resonance imaging (MRI). This lesion showed diffusion restriction with necrotic and hemorrhagic areas, extending into inferior vena cava (IVC), nearly occluding the lumen. Physical examination revealed only an elevated arterial blood pressure (153/100 mmHg) without clinical signs of hypercortisolism. Biochemical evaluation showed borderline hypokalemia (3.5 mmol/L) with normal electrocardiography. Hormonal assessment demonstrated low-normal ACTH levels (4.99 pg/mL), normal levels of morning serum cortisol (11.76 µg/dL), adrenal androgens, aldosterone and renin. Serum cortisol ailed to suppress after both low and high-dose dexamethasone suppression tests (suppressed cortisol = 9.4 ug/dL; respectively 11.99 ug/dL) and 24-hour urinary free cortisol was three times the upper limit of normal (4316 ug/dL), indicating autonomous cortisol secretion. Neoadjuvant mitotane therapy (up to 4 g/day) was initiated. In July 2025, the patient underwent right adrenalectomy with IVC tumor thrombus excision. However, postoperative evolution was unfavorable, with rapid thrombus recurrence causing 75% IVC obstruction. Histopathological examination revealed diffuse architecture, focal necrosis, vascular and capsular invasion, significant nuclear atypia and a mitotic rate >5/50 high-power fields with a Ki-67 index of 20% (Weiss score 9). The cells exhibited positive immunohistochemical staining for inhibin, calretinin, Melan-A and most important, focal ACTH, proving the ability to synthesize ACTH. Microsatellite instability was absent. This case was reviewed by a Multidisciplinary Tumor Board, which decided for chemotherapy in combination with mitotane and oral anticoagulant therapy. Unfortunately, the tumor exhibited aggressive behavior, in November 2025 on 4 g mitotane/day, with a plasma level of 11.46 mg/L, ACTH levels were markedly elevated (257.6 pg/mL), with high serum cortisol (38.22 ug/dL) and persistent lack of suppression after dexamethasone. Functional imaging test revealed marked enlargement of the IVC tumor thrombus and newly developed left macronodular adrenal hyperplasia. In January 2026, systemic chemotherapy was initiated.

This case highlights a rare ACC with aberrant ACTH production causing ACTH-dependent hypercortisolism. ACTH expression in adrenocortical tumors is an unusual finding and is thought to reflect tumor dedifferentiation and aggressive biological behavior. Up until now, only two other cases of ACC with ectopic ACTH secretion have been reported.

EP19 - ECE_3636 - Primary aldosteronism beyond potassium: a multi-electrolyte disorder

Kalliopi Pantelia, Vasiliki Antonopoulou, Andromachi Panagiotopoulou, Marinella Tzanela and Theodora Stratigou

Department of Endocrinology "D. Ikkos", Diabetes Center, EndoERN-Evangelismos General Hospital, Athens, Greece

Background: Primary aldosteronism (PA) is a common cause of secondary hypertension, typically presenting with hypokalemia and metabolic alkalosis. Less recognized are disturbances in calcium homeostasis.

Case Presentation: We describe the case of a 39-year-old woman with a four-year history of hypertension, initially diagnosed during pregnancy, who presented with severe hypokalemia (K^+ 1.9 mmol/L), metabolic alkalosis (pH 7.508, HCO_3^- 33.1 mmol/L), and electrocardiographic abnormalities (U waves, ST-segment depression). Notably, during blood pressure measurement on admission, a positive Trousseau sign was elicited; the patient reported that it had been present for approximately four years during prior blood pressure measurements. Biochemical evaluation revealed suppressed renin (<0.5 µU/mL) and markedly elevated plasma aldosterone (33.9–35.9 ng/dL), with an aldosterone-to-renin ratio (ARR) >67.8, supporting a diagnosis of PA. Imaging identified a 3-cm right adrenal lesion; adrenal venous sampling confirmed right-sided aldosterone excess.

During hospitalization, the patient exhibited symptomatic hypocalcemia (albumin-corrected Ca 7.44 mg/dL) with mild vitamin D insufficiency (25[OH]D 18.9 ng/mL), high-normal PTH (62 pg/mL), and hypercalciuria (479 mg/24 h). Serum magnesium and phosphorus levels were within reference ranges. Bone mineral density, trabecular bone score, and bone turnover markers were within normal limits. Hypocalcemia required high-dose oral calcium (4 g/day) for stabilization; after correction the Trousseau sign resolved. Potassium supplementation was administered, and spironolactone was initiated and titrated to150 mg/day.

The patient underwent right adrenalectomy; histology confirmed a 3-cm adrenal cortical adenoma with strong, diffuse CYP11B2 positivity. Ten days postoperatively, serum potassium and calcium, as well as blood pressure normalized without supplementation or antihypertensive therapy. According to PASO criteria, the patient achieved complete clinical and biochemical success.

Conclusions: This case illustrates that PA can present with chronic, multisystem electrolyte disturbances including hypokalemia, hypocalcemia and hypercalciuria, associated with long-standing neuromuscular irritability. Expansion of effective circulating volume in PA patients decreases proximal tubule reabsorption of calcium as well as sodium because calcium reabsorption is coupled to transtubular sodium uptake. Although the distal nephron can reabsorb calcium, excessive delivery can overwhelm its absorptive capacity. This could lead to hypercalciuria and hypocalcemia. Curative adrenalectomy can fully reverse these disturbances, highlighting that PA is not solely a disorder of potassium homeostasis.

EP20 - ECE_2858 - Down syndrome and autoimmune polyglandular syndrome

Rugile Braukyliene[1], Laura Dudonytė[1], Agne Rimkute[1], Agne Kadusauskiene[2], Birutė Žilaitienė[2], Rasa Verkauskiene[3] and Aiste Kondrotiene[2]

[1]*Medical Academy, Lithuanian University of Health Sciences, Kaunas 44307, Lithuania;* [2]*Institute of Endocrinology, Lithuanian University of Health Sciences, Kaunas 44307, Lithuania;* [3]*Kaunas, Lithuania*

Introduction: Autoimmune polyglandular syndrome (APS) is a rare group of immune-mediated disorders. APS type 2 is the most common subtype with a characteristic clinical triad, which includes adrenal insufficiency, autoimmune thyroiditis and diabetes mellitus (DM) type 1.[1]

Case Presentation: A 37-year-old woman with Down syndrome (DS) and autoimmune thyroiditis treated with levothyroxine, was admitted to the emergency department with an 8-day

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

history of progressive weakness, nausea, and dizziness. The patient's height 142 cm, weight 47 kg, BMI 23 kg/m^2.'Initial laboratory evaluation revealed hyperkalemia 8.02 mmol/L (3.5-5.1) and hyponatremia 130 nmol/L (136-144). Patient was hospitalized to the intensive care unit. Patient developed persistent hypotension (79/50 mmHg) and ongoing hyperkalemia (6.1 mmol/L), hyponatremia (130 nmol/L) raising suspicion for adrenal crisis. Diagnostic evaluation confirmed adrenal insufficiency with markedly elevated ACTH level of 210.8 pmol/L (1.63-14.5) and low cortisol level of 101.18 nmol/L. Immediate treatment consisted of intravenous hydrocortisone 100 mg IV bolus. Hydrocortisone 200 mg /24 h was administered further using automatic syringe pump. After correcting the electrolyte imbalance, maintaining stable blood pressure, oral hydrocortisone was administered, gradually decreasing to a maintenance dose (30 mg/day). In the presence of a tendency to slight hypotension, with signs of aldosterone deficiency, elevated renin concentration of 134.9 ng/L (3.78-32.61), fludrocortisone was added resulting in systolic blood pressure increase toto 90-100 mmHg. Anti-GAD65, anti-IA2 antibodies were negative and glucose tolerance test was within normal range. At discharge, the patient's treatment consisted of hydrocortisone (15/10/5 mg), fludrocortisone 50 μg per day and levothyroxine 75 μg per day. A month later, laboratory tests revealed elevated renin level of 401 ng/L (3.78-32.61) and elevated TSH level of 14.78 mU/L (0.4-3.6), sodium 133 mmo/L (135-144), potassium 4.7 nmol/L (3.5-5.1), a tendency to a lower blood pressure was found. Fludrocortisone dose was increased to 75 μg per day and levothyroxine—to 100 μg per day, hydrocortisone dose was unchanged and follow up visit was planned in 2 months.

In conclusion, DS is associated with an increased risk of autoimmune diseases due to disruption of immune tolerance.[2] This case highlights the challenges and risks of APS type 2 in patients with DS, indicating the need for screening and timely treatment of these serious endocrine conditions.[3]

EP21 - ECE_1753 - GDF15 in patients with autoimmune primary adrenal insufficiency

Aleksandra Zdrojowy-Welna, Jowita Halupczok-Żyła, Katarzyna Kolačkov, Justyna Kuliczkowska-Płaksej, Aleksandra Jawiarczyk-Przybyłowska, Barbara Stachowska, Anna Brona, Iga Zendran-Zahorska and Marek Bolanowski
Wroclaw Medical University, Department of Endocrinology and Internal Diseases, Wrocław, Poland

Background: GDF15 is a stress response protein that acts as a hormone signaling distress from cells to the brain. Increased GDF15 is associated with reduced appetite and weight loss, symptoms that resemble the clinical picture of primary adrenal insufficiency (PAI). It has been shown that GDF15 levels are elevated in glucocorticoid deficiency. However, there are no studies analyzing clinical factors related to GDF15 in patients with PAI.

Objectives: The aim of our study was to evaluate circulating GDF15 in patients with autoimmune PAI in comparison to controls and to assess correlations between GDF15 and anthropometric, metabolic, and hormonal parameters in both groups.

Materials and Methods: We included 37 patients (59.5% females, mean age 48.9 ± 13.1 years) with autoimmune PAI, and 47 age-, sex- and BMI-matched controls. The mean duration of PAI was 11.3 ± 12.7 years. Laboratory examinations, including serum GDF15 levels, hormonal and biochemical parameters were performed. The percentage of body fat was evaluated using dual-energy X-ray absorptiometry.

Results: Patients with PAI had significantly higher GDF15 levels than controls (1276.8 ± 952.1 vs 682.8 ± 270.2 pg/mL, $P < .001$). In both groups of patients with PAI and controls, GDF-15 levels correlated positively with age ($P < .001$). In the PAI group, there were positive correlations between GDF15 and the duration of PAI and autoimmune thyroid disease, gonadotropin levels, waist-to-hip ratio, and the percentage of body fat, while negative correlations with DHEAS and sex hormones levels. In controls, GDF15 correlated positively with fasting glucose, while negatively with IGF-1.

Conclusions: Circulating GDF15 levels are significantly higher in patients with PAI than in controls and correlate with older age and the duration of autoimmune diseases. There are also correlations between GDF15 and metabolic parameters related to unfavorable body composition.

EP23 - ECE_2270 - Routine inflammation-based blood indices reflect cortisol excess severity and might identify mild autonomous cortisol secretion in adrenal incidentalomas

Vlad Radulescu[1,2], Beatrice Cristea[2], Roxana Fota[2], Ioana Maria Posea[2], Anda Dumitrașcu[2], Madalina Musat[1,2], Monica Livia Gheorghiu[1,2] and Corin Badiu[1,2]
[1]Endocrinology, Endocrinology, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania; [2]Adult Endocrinology, Endocrinology IV, National Institute of Endocrinology "C.I Parhon", Bucharest, Romania

Objective: Mild autonomous cortisol secretion (MACS) is associated with increased cardiometabolic risk but remains difficult to recognize using simple clinical parameters. While overt Cushing's syndrome (CS) is known to induce immune and hematological changes, the diagnostic value of inflammation-based indices in detecting low-grade cortisol excess has not been clearly established. We aimed to evaluate whether routinely available inflammation-based blood indices reflect cortisol excess severity and can discriminate between non-functioning adrenal tumors (NFAT), MACS and overt CS.

Design and Methods: We retrospectively analyzed 350 patients with benign adrenal adenomas evaluated at a tertiary endocrine center: 186 NFAT, 136 MACS and 28 CS in a cross-sectional

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

approach before any adrenal-directed treatment. Patients aged between 18-75 years old were analyzed. Patients with other secreting adrenal tumors, active infections, malignancy, hematologic disorders, chronic kidney disease ≥G3b, or current glucocorticoid/immunosuppressive/psychiatric therapy as well as other acute conditions that could modify full blood count values at time of testing were excluded. Neutrophil-to-lymphocyte ratio (NLR), lymphocyte-to-monocyte ratio (LMR), systemic immune-inflammation index (SII) and eosinophil-to-basophil ratio (EBR) were calculated from complete blood counts. Group differences were assessed using non-parametric tests. Receiver operating characteristic analyses were performed to assess discrimination between groups, and optimal cutoffs were derived using Youden's index.

Results: Inflammation-based indices showed a graded response to cortisol excess. NLR and SII increased progressively from NFAT to MACS and were highest in CS, while LMR and EBR decreased across the same spectrum (all adjusted $P < .01$). For identification of MACS versus NFAT, NLR showed an AUC of 0.604 (95% CI 0.542–0.667) with an optimal cutoff of 2.21 (sensitivity 64.7%, specificity 55.4%), while SII showed an AUC of 0.597 (95% CI 0.533–0.660) with a cutoff of 635 (sensitivity 50.7%, specificity 69.4%). LMR and EBR demonstrated statistically significant but lower discriminatory accuracy. Similar progressive changes were observed in total leukocyte, neutrophil and monocyte counts.

Conclusions: Inflammation-based indices derived from routine blood tests demonstrate a clear gradient of increased cardiometabolic risk across increasing degrees of cortisol excess and can distinguish patients with MACS from those with non-functioning adrenal tumors. Although individual diagnostic accuracy is moderate, these markers reflect early immune dysregulation in low-grade hypercortisolism and may support clinical risk stratification and follow-up decisions in patients with adrenal incidentalomas.

EP24 - ECE_2306 - Lipotoxic versus glucotoxic phenotypes: differential visceral adiposity profiles in Cushing's disease and mild autonomous cortisol secretion

Aslihan Pekmezci[1], Mehmet Arikan[2], Merve Korkmaz[1], Aytul Yardımcı[2], Mutlu Niyazoğlu[1,3] and Esra Hatipoglu[1,3]
[1]*Department of Endocrinology and Metabolism, University of Health Sciences, Basaksehir Cam and Sakura City Hospital, Istanbul, Türkiye;* [2]*Department of Radiology, University of Health Sciences, Basaksehir Cam and Sakura City Hospital, Istanbul, Türkiye;* [3]*Pituitary Disorders Research Center, University of Health Sciences, Istanbul, Türkiye*

Background and Objective: Cortisol excess is associated with adverse cardiometabolic outcomes, yet its metabolic expression is heterogeneous and inadequately captured by conventional anthropometric measures. Using magnetic resonance imaging (MRI)–derived proton density fat fraction (PDFF), we aimed to characterize differential adiposity profiles across the spectrum of cortisol excess, distinguishing adipose tissue expansion from organ-specific fat accumulation.

Methods: Herein, preliminary results from an ongoing study included patients with overt Cushing's disease (CD) ($n = 19$, 7 active,12 in remission), mild autonomous cortisol secretion (MACS) ($n = 12$), and age- and sex-matched metabolically healthy controls (HC) ($n = 10$). Regional adipose tissue distribution and organ-specific fat accumulation were assessed using quantitative MRI–derived PDFF. Bonferroni correction was applied for multiple group comparisons, with a corrected significance threshold of $P < .0167$.

Results: Quantitative MRI demonstrated increased subcutaneous adipose tissue (SAT) in both CD (310.4[IQR:207.3–513] cm^2) and MACS (253.2[209.8–409.5] cm^2) compared with HC (182.9[136.2–198.3] cm^2; both $P < .0167$), with no difference between the two cortisol excess groups ($P > .0167$). Visceral adipose tissue (VAT) was higher in MACS than in HC (251[203.7–293.7] vs 107.5[83.7–176.5] cm^2; $P = .003$), whereas the increase in CD (195.8[158.5–267.2] cm^2) did not remain statistically significant ($P > .0167$). Within-group analyses demonstrated that SAT exceeded VAT in all groups; reaching statistical significance only in CD($P = .016$). Among patients with CD, a significant predominance of subcutaneous over visceral adipose tissue was observed in the active disease state ($P = .02$), whereas this difference was no longer evident in patients in remission ($P = .398$). Body mass index (BMI) was higher in both cortisol excess groups compared with HC (32.5 and 32.2 vs 25.4 kg/m^2; $P < .0167$). SAT showed a positive correlation with BMI in both CD and MACS (all $P < .01$), whereas VAT was associated with triglyceride (TG) levels in CD and with HbA1c in MACS(all $P < .01$). MRI-derived PDFF of the liver and pancreas did not differ between groups or between active and remission states in CD(all $P > .05$).

Conclusions: Our findings suggest differential visceral adiposity–related metabolic profiles across the spectrum of hypercortisolism, with CD showing a predominantly lipotoxic pattern (VAT–TG association) and MACS a more glucotoxic pattern (VAT–HbA1c association). SAT correlated with BMI irrespective of disease severity, indicating a marker of general adiposity rather than cortisol-specific effects. Notably, hepatic and pancreatic MRI-derived PDFF values did not differ between groups or disease states, suggesting limited discriminatory value for metabolic phenotyping. These associations support a phenotype-oriented approach to cardiometabolic risk stratification in cortisol autonomy.

Background: Mild autonomous cortisol secretion (MACS) as well as non-functional adrenal incidentalomas (NFAI) are associated with increased metabolic and cardiovascular risk suggesting a subtle secretion of cortisol or of other precursors of steroidogenesis.

Aim: To investigate steroid metabolites levels in patients with MACS and NFAI benign adrenal tumours as well as in adrenocortical carcinomas (ACC). Controls were defined as patients with normal adrenals on imaging.

Methods: Liquid chromatography-tandem mass spectrometry (LC-MS/MS) was used for the steroidomics analysis of several steroid precursors [cortisol (F), corticosterone (B,CORT),11-deoxycorticosterone (DOC), 11-deoxycortisol (11-DOC, compoundS), 21-deoxycortisol (21-DOF), aldosterone (ALDO), testosterone (T), dihydrotestosterone (DHT), androstenedione (A4), androsterone (AN), dehydroepiandrosterone (DHEA), dehydroepiandrosterone Sulfate (DHEAS), progesterone (P4), 17-hydroxyprogesterone (17-OHP4), pregnenolone (P5), 17-hydroxypregnenolone (17-OHP5), estradiol (E2), estrone (E1)] in the blood of 53 patients. The categorisation of patients in functional or NFAI was based on functional hormonal blood tests [1 mg overnight dexamethasone suppression test (ODST)] based on current guidelines. All ACC cases were confirmed histopathologically.

Results: A total of 46 patients (12 males) with adrenal tumors [($n = 20$ with NFAI, $n = 15$ with MACS and $n = 11$ with ACC] and 7 controls were included. Tumor size was significantly higher in ACC compared to NFAI and MACS patients.

LC-MS/MS analysis showed that the median blood steroid levels of cortisol, 11-deoxycorticosterone, 21-deoxycortisol were significantly higher ($P < .05$) in ACC patients compared with NFAI, MACS.

Regarding patients with benign tumors, median levels of baseline morning cortisol, 11-deoxycorticosterone and 21-deoxycortisol were significantly higher in MACS compared with NFAI ($P = .04$, $P = .01$, $P = .01$ respectively). Baseline median levels of 11-deoxycorticosterone were significantly higher in NFAI compared with controls ($P = .03$) whereas progesterone was significantly lower in NFAI and MACS compared with controls ($P = .001$, $P = <0.001$ respectively).

Among comorbidities hypertension, hyperlipidemia and diabetes mellitus prevalence was higher in patients with adrenal tumors compared to controls as well as between NFAI and controls.

Conclusions: Cortisol, 11-deoxycorticosterone, and 21-deoxycortisol levels were significantly higher in ACC compared with MACS and NFAI. In benign adrenal tumors, cortisol, 11-deoxycorticosterone, 21-deoxycortisol, and progesterone differed significantly between MACS and NFAI and may represent supplementary biochemical markers of adrenal functional status**.**

EP27 - ECE_2912 - Non-functioning adrenal incidentalomas: a diagnosis we can still trust?

Vittoria Favero[1,2], Cristina Eller Vainicher[3], Valentina Morelli[4], Serena Palmieri[3], Alfredo Scillitani[5], Irina Bancos[6] and Iacopo Chiodini[1,2]

[1]University of Milan, Department of Medical Biotechnology and Translational Medicine, Milan, Italy; [2]ASST Grande Ospedale Metropolitano Niguarda, Unit of Endocrinology, Milan, Italy; [3]Unit of Endocrinology, Fondazione IRCCS Cà Granda-Ospedale Maggiore Policlinico, Milan, Italy; [4]Department & Lab of Endocrine and Metabolic Research, IRCCS Istituto Auxologico Italiano, Milan, Italy; [5]IRCCS Ospedale "Casa Sollievo della Sofferenza", San Giovanni Rotondo, Foggia, Italy; [6]Mayo Clinic; [7]Division of Endocrinology, Metabolism, and Nutrition, Department of Laboratory Medicine and Pathology, Rochester, Italy

Introduction: Non-functioning adrenal incidentalomas (NFAI) are defined by post–1 mg dexamethasone suppression test (F-1mgDST) cortisol levels <1.8 µg/dL. However, emerging evidence suggests that many individuals classified as having NFAI may exhibit subtle cortisol excess associated with increased cardiometabolic and skeletal risk.

Objective: To compare F-1mgDST levels between patients with NFAI and control subjects and to identify the F-1mgDST threshold most accurately associated with the presence of NFAI.

Materials and Methods: Pooled individual participant data analysis of 7 retrospective and prospective studies evaluating cortisol secretion in patients with type 2 diabetes, osteoporosis and/or fragility fractures, hypertension, or adrenal incidentalomas. The study included 1681 participants (915 with NFAI and 766 controls), all with F-1mgDST <1.8 µg/dL. Data collected included age, sex, body mass index (BMI), F-1mgDST, and adrenocorticotroph hormone (ACTH, available for all NFAI patients and for 176 controls).

Main outcomes included between-group differences in F-1mgDST and ACTH levels; diagnostic accuracy of F-1mgDST for identifying NFAI via receiver operating characteristic (ROC) analysis; and sensitivity, specificity, and odds ratios (ORs) for predicting NFAI across various F-1mgDST thresholds.

Results: Compared to controls, patients with NFAI were younger and had lower BMI and ACTH levels but significantly higher F-1mgDST values. ROC analysis demonstrated that an F-1mgDST threshold of 1.1 µg/dL (30 nmol/L) provided the best balance of sensitivity (54.8%) and specificity (57.2%), while an F-1mgDST threshold of 0.6 µg/dL (17 nmol/L) and of 1.7 µg/dL (47 nmol/L) the best sensitivity (93%) and specificity (93.5%), respectively, for distinguishing between control subjects and patients with NFAI. An F-1mgDST >1.1 µg/dL was independently associated with NFAI (OR, 1.58; 95% CI, 1.30–1.92) after adjusting for age, BMI, sex and presence of hypertension, type 2 diabetes and osteoporosis. The combination of obesity and male sex amplified the association, with obese men and F-1mgDST >1.1 µg/dL showing a nearly 3-fold higher likelihood of NFAI (OR, 2.87; 95% CI, 2.02–4.09).

Conclusions and Relevance: Among individuals with cortisol concentrations within the currently accepted normal range after dexamethasone suppression, those with NFAI display significantly higher F-1mgDST levels than control subjects. These findings indicate that the widely used threshold of 1.8 µg/dL may not reliably exclude mild autonomous cortisol secretion. A lower threshold of 1.1 µg/dL is the may improve identification of individuals with NFAI.

[3]Department of Radiology, LMU University Hospital, Munich, Germany

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) is closely linked to obesity, diabetes mellitus, and dyslipidemia. Patients with primary aldosteronism (PA), mild autonomous cortisol secretion (MACS), and Cushing's syndrome (CS) frequently exhibit metabolic abnormalities; however, the prevalence of MASLD and the relative contribution of hormonal excess versus metabolic factors remain unclear. We aimed to evaluate the prevalence of MASLD and its metabolic and hormonal determinants in patients with PA, CS, and MACS.

Methods: This cross-sectional study included 229 treatment-naive patients who underwent unenhanced abdominal computed tomography (CT). Eigthy-eigth with PA, 81 with MACS (including 34 with concomitant PA and cortisol cosecretion), and 60 with CS. Hepatic steatosis was assessed using the liver-to-spleen (L/S) attenuation ratio. Noninvasive steatosis and fibrosis indices, including the hepatic steatosis index (HSI), triglyceride–glucose (TyG) index were calculated.

Results: The prevalence of MASLD was 28.4% in PA, 26.6% in CS, and 29.6% in MACS ($P > .05$). Liver attenuation and L/S ratio did not differ significantly among groups but were strongly correlated with visceral adiposity, fasting glucose, insulin, HbA1c, triglyceride levels, HSI, and TyG index (all $P < .05$). In the multivariable linear regression diabetes mellitus was independently associated with lower liver attenuation after adjustment for age, sex, and body mass index ($\beta = -11.10$ HU, 95% CI: −16.40 to −5.79). In contrast, no significant associations were observed between hepatic steatosis and measures of cortisol excess (serum cortisol, 24-hour urine free cortisol, or midnight salivary cortisol) or aldosterone levels.

Conclusions: Hepatic steatosis is prevalent and shows a comparable distribution among patients with PA, CS, and MACS. Its presence is primarily driven by metabolic factors, particularly diabetes mellitus, BMI, visceral adiposity, and hypertriglyceridemia, rather than by the direct effects of hormonal excess.

EP30 - ECE_2006 - Sex differences in clinical phenotype and therapeutic response of renin-independent aldosterone production in adrenal incidentalomas: a prospective Latin American cohort study

Thomas Uslar[1,2], Benjamín Sanfuentes[1], Roberto Olmos[3], Alberth Burnier[4], Pauline Böhm[5], Cristian Carvajal[1], Carlos Fardella[1], Fidel Allende[1], Sandra Solari[1], Anand Vaidya[6], Felix Beuschlein[2] and René Baudrand[1]

[1]CETREN-UC, Red de Salud UC-CHRISTUS, Endocrinology, Pontificia Universidad Católica de Chile, Santiago, Chile; [2]Department of Endocrinology, Diabetology and Clinical Nutrition, University of Zurich, Universitätsspital Zürich, Zürich, Switzerland; [3]Fund Arturo López Pérez, Endocrinology, Santiago, Chile; [4]Hospital Las Higueras, Talcahuano, Chile; [5]Pontificia Universidad Católica de Chile, Santiago, Chile; [6]Endocrinology, Brigham and Women's Hospital, Harvard Medical School, Boston, United States

Background: Biological sex influences clinical presentation and treatment response in primary aldosteronism (PA). However, sex-related differences across the spectrum of renin-independent aldosterone production, including mild phenotypes, remain insufficiently characterized. This knowledge gap is particularly relevant in Latin America, where data on adrenal incidentalomas and PA are scarce.

Objective: To evaluate sex differences in clinical presentation and therapeutic response across the spectrum of renin-independent aldosterone production in patients with incidental adrenal adenomas from a Latin American population.

Design: Prospective cohort study.

Methods: We included 383 consecutive patients with incidental adrenal adenomas (298 women, 85 men). Baseline clinical and biochemical characteristics were compared by sex. Low-renin was defined by direct renin <10 μU/mL and the severity of aldosterone production was classified according to plasma aldosterone concentrations (PAC), measured by immunoassay, as mild (PAC > 5 ng/dL), moderate (PAC 5-15 ng/dL), or severe (PAC > 15 ng/dL). Hypertensive patients ($n = 253$) were followed for a median of 20 (10-33) months and managed according to the level of adrenal hormone excess: conventional treatment for non-functioning lesions, or mineralocorticoid receptor antagonists (MRA) or adrenalectomy for low-renin hypertension. Treatment response was assessed using PAMO criteria for MRA therapy and PASO criteria for surgical treatment.

Results: At baseline, men showed a higher prevalence of hypertension (66% vs 52%, $P = .021$) and required more antihypertensive medications (defined daily dose 2.00 [1.00–3.00] vs 1.25 [0.60–2.50], $P = .018$). A low-renin phenotype was identified in 153 patients (40%). Women more frequently presented with mild aldosterone production (61.8% vs 33.3%, $P = .005$), whereas men had higher prevalence of severe phenotype (43.3% vs 13.8%, $P < .001$). Men exhibited higher PAC, aldosterone-to-renin ratio, and 24-hour urinary aldosterone and potassium excretion, along with lower plasma potassium, while natriuresis was similar between sexes. With individualized aldosterone-targeted therapy, blood pressure and renin improved across all magnitudes of renin-independent aldosterone production. There were no sex differences in treatment modality (MRA vs surgery) or MRA dose. Complete clinical response was comparable between sexes, whereas complete biochemical response was more frequent in men (100% vs 79%, $P = .016$).

Conclusions: In this prospective Latin American cohort, renin-independent aldosterone production was highly prevalent among patients with adrenal incidentalomas and was associated with a more severe clinical and biochemical phenotype in men. Aldosterone-directed therapy improved outcomes even in the mild phenotype, with superior biochemical response in men. These findings highlight the relevance of biological sex in the evaluation and personalized management of renin-independent aldosterone production, particularly in underrepresented populations.

Affiliated Hospital Zhejiang University School of Medicine, Hangzhou, China; [5]Hangzhou, China; [6]Endocrinology, The First People's Hospital of Xiaoshan District, Hangzhou, China

Background: Primary aldosteronism (PA) is a common cause of refractory hypertension, and adrenal venous sampling (AVS) is the gold standard for lateralizing PA. Although preprocedural supine rest is recommended to reduce posture-related hormonal fluctuations, its optimal duration remains unclear.

Objective: To evaluate whether a preprocedural supine time of overnight versus 2 hours before AVS affects PA subtype classification.

Methods: This single-center retrospective study included patients with confirmed PA who underwent AVS between 2016 and 2025. AVS was performed without adrenocorticotropic hormone stimulation. Patients were retrospectively grouped according to preprocedural supine duration (overnight vs 2 hours). Successful catheterization was defined by a selectivity index (SI) ≥ 2.0, and lateralization by a lateralization index (LI) ≥ 2.0. Between-group comparisons were performed using appropriate parametric or nonparametric tests. A two-sided $P < .05$ was considered statistically significant.

Results: A total of 251 patients with successful AVS were included (overnight group, $n = 116$; 2-hour group, $n = 135$). AVS results revealed no significant differences in aldosterone concentrations between the overnight and 2-hour groups (right adrenal vein: 2472.50 [821.75–12,262.50] pg/mL vs 3130.00 [1100.00–18600.00] pg/mL, $P = .3266$; left adrenal vein: 2285.00 [716.75–8220.00] pg/mL vs 2220.00 [654.50–9390.00] pg/mL, $P = .7802$). Cortisol concentrations were also comparable between groups (right adrenal vein: 2902.00 [1121.50–6626.00] nmol/L vs 2407.00 [1216.00–7692.00] nmol/L, $P = .9381$; left adrenal vein: 2040.00 [912.89–4620.50] nmol/L vs 2056.00 [899.00–3763.50] nmol/L, $P = .7417$), resulting in similar SI values (right adrenal vein: 13.14 [6.32–22.65] vs 14.03 [5.24–28.05], $P = .7058$; left adrenal vein: 10.07 [4.81–21.61] vs 8.65 [4.29–19.80], $P = .6027$).

LI and contralateral suppression index (CI) values showed no significant differences between the overnight and 2-hour groups in patients with left-sided dominance ($n = 94$; LI 7.55 [3.26–28.60] vs 23.41 [3.60–87.80], $P = .0895$; CI 0.35 [0.15–0.72] vs 0.32 [0.12–0.80], $P = .7883$), right-sided dominance ($n = 100$; LI 12.03 [4.50–30.75] vs 14.15 [4.09–38.65], $P = .9132$; CI 0.30 [0.13–0.53] vs 0.35 [0.13–0.67], $P = .4751$), or bilateral aldosterone secretion ($n = 57$; LI 0.97 [0.77–1.36] vs 1.09 [0.73–1.30], $P = .8795$).

Conclusions: In this retrospective cohort, overnight versus 2-hour preprocedural supine rest was not associated with differences in AVS selectivity index, lateralization, or PA subtype classification. These findings suggest that a shorter supine duration may be feasible without compromising AVS interpretation.

Background: Finerenone, a novel nonsteroidal mineralocorticoid receptor antagonist (MRA), has demonstrated short-term efficacy and safety in patients with primary aldosteronism (PA). However, evidence for its long-term effectiveness and safety versus spironolactone in real-world settings remains scarce.

Aim: To compare the long-term effectiveness and safety of treatment strategies centered on finerenone versus spironolactone in PA patients in a real-world setting.

Methods: The multicenter prospective cohort included PA patients from eight hospitals in China who had completed a prior single-arm trial of finerenone. According to the actual treatment during follow-up (>6 months), the patients were categorized into finerenone continuation (FIN) or spironolactone switch (SPI) groups. Concomitant antihypertensive therapy followed routine practice. The primary endpoint was the integrated control rate (office BP <140/90 mmHg and normokalemia without potassium supplementation). Secondary endpoints included changes in ambulatory and office BP parameters, plasma renin activity (PRA), Primary Aldosteronism Medical Treatment Outcome (PAMO) response rates, and adverse events. Multivariable models were adjusted for baseline and defined daily dose (DDD) changes.

Results: A total of 37 PA patients were included (FIN: 26; SPI: 11) and received mean daily doses of 21.9 mg of finerenone or 40 mg of spironolactone, respectively. Baseline characteristics were comparable between the groups. Primary endpoint: After adjustment for the DDD, no significant difference in integrated control rate was observed (FIN: 53.8% vs. SPI: 63.6%; adjusted OR = 0.289; 95% CI 0.039–2.127; $P = .223$). Secondary endpoints: Office BP decreased significantly in both groups (FIN: −15.4/−10.0 mmHg; SPI: −19.9/−10.9 mmHg; adjusted $P > .05$ between groups). Daytime systolic BP decreased similarly (FIN: 11.0 mmHg; SPI: 13.7 mmHg; adjusted $P = .677$). No significant differences were observed in posttreatment serum potassium concentrations (FIN: 4.06 mmol/L vs. SPI: 4.10 mmol/L; $P = .611$) or PRA (FIN: 0.41 [0.14–1.01] ng/mL/h vs. SPI: 0.53 [0.09–1.11] ng/mL/h; $P = .088$). The PAMO complete biochemical (23.1% vs. 27.3%; adjusted $P = .179$) and clinical (11.5% vs. 9.1%; adjusted $P = .772$) response rates were comparable. No gonadal adverse events occurred in the FIN group; 3 cases of breast

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

pain (27.3%) were reported in the SPI group ($P = .021$). No hyperkalemia occurred, and eGFR remained stable in both groups.

Conclusions: This real-world study indicates that finerenone- and spironolactone-based strategies demonstrate similar efficacy against PA in terms of long-term blood pressure control, biochemical improvement, and PAMO response. Furthermore, finerenone is not associated with gonad-related adverse effects. This study extends the evidence and supports the use of finerenone in the management of PA.

EP33 - ECE_2563 - Revisiting the 10-HU threshold: unenhanced CT attenuation in functional adrenal adenomas

Tugce Apaydin[1,2], Isabel Stüfchen[2], Júnia Ribeiro De Oliveira Longo Schweizer[2], Elisabeth Nowak[2], Christine Schmid-Tannwald[3], Felix Herr[4], Martin Reincke[2], Nabeel Mansour[3] and Friederike Völter[2]

[1]Acıbadem Ataşehir Hospital, Istanbul, Türkiye; [2]Department of Medicine IV, LMU University Hospital, Munich, Germany; [3]Department of Radiology, LMU University Hospital, Munich, Germany; [4]Radiology, Department of Radiology, LMU University Hospital, Munich, Germany

Background: Although adrenocortical adenomas typically show low unenhanced attenuation (≤10 HU) on CT, this benignity criterion has limited sensitivity, particularly in lipid-poor and hormonally active tumors. We aimed to evaluate unenhanced CT attenuation across different functional and non-functioning adrenal adenoma subtypes.

Methods: In this retrospective study, 167 surgically proven patients with non-enhanced CT of the adrenals as well as complete clinical and biochemical records were included: unilateral primary aldosteronism (PA) defined by complete or partial biochemical success after adrenalectomy ($n = 64$), mild autonomous cortisol secretion (MACS) ($n = 48$), Cushing's syndrome (CS) ($n = 31$), and compared to non-functioning adrenal adenomas (NFA) ($n = 24$, no surgical proof). After testing for normality, attenuation values were compared using the Kruskal-Wallis test. Frequencies were compared using Fisher's exact test.

Results: Adrenal adenomas in CS showed higher attenuation (19.3 ± 14.0 HU) than PA (10.5 ± 12.7 HU), MACS (6.8 ± 16.0 HU), and NFA (5.4 ± 19.9 HU, $P = .003$). Notably, lesions with >10 HU were common not only in CS (67.7%) but also in PA (48.4%) and MACS (43.7%). Values >20 HU were significantly more common in CS than in the other groups (51.6%, $P = .029$). In CS, attenuation correlated positively with baseline cortisol ($r = 0.508$, $P = .035$), midnight salivary cortisol ($r = 0.454$, $P = .013$), and 1 mg DST ($r = 0.611$, $P < .001$). In multivariable analysis, cortisol ($P = .014$) and 1 mg DST ($P = .015$) independently predicted attenuation ($R^2 = 26.2\%$).

Conclusions: Unenhanced CT attenuation >10 HU is common in cortisol-producing adenomas, observed in approximately two-thirds of patients, and is also frequently seen in PA and MACS. This finding should be carefully considered in routine clinical decision-making.

Introduction: 18-OXOF is a hybrid adrenal steroid extensively studied in primary aldosteronism (PA), where its production reflects dysregulated aldosterone synthesis under combined renin–angiotensin and adrenocorticotropic hormone (ACTH) influence. Although typically considered a marker of mineralocorticoid pathway activation, we identified measurable 18-OXOF concentrations in patients with CAH, raising the possibility that it reflects altered adrenal steroidogenic activity beyond mineralocorticoid regulation.

Methods: Clinical, biochemical, and treatment data were analysed in patients with CAH to evaluate 18-OXOF as a candidate marker of disease control. Established biochemical markers included 17-hydroxyprogesterone (17-OHP), androstenedione, testosterone, 11-ketotestosterone, hydrocortisone dose normalised to body surface area (HCBSA), and 21-deoxycortisol. Mineralocorticoid control was assessed using plasma renin concentrations adjusted for fludrocortisone dose per body surface area. Serum steroids were measured by LC-MS/MS. Multivariable linear regression models were used to examine associations between 18-OXOF and biochemical indicators of CAH control, conceptualised as a marker of ACTH and renin modulated adrenal steroidogenesis.

Results: Eighty-four patients from 13 UK sites were included (age 8–18 years; mean HCBSA 14.03 mg/m^2, SD 3.8). 18-OXOF, detectable in sixty patients, showed strong independent associations with 18-OHF, 21-deoxycortisol, and 17-OHP, explaining a significant proportion of variance after adjustment for age and sex (R^2

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

= 0.66, $P < .001$). There is a significant positive correlation between 18-OXOF with both actual hydrocortisone dose and when controlled for using HCBSA ($P = .01$, $P = .047$ respectively). 18-OXOF was not associated with plasma renin concentrations after adjustment for fludrocortisone dose normalised to body surface area and age ($R^2 = 0.23$, $P = .20$), nor was it strongly associated with blood pressure, indicating that 18-OXOF does not reflect mineralocorticoid control in CAH. Although 18-OXOF is traditionally considered a marker of aldosterone pathway activation in PA, the physiological basis for its measurable concentrations in CAH is unclear. This finding suggests that 18-OXOF may reflect alternative steroidogenic pathways in CAH and highlights its potential as a confounding factor in the biochemical evaluation of PA.

Conclusions: 18-OXOF is produced via hybrid adrenal steroidogenic pathways that involve both cortisol and aldosterone biosynthesis, rendering it sensitive to altered steroid flux characteristic of CAH. Its strong association with proximal pathway intermediates and lack of association with mineralocorticoid control suggest that 18-OXOF may reflect glucocorticoid dependent adrenal activity rather than treatment dosing or haemodynamic status. These findings support 18-OXOF as a pathway specific biomarker of biochemical CAH disease control, with potential utility for monitoring disease, warranting further investigation.

EP36 - ECE_3906 - Study design of a phase 3, randomized, double-blind, placebo-controlled trial (CALM-CAH) to evaluate atumelnant in adult patients with congenital adrenal hyperplasia

Nicole Reisch[1], Deborah Merke[2], Tania Bachega[3], Richard Auchus[4], Alejandro Ayala[5], Yang Wu[5], Eduardo De La Torre[5] and Umasuthan Srirangalingam[6]

[1]Medizinische Klinik and Poliklinik IV, Klinikum der Universität München, LMU München, Munich, Germany; [2]National Institutes of Health Clinical Center and Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD, United States; [3]Laboratorio de Hormonios e Genetica Molecular-LIM 42, da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil; [4]Division of Metabolism, Endocrinology, and Diabetes and the Departments of Internal Medicine and Pharmacology, University of Michigan, Ann Arbor, MI, United States; [5]Crinetics Pharmaceuticals, Inc., San Diego, CA, United States; [6]Endocrinology & Diabetes, University College London Hospitals NHS Foundation Trust, London, United Kingdom

In classic (21-hydroxylase deficiency) congenital adrenal hyperplasia (CAH), normal steroidogenesis pathways are disrupted, leading to hypocortisolism and hyperandrogenism. CAH management traditionally relied on glucocorticoid (GC) dosing to suppress excess adrenocorticotropic hormone. This approach often fails to normalize adrenal androgens without supraphysiologic GC exposure, which results in considerable health impairment in patients with CAH. There is substantial unmet need for therapies that reduce GC dosing to physiologic levels while maintaining normalized androgen levels. Atumelnant (CRN04894) is a first-in-class, once-daily, oral, selective melanocortin type 2 receptor antagonist in development for CAH treatment. In a 12-week, Phase 2, open-label study in patients with CAH (NCT05907291), atumelnant induced rapid, substantial, and sustained reductions in serum androstenedione (A4) and 17-hydroxyprogesterone (17-OHP) levels and reduced total adrenal volume in most participants. CALM-CAH (NCT07144163) is a Phase 3, randomized, double-blind, placebo-controlled trial to evaluate the efficacy, safety, pharmacokinetics, and pharmacodynamics of atumelnant in adults (≥18-75) with classic CAH. Patients on a stable GC dose for ≥3 months and A4≥the upper limit of normal (ULN) or those with A4<ULN receiving ≥14 mg/m^2/d GC doses are eligible. Patients will be randomized 2:1 to atumelnant 80 mg or placebo once daily for 32 weeks with optional dose escalation to 120 mg once daily at Week 20. GC dose reduction occurs from Weeks 2-12 and Weeks 16-28, to reach the target physiologic dose of <11 mg/m^2/d hydrocortisone equivalent. Patients who complete treatment may enroll in an open-label extension. The primary endpoint is proportion of patients with morning post-GC (2-3 hours after GC dosing) A4≤ULN who are on physiologic GC replacement at Week 32. Key secondary endpoints include Week 2 morning A4 percent change from baseline (CFB) and, at Week 32, proportion of patients with morning pre-GC A4≤ULN who are on physiologic GC replacement, percent CFB in morning 17-OHP, and CFB in GC daily dose when post-GC A4≤ULN. In an optional male reproductive health substudy, endpoints include changes in semen quality, reproductive biomarkers, and testicular adrenal rest tumor volume. Safety endpoints include incidence of treatment-emergent adverse events. This global Phase 3 trial, currently enrolling participants, will evaluate efficacy and safety of atumelnant in patients with CAH. These results will determine if atumelnant's novel mechanism of action at the adrenal gland allows for clinically meaningful GC reductions without compromising androgen control, providing critical insight into patient benefits and risks.

EP37 - ECE_2711 - Two cases of renovascular hypertension diagnosed after stillbirth and successfully treated with percutaneous transluminal renal angioplasty

Saya Takebe[1], Yasufumi Seki[1], Saori Kitayama[1], Kiyotaka Hirata[1], Noriyoshi Takano[1], Daisuke Watanabe[1], Tomohiro Kawaji[2], Satoru Morita[2] and Atsuhiro Ichihara[1]

[1]Department of Endocrinology and Hypertension, Tokyo Women's Medical University, Tokyo, Japan; [2]Department of Diagnostic Imaging & Nuclear Medicine, Tokyo Women's Medical University, Tokyo, Japan

Background: Renovascular hypertension (RVHT) is a potentially reversible etiology of secondary hypertension if treated with vascular intervention. Recently, RVHT has been reported as a risk of stillbirth in pregnancy. However, the association between vascular intervention and subsequent fetal outcomes in patients with RVHT has been unclear. Herein, we report two cases of RVHT diagnosed after stillbirth and treated with percutaneous transluminal renal angioplasty (PTRA), resulting in successful subsequent pregnancies.

Case 1: A 40-year-old woman (gravida 2, para 1) presented with elevated blood pressure (BP) of 150/100 mmHg and proteinuria at 10 weeks' gestation. She had a history of preeclampsia during her first pregnancy at 36 years of age, and the BP normalized

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

after the delivery. Although α-methyldopa 500 mg daily was initiated and reduced her BP to 140/90 mmHg, intrauterine fetal death occurred at 17 weeks' gestation. Antihypertensive therapy was switched to nifedipine 40 mg daily. Contrast-enhanced computed tomography angiography three months postpartum demonstrated right renal artery stenosis. PTRA successfully normalized her BP and diminished the proteinuria, which allowed discontinuation of the antihypertensive drug. Three months after the PTRA, she conceived again and remained normotensive without proteinuria during her third pregnancy, resulting in a successful delivery.

Case 2: A 41-year-old woman (gravida 1, para 0) with no prior history of hypertension developed hypertension during her first pregnancy and experienced intrauterine fetal death at 15 weeks' gestation. Hypertension persisted postpartum with BP of 145/90 mmHg, and treatment with amlodipine 5 mg daily was initiated. One month postpartum, contrast-enhanced computed tomography angiography revealed left renal artery stenosis. PTRA improved her BP and allowed discontinuation of antihypertensive medication, but residual stenosis was revealed six months after the PTRA. One year after the PTRA, she conceived again. From 25 weeks' gestation, her BP gradually increased, and she underwent a cesarean delivery at 35 weeks' gestation, resulting in the birth of a healthy baby. Antihypertensive therapy with amlodipine 2.5 mg daily was resumed after delivery.

Discussion: We present two cases of RVHT suspected to be caused by fibromuscular dysplasia (FMD), which were diagnosed after stillbirth and treated with PTRA, resulting in successful subsequent fetal outcomes. Our cases suggest that PTRA may be associated with improved pregnancy outcomes in pregnant women with RVHT and a history of stillbirth.

[1]Department of Medicine, Royal College of Surgeons in Ireland, Dublin, Ireland; [2]Department of Endocrinology, Beaumont Hospital, Dublin, Ireland; [3]Institute of Metabolism and Systems Research, Birmingham, United Kingdom; [4]Department of Nephrology, Beaumont Hospital, Dublin, Ireland; [5]Medical Research Council Laboratory of Medical Sciences, London, United Kingdom; [6]Institute of Clinical Sciences, Imperial College London, London, United Kingdom

Background: Disruption of adrenal steroid metabolism is increasingly recognised as a feature of advanced chronic kidney disease (CKD), yet the influence of dialysis modalities and the extent of dialytic steroid clearance remain unclear. We have previously shown the contributing role of impaired 11β-hydroxysteroid dehydrogenase type 2 (11β-HSD2) activity to cardiovascular risk in CKD. We sought to further review the impact of renal replacement therapy on adrenal steroid metabolism and biosynthesis providing the first comprehensive evaluation of adrenal steroidogenesis in end-stage renal disease (ESRD).

Methods: Thirty patients [intermittent haemodialysis (HD) $n = 15$; nocturnal automated peritoneal dialysis (PD) $n = 15$] underwent serial serum and dialysate sampling over approximately four hours during a morning HD session or peritoneal equilibrium test (PET). Two matched control cohorts: non-dialysis dependent CKD stage 5 ($n = 15$) and healthy controls ($n = 15$), were included in the analysis of baseline samples. Samples were analysed using liquid chromatography–tandem mass spectrometry.

Results: ESRD was associated with profound adrenal steroid perturbations, driven primarily by reduced 11β-HSD2 activity and impaired urinary clearance of steroids which did not resolve with either dialysis modality. HD caused a marked fall in serum aldosterone [542.5 pmol/L (196.5-1550) at baseline vs 65.3 pmol/L (29.2-376.4) at end, $P < .01$] in parallel with potassium reduction, whereas PD showed no significant aldosterone change.

Neither modality effectively cleared mineralocorticoids in dialysate fluid. PD produced a significant decline in serum cortisol falling from 362.0 nmol/L (261.0–445.9) at baseline to 267.0 nmol/L (202.0–287.0) at 240 minutes ($P = .02$) with reciprocal glucocorticoid accumulation in dialysate. HD showed minimal steroid recovery in effluent and no change in circulating serum glucocorticoids. To further demonstrate removal of glucocorticoids in dialysate we calculated delta fluid concentrations which were significantly higher in PD compared to HD [δPD fluid cortisol 9.3 nmol/l (7.7-12.4) vs δHD fluid cortisol 1.3 nmol/L (−7.1 to 5.8), $P = .0004$; δPD fluid cortisone 8.8 nmol/L (6.7-10.0) vs δHD fluid cortisone 1.0 nmol/L (−0.8 to 2.5), $P < .0001$].

PD also demonstrated superior clearance of adrenal androgens (androstenedione, 11β-hydroxyandrostenedione and 11-ketoandrostenedione), which were largely unquantifiable in HD fluid. These differences likely reflect the greater permeability of the peritoneal membrane to protein-bound solutes.

Conclusions: PD achieved meaningful glucocorticoid and androgen clearance and preserved expected cortisol decline, whereas HD showed negligible corticosteroid dialysate concentration. These differences likely reflect superior clearance of protein-bound solutes, higher membrane permeability and haemodynamic stability associated with PD. PD may therefore better support physiological adrenal corticosteroid exposure in patients with ESRD.

EP39 - ECE_1123 - Hyporeninemic hypoaldosteronism as a manifestation of long-COVID: a case report

Maria Chrysoula Tatarida Palla, Marika Kokkorou, Galateia Stathori, Andreas Bampilis, Michalis Magklis, Myrsini Chamakioti, Olga Tsantarlioti, Eleni Papanikolaou and George Chrousos
Endocrine Unit, National and Kapodistrian University of Athens, Athens, Greece

COVID-19 is increasingly recognized to cause persistent multisystem dysregulation, including autonomic and/or renin–angiotensin–aldosterone system (RAAS) disturbances. Hyporeninemic hypoaldosteronism (HH) is a rare finding after COVID-19 and may reflect autonomic or systemic dysfunction.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

We report a case of a previously healthy 56-year-old man who presented with persistent mild hyperkalemia during follow-up at a post-COVID (Long COVID) clinic. The patient had a history of SARS-CoV-2 infection several months earlier, followed by chronic fatigue, scapular pain, and reduced exercise tolerance. He had no prior renal, rheumatologic, or endocrine disorders.

Nephrological evaluation excluded kidney disease, and rheumatologic screening for fibromyalgia and autoimmune pathology was negative. Endocrine assessment revealed low plasma renin activity and aldosterone levels, consistent with hyporeninemic hypoaldosteronism. Cortisol and other hormonal parameters were within normal limits. The patient did not report symptoms of hypotension or volume depletion.

In the absence of structural renal or adrenal pathology, the findings suggest post-COVID dysregulation of RAAS, likely secondary to autonomic dysfunction or persistent ACE2/angiotensin II imbalance. This case highlights a potential mechanism of post-viral RAAS impairment manifesting as subclinical hyporeninemic hypoaldosteronism without overt electrolyte derangement.

Hyporeninemic hypoaldosteronism may represent an underrecognized endocrine manifestation of long COVID, reflecting persistent autonomic or systemic dysregulation. Awareness of this entity is important for the evaluation of unexplained hyperkalemia in post-COVID patients.

EP40 - ECE_1628 - Case of differential diagnosis in a male patient with adrenal incidentaloma

Irina A. Vaychulis

Internal Medicine Department, South-Ural State Medical University, Chelyabinsk, Russia

Adrenal incidentalomas represent a heterogeneous condition, requiring a large differential diagnosis. Clinical, biochemical and radiological assessment is mandated to stratify patients into those requiring radiological surveillance, medical management or surgical intervention.

A 48-year-old male was referred to a surgeon with complaints of the left thigh muscle pain, weakness and heaviness in the legs, ossalgias, arthralgias, frequent feeling of heat and cold, subfebrile temperature, weight loss for about 6-8 months. US, MRI and CT showed a left thigh soft tissue mass with muscle rupture, edema, periostitis and contact destruction of the left femoral bone anterior surface. Diffuse connective tissue diseases were ruled out.

CT of the abdomen revealed right adrenal incidentaloma 39 × 23 mm, suspicious for malignancy (precontrast phase +50 HU, venous phase +65 HU, delayed phase +58 HU, absolute washout 47%, relative washout 11%). Laboratory examination showed elevated total and free normetanephrine in 24 h urine—721 (ULN 451) and 79,5 (ULN 43,2) mcg/24 h, respectively, and patient was referred for the preoperative preparation with preliminary diagnosis of (malignant?) pheochromocytoma (PCC).

On admission to our endocrine department, the diagnosis of PCC seemed doubtful, considering the presence of two separate lesions, accompanied by the signs of paraneoplastic syndrome, in the absence of arterial hypertension (AH) and any clear paroxismal manifestations. No alfa-adrenoblockers were administered. Further examination demonstrated normal serum electrolytes, TSH and PTH, adequate suppression of cortisol after overnight DST, normal blood pressure on 24 h monitoring, anemia, elevated ESR and CRP, hypoproteinemia.

Chest CT revealed the signs of central right cancer, the right lung and intrathoracic lymphatic nodules metastases. Biopsy results confirmed non-small cell lung cancer (adenocarcinoma). The same cells were found in the lymphatic nodules and femoral soft tissue mass. Repeated CT of the abdomen showed the rapid growth of adrenal mass up to 53 mm. Bone metastases were detected on SPECT. Preliminary diagnosis was reconsidered, and adrenal neoplasm was interpreted as a metastatic lesion, secondary to the lung adenocarcinoma with multiple metastases. Systemic anti-cancer therapy has been initiated.

Conclusions: We present the case of metastatic adrenal mass that had been revealed prior to the previously unknown primary lung cancer. Clinically silent adrenal incidentaloma was accompanied by moderate hormonal hyperscretion, and initially was regarded as PCC. Discordance between the laboratory and clinical data (elevated metanepfrines in the absence of AH and paroxysmal manifestations) requires rigorous systematic examination to avoid misdiagnosis and incorrect treatment.

EP41 - ECE_1093 - Changes in carotid arterial stiffness and strain parameters after treatment in primary aldosteronism: A prospective follow-up study using speckle tracking ultrasonography

Tugba Barlas[1], Mahinur Cerit[2], Halit Sendur[2], Sabri Engin Altıntop[1], Mehmet Muhittin Yalcin[1], Altinova Alev[1], Mujde Akturk[1], Fusun Toruner[1], Ayhan Karakoc[1] and Ethem Turgay Cerit[1]

[1]*Gulhane Training and Research Hospital, Endocrinology and Metabolism, Ankara, Türkiye;* [2]*Faculty of Medicine, Radiology, Gazi University, Ankara, Türkiye*

Aim: Although cardiovascular morbidity in primary aldosteronism (PA) can be partly prevented with appropriate treatment, the reversibility of vascular alterations remains uncertain. This study investigated vascular alterations in patients with PA using speckle tracking carotid strain (STCS) ultrasonography, which allows simultaneous assessment of arterial structure and function. It also aimed to evaluate changes in arterial stiffness and strain parameters during follow-up, comparing outcomes between unilateral adrenalectomy and mineralocorticoid receptor antagonist (MRA) treatment.

Methods: This study was conducted with a prospective follow-up design. All participants underwent a standardized diagnostic work-up for PA according to the current clinical guidelines, and the sample size was determined based on a priori power analysis. STCS ultrasonography was performed at baseline and six months post-treatment (surgical/medical). A 5-mm segment of the common carotid artery below the bulb was analyzed to quantify arterial compliance and distensibility (reflecting elasticity); elastic modulus, β-stiffness index, and pulse wave velocity (reflecting stiffness); as well as strain-related parameters, including displacement, strain, and strain rate.

Results: Thirty patients were included, of whom 22 received MRA therapy and 8 underwent unilateral adrenalectomy. Arterial

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

compliance increased in the overall cohort in both transverse and longitudinal planes and this improvement was significant in the surgical group in subgroup analyses ($P < .05$). Between-group comparisons revealed greater improvements in arterial compliance in the surgical than medical groups ($P = .033$). Arterial distensibility also increased in the transverse plane ($P < .05$), whereas no significant changes were observed in β-stiffness index, elastic modulus, PWV, or strain parameters in the overall group ($P > .05$). CIMT significantly decreased after treatment in the overall and medical groups ($P < .05$). Negative correlation was observed between the duration of hypertension and the post-treatment changes in PWV ($r = -0.429$, $P = .041$), β-stiffness index ($r = -0.389$, $P = .034$), and elastic modulus ($r = -0.537$, $P = .002$). Multivariate linear regression analysis identified younger age, shorter hypertension duration, male sex, and surgical treatment as independent predictors of greater post-treatment improvement in arterial compliance ($P < .05$).

Conclusions: This study is the first to longitudinally assess vascular changes in PA using STCS technique. Arterial compliance improved after treatment, particularly after adrenalectomy, whereas other stiffness parameters remained unchanged. Surgical treatment, younger age, male sex, and shorter hypertension duration independently predicted greater compliance improvement.

Abstract citation ID: lvag096.652

EP42 - ECE_2361 - Diagnostic value of positive saline infusion test for predicting lateralisation in intermediate-probability primary aldosteronism

Prethivan Pillai Gopalakrishnan, Ian Dorrington, Mohammed Shamsaldeen, Hamza Khan, Sarah Davies, Pallavi Hegde and Andrew Davison
Royal Liverpool University Hospital, Liverpool, United Kingdom

Background: Endocrine Society guidelines recommend aldosterone suppression testing to predict the likelihood of unilateral primary aldosteronism (PA) in patients with intermediate probability of lateralisation before adrenal vein sampling (AVS). This is based on limited evidence that incomplete suppression may suggest unilateral disease in intermediate subgroup. We aimed to evaluate whether saline infusion test (SIT) predicts unilateral disease among SIT-positive patients.

Method: We retrospectively reviewed 102 patients with biochemical evidence of PA from 2016-2025. Thirty-three patients with a positive SIT (post-SIT aldosterone >160 pmol/L) underwent AVS and or 18F-CETO PET-CT. AVS lateralisation was defined as a lateralisation index >4 without ACTH stimulation. Diagnostic performance of pre- and post-SIT aldosterone (iSyS immunoassay, IDS), renin (iSyS immunoassay, IDS), aldosterone-renin ratio, nadir potassium during screening, age, and sex were assessed using multivariable logistic regression and ROC analysis with 1000-bootstrap validation. Lateralisation probability was defined as: high; hypokalaemia (K < 3.5 mmol/L), aldosterone >554 pmol/L, and suppressed renin <5 mIU/L (assay detection limit), low; normokalaemia (3.5-5.3 mmol/L) and aldosterone <305 pmol/L and intermediate; aldosterone 305-554 pmol/L, aldosterone >554 pmol/L with normokalaemia and/or unsuppressed renin, or aldosterone <305 pmol/L with hypokalaemia.

Results: Of 33 SIT-positive patients, 39% had unilateral disease. Most were intermediate-probability ($n = 30$, 40% unilateral). Median age was 47 years in unilateral disease and 44 years in bilateral disease. Unilateral disease was more frequent in males (53%) than females (25%). In the intermediate subgroup, unilateral disease was associated with lower nadir potassium (median 3.0 mmol/L [IQR 2.8-3.6] vs 3.8 [3.6-3.9], $P = .002$) and higher post-SIT aldosterone (518 pmol/L [IQR 400-704] vs 248 [205-428], $P = .002$). Other variables were not significant. In multivariable analysis, only nadir potassium was independently associated with unilateral disease (adjusted OR 1.3 per 0.1 mmol/L decrease, 95% CI 1.1-1.9). Hypokalaemia had 89% specificity which increased to 100% when the cut off of K is ≤2.8 mmol/L. Among normokalaemic intermediate patients, post-SIT aldosterone is significantly higher in unilateral cases (466 pmol/L [IQR 450-524] vs 235 [197-421], $P = .02$) with AUC 0.89 (95% CI 0.68-1.00).

Conclusions: Post-SIT aldosterone does not independently predict PA subtype in SIT-positive patients with intermediate probability of lateralisation and most patients had bilateral disease. However, it shows good discrimination in normokalaemic intermediate patients. Hypokalaemia is a strong predictor of unilateral disease. SIT may aid surgical decision-making selectively in normokalaemic intermediate-probability patients. Threshold interpretation should consider local assay context when applying guideline-recommended cut-offs. Further research should include SIT-negative patients to assess overall diagnostic performance.

EP43 - ECE_3524 - Visceral adiposity index predicts metabolic syndrome and cardiometabolic risk in patients with adrenal incidentalomas

Sanja Ognjanovic, Bojana Popovic, Valentina Elezovic Kovacevic, Dusan Ilic, Milica Opalic Palibrk, Lena Radic, Katarina Krstic, Natalija Dragicevic and Djuro MacUt
Department for Endocrine Tumors and Hereditary Cancer Syndromes, Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Centre of Serbia, Belgrade, Serbia

Introduction: Patients with non-functioning adrenal incidentalomas (AIs) and autonomous cortisol secretion (ACS) are at increased risk of cardiometabolic disorders and mortality. Visceral adipose tissue accumulation contributes to insulin resistance and metabolic syndrome (MetS), and the Visceral Adiposity Index (VAI), a mathematical model that indirectly reflects cardiometabolic risk, has been proposed as a marker of visceral adipose tissue dysfunction. This study aimed to determine whether the VAI can serve as a predictor of MetS in patients with AIs.

Subjects and Methods: This retrospective cross-sectional study (2019–2024) included 167 patients with adrenal incidentalomas (AIs) (men, $n = 41$, 24.6%; women, $n = 126$, 75.4%). Anthropometric (BMI, waist circumference), biochemical (LDL, HDL, triglycerides), and hormonal (cortisol at 08:00 and 24:00, ACTH at 08:00, post-1 mg dexamethasone cortisol) assessments were performed. Insulin sensitivity was evaluated using HOMA-

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

IR, and MetS was assessed according to IDF, AHA/NHLBI, and NCEP-ATP III criteria.

Results: Mean age, BMI, and waist circumference, as well as prevalence of diabetes, hypertension, and dyslipidemia, were similar between sexes. The prevalence of MetS according to IDF, AHA/NHLBI, and NCEP-ATP III criteria was 48.4%, 46.3%, and 41.5% in men, and 55.6%, 50.0%, and 44.4% in women, respectively. Unilateral AIs were present in 27 men (65.9%) and 69 women (54.8%), while bilateral AIs occurred in 14 men (34.1%) and 57 women (45.2%), with men exhibiting larger tumors (42.9 ± 21.5 mm vs 32.5 ± 17.7 mm, $P = .002$) and higher frequency of ACS (64.1% vs 45.7%, $P = .047$). Men had a higher prevalence of coronary artery disease, with no significant sex differences in cerebrovascular events. No significant differences were observed in ACTH, morning, midnight, or post-DST-1 mg cortisol levels. The VAI was significantly associated with blood pressure, fasting glucose, HbA1c, diabetes, HOMA-IR, and MetS, and emerged as the strongest predictor of MetS development (OR = 12.7, 95% CI 2.390–20.057, $P = .001$), alongside age and post-DST-1 mg cortisol.

Conclusions: In patients with AIs, VAI strongly predicts MetS and is associated with hypertension, impaired glucose metabolism, and insulin resistance, emphasizing the need for regular assessment to reduce long-term cardiometabolic risk.

EP44 - ECE_3714 - Adrenal incidentaloma and risk of metabolic dysfunction–associated fatty liver disease (MAFLD) and liver fibrosis assessed by non-invasive scores

Theodora Michalopoulou[1,2], Cristina Franco[1], Laia Martinez Guasch[1], Silvia Näf Cortes[1], Ariadna Prats Custal[1], Maria Castell[1], Luis Herrador[1], Nerea Tomas[1] and Ana Megia[1]
[1]*Hospital Universitario de Tarragona Joan XXIII, Tarragona, Spain;* [2]*Universitat Rovira I Virgili, Tarragona, Spain*

Background: Adrenal incidentalomas (AI) are frequently associated with adverse metabolic profiles, even in the absence of overt hormonal hypersecretion. Mild autonomous cortisol secretion (SAC) may contribute to insulin resistance, dyslipidemia, and chronic low-grade inflammation, key drivers of MAFLD and liver fibrosis (LF). However, the prevalence of MAFLD and its relationship with AI characteristics remain poorly defined.

Objective: To assess the prevalence of MAFLD and LF using non-invasive scores (FIB-4 and APRI) in patients with AI and to evaluate their association with tumor characteristics after adjustment for metabolic risk factors.

Methods: Retrospective observational study including 76 patients with radiologically diagnosed AI followed at a specialized adrenal pathology clinic. Epidemiological and metabolic data were collected. AI were classified according to hormonal functionality (non-functioning vs SAC), maximal tumor diameter, and laterality (unilateral vs bilateral). MAFLD was defined according to standard criteria using liver imaging and metabolic factors. LF risk was estimated using FIB-4 and APRI scores and categorized as low vs intermediate/high. Group comparisons were performed using t-tests, chi-square tests, and Pearson correlations. Multivariable binary logistic regression was used to identify independent predictors of intermediate/high fibrosis risk.

Results: Mean age was 63 ± 10.5 years, 54% were women, and 49% had obesity. Non-functioning adenomas were present in 44.7% and SAC in 55.3%. Low fibrosis risk was observed in 92.1% by APRI and 56.6% by FIB-4, while 43.4% had intermediate/high risk by FIB-4. MAFLD prevalence was 27.6%. In multivariable analysis, age was inversely associated with low fibrosis risk (OR 0.85, 95% CI 0.77–0.93; $P < .001$). Metabolic factors (BMI, type 2 diabetes, dyslipidemia, and hypertension) were independently associated with intermediate/high fibrosis risk (adjusted OR 1.3–2.5, all $P < .05$). Tumor functionality, size, and laterality were not independently associated with fibrosis scores.

Conclusions: More than one-quarter of patients with AI have MAFLD, and a substantial proportion show intermediate/high risk of liver fibrosis. Fibrosis risk is mainly driven by metabolic comorbidities rather than adrenal tumor characteristics, highlighting the need for systematic metabolic and hepatic assessment in all patients with AI.

EP45 - ECE_3825 - Urinary bladder paraganglioma: experience from a mini case series

Amina Al-Qaysi[1], Anoud Ramadan[1], Aisha Naseer[2] and Christine May[1]
[1]*Oxford Centre for Diabetes, Endocrinology and Metabolism (OCDEM), Oxford, United Kingdom;* [2]*Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom*

Background: Urinary bladder paraganglioma is a rare neuroendocrine tumour and an uncommon cause of urinary bladder neoplasia. Because of its low incidence and variable clinical presentation, diagnosis may be delayed, particularly in non-functional cases. Functional tumours carry a risk of catecholamine-mediated perioperative complications.

Methods: A retrospective review was undertaken of patients with histologically confirmed urinary bladder paraganglioma managed at the Oxford University Hospitals NHS Foundation Trust. Data on clinical presentation, biochemical assessment, imaging, perioperative management, surgical treatment, and follow up outcomes were analysed.

Results: Four patients were included: three females and one male, with ages at presentation ranging from 16 to 41 years. None had a prior history of pheochromocytoma or paraganglioma. Clinical presentation was variable. One patient experienced functional symptoms characterised by post-micturition headache; one presented with haematuria; two also reported abdominal pain; and one tumour was detected incidentally during SDHB surveillance. Preoperative biochemical evaluation varied. One patient did not undergo testing because the diagnosis was not suspected preoperatively and was only made on histopathological examination. Two patients had urinary metanephrines measured, and one underwent both plasma and urinary assessment. Elevated normetadrenaline levels were identified in three patients. MIBG scintigraphy was performed in three patients, demonstrating uptake in two cases, while one lesion was non-avid; this lesion was smaller than those in the other cases. Preoperative blockade was administered in three patients, as one tumour was not suspected preoperatively. Surgical management consisted of transurethral resection of bladder tumour in three cases and laparoscopic partial cystectomy in one.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

No intraoperative haemodynamic instability or other complications were observed. Ongoing follow-up revealed no metastatic disease, recurrence, or additional pheochromocytoma or paraganglioma, with follow-up periods ranging from 50 to 118 months.

Conclusions: This mini case series highlights the heterogeneous clinical and biochemical presentations of urinary bladder paraganglioma, as well as the diagnostic challenges associated with this rare tumour. With appropriate perioperative preparation, surgical management can be undertaken safely and yield favourable outcomes. Increased awareness is essential to facilitate timely diagnosis, optimise perioperative care, and guide long term surveillance.

Abstract citation ID: lvag096.656

EP46 - ECE_2305 - CYP11B2 immunohistochemistry should be incorporated into the routine clinical diagnostic workup of primary aldosteronism: a case report

Iciar Martín Timón, Marta Leon del Campo, Olalla Meizoso-Pita, Isabel Huguet, Maria Llavero Valero, Mikaela Zubillaga, Alberto García Piorno, Inmaculada Moreno-Ruiz and Cristina Sevillano-Collantes
Endocrinology, Infanta Leonor University Hospital, Madrid, Spain

Primary aldosteronism (PA) is associated with an increased risk of cardiovascular complications compared with primary hypertension. Despite effective methods for diagnosing and treating PA, it remains markedly underdiagnosed and undertreated. This may in part be due to misconceptions that PA is only present in the setting of hypokalemia, adrenal macro-nodules, frankly elevated aldosterone levels, or severe hypertension

Case Report: A 48-year-old male was referred to our outpatient clinic of endocrinology for poorly controlled arterial hypertension despite treatment with Olmesartan 40 mg, Amlodipine 5 mg, Hydrochlorothiazide 25 mg, and Nebivolol 5 mg, also presenting with active smoking, type 1 obesity, obstructive sleep apnea, and dilated cardiomyopathy. Given the suspicion of secondary arterial hypertension, a PA screening test was performed with results of direct renin concentration: 2.95 mUI/mL, aldosterone: 25.50 ng/dL, and aldosterone/renin ratio: 8.24

A confirmation test is performed using the Captopril test, which shows an aldosterone increase of 28% (aldosterone before and after of 11.9 ng/dL and 15.3 ng/dL, respectively), with renin levels before and after of 0.51 mUI/mL and 1.3 mUI/mL, and cortisol remaining stable at 11.2 µg/dL. After the biochemical confirmation of primary aldosteronism (PA), a computed tomography (CT) scan is requested, which shows no adrenal lesions, leading to an adrenal vein sampling that ultimately demonstrates right adrenal lateralization. After the right adrenalectomy, pathological anatomy confirms the presence of multiple micronodules producing aldosterone (Immunohistochemistry positive for CYP11B2).

Currently, 3 months after surgery, the patient presents a complete response according to PASO criteria, maintaining normal blood pressure without antihypertensive treatment

Conclusions: PA is a form of curable arterial hypertension; therefore, it is important to make an accurate diagnosis. Adrenal venous sampling is the gold standard for diagnosing PA, being particularly important when imaging tests are inconclusive, either due to the high prevalence of non-functioning adrenal incidentalomas or due to the presence of millimetric lesions producing aldosterone. In our case the relevance of histopathology with morphologic and IHC evaluation in the clinical management of unilateral PA is confirmed. Histopathologic examination of adrenalectomy specimens with CYP11B2 IHC is therefore recommended for all patients operated for unilateral PA

Abstract citation ID: lvag096.657

EP48 - ECE_1265 - Psychosocial wellbeing index short form and cardiovascular disease risk: updated associations beyond Life's Essential 8 in a Korean Prospective Cohort

Seung Jin Han, Ja Young Jeon, Hae Jin Kim, Dae Jung Kim and Kwan-Woo Lee
Ajou University School of Medicine, Suwon, South Korea

Background: Psychological health is increasingly recognized as a relevant determinant of cardiovascular disease (CVD), yet psychosocial stress remains unaccounted for in the recently updated cardiovascular health metrics, known as Life's Essential 8 (LE8). Whether psychosocial stress independently contributes to CVD risk beyond LE8 components remains unclear. This study aimed to evaluate the association between psychosocial stress and incident CVD using updated analyses from a large Korean community-based cohort.

Methods: A total of 6410 adults from the Ansung–Ansan cohort of the Korean Genome and Epidemiology Study were included after excluding individuals with baseline CVD and those without complete data on psychosocial stress or LE8 metrics. Psychosocial stress was assessed using the Psychosocial Wellbeing Index Short Form (PWI-SF). LE8 cardiovascular health metrics were calculated according to modified American Heart Association recommendations. Incident CVD events—including myocardial infarction, coronary artery disease, cerebrovascular disease, and congestive heart failure—were identified via physician-diagnosed self-report. Cox proportional hazards models were used to evaluate associations, adjusting for age, sex, socioeconomic factors, and all LE8 metrics.

Results: Over a median follow-up of 13.8 years, 500 new CVD cases occurred. Higher PWI-SF scores were significantly associated with a greater risk of incident CVD even after full adjustment, including all LE8 components (HR: 1.321; 95% CI: 1.067–1.636; $P = .011$). This association remained robust in sensitivity analyses stratified by sex and baseline cardiovascular health status.

Conclusions: Elevated psychosocial stress is independently associated with increased CVD risk beyond Life's Essential 8 metrics in a large Korean adult cohort. These findings highlight a meaningful gap in current cardiovascular health assessment frameworks and support the integration of psychosocial factors into future risk stratification and prevention strategies.

EP49 - ECE_3754 - Aldosterone, renin and their ratio (ARR) in patients with newly diagnosed and untreated hypertension

Harpa Gunnarsdottir[1], Gudmundur Sigthorsson[1], Isleifur Olafsson[1], Thor Aspelund[2,3], Vilmundur Gudnason[2,4] and Helga Sigurjónsdóttir[1,2]
[1]*Landspitali University Hospital, Reykjavik, Iceland;* [2]*University of Iceland, Reykjavik, Iceland;* [3]*Borgarbyggd, Iceland;* [4]*Icelandic Heart Associations, Reykjavik, Iceland*

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Background: Primary aldosteronism (PA) is a common and potentially curable cause of hypertension, yet it remains substantially underdiagnosed. In Iceland, little is known about the prevalence and biochemical characteristics of PA among patients with newly diagnosed, untreated hypertension.

Objectives: To evaluate baseline serum aldosterone, plasma renin, and the aldosterone-to-renin ratio (ARR) in newly diagnosed, untreated hypertensive individuals, and to compare these measures with normotensive counterparts.

Methods: This cross-sectional study was conducted within the REFINE-Reykjavik Study, a population-based cohort established in Iceland between 2005 and 2006. From the original cohort, 420 participants with newly diagnosed untreated hypertension at inclusion and 220 normotensive controls were selected. Stored baseline plasma samples were analyzed for aldosterone, direct renin, potassium, and ARR. Possible PA was defined according to the newly presented Endocrine Society screening criteria (2025): plasma aldosterone $\geq$ 277 pmol/L, plasma renin $\leq$ 8.2 mIU/L, and ARR > 70. Clinical and biochemical characteristics were compared between participants who met and did not meet these criteria.

Results: Complete aldosterone and renin measurements were available for 609 participants. Of these, 32 individuals (5.2%) fulfilled the biochemical criteria for possible PA. Participants meeting PA criteria were significantly older (57.3 ± 7.4 vs 50.4 ± 12.0 years, $P = .001$) and had higher systolic (151.0 ± 19.1 vs 138.6 ± 21.1 mmHg, $P = .009$), diastolic (84.6 ± 11.3 vs 77.1 ± 12.9 mmHg, $P < .001$), and mean arterial blood pressure (106.7 ± 12.0 vs 97.6 ± 13.9 mmHg, $P < .001$) compared with those who did not meet criteria. Serum potassium concentrations were slightly but significantly lower in the PA group (4.1 ± 0.3 vs 4.2 ± 0.3 mmol/L, $P = .014$). No significant differences were observed between groups with respect to sex distribution, body mass index, smoking status, or diabetes prevalence.

Conclusions: In this population-based Icelandic cross-sectional study of newly diagnosed, untreated hypertensive individuals, approximately 5% met biochemical screening criteria for possible primary aldosteronism. These findings indicate that PA may be present in a substantial proportion of patients at the time of hypertension diagnosis and support broader implementation of systematic PA screening in accordance with recent international guidelines.

EP50 - ECE_1994 - Cortisol regulation, cardiometabolic risk factors and genetic variants in the glucocorticoid receptor in patients without Cushing's syndrome

Franziska Schnait, Konstantin Fuhrberg, Helena Niziolek, Nicole Kober, Greisa Vila, Sabina Baumgartner-Parzer and Marie Helene Schernthaner-Reiter
Wien, Austria

Background: Genetic variants in the glucocorticoid receptor gene have been shown to modulate hypothalamus-pituitary-adrenal axis activity. Moreover, there is increasing evidence that cortisol levels exert a continuous effect on cardiometabolic risk factors even in patients with physiological cortisol suppression during dexamethasone suppression testing (DST). As existing data are largely based on patient collectives with non-functioning adrenal adenomas, this study aims to investigate associations in a more heterogeneous cohort.

Method: Cardiometabolic risk factors were collected retrospectively in 470 patients with physiological suppression in the 1 mg overnight DST (cortisol < 1.8 µg/dL). Exons and flanking intronic regions in the glucocorticoid receptor gene (*NR3C1*) were analysed in 23 patients using Sanger sequencing.

Results: In comparison to patients with lower post-DST cortisol values (<1,2 µg/dL), the prevalence of diabetes (11.2% vs 23.7%; $P = .002$), hypertension (57.7% vs 74.2%; $P = .004$) and hyperlipidaemia (45.2% vs 57.0%; $P = 0{,}042$) was higher in patients with higher post-DST cortisol values of 1.2-1.79 µg/dL. They had older age (median: 37.8 vs. 56.2; $P < 0{,}001$), but BMI and sex distribution were comparable. The most frequent indications for performing DST were hypertension (32.6%), obesity (32.1%), and adrenal incidentalomas (26.8%).

Post-DST cortisol values were significantly associated with glucose and glycated hemoglobin (HbA1c) in patients without current antidiabetic medication. This association remained significant even when controlling for age, BMI and sex in a partial Spearman´s rank correlation analysis (glucose: $r_s = 0.184$, $P = .001$; HbA1c: $r_s = 0.157$, $P = .013$). No significant associations were detected for blood pressure, BMI or lipid parameters.

Sequence analysis identified the following *NR3C1*-variants: ER22/23EK (rs6189, rs6190), GR-9β (rs6198), rs4986593, rs6188 and rs6196. The respective allele frequencies were 4.5%, 21.7%, 28.3%, 32.6% and 15.2% and they were comparable to prevalences reported for the general population (gnomAD). Furthermore, in one sample a novel duplication was detected adjacent to the exon-intron 5 boundary (c.1747 + 13dup).

Conclusions: Patients without endogenous hypercortisolism showed a significant association between post-DST cortisol values and parameters of glucose metabolism. Moreover, a higher prevalence of cardiovascular risk factors, including diabetes, hypertension and hyperlipidaemia, was found in patients with post-DST cortisol values of 1.2-1.79 µg/dL.

Objective: four glucocorticoid receptor polymorphisms (GRp) have been linked with increased resistance (ER22/23EK, GR-9β)

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

or sensitivity (N363S, BclI) to glucocorticoids (GC) conferring a better, or worse, metabolic and cardiovascular risk. The aim of the present study was to evaluate the biochemical and clinical impact of GRp in a group of patients with apparent essential hypertension.

Methods: in this cross-sectional study, we evaluated in 99 hypertensive patients (aged 37-70 years, 51 females): anthropometric variables; hypotalamus-pituitary-adrenal (HPA) axis parameters [(basal cortisol levels, cortisol after 1 mg-Dexamethasone suppression test, ACTH levels, urinary free cortisol (UFC)]; glycemic and lipidic profile; carotid intima-media thickness (cIMT) and presence of carotid stenosis; presence of uncontrolled blood pressure (UBP) defined as 24 h-mean BP at ambulatory blood pressure monitoring or mean office BP > 140/90 mmHg despite antihypertensive treatment; gene variants of ER22/23EK, GR-9β, N363S and BclI. Exclusion criteria were signs suggestive for secondary hypertension and presence of obesity or diabetes mellitus. Patients were defined as carriers of a resistant (RS) or sensitive (SN) phenotype based on the presence of at least one associated GRp. Thirteen patients who presented both types of GRp were excluded from statistical analysis to avoid phenotype overlapping.

Results: we found 32 RS (32.3%), 54 SN (54.5%) and 26 wild-type patients (26.3%). GR-9β was the most prevalent GRp in RS (32/32 cases) while BclI was the most prevalent among SN patients (52/54 cases).

Comparing RS patients with non-RS patients, no differences were found in anthropometric variables, glycemic and lipidic profile, HPA axis parameters, number of antihypertensive drugs. We did not observe any difference in the prevalence of impaired fasting glucose/impaired glucose tolerance (IFG/IGT) and altered cIMT. RS patients showed a higher prevalence of carotid stenosis (36% vs 61%, $P = .056$) and UBP (34.3% vs 63.2%, $P = .024$) than non-RS patients. RS phenotype was associated with UBP (OR:5.6, $P = .007$) independently of age, sex, BMI, number of antihypertensive drugs, smoking status, prevalence of IFG/IGT, UFC.

SN patients showed lower ACTH (30.4 vs 24.0 ng/L, $P = .042$) and higher HDL cholesterol ($P = .043$) than non-SN patients. We did not find any statistically significant difference in any other variables. After stratification for sex, we found that HDL cholesterol levels remained statistically significant in female SN patients (57.3 vs 66.3 mg/dL, $P = .046$) but not in male ones (50 vs 51.1 mg/dL, $P = .77$).

Conclusions: GR-9β polymorphism, associated with RS, could be linked with UBP independently from common cardiovascular risk factors. In female SN patients higher HDL cholesterol was observed, suggesting a sex-dependent effect of GC on cholesterol.

EP52 - ECE_1187 - When weight loss hides Cushing's: a tirzepatide pitfall

Aparajita Roy[1], David Llewellyn[1], Amina Khanam[1], Ben Whitelaw[2] and Mohamed Bakhit[1]
[1]*Lewisham University Hospital, London, United Kingdom;* [2]*King's College Hospital NHS Foundation Trust, London, United Kingdom*

Background: The increasing use of glucagon-like peptide-1/glucose-dependent insulinotropic polypeptide receptor agonists may modify the clinical presentation of endocrine disorders. We describe a case of autonomous cortisol excess in which treatment with Tirzepatide (Mounjaro) potentially masked classical clinical features.

Case Presentation: A 37-year-old woman was referred following the incidental discovery of a right adrenal lesion on cardiac MRI performed for hypertension and exercise intolerance. Dedicated adrenal CT demonstrated a 3.3 cm right adrenal lesion.

At initial endocrine review, she reported significant weight gain of 50 kg from 2018 to 2021, accompanied by anxiety, palpitations and sweating, initially attributed to long COVID. She had commenced Tirzepatide privately, titrated to 15 mg weekly, achieving a 50 kg weight loss in 4 years. On examination her weight was 92 kg (BMI 33.8 kg/m^2) with no overt Cushingoid features. Her past medical history included essential hypertension, ovarian cysts and liver haemangioma. Medications included ramipril, amitriptyline and sertraline.

Overnight dexamethasone suppression tested twice showed non-suppressed cortisol levels of 113 nmol/L and 130 nmol/L with a corresponding dexamethasone level of 7.5 nmol/L. ACTH was 5 ng/L, DHEAS was 1.8 µmol/L(0.9-11.6),24-hour urinary free cortisol was 43 nmol/L, plasma metanephrines, normetanephrines, 3-methoxytyramine, renin and aldosterone were normal. HbA1c was 28 mmol/mol. A repeat CT adrenal imaging showed a 3 cm right adrenal lesion, pre-contrast attenuation of 22 HU and absolute contrast washout of 44% stable over three years.

Follow-Up: Continued Tirzepatide therapy led to further reduction in BMI to 19 kg/m^2, prompting dose reduction. Blood pressure improved significantly, allowing cessation of antihypertensive therapy.

Further review revealed symptoms suggestive of cortisol excess, including easy bruising, recurrent urinary tract infections, poor wound healing and proximal muscle weakness. Following discussion at a regional adrenal multidisciplinary team meeting, right adrenalectomy was recommended. Metyrapone 250 mg once daily was initiated as bridging therapy, later stopped due to side effects.

Conclusions: This case demonstrates that Tirzepatide may mask clinical features of cortisol excess by improving weight, blood pressure, and glycaemic control. Combined catabolic effects of hypercortisolism and rapid weight loss may worsen sarcopenia. Clinicians should retain suspicion for cortisol excess in patients using incretin mimetics, even without a Cushingoid appearance. Measuring serum dexamethasone levels during ONDST is essential, as GLP-1 agonists can affect gastric emptying and drug absorption. Such therapies must be prescribed and monitored by clinicians with endocrinology and/or obesity management expertise to ensure that endocrine causes of obesity are not missed.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Objective: Endogenous Cushing syndrome (CS) is associated with increased risk of morbidity and mortality, and infections are among its major complications. This study aimed to evaluate the predictive value of cortisol-related indices, blood cell-derived inflammatory indices, and the prognostic nutritional index (PNI) for perioperative infection and to identify risk factors.

Methods: A total of 113 patients with confirmed CS were included: 71 pituitary CS, 37 adrenal CS, and 5 ectopic CS. Perioperative systemic infection statuses were determined. Cortisol-related indices, blood cell-derived inflammatory indices, PNI, and clinical features were evaluated. Receiver Operating Characteristic (ROC) analysis identified optimal cut-off values for predicting infection. Variables associated with perioperative infection in univariate analysis were entered into multivariable regression models, and the model with the best discrimination was chosen as the final model.

Results: Thirty-five CS patients (31%) developed infection. The most common infections were urinary tract infections, followed by pneumonia. PNI demonstrated significant negative correlations with all cortisol-related indices, particularly for 1-mg overnight dexamethasone suppression test (1-mg DST) ($\rho = -0.605$, $P < .001$) and 24-hour urinary free cortisol (UFC) × upper limit of normal (xULN) ($n = 38$, $\rho = -0.605$, $P < .001$). Among the blood cell-derived indices, neutrophil-to-lymphocyte ratio demonstrated significant positive correlations with all cortisol-related indices, particularly UFC (xULN) ($n = 38$, $\rho = 0.735$, $P < .001$), low dose dexamethasone suppression test ($n = 104$, $\rho = 0.621$, $P < .001$), and 1-mg DST ($\rho = 0.589$, $P < .001$).ROC analysis demonstrated that 1-mg DST (AUC = 0.852; cut-off ≥ 17.2 µg/dL; $P < .001$) and PNI (AUC = 0.845; cut-off ≤51.4; $P < .001$) were the strongest predictors of infection. In the final multivariable model, 1-mg DST values ≥17.2 µg/dL (OR: 9.741; 95% CI: 2.801–33.883; $P < .001$), PNI values ≤51.4 (OR: 9.569; 95% CI: 2.683–34.122; $P < .001$), the presence of diabetes mellitus (OR: 3.963; 95% CI: 1.128–13.925; $P = .032$), and presence of bone fracture(s) or a T-score ≤–3 (OR: 3.574; 95% CI: 1.003–12.730; $P = .049$) were identified as independent risk factors for infection.

Conclusions: Perioperative infection was associated with elevated cortisol and lower PNI levels in patients with CS. Infection risk is modulated by hormonal, nutritional, and clinical parameters. Assessment of 1-mg DST and PNI, in conjunction with diabetes mellitus status and bone health, may enhance the identification of high-risk patients and guide targeted preventive strategies.

EP54 - ECE_1741 - Metyrapone treatment improves blood pressure and lowers epicardial fat in patients with mild autonomous cortisol secretion

Helena Niziolek[1], Ivica Just[1], Clemens Baumgartner[1], Anna Tosin[1], Konrad Körmöczi[1], Hansjörg Habisch[2], Paul Fellinger[1], Hannes Beiglboeck[1], Oliver Domenig[3], Luise Bellach[1], Anton Luger[1], Marie Helene Schernthaner-Reiter[1], Siegfried Trattnig[4], Maximilian Zeyda[5], Thomas Scherer[1], Alexandra Kautzky-Willer[1], Florian Kiefer[1], Greisa Vila[1], Andreas Kammerlander[6], Tobias Madl[2,7,8], Michael Leutner[1], Michael Krebs[1], Martin Krssak[1] and Peter Wolf[1]

[1]Division of Endocrinology and Metabolism, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria; [2]Medical University of Graz, Graz, Austria; [3]Vienna, Austria; [4]Department of Biomedical Imaging and Image Guided Therapy, Medical University of Vienna, Vienna, Austria; [5]Division of Pediatric Pulmonology, Allergology and Endocrinology, Department of Pediatrics and Adolescent Medicine, Medical University of Vienna, Vienna, Austria; [6]Division of Cardiology, Department of Internal Medicine II, Medical University of Vienna, Vienna, Austria; [7]BioTechMed-Graz, Graz, Austria;

Background: Mild autonomous cortisol secretion (MACS) is associated with increased mortality, mainly because of cardiovascular disease. Here we investigated the effects of cortisol-lowering medical treatment on blood pressure regulation, cardiac fat depots, heart function and morphology, the lipid profile and branched-chain amino acid (BCAA) concentrations.

Methods: In this secondary analysis of our prospective, open-label, exploratory study, we investigated 15 patients with MACS (12 females; age 59 [53–64] years) before and after 12 weeks of treatment with evening doses of metyrapone (500 mg at 6 p.m. and 250 mg at 10 p.m.). Cardiac fat stores, morphology and myocardial function were evaluated using cardiac magnetic resonance imaging and spectroscopy. Orthostatic blood pressure regulation was measured by standardized protocols. Lipidomics, renin-angiotensin-aldosterone-system activity and BCAA concentrations were assessed.

Results: Mean supine systolic (137[121-139] vs 122[115-129] mmHg; $P = .041$) and diastolic (89[80-93] vs 75[71-86] mmHg; $P = .045$) blood pressure decreased after treatment. Epicardial fat was lower at follow up compared to baseline (1032.70[894.23-1482.90] vs 929.37[736.12-1317.15]mm^2; $P = .022$). No changes in paracardial- and intramyocardial fat, as well as in cardiac function and morphology were observed. The aldosterone-to-angiotensin II ratio(AA2-ratio) was lower at follow up (1.56[0.87–2.82] vs 1.21[0.98–1.92]; $P = .042$) and alterations in lipid profiles, but not in BCAA levels were identified.

Conclusions: Treatment with evening doses of metyrapone improved blood pressure and reduced epicardial adipose tissue, highlighting the causal role of hypercortisolism for the development of cardio-vascular comorbidities in MACS.

Metabolism, Hudson Institute of Medical Research, Clayton, Victoria, Australia; [10]Department of Medicine, Monash University, Clayton, Victoria, Australia; [11]Melbourne, Australia; [12]Radboud University Medical Center, Nijmegen, The Netherlands; [13]Department of Internal Medicine, Nijmegen, The Netherlands

Introduction: The 1-mg overnight dexamethasone suppression test (DST) is widely used to assess autonomous cortisol secretion (ACS) in patients harboring adrenal adenomas or in whom there is suspicion of cortisol excess. Interpretation of DST results assumes adequate dexamethasone concentrations. However, insufficient or no dexamethasone intake may result in apparent failure of cortisol suppression and false-positive test results. Measurement of plasma dexamethasone (DXM) concentrations is therefore critical to ensure valid interpretation of DST outcomes.

Results: Among 347 patients undergoing DST with concomitant plasma dexamethasone measurement, 22 individuals were identified with insufficient dexamethasone exposure, defined as plasma concentrations below 3.3 nmol/L. These patients included twelve females and ten males. Mean age was 53.6 years in female patients and 52 years in male patients. Underlying diagnoses were heterogeneous and included adrenal adenoma ($n = 10$), primary aldosteronism ($n = 3$), and primary hypertension ($n = 9$). Median DXM concentrations were below the limit of detection (0.510 nmol/L) in 7 cases (32%), suggesting non-compliant DXM intake. In these patients, DST cortisol concentrations were frequently elevated, ranging from 11.65 to 396.05 nmol/L, with a median cortisol concentration of 54.6 nmol/L. Concentrations exceeded the diagnostic threshold for cortisol suppression in eleven cases, 3.2% of the total.

Conclusions: Absent or insufficient dexamethasone concentration represents a clinically relevant cause of false-positive dexamethasone suppression tests, accounting for 3.2% of all tested patients in our cohort. Elevated post-DST cortisol concentrations in the context of low or undetectable dexamethasone highlights the necessity of measuring dexamethasone to ensure valid interpretation of DST results. Routine incorporation of plasma dexamethasone measurement improves diagnostic accuracy and prevents misclassification of patients evaluated for cortisol autonomous secretion.

EP56 - ECE_3989 - Potential impact of multiple paired adrenal vein samples on lateralisation interpretation in adrenal vein sampling for primary aldosteronism: a retrospective case series

August Palma[1], James MacFarlane[1], Nicholas Hilliard[2] and Mark Gurnell[1,3]

[1]Endocrinology, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; [2]Radiology, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; [3]University of Cambridge, Cambridge, United Kingdom

Background: Adrenal vein sampling (AVS) is widely used to differentiate unilateral from bilateral disease in primary aldosteronism (PA). However, rates of successful bilateral adrenal vein cannulation vary considerably between centres, commonly reflecting differences in interventional radiologist expertise. Furthermore, reliance on a single paired adrenal vein samples may reduce the likelihood of identifying unilateral disease, even when present, due to fluctuations in hormonal secretion and catheter instability. We hypothesised that obtaining multiple paired adrenal vein samples during AVS would improve confirmation of selectivity and increase detection of aldosterone lateralisation.

Objectives: To examine within-patient variability in adrenal vein sampling (AVS) findings using a tertiary referral centre database in which multiple paired adrenal vein samples were systematically collected, and to assess whether additional paired samples improved confirmation of successful bilateral cannulation and enhanced detection of aldosterone lateralisation, thereby influencing AVS interpretation and clinical decision-making.

Methods: A retrospective review of AVS procedures performed by a single operator at Cambridge University Hospitals between January 2020 and January 2025 was conducted. The practice of the operator is to take multiple samples from the site of each adrenal vein (minimum 3). We identified five patients with confirmed PA who had undergone adrenocorticotropic hormone (ACTH)-stimulated AVS and demonstrated variability in selectivity indices (SI) and lateralisation indices (LI). Sequential paired samples were obtained from both adrenal veins during each procedure. SI was calculated using standard adrenal-to-peripheral cortisol ratios for ACTH-stimulated AVS ($SI \geq 3.0$), and LI was calculated for each paired sample using a standard cut-off of ≥ 4.0. Diagnostic interpretations based on the initial paired sample were compared with interpretations incorporating all paired samples.

Results: Multiple paired adrenal vein samples were successfully obtained in all cases. Sequential sampling demonstrated that, in some patients, the initial paired sample did not meet selectivity criteria for successful bilateral cannulation, whereas subsequent paired samples confirmed adequate cannulation. All 5 cases had pairs of samples yielding LI both above and below 4.0 resulting in differing diagnostic interpretations, with some samples indicating unilateral disease and others suggesting bilateral disease. Significant intrasampling variability was captured, including a case with LI varying between 2.3 and 8.51.

Conclusions: In this small case series, systematic collection of multiple paired adrenal vein samples was feasible and improved confirmation of bilateral cannulation and diagnostic confidence. This approach may enhance the diagnostic yield of AVS, support more accurate clinical decision-making, and reduce the need for repeat procedures in patients with PA.

Medical University of Lodz, Lodz, Poland; [3]Faculty of Mathematics and Computer Science, University of Lodz, Lodz, Poland; [4]Department of Endocrinology & Metabolic Diseases, Medical University of Lodz, Lodz, Poland

Background: Seated Saline Infusion Test (SSIT) is widely used for investigation of primary hyperaldosteronism (PA), however, the impact of one hour sitting period prior to SSIT (as recommended by the Endocrine Society) on the test outcome remains unclear.

Patients & Methods: In 82 individuals (23 males) age 57.3 ± 12.6 years, BMI 28.3 ± 5.1 kg/m^2, with adrenal incidentalomas, we performed a SSIT (two litre of 0.9% saline/4 hours) preceded by a two hour postural test (1st protocol), or immediately after waking, ie, without any period of sitting, or standing prior to the test (2nd protocol, a cross-over design).

Results: Though aldosterone & renin concentrations before the onset of saline infusion were higher after 1st protocol (aldosterone: 16.27 ± 1.28 ng/dL (mean ± SEM) vs 9.51 ± 1.20 ng/mL, $P <$ .001, renin: 23.52 ± 2.19 µIU/mL versus 8.09 ± 0.91 µIU/mL, $P <$ .001), an overall suppression of aldosterone secretion was not different after 1st protocol versus 2nd protocol (6.34 ng/dL ± 0.68 ng/dL (mean ± SEM) vs 5.74 ± 0.66 ng/dL, P = .124). In contrast renin concentrations were lower after 2nd protocol (7.32 ± 0.74 µIU/mL vs 5.13 ± 0.45 µIU/mL, P = .027). There was, however, no significant difference between the number of individuals who had clearly non-suppressible aldosterone concentration (>10 ng/mL), ie, 9 (11%) for 1st protocol versus 8 (9.75%) (2nd protocol), P = 82, as well as for individuals in the "grey zone" (7.8-10 ng/mL), ie, five (6.1%) individuals for each protocol, P = 1.0).

Conclusions: A period of ambulation (or sitting) before SSIT does not significantly impact the chance of detection of PA, so formal recommendation of at least one hour sitting period prior to SSIT can be safely avoided.

EP58 - ECE_1318 - Risk factors and outcomes of critical illness-related corticosteroid insufficiency

Moeber Mahzari[1], Omar Alluhayyan[2], Reema Alkalefah[3], Shahad Yarkandi[3], Yara Aleidi[3], Shaden Almutairi[3], Faisal Almutawa[1], Rakan Alotaibi[1] and Husam Ardah[1,4]
[1]KSAU-HS, Riyadh, Saudi Arabia; [2]KAMC, Riyadh, Saudi Arabia; [3]COSHP-R_F, Riyadh, Saudi Arabia; [4]Riyadh, Saudi Arabia

Introduction: Critical illness-related corticosteroid insufficiency (CIRCI) refers to inadequate corticosteroid activity compared to an illness's stress severity.

Endocrine outcomes associated with critical illness, specifically relating to adrenal insufficiency and hypothalamic–pituitary–adrenal (HPA) axis dysfunction, are not adequately assessed.

To overcome these limitations, this study aims to assess the risk factors and outcomes of CIRCI.

Methodology: This retrospective cohort study included adult intensive care unit (ICU) patients treated for suspected CIRCI between 2016 and 2024. Demographic, clinical, laboratory, and treatment data were extracted from electronic medical records. Outcomes assessed included mortality, CIRCI, readmission, and continuation of steroid therapy after hospital discharge.

Results: A total of 390 critically ill patients who received glucocorticoids in an ICU during the study period were included in the analysis. The mean age was 62.5, and 57.7% of the patients were male. The most common primary reason for ICU admission was sepsis, affecting 52.5% of the patients. Among critically ill patients, 118 (32.4%) met the criteria for CIRCI, defined as a serum cortisol level of ≤275 nmol/L, while 246 (67.6%) did not meet these criteria. CIRCI was more frequently observed among patients with neurological reasons for ICU admission (13.7% vs 5.7%, P = .009) and those requiring mechanical ventilation (80.5% vs 68.7%, P = .018).

Upon follow-up, the frequency of adrenal crisis events was significantly higher among patients with a history of CIRCI compared with those without CIRCI (mean 0.96 vs 0.36, P = .034). Longer duration of post-ICU glucocorticoid therapy was associated with a higher frequency of adrenal insufficiency events over follow-up (r = 0.59, P = .002). Post–critical illness, only 10.3% of patients underwent HPA axis assessment during follow-up, indicating limited evaluation of adrenal function.

In multivariable analysis, Mortality was independently associated with older age (estimate 0.01, P = .006), longer ICU length of stay (estimate 0.01, P = .01), and the presence of cardiogenic shock (estimate 1.26, P = .02). In contrast, baseline cortisol levels (P = .92) and duration of glucocorticoid treatment (P = .59) were not associated with mortality. During follow-up, patients who had a lower baseline cortisol level during ICU were more likely to continue steroids upon discharge (estimate −0.03, $P <$ .0001).

Conclusions: CIAI is common in critical illness and reflects endocrine vulnerability rather than mortality risk. Lower baseline cortisol identifies patients at risk for prolonged steroid dependence and recurrent adrenal insufficiency events, supporting the need for targeted post-ICU endocrine follow-up and assessment of the HPA axis.

EP59 - ECE_2265 - Upregulated glutamate receptor subunit NETO2 in primary aldosteronism promotes CYP11B2 expression in human adrenocortical cells

Yingxian Pang and Tracy Ann Williams
Munich, Germany

Background: Neuropilin and Tolloid-Like 2 (NETO2) is a key auxiliary subunit of kainate-type glutamate receptors and is involved in the regulation of sodium, potassium, and calcium homeostasis in the human brain. However, its role in primary aldosteronism remains poorly understood.

Objective: We examined NETO2 expression in primary aldosteronism and investigated its effects on CYP11B2 (aldosterone synthase) expression and the underlying mechanisms in human adrenocortical cells.

Results: Spatial transcriptomic analysis of adrenal glands from patients with APA and APM revealed high expression of *NETO2* and *CYP11B2* in aldosterone-producing lesions compared to adjacent adrenal cortex. *GLUK1*, *GLUK2*, *GLUK3*, and *GLUK5* of kainate receptors were mainly expressed in the medulla, whereas *GLUK4* gene was distributed throughout the entire adrenal tissue. Western blot showed elevated NETO2 protein in APAs versus adjacent adrenal tissue (2.9-fold change, $P <$ .01). In HAC15 cells,

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

NETO2, *GLUK2* and *GLUK4* were highly expressed, whereas *GLUK1* and *GLUK5* were low and *GLUK3* undetectable. *NETO2* overexpression increased *CYP11B2* mRNA (4.7-fold change, $P < .001$), *NR4A2* mRNA (6.3-fold change, $P < .001$), and modestly *CYP11B1* mRNA (1.4-fold change, $P < .05$), with no effect on *CYP11A1* and *CYP17A1* mRNA levels. *NETO2* silencing had opposite effects.

Conclusions: NETO2 is highly expressed in primary aldosteronism and promotes *CYP11B2* expression in human adrenocortical cells. Further studies are warranted to investigate the effects of NETO2 on intracellular calcium signaling.

EP60 - ECE_2611 - Evaluation of salivary cortisone and cortisol for diagnosing mild autonomous cortisol secretion in patients with adrenal incidentalomas

Nanna Thurmann Jørgensen[1], Christina Christoffersen[2], Linda Hilsted[2], Kasper Brødbæk[2], Niklas Jørgensen[2], Randi Ugleholdt[3], Claus Feltoft[3], Åse Krogh Rasmussen[1], Ulla Feldt-Rasmussen[4], Marianne Klose[1] and Stina Willemoes Borresen[1]

[1]Department of Nephrology and Endocrinology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark; [2]Department of Clinical Biochemistry, Copenhagen University Hospital, Copenhagen, Denmark; [3]Department of Endocrinology and Internal Medicine, Copenhagen University Hospital, Herlev, Herlev, Denmark; [4]Dept of Growth and Reproduction, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark

Objective: Salivary cortisol and cortisone are promising alternatives to plasma measurements. This study investigates their diagnostic accuracy in mild autonomous cortisol secretion (MACS) and assesses agreement between liquid chromatography–tandem mass spectrometry (LC-MS/MS) and the iSYS immunoassay for salivary cortisol.

Design and Methods: This cross-sectional study prospectively included patients with adrenal incidentalomas ($N = 108$) and age- and sex-matched healthy controls ($N = 101$). Saliva was collected at 0800-0900 h, 2300-2400 h, and at 0800-0900 h following a 1-mg overnight dexamethasone suppression test (DST). Salivary cortisone was measured by LC-MS/MS, and salivary cortisol by LC-MS/MS and the iSYS immunoassay. Diagnostic accuracy was assessed using the area under the receiver operation characteristic curve (ROC-AUC) with the guideline-recommended post-DST plasma cortisol cut-off value of 50 nmol/L as the gold standard for MACS. Furthermore, an alternative cut-off value for MACS was defined as the 97.5th percentile of post-DST plasma cortisol in controls (72 nmol/L). Salivary cut-off values were based on Youden's index and the 97.5th percentile of control distributions. Method agreement was evaluated using Bland-Altman plots and Passing-Bablok regression.

Results: A post-DST salivary cortisone cut-off value of 3.1 nmol/L showed the highest discriminatory ability (sensitivity and specificity 90%) compared with post-DST salivary cortisol and late-night cortisol and cortisone (sensitivities 69-79%, specificities 66-91%). Percentile-derived cut-off values were two- to threefold higher with consequently lower sensitivities (13-17%). The MACS plasma cortisol cut-off value of 72 nmol/L significantly improved the diagnostic accuracy of post-DST salivary cortisol compared with the cut-off value of 50 nmol/L (ROC-AUC 0.78 vs 0.92, $P = .006$), whereas AUCs for post-DST salivary cortisone and late-night salivary cortisol and cortisone were unchanged. The immunoassay systematically overestimated salivary cortisol compared with LC–MS/MS in controls and patients (mean bias 10.8 vs 14.6 nmol/L at 0800-0900 h, 3.0 vs 4.8 nmol/L at 2300-2400 h, and 1.6 vs 2.9 nmol/L post-DST, respectively), but demonstrated comparable diagnostic accuracy for MACS at 2300 2400 h (ROC-AUC 0.75 vs 0.77, $P = .5$) and post-DST (ROC-AUC 0.82 vs 0.78, $P = .4$).

Conclusions: Post-DST salivary cortisone showed high diagnostic accuracy, whereas post-DST salivary cortisol and late-night salivary cortisol and cortisone had lower predictive value. A cut-off value of 72 nmol/L significantly improved post-DST salivary cortisol performance compared with 50 nmol/L. Percentile-derived salivary cut-off values were inferior to those based on the Youden's index. Despite systematic overestimation by the iSYS immunoassay compared with LC-MS/MS, diagnostic accuracy for MACS was comparable.

EP61 - ECE_2814 - Characterization of diffuse CYP11B2-positivity and multiple micronodules in autopsy samples from adults without primary aldosteronism

Juhani Isojärvi[1], Antero Ylänen[1,2], Antti Virtanen[3], Helena Leijon[4], Tiina Vesterinen[4], Heini Huhtala[5], Eeva Kokko[1], Marianna Viukari[6,7], Ilkka Pörsti[1], Niina Matikainen[6,7] and Pasi Nevalainen[2]

[1]Faculty of Medicine and Health Technology, Tampere University, Tampere, Finland; [2]Tampere University Hospital, Tampere, Finland; [3]Forensic Medicine Unit, Finnish Institute for Health and Welfare, Helsinki, Finland; [4]HUS Diagnostic Center, Department of Pathology, Helsinki University Hospital and University of Helsinki, Helsinki, Finland; [5]Health Sciences, Faculty of Social Sciences, Tampere University, Tampere, Finland; [6]Endocrinology, Helsinki University Hospital, Helsinki, Finland; [7]University of Helsinki, Helsinki, Finland

Background: The introduction of HISTALDO consensus has revolutionised the histopathological assessment of unilateral aldosterone-producing adrenocortical findings. Less is known about the structure of the zona glomerulosa based on aldosterone synthase (CYP11B2) immunohistochemistry in healthy adults. Previous studies have identified a negative correlation between age and adrenal CYP11B2-expressing area, as well as ageing-related transition in ZG structure from continuous CYP11B2 expression into more fragmented appearance in individuals without primary aldosteronism (PA). However, these studies have been limited to unilateral adrenal samples or small, specific cohorts, preventing a comprehensive analysis of bilateral adrenal CYP11B2 expression in the general population.

Methods: We explored the characteristics, symmetry, and clinical relevance of adrenocortical findings expressing CYP11B2 in unselected adults without known primary aldosteronism. Bilateral adrenal CYP11B2 immunohistochemistry was performed on 145 consecutive autopsy cases who died from exogenic causes and analysed following the HISTALDO consensus when applicable. A four-grade classification was used: 1) diffuse CYP11B2 positivity, 2) ≥20 aldosterone-producing micronodules (APMs), 3) <20 APMs, and 4) aldosterone-producing nodules or adenomas

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

(APNs/ APAs). Autopsy findings were documented, and ante-mortem data including diagnoses, prescriptions, and laboratory results were collected. This study was registered in ClinicalTrials.gov (NCT05446779).

Results: The cohort included 104 males and 41 females, with a median age of 53.9 years. Bilateral diffuse CYP11B2 positivity was observed in 12 subjects (8.3%). APMs were identified in 131 subjects (90.3%), with ≥20 APMs in 42 (32.1%) and <20 APMs in 89 (67.9%). Two subjects had an APN, while no APAs were detected. CYP11B2 staining patterns were symmetric between the adrenals in 72.4% of subjects. Diffuse CYP11B2 positivity was more frequent in females than in males ($P = .005$). The CYP11B2 expression groups showed no association with age, hypokalaemia, hypertension, or autopsy-identified cardiovascular pathologies, nor did they differ between individuals with or without cardiovascular disease. Detailed analyses about the diffuse positivity are under way and will be presented in ECE2026, Prague.

Interpretation: Taken together, bilateral multiple APMs were frequently found in this unselected adult population and showed considerable side-to-side symmetry, while diffuse CYP11B2 positivity, considered as normal ZG, was rare. Our results suggest that presence of bilateral CYP11B2-positive APMs without clinical signs of primary aldosteronism is a common non-pathological finding.

EP62 - ECE_3022 - Androgen profiling in adrenal incidentalomas: differentiating mild autonomous cortisol secretion from non-functioning adrenal incidentaloma

Sara Cerrato[1], Filippo Vignali[1], Lucia Zirilli[2], Bruno Madeo[2], Laura Roli[3], Maria Cristina De Santis[3], Giulia Canu[3], Tommaso Fasano[3], Sara De Vincentis[1] and Vincenzo Rochira[1,2]

[1]Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; [2]Endocrinology, Department of Specialty Medicine, Azienda Ospedaliero-Universitaria of Modena, Modena, Italy; [3]Department of Laboratory Medicine and Pathology, Azienda USL Modena, Modena, Italy

Introduction: Mild autonomous cortisol secretion (MACS) is increasingly recognised among patients with adrenal incidentalomas (AI). Growing evidence suggests that adrenal androgen production is lower in MACS compared to non-functioning adrenal incidentaloma (NFAI); however, current evidence remains conflicting.

Objective: To investigate the androgen profile of AI and delineate key biochemical differences between MACS and NFAI.

Materials and Methods: We performed a retrospective monocentric study including adult patients with AI, referred to the Endocrinology Unit of the AOU-Modena (2013-2025). Patients with overt Cushing syndrome, primary aldosteronism, aldosterone–cortisol co-secretion, interfering medications, or major confounders were excluded. Morning serum values of dehydroepiandrosterone sulphate (DHEA-S), 17-hydroxyprogesterone (17OH-P), and androstenedione were measured. The DHEA-S ratio (DHEA-S divided by the age and sex-adjusted lower limit of the reference range) and DHEA-S ULN (DHEA-S divided by the upper limit of the reference range) were also calculated. Results are expressed as median and IQR.

Results: A total of 178 patients were included (60 MACS, 118 NFAI). Patients with MACS (0,39 [0,22-0,73] μg/L) showed significantly lower DHEA-S levels compared to those with NFAI (0,78 [0,40-1,33] μg/L; $P < 0,001$), as well as lower DHEA-S ULN values (0,20 [0,14-0,31] vs 0,32 [0,21-0,50]; $P < 0,005$). In contrast, the DHEA-S ratio did not differ significantly between the two groups ($P = 0,367$). ROC analysis confirmed the superiority of DHEA-S [area under the curve (AUC) 0.707] and DHEA-S ULN (AUC 0.692) over DHEA-S ratio (AUC 0.597) in discriminating MACS from NFAI. The optimal diagnostic cut-off identified for DHEA-S was ≤0.63 mg/L, and ≤0.22 for DHEA-S ULN, both providing the best balance between sensitivity (72,9% DHEAS; 57.6% DHEA-S ULN) and specificity (62,7% DHEAS; 74,6% DHEA-S ULN) in discriminating MACS from NFAI. No significant differences were observed for 17OH-P levels (0,90 [0,50-1,38] ng/mL in MACS vs 1,00 [0,70-1,30] ng/mL in NFAI; $P = 0,684$) and androstenedione (0,73 [0,50-1,50] ng/mL in MACS vs 1,08 [0,61-1,58] ng/mL in NFAI; $P = 0,462$).

Conclusions: MACS exhibit lower DHEA-S levels compared to NFAI, reflecting the inhibitory effect of autonomous cortisol on the hypothalamic-pituitary-adrenal axis. The lack of significance for the DHEA-S ratio in our cohort suggests that age-related decrease of the lower reference limit may obscure pathological androgen suppression in elderly patients. Given the advanced median age at diagnosis of AI (63 years in our results), the use of DHEA-S ULN appears to better preserve information on absolute adrenal androgen reduction and may represent a reliable biomarker of cortisol autonomy in clinical practice.

EP63 - ECE_3317 - Natural history of large adrenal tumors

Magdalena Macech[1], Maclej Stępień[1], Joanna Podgórska[2], Sadegh Toutounchi[3], Lukasz Koperski[4], Joanna Barankiewicz[5], Malgorzata Bobrowicz[1], Agnieszka Kondracka[1] and Urszula Ambroziak[1]

[1]Department of Internal Medicine and Endocrinology, Medical University of Warsaw, Warsaw, Poland; [2]Warsaw, Poland; [3]Department of General, Vascular, Endocrine and Transplant Surgery, Medical University of Warsaw, Warsaw, Poland; [4]Department of Pathology, Medical University of Warsaw, Warsaw, Poland; [5]Laboratory of Cellular and Genetic Therapies, Center for Preclinical Research, Medical University of Warsaw, Warsaw, Poland

Objective: The aim of this study was to characterize large adrenal tumors (LATs), assess the accuracy of imaging diagnostics in detecting malignant LATs, and determine whether further follow-up of seemingly benign LATs is necessary.

Patients and Methods: We investigated the clinical, biochemical, and imaging characteristics at presentation and follow-up in a retrospective single-center cohort of patients with adrenal tumors ≥4 cm in diameter during the period from June 2013 to June 2023.

Results: Of 1473 patients with adrenal tumors, 269 (18.3%) had adrenal masses measuring ≥4 cm in diameter, 220 patients were included in the study. Among LATs 34.6% were

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

adrenocortical adenomas, 27.3% other benign adrenal tumors, 17.3% adrenocortical carcinomas, 11.4% other malignant tumors, 9.6% pheochromocytomas. 44.7% of tumors were non-functioning and 37.8% were producing corticosteroids.

Sensitivity of an unenhanced computed tomography attenuation in detecting malignancy was 100% using the threshold >10 Hounsfield Units and 89.5% for >20 Hounsfield Units (with specificity 66.1% and 81.4% respectively). Magnetic resonance with chemical shift analysis also had high sensitivity (94.4%), but low specificity (56.8%). ^{18}F-fluorodeoxyglucose-positron emission tomography integrated with computed tomography had 100% sensitivity using adrenal liver ratio >1, when the maximum standardized uptake value >5 cutoff was employed, sensitivity remained high (100%) while specificity improved (82.1% vs 100%).

87 tumors remained under follow-up. The mean follow-up was 30.1 months. Significant tumor growth was observed in 4 cases (4.6%). 3 of these tumors were myelolipomas, 1 was indeterminate mass in a patient with extraadrenal malignancy. Adrenalectomy was performed in 6 patients (6.9%). While they were initially assessed as adrenocortical adenomas, in 5 of them histopathology revealed benign lesions and in one an adrenocortical carcinoma. The risk of developing mild autonomous cortisol secretion among non-functioning lesions was 6.7%. No progression to overt Cushing's syndrome was observed.

Conclusions: While the risk of malignancy increases with tumor size, most large adrenal tumors are benign. Imaging sensitivity for detecting malignancy is high in LATs. No malignancy was diagnosed in lesions with certain benign features (homogenous <10 HU). LATs that do not meet these criteria **s**hould be assessed by a multidisciplinary team and be subjected to continued follow-up.

EP64 - ECE_3408 - Evaluating variability in 24-hour urine free cortisol measurements: impact of sample collection errors

Ömer Ozcan[1], Karlijn Koops[1], Jacquelien Hillebrand[1], Antonius van Herwaarden[2], Annenienke van de Ven[3], Peter Bisschop[4], Wendy den Elzen[5] and Annemieke C. Heijboer[1]

[1]Endocrine Laboratory, Amsterdam UMC, Amsterdam, The Netherlands; [2]Laboratory Medicine, Radboud UMC, Nijmegen, The Netherlands; [3]Department of Internal Medicine, Division of Endocrinology, Radboud UMC, Nijmegen, The Netherlands; [4]Endocrinology, Amsterdam UMC, Amsterdam, The Netherlands; [5]Laboratory Specialized Diagnostics & Research, Amsterdam UMC, Amsterdam, The Netherlands

Introduction: Twenty-four hour urine free cortisol (UFC) reflects systemic cortisol exposure. It shows high variability and therefore requires multiple collections for Cushing's syndrome (CS) screening. This variability arises from both inherent biological variation and variation introduced by collection errors. Importantly, UFC results are interpreted using a cut-off based on the 24-hour collection, rather than per liter or normalized to creatinine, making the accuracy of urine collection volume critical for correct interpretation. This study aimed to determine the proportion of inaccurately collected samples and evaluate the impact on UFC variability.

Methods: Two 24-hour UFC measurements from the same subjects ($n = 552$) from two Dutch academic hospitals were evaluated retrospectively. The UFC results were considered inaccurately collected when they met 1) a creatinine difference of more than 4.0 mmol/24 hours and 2) a volume discrepancy of more than 55% between the two collections.

Results: 19% of 24-hour urine samples were inaccurately collected. Notably, UFC concentrations between the two collections varied less ($P < .001$) among accurately collected samples (Coefficient of variation; 17%), than among inaccurate collected samples (Coefficient of variation; 33%).

Conclusions: This study demonstrates that there is a substantial amount of incorrectly collected samples. These errors contribute considerably to the total variability of 24-hour UFC measurements. This highlights the importance of patient instruction and adherence to collection protocols for reproducibility of UFC measurements.

EP65 - ECE_1827 - Transient Thyroiditis as a Confounding Feature in Autoimmune Polyglandular Syndrome Type 2

Vijay Ramadoss, Ryan Goindoo, Lisa Owen and Michael Pierides

Leicester, United Kingdom

Background: Autoimmune Polyglandular Syndrome type 2 (APS-2) is characterised by autoimmune adrenal insufficiency (AI) with autoimmune thyroid disease and/or type 1 diabetes mellitus or primary ovarian insufficiency. Thyroid dysfunction most commonly manifests as Graves' disease or Hashimoto's thyroiditis. We describe a case of APS-2 presenting with primary AI and a transient thyrotoxic phase most consistent with thyroiditis, highlighting important diagnostic and therapeutic considerations.

Case Presentation: A 45-year-old woman presented with a 12-month history of salt craving, postural dizziness, nausea, vomiting and fatigue. Examination revealed generalised hyperpigmentation. She was clinically euvolaemic with otherwise unremarkable cardiovascular, respiratory and abdominal examinations. Ocular examination demonstrated lid lag without features of Graves' ophthalmopathy. There was no goitre or thyroid tenderness.

Her medical history included attention deficit hyperactivity disorder treated with lisdexamfetamine. She had three successful pregnancies and one termination at 15 weeks' gestation without excessive bleeding. She reported secondary amenorrhoea for 18 months and had no family history of autoimmune disease.

Initial investigations demonstrated hyponatraemia (123 mmol/L), borderline hyperkalaemia (5.3 mmol/L), low serum osmolality (266 mOsm/kg), elevated urine osmolality (556 mOsm/kg) and elevated urine sodium (83 mmol/L). Thyroid function tests suggested biochemical thyrotoxicosis (TSH < 0.01 mIU/L, FT4 29.5 pmol/L). Gonadotropins were elevated with low oestradiol, consistent with primary ovarian failure.

Morning cortisol was 417 nmol/L, inappropriately normal for the clinical context. Given the high pre-test probability of AI, a short Synacthen test was performed, demonstrating suboptimal peak cortisol of 306 nmol/L, without any rise, and with markedly elevated ACTH (914 ng/L), confirming primary AI.

Management: The patient was commenced on hydrocortisone (10/5/5 mg) and fludrocortisone 100 micrograms daily. Antithyroid therapy was deferred until steroid repletion to avoid

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

precipitating adrenal crisis. At four-week follow-up, there was biochemical resolution of hyponatraemia and hyperkalaemia with significant symptomatic improvement. Thyroid function normalised spontaneously (FT4 12.8 pmol/L, TSH 1.31 mIU/L) without specific therapy. TSH receptor and anti-TPO antibodies were negative, while adrenal and ovarian antibodies were positive, confirming APS-2 with primary AI and ovarian failure.

Conclusions: This case highlights the importance of dynamic adrenal testing despite an adequate baseline cortisol when clinical suspicion is high. Thyroid dysfunction in APS-2 may be transient, and thyroid-directed therapy should be deferred until patients are steroid replete. To our knowledge, this adds to the limited literature describing APS-2 presenting with features most consistent with painless thyroiditis, raising the possibility of an unusual temporal association in the context of prolonged untreated AI.

EP68 - ECE_3024 - Clinical outcomes of patients with adrenocortical carcinoma—a single centre experience

Theodora Nistor[1], Monalisa Preda-Ivascu[1], Roxana Enachescu[1], Cristina Coman[2], Roxana Nita[3], Radu Iorgulescu[2], Roxana Dusceac[1], Dan Niculescu[1,4], Simona Galoiu[1,4], Serban Radian[1,4] and Catalina Poiana[1,4]
[1]Institutul Național de Endocrinologie CI Parhon, București, Romania; [2]Spitalul Clinic de Urgență Sfântul Ioan București, București, Romania; [3]Spitalul de Boli Cronice Sfântul Luca București, București, Romania; [4]Ramnicu Valcea, Romania

Background: Adrenocortical carcinoma (ACC) is a rare endocrine malignancy with aggressive clinical behaviour and poor prognosis, due to limited therapeutic options. Management relies on a multidisciplinary approach, in order to improve outcomes.

Methods: A retrospective, observational study was conducted in a tertiary endocrine centre. Clinical findings, hormone secretion, histopathological characteristics, treatment modalities and outcomes were reviewed. Overall survival (OS) and progression- free survival (PFS) were analyzed using the Kaplan-Meier method.

Results: Thirteen patients were included, predominantly female (76.9%), median age at diagnosis 49 years (range 22-76). 76.9% of tumors were functional, 40% of these having mixed glucocorticoid and androgen secretion. The mean axial tumor diameter at diagnosis was of 8.3 cm. The median Weiss score was 6 (range 4-8) and median Ki-67 index was 17.5% (range 5-80). All patients underwent surgical resection of primary tumors, with selected patients undergoing resections of metastases. Adjuvant therapy was used in most patients: Mitotane (76.9%), chemotherapy (53.8%) and radiotherapy (30.8%).

Metastatic disease was present at diagnosis in 4 patients and developed during follow-up in five. Median follow-up was 18 months (1-84) and median survival was 13.5 months (10-17), for the deceased patients. Median OS was not reached, while median PFS was 24 months.

Conclusions: In routine clinical practice, aggressive surgical management combined with individualized adjuvant treatment is associated with significant survival in selected patients with ACC, ideally provided in a multidisciplinary setting.

EP69 - ECE_3356 - When adrenal masses are not metastasis: a Primary Adrenal Lymphoma

Beatriz R. Pereira[1], Joana Vinhais[1], David Verissimo[1], Catarina Ivo[1], Ana Cláudia Martins[1], D'jalma Soulé[2], Miguel Valente[2], Ascension Lopez[2], Luis Lopes[1], Dolores Passos[1], Mafalda Marcelino[1], João Jácome de Castro[1] and João Nunes Silva[1]
[1]Endocrinology, Hospital Das Forças Armadas, Lisboa, Portugal; [2]Lisboa, Portugal

Introduction: Primary adrenal lymphoma is rare, accounting for less than 1% of non-Hodgkin lymphomas. It typically manifests as bilateral adrenal masses, often associated with adrenal insufficiency.

Case-Report: An 83-year-old male was admitted to the emergency room with fatigue, vomiting, progressive abdominal distension and a 16 kg weight loss over two months. His medical history included type 2 diabetes, hypertension and dyslipidemia, managed with once a day metformin 1000 mg, carvedilol 6.25 mg and simvastatin 20 mg. On examination no differentiating features were found other than distended painless abdomen.

Initial laboratory tests showed hypoglycemia (61 mg/dL), hypercalcemia (11.9 mg/dL) and hyponatremia (126 mmol/L), which improved with intravenous fluids. Abdominal CT revealed two large solid adrenal masses (14 cm on the right and 11 cm on the left), with adjacent lymphadenopathy, suggesting lymphoproliferative disease. Hence, he was admitted with suspected bilateral adrenal neoplasm.

Complementary evaluation showed low-to-normal cortisol (10.9 ug/dL), elevated ACTH (137 pg/mL), low PTH (3.8 pg/mL), elevated 1,25-dihydroxyvitamin D (117 pg/mL), and suppressed PTHrP (<1.2 pmol/L). Remaining adrenal function and its precursors were within normal range. Due to presumed adrenal insufficiency along with $1,25(OH)_2D$ mediated hypercalcemia prednisolone was initiated.

FDG PET/CT revealed bulky upper-abdominal disease with extensive visceral and perivascular lymphadenopathy. An inguinal node was biopsied, confirming diffuse large B-cells lymphoma. Despite sustained correction of sodium, calcium and glucose, the patient died of disease progression on day 20 of admission.

Discussion/Conclusions: This is a rare case of primary adrenal lymphoma, presenting with bilateral adrenal masses and adrenal insufficiency. Also exhibiting calcitriol-mediated hypercalcemia, the predominant mechanism in lymphoma, although an uncommon cause of malignancy-related hypercalcemia.

Despite metastases accounting for most adrenal masses, the fulminant course requires a high index of suspicion for primary adrenal lymphoma. Targeted therapy requires timely diagnosis, which was not possible due to rapid clinical decline. When adrenal insufficiency is suspected, prompt glucocorticoid therapy is needed to mitigate acute complications that contribute to mortality. Given its distinctive features and aggressiveness, primarily adrenal lymphoma should remain in the differential diagnosis of bilateral adrenal masses.

EP70 - ECE_3476 - ACTH-producing pheochromocytomas

Barbora Holá, Michal Krsek, Tomáš Zelinka, Ondrej Petrák, Zuzana Krátká and Václav HánaJr
Prague, Czech Republic

Background: Adrenocorticotropic hormone (ACTH) secreting pheochromocytoma is a rare and severe cause of ACTH-dependent Cushing syndrome (CS) that is associated with high morbidity.

The aim of this study is to describe clinical and biochemical characteristics of patients with ACTH-secreting pheochromocytoma.

Methods: This is a retrospective case series of patients with the diagnosis of pheochromocytoma associated with biochemical evidence of ACTH excess production, collected from one centre between the years 1994 and 2024. The data included demographic characteristics, tumour size, presence of clinical signs of CS, metabolic and electrolyte disturbances, catecholamine secretion and cortisol parameters.

Results: In total, there were 7 patients included (4 women, 3 men), with a median age at diagnosis of 51 years (range 26–72). Median size of tumour was 52 mm (range 26-95). At the time of diagnosis, hypertension and diabetes mellitus or impaired glucose metabolism were present in 6 (86%) patients, and hypokalaemia in all patients. Cushingoid phenotype was apparent in 4 patients (57%). ACTH levels were markedly elevated in most patients (up to 40 of upper limit of normal), accompanied by elevated urinary free cortisol reaching over 100 of upper limit of normal in few cases. Cortisol levels remained high in dexamethasone suppression test performed in 4 patients. Catecholamine excess production was measured in all 7 patients but varied greatly, in 5 patients (70%) adrenergic type of pheochromocytoma was confirmed and 2 patients (30%) had noradrenergic type of pheochromocytoma.

Conclusions: This case series confirms that ACTH-secreting pheochromocytomas frequently present with severe hypercortisolism, hypokalaemia, diabetes and hypertension. Our findings are consistent with available published data and further support the need to consider ectopic ACTH secretion in patients with clinical and laboratory signs of Cushing syndrome and adrenal masses.

EP72 - ECE_1861 - Mixed corticomedullary tumor of the adrenal gland with component of cortical adenoma, pheochromocytoma and ganglioneuroma: a rare case report

Marie Cornec[1], Emmanuel Sonnet[1], Vincent Joulin[2], Jean-Romain Risson[3], Laurent Doucet[4] and Philippe Thuillier[1]
[1]*Department of Endocrinology, University Hospital of Brest, Brest, France;* [2]*Department of Urology, University Hospital of Brest, Brest, France;* [3]*Department of Radiology, University Hospital of Brest, Brest, France;* [4]*Department of Pathology, University Hospital of Brest, Brest, France*

Background: Mixed corticomedullary tumors (MCMTs) of the adrenal gland are extremely rare lesions containing both medullary and cortical cells within a single mass. First documented in 2011, we describe an even rarer adrenal MCMT case with cortical adenoma, pheochromocytoma and ganglioneuroma components.

Case Presentation: A 77-year-old man, under medical follow-up in urology for elevated prostate-specific antigen, was referred to our clinic in 2025 after the discovery of a left adrenal incidentaloma on MRI. Clinical assessment highlighted labile hypertension associated with malaise, palpitations and flushes. Cardiac echography showed a left ventricular hypertrophy without heart failure.

Biological findings ruled out primary hyperaldosteronism, hypercortisolism and androgen excess. Both the 24-hour urine and plasma normetanephrine levels were elevated (respectively 4.08 µmol (0.2–1.5) and 0.86 nmol/L (<0.36)), while metanephrine levels remained normal.

Computed tomography revealed a left hypervascular heterogeneous mass (46 mm) with necrosis and spontaneous density of 18 Hounsfield Units. The patient underwent an 18F-DOPA PET/CT which revealed intense radiotracer uptake by the lesion.

The association of his clinical presentation, biological and imaging findings raised a high suspicion of pheochromocytoma and surgery was scheduled. Patient received alpha-blocker treatment (Urapidil) preoperatively, which was poorly tolerated (severe hypotension that required volume expansion). A robot-assisted laparoscopic left adrenalectomy was performed without complication.

Gross and microscopic examination revealed a 40×20 mm mass, composed of cortical adenoma (50%), pheochromocytoma (25%) and ganglioneuroma (25%).

The areas were topographically distinct, within the same non-encapsulated lesion. Immunohistochemistry confirmed SF1, inhibin and Calretinin positivity on the cortical component, Chromogranins A & B positivity on pheochromocytoma cells and neurofilament and calretinin on ganglioneuroma component. Ki67 was <1%, PASS score 2/20 and WEISS score 0/9.

NGS did not detect any pathogenic variants or mutations associated with pheochromocytoma. Additional analyses are ongoing.

Discussion: This case represents an extremely rare adrenal tumor, confirmed by immunohistochemistry. To our knowledge, this is only the fourth case ever reported.

The pathogenesis of MCMTs remains unclear, as medullary and cortical cells derive from different embryonic lineages. Two previously reported cases presented with Cushing's syndrome, and the third case showed both catecholamine and cortisol excess. In contrast, our patient experienced isolated catecholamine excess without hypersecretion from the cortical adenoma component.

The existence of MCMTs seems to be rare, and suggests screening for hypercortisolism in some cases of patients with a strong suspicion of pheochromocytoma.

EP73 - ECE_1335 - From trauma to tumour: incidental giant left adrenal myelolipoma in congenital adrenal hyperplasia

Emily Mayar, Anna Crown and Sing Yang Sim
University Hospitals Sussex NHS Foundation Trust, Brighton, United Kingdom

Background: Adrenal myelolipomas are rare, benign tumours with an estimated prevalence of 0.08-0.4%. With increasing

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

utilisation of CT scans, these lesions are being detected more often, accounting for about 6% to 16% of all adrenal incidentalomas. Patients with congenital adrenal hyperplasia (CAH) are predisposed to adrenal hyperplasia and, occasionally, giant or bilateral myelolipomas due to persistent ACTH stimulation which induces tumorigenesis. Giant myelolipomas (>10 cm) involve a 3-6% risk of spontaneous rupture. CAH patients are 30 times more likely to develop myelolipomas compared to the general population.

Case history: A 49-year-old female with CAH underwent a CT scan after sustaining a stab wound to her abdomen, which demonstrated a superficial abdominal wall injury. There was an incidental finding of a 12 cm encapsulated left adrenal lesion containing fat, soft tissue, and calcification, suggestive of a giant myelolipoma. She was diagnosed with CAH at birth due to the presence of ambiguous genitalia. Her brother has CAH and bilateral adrenal myelolipomas.

The patient was reviewed in an endocrine clinic and reported good adherence to hydrocortisone 10 mg twice daily and fludrocortisone 200 mcg daily. However, her persistently elevated androstenedione, 17-OHP and renin levels indicated possible non-compliance with medication.

Biochemistry:

Parameter	Result	Reference ranges
17-hydroxyprogesterone	117.5	1-8.7 nmol/L
Androstenedione	18.8	2-5.4 nmol/L
Renin	191.0	5.4-60 mU/L
Testosterone	4.3	0.29-1.67 nmol/L
Sodium	135	136-145 mmol/L
Potassium	4.9	3.5-5.1 mmol/L
eGFR	>60	60-90 mL/min

Given the size of the adrenal myelolipoma and potential risk of spontaneous rupture the case was reviewed in the adrenal MDT meeting and a left adrenalectomy was offered to her.

Discussion: Giant lesions may rupture and usually need surgical excision, preferably at a specialist centre because of operative complexity. It is important to integrate clinical history, biochemical markers and imaging to effectively risk stratify. In CAH, bilateral adrenal involvement is a result of ACTH overstimulation. This leads to adrenal hyperplasia, which later undergoes metaplastic transformation into hematopoietic tissue, resulting in the formation of myelolipomas. Multidisciplinary management is paramount to determine if surgery is required, arrange steroid cover and monitor the contralateral adrenal gland.

Conclusions: Our case illustrates a rare giant myelolipoma in a CAH patient emphasizing the importance of biochemical and imaging surveillance. Multidisciplinary management will help guide management. Future research could help establish imaging protocols for early detection to reduce risk of spontaneous rupture.

Abstract citation ID: lvag096.680

EP74 - ECE_1908 - Acute dilated cardiomyopathy revealing oncocytic adrenocortical adenoma induced ACTH-independent Cushing's syndrome in a young adult harbouring an ARMC5 variant

Fatma Alshamsi, Budoor Alemadi, Elamin Abdelgadir and Fatheya Alawadi
Dubai Hospital, Dubai, United Arab Emirates

Background: ACTH-independent Cushing's syndrome (CS) due to adrenocortical adenomas is uncommon, and acute cardiomyopathy is a rare initial manifestation. Excess cortisol impairs myocardial contractility and metabolism. Pediatric-onset CS guidelines recommend genetic testing directed at the source of hypercortisolemia, and genomic testing is advised for patients with bilateral adrenal masses and ACTH-independent cortisol excess. Guidelines for young adults with unilateral adenomas is limited.

Case Presentation: A 22-year-old man presented with progressive obesity, uncontrolled type 2 diabetes mellitus requiring insulin, and hypertension, culminating in acute heart failure. Echocardiography demonstrated severe left ventricular dysfunction with an ejection fraction of 25%. Causes of non-ischemic cardiomyopathy were excluded. Cushingoid features prompted endocrine evaluation, confirming ACTH-independent hypercortisolemia. Laboratory results included: 24-hour urinary free cortisol >570 µg/24 h (11.5–102), AM cortisol 614 nmol/L; repeat 24-hour urinary free cortisol 262 µg/24 h; salivary cortisol 6.37 µg/L (late evening <1.1 µg/L); ACTH <1.5 pg/mL; AM cortisol 579 nmol/L; DHEAS 5.48 µmol/L; subsequent 24-hour urinary free cortisol 324 µg/24 h; and salivary cortisol 7.08 µg/L.

CT imaging demonstrated a benign-appearing right adrenal mass with wedge compression fractures of the D10–D12 vertebral bodies. Bone densitometry confirmed osteoporosis. Given the patient's young age and a brother with obesity, poorly controlled diabetes, and erectile dysfunction in his twenties, germline genetic testing was performed, identifying a heterozygous ARMC5 variant of uncertain significance, previously associated with ACTH-independent macronodular adrenal hyperplasia.

The patient underwent right adrenalectomy. Gross examination revealed a $5.0 \times 4.0 \times 4.0$ cm well-circumscribed nodular adrenal mass with a well-defined capsule. Histopathology confirmed a benign oncocytic adrenocortical adenoma. Postoperatively, serum cortisol normalized, insulin therapy was discontinued following improved glycemic control, and left ventricular function improved to an ejection fraction of 47%.

Discussion: Severe, reversible cardiomyopathy may be the presenting feature of ACTH-independent CS. Current guidelines recommend genetic testing in pediatric-onset disease and bilateral adrenal pathology; however, this case suggests that young adults with unilateral adenomas may also harbor clinically relevant genetic variants. Identification of germline mutations is essential for individualized management, genetic counselling, and family screening. Early recognition and surgical intervention can allow cardiac recovery.

Conclusions: This abstract reports a case of severe decompensated cardiomyopathy due to genetically mediated ACTH-independent Cushing's syndrome in a 22-year-old man and describes an ARMC5 variant associated with a unilateral oncocytic adrenal

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

adenoma. Genetic testing beyond current guidelines may be warranted in young patients with ACTH-independent hypercortisolism. Timely adrenalectomy can reverse cardiovascular and metabolic complications.

EP75 - ECE_2199 - Incidental adrenal angiomyolipoma revealing primary hyperaldosteronism

Hamza El Fekih[1], Eya Zorai[2], Wiem Saafi[2], Sawsen Nouira[2], Ayoub Gasmi[3], Imen Halloul[2], Ach Taieb[1], Ghada Saad[2] and Yosra Hasni[2]

[1]Faculty of Medicine of Sousse, Department of Endocrinology and Diabetology/ Laboratory of Exercise Physiology and Pathophysiology (LR19ES09), Farhat Hached University Hospital, University of Sousse, Sousse, Tunisia; [2]Department of Endocrinology and Diabetology, Farhat Hached University Hospital, Sousse, Tunisia; [3]Department of Radiology, Farhat Hached University Hospital, Sousse, Tunisia

Introduction: Angiomyolipoma is an extremely rare mesenchymal tumor without malignant characteristics composed, in varying proportions, of blood vessels, smooth muscle cells, and adipocytes. It usually affects the kidney. Extra-renal angiomyolipoma is rarein clinical practice, particularly in the adrenal gland-which limits our understanding of the disease.We herein report the case of a patient with an incidentally discovered adrenal angiomyolipoma, who was diagnosed with primary hyperaldosteronism during the diagnostic workup.

Case Presentation: A 58-year-old woman, with grade I arterial hypertension, had an abdominal ultrasoundfor diffuse abdominal pain which revealed a right adrenal mass of 4 cm, with a heterogeneous and hypoechoic appearance. The patient had manysuggestive clinical features of essential hypertension: family history of hypertension, her age, class II obesity, no target organ damage, nor clinical signs suggestive of hormonal hypersecretion. Serum potassiumlevels were normal. Computed tomography scan confirmed the presence of a right adrenal incidentaloma measuring 50 × 32 mm, with radiological features suggesting an angiomyolipoma. Hormonal assessmentwas systematically done confirming primary hyperaldosteronism, with elevated plasma aldosterone levels (561 pmol/L) and aldosterone-to-renin ratio.

Discussion: Adrenal angiomyolipoma is a rare benign tumor, commonly discovered incidentally during radiological investigations. Although usually considered non-functioning, hormonal hypersecretion may be foundin a few cases of patients with adrenal angiomyolipoma. This association should alert clinicians to the possibility of a potentially curable cause of secondary hypertension requiring specific treatment.

EP76 - ECE_2610 - Adult-onset X-linked adrenoleukodystrophy with ABCD1 gene mutation

Zehra Irshad and Pratibha Natesh

Coventry, United Kingdom

X-linked adrenoleukodystrophy (X-ALD) is a progressive neurodegenerative disorder associated with mutation of ABCD1 gene encoded protein adrenoleukodystrophy protein (ALDP). This results in accumulation of very long chain fatty acids which damages the myelin sheath in the brain, spinal cord and adrenal glands causing adrenal insufficiency and neurology. Here we describe a case of delayed diagnosis of adult-onset X-ALD.

A 50-year-old gentleman was referred to Neurology with progressive poor mobility and spasticity which started in his 20s. He had a strong family history of neurological conditions. His mother was diagnosed with late-onset peripheral neuropathy and his maternal uncle passed away in early 30s with poor mobility. He was diagosed as Hereditary spastic paraparesis and was managed with Baclofen and physiotherapy under Neurology. However, his symptoms continued to progress and further investigations (EMG, nerve conduction studies, MRI head and spine and ERG) did not show any supportive findings. He was sent for further gene analysis which identified mutation in ABCD1 and was hence referred to Endocrine to review adrenal involvement. He denied symptoms of fatigue, dizziness, weight-loss, headaches, palpitation or sweating. His observations showed blood pressure of 158/81 and BMI of 30. There was absence of stigmata of adrenal disease. His 9am biochemical profile showed elevated plasma ACTH (435 ng/L ref <30 ng/L) with normal sodium, potassium, serum aldosterone, plasma renin and cortisol (357 nmol/L; ref 145-619). His plasma metnephrines and normetnephrines were also within normal range. He was referred for urgent short synacten test which confirmed adrenal insufficiency and hence he was started on hydrocortisone.

X-ALD manifests as adrenal insufficieny in 90% of the patients independently of the neurological affection which affects 50% of the males.[1] Diagnosis is usually confirmed with gene analysis. Treatment requires multidiscliplinary involvement for symptoms management. Our case highlights the importance of early gene analysis in patients with strong family history of neurodegeneration to support early diagnosis and management in absence of overt adrenal symptoms.

EP77 - ECE_2193 - An insidious case of food-dependent Cushing's syndrome associated with a germline KDM1A variant in Bilateral Macronodular Adrenal Disease (BMAD)

Dorota Leszczynska[1], Julia Latocha[2], Alicja Duquenne[2,3,4], Beata Woźniak[3], Wojciech Zgliczyński[3] and Piotr Glinicki[3,4]

[1]Centre of Postgraduate Medical Education, Endocrinology, Warsaw, Poland; [2]Centre of Postgraduate Medical Education, Student Scientific Group at the Department of Endocrinology, Warsaw, Poland; [3]Centre of Postgraduate Medical Education, Department of Endocrinology, Warsaw, Poland; [4]Centre of Postgraduate Medical Education, EndoLab Laboratory, Warsaw, Poland

Background: Bilateral Macronodular Adrenal Disease (BMAD) is characterized by the presence of benign bilateral adrenal lesions larger than 10 mm and by variable degrees of cortisol overproduction. It may account for up to 30% of cases of bilateral

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

adrenal incidentalomas. Cortisol secretion in BMAD is regulated by aberrantly expressed adrenal receptors.

Case Presentation: A 44-year-old woman was referred to a tertiary endocrine center because of incidentally detected bilateral adrenal nodules. The patient reported unintentional weight gain of 4 kg over six months and sleep disturbances. Physical examination revealed central obesity and easy bruising, and her medical history was notable for well-controlled hypertension on monotherapy. Laboratory evaluation revealed low morning serum cortisol (4.8 µg/dL) with suppressed plasma ACTH levels, loss of circadian cortisol rhythm, lack of cortisol suppression in the 1 mg overnight dexamethasone suppression test and elevated 24-hour urinary free cortisol excretion.

Computed tomography demonstrated bilateral macronodular adrenal hyperplasia with a dominant lesion in the right adrenal gland. Magnetic resonance imaging revealed signal drop on out-of-phase sequences in all adrenal lesions, consistent with lipid-rich nodules.

Receptor stimulation testing was performed with cortisol and ACTH measurements at baseline and at 60 and 120 minutes. The diagnostic work-up included supine-to-upright posture testing, stimulation with octreotide, metoclopramide, desmopressin, gonadotropin-releasing hormone (GnRH), tetracosactide (ACTH 1–24), oral glucose tolerance test, and a mixed meal. A greater than 50% increase in serum cortisol following the mixed meal, oral glucose tolerance test, and GnRH stimulation was interpreted as a positive response, suggesting gastric inhibitory polypeptide (GIP)- and GnRH-dependent hypercortisolaemia.

Molecular testing identified a heterozygous *KDM1A* variant (c.982G>A; p.Glu328Lys, exon 7), classified as potentially pathogenic. The patient's family history was notable for her mother, who had bilateral adrenal lesions and underwent bilateral adrenalectomy because of ACTH-independent hypercortisolaemia. The patient's only daughter was tested negative for the *KDM1A* variant.

Conclusions: The presented case underlines the necessity of including bilateral macronodular adrenal disease (BMAD) in the differential diagnosis of bilateral adrenal incidentalomas. The mild and insidious clinical course of hypercortisolaemia in most patients may lead to delayed diagnosis. Germline KDM1A variants are the most prevalent genetic cause of BMAD associated with food-dependent Cushing's syndrome (FDCS). Loss of KDM1A, a tumour suppressor gene, results in aberrant adrenal GIP receptor expression and postprandial stimulation of cortisol secretion. Identification of FDCS should prompt biochemical and genetic screening of relatives.

Abstract citation ID: lvag096.684

EP78 - ECE_2622 - Baseline cortisol as a predictor of adrenal insufficiency and the value of the 60-minute post-synacthen cortisol

Simon Mifsud[1], Jacob Cassar[2] and Charlton Agius[2]
[1]*Department of Diabetes and Endocrinology, Mater Dei Hospital, Msida, Malta;* [2]*Department of Pathology, Clinical Chemistry Section, Mater Dei Hospital, Msida, Malta*

Introduction: The short synacthen test (SST) evaluates the integrity of the hypothalamic-pituitary-adrenal axis. The study aimed to evaluate (1) the diagnostic performance of morning baseline serum cortisol for adrenal insufficiency (AI) and (2) the agreement between the 30- and 60-minute cortisol measurements.

Method: Adult SSTs performed using the Siemens IMMULITE® 2000 cortisol immunoassay between January 2024 and August 2025 were retrospectively analyzed. AI was defined as peak cortisol <500 nmol/L.

Results: The cohort included 282 adults (mean age 50.6 years [SD 16.5]) with a female predominance (59.2%). AI was diagnosed in 45 patients (16.0%).

Patients with AI had a significantly lower baseline cortisol compared to those with adrenal sufficiency (median 192 nmol/L [IQR:144.5–249.5] vs 255 nmol/L [IQR:198–331], $P < .001$). Baseline cortisol demonstrated moderate discrimination for AI (AUC 0.728, 95% CI 0.653–0.803). A baseline cortisol threshold ≤124 nmol/L achieved 95.4% specificity (sensitivity 22.2%) for AI, whereas a threshold >291 nmol/L excluded AI with 95.6% sensitivity (specificity 36.7%). In this cohort, baseline cortisol thresholds of ≤89.5 nmol/L and >376.5 nmol/L provided 100% specificity and 100% sensitivity, respectively.

Median cortisol increased from 241.5 nmol/L (IQR:180.5–309) at 0-minutes to 528.5 nmol/L (IQR:464-590) at 30-minutes and 605.5 nmol/L (IQR:541-683.3) at 60-minutes post-synacthen. Wilcoxon signed-rank tests confirmed statistically significant increases for all pairwise comparisons (0 vs 30 min: $Z = -14.492$; 30 vs 60 min: $Z = -14.180$; 0 vs 60 min: $Z = -14.473$, all $P < .001$; Bonferroni-adjusted $\alpha = 0.0167$). The largest increase occurs between 0 vs 30 minutes, but the 30 vs 60 minutes also shows a significant rise, capturing late responders.

When examining consistency across the 30- and 60-minute intervals within our cohort, 168 patients passed at both time intervals, 68 passed at 60-minutes only, and 1 passed at 30-minutes only ($\kappa = 0.435$, $P < .001$). These findings indicate moderate agreement between the 30- and 60-minute classifications.

McNemar's test demonstrated significant asymmetry ($P < .001$), with substantially more individuals passing the SST at 60-minutes but failing at 30-minutes than the reverse. Reliance on the 30-minute cortisol alone would have misclassified 28.6% ($n = 68/237$) as adrenal insufficient despite passing at 60-minutes.

Conclusions: Morning baseline cortisol was associated with SST outcome and demonstrated moderate discrimination for AI in our cohort. In addition, cortisol continued to increase significantly between 30 and 60-minutes post-synacthen. This supports inclusion of the 60-minute cortisol measurement to identify late-responders and reduce false-positive diagnoses of AI compared with relying solely on the 30-minute cut-off.

[4]Department of Clinical Biochemistry, Jagiellonian University Medical College, Institute of Paediatrics, Cracow, Poland

Introduction: Mild autonomous cortisol secretion (MACS) represents the most common hormonal abnormality in patients with adrenal incidentalomas. The 1 mg dexamethasone suppression test (DST), using a cortisol cutoff value of 1.8 µg/dL, is currently recommended to exclude hypercortisolism. However, growing evidence suggests that adrenal tumors classified as non-functioning may still secrete low amounts of cortisol that remain below the established cutoff yet contribute to an increased cardiometabolic risk. This observation raises concerns that the currently accepted cutoff value may underestimate clinically relevant cortisol excess.

Objectives: The aim of this study was to reassess the cortisol cutoff value in the 1 mg DST for identifying increased cardiometabolic risk in patients with adrenal incidentalomas.

Methods: This retrospective, cross-sectional observational study included patients with adrenal incidentalomas treated at a tertiary endocrinology center between 2017 and 2020. Of 1077 initially screened patients, 807 met the inclusion criteria based on complete hormonal evaluation, adrenal CT imaging, and histopathological confirmation in surgically treated cases. All patients underwent a 1 mg DST. Receiver operating characteristic (ROC) curve analysis and area under the curve (AUC) calculations were used to evaluate the ability of post-DST cortisol concentrations to predict cardiometabolic diseases. Multivariable logistic regression models adjusted for age, sex, obesity, and smoking status were applied.

Results: Post-DST cortisol concentrations were significantly higher in patients with hypertension, coronary heart disease (CHD), chronic heart failure (CHF), diabetes mellitus, chronic obstructive pulmonary disease (COPD), and chronic kidney disease (CKD) compared with patients without these conditions. In multivariable analyses, cortisol thresholds lower than the conventional 1.8 µg/dL were significantly associated with increased disease risk: 1.46 µg/dL for CHD, 1.64 µg/dL for CHF, 1.20 µg/dL for diabetes mellitus, and 1.37 µg/dL for CKD. A common cortisol threshold of 1.35 µg/dL was identified, above which the risk of CHD, diabetes mellitus, and CHF increased significantly.

Conclusions: The findings of this study suggest that the currently recommended DST cutoff value of 1.8 µg/dL may fail to detect clinically relevant cortisol excess in patients with adrenal incidentalomas. Lower cortisol thresholds may better identify individuals at increased cardiometabolic risk and could improve clinical risk stratification and management.

EP80 - ECE_2865 - Circadian profiling of steroid hormones and metabolites in dried blood spots (DBS) by Liquid Chromatography-Mass Spectrometry (LC-MS/MS): a pilot study

Greta Galante[1,2], Mathieu Galmiche[2,3], Valentina Bissi[1], Federico Mao[1,4], Gianmarco Pizza[1,4], Alessia Gennai[1], Laura Tribotti[1,4], Francesca Donnarumma[1,4], Guido Di Dalmazi[1,4], Uberto Pagotto[1,4], Serge Rudaz[2,3] and Flaminia Fanelli[1]

[1]Center for Applied Biomedical Research, CRBA, University of Bologna, Bologna, Italy; [2]School of Pharmaceutical Sciences, University of Geneva, CMU- Rue Michel-Servet 1, Geneva, Switzerland; [3]Institute of Pharmaceutical Sciences of Western Switzerland, University of Geneva, CMU - Rue Michel-Servet 1, Geneva, Switzerland; [4]Division of Endocrinology and Diabetes Prevention and Care, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy

Introduction: Altered steroid hormone levels have been reported in a wide range of endocrine and non-endocrine disorders. However, the investigation of perturbation of circadian steroid secretion remains challenging, mainly due to the need for frequent blood sampling and highly sensitive analytical methods. DBS from finger-prick allows autonEomous and non-invasive home sampling. In parallel, recent advances in LC-MS/MS provides high sensitivity for measurements of small blood volumes, while quantitation based on internal calibration enhances throughput and ensures accuracy.

Aim: To assess the feasibility of DBS sampling combined with LC-MS/MS and internal calibration quantitation as a tool to investigate steroid circadian fluctuation.

Methods: DBS were collected from 6 healthy subjects (3 males, 3 females) at nine time points of an ordinary day (07:00, 08:30, 10:00, 12:30, 14:00, 16:00, 19:30, 21:00 and 23:00). After the addition of isotopically labelled internal calibrants, cortisol, cortisone, 11-deoxycortisol, 11-deoxycorticosterone, 17OH-progesterone, androstenedione and testosterone were quantified by LC-MS/MS from extracts of two 6 mm DBS punches. Data were reported in ng/mL and analysed by non-parametric tests. The analytical method also included a relative quantitation of a broad panel of steroids and related metabolites. For the latter, normalized peak areas were used for exploratory analyses to evaluate global temporal metabolic patterns.

Results: Cortisol, cortisone, and 11-deoxycortisol showed the expected circadian fluctuation (all $P < .001$), with higher levels in the morning and a progressive decline throughout the day. When spit by sex, these trends remained significant within both males and females (cortisol $P < .001$ and 0.037; cortisone $P < .001$ and .005; 11-deoxycortisol $P = .006$ and .003 respectively). 17OH-progesterone ($P < .001$), androstenedione ($P < .001$) and testosterone ($P = .014$) showed a circadian modulation in males but not in females. 11-deoxycorticosterone and progesterone showed no fluctuations either in males or females. Exploratory analyses showed that several glucocorticoid metabolites (20α- and 20β-dihydrocortisol, 5β-dihydrocortisol, 18-hydroxycortisol, and 11-dihydrocorticosterone) followed the same circadian pattern as their parent compound cortisol, displaying a significant decrease from morning to evening (all $P < .005$). In contrast, androgen-related metabolites, including androstenediol ($P = .027$), androsterone-3α-glucuronide ($P = .003$), and 11β-hydroxyetiocholanolone ($P = .023$), showed increasing trends over the day.

Conclusions: These preliminary findings in a small control group demonstrate the feasibility of using DBS combined with internal calibration LC-MS/MS quantitation to explore circadian steroid patterns, paving the way for future studies in larger cohorts and diverse physiological states.

EP82 - ECE_2910 - Clinical characteristics, diagnosis, and treatment of Cushing's syndrome: analysis of a multicenter registry in Antioquia, Colombia

Alejandro Roman-Gonzalez[1], Wilfredo Rivera[1], Maria Ramirez[1], Stefania Cruz[2], Nestor Diaz[2], Johnayro Gutierrez Restrepo[1,3], Natalia Aristizabal[2,4], Pablo Castano[3], Catalina Tobon[3], Nestor Lopez[3], Jorge Donado[5] and Carlos Builes Montaño[1,5]
[1]*Endocrinology, Universidad de Antioquia, Medellín, Colombia;* [2]*Universidad Pontificia Bolivariana, Medellín, Colombia;* [3]*Clinica Somer, Rionegro, Colombia;* [4]*Clínica Las Américas Auna, Medellin, Colombia;* [5]*Hospital Pablo Tobón Uribe, Medellín, Colombia*

Introduction: Cushing's syndrome (CS) is an endocrine disorder characterized by chronic hypercortisolism, leading to multiple comorbidities and complications. This research sought to characterize the clinical, diagnostic, and therapeutic features of patients with CS and to assess the results of surgery for Cushing's disease according to the surgical team's expertise at six medical centers in the department of Antioquia, Colombia, between 2010 and 2024.

Methods: We conducted a retrospective observational study through a review of electronic medical records. Demographic, clinical, diagnostic test data, treatment modalities, and postoperative outcomes were gathered.

Results: A total of 130 patients with CS were included; 86.9% were women, with a mean age of 50.7 years (SD: 15.04). The most common clinical presentation was weight gain (79.2%). The most frequent etiology was Cushing's disease (74.6%), then adrenal CS (16.9%) and ectopic CS (1.5%). Hypertension (66.2%) and obesity (61.5%) were the most prevalent comorbidities. Urinary free cortisol and the low-dose dexamethasone suppression test had the highest proportion of positive results at diagnosis. Transsphenoidal resection was the most commonly used treatment for pituitary disease (81.4%). The overall postoperative remission rate was 63.3%, with no significant differences according to neurosurgical expertise (68.2% with expert surgeons vs. 59.1% with others). Similarly, no differences were observed in recurrence, persistence, or postoperative complication rates.

Conclusions: This study emphasizes the diversity in symptoms, diagnosis, and therapy for CS, with a high prevalence of comorbidities and a considerable rate of postoperative recurrence. Using both use of late-night salivary cortisol and low-dose dexamethasone suppression testing may improve diagnostic accuracy in Colombia. Surgical outcomes for Cushing's disease in Antioquia are comparable to those reported by specialized pituitary centers worldwide.

EP84 - ECE_3411 - Can the monocyte-to-HDL cholesterol ratio predict cardiovascular risk in patients with primary aldosteronism?

Gökhan Rıza Baykal[1], Muzaffer Serdar Deniz[1], Şefika Burçak Polat[2], Samet Senel[3], Abbas Ali Tam[2], Oya Topaloglu[2], Reyhan Ersoy[2] and Bekir Cakir[2]
[1]*Department of Endocrinology and Metabolism, Ankara Bilkent City Hospital, Ankara, Türkiye;* [2]*Department of Endocrinology and Metabolism, Endocrinology and Metabolism, Ankara Yıldırım Beyazıt University Faculty of Medicine, Ankara Bilkent City Hospital, Ankara, Türkiye;* [3]*Department of Urology, Ankara Bilkent City Hospital, Ankara, Türkiye*

Background: Primary aldosteronism (PA) is associated with a disproportionately high cardiovascular (CV) risk. The monocyte-to-HDL cholesterol ratio (MHR) is an emerging inflammatory marker, but its role in PA is unclear. We aimed to evaluate the relationship between MHR and estimated 10-year CV risk and to explore differences across PA subtypes.

Methods: In this single-centre retrospective study, we included 56 patients with biochemically and radiologically confirmed PA (mean age 53.5 ± 7.6 years, 66% women). Demographic and clinical data, blood pressure, lipid profile, and full blood count were retrieved from medical records. MHR was calculated as monocyte count ($\times 10^9$/L) divided by HDL-cholesterol (mg/dL). Neutrophil-to-lymphocyte ratio (NLR) and systemic immune-inflammation index (SII) were derived from the same blood tests. Ten-year CV risk was estimated using SCORE2 according to ESC recommendations. Correlations between MHR, inflammatory indices and SCORE2 were assessed, and MHR was compared between unilateral and bilateral PA.

Results: Median MHR was 8.29 (IQR 5.95–10.29). Mean SCORE2 was 5.87 ± 3.84%, and 34% of patients had SCORE2 ≥7.5%. MHR correlated positively with SCORE2 (Spearman $\rho = 0.48$, $P = .0002$) and increased stepwise across MHR tertiles, paralleled by higher SCORE2 values (median 2.6%, 5.2% and 7.6% in the lowest, middle and highest tertiles; P for trend = 0.00013). MHR also correlated with NLR ($\rho = 0.38$, $P = .0035$) and SII ($\rho = 0.43$, $P = .0009$). Patients with bilateral PA had higher MHR than those with unilateral disease (9.97 ± 3.92 vs 7.48 ± 2.54; $P = .031$).

Conclusions: In patients with PA, higher MHR is associated with greater estimated 10-year CV risk and higher inflammatory burden and is more pronounced in bilateral disease. MHR may represent a simple, inexpensive adjunct marker for CV risk stratification in PA, warranting confirmation in larger, prospective cohorts.

EP85 - ECE_2015 - Hair cortisol in dogs with congenital portosystemic shunts: a potential marker of chronic stress

Joelle Leiwy[1], Emily Stacey[1], Alex Chan[2], Victoria Lipscomb[3], Rhiannon Strickland[3], Michael Tivers[4] and Rob Fowkes[5]
[1]*Comparative Biomedical Sciences, Royal Veterinary College, University of London, London, United Kingdom;* [2]*Bristol Vet Specialists, Bristol, United Kingdom;* [3]*Clinical Sciences & Services, Royal Veterinary College, University of London, Hatfield, United Kingdom;* [4]*Paragon Veterinary Referrals, Wakefield, United Kingdom;* [5]*Small Animal Clinical Sciences, Michigan State University College of Veterinary Medicine, East Lansing, United States*

Congenital portosystemic shunts (cPSS) are vascular abnormalities that affect the development and function of the liver. In companion animals, cPSS are serious disorders that can present as a failure to thrive, metabolic abnormalities, neuronal complications and in severe cases, coma and death. Associated conditions such as hyperammonaemia and hepatic encephalopathy present increased morbidity in affected animals, as well as

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

causing deleterious quality of life issues. In this study, we examined the use of hair cortisol concentrations (HCC) as a potential marker of chronic stress and hypercortisolism in dogs with cPSS. Hair samples were collected from a cohort ($n = 75$) of dogs with cPSS recruited from two referral hospitals for attenuation surgery to treat either intrahepatic (IHPSS) or extrahepatic (EHPSS) shunts, along with samples from 15 healthy dogs. HCC in affected dogs was significantly higher than those without hepatic disease, regardless of shunt origin (0.730 ± 0.12 μg/dL in cPSS dogs vs 0.16 ± 0.02 μg/dL in healthy dogs, $P < .001$). However, in dogs that required a second attenuation surgery, HCC was not significantly altered following their initial attenuation surgery. Furthermore, HCC did not correlate with serum bile acid ($P = .9$) and ammonia ($P = .93$) concentrations for dogs where these parameters were available. Hair colour did not significantly affect HCC. These data indicate that dogs with cPSS exhibit hypercortisolism which could indicate chronic stress, as determined by elevated HCC. HCC has potential in future cPSS studies in assessing severity and outcome as a minimally-invasive Quality of Life indicator.

EP86 - ECE_2180 - 11-Oxygenated androgens and endocrine disruptors in women with Polycystic ovary syndrome or Idiopathic hirsutism

Anežka Varausová[1], Jana Vitku[1], Tereza Skodova[1], Lucie Kolatorova[1], Michala Vosátková[2], Josef Vcelak[3], Jana Vrbikova[4], Markéta Šimková[1] and Michaela Svojtková[1]
[1]*Department of Steroids and Proteofactors, Institute of Endocrinology, Prague, Czech Republic;* [2]*Department of Clinical Biochemistry, Institute of Endocrinology, Prague, Czech Republic;* [3]*Prague, Czech Republic;* [4]*Department of Clinical Endocrinology, Institute of Endocrinology, Prague, Czech Republic*

Introduction: Polycystic ovary syndrome (PCOS) and idiopathic hirsutism (IH) represent androgen excess disorders traditionally diagnosed using conventional androgen measurements. The contribution of 11-oxygenated androgens and endocrine disruptors (EDs) to these conditions remains incompletely defined.

Aim: This study investigates the role of less common steroid hormones, endocrine disruptors, and cytokines in polycystic ovary syndrome and idiopathic hirsutism to provide a comprehensive understanding of their pathophysiology.

Methods: 25 steroid hormones and 18 EDs were measured by using liquid chromatography–tandem mass spectrometry, biochemical markers were analyzed using routine methods on a Cobas® 6000 analyzer and 27 cytokines were determined with a Bio-Plex Pro™ Human Cytokine 27-plex assay kit Comparisons included non-obese women with PCOS ($n = 10$), women with IH ($n = 12$) and controls ($n = 20$), and non-obese PCOS women were compared to obese women with PCOS ($n = 9$).

Results: Levels of 11-oxygenated androgens were higher in women with PCOS compared with women with IH, with no statistically significant difference compared to controls. Women with IH exhibited lower 11-oxygenated androgen levels compared with controls. Cytokine concentrations did not differ between women with IH and controls. BPA levels were higher in obese women with PCOS than in non-obese women with PCOS. Bisphenol S was detected more frequently in women with PCOS (90%) than in controls (65%) and women with IH (50%). Significant correlations were observed between 11-ketotestosterone, androstenedione, and testosterone and insulin levels and HOMA-IR, and between immunomodulatory 7-oxygenated DHEA metabolites and nine interleukins. Our data confirms that PCOS is a multiendocrine gland disorder. Higher BPA levels in obese women with PCOS might exacerbate metabolic abnormalities. IH was not associated with inflammatory markers or altered ED levels, however it was associated with decreased 11-oxygenated androgens.

Conclusions: 7-oxygenated DHEA metabolites were associated with inflammatory cytokines, supporting their immunomodulatory role, while androgens correlated with insulin resistance and metabolic parameters, indicating a link between androgen excess and metabolic dysfunction. PCOS was confirmed as a complex disorder involving both ovarian and adrenal steroidogenesis, with a prominent contribution of 11-oxygenated androgens, low-grade inflammation driven mainly by obesity, and a potential aggravating role of BPA in obese women. In contrast, idiopathic hirsutism differed in the profile of androgens of adrenal origin without evidence of systemic inflammation or BPA involvement, suggesting differing pathophysiological mechanisms from PCOS.

EP87 - ECE_1759 - Primary adrenal insufficiency and subclinical hypothyroidism induced by immune checkpoint inhibitors: a rare endocrine immune-related adverse event

Roxana Novac
CLINICA DR. NOVAC, Bacau, Romania

Background: Immune checkpoint inhibitors (ICIs), including CTLA-4 monoclonal antibodies, are increasingly used in oncology and are associated with immune-related endocrine adverse events. While hypophysitis with secondary adrenal and thyroid insufficiency is relatively common, primary adrenal insufficiency remains extremely rare, with only isolated cases reported in the literature.

Case Presentation: We report the case of a 58-year-old male diagnosed with right renal cell carcinoma, treated with an immune checkpoint inhibitor in combination with a CTLA-4 monoclonal antibody. After approximately 8 months of therapy, the patient developed progressive asthenia and recurrent episodes of hypotension, leading to multiple emergency department admissions. Despite repeated evaluations, no definitive diagnosis was established until August 2025, when the patient was referred to the endocrinology department.

Endocrine assessment revealed primary adrenal insufficiency, confirmed by low cortisol levels with elevated ACTH (>1300 pg/mL), and subclinical hypothyroidism, characterized by elevated TSH (8,6 uUI/mL n.v. 0,4-4,2) with normal free thyroxine levels. No clinical or biochemical evidence of hypopituitarism was identified. Adrenal imaging excluded metastatic involvement. Hormone replacement therapy resulted in significant clinical improvement.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Discussion: Primary adrenal failure induced by ICIs is exceptionally rare, particularly in contrast to secondary adrenal insufficiency due to hypophysitis. The coexistence of primary adrenal insufficiency with hypothyroidism is noteworthy, as immune checkpoint–related endocrine toxicity typically involves pituitary dysfunction leading to combined secondary adrenal and thyroid deficiencies. This case highlights an unusual pattern of endocrine immune-related adverse events and emphasizes the importance of early endocrine referral in patients receiving ICIs with nonspecific symptoms such as fatigue and hypotension.

Conclusions: This case underscores the need for increased awareness of rare endocrine immune-related adverse events associated with immune checkpoint inhibitors. Early recognition and prompt endocrine evaluation are essential to prevent diagnostic delay and potentially life-threatening complications.

EP88 - ECE_3576 - Not everything is as it seems—drug-induced endocrinopathy?

Jana Lešková[1,2], Helena Urbankova[1,2], Juliana Gregova[1,2], Martin Straka[1,2] and Peter Vanuga[1,2]
[1]*National Institute of Endocrinology and Diabetology, L'ubochňa, Slovakia;* [2]*5th Department of Internal Medicine, Faculty of Medicine, Clinical Research Unit in Endocrinology and Osteology, Comenius University and University Hospital, Bratislava, Slovakia*

Case Report: A 72-year-old female patient is followed up at an endocrinology outpatient clinic for autoimmune thyroiditis in the stage of hypothyroidism on thyroxine replacement therapy. Her past medical history: recurrent breast carcinoma (surgery in 2006 and 2021; treated with an aromatase inhibitor therapy, currently in remission), seronegative rheumatoid arthritis, osteopenia, sick sinus syndrome (bradycardia–tachycardia syndrome) with a pacemaker implanted, paroxysmal atrial fibrillation (AF) on oral anticoagulation, arterial hypertension (antihypertensive therapy affecting the renin–angiotensin–aldosterone system—RAAS), and chronic heart failure (eplerenone therapy).

The patient was newly diagnosed with diffuse large B-cell Non-Hodgkin lymphoma and received immunochemotherapy due to incomplete remission of the disease. She presents for endocrinological examination after the 9th administration of a monoclonal antibody. She complains of weakness, fatigue, dyspnoea, tremor, hair loss, weight loss, frequent stools, memory impairment and darkening of the skin, which she reports over the last month. Based on the clinical picture, Addison's disease was strongly suspected.

Hypocorticism was not confirmed after evaluation of laboratory parameters (renin > 500 mIU/L, aldosterone: 2.77 nmol/L, ACTH: 20.1 pg/mL, cortisol: 754.5 nmol/L, TSH: 28.1 mIU/L, fT4: 14.0 pmol/L, K+: 2.87 mmol/L, Na+: 135.0 mmol/L, Cl-: 96 mmol/L, WBC: 3.11 × 10^9/l).

Differential diagnosis of hyperpigmentation with a high renin level and mineral imbalance:

- Hyperpigmentation within a paraneoplastic syndrome (increased melanotropin or fragments of proopiomelanocortin)
- Loncastuximab tesirine, as a monoclonal antibody, contains a pyrrolobenzodiazepine cytotoxic payload, which causes DNA damage not only in tumour cells but may also affect healthy skin, which may lead to increased melanin production
- Secondary hyperaldosteronism in congestive heart failure
- Adverse effects of drugs affecting RAAS

Conclusions: The coexistence of malignancies and their targeted therapies in the patient complicated the assessment of the hypothalamic–pituitary–adrenal axis. We concluded that the patient's clinical picture and laboratory findings were most likely attributable to adverse drug effects (eplerenone, ACE inhibitor, diuretic, and the monoclonal antibody loncastuximab tesirine) and/or within a paraneoplastic syndrome.

EP89 - ECE_2606 - A rare endocrine duo: concurrent pheochromocytoma and hyperparathyroidism in neurofibromatosis-1

Shebina Liz Mathews, Muhammad Akhtar, David Lopez-Lazaro and Cornelius Fernandez
Diabetes and Endocrinology, Pilgrim Hospital, Boston (United Lincolnshire Hospitals NHS Trust), Boston, United Kingdom

Introduction: We present a young woman with Neurofibromatosis-1 (NF1) with incidentally detected bilateral pheochromocytomas (PCCs) and primary hyperparathyroidism (PHPT) following evaluation for flank pain.

Case Presentation: A 47-year-old woman presented with left flank pain, found to have a right adrenal mass. Dedicated adrenal CT revealed a large heterogeneous right adrenal mass 7.6 × 6.9 × 5.6cm with irregular necrotic areas and pre-contrast density of 50HU, suspicious for an aggressive lesion. An indeterminate left adrenal 1 cm nodule was also noted. Compared to the CT aortogram done 6 years ago, which showed bilateral adrenal nodules, though overlooked, the right adrenal lesion had grown. In retrospect, she reported occasional palpitations and headache, but remained normotensive.

Plasma Metanephrines 16 746 (0-509), Normetanephrines 10 553 (0-1179) and 3-Methoxytyramine <60 (0-179) in pmol/L. Calcium was elevated at 3.12 mmol/L with PTH of 17.9 (1.6-6.9 pmol/L), suggestive of PHPT with asymptomatic moderate hypercalcemia, for which Cinacalcet was initiated.

Further to the discussion in Adrenal MDT, MIBG confirmed bilateral PCCs. Although USS Neck wasn't contributory, SESTAMIBI revealed a left inferior parathyroid adenoma. A syndromic association was considered, and genetic test results are awaited, with ongoing input from the adrenal MDT.

Discussion: Given the patient's young age and concurrence of two endocrine neoplasia, it is important to think of genetic syndromes. Hereditary PCC may be associated with VHL, MEN2A or NF1. While MEN2A could explain this concurrence, MTC (70-100% by 70 years) was not present in this patient. Incidence of PCC and PHPT in MEN2A is ≤50% and ≤30%, respectively.

Nearly 1-5% of NF1 patients can develop PCCs; however, they are usually solitary, benign, rarely bilateral, and often asymptomatic or present atypically. This is due to a "two-hit mutation" leading to somatic loss of the second NF1 allele in adrenal chromaffin cells.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

It is also possible that there may be no syndromic association between the two endocrine neoplasia. However, given bilateral PCCs, genetic association is highly likely.

Conclusions: Genetic testing is paramount here to guide further management, especially surveillance for associated tumours. In asymptomatic patients with NF1, there are no guidelines that mandate screening for PCC; however, missing a diagnosis of PCC may lead to untoward outcomes. Keeping a high index of suspicion is crucial, screening ideally all patients with NF1.

EP91 - ECE_1558 - Adrenocortical response during HUT test in patients with vasovagal syncope

Barbora Pavlovič Bačkorová[1], Zora Lazúrová[2], Peter Mitro[3] and Ivica Lazúrová[1]

[1]Department of Internal Medicine 1, Medical Faculty P.J. Šafárik University, Košice, Slovakia; [2]4th Department of Internal Medicine, Medical Faculty P.J. Šafárik University, Košice, Slovakia; [3]Department of Cardiology 1, Medical Faculty P.J. Šafárik University, Košice, Slovakia

The objective of this prospective observational study was to evaluate the effect of head-up tilt (HUT)–induced vasovagal syncope on adrenocortical hormones (cortisol and aldosterone) and their relationship to hemodynamic changes.

Subjects and Methods: Blood samples from 79 patients who underwent the HUT test (48 women and 31 men, aged 19–73 years) were analyzed for serum aldosterone and cortisol levels. Based on their response to the HUT test, patients were divided into two groups: 50 HUT-positive (HUT+) and 29 HUT-negative (HUT−) individuals.

Results: Patients in the HUT+ group exhibited significantly lower baseline aldosterone levels compared to the HUT− group (203.1 ± 78.8 vs 266.2 ± 76.3 pg/mL, $P = .0009$). Similarly, post-HUT aldosterone levels were lower in HUT+ patients than in HUT− patients (249.5 ± 101.3 vs 351.4 ± 98.1 pg/mL, $P < .0001$). In contrast, no significant differences in serum cortisol levels were observed between the two groups. In response to the HUT test, aldosterone levels increased in both groups. Furthermore, aldosterone concentrations showed a positive correlation with systolic and diastolic blood pressure as well as heart rate. The integration of aldosterone measurement with clinical assessment and additional laboratory parameters may improve diagnostic accuracy and risk stratification in patients with syncope.

Conclusions: HUT+ patients were characterized by lower serum aldosterone concentrations and associated hemodynamic changes during orthostatic stress induced by the HUT test. These findings suggest a potential role of aldosterone in the pathophysiology of vasovagal syncope. Serum cortisol levels showed no discriminatory value between HUT-positive and HUT-negative patients.

EP92 - ECE_2235 - The effect of cyclic transdermal 17-β-estradiol on glucose metabolism and cardiovascular risk factors in postmenopausal women: a secondary analysis

Rona Brokkelkamp[1], Esther M. Speksnijder[1], Dirk Jan Stenvers[1,2], Peter Bisschop[1] and Sarah Siegelaar[1]

[1]Endocrinology and Metabolism, Amsterdam UMC, University of Amsterdam, Amsterdam, The Netherlands; [2]Endocrinology and Metabolism, Amsterdam UMC, Vrije Universiteit Amsterdam, Amsterdam, The Netherlands

Background: Menopausal hormone therapy (MHT) is widely used to manage menopausal symptoms, but its impact on cardiovascular risk remains debated. Many different regimens and doses of transdermal MHT are available; however, randomized controlled trials evaluating their cardiometabolic effects are scarce, and transdermal estrogen is typically administered continuously rather than in a more physiological, cyclic pattern. Therefore, we investigated the effect of cyclic 17-β-estradiol, compared to continuous 17-β-estradiol on glucose metabolism and cardiovascular risk factors in postmenopausal women.

Methods: This was a randomized, controlled, open-label trial involving 42 postmenopausal women. Participants were randomly assigned to receive one of the following treatments for 16 weeks: cyclic transdermal 17-β-estradiol (alternating 25 μg/24 h and 50 μg/24 h 17-β-estradiol in a four-week cycle), continuous 25 μg/24 h transdermal 17-β-estradiol or continuous 50 μg/24 h transdermal 17-β-estradiol. In all treatment arms, 17-β-estradiol therapy was combined with continuous 100 mg oral micronized progesterone daily. The primary outcome of the study was the effect of 17-β-estradiol on bone turnover markers. In this secondary analysis, the following outcomes are presented: glucose metabolism assessed with an oral glucose tolerance test (OGTT), body mass index (BMI), waist circumference, controlled attenuation parameter (CAP) score of the liver, lipid profile and blood pressure before and after the allocated intervention.

Results: The mean age of participants was 53.3 ± SD 3.3 years, with a median age at final menstrual period of 51.0 (IQR 48.0–53.3) years. Median BMI was 25.0 (IQR 23.2–27.9) kg/m^2 and mean HbA1c level was 37.4 ± SD 2.5 mmol/mol. Mean Greene Climacteric Scale (GCS) scores were 17 ± SD 7. After 16 weeks of treatment, no differences were found between the three treatment groups in terms of change in fasting glucose and insulin, glucose, and insulin levels 2 h post-OGTT, HOMA-IR, BMI, CAP-score, HDL, LDL-C, total cholesterol, and triglyceride levels. After 16 weeks of treatment, the continuous 25 μg/24 h group showed a greater reduction in waist circumference compared to the continuous 50 μg/24 h group (mean difference: −3.7 cm, SE 1.3, [95% CI -6.8,-0.5], $P = .018$), and the continuous 50 μg/24 h group showed a greater reduction in diastolic blood pressure compared to the continuous 25 μg/24 h group (mean difference: 10 mmHg, SE 3, [95% CI 2,18], $P = .011$).

Conclusions: Cyclic transdermal 17-β-estradiol combined with continuous progesterone showed similar effects to standard-dose and low-dose continuous transdermal 17-β-estradiol therapies regarding cardiovascular risk factors. All three treatment regimens showed a neutral effect on glucose metabolism, lipid profile, and blood pressure in healthy postmenopausal women.

EP93 - ECE_2628 - Atypical presentation of silent pheochromocytoma in a young patient

Alexandra Mirica[1], Georgiana Taujan[1], Mihaela Rosu[2] and Iconaru Laura[3]
[1]Kraainem, Belgium; [2]CHU Brugmann, Bruxelles, Belgium; [3]CHU Brugmann Site Victor Horta, Bruxelles, Belgium

Title: A biochemically silent pheochromocytoma in a young patient

Background: Pheochromocytoma is a catecholamine-secreting tumor originating from chromaffin cells of the adrenal medulla. The majority of tumors that secrete catecholamines are sporadic. The catecholamine-secreting tumors are more likely to be bilateral adrenal pheochromocytomas or paragangliomas in about 40% of people who have the condition as part of a hereditary disorder.

Aim: To describe an atypical presentation of pheochromocytoma as an adrenal incidentaloma in a young adult and to emphasize the importance of recognizing hereditary tumor syndromes.

Methods: A 25-year-old asymptomatic man of Guinean origin was found to have a right adrenal mass during abdominal ultrasound performed for abnormal liver function tests. Clinical evaluation, biochemical investigations, multimodal imaging (adrenal MRI, PET-DOTANOC), and surgical management were undertaken. In this case of a young patient with an adrenal tumor showing imaging signs of pheochromocytoma, we also performed genetic testing.

Results: Adrenal MRI revealed a right adrenal mass measuring approximately 3 cm. Urinary catecholamines were normal, and blood tests showed only a slight elevation of neuron-specific enolase. PET-DOTANOC revealed an adrenal lesion with marker uptake at the tumor site. No lymphadenopathy or other visceral lesions were detected. Right adrenalectomy was performed. Histopathology confirmed a completely excised pheochromocytoma without capsular invasion, with one mitosis per 10 mm^2 and a low Ki-67 index of 1%.The genetic panel performed indicated the presence of the VHL gene mutation, confirming Von Hippel Lindau syndrome.

Conclusions: This case highlights the diagnostic challenges of biochemically silent pheochromocytomas in young patients. Genetic testing including VHL gene mutations should be strongly considered in such cases to allow early diagnosis, appropriate surveillance, and family screening.

EP94 - ECE_2718 - LINC CARE Phase IV study design: Efficacy and safety of osilodrostat in patients with hypertension caused by Cushing's syndrome with mean urinary free cortisol ≤2× the upper limit of normal

Irina Bancos[1], Javed Butler[2], Richard Auchus[3], Oksana Hamidi[4], Amir Hamrahian[5], Andrea Piacentini[6], Massimo Casi[6], Michal Sarnecki[7] and Martin Reincke[8]
[1]Division of Endocrinology, Metabolism and Nutrition, Mayo Clinic, Rochester, MN, United States; [2]Department of Medicine, Baylor Scott and White Research Institute and University of Mississippi, Dallas, TX and Jackson, MS, United States; [3]Department of Pharmacology and Division of Metabolism, Endocrinology and Diabetes, University of Michigan, Ann Arbor, MI, United States; [4]Division of Endocrinology, University of Texas Southwestern Medical Center, Dallas, TX, United States; [5]Division of Endocrinology, Diabetes and Metabolism, Department of Medicine, Johns Hopkins University, Baltimore, MD, United States; [6]Recordati SpA, Milan, Italy; [7]Recordati AG, Basel, Switzerland; [8]Department of Medicine IV, LMU Hospital, Ludwig-Maximilians-Universität München, Munich, Germany

Introduction: Hypertension and dysglycaemia are common comorbidities in patients with Cushing's syndrome (CS), driven by cortisol excess of varying severity. Data from a pooled analysis of two Phase III studies (LINC 3, LINC 4) highlight that 66.7% and 47.4% of patients with Cushing's disease and mean urinary free cortisol (mUFC) ≤2× the upper limit of normal (ULN) had hypertension and dysglycaemia at baseline, respectively. In LINC 3 and LINC 4 analyses, osilodrostat, a potent inhibitor of 11β-hydroxylase and aldosterone synthase, decreased blood pressure and glycaemic parameters in patients with CS and comorbid hypertension and/or diabetes mellitus. LINC CARE (NCT07247162) will evaluate the efficacy and safety of osilodrostat in patients with hypertension caused by CS with mUFC≤2xULN.

Methods: ~63 CS patients (aged ≥18 years) with uncontrolled hypertension despite medication (systolic blood pressure [SBP] ≥135 mmHg or diastolic blood pressure [DBP] ≥85 mmHg) and mUFC>1–≤2xULN will enrol across ~75 sites (Europe, USA, Canada, Latin America). Following a ≤3-week (W) screening period, the 30W randomised, double-blind, placebo-controlled study will comprise an 18W dose-titration and 12W dose-maintenance phase. Patients will be randomly allocated to osilodrostat 1 mg once daily (evening) or matching placebo (2:1 ratio). During the dose-titration phase, treatment will be titrated every 3W according to serum cortisol levels and clinical response. In the dose-maintenance phase, patients will continue on the dose received at the end of the titration phase unless there is a need to reduce or discontinue the medication for safety reasons. The primary endpoint is the proportion of patients with mUFC≤ULN at W30. The key secondary endpoint is the proportion of blood pressure responders (≥5 mmHg reduction in mean SBP and/or DBP, assessed by ambulatory blood pressure monitoring) at W30. Other secondary endpoints (assessed at W21 and W30 unless otherwise specified) include: proportion of responders in glycaemia (≥25% reduction in glucose from baseline during oral glucose tolerance test in patients with baseline glycated haemoglobin ≥6%) and body weight (≥5% decrease from baseline); change from baseline in SBP, glycaemic parameters, and antihypertensive and antidiabetic medication; change in body weight and proportion of patients with mUFC≤ULN over time; and occurrence of adverse events, including hypocortisolism.

Conclusions: LINC CARE will provide valuable data on the efficacy, safety and dosing of osilodrostat in patients with hypertension caused by CS and with mUFC ≤ 2xULN.

EP95 - ECE_2721 - Adrenal masses in advanced cutaneous melanoma: prevalence, clinical features, and prognostic implications in a large retrospective cohort

Erika Messina[1], Francesca Dughera[1], Giuseppe Ferruzza[2], Gabriele Roccuzzo[2], Emanuele Koumantakis[1], Soraya Puglisi[1], Marianna Torchio[1], Massimo Terzolo[1], Pietro Quaglino[2] and Giuseppe Reimondo[1]
[1]*Orbassano, Italy;* [2]*Department of Medical Sciences, Section of Dermatology, University of Turin, Turin, Italy*

Background: Cutaneous melanoma frequently metastasizes to the adrenal glands, but radiological data on adrenal involvement and its clinical significance in advanced melanoma remain limited.

Objective: To evaluate the prevalence, radiological characteristics, and prognostic impact of adrenal lesions, both metastatic and non-metastatic, in patients with stage III–IV cutaneous melanoma.

Methods: We retrospectively studied 680 patients with stage III-IV melanoma followed at the Dermatology Unit of the "Città della Salute e della Scienza" of Turin through December 2023. All patients underwent at least one CT scan for disease staging. Adrenal findings were classified as: no lesions, metastasis, or non-metastatic lesions. Clinical, cardiometabolic, and genetic data (BRAF and NRAS mutational status) were collected.

Results: The cohort had a mean age at diagnosis of 61 years and a male predominance (57.4%). Stage IV disease was more common than stage III (64.3% vs 35.7%). Compared with stage III patients, those with stage IV melanoma were older ($P = .025$), had a higher prevalence of hypertension ($P = .036$), and higher mortality during follow-up ($P < .001$), while sex distribution and diabetes prevalence were similar. No significant differences in BRAF or NRAS mutational status were observed between stages.

Overall, adrenal lesions were detected in 13.5% of patients, including 8.1% non-metastatic and 5.4% metastatic lesions. Adrenal involvement was strongly associated with disease stage. Metastatic adrenal lesions were rare in stage III (0.8%) but occurred in 8% of stage IV patients; non-metastatic lesions were also more frequent in stage IV than in stage III (10.1% vs 4.5%).

Patients with non-metastatic adrenal lesions tended to be older and showed a higher prevalence of hypertension without an increase in cardiovascular mortality.

Five-year overall survival worsened with advancing stage, reaching 90% in stage III and 76% in stage IV melanoma. When stratified by adrenal CT findings, five-year survival was similar in patients with metastatic (72%) and non-metastatic adrenal lesions (74%), and lower than in patients without adrenal involvement (81%). Survival curves for metastatic and non-metastatic adrenal lesions largely overlapped, suggesting that adrenal metastases did not confer additional prognostic impairment beyond advanced disease stage.

Conclusions: In advanced melanoma, adrenal involvement is more frequent in stage IV disease. Non-metastatic adrenal lesions are associated with a prognosis comparable to that of adrenal metastases, despite representing a condition with low intrinsic mortality. This unexpected overlap in survival suggests that non-metastatic adrenal lesions warrant careful identification and clinical characterization, as they may be associated with mild autonomous hormonal activity.

EP96 - ECE_3316 - Differences in renal outcomes in ethnic groups and between surgical and medical treatment in primary aldosteronism: a retrospective cohort study

Yuliya Manova[1], Russell Senanayake[1,2], Anand Velusamy[1], Johnathan Hubbard[1] and Paul Carroll[1]
[1]*Departments of Endocrinology and Endocrine Surgery, Guy's and St Thomas' NHS Foundation Trust, Endocrine Clinic, London, United Kingdom;* [2]*School of Biomedical Engineering & Imaging Science, King's College, London, United Kingdom*

Background: Primary aldosteronism (PA) is associated with impaired renal function. Treatment with surgery (adrenalectomy) or medical treatment with mineralocorticoid receptor antagonists (MRAs) leads to a change in eGFR by eliminating aldosterone-induced hyperfiltration. However, data comparing renal outcomes by treatment modality across different ethnic groups remain limited.

Objectives: To compare renal outcomes between treatment modalities and ethnic groups.

Methods: We conducted a single-centre retrospective cohort study using electronic health records of patients aged >18 years old with a confirmed diagnosis of PA between January 2000 and December 2024, based on Endocrine Society 2016 guidelines. Variables collected included demographics (age, sex, ethnicity), treatment modality, and renal outcomes (creatinine and eGFR). Statistical calculations were performed on SPSS including Wilcoxon signed rank for comparison of non-parametric data sets.

Results: A total of 121 patients were identified. Mean age was 53.9 years; 63 (52.1%) were male and 69 (57.0%) were of Black ethnicity. Adrenalectomy for suitable patients with unilateral disease was performed in 53 patients (43.8%), and 68 (56.2%) received medical treatment with MRAs.

In the total cohort of 121 patients, the average eGFR at baseline was 77.7 mL/min (±19.2) and after intervention 67.3 mL/min (±18.1, $P < .001$). Within the treatment groups, there was no change in the average decline in eGFR (mL/min) in the surgical (−9.4,11.8%) and medical treatment group (−11.2,14.7%) ($P = .23$, $\alpha = 0.05$). There was no difference in eGFR between black and other ethnicity ($P = .082$). There was no significant difference in creatinine change between surgical (+13.2 umol/L, 15.9%) and medical treatment (+15.0 umol/L, 17.3%) groups ($P = .4$), and no difference between Black and other ethnicities ($P = .8$). The average increase in renin mass 18.4 mU/L (579%) in the surgical group and 15.4 (438%) in the medical group, with no significant difference ($P = .19$). Average K was 3.4 mmol/L (±0.44) at baseline and 5.0 mmol/L (±7.44) after treatment. Aldosterone demonstrated a positive correlation with pre- and post-treatment creatinine ($r = 0.179$ and 0.048, respectively) and an inverse correlation with pre- and post-treatment eGFR ($r = -0.223$ and −0.160, respectively).

No ethnic differences were observed with changes in renin ($P = .28$), potassium ($P = .18$), systolic BP ($P = .11$), or diastolic BP ($P = .08$) between treatment groups.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Conclusions: eGFR fell significantly following both surgical and medical treatment of PA, regardless of ethnicity. Clinicians should be aware that successful treatment of PA may be associated with a reduction in eGFR, which pre-treatment may be falsely reassuring because of PA induced hyperfiltration.

EP97 - ECE_3460 - Preoperative CT-derived abdominal fat volume predicts clinical outcome in patients with primary aldosteronism undergoing unilateral adrenalectomy

Matthias Oettle[1], Markus Kroiss[1], Raphael Hirner[1], Erik Petersenn[1], Felix Herr[2], Isabel Stüfchen[1], Petra Zimmermann[3], Tracy Ann Williams[1], Nicole Reisch[1], Martin Reincke[1], Jens Ricke[2], Lalith Kumar Shiyam Sundar[2], Christine Schmid-Tannwald[2], Wolfgang Kunz[2], Lukas Gold[2] and Nabeel Mansour[2]

[1]Department of Medicine IV, LMU University Hospital, LMU Munich, Munich, Germany; [2]Department of Radiology, LMU University Hospital, LMU Munich, Munich, Germany; [3]Department of General, Visceral and Transplantation Surgery, LMU University Hospital, LMU Munich, Munich, Germany

Purpose: Lateralized primary aldosteronism (PA) represents a potentially curable cause of secondary hypertension, yet, clinical outcomes following unilateral adrenalectomy vary substantially. Beyond conventional anthropometric measures, computed tomography (CT)-derived assessments of visceral fat volume and body fat distribution may provide additional prognostic information in patients with lateralized PA.

Methods: This retrospective study included 70 patients with lateralized PA from the German Conn Registry, Ludwig-Maximilian-University Hospital Munich, who underwent unilateral adrenalectomy. Preoperative non-contrast CT-based body composition parameters, including visceral fat volume (VFV), subcutaneous fat volume (SFV), the VFV/SFV ratio, and the VFV-to-skeletal muscle volume (VFV/SMV) ratio, were analyzed at the third lumbar vertebral (L3) level using a fully automated software tool (Visage Imaging GmbH, Berlin, Germany). Associations between body composition parameters and preoperative plasma aldosterone concentrations (PAC) were assessed by linear regression models using log-transformed PAC. PAC was measured using Chemiluminescent Immunoassay. Clinical outcomes after adrenalectomy were classified according to the PASO criteria, and their association with body composition parameters analyzed using ordinal logistic regression models. Effect sizes were reported as odds ratios per standard deviation increase.

Results: No significant associations were observed between preoperative PAC ($n = 70$; median 227.5 ng/L, IQR 157.0–363.8 ng/L) and body composition parameters, including VFV, SFV and distribution-based ratios (all $P > .05$). Postoperative clinical outcome data were available for 52 patients (23 female; median age 49 years), including 11 with absent, 31 with partial, and 10 with complete clinical success. Higher body mass index (BMI) was associated with a lower likelihood of achieving a better clinical outcome (OR 0.37 per SD increase, 95% CI 0.19–0.71). Similar, higher VFV and SFV were each associated with a lower likelihood of a better clinical outcome (OR 0.51 per SD increase, 95% CI 0.28–0.92 and OR 0.46 per SD increase, 95% CI 0.25–0.83 respectively). In contrast, neither the VFV/SFV ratio (OR 0.77 per SD increase, 95% CI 0.45–1.31) nor the VFV/SMV ratio (OR 0.63 per SD increase, 95% CI 0.35–1.11) was associated with clinical outcome.

Conclusions: Fully automated CT-based body composition analysis enables rapid and standardized quantification of visceral adiposity. In patients with lateralized PA, CT-derived visceral and subcutaneous fat volume were predictive of clinical outcomes following unilateral adrenalectomy, while distribution-based ratios showed no associations. However, BMI was more strongly associated with clinical outcome, suggesting that the incremental clinical value of CT-based body composition assessment beyond conventional measures was limited in our cohort.

EP98 - ECE_3554 - Cushing Syndrome's lipid and amine metabolic peripheral blood signatures are partially reflected in other states of cortisol excess and insufficiency

Flaminia Fanelli[1], Greta Galante[1], Carlo Mengucci[2], Lorenzo Tucci[1,3], Kimberly Coscia[1,3], Valentina Bissi[1], Giacomo Colombin[1,3], Alessandro Perrone[1], Valentina Vicennati[1,3], Uberto Pagotto[1,3], Francesco Capozzi[2] and Guido Di Dalmazi[1,3]

[1]Center for Applied Biomedical Research, CRBA, University of Bologna, Bologna, Italy; [2]Department of Agricultural and Food Sciences, DISTAL, University of Bologna, Bologna, Italy; [3]Division of Endocrinology and Diabetes Prevention and Care, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy

Introduction: Cushing's syndrome (CS), adrenal insufficiency under replacement therapy (AIRT), and adrenocortical tumours with mild autonomic cortisol secretion (MACS) display different alterations of cortisol rhythm. Circadian alterations of metabolic pathways in these diseases were not characterized yet.

Objective: To identify peripheral blood molecular patterns characterizing CS, and verify their dysregulation in AIRT and MACS.

Methods: We enrolled 10 healthy subjects (HS), 9 newly diagnosed CS, 8 AIRT taking dual-release hydrocortisone and 12 MACS patients. All followed 7-days standardised isocaloric Mediterranean diet. On day seven, they collected dried blood spots from finger-prick 30 min before and 2 h after breakfast, lunch and dinner, and at 11 pm. We used a targeted metabolomic LC-MS/MS method measuring 42 amino acids and biogenic amines, 40 acylcarnitines, 15 sphingomyelins and 90 glycerophospholipids. A BORUTA algorithm was trained to separate HS and CS, as the most divergent phenotypes, and defined the most informative features. These were reduced by Factor Analysis (FA). The circadian fluctuation of molecular patterns was evaluated by combining molecule concentrations and FA-coefficients along the 7 time-points. Resulting patterns were analyzed within AIRT and MACS groups. Kinetics for each class were fit using second (SOP) or third order polynomial (TOP), or power law ($y = Axk + c$).

Results: Two patterns distinguished CS patients from HS, with top 5 informative molecules being phosphatidylcholines (PC) aa-C38:0, ae-C44:3, aa-C38:6, ae-C42:5 and aa-C36:0 (PCs) for pattern A; and carnitine, histidine, creatinine, asparagine and spermidine for pattern B. Pattern A PC levels and fluctuation

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

were markedly divergent in HS and CS ($P < .05$ at each time point): HS showed a U-shaped (SOP) rhythm with minimum levels before lunch, whereas CS displayed low levels reaching a plateau in the evening (TOP). HS exhibited a U-shaped rhythm also for pattern B amines. Conversely, CS showed persistently high amine levels ($P < .05$ from 9:30 to 23:00), with maximal divergence from HS in early afternoon. AIRT exhibited pattern A and B levels resembling CS and HS, respectively, with pronounced morning oscillations. MACS showed pattern A levels similar to CS, with U-shaped fluctuation similar to HS, and pattern B levels intermediate to HS and CS, with TOP oscillation.

Conclusions: PC and amines in CS displayed deranged rhythms and opposite dysregulation of levels. In AIRT, PC and amines were overall low, with marked morning oscillation probably derived by glucocorticoid intake after awakening. PC dysregulation in MACS was similar to CS, while amine imbalance displayed an intermediate pattern.

EP99 - ECE_3694 - Mild Autonomous Cortisol Secretion (MACS)—silent autonomy or hidden danger? Predictors and metabolic consequences: a multidimensional comparison of functional adrenal incidentaloma phenotypes

Ksenia Janas[1], Janusz Strzelczyk[1], Krzysztof Bylok[2], Adrian Bukała[3], Wiktoria Borowska[4], Oliwia Jewuła[5] and Natalia Aleksander[2]

[1]Department of Endocrinology and Neuroendocrine Tumours, Medical University of Silesia, Katowice, Poland; [2]Student Scientific Society at the Clinic of Endocrinology and Neuroendocrine Tumors of the Department of Pathophysiology and Endocrinology of the Silesian Medical University in Zabrze, Medical University of Silesia in Katowice, 35 Ceglana St., Katowice 40-514, Poland; [3]Student Scientific Society at the Clinic of Endocrinology and Neuroendocrine Tumors of the Department of Pathophysiology and Endocrinology of the Silesian Medical University in Zabrze, Medical University of Silesia in Katowice, 35 Ceglana St., Katowice 40-514; [4]Student Scientific Society at the Clinic of Endocrinology and Neuroendocrine Tumors of the Department of Pathophysiology and Endocrinology of the Silesian Medical University in Zabrze, Medical University of Silesia in Katowice, 35 Ceglana St., Katowice 40-514, Poland; [5]Student Scientific Society at the Clinic of Endocrinology and Neuroendocrine Tumors of the Department of Pathophysiology and Endocrinology of the Silesian Medical University in Zabrze, Medical University of Silesia in Katowice, 35 Ceglana St., Katowice 40-514, Poland

Introduction: Adrenal incidentalomas (AI) are found in 4-10% of adults. Mild autonomous cortisol secretion (MACS) is the most frequent functional abnormality, associated with increased cardiometabolic risk. This study aimed to characterize Polish patients with AI, focusing on identifying independent predictors and metabolic consequences of the MACS phenotype.

Material and Methods: This retrospective observational study analyzed 404 consecutive patients (73.5% female, mean age 62.5 years) hospitalized at a tertiary endocrine center (2024-2025). MACS was defined as cortisol >1.8 µg/dL after a 1-mg dexamethasone suppression test (DST) in patients without overt Cushing's syndrome (CS), according to ESE/ENSAT 2023 guidelines. Subjects were categorized into: non-functioning AI (NFAI, 69.6%), MACS (20.8%), pheochromocytoma (PCC, 5.7%), CS (2.7%), and primary aldosteronism (PA, 1.2%). Hormonal profiles (8:00/23:00 serum cortisol, ACTH) and metabolic status were evaluated. Statistical analysis included Kruskal-Wallis tests and multivariable logistic regression using backward stepwise selection; glucose levels were centered to the mean to mitigate collinearity in interaction models. Due to small sample sizes in the CS and PA groups, comparisons involving these phenotypes were treated as exploratory.

Results: MACS patients were significantly older (66.6 ± 10.8 years) than NFAI patients ($P = .007$). The multivariable regression model showed high discriminatory power (AUC = 0.836) and identified age (OR = 1.042) and late-night serum cortisol (OR = 1.685; $P < .001$) as independent predictors of MACS. Exploratory ROC analysis established cutoff points for late-night cortisol (>4.07 µg/dL, NPV = 89.1%) and ACTH (<10.32 pg/mL, NPV = 85.0%), though these require validation in independent cohorts. Regarding metabolic impact, the multivariable model revealed that MACS tripled the risk of hypertension (OR = 2.957). A significant interaction between hypertension and fasting glycemia was found (OR = 1.097, $P = .002$); each 1 mg/dL increase in glucose intensified the association between MACS and hypertension by 9.7%. Lipid parameters were not independent predictors in the multivariable model.

Conclusions: MACS risk increases with age, which is consistent with the hypothesis of progressive functional evolution of adrenal adenomas. The identified synergistic effect of glycemia on hypertension highlights that MACS patients with impaired glucose metabolism represent a particularly high-risk cardiovascular group. Late-night serum cortisol and ACTH levels show high negative predictive values, suggesting their potential utility in excluding MACS, although standardized collection and external validation are necessary.

EP100 - ECE_2028 - Apparent bilateral aldosterone suppression during non-stimulated adrenal vein sampling: an artifact of the Liaison immunoassay and other causes

Christina Pamporaki[1], Carmina Teresa Fuss[2], Ralph Kickuth[3], Lydia Kuerzinger[3], Mirko Peitzsch[4], Sybille Fuld[4], Manuel Schulze[5], Jun Yang[6], Martin Reincke[7], Sven Gruber[8], Felix Beuschlein[8], Jacques Lenders[9] and Graeme Eisenhofer[4]

[1]Medical Clinic III, University Hospital Carl Gustav Carus Dresden, Dresden, Germany; [2]Würzburg University Hospital, Würzburg, Germany; [3]Würzburg University Hospital Straubmühlweg Heliport, Würzburg, Germany; [4]University Hospital Carl Gustav Carus Dresden, Dresden, Germany; [5]Technische Universität Dresden Medizinische Fakultät, Dresden, Germany; [6]Monash Institute of Medical Research, Clayton, Australia; [7]Ludwig Maximilian University, Munich, Germany; [8]University Hospital, Zürich, Switzerland; [9]Radboud Universiteit, Nijmegen, The Netherlands

Objective: Subtyping of primary aldosteronism usually requires adrenal vein sampling (AVS). Interpretation can be compromised by apparent bilateral aldosterone suppression (ABAS), which we hypothesized reflects an artifact of the Liaison immunoassay of aldosterone. We therefore compared measurements of aldosterone by liquid chromatography-tandem mass spectrometry (LC-

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

MS/MS) with measurements by the Liaison immunoassay and a different immunoassay.

Design: retrospective cross-sectional multicenter study.

Patients: The study involved 222 patients who underwent bilaterally selective non-stimulated AVS.

Measurements: Adrenal and peripheral venous plasma aldosterone concentrations were measured by Liaison and iSYS immunoassays in 112 and 110 respective samplings compared to LC-MS/MS in all samplings. Ratios of aldosterone to cortisol below 1.0 in adrenal versus peripheral vein samples defined suppression of aldosterone secretion.

Results: Among all AVS procedures, 9.5% (21/222) of samplings with immunoassay measurements showed ABAS, 3-fold more ($P = .0004$) than the 3.2% (7/222) with LC-MS/MS measurements. Rates of ABAS were particularly high with the Liaison immunoassay compared to LC-MS/MS (14.2% vs 0.9%, $P < .0001$) and remained higher after substitution of LC-MS/MS measurements of cortisol in the ratio with immunoassay measured aldosterone (9.8% vs 0.9%, $P = .0064$). Among 110 procedures involving iSYS immunoassay measurements, rates of ABAS at 4.6% were a third ($P = .0132$) those of the Liaison immunoassay and did not differ from LC-MS/MS measurements (5.5%). ABAS confined to LC-MS/MS measurements in one patient was resolved with a second right adrenal vein sampling.

Conclusions: ABAS occurs more frequently using the Liaison immunoassay of aldosterone than the iSYS immunoassay and LC/MS-MS measurement. In addition to this artefact, ABAS can also reflect adrenal vein catheter placement.

EP101 - ECE_2354 - The silent emergency: acute adrenal crisis in the emergency department—experience from a Moroccan tertiary center

Mohamed Nhili[1] and Mohamed Amine Elhasnaoui[2]
[1]*Endocrinology, Diabetology and Metabolic Diseases Department, Mohammed VI University Hospital of Tangier, Tangier, Morocco;* [2]*Emergency Department, Mohammed VI University Hospital of Tangier, Tangier, Morocco*

Background: Acute adrenal crisis (AC) is a rare but life-threatening endocrine emergency, with reported mortality rates ranging from 6% to 15% despite appropriate treatment. Diagnosis is frequently delayed due to nonspecific clinical presentation, including digestive, neurological, and cardiovascular symptoms. Early recognition and prompt initiation of glucocorticoid replacement are key determinants of prognosis.

Objective: To describe diagnostic delays, management strategies, and outcomes of patients presenting with acute adrenal crisis in a Moroccan emergency department, and to identify areas for improvement in early recognition and prevention.

Methods: We conducted a retrospective, descriptive, single-center study at the emergency department of Mohammed VI University Hospital, Tangier, between November 2023 and August 2025. We included patients admitted for acute adrenal crisis as well as those who were diagnosed during hospitalization for another condition in the emergency department. Data were collected from electronic medical records using a standardized data extraction form and analyzed descriptively.

Results: Thirteen patients were included (mean age 43.7 years, range 21-65), with a female predominance (9 women, 4 men; F/M ratio 2.25). Chronic adrenal insufficiency was previously known in 8 patients (61.5%), while AC was inaugural in 5 cases (38.5%). Diagnostic delay was markedly longer in patients without known adrenal insufficiency, with a median pre-hospital symptom duration of 15 days, compared with less than 24 hours in known patients. Triggering factors included infections, corticosteroid withdrawal or non-adherence, and metabolic disturbances. Hyponatremia was observed in 58% and hyperkalemia in 42% of cases. In all patients (100%), AC management was started immediately upon clinical suspicion, without waiting for cortisol assay results, using intravenous hydrocortisone and fluid resuscitation. Vasopressors were required in one patient (7.7%). Eleven patients had a favorable outcome, one left against medical advice, and one died in intensive care, resulting in an in-hospital mortality rate of 7.7%.

Conclusions: Acute adrenal crisis remains a major diagnostic challenge in the emergency setting, particularly in patients without known adrenal insufficiency. Early treatment based on clinical suspicion allows outcomes comparable to international series. Improving frontline healthcare provider awareness, standardizing emergency protocols, and strengthening preventive strategies during hospitalization are essential to further reduce mortality.

EP102 - ECE_3642 - Optimizing patient selection for adrenal vein sampling in primary hyperaldosteronism

Meir Frankel, Gabriel Munter, Gavriel Lichewitz, Noa Sylvetsky and Anthony Verstandig
Faculty of Medicine, Hebrew University of Jerusalem, Jerusalem, Israel

Background: Primary hyperaldosteronism (PA) is caused by excessive aldosterone production from one or both adrenal glands. Diagnostic evaluation includes biochemical testing, imaging, and in most patients requires adrenal vein sampling (AVS) to differentiate unilateral disease, which may benefit from surgical treatment, from bilateral disease, which is managed medically. According to 2025 Endocrine Society guidelines, screening for PA is recommended in all patients with hypertension, a strategy that is expected to increase PA detection. Following biochemical confirmation, AVS is generally recommended for patients with a moderate/high likelihood of unilateral disease, while those with a low probability are managed with medical therapy as first-line treatment. Identifying clinical predictors of unilateral aldosterone secretion may therefore optimize patient selection for AVS.

Methods: We retrospectively analyzed all patients with confirmed PA who underwent AVS at Shaare Zedek Medical Center during 2019-2025, with successful determination of unilateral or bilateral aldosterone secretion according to accepted criteria. Baseline demographic, clinical, and imaging variables were evaluated using statistical analyses to identify predictors of unilateral disease and to develop a predictive model for AVS outcomes.

Results: During the study period, 85 patients with PA underwent AVS with definitive classification of aldosterone secretion as unilateral or bilateral. Unilateral aldosterone secretion was

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

identified in 55 patients (65%), while 30 (35%) had bilateral disease. In univariable analysis, hypokalemia was strongly associated with unilateral aldosterone secretion (odds ratio [OR] = 16.7), as was a lowest recorded serum potassium level <3.3 mEq/L (OR = 8.3). An aldosterone-to-renin ratio (ARR) >10 was also significantly associated with unilateral disease (OR = 4.5). Chronic kidney disease was significantly associated with bilateral aldosterone secretion (OR = 0.3). Baseline low renin levels demonstrated a borderline association with unilateral disease (OR = 1.9). Age, Gender, age at hypertension diagnosis, serum aldosterone level and adrenal mass (uni or bilateral) in imaging were not significantly associated with AVS results. In multivariable logistic regression analysis, a lowest serum potassium level <3.3 mEq/L and ARR >10 remained independently and strongly associated with unilateral aldosterone secretion. A predictive model based on the variables achieved an overall accuracy of approximately 80% in predicting AVS outcomes.

Conclusions: Patients with PA and unilateral aldosterone secretion exhibit distinct baseline clinical and biochemical characteristics compared to patients with bilateral disease. These findings, together with the predictive model developed in this study, may assist clinicians in determining whether to initiate medical therapy as first-line treatment or to proceed with AVS to evaluate candidacy for surgical management of unilateral disease.

EP103 - ECE_3176 - Evaluation of hypokalaemia correction practices in hospitalised patients: a retrospective audit of guideline compliance and monitoring in renal impairment

Aparna Ravikumar[1], Seth King[1], Rubern Rajasivam[1], Sarath Vayolipoyil[1] and Tadeusz Pawlak[2]
[1]*York and Scarborough Teaching Hospitals NHS Foundation Trust, Scarborough, United Kingdom;* [2]*Endocrinology and Diabetes, York and Scarborough Teaching Hospitals NHS Foundation Trust, Scarborough, United Kingdom*

Background: Hypokalaemia affects up to 20% of hospitalised patients and is associated with significant cardiovascular morbidity and mortality. Potassium homeostasis is largely regulated by renal handling, and patients with acute or chronic renal impairment are particularly vulnerable to over-correction due to impaired clearance and altered intracellular–extracellular potassium shifts. Safe correction requires cautious replacement supported by biochemical and cardiac monitoring, including post-infusion checks.

Objective: This Retrospective audit evaluated adherence to local guidelines for safe hypokalaemia correction in hospitalised patients, with particular focus on monitoring during replacement therapy in those with renal impairment.

Methods: A retrospective audit was conducted over one year including adult medical inpatients with serum potassium <3.5 mmol/L admitted to a UK district general hospital. Data collected included hypokalaemia severity, documented aetiology, presence of acute kidney injury (AKI) or chronic kidney disease (CKD), appropriate route of potassium replacement, ECG monitoring during replacement, post-infusion serum potassium monitoring, serum magnesium monitoring (given its role in potassium homeostasis), and time to correction. Practice was assessed against local hypokalaemia management guidelines.

Results: Fifty-five patients were included. Hypokalaemia was predominantly mild (73%), with moderate (24%) and severe (3%) cases. An underlying cause was documented in 49% of patients, most commonly gastrointestinal potassium loss (33%). Renal impairment (AKI or CKD) was present in 49%. Among patients with mild to moderate hypokalaemia, oral potassium replacement was used in 68%, consistent with guideline recommendations. However, 35% received intravenous potassium, with documented severity or symptoms supporting IV use in only 16%. ECG's were performed in 45% of mild, 69% of moderate, and 100% of severe cases; among those receiving IV potassium, Continuous Cardiac monitoring occurred in 37% receiving IV Potassium. Post-correction potassium checks were undertaken in 84% patients. In renal impairment, daily serum potassium monitoring during active replacement was documented in 36% of patients with CKD & 54% with AKI. Median time to correction was 2 days in patients without renal impairment and 3 days in those with renal dysfunction. Magnesium levels were checked in 78% of patients with renal impairment.

Conclusions: Although hypokalaemia correction was generally achieved, variability in monitoring practices has important patient-safety implications, particularly in renal impairment. Inconsistent ECG surveillance and incomplete daily biochemical monitoring during replacement may increase the risk of arrhythmias and over-correction. These findings support the need for cautious, closely monitored correction strategies and improved adherence to guidelines through structured monitoring prompts.

EP104 - ECE_3291 - oxLDL and early launch of menopausal hormone replacement therapy among women with vasomotor syndrome

Iryna Muryzina
Obstetrics and Gynaecology, ABC Clinic, Kharkiv National Medical University, Kharkiv, Ukraine

Introduction: Menopausal vasomotor syndrome is a well-known risk factor for future cardiovascular events (CVE). Endothelial dysfunction (ED) is viewed as a favourable ambience for rebuilding cascade in subepithelial layer triggered by binding oxidized LDL (oxLDL) to scavenger receptors of macrophages. Obviously at first estrogen decline weakens natural repair work spurring up impairment of an arterial wall, as well as oxLDL-related suppression of NO release. On the other hand menopausal hormone replacement therapy (MHRT) turns into a foe, if it is prescribed when intima-media impairment becomes evident. The question is whether VMS are associated with raised oxLDL and if MHRT is capable to curb oxLDL production.

Objective: The study aimed to evaluate serum oxLDL in women experienced VMS and if oxLDL is affected by MHRT.

Methods: The study accrued 51 women 46-54 y.o. with VMS debut (1 group) and 30 pts without VMS otherwise matching (control). The 1st group was split into two arms: MHRT (23 pts) and without MHRT (28 pts). They were tested twice (at accrual, in 1 year) for serum oxLDL, lipoproteins, C-reactive protein (CRP),

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

IL6, TNFα, ApoB, brachial artery dilation, coronary CT angiography, cross-sectional associations were examined.

Results: It turned out that VMS-patients showed raised oxLDL in comparison with control group. Then MHRT-women experienced drop in oxLDL (still a bit higher than in control but not significantly, $P > .05$), whereas non-MHRT-patients were recognized with staggering trend to grow despite improvement in VMS course attained by non-hormonal treatment ($P < .0001$), lower vasodilation response, higher total plaque burden with remodeling index >1 comparatively to the women MHRT.

Conclusions: Earlier launch of MHRT is associated with slower pace of ED considering the fluctuations of oxLDL as a very sensitive high risk of CVE.

Abstract citation ID: lvag096.708

EP106 - ECE_3567 - Hidden congenital adrenal hyperplasia in APS-2: a case of non-classical 21-hydroxylase deficiency

Emma Capparelli, Luca Manetti, Elisabetta Sciarroni, Giulia Marconcini, Claudio Urbani, Maurizio Carbonari, Martina Parenti, Alessio Basolo, Ferruccio Santini and Isabella Lupi
Department of Clinical and Experimental Medicine, Unit of Endocrinology 1, Pisa University Hospital, Pisa, Italy

Background: Primary adrenal insufficiency (PAI) is most frequently caused by autoimmune adrenalitis (70%-80%), followed by tuberculosis and rare genetic disorders. Autoimmune Addison's disease may occur within Autoimmune Polyendocrine Syndrome type 2 (APS-2), in association with autoimmune thyroid disease and type 1 diabetes mellitus. Congenital adrenal hyperplasia (CAH) due to 21-hydroxylase deficiency is a rare genetic condition resulting from impaired steroidogenesis and may present as classical or non-classical disease. The non-classical form is typically characterized by late-onset hyperandrogenic manifestations. Standard therapy for primary adrenal insufficiency consists of glucocorticoid and mineralcorticoid (fludrocortisone) replacement; in CAH, tailored glucocorticoid timing may be required to control androgen excess.

Case Presentation: A 28-year-old woman with APS-2, diagnosed at 14 years of age, was referred to our Endocrinology Unit. She was treated with modified-release hydrocortisone (Plenadren®) 40 mg/day and fludrocortisone 0.2 mg/day. Menarche occurred at 13 years; she reported secondary amenorrhea for eight months. Biochemical evaluation showed normal electrolytes and HbA1c of 7.1%. Suspecting glucocorticoid overtreatment, hydrocortisone was progressively reduced to 20 mg/day, leading to the resumption of menstrual cycles, although oligomenorrhea persisted. Hormonal assessment excluded premature ovarian insufficiency but revealed markedly elevated 17-hydroxyprogesterone levels (15.54 µg/L). Genetic analysis identified a heterozygous c.955C>Tp.(Gln319*) mutation in the CYP21A2 gene, without gene deletion or conversion, leading to the diagnosis of non-classical 21-hydroxylase deficiency. Glucocorticoid therapy was switched to modified-release hydrocortisone specifically approved for CAH (Efmody®), administered as 10 mg in the morning and 15 mg in the evening. After four months, significant biochemical improvement was observed, with normalization of 17-hydroxyprogesterone (0.54 µg/L) and androstenedione (0.61 µg/L). Menstrual regularity improved, and the patient achieved spontaneous pregnancy. Partner genetic screening was negative.

Conclusions: This case highlights the importance of considering coexisting genetic adrenal disorders in patients with APS-2. Identification of non-classical 21-hydroxylase deficiency enabled personalized glucocorticoid therapy, resulting in improved biochemical control, restoration of reproductive function, and safe pregnancy planning.

EP108 - ECE_2322 - Diagnostic and therapeutic challenges in a patient with acute pain and a large adrenal mass

Christina Lymniati[1], Anastasia Filippidou[1], Georgios Kyriakopoulos[2], Eleni Statiri[1], Anastasios Chatzinikolaou[1] and Charalampos Tsentidis[1]
[1]*Endocrinology, Diabetes Mellitus and Metabolism Department, General Hospital of Nikaia Piraeus "Ag. Panteleimon", Piraeus, Greece;* [2]*Department of Pathology, Evangelismos Hospital, Department of Biological Chemistry, Medical School, National and Kapodistrian University of Athens, Athens, Greece*

Aim: To highlight the diagnostic challenges and clinical decision-making process in a patient presenting with acute pain and a large adrenal mass, emphasizing the importance of considering silent pheochromocytoma and metastatic disease despite inconclusive biochemical and imaging findings.

Summary/Methods: We report the case of a 51-year-old male who presented to the emergency department with acute right-sided flank pain. Initial clinical assessment suggested renal colic; however, abdominal computed tomography revealed a heterogeneous right adrenal mass measuring 6 cm, with attenuation values exceeding 20 Hounsfield units. Although the scan was not performed using a dedicated adrenal protocol, the lesion's size and imaging characteristics prompted further investigation. Magnetic resonance imaging demonstrated a large adrenal mass with heterogeneous signal intensity on T1- and T2-weighted sequences and atypical imaging and hemodynamic features. Differential diagnoses included pheochromocytoma, adrenocortical carcinoma, and metastatic disease. **Preoperative imaging did not demonstrate any evident metastatic lesions or pulmonary primary focus.** Comprehensive endocrinological evaluation showed normal cortisol, ACTH, renin–aldosterone axis, sex steroids, steroid precursors, and 24-hour urinary free cortisol. Chromogranin A was mildly elevated, while plasma normetanephrine levels were borderline increased. No hypertensive episodes were recorded on 24-hour blood pressure monitoring, cardiac evaluation was unremarkable, and MIBG scintigraphy was negative. Despite the absence of classical symptoms or definitive biochemical evidence of catecholamine excess, a silent pheochromocytoma could not be excluded. In accordance with international guidelines, preoperative alpha-adrenergic blockade with doxazosin was administered prior to adrenalectomy.

Results: The patient underwent right adrenalectomy with an uncomplicated perioperative course. Histopathological and immunohistochemical analysis revealed a highly proliferative metastatic neuroendocrine neoplasm of pulmonary origin.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Postoperatively, a rapid and marked clinical and radiological deterioration was observed, with PET imaging confirming widespread metastatic disease, including involvement of the contralateral adrenal gland and brain. Partial adrenal insufficiency was diagnosed postoperatively, and glucocorticoid replacement therapy was initiated. Despite prompt oncological management, the disease followed an aggressive course, and the patient ultimately died from complications of advanced metastatic cancer.

Abstract citation ID: lvag096.710

EP109 - ECE_2637 - Pheochromocytoma with catecholamine-induced Takotsubo cardiomyopathy: a case series from a tertiary centre

Sabahat Ahmad[1], Umesha Wijenayake[1], Bahram Jafar-Mohammadi[1], Radu Mihai[1], Shahab Khan[1], El-Muhtadi Saeed Biallah[2] and Christine May[1]
[1]*Endocrinology and Diabetes, Churchill Hospital, Oxford, United Kingdom;* [2]*Royal Berkshire Hospital, Reading, London, United Kingdom*

Pheochromocytomas (PCC) are classically associated with symptoms of headache, palpitations and diaphoresis. Rarely, they can present as Catecholamine-induced Takotsubo cardiomyopathy. The initial presentation maybe difficult to distinguish from ischemic cardiomyopathy. We discuss 5 patients with pheochromocytoma presenting with cardiomyopathy at our tertiary centre.

Case 1: A 40-year-old female, presented with severe LVF (LV failure) and cardiogenic shock but had unobstructed coronaries. Imaging revealed 6 cm adrenal Pheochromocytoma and elevated urinary metanephrines. Her Cardiac MRI revealed normal cardiac function 3 weeks post-event. Adrenalectomy was done. Patient remains under our follow-up, recurrence free for 20 years.

Case 2: A 65-year-old female, admitted with chest pain and STEMI, underwent thrombolysis, but went into cardiogenic shock with LVF, needing IABP. CT angiogram revealed normal coronaries. CT Abdomen revealed: 5 cm LT adrenal mass with 30 HU and elevated Urinary Normetadrenalines: 7.72[0-3.65 micromol/24 hours]) and metadrenalines: 15.64 (0-1.4 micromol/24 hours), leading to PCC diagnosis. Echo revealed severe biventricular dysfunction, which improved quickly. She underwent adrenalectomy and Histopathology revealed PASS 5/20. She has stayed recurrence free during follow-up (15 years).

Case 3: A 75-year-old Female, admitted with central chest pain, BP 226/106, Troponin 270, ECG revealed dynamic changes, progressing to ST elevation on initiation of beta blockade. Echo: Ejection fraction (EF) 35% and inferolateral hypokinesia. PCI found no obstructive lesions. CT-angiogram revealed 5 cm adrenal lesion, and elevated urinary metadrenalines 34, nor-metadrenalines 26. She underwent adrenalectomy (PASS score 6/20).

Case 4: A 54-year-old male, admitted peri-arrest with pulmonary oedema and EF 12%. He had known heart failure secondary to PCC catecholamine exposure. Coronary angiogram revealed concomitant mild-moderate stenosis. He was stabilized medically and was able to have successful adrenalectomy with IABP. Post-operative significant improvement of cardiac status noted, with EF 45%. Histopathology revealed 9 cm tumour, PASS 2/20.

Case 5: A 55-year-old female, initially presented with severe LV impairment: Ejection fraction 30%, frequent ectopics and non-sustained Ventricular tachycardia on Holter monitoring. She was found to have Rt adrenal pheochromocytoma with normetadrenalines of 55.1(0-3.65). Cardiac MRI once stabilized revealed mild LV dysfunction with EF 51% and mitral-regurgitation. She underwent successful adrenalectomy: 75 mm tumour, benign histology and negative genetics. EF post-operatively improved to 57% with improvement in ectopics.

Conclusions: Catecholamine-induced Cardiomyopathy is a rare presenting feature of Pheochromocytoma. Early appropriate diagnosis is essential and allows establishment of alpha-blockade before beta blockade initiation. Despite initial dramatic presentation, all our patients had significant improvement of their cardiac function after removal of pheochromocytoma, indicating reversibility of cardiac impairment and good long-term outcomes.

EP112 - ECE_3340 - DHEAS levels in premenopausal versus postmenopausal women with mild autonomous cortisol secretion

Ioana Maria Posea[1], Vlad Radulescu[1,2], Beatrice Cristea[1], Roxana Fota[1], Monica Livia Gheorghiu[1,2] and Corin Badiu[1,2]
[1]*Adult Endocrinology, Endocrinology IV, National Institute of Endocrinology "C.I Parhon", Bucharest, Romania;* [2]*Department of Endocrinology, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania*

Background: Mild autonomous cortisol secretion (MACS) represents a spectrum of subtle hypercortisolism in patients with adrenal incidentalomas. A low or low–normal circulating dehydroepiandrosterone sulfate (DHEAS) levels are one of the characteristic biochemical feature of this condition. Although the vast majority of circulating DHEAS is of adrenal origin, its secretion demonstrates a well-described physiological decline with advancing age and during the menopausal transition. Consequently, menopausal status may further exacerbate the relative hypoandrogenism already present in MACS. However, the extent to which menopausal status independently influences DHEAS concentrations in women with MACS has not been sufficiently characterized.

Objective: To compare serum DHEAS levels between premenopausal and postmenopausal women diagnosed with MACS and to evaluate whether menopausal status independently predicts DHEAS concentrations after adjustment for potential confounding factors.

Methods: We conducted a cross-sectional observational study including 98 women with MACS. Patients were stratified according to menopausal status into premenopausal and postmenopausal groups. Serum DHEAS, age, body mass index (BMI), basal adrenocorticotropic hormone (ACTH) and cortisol levels after 1-mg dexamethasone suppression (post-1 mg DST) testing were analyzed. Normality was assessed using Shapiro–Wilk and Kolmogorov–Smirnov tests, which demonstrated non-normal distribution for DHEAS and hormonal variables. Therefore, group comparisons were performed using the Mann–Whitney U test. Multivariable linear regression (ANOVA) was applied to evaluate the independent association between menopausal status and DHEAS levels, adjusting for age, BMI, lesion size, and basal ACTH.

Results: Premenopausal women ($n = 14$) demonstrated significantly higher DHEAS levels [median 76.60 μg/dL (27.87-

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

123.67 ug/dL)] compared to postmenopausal women ($n = 84$) [median 36.65 μg/dL (21.6-69.6 ug/dL)]. Both groups had similar BMI, basal ACTH and cortisol levels post-1 mgDST. Mann-Whitney U test demonstrated a statistically significant difference in DHEAS levels between premenopausal and postmenopausal women ($P = .036$). Multiple linear regression analysis confirmed that menopausal status was an independent predictor of DHEAS levels ($P = .002$) after controlling for age, BMI, tumor diameter, and basal ACTH. The overall regression model was statistically significant ($P = .006$).

Conclusions: Women with MACS show significantly different DHEAS profiles according to menopausal status. Premenopausal patients exhibit higher adrenal androgen levels independent of age, BMI, lesion size, and ACTH. This phenomenon suggests endocrine interaction between ovarian decline and adrenal steroidogenesis, making the influence of menopause on DHEAS physiologically interesting despite its predominantly adrenal origin. Menopausal status should therefore be considered when interpreting DHEAS values in women with MACS, as it represents an important determinant of adrenal androgen secretion in this population.

EP113 - ECE_3355 - When an adrenal mass is not adrenal: renal vein leiomyosarcoma presenting as an adrenal incidentaloma

Danai Barlampa[1], Athanasios Fountas[1], Irini Giagourta[1], Dimitra Zerva[1], Dimitrios Bouklas[2], Marina Sassi[2], Labrini Papanastasiou[1] and Athina Markou[1]
[1]*Unit of Endocrinology and Diabetes, Department of Endocrinology, G. Gennimatas General Hospital of Athens, Athens 11527, Greece;* [2]*Surgical Pathologist Department, "G. Gennimatas" General Hospital of Athens, Athens, Greece*

Background: Adrenal incidentalomas represent a common clinical scenario and, while in most cases lesions are benign, large adrenal masses with atypical imaging features raise concern for malignancy. Herein, we present a case of a large mass initially suspected to arise from the left adrenal gland but proven to be a renal vein leiomyosarcoma.

Case Presentation: An 82-year-old woman with a history of arterial hypertension and glaucoma was referred to the Endocrinology Department for evaluation of a left adrenal incidentaloma. Patient underwent an abdominal ultrasound as part of preventive screening which revealed a hypoechoic solid mass with calcifications measuring approximately 6×4.6 cm. Non-contrast CT demonstrated a rounded adrenal lesion with soft tissue density and calcifications measuring 5.65×5.1 cm. Subsequent an adrenal MRI revealed a large, well-defined oval retroperitoneal mass, measuring $6.17 \times 6.48 \times 9.59$ mm, presumed to originate from the left adrenal gland; the lesion exhibited intermediate signal intensity on T1-weighted images, intermediate-to-high signal intensity on T2-weighted and fat-suppressed sequences and heterogeneous intense contrast enhancement. Due to its size, the mass exerted compressive effects on the left kidney with posterior displacement. Endocrine evaluation excluded cortisol and aldosterone hypersecretion while plasma free metanephrine and normetanephrine levels as well as urinary fractionated metanephrines were within normal range. Taking into account the radiological features of the adrenal mass which raised strong suspicion for malignancy an uneventful adrenalectomy was performed. Surprisingly, histopathological examination revealed a leiomyosarcoma of intermediate grade arising from the wall of the left renal vein, with no infiltration of the adrenal cortex. Immunohistochemistry was positive for SMA, desmin, and h-caldesmon, with a Ki-67 index of approximately 35%.

Conclusions: This case highlights the diagnostic complexity of large adrenal-region masses and emphasizes that non-adrenal malignancies, including vascular leiomyosarcomas, may radiologically mimic adrenal tumors.

EP114 - ECE_3413 - Is mild autonomous cortisol secretion (MACS) truly mild?

Mari Minasyan[1], Aleksandra Gamrat-Żmuda[2,3], Maria Borysowicz[4], Alicja Hubalewska-Dydejczyk[1] and Aleksandra Gilis-Januszewska[1]
[1]*Chair and Department of Endocrinology, Jagiellonian University Medical College, Krakow, Poland;* [2]*Department of Endocrinology, Jagiellonian University Medical College, Krakow, Poland;* [3]*Doctoral School of Medical and Health Sciences, Jagiellonian University Medical College, Krakow, Poland;* [4]*Students' Scientific Circle of Department of Endocrinology, Jagiellonian University Medical College, Krakow, Poland*

Introduction: Mild autonomous cortisol secretion (MACS) is a condition of mild cortisol excess due to autonomous secretion by adrenal tumor(s). Patients lack typical Cushing syndrome symptoms but face increased risks of cardiovascular, metabolic, and skeletal complications.

Materials and Methods: We reviewed clinical characteristics of MACS patients hospitalized at a reference endocrinology center in southeastern Poland from 2018-2024. Inclusion criteria: serum cortisol $\geq$1.8 μg/dL in 1 mg dexamethasone suppression test (post-DST), ACTH $\leq$ 20 pg/mL, benign adrenal lesion(s) on imaging. Exclusion criteria: active malignancy, steroid therapy, active infection, alcohol abuse.

Results: A total of 203 patients fulfilled inclusion criteria (74% women; mean age 67 ± 10 years). Mean ACTH concentration was 12.7 ± 4.4 pg/mL, and median post-DST cortisol was 2.83 μg/dL (IQR 1.8-13.9). All patients were referred for evaluation of adrenal incidentalomas. Imaging revealed bilateral adenomas in 37.5%, unilateral left adenomas in 36.5%, unilateral right adenomas in 22%, adrenal hyperplasia in 3.5%, and adrenal trunk thickening in 0.5%. ARMC5 mutations were identified in 7% of patients with bilateral adenomas. Comorbidities were highly prevalent: obesity in 40.5%, overweight in 28%, and disturbances of glucose metabolism in 48%, including poorly controlled diabetes in 23%. Hypertension was present in 84%, with poor control in 23%, dyslipidemia in 71%, and coronary heart disease in 20%. Pathological fractures occurred in 11% of patients, predominantly vertebral (73%). Osteoporosis or osteopenia of the femoral neck was detected in 12.8%, and of the lumbar spine in 13%. Hepatic complications icluded isolated steatosis in 14%, isolated elevation of liver enzymes in 15%, and both in 7.5%.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Thromboembolic events were documented in 5.4%, including deep vein thrombosis (64%), pulmonary embolism (27%) and both in 9%. Psychiatric manifestations included depression (12.8%), anxiety (4.5%), and insomnia (4.5%). Nineteen patients underwent adrenal surgery. All patients with unilateral adenomas (11) achieved remission, whereas outcomes in bilateral disease were heterogeneous (50% no remission, 25% temporary [21-276 months], 25% permanent). 9 patients were included in relacorilant trial (6 bilateral adenomas, 3 post-unilateral relapse).

Conclusions: MACS patients have significant prevalence of cardiometabolic, thromboembolic, skeletal, hepatic and psychological complications. These findings challenge the perception of MACS as a benign condition and underscore the need for refined risk stratification and prospective studies to better define morbidity and guide treatment strategies.

EP115 - ECE_3519 - Assessment of hypothalamic-pituitary-adrenal axis function in adults with sickle cell disease: a retrospective study

Kalliopi Pantelia[1], Vasiliki Antonopoulou[1], Galateia Stathori[1], Stella Tsanaxidou[1], Aikaterini Kapama[1], Andromachi Panagiotopoulou[1], Sofia Chatzi[1], Anna Louisa Chaliasou[1], Angelos Theocharis[1], Chrysa Kalkana[2], Loukia Evliati[2], Marinella Tzanela[1] and Georgia Ntali[1]
[1]*Department of Endocrinology "D. Ikkos", Diabetes Center, EndoERN-Evangelismos General Hospital, Athens, Greece;* [2]*Thalassaemia and Sickle Cell Unit, Evangelismos General Hospital, Athens, Greece*

Introduction: Sickle cell disease (SCD) is a chronic inherited hemoglobin disorder associated with recurrent pain, anemia, and multisystem complications. Endocrine involvement, including dysfunction of the hypothalamic–pituitary–adrenal (HPA) axis, has been described, but remains poorly characterized. Proposed mechanisms include pituitary siderosis in transfusion-dependent patients and hypoxic–vascular injury during sickling episodes, though data in adults with SCD are limited.

Objective: To evaluate HPA axis through basal cortisol/ACTH levels and androgen levels in patients with SCD.

Methods: We conducted a retrospective study of adult patients with SCD followed at the Mediterranean Anemia and Sickle Cell Disease Unit who underwent assessment of basal ACTH and cortisol levels between January 2019 and January 2026. Patients with borderline or low cortisol levels underwent Synacthen stimulation testing, with cortisol measured at 0, 30, and 60 minutes. Serum DHEA-s were evaluated using sex/age-adjusted reference ranges.

Results: Twenty-three patients were included (mean age 53.2 ± 10.6 years, 15 females—8 males); 20/23 (87%) had sickle cell thalassemia, and 3/23 (13%) had homozygous sickle cell disease. Basal serum cortisol levels ranged from 2.3 to 27.6 μg/dL (mean 13.9 ± 5). 3/23 (13%) patients had cortisol levels <10 μg/dL; all underwent Synacthen testing and demonstrated adequate adrenal responses (peak cortisol 21.1-26.2 μg/dL). 11/23 (48%) patients had cortisol levels between 10 and 15 μg/dL and 3/11 (27%) underwent Synacthen testing with adequate peak responses (22-26 μg/dL). 9/23 (39%) had basal cortisol levels >15 μg/dL. Basal ACTH levels ranged from <5 to 58.6 pg/mL, with a mean value (±SD) 24.1 (±14.3) pg/mL. DHEA-s levels were available for 11/23 (47.8%) patients. Reduced DHEA-s levels were noted in 8/11(73%) patients while 3/11 (27%) had levels within the reference range. One patient had DHEA-s levels below the assay detection threshold (<15 μg/dL).

Conclusions: HPA axis function appears largely preserved in patients with SCD at our center, possibly reflecting improved contemporary disease management. However, low DHEA-s levels were observed in the majority of patients, the clinical significance of this finding remains unclear. Limited data—particularly in patients with microdrepanocytic anemia, who comprised most of our cohort—highlight the novelty of this analysis and the need for further studies to better characterize endocrine function in this population.

EP116 - ECE_3742 - The effect of hepatic impairment on the pharmacokinetics of atumelnant for the treatment of congenital adrenal hyperplasia and adrenocorticotropic hormone-dependent Cushing syndrome

Xiaoli Wang[1], Rosa Luo[2], Daria Stypinski[3], Scott Brantley[1], Lei Xu[1], Eduardo De La Torre[1], Alejandro Ayala[1] and Lise Kjems[1]
[1]*Princeton, NJ, United States;* [2]*A2-Ai LLC, Ann Arbor, MI, United States;* [3]*DS Clinical Pharmacology Consulting LLC, Manson, WA, United States*

Atumelnant is a first-in-class, once-daily, oral, selective, melanocortin type 2 receptor antagonist in development for congenital adrenal hyperplasia and adrenocorticotropic hormone-dependent Cushing syndrome. The objective of this study was to compare the pharmacokinetics (PK) of a single dose of atumelnant in participants with varying degrees of hepatic impairment with that of healthy matched control participants. Safety and tolerability of a single dose of atumelnant were assessed.

This was a Phase 1 single-dose, open-label, parallel study. Male and female adults were screened and assigned to a study group according to hepatic function (mild, moderate, or severe impairment) using the Child-Pugh classification system. Healthy control participants were matched with participants with hepatic impairment of varying degrees according to sex, age (±10 years), and body mass index (±20%). All participants received a single oral dose of 10 mg atumelnant in the morning following an overnight fast of ≥10 hours. Participants remained fasted for 4 hours after dosing. Serial blood samples for PK analysis of atumelnant concentrations were collected within 15 minutes before and ≤144 hours after atumelnant administration. Area under the curve (AUC) and maximum plasma concentration (C_{max}) were determined for both total and unbound atumelnant. Adverse events were summarized.

Twenty-three participants with hepatic impairment of varying degrees were included (mild, $n = 8$; moderate, $n = 8$; severe, $n = 7$) and matched with healthy control participants ($n = 13$). Participants with mild, moderate, and severe hepatic impairment exhibited a modest decrease (25%, 57%, and 25%, respectively) in total AUC compared with healthy controls. However, 90% CIs of geometric mean ratio (GMR) of AUC for comparison of mild and severe hepatic impairment relative to normal

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

function included unity. After taking into consideration the fraction of protein binding, the unbound AUC and C_{max} were similar between hepatic impairment groups and healthy controls; GMRs for AUC in mild, moderate, and severe impairment were 0.94, 0.71, and 1.43, respectively, and 1.00, 0.74, and 0.95 for C_{max}, respectively. The 90% CIs for all unbound exposure parameters included unity. There were 5 treatment-emergent adverse events (drug related, $n = 3$, all mild; not drug related, $n = 2$, 1 severe and 1 moderate); all resolved by end of study.

Hepatic impairment did not result in clinically meaningful changes in the total or unbound atumelnant exposures; therefore, dose adjustment of atumelnant is not required in participants with mild, moderate, or severe hepatic impairment. A single 10-mg dose was well tolerated in participants with varying degrees of hepatic impairment.

EP121 - ECE_3641 - Evaluation of the high-dose dexamethasone suppression test in mild autonomous cortisol secretion: what does it add compared with the low-dose dexamethasone suppression test?

Zeynep Elüstü Belten, Ozge Sahin Kimyon, Selin Celik, Hamide Piskinpasa, Meral Mert and Sema Ciftci
Endocrinology and Metabolism, Sağlık Bilimleri Üniversitesi Bakırköy Doktor Sadi Konuk Eğitim Ve Araştırma Hastanesi, Bakırköy, Türkiye

Objective: Mild autonomous cortisol secretion (MACS) is a common hormonal abnormality in patients with adrenal incidentalomas and is characterized by biochemical hypercortisolism in the absence of the classical clinical features of Cushing syndrome. Diagnosis is based on a morning serum cortisol level >1.8 μg/dL following the 1-mg dexamethasone suppression test (DST). However, treatment strategies remain individualized, and clear criteria for adrenalectomy are still lacking. This study aimed to assess the clinical usefulness of the recently recommended high-dose (8-mg) DST in guiding adrenalectomy decisions in patients with MACS.

Methods: Seventy-four patients diagnosed with MACS based on the 1-mg DST during the evaluation of adrenal incidentalomas at a tertiary endocrinology clinic were included. All patients underwent an 8-mg DST, and post-test serum cortisol levels >1.8 μg/dL were considered indicative of a lack of suppression. The frequency of cortisol suppression with the high-dose DST, its association with metabolic and clinical features, its influence on adrenalectomy decisions, and its correlation with 1-mg DST results were analyzed.

Results: The study population comprised 5 men and 69 women, with a mean age of 57 ± 8 years. Mean basal ACTH levels were 6.2 ± 3.3 ng/L. The mean cortisol concentration after the 1-mg DST was 3.3 ± 1.3 μg/dL. Age-and sex-adjusted DHEA-S levels were suppressed in 14% of patients and were within the normal range in the others. Imaging revealed unilateral adrenal adenomas in 70% of cases and bilateral macronodular hyperplasia in the remaining 30%. Only three patients (4.1%) demonstrated cortisol suppression following the 8-mg DST. Paradoxical increases in cortisol levels after the 8-mg DST compared with the 1-mg DST were observed in 50 patients. The three patients who achieved cortisol suppression had metabolic comorbidities but no osteoporosis or osteopenia. Among the remaining patients, cardiometabolic complications were common, including obesity, diabetes or prediabetes, hypertension, dyslipidemia, and reduced bone mineral density. Adrenalectomy was performed in seven patients based on clinical judgment. None of these patients showed cortisol suppression with the 8-mg DST. All patients had suppressed ACTH levels, and DHEA-S levels were suppressed in more than half of them. Positive correlation was observed between cortisol levels after the 1-mg and 8-mg DSTs ($r = 0.656$, $P < .001$).

Conclusions: In patients with MACS, the high-dose DST largely parallels the results of the standard 1-mg DST and provides limited additional diagnostic or therapeutic guidance. Based on the present findings, its role in guiding adrenalectomy decisions remains uncertain. Larger prospective studies are required to clarify the clinical relevance of the 8-mg DST in the management of MACS.

EP122 - ECE_2324 - From cardiac crisis to endocrine diagnosis: pheochromocytoma-induced myocarditis

Ruxandra Costinescu[1], Dana Tilici[1,2,3], Adina Onofrei[1], Mirona Costea[1,2], Beatrice Grecu[1], Claudia Nacea[1], Ana-Maria Arnautu[1], Daniela Greere[1,4] and Diana Paun[1,2,4]
[1]Endocrinology, University Emergency Hospital of Bucharest, Bucharest, Romania; [2]Doctoral School, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania; [3]University Emergency Hospital of Bucharest, Bucuresti, Romania; [4]Bucharest, Romania

Introduction: Recent guidelines and clinical experience indicate a significant increase in the incidence of secondary hypertension. Additionally, secondary hypertension resulting from endocrine disorders is increasingly prevalent. Therefore, in patients presenting with cardiac dysfunction of unknown origin, clinicians should consider the possibility of pheochromocytoma. This approach is especially important, as the literature reports that up to 11% of these cases may develop catecholamine-induced cardiomyopathy. Myocarditis represents a potential manifestation of this form of cardiomyopathy. Given its potential to threaten patient survival, rapid diagnosis is critical for optimal outcomes. Although surgical intervention remains the standard curative approach, preoperative preparation is often challenging and does not eliminate the risk of intraoperative complications.

Purpose: A clinical case from the Bucharest University Emergency Hospital emphasizes the importance of considering pheochromocytoma in the differential diagnosis of patients presenting with unexplained myocarditis, especially when infectious, autoimmune, or toxic causes have been excluded.

Results: A 45 year-old female patient with no prior cardiovascular history presented to the emergency room with acute substernal pain, palpitations, and severe hypertension (SAP = 230 mmHg). Initial evaluation revealed negative T waves in the lateral leads, elevated cardiac troponin I (>6000 ng/L) and increased NT-proBNP (4271 pg/mL). Echocardiography demonstrated diffuse left ventricular hypokinesia with a LVEF of 30%-35%. Emergency coronary angiography showed normal coronary arteries. Cardiac MRI revealed findings consistent with acute

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

myocarditis. The differential diagnosis of acute myocarditis was performed, with infectious, toxic, and autoimmune causes excluded by specific tests. During hospitalization, a chest CT scan incidentally identified a 3.5 cm mass in the left adrenal gland. Endocrinological evaluation, including a detailed history, revealed a pattern of hypertensive episodes at home over the preceding 18 months, associated with severe headache, nausea, and vomiting. Biochemical screening for secondary hypertension demonstrated plasma metanephrine levels exceeding 1.5× ULN and plasma normetanephrine levels exceeding 4× ULN. An abdominal CT scan was done to confirm the presence of an adrenal mass and to exclude paragangliomas. Subsequently, left adrenalectomy was performed following established preoperative protocols. Despite dual therapy with alpha and beta adrenergic receptor blockers, the patient experienced an intraoperative hypertensive episode that resolved spontaneously. Histopathological analysis confirmed pheochromocytoma, and postoperative cardiac function normalized, with a LVEF of 60%.

Conclusions: This case highlights the importance of considering pheochromocytoma in young patients presenting with heart disease of unknown etiology, including myocarditis. Implementing a multidisciplinary approach and developing standardized protocols are crucial for ensuring accurate treatment and favorable long-term outcomes.

EP123 - ECE_1220 - Evolving optimism in the medical management of Cushing's syndrome

Efthymia Kallistrou, Christos Savvidis, Vasiliki Tsiama, Stella Proikaki, Konstantinos Belis, Dimitra Ragia, Dimitra Motsiou and Ioannis Ilias
Department of Endocrinology, Hippokration Hospital, Athens, Greece

Background: Cushing's syndrome (CS) is a therapeutically challenging disorder. Hypercortisolism may persist and CS-related comorbidities are numerous. While medical therapies for CS have evolved, such as with steroidogenesis inhibitors and glucocorticoid antagonists, the perception of their efficacy and safety in the medical literature remains underexplored. Sentiment analysis (SA) of the medical literature—using Artificial Intelligence (AI)—can provide a new assessment metric, which has been shown to be analogous to meta-analysis. Furthermore, SA represents an area that might project researcher attitudes toward therapeutic interventions, possibly highlighting biases or progress.

Methods: From a total of 239 relevant publications, in the years 2000-2025 (PubMed), 30 relevant abstracts were manually extracted by two expert endocrinologists and were included in the analysis. Only abstracts of original publications were retained. Each abstract was reviewed for sentiment attribution by an expert AI (ChatGPT version of October 2, 2025). Sentiments were categorized as positive (with a score of +1: emphasizing efficacy/safety), neutral (0: descriptive/protocols), or negative (−1: highlighting limitations/adverse effects). The distribution of SA scores was assessed by the chi-square test. Temporal trends in SA scores against publication year were evaluated using linear regression and the chi-square for trend across year groups (2000-2009, 2010-2019, 2020-2025).

Results: Eighteen abstracts (60%) were classified as being positive, focusing on drugs like metyrapone and osilodrostat; nine (30%) were neutral, often emphasizing trial protocols and three (10%) were negative, noting toxicity or incomplete remission. Chi-square analysis disclosed significant sentiment differences, with $x^2 = 15.8$, $df = 2$, $P < .001$, with positives being predominant. Linear regression revealed increasing positive sentiments over time, with $\beta = .12$/year, $P = .04$, $R^2 = 0.15$ (Grouped analysis: 2000-2009, $n = 15$, 7 positive, 5 neutral, 3 negative; 2010-2019, $n = 5$, 3 positive, 2 neutral, 0 negative; 2020-2025, $n = 10$, 8 positive, 2 neutral, 0 negative, confirming upward trend, $P = .03$).

Conclusions: Positive sentiments dominate the recent medical literature on CS therapy, apparently reflecting therapeutic advancements. This trend also suggests growing optimism among researchers and may influence clinical adoption. However, the underrepresentation of negatives may also suggest the presence of publication bias.

EP124 - ECE_1276 - Overnight hypoglycaemic episodes in adrenal insufficiency alleviated with modified release hydrocortisone (Efmody); a case report

Muhammad Fahad Arshad[1,2] and Miguel Debono[1,2]
[1]*Endocrinology, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom;* [2]*School of Medicine and Population Health, University of Sheffield, Sheffield, United Kingdom*

Background: Hypoglycaemia is a recognised symptom of adrenal insufficiency (AI), albeit more common in children. Rarely, hypoglycaemia can occur in people with AI despite conventional immediate-release hydrocortisone, due to its inability to mimic the physiological cortisol circadian rhythm.[1]

Case Details: We present the case of a 53-year-old Caucasian female (general practitioner doctor). She was referred to endocrinology for suspected tertiary AI resulting from frequent oral glucocorticoid courses and long-term inhaled glucocorticoids for asthma. AI was confirmed with an abnormal short synacthen test (0 min cortisol 63 nmol/L; 30 min cortisol 197 nmol/L; normal response >430 nmol/L) with low plasma adrenocorticotrophic hormone (ACTH) levels (5 ng/L, reference range 7.2-63.3). Rest of the pituitary function tests and magnetic resonance imaging (MRI) scan of pituitary gland were normal. She was started on hydrocortisone 15 mg per day in divided doses as per her body weight (60.3 kg). However, she started to notice symptoms suggestive of hypoglycaemia, especially around late night and early morning. Low glucose readings were confirmed on capillary glucose testing as well as continuous glucose monitoring (CGM) using Dexcom G6® and Freestyle Libre®. She also underwent a 72-hour fast which ruled out hyperinsulinaemia. Hydrocortisone dose was then increased to total 20 mg/day, but this did not alleviate the symptoms. A trial of increasing the dose beyond 20 mg resulted in manic episodes and therefore abandoned. In view of the timing of symptoms, it was decided to try off-label use of modified-release hydrocortisone, Efmody® 20 mg at nighttime followed by 10 mg in the morning. Efmody® instantly resulted in complete resolution of her symptoms and the low

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

glucose readings on CGM. The dose was then subsequently successfully reduced to 10 mg nocte and 5 mg on waking while under careful monitoring to maintain euglycaemia.

Conclusions: Efmody® mirrors the physiological early morning rise in cortisol compared to conventional glucocorticoid regimens.[1] Though it is currently licensed for patients with congenital adrenal hyperplasia, it can be used in some patients with other causes for AI with inadequate response to standard hydrocortisone treatment.

[1]Cardiff, United Kingdom; [2]Cardiff University, Cardiff, United Kingdom; [3]Living with CAH Patient Support Group, Cambridge, United Kingdom; [4]Royal Hospital for Children, University of Glasgow, Glasgow, United Kingdom; [5]Division of Clinical Medicine, School of Medicine and Population Health, University of Sheffield, Sheffield, United Kingdom; [6]Royal College of Surgeons in Ireland (RCSI), Dublin, Ireland; [7]School of Health and Medical Sciences, City St George's, University of London, London, United Kingdom; [8]Oxford Centre for Diabetes, Endocrinology and Metabolism, NIHR Oxford Biomedical Research Centre, University of Oxford, Oxford, United Kingdom; [9]Neuroscience and Mental Health Innovation Institute, School of Medicine, Cardiff University, Cardiff, United Kingdom

Introduction: There is ongoing debate over the timing of genital surgery in girls with congenital adrenal hyperplasia (CAH), with calls to delay surgery until the girl can consent. However, research suggests patients and parents prefer early surgery with minimal regret.

Aim: To explore adult women's experiences of childhood genital surgery in CAH.

Methods: Virtual semi-structured interviews were conducted with adult women with CAH who had childhood genital surgery and/or their parents, recruited via the Living with CAH support group. Interviews were audio-recorded, transcribed verbatim and analysed using inductive thematic analysis. Ethical approval was obtained.

Results: Twelve women with CAH (aged 20-62 years) and two mothers were interviewed. Most women ($n = 10$) had multiple surgeries in childhood and adolescence, with three undergoing additional adult surgery. Early childhood surgery was not recalled. Three women described trauma from later surgery (>6 years) relating to hospital care (eg, cannulation, exposure to child's death). Ten women were unaware of the procedure performed, while others had a clitoral reduction ($n = 1$) with vaginoplasty ($n = 1$). Eight women reported adverse surgical and psychosexual effects (eg, vaginal stenosis, urinary tract infections, scar tissue, dyspareunia, low libido, genital dysmorphia), with distress limited to two women with incontinence and labial infections. Views on childhood feminising surgery were polarising. Both women distressed by surgical outcomes opposed childhood surgery, reporting their parents were *"forced"* by clinicians. The participants mothers reported acting in their daughter's best interest based on medical advice, with one stating surgery was medically necessary for urogenital sinus. The mothers and daughters blamed clinicians, citing inadequate information about surgery and long-term complications. All other participants felt surgery had been in their best interests, describing it as sex-affirming and medically necessary. They viewed surgery as complementing their female sex and reproductive anatomy, with early surgery perceived to reduce psychological trauma from awareness of the procedure, bullying and male rearing. These women were concerned that labelling CAH as intersex and gender-identity activism were negatively influencing surgical decision for what they viewed an endocrine disorder rather than gender dysphoria. Others supported childhood surgery for medical indications, with *"cosmetic"* feminising procedures delayed until the girl could make an informed decision.

Discussion: Views on genital surgery timing in CAH are varied, with most supporting early surgery despite psychosexual impact. Irrespective of timing, patients and their parents require comprehensive information on surgical treatment and psychological support to enable informed decision making. Larger studies are needed to explore temporal trends.

EP127 - ECE_3655 - Endoscopic ultrasound-guided trans-gastric radiofrequency ablation: an effective and safe alternative treatment for left-sided unilateral aldosterone-producing adenoma

Furnica Raluca, Deprez Pierre, Loubet Antoine and Dominique Maiter

Endocrinologie, Cliniques Universitaires Saint Luc, Brussels, Belgium

Background: Unilateral aldosterone-producing adenomas (APAs) are a potentially curable cause of hypertension through laparoscopic adrenalectomy. However, surgery may not be appropriate for all patients, especially those with significant comorbidities or preferences for less invasive management. Endoscopic ultrasound (US)-guided trans-gastric (TG) radiofrequency ablation (RFA) offers a minimally invasive alternative to treat left-sided APAs which are in close proximity with the stomach.

Methods: This novel approach was successfully performed at our center in two patients with confirmed left-sided APAs and a preference for minimally invasive curative treatment with preservation of left adrenal tissue. Prior to the procedure, co-secretion of cortisol was excluded. Both patients underwent medical preparation with spironolactone (50 mg/day) and an alpha-blocker (terazosin 2.5 mg twice daily for two weeks). Under general anesthesia, the left adrenal nodule was ablated using a 10 mm STARMed needle (Taewoong Medical, Seoul, South Korea) and a generator set at 30 W. No immediate complications were noted post-procedure. Case 1: A 35-year-old woman with familial adenomatous polyposis and a history of total colectomy was diagnosed with a left-sided APA. Abdominal CT-scan imaging

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

showed bilateral adrenal nodules (left: 23 × 16 mm and right: 17 × 12 mm), both evoking benign adenomas. Adrenal vein sampling showed a clear lateralization ratio (10.0) of aldosterone secretion from the left side. Within one week after the procedure, she achieved complete clinical remission of hypertension, allowing discontinuation of spironolactone. At one-month follow-up, her blood pressure remained normal without medication, biochemical cure of PA was confirmed, and CT imaging showed a stable left adrenal lesion with focal areas of necrosis but no delayed complications. Case 2: A 52-year-old woman with a 20-year history of hypertension and a 12 × 19 mm left-sided APA confirmed by adrenal vein sampling, experienced improvement in blood pressure after the procedure. Follow-up is ongoing.

Conclusions: EUS-RFA was an effective and safe alternative treatment for left-sided APAs, devoid of major immediate complications. Long-term follow-up is essential to assess the sustained effectiveness and safety of this innovative technique.

EP128 - ECE_2357 - Autoimmune Addison's disease mimicking tuberculous pleuro-pericardial effusions: a rare presentation and diagnostic pitfall

Mohamed Nhili[1], Aziouaz Fatima[1] and Benkacem Mariem[1]
[1]*Endocrinology, Diabetology and Metabolic Diseases Department, Mohammed VI University Hospital of Tangier, Tangier, Morocco*

Introduction: Primary adrenal insufficiency is a rare but potentially life-threatening condition with nonspecific manifestations. In tuberculosis-endemic regions, its association with pleuro-pericardial effusions often suggests disseminated tuberculosis, representing a major diagnostic pitfall.

Clinical Case: A 51-year-old man with no significant medical history was admitted for severe asthenia, weight loss, anorexia, and hemodynamic instability. Echocardiography revealed a large pericardial effusion requiring urgent drainage. Pericardial fluid analysis showed a hemorrhagic exudate with neutrophil predominance, elevated LDH, and sterile cultures. Laboratory tests revealed normochromic normocytic anemia, neutrophilic leukocytosis, elevated C-reactive protein, and mild hypoalbuminemia. Chest X-ray showed bilateral pleural effusions and upper-lobe opacities. CT scan (CTAP) demonstrated bilateral pleural effusions, apical pulmonary micronodules-highly suggesting tuberculosis-, mild ascites, and a tumefied medial limb of the left adrenal gland without destructive lesions. Pleural fluid analysis revealed a lymphocytic exudate with negative bacteriology and GeneXpert testing. Blood, urine, and sputum cultures were negative. In the setting of hypotension with hyponatremia and hyperkalemia, morning cortisol was markedly low with elevated ACTH levels. Anti-21-hydroxylase antibodies were positive, confirming autoimmune Addison's disease. Hormonal replacement with hydrocortisone and fludrocortisone led to rapid clinical and biological improvement.

Conclusions: Autoimmune Addison's disease may rarely present with pleuro-pericardial effusions and closely mimic disseminated tuberculosis. This association should be considered in patients with unexplained serous effusions and biological features of adrenal insufficiency.

EP129 - ECE_3967 - Primary hyperaldosteronism: a rare cause of hypertension in pregnancy

Georgiana Taujan, Alexandra Mirica, Mihaela Rosu and Iconaru Laura
Department of Endocrinology, CHU Brugmann, Bruxelles, Belgium

Background: Primary hyperaldosteronism is one of the main causes of secondary hypertension, but remains a rare cause of hypertension during pregnancy, with less than 80 cases described in the literature. It presents significant diagnostic and therapeutic challenges, as the physiological activation of the renin–angiotensin–aldosterone system during pregnancy may mask biochemical abnormalities and complicate interpretation of standard diagnostic tests. It also associates an increase risk of maternal and fetal complications.

Case Report: We present the case of a 34 years old pregnant patient with severe hypertension and hypokalemia suggestive of mineralocorticoid excess. The patient associated a history of severe pre-eclampsia during her previous pregnancy, with residual hypertension after the birth. No endocrinological evaluation was done between the pregnancies. The patient presented in the obstetrical clinic at 20 weeks of pregnancy for low abdominal pain. The initial evaluation showed a high-normal blood pressure despite triple therapy and severe growth restriction in the foetus. The laboratory evaluation revealed severe hypokalemia (1.5 mmol/L), with very high aldosterone level (2350 ng/dL) and a low-normal renin (5.4 mUI/L), haemolytic anemia (Hb 9.2 g/DL, LDH 870 U/L) and elevated liver enzymes (ALT 167 U/L, GGT 367 U/L). The abdominal IRM confirmed the presence of a right 2.2 cm adrenal adenoma, with all data supporting the diagnosis of primary hyperaldosteronism with severe preeclampsia and HELPP syndrome. Unfortunately, the baby did not survive. The hypokalemia was corrected with iv and oral supplementation and the patient maintained a high-normal blood pressure despite quadruple therapy. She underwent a right adrenalectomy 1 month later, with complete resolution of hypertension and hypokalemia.

Conclusions: Primary hyperaldosteronism is uncommon in pregnancy and early recognition and individualized management are essential to reduce maternal and fetal morbidity. Multidisciplinary collaboration is crucial for optimal outcomes.

Graz, Graz, Austria; [4]Vienna, Austria; [5]Department of Pediatrics and Adolescent Medicine, Division of Pediatric Pulmonology, Allergology and Endocrinology, Medical University of Vienna, Vienna, Austria; [6]BioTechMed-Graz, Graz, Austria

Research Question: Adrenal incidentaloma are common in the general population. Mild autonomous cortisol secretion (MACS) is associated with an increased cardiovascular mortality, but even patients with non-functioning adrenal adenoma (NFA) might be at risk for cardio-metabolic comorbidities compared to a control group with absence of an adrenal tumor (CON).

Materials and Methods: Seventy-four patients were included in cross sectional analysis [MACS: $n = 25$ (84% females), age: 63 (55-67) years, BMI: 27.00 (24.20-30.50); NFA: $n = 25$ (84% females), age: 61 (54-68) years, BMI: 28.50 (27.50-32.20) and CON: $n = 24$ (75%females), age: 58 (51-64) years, BMI: 27.39 (22.03-30.17). Visceral and ectopic fat stores, as well as heart function were assessed by magnetic resonance imaging and spectroscopy. Orthostatic blood pressure regulation was measured by Schellong tests. Blood was drawn in the fasting state and during an oral glucose tolerance test to assess glucose and lipid metabolism.

Results: The prevalence of hypertension (MACS: 84% vs NFA: 76% vs CON: 43.5%), dyslipidemia (MACS: 96% vs NFA 80% vs CON 62.5%) and prediabetes (MACS: 56% vs NFA 72% NFA vs CON 29.17%) was significantly different between the groups, being highest in MACS. HbA1c ($P = .0429$), HOMA_IR ($P = .007$), fasting insulin ($P = .014$) and c-peptide ($P = .018$) were highest in MACS, indicating worse insulin sensitivity. Epicardial adipose tissue was markedly increased in MACS patients, followed by NFA, with lowest values in CON (MACS: 1159 [930, 1454] mm^2 vs NFA: 873 [638, 1195] mm^2 vs HC: 672 [549, 890] mm^2; $P < .001$). No between-group-differences in cardiac function, intramyocardial fat or intrahepatic fat were observed.

Conclusions: MACS is associated with epicardial adiposity and an adverse cardio-metabolic risk profile, but even NFA might be at higher risk compared to CON.

EP133 - ECE_2419 - Basal cortisol as a predictor of short Synacthen test outcome in a 16-month outpatient audit

Du Soon Swee, Ling Zhu, Shao Ting Lim, Lih Ming Loh and Peng Chin Kek
Department of Endocrinology, Singapore General Hospital, Singapore, Singapore

Background: Outpatient short Synacthen testing (SST) is labour-intensive and capacity-limited. Basal cortisol thresholds that reliably predict SST outcome may support more efficient triage and reduce unnecessary testing. Interpretation of SST results is also influenced by assay methodology. The cortisol assay used at our institution is the Beckman Coulter Access platform, for which a lower pass threshold of 450 nmol/L has been shown to be comparable to the traditional 500 nmol/L criterion. We evaluated the predictive performance of basal cortisol using 500 nmol/L as the reference standard, and explored the potential impact of applying a 450 nmol/L cutoff.

Methods: We conducted a retrospective audit of all outpatient SSTs performed over 16 months (Aug 2024-Dec 2025) at a tertiary centre. Data included SST dose (1 µg vs 250 µg), clinical indication, diagnosis, basal cortisol (SSTbasal, 0 min), and peak cortisol (SSTpeak, 1 µg: 15, 30 or 45 min; 250 µg: 30 or 60 min). Predictive performance of SSTbasal was assessed using receiver operating characteristic (ROC) analysis, using the conventional definition of pass (SSTpeak ≥500 nmol/L) as the primary endpoint, with a secondary exploratory analysis using SSTpeak ≥450 nmol/L. In addition to Youden index thresholds, clinically oriented cutoffs prioritising high sensitivity and high specificity were derived.

Results: A total of 600 outpatient SSTs were analysed (1 µg: 64%; 250 µg: 36%). Using the standard ≥500 nmol/L definition, 314 tests (52.3%) passed; applying the exploratory ≥450 nmol/L definition, 417 tests (69.5%) would be classified as normal, thereby reclassifying 103 (17.2%) as pass. SSTbasal showed good discrimination for predicting outcome under both ≥500 and ≥450 nmol/L criteria: AUC 0.793 and AUC 0.816 respectively, with consistent performance across doses (AUC 0.804-0.848). For SSTpeak ≥500 nmol/L, a basal cortisol ≥338 nmol/L predicted pass with 95% specificity, while <165 nmol/L identified likely failures with 95% sensitivity. For SSTpeak ≥450 nmol/L, corresponding thresholds were ≥320 nmol/L (95% specificity) and <160 nmol/L (95% sensitivity). Basal values between approximately 160-330 nmol/L constituted an indeterminate zone where SST remained most informative.

Conclusions: Basal cortisol provides robust prediction of SST outcome. Exploratory analysis suggests that a 450 nmol/L threshold potentially avoids further evaluation in close to one-fifth of patients. Clinically oriented basal cortisol thresholds enable rational triage of testing, and incorporation of basal cortisol-guided pathways may improve utilisation of limited SST capacity and streamline outpatient endocrine workflows.

Background: Sexual dimorphism in maternal-fetal-placental interactions contributes to higher placental (PW) and birth weights

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

(BW) in boys compared to girls; potentially, maternal progesterone may add to this sexual dimorphism. Progesterone levels increase during healthy pregnancy and promote plasma volume expansion. Diurnal urine (u-) progesterone metabolite pregnanediol-3-glucuronide (PdG) provides a more integrated estimate of overall progesterone exposure compared to serum (s-) progesterone.

Objective: To investigate associations between maternal third trimester progesterone exposure and PW or BW in offspring, including potential effects of fetal sex. Secondarily, to examine associations between 24-hour (h) u-PdG and 24 h u-sodium retention, as well as maternal blood pressure (BP).

Methods: This prospective observational study included 1503 mother-child dyads (786 boys and 703 girls) from the Odense Child Cohort. Maternal progesterone exposure was assessed in gestational week 28 by measurement of fasting morning s-progesterone ($n = 1503$) and 24 h u-PdG ($n = 566$). 24 h u-sodium retention was estimated from 24 h u-sodium excretion. Progesterone and sodium concentrations were quantified using liquid chromatography-tandem mass spectrometry.

Results: In boys, 1 µmol/day increase in maternal u-PdG was associated with higher PW and BW (β = 1.11 g [95% CI: 0.61; 1.39]) and (β = 2.14 g [95% CI: 0.97; 3.31]), respectively; there was no significant association in girls. Higher maternal 24 h u-PdG was associated with higher PW and BW (β = .69 g [95% CI: 0.41; 0.96]) and (β = 1.49 g [95% CI: 0.65; 2.33]), respectively, in the whole cohort. In boys, 1 nmol/L increase in maternal s-progesterone was associated with higher PW and BW of 0.42 g (95% CI: 0.27; 0.56) and 0.73 g (95% CI: 0.31; 1.15), respectively; correspondingly in girls, s-progesterone associated with higher PW and BW of 0.44 g (95% CI: 0.28; 0.61) and 0.95 g (95% CI: 0.46; 1.44), respectively. Higher maternal s-progesterone was positively associated with higher PW and BW (β = .43 g [95% CI: 0.32; 0.54]) and (β = .82 g [95% CI: 0.49; 1.15]), in the whole cohort. One mmol/day increase in maternal 24 h u-PdG was associated with more retention of diurnal u-sodium of −0.21 mmol/day (95% CI: −0.30; −0.11). No significant association was found between u-PdG or s-progesterone and maternal BP.

Conclusions: Maternal diurnal progesterone exposure may add to the higher PW and BW in boys compared to girls. Furthermore, higher progesterone exposure was associated with more sodium retention, but there was no association between progesterone exposure and maternal BP.

EP136 - ECE_2691 - The impact of exogenous corticosteroids on outcomes in medical admissions

Jessica Mangion[1], Rebecca Attard[2], Brett Grech[2], Jasmine Borg[2], Jade Borg[2] and Mark Gruppetta[1]
[1]*Endocrinology & Diabetes Division, Department of Medicine, Mater Dei Hospital, Msida, Malta;* [2]*Department of Medicine, Mater Dei Hospital, Msida, Malta*

Introduction: Glucocorticoids are commonly prescribed; however, the impact of chronic corticosteroid use on outcomes during medical admissions is less studied. This case-control study aims to evaluate their effects on mortality, re-hospitalization rates, biochemical markers, blood count indices and serum inflammation-based scores.

Method: A retrospective analysis of 5565 medical admissions from October 2021, February 2022 and June 2022 was performed. Among these, 230 patients who were on chronic corticosteroids were matched with controls based on age, sex, and diagnosis. Clinical and biochemical data were collected, and patients were followed up until June 2025 or death. Univariate analysis identified differences between cases and controls.

Results: 22.8% ($n = 105$) of cases were males, and the median age was 72 years (IQR 64-81). Inhaled corticosteroids were the most common in 67.0% ($n = 154$), followed by oral prednisolone in 17.8% ($n = 41$) and oral dexamethasone in 9.6% ($n = 22$). Respiratory diseases accounted for 73.9% ($n = 170$) of corticosteroid indications, followed by malignancy in 10.9% ($n = 25$). The type of corticosteroid was associated with mortality at 90 days ($P < .001$) and at 1 year ($P < .001$). Statistically significant differences were noted in the neutrophil-lymphocyte ratio (NLR) (P .001), lymphocyte-monocyte ratio (LMR) (P .001), platelet-lymphocyte ratio (PLR) (P .004) and systemic immune-inflammation index (SIII) (P .019). Patients on corticosteroids had a significantly higher 1-year mortality compared to controls (9.3% vs 4.6%, $P = .003$). Cases had lower serum urea (P .027) and serum chloride (P .001). These remained significant when those on oral corticosteroids were compared to their controls (1 year mortality $P = .022$; urea $P = .004$; chloride $P < .001$). Additionally, patients on oral corticosteroids also had a higher NLR ($P = .007$). Patients on dexamethasone and prednisolone had lower serum sodium (P .008) and chloride ($P < .001$) and elevated NLR (P .002) compared to their controls. Additionally, they also exhibited a lower LMR ($P = .038$) and higher SIII ($P = .027$). Sodium, chloride, NLR and SIII remained significant even after malignancy was excluded. Inhaled corticosteroid users showed no significant biochemical or haematological differences but showed a significantly higher 1-year mortality than their controls ($P = .049$).

Conclusions: These results indicate distinct biochemical and inflammatory profiles in patients on chronic corticosteroids, particularly those on higher potency, which may correlate with poorer prognosis during medical admissions. However, larger studies are required to validate these associations and clarify underlying mechanisms.

EP137 - ECE_1773 - Twenty-one years of cardiometabolic risk evolution in women with NCCAH: a longitudinal cohort analysis

Jéssica Me Lin Ie, Ana Carolina Maués de Oliveira, Nicholas Silvestre de Souza Trigueiro, Guiomar Madureira, Larissa Gomes, Ana Claudia Latronico, Berenice Bilharinho de Mendonça, Marisa Passarelli and Tania Bachega
Division of Endocrinology and Metabolism, Laboratory of Hormones and Molecular Genetics (LIM/42), Hospital das Clínicas, Faculty of Medicine, University of São Paulo, São Paulo, Brazil

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Context: Evidence of cardiometabolic risk in nonclassical congenital adrenal hyperplasia (NCCAH) is still limited and largely derived from cross-sectional or mixed cohorts. The long-term metabolic impact of glucocorticoid (GC) therapy and hyperandrogenic exposure remains unclear.

Objective: To characterize long-term trajectories of metabolic markers and the influence of GC use and hyperandrogenic exposure in women with NCCAH.

Design, Setting, and Participants: Longitudinal cohort of 31 women with NCCAH at a tertiary reference center, contributing up to 21 years of follow-up (477 patient-years). Annual assessments included body mass index (BMI), blood pressure (BP), HDL-c, fasting plasma glucose (FPG), triglycerides (TG), 17-hydroxyprogesterone (17O HP) and total testosterone levels. Longitudinal determinants were evaluated using linear mixed-effects models.

Results: BMI increased progressively over time and showed the strongest associations across cardiometabolic parameters. Higher BMI was associated with lower HDL-c ($P = .001$), higher FPG ($P = .007$), and higher systolic and diastolic BP ($P = .001$). Current GC use was associated with lower BMI ($P = .01$) and higher HDL-c ($P = .015$), whereas cumulative duration of GC therapy correlated with higher BMI and lower HDL-c, largely reflecting between-subject differences rather than within-individual effects. The intraclass correlation indicated that most BMI variability reflected inter-individual differences rather than changes over time within the same individual. Testosterone showed no independent metabolic associations except for an inverse relationship with HDL-c ($P = .039$). HDL-c and TG shifted unfavorably over time but remained within reference ranges; no independent predictors of TG trajectories were identified.

Conclusions: In this cohort, long-term cardiometabolic trajectories were mainly characterized by progressive increases in BMI. Current physiological GC use was not associated with adverse changes in the metabolic parameters evaluated. However, a negative impact of hyperandrogenism on HDL-c levels was observed.

EP138 - ECE_2888 - Higher frequency of meningiomas in patients with pathogenic variants of the ARMC5 gene predisposing to primary bilateral macronodular adrenal hyperplasia

Victoria De Wit[1], Lucas Bouys[1], Anna Vaczlavik[1], Laurence Guignat[1], Anne Jouinot[1], Lionel Groussin[1], Guillaume Assié[1], Albain Chansavang[2] and Jérôme Bertherat[1]

[1]Reference Center for Rare Adrenal Diseases, Endocrinology Department, Cochin Hospital, Paris 75014, France; [2]Oncogenetic Unit, Genetic Department, Cochin Hospital, Paris 75014, France

Context: Primary Bilateral Macronodular Adrenal Hyperplasia (PBMAH) is a rare etiology of Cushing syndrome. Inactivating pathogenic germline variants in *armadillo repeat-containing 5 (*ARMC5) gene are responsible for 20%-25% of PBMAH. ARMC5 is expressed in many organs and previous findings suggest an association of PBMAH due to *ARMC5* mutations with specific clinical characteristics, as the presence of meningiomas. This study aims to assess the prevalence of meningiomas in patients with pathogenic *ARMC5* mutations.

Results: This retrospective monocentric study included fifty-five individuals with *ARMC5* pathogenic variant (38 index cases and 17 related cases). Thirty-five (64%) were women and the median age was sixty years old (21-93). Thirty-one patients underwent a neuroimaging. Among those, five had a radiological diagnosis of meningioma (3 index cases and 2 related cases). Four of them had unique lesions and one patient had two localizations. One patient underwent surgical treatment, another received radiotherapy and three had neuroimaging follow-ups.

Conclusions: We report a higher prevalence of meningiomas in patients with pathogenic *ARMC5* mutations (16%) than in the general population (0.5%-2%). Larger studies are needed to confirm our data. A systematic neuroimaging to exclude the presence of meningiomas in patients with *ARMC5* pathogenic variants should be considered. Use of treatment known to favor meningiomas (cyproterone acetate or Nomégestrol/Chlormadinone acetate) should also be cautious in such patients.

Abstract citation ID: lvag096.730

EP139 - ECE_3392 - Assessment of HPA axis in adult patients with β-thalassemia: a retrospective study

Kalliopi Pantelia[1], Vasiliki Antonopoulou[1], Galateia Stathori[1], Stella Tsanaxidou[1], Aikaterini Kapama[1], Andromachi Panagiotopoulou[1], Sofia Chatzi[1], Sofia Georgiadi[1], Chrysa Kalkana[2], Loukia Evliati[2], Marinella Tzanela[1] and Georgia Ntali[1]

[1]Department of Endocrinology "D. Ikkos", Diabetes Center- EndoERN-Evangelismos General Hospital, Athens, Greece; [2]Thalassaemia and Sickle Cell Unit, Evangelismos General Hospital, Athens, Greece

Introduction: β-thalassemia is a chronic inherited hemoglobin disorder characterized by ineffective erythropoiesis, chronic anemia, and iron overload, particularly in transfusion-dependent patients. Endocrine complications are well recognized and are largely attributed to iron deposition in endocrine organs. Impairment of the hypothalamic–pituitary–adrenal (HPA) axis has been described, although its prevalence and clinical relevance in adults remain incompletely defined. In addition, adrenal androgen production, as reflected by serum DHEA-S is frequently reduced despite preserved HPA axis function, suggesting dissociation of cortisol and adrenal androgen secretion.

Objective: To evaluate cortisol/ACTH and adrenal androgen levels in adult patients with β- thalassemia.

Methods: This retrospective study included adult patients with β-thalassemia followed at the Mediterranean and Sickle Cell Anemia Unit of our hospital who underwent assessment of basal ACTH and cortisol between January 2019 and January 2026. Patients with borderline or low morning cortisol levels underwent dynamic testing with Synachten with cortisol measured at baseline, 30, and 60 minutes. DHEA-S levels were interpreted according to sex and age-adjusted reference ranges.

Results: A total of 60 patients with β-thalassemia were included (mean age 51.3 years, SD: 10.3), the majority of whom were transfusion-dependent. Basal cortisol levels ranged from 7.8 to 41 μg/dL, with a mean value (±SD) of 15.1 (±5.8) μg/dL. 6/60 (10%)

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

patients had morning cortisol levels <10 μg/dL and Synachten was performed in two of them. 28/60 (47%) demonstrated morning cortisol between 10-15 μg/dL and Synachten was performed in 6 of them. 26/60 (43%) had morning cortisol >15 μg/dL. Dynamic testing resulted in adequate cortisol responses in all cases. Basal ACTH levels ranged from <5 to 127 pg/mL, with a mean value (±SD) of 28 (±25.6). DHEA-S levels were available in 51 patients and were interpreted according to sex and age-adjusted reference ranges. DHEA-S levels were decreased in 30/51(59%) and normal in 21/51 (41%) patients.

Conclusions: In this cohort of adult patients with β-thalassemia, adrenal responsiveness was largely preserved despite longstanding disease and transfusion exposure. These findings may reflect improved iron chelation strategies and contemporary multidisciplinary care. Nevertheless, low DHEA-S levels were observed in a subset of patients. DHEA-S could theoretically represent a sensitive marker of subtle adrenal dysfunction in this population. Further prospective studies are needed to better define HPA axis function and its relationship with iron burden and other endocrine abnormalities in thalassemia.

EP140 - ECE_3179 - Android/gynoid fat ratio correlates with atherogenic and insulin resistance indices after 6 months of testosterone therapy in trans men

Gökçen Ünal Kocabaş[1], Ezgi Ulaş[1], Banu Sarer Yurekli[1], Hüseyin Cihan[2,3], Mehmet Yigit[1], Melih Bektas[1], Aysel Mammadyarzada[1], Esma Pehlivan[1], F. Kübra Gülpınar[1], Sercan Kamalak[1] and Murat Tozman[1]
[1]*Izmir, Türkiye;* [2]*University of Basel, Basel, Switzerland;* [3]*Department of Endocrinology, University Hospital Zürich, Zurich, Switzerland*

Background: Testosterone used as gender-affirming hormone therapy (GAHT) in trans men may alter regional fat distribution and cardiometabolic risk. We evaluated DXA-derived adiposity indices and their associations with the atherogenic index of plasma (AIP) and triglyceride–glucose (TyG) index during early testosterone therapy.

Methods: Twenty-one trans men initiating intramuscular testosterone esters (every 3 weeks) were assessed at baseline and month 6. Anthropometrics, fasting glucose/insulin and lipid parameters were obtained; body composition was measured by DXA. AIP was calculated as log(triglycerides/HDL-C), HOMA-IR was derived, and TyG index was calculated as log(triglycerides [mmol/L] × glucose [mg/dL]).

Results: Mean age was 27.43 ± 4.98 years. HOMA-IR did not change significantly (baseline 1.9 [IQR 2.65] vs month 6 2.07; $P = .156$). DXA demonstrated decreased trunk fat percentage (37.47 ± 9.04-35.00 ± 9.10; $P = .007$) and total fat percentage (39.84 ± 7.58-36.26 ± 7.68; $P < .001$), with increased trunk lean + BMC (20 140.55 ± 3418-22 581 ± 4193.7 g; $P < .001$). Android/gynoid ratio increased (0.924 ± 0.14-0.97 ± 0.14; $P < .001$) and correlated positively with AIP ($r = 0.653$, $P = .003$) and TyG index ($r = 0.512$, $P = .03$) at month 6.

Conclusions: DXA-derived android/gynoid ratio is associated with AIP and TyG index in trans men receiving testosterone GAHT, suggesting that regional fat distribution may serve as an early marker of cardiometabolic risk during therapy.

Parameter	Testosterone (Month 0)	Testosterone (Month 6)	*P* value

EP141 - ECE_3552 - Resistant hypertension and severe osteoporosis associated with mild autonomous cortisol secretion

Mariam Orjonikidze, Nino Zavrashvili and Mariam Bulashvili
Tbilisi Institute of Medicine (TIM), Tbilisi, Georgia

Background: Adrenal incidentalomas are commonly encountered in clinical practice, with prevalence increasing with age. While most lesions are benign and non-functioning, a subset exhibits subtle hormonal activity. Mild autonomous cortisol secretion (MACS) is the most frequent functional abnormality and is defined by incomplete cortisol suppression after dexamethasone administration in the absence of overt Cushingoid features. Despite its mild biochemical presentation, MACS is associated with increased cardiometabolic risk, including resistant hypertension, diabetes, and skeletal fragility.

Case Presentation: We report the case of a 61-year-old woman with a history of an adrenal incidentaloma detected in 2021 without subsequent follow-up and established osteoporosis treated with denosumab. In December 2023, she presented with resistant hypertension, with systolic blood pressure persistently around 160 mmHg despite triple antihypertensive therapy. Associated symptoms included tachycardia, dizziness, and hyperhidrosis. Initial hormonal evaluation revealed inadequate cortisol suppression following a 1 mg dexamethasone suppression test (DST), with a cortisol level of 0.9 μg/dL. Repeat DST in February 2024 confirmed MACS, demonstrating a cortisol level of 3.0 μg/dL. Investigations: Computed tomography of the abdomen identified a 30 mm left adrenal mass with radiological characteristics consistent with a benign adenoma. No clinical signs of overt hypercortisolism were present.

Management and Outcome: Given the presence of resistant hypertension and severe osteoporosis in the context of confirmed MACS, the patient underwent left adrenalectomy in May 2025. Histopathological examination confirmed an adrenocortical adenoma. The postoperative course was uncomplicated,

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

and the patient continues follow-up for reassessment of antihypertensive therapy and osteoporosis management.

Conclusions: This case illustrates that MACS, despite the absence of classic Cushingoid features, may have clinically significant consequences, including resistant hypertension and skeletal fragility. It highlights the importance of systematic hormonal evaluation and long-term follow-up of adrenal incidentalomas. Early recognition and timely surgical intervention in selected patients may reduce cardiometabolic and skeletal complications and improve clinical outcomes.

EP142 - ECE_1255 - Impact of maternal hypertension subtypes on offspring growth and endocrine development: a structured review

Ashraf Soliman, Fawziya Alyafei, Manal Musallam, Nada Alaaraj, Noor Hamed and Shayma Ahmed
Pediatric Endocrinology, Hamad Medical Center, Doha, Qatar

Background: Maternal hypertension—including preeclampsia, gestational hypertension, and chronic hypertension—is a major contributor to fetal growth restriction and neonatal complications. Evidence indicates these conditions also influence long-term endocrine and metabolic programming in offspring.

Objective: To compare how different forms of maternal hypertension affect offspring growth patterns and endocrine function from birth through adolescence.

Methods: A structured review of cohort and clinical studies published in the past 25 years was conducted. Outcomes were categorized by hypertension subtype and developmental stage, with a focus on birth anthropometry, growth trajectories, GH–IGF-1 and HPA axes, insulin sensitivity, and pubertal development.

Results: Preeclampsia demonstrated the greatest adverse impact. Offspring had markedly reduced birth weight and length, high rates of SGA, and low IGF-1, IGFBP-3, and leptin levels at birth. Neonates frequently exhibited elevated cortisol and ACTH, indicating heightened HPA-axis activation. These children showed slower or incomplete catch-up growth, persistently lower IGF-1 levels, and increased risk of insulin resistance, adiposity rebound, and earlier puberty, especially when rapid postnatal weight gain occurred. Bone age was often delayed initially but could accelerate during catch-up, potentially reducing adult height. **Chronic hypertension** was associated with moderate growth restriction, particularly in longstanding or poorly controlled cases. Birth weight and length were reduced but typically to a lesser degree than in preeclampsia. Endocrine alterations included mildly reduced IGF-1, slightly elevated cortisol, increased BMI in later childhood, and higher adolescent metabolic risk, especially in offspring born SGA. **Gestational hypertension** produced the mildest and most variable effects. Most infants had near-normal growth parameters, though some demonstrated mild reductions in birth size or subtle hormonal changes. Long-term endocrine outcomes were generally preserved unless gestational hypertension developed early or was accompanied by placental dysfunction. Across all subtypes, infants born SGA—regardless of maternal hypertension category—showed increased risk of reduced insulin sensitivity, central adiposity, earlier pubertal onset, and altered HPA-axis reactivity. Thyroid function remained largely intact in all groups.

Conclusions: Maternal hypertension exerts subtype-specific effects on growth and endocrine programming. Preeclampsia carries the highest risk, chronic hypertension confers moderate risk, and gestational hypertension causes limited long-term disruption. Early endocrine and growth monitoring in exposed offspring is recommended to mitigate adverse developmental outcomes.

EP143 - ECE_1333 - Audit of plasma free metanephrine and outcomes in patients with borderline elevations

Bengur Taskiran[1,2], Lakshmi Sankaran[1], Simon Whitehead[1] and Jimmy Li Voon Chong[1]
[1]*Winchester, United Kingdom;* [2]*Endocrinology, General Internal Medicine, Hampshire Hospitals Foundation Trust, Winchester, United Kingdom*

Background: There are currently no dedicated guidelines for the management of borderline or non-conclusive plasma or urinary metanephrine results. Interpretation is particularly challenging when values are less than three times the upper limit of normal. Test results may be influenced by dietary factors, medications, and pathophysiological conditions. False positive results occur in approximately 20% of cases and 20%-30% of patients with pheochromocytoma/paraganglioma may present with borderline elevations. Although follow-up is recommneded for all elevated borderline results, previous reports indicate that only 28% of patients with elevated values receive appropriate follow-up.

Aim: To identify patients with borderline elevated plasma free metanephrine levels, and to evaluate their management and testing conditions.

Methods: A retrospective review from a cohort of 137 patients aged 16 or above, who underwent plasma metanephrine testing between April 2024 and March 2025, was conducted. Plasma metanephrines were measured using high-performance liquid chromatography.

Results: The most common indications for testing were adrenal masses and/or blood pressure related disorders. Eighty-eight patients had hypertension. Seventeen had elevated normetanephrines and 3 had elevated metanephrines; all were less than 3 times upper normal limit. None had both elevated normetanephrines and metanephrines. All patients had normal levels of 3-methoxytyramine. Twelve were male. Mean age was 46.85 ± 2.21 years. Sixteen had hypertension. Six had adrenal mass on imaging. Glomerular filtration rate ranged between 59 and >90. Nine tests were done by endocrine specialist nurse following a protocol including supine position and 30 min rest, 5 were done as inpatient without following a certain protocol. The two groups (high vs normal) did not differ significantly according to gender, smoking status, protocol of testing, test setting, hypertension status, or stopping medications with interference with results. Mean age of normal group was significantly higher. Eleven patients had repeat tests and appropriately managed by endocrinology. Nine patients were lost to follow-up despite five with high repeat tests.

Conclusions: Aging and adherence to testing protocol did not significantly influence borderline elevations in plasma metanephrine levels in this cohort. However, the small size of the

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

study may have limited to detect meaningful differences. Despite a substantial loss to follow-up rate (45%), this remained lower than previously reported in the literature (72%). Targeted measures are needed to reduce to improve drop-out rates and address system related factors such as delayed appointments.

EP145 - ECE_2148 - Histopathological diagnosis of surgically treated indeterminate adrenal masses

Sofia Georgiadi[1], Chrysoula Koukoula[1], Eleni Lazaridou[2], Stavroula Tzamouri[2], Georgios Kyriakopoulos[3], Sofia Avgousti[3], Kalliopi Koniari[3], Olga Papalou[1], Angeliki Angelidou[1], Sofia Chatzi[1], Stylianos Kapiris[4], Maria Sotiropoulou[4], Marinella Tzanela[1] and Dimitra Argyro Vassiliadi[1]

[1]Department of Endocrinology "D. Ikkos", Diabetes Center- EndoERN - Evangelismos General Hospital, Athens, Greece; [2]Department of CT/MR, Evangelismos General Hospital, Athens, Greece; [3]Department of Pathology, Evangelismos General Hospital, Athens, Greece; [4]Third Department of Surgery, Evangelismos General Hospital, Athens, Greece

Introduction: Adrenal incidentalomas are increasingly detected due to widespread use of advanced imaging modalities. Imaging evaluation plays a central role in assessing the risk of malignancy, with homogeneous, lipid-rich lesions (<10 Hounsfield units [HU] on unenhanced CT) considered benign. However, a substantial proportion of adrenal masses do not meet these criteria and are classified as indeterminate. Indeterminate adrenal masses are incidentally discovered lesions lacking definitive imaging or biochemical features of benignity or malignancy. While many are ultimately benign—most commonly lipid-poor adrenocortical adenomas—the differential diagnosis includes adrenocortical carcinoma and other rare malignant entities, posing a significant diagnostic challenge.

Aim: To report histopathological diagnoses of surgically treated indeterminate adrenal masses and assess their relationship with preoperative imaging characteristics, including CT in all patients and MRI and/or FDG-PET, where available.

Methods: We retrospectively identified patients who underwent adrenalectomy for indeterminate masses between 2022 and 2025. Patients with lesions showing clear features of malignancy (metastases, compatible biochemical findings, or known extra-adrenal primary malignancy) or diagnostic biochemical evidence of pheochromocytoma were excluded. Collected data included demographics, hormonal activity, imaging features and histopathological diagnosis.

Results: 32 patients were included (mean age 60.5 ± 12.4 years). Mean tumor size was 5.9 ± 3.2 cm (range 2.4-17 cm), with a mean unenhanced CT attenuation of 26.5 ± 9.7 HU. FDG-PET was available in 19 patients, with a mean SUVmax of 4.6 ± 2.0. Twenty patients (63%) had benign lesions: 16 lipid-poor adrenocortical adenomas, one black adenoma, one adrenal oncocytoma, two ganglioneuromas. Three patients had adrenocortical oncocytic neoplasms of uncertain malignant potential. Nine patients (28%) had malignant lesions: five adrenocortical carcinomas and four non-adrenocortical malignancies (metastasis, angiosarcoma, lymphoma, liposarcoma). Regarding hormonal activity, 12 patients exhibited mild autonomous cortisol secretion. Tumor size (5.4 vs 5.9 cm), unenhanced CT attenuation (26.4 vs 29.5 HU), and SUVmax (4.7 vs 6.7) did not differ significantly between benign and malignant lesions. Notably, no malignant lesion had unenhanced CT attenuation <20 HU, whereas five benign lesions and one of uncertain malignant potential did.

Conclusions: Indeterminate adrenal masses represent a diagnostic challenge, encompassing a broad spectrum of benign and malignant conditions. Although additional imaging modalities may aid risk stratification, no single technique reliably establishes a definitive diagnosis, and significant overlap exists between benign and malignant lesions, including FDG-PET uptake. Consequently, final diagnosis often remains dependent on histopathological evaluation following surgery, underscoring the need for individualized, multidisciplinary diagnostic approach.

EP146 - ECE_2248 - Primary aldosteronism and prolactinoma: an intriguing coincidence or partners in crime?

Sanja Borozan[1], Snezana Vujosevic[1], Sreten Kavaric[1], Emir Muzurovic[1], Natasa Radovic[2], Aleksandar Filipovic[1,3] and Karin Zibar Tomsic[4]

[1]Department of Endocrinology, Clinical Centre of Montenegro, Podgorica, Montenegro; [2]Intermedica Clinic, Herceg Novi, Montenegro; [3]Department of Endocrine Surgery, Clinical Centre of Montenegro, Podgorica, Montenegro; [4]Clinical Centre Zagreb, Zagreb, Croatia

Primary aldosteronism (PA) and prolactinoma are common endocrine disorders, yet their co-occurrence has occasionally been documented. However, emerging data suggest this conjunction may be more than coincidental. Recent analyses, including small case series and retrospective reviews, have reported a higher-than-expected prevalence of hyperprolactinemia among PA cohorts. Although a definitive causal link remains elusive, hypotheses suggest shared pathogenic mechanisms, such as the paracrine effects of elevated aldosterone on pituitary lactotrophs, or a higher expression of the prolactin receptor gene in aldosterone-producing adenomas. We describe a case that contributes to this evolving clinical discourse.

A 55-year-old man presented with profound fatigue, muscle weakness, palpitations, and polyuria-polydipsia syndrome. Laboratory evaluation revealed severe hypokalemia (1.67 mmol/L) with kaliuresis. A retrospective review identified persistent hypokalemia over the preceding three years, previously uninvestigated. His past medical history included hypertension diagnosed at age 42, poorly controlled on perindopril 10 mg and amlodipine 10 mg. Initial endocrine workup showed adequate suppression of cortisol on the 1 mg overnight dexamethasone test. However, his plasma aldosterone level was 785 pmol/L, with a suppressed plasma renin concentration of 1.9 mIU/L, yielding an elevated aldosterone-to-renin ratio (ARR) of 413.2 pmol/mIU. A confirmatory saline infusion test demonstrated non-suppressible aldosterone (937 pmol/L), confirming PA. Adrenal CT suggested bilateral hyperplasia, but adrenal vein sampling lateralized to the right. The patient underwent a successful right laparoscopic adrenalectomy, resulting in normokalemia without supplementation and normalization of blood pressure off all antihypertensive therapy. Concurrent hormonal evaluation revealed persistently elevated prolactin levels in profile

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

(ranging from 6829 to 9755 mIU/L after dilution; macroprolactin negative), with all other pituitary axes within normal limits and no symptoms of sexual dysfunction. Subsequent pituitary MRI identified a microadenoma consistent with a prolactinoma, for which therapy with cabergoline was initiated.

This case of concurrent lateralized PA and prolactinoma adds to the growing evidence challenging the notion of a purely incidental association. It underscores the importance of a holistic endocrine evaluation, while further investigations of common genetic markers or proliferative pathways could unlock new insights into the pathogenesis of both conditions.

EP147 - ECE_1599 - Pregnancy-induced Cushing syndrome: diagnosis and management of a rare endocrine disorder

Ronit Koren[1,2,3], Efrat Markus[4,5], Yifat Wiener[1,2,3] and Yona Greenman[3,6,7]

[1]Shamir Medical Center, Zerifin, Israel; [2]Division of Maternal Fetal Medicine, Department of Obstetrics and Gynecology, Beer Yaakov, Israel; [3]Gray Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; [4]Shamir Medical Center, Zerifin, Israel; [5]Endocrine Institute, Beer Yaakov, Israel; [6]Tel Aviv-Sourasky Medical Center, Tel Aviv 64239, Israel; [7]Institute of Endocrinology, Metabolism, Diabetes and Hypertension, Tel Aviv, Israel

Introduction: Endogenous Cushing syndrome (CS) during pregnancy is a rare condition associated with substantial maternal and fetal morbidity and mortality. Pregnancy-induced Cushing syndrome (PICS) represents an exceptionally rare subtype, resulting from aberrant expression of luteinizing hormone (LH) and/or human chorionic gonadotropin (hCG) receptors on maternal adrenal cortical cells. We report a case of PICS without detectable adrenal abnormalities on imaging, successfully managed with medical therapy until delivery.

Case Report: A 25-year-old woman presented at 26 weeks of gestation with newly diagnosed hypertension. Physical examination revealed severe acne, hirsutism, a dorsocervical fat pad, and extensive violaceous striae over the abdomen, arms, and legs. Biochemical evaluation demonstrated markedly elevated urinary free cortisol (UFC) levels (1659 μg/24 h; reference range 13-75 μg/24 h). Serum cortisol concentrations were significantly elevated in the morning (47.56 μg/dL) and remained unsuppressed at midnight (47.12 μg/dL). Midnight salivary cortisol was >3 μg/dL (reference <0.12 μg/dL), and plasma adrenocorticotropic hormone (ACTH) was suppressed (1.5 pg/mL; reference range 7.2-63 pg/mL), consistent with ACTH-independent hypercortisolism. Pituitary, adrenal, and ovarian imaging revealed no pathological findings. Medical treatment with metyrapone was initiated and gradually titrated to 2 g/day. Additional therapies included unfractionated heparin for venous thromboembolism prophylaxis, vitamin D and calcium supplementation, antihypertensive treatment with labetalol and amlodipine, insulin detemir for glycemic control, and Pneumocystis jirovecii pneumonia prophylaxis with trimethoprim-sulfamethoxazole due to severe hypercortisolism. Clinical and biochemical improvement was observed, with serum cortisol decreasing to 32 μg/dL, UFC to 530 μg/24 h, and midnight salivary cortisol to 0.59 μg/dL. A multidisciplinary team recommended on a cesarean section, that was performed at 34 + 5 weeks of gestation, resulting in the delivery of an appropriate-for-gestational-age healthy neonate, who required cortisol supplementation for several months. Following delivery, all medications were discontinued, with normalization of cortisol levels and marked clinical improvement. An hCG stimulation test confirmed the diagnosis of PICS: following administration of 13 000 units of hCG, serum cortisol increased from 15.6 μg/dL at baseline to 34 μg/dL at 48 hours, ACTH decreased from 14.4 pg/mL to undetectable levels, and UFC increased from 28 μg/24 h to 293 μg/24 h. The patient elected conservative medical management in future pregnancies.

Conclusions: PICS is a rare and diagnostically challenging cause of hypercortisolism during pregnancy. This case highlights successful medical management of severe PICS presenting in the second trimester, despite the absence of adrenal abnormalities on imaging. Early recognition, close biochemical monitoring, and comprehensive multidisciplinary care enabled favorable maternal and neonatal outcomes.

EP148 - ECE_3551 - Three newly diagnosed patients with Addison's disease presenting with adrenal crisis: illustrative case reports

Gergő Csitári

DBC-SZIEOK, Budapest, Hungary

Autoimmune primary adrenal insufficiency is an uncommon but life-threatening endocrine disorder in which diagnosis is frequently delayed, despite a recognisable yet nonspecific clinical constellation. The leading cause in high-income countries is autoimmune adrenalitis, with an incidence of only a few cases per million population per year, so the disease is rarely considered in routine internal medicine practice. The typical manifestations—weight loss, fatigue, gastrointestinal symptoms, hyponatraemia, hyperkalaemia and hypotension—overlap with many more prevalent conditions, which contributes to prolonged diagnostic odysseys and, not infrequently, presentation with adrenal crisis.

This abstract describes three instructive cases of newly diagnosed autoimmune Addison's disease, each culminating in adrenal crisis or incipient crisis during hospitalization. The objective is to highlight the protean clinical presentation and the extent of gastroenterological, nephrological, neurological and psychiatric work-up that may precede consideration of primary adrenal insufficiency. In all three patients, progressive haemodynamic instability and neurocognitive or behavioural deterioration occurred despite apparently appropriate management of the presumed alternative diagnoses.

The first case involves a 45-year-old man with abdominal pain, marked weight loss, progressive renal impairment, severe hyponatraemia and hyperkalaemia, in whom focal neurological signs led to a planned lumbar puncture before pronounced orthostatic hypotension and cutaneous hyperpigmentation prompted endocrine reassessment. The second case concerns a 51-year-old woman thoroughly investigated for suspected malignancy and subsequently labelled as having catatonic psychosis; the coexistence of vitiligo, mild hyponatraemia, hypotension, hypoglycaemia and clinical dehydration finally raised suspicion of primary adrenal insufficiency. The third case is a 35-year-old man with severe, partly iatrogenic hyponatraemia, persistent mild hyperkalaemia, significant weight loss and improved glycaemic control initially attributed to GLP-1 receptor agonist therapy, who experienced

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

recurrent syncope with low–normal blood pressure and tachycardia, necessitating transfer to intensive care.

In all three patients, biochemical evaluation confirmed primary adrenal insufficiency, prompting immediate initiation of intravenous 0.9% saline and stress-dose hydrocortisone, while cross-sectional adrenal imaging revealed no structural abnormalities. The subsequent demonstration of adrenal cortex autoantibodies was consistent with autoimmune adrenalitis as the underlying aetiology in each case. These cases underscore that Addison's disease remains a "great mimicker" in contemporary clinical practice and emphasise the need for a high index of suspicion for primary adrenal insufficiency in patients with otherwise unexplained hyponatraemia, hyperkalaemia, hypotension, hyperpigmentation or autoimmune stigmata, particularly when clinical status deteriorates despite standard therapy.

EP149 - ECE_2353 - Extrapulmonary tuberculosis—the clinical challenge and significance of adrenal insufficiency

Boban Stepanovic[1], Ljiljana Marina[2,3], Kristina Saravinovska[2,3], Sara Odalovic[2], Marina Stojanovic[1,3], Katarina Tausanovic[1,3], Dijana Jankovic[2], Vladan Zivaljevic[1,3] and Milan Jovanovic[1,3]
[1]*Clinic of Endocrine Surgery, University Clinical Centre of Serbia, Belgrade, Serbia;* [2]*Clinic of Endocrinology, Diabetes and Metabolic Diseases, University Clinical Centre of Serbia, Belgrade, Serbia;* [3]*Faculty of Medicine, University of Belgrade, Belgrade, Serbia*

Introduction: Adrenocortical insufficiency, or Addison's disease, most commonly develops as a consequence of progressive bilateral destruction of the adrenal cortex, most often due to autoimmune adrenalitis. However, a wide range of etiologies has been described, among which adrenal tuberculosis represents a rare but important cause. Here, we present a rare case of adrenal tuberculosis manifesting as adrenal insufficiency.

Case Presentation: A 38-year-old man was diagnosed with a right adrenal mass accompanied by regional paraaortic lymphadenopathy. Multislice computed tomography (MSCT) of the abdomen revealed a poorly demarcated lesion of the right adrenal gland—60 × 37 × 36 mm, with signs of necrosis and cystic degeneration, as well as pathologically enlarged paraaortic and interaortocaval lymph nodes measuring up to 28 × 16 mm. Clinically, the patient presented with generalized skin hyperpigmentation, hypotension, loss of appetite, and abdominal pain. Hormonal evaluation confirmed primary adrenal insufficiency, with low morning serum cortisol (78 nmol/L), markedly elevated ACTH (>440 pmol/L), hyponatremia (122 mmol/L), and hyperkalemia (5.6 mmol/L), and hydrocortisone replacement therapy was initiated. The patient underwent surgery, where a right adrenalectomy with excision of the affected lymph nodes was performed via an open surgical approach. Postoperatively, the patient developed lymphorrhea and paralytic ileus, both of which were managed conservatively, alongside appropriate hydrocortisone and fludrocortisone substitution. Histopathological examination revealed granulomatous inflammation with central caseous necrosis, highly suggestive of tuberculosis. The patient tested negative for HIV.

Conclusions: The clinical course and disease presentation in our patient highlight the importance of considering adrenal tuberculosis in the differential diagnosis of adrenal masses associated with primary adrenal insufficiency, even in immunocompetent patients. Early recognition, appropriate hormonal replacement, and timely diagnosis are essential to optimize outcomes in this rare but clinically significant condition.

EP150 - ECE_2250 - Mild autonomous cortisol secretion and cardiovascular risk: a retrospective study

Zaira Benetti[1], Marianna Scordo[1], Simona Buti[1], Chiara Badiale[2], Luisa Pignata[1], Pierpaolo Falcetta[1], Elena Benelli[1], Lucia Montanelli[1], Emilio Fiore[1] and Massimo Tonacchera[1]
[1]*Department of Clinical and Experimental Medicine, Endocrine Unit, University of Pisa, Pisa, Italy;* [2]*University of Pisa, Pisa, Italy*

Mild autonomous cortisol secretion (MACS) is a condition characterized—according to the new European guidelines for adrenal incidentalomas (AIs)—by the presence of serum cortisol levels >1.8 µg/dL (50 nmol/L) after a 1 mg dexamethasone suppression test in patients with adrenal incidentalomas, in the absence of clinical signs of overt Cushing's syndrome. Several studies in the literature have demonstrated that patients with MACS show an increase in cardiovascular risk factors.

The purpose of this study was to evaluate the SCORE2, SCORE2-OP and SCORE2-Diabetes scores—developed by the European Society of Cardiology (ESC) and used to predict the 10-year risk of cardiovascular events—comparing patients with MACS to patients with non-secreting AIs. Body weight was also assessed through the calculation of body mass index (BMI).

In this retrospective study 198 consecutive patients, with no history of cardiovascular events and without clinical signs of hypercortisolism, were recruited at the Endocrinology Department of Pisa. Patients were divided into three categories: adults aged 40-69 years without diabetes mellitus (Group A—114 patients, 57.6%), adults aged 40-69 years with diabetes mellitus (Group B—14 patients, 7.1%), and elderly patients aged ≥70 years (Group C—70 patients, 35.4%).

For each patient, MACS was evaluated using the overnight 1 mg dexamethasone suppression test and data on smoking habits, systolic blood pressure (SBP), total cholesterol (TC), HDL cholesterol (HDL-C), and BMI were collected. In diabetic patients, creatinine and glycated hemoglobin (HbA1c) levels were also assessed.

No statistically significant differences were found in individual cardiovascular risk factors (SBP, TC, HDL-C, and BMI) or in the 10-year cardiovascular risk scores. In Group A, the prevalence of MACS was 23.7% (27/114 patients), and the median SCORE2 in these patients was 4.7% compared to 4.6% in patients with non-secreting AI ($P = .961$). In Group B, the prevalence of MACS was 21.4% (3/14 patients) with median SCORE2-Diabetes of 9.4% compared to 10.7%, respectively ($P = .769$). In Group C, the prevalence of MACS was 38.6% (27/70 patients), with median SCORE2-OP of 14.7% compared to 12.3% ($P = .234$).

In diabetic patients, the difference in HbA1c values between the two subgroups was not statistically significant (50 vs 50 mmol/L $P = .659$), whereas creatinine values were significantly higher in patients with MACS compared to those with non-secreting AIs (0.96 vs 0.72 mg/dL, $P = .038$).

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

In conclusion, no statistically significant differences in cardiovascular risk factors were observed between patients with MACS and those with non-secreting AIs.

EP151 - ECE_3033 - Early postoperative aldosterone as a predictor of biochemical cure after adrenalectomy for primary hyperaldosteronism

Tatiana Rojas López, Jorge Escobar Gómez, Paola Parra-Ramírez, Patricia Martín Rojas-Marcos, María Luisa González Casaus, Joaquín Gómez Ramírez, Raquel Arranz and Maria Cristina Alvarez Escola
Hospital Universitario La Paz, Madrid, Spain

Introduction: The identification of early markers of cure after adrenalectomy in patients with primary hyperaldosteronism (PA) is key to optimizing follow-up and adjusting treatment more efficiently. This study aimed to evaluate the usefulness of postoperative aldosterone levels and their percentage reduction relative to preoperative values as predictors of cure.

Materials and Methods: Retrospective cohort study of patients with confirmed PA who underwent unilateral adrenalectomy between 2021 and 2025 at a tertiary hospital. Patients with plasma aldosterone measurement between 24 hours and the first postoperative week were included, and the percentage reduction relative to baseline values obtained in the confirmatory test was calculated. Associations between postoperative aldosterone concentrations and their percentage reduction with biochemical and clinical cure, according to the PASO criteria (partial or complete cure vs no cure), were analyzed. ROC curves were constructed for each parameter, the area under the curve (AUC) was estimated, and the optimal cutoff was determined using the Youden index.

Results: Sixteen patients were included, with a mean age of 57.8 ± 10.0 years, 62.5% male. Nine patients achieved biochemical cure (2 of them complete), and 13 achieved clinical cure (3 of them complete). Patients with biochemical cure had a significantly greater percentage reduction in aldosterone (mean: 55.9% ± 36.8% vs −60.1% ± 60%; $P < .01$) and lower postoperative levels (mean: 8.7 ± 6.7 ng/dL vs 30.2 ± 18.8 ng/dL; $P < .01$) compared to those without cure. No significant differences were found regarding clinical cure. In the ROC analysis, the percentage reduction in aldosterone showed an AUC of 0.94 (95% CI 0.81-1.00), with a cutoff point of 47.5%, sensitivity of 78%, and specificity of 100%. Postoperative concentration presented an AUC of 0.92 (95% CI 0.75-1.00).

Conclusions: The reduction in plasma aldosterone in the first days after adrenalectomy is significantly associated with biochemical cure of PA, supporting its value as an early prognostic marker of surgical success.

EP152 - ECE_3625 - Long-term outcome in autoimmune Addison's disease: a single-center real-world study

Ylenia Alessi[1], Carla Paola Costa[2], Elena Sofia Blanca[2], Giordana Siracusano[2], Federica Galletta[2], Damiano Siligato[2], Annalisa Giandalia[3], Angela Alibrandi[4], Salvatore Cannavò[3] and Francesco Ferraù[3]
[1]*Department of Biomedical, Dental and Morphological and Functional Imaging Sciences, University of Messina, Messina, Italy;* [2]*Endocrine Unit, University of Messina, Messina, Italy;* [3]*Department of Human Pathology of Adulthood and Childhood, University of Messina, Messina, Italy*
[4]*Department of Economics, University of Messina, Messina, Italy*

Background: Autoimmune Addison's disease (aAD) is a rare endocrine disorder characterized by primary adrenal insufficiency and frequently associated with other autoimmune conditions. Despite effective glucocorticoid (GC) replacement therapy, patients with aAD exhibit increased morbidity and reduced quality of life, suggesting that the disease should be considered a multisystem disorder. Long-term data on the evolution of cardiometabolic, skeletal and autoimmune comorbidities in aAD are still limited.

Aim: The aim of this study was to characterize the long-term clinical, metabolic and autoimmune profile of patients with aAD followed at a tertiary referral center, and to evaluate the impact of sex, disease duration and GC therapy on the development and progression of major comorbidities.

Methods: We retrospectively evaluated 53 consecutive patients with aAD (37 females; mean age at diagnosis 37 ± 14.5 years) followed between 2008 and 2025. Anthropometric, clinical, biochemical and metabolic parameters, comorbidities and associated autoimmune diseases were assessed at first evaluation and at last follow-up (mean follow-up 111 ± 89.8 months). Throughout the entire follow-up, clinical/biochemical evidence of GC overtreatment was excluded in all patients based on UFC values. Patients were also stratified according to sex and disease duration (≤10 vs >10 years).

Results: At last follow-up, body weight, BMI ($P < .001$ both) and waist circumference (P .04) were significantly increased, together with a rise in fasting glucose levels (P .031), while lipid profile and electrolytes remained stable. The prevalence of arterial hypertension increased from 7.5% to 20.7%, type 2 diabetes mellitus from 3.7% to 5.6%, and osteoporosis from 11.3% to 22.6%, although these changes did not reach statistical significance. At last follow-up, female patients showed higher HDL cholesterol and HbA1c levels, while lumbar spine bone density tended to be lower compared with males. In patients with longer disease duration (>10 years), a trend toward higher rates of hypertension, diabetes, osteoporosis and rheumatological autoimmune disorders was observed. GC dosage did not significantly impact on any of the evaluated variables. Logistic regression identified disease duration as a potential predictor of new-onset hypertension, independent of other factors.

Conclusions: Autoimmune Addison's disease is associated with a progressive burden of cardiometabolic, skeletal and autoimmune comorbidities, even despite optimal replacement treatment. The increase in the prevalence of arterial hypertension appears to be driven primarily by disease duration. These results highlight the critical need for ongoing, multidisciplinary management that goes beyond hormone dose adjustments, ensuring comprehensive care throughout the patient's lifetime.

EP153 - ECE_1181 - Splenic infarction unmasking endocarditis in subclinical hyperthyroidism: a case easily confused with thyrocardiac disease

Hadami Ben Yamna, Rachel Gauvin, Sarra El Younsi, Bilariki Kalliopi and Etienne Justinien
Endocrinology Department, Compiègne Hospital Center, Compiègne, France

Introduction: Splenic infarction is an uncommon complication of infective endocarditis, usually reflecting embolic dissemination from valvular vegetations. Subclinical hyperthyroidism may obscure the clinical presentation, leading clinicians to initially attribute cardiovascular symptoms to thyroid dysfunction rather than infection. We report a case in which splenic infarction led to the diagnosis of underlying infective endocarditis in a patient with subclinical hyperthyroidism, highlighting a potential diagnostic pitfall.

Case Presentation: A 68-year-old man, previously operated four months earlier for an upper–mid rectal adenocarcinoma (pT1), presented with newly discovered subclinical hyperthyroidism. Initial laboratory tests showed persistently suppressed TSH levels (0.008 then 0.0079 mUI/L) with negative antibodies (anti-TPO, anti-Tg, and TRAb antibodies). Cervical ultrasound revealed a multinodular goiter, and scintigraphy confirmed a toxic multinodular goiter. He was started on Neomercazole 5 mg daily. He presented two weeks later to the emergency department with epigastric pain and low-grade fever (38.2 °C), and vomiting. Physical examination found isolated epigastric tenderness. An abdominopelvic CT scan demonstrated a large splenic infarction with no abnormalities of the splenic vessels. ECG showed sinus rhythm. Because of the unexplained embolic event, transthoracic echocardiography was performed and revealed a tricuspid aortic valve carrying a mobile vegetation, associated with non-severe aortic regurgitation. These findings confirmed infective endocarditis complicated by splenic embolism. The patient underwent aortic valve replacement. Postoperative evolution was favorable.

Conclusions: Despite an initial suspicion of hyperthyroidism-related paroxysmal arrhythmias, the unexpected finding of infective endocarditis underscores the importance of considering differential diagnosis in patients with subclinical hyperthyroidism who present with embolic phenomena.

EP156 - ECE_2971 - Interpreting diabetic kidney disease risk in type 2 diabetes using explainable AI

Daria Varbanets, Yanina Saienko, Yanina Rebrova, Dmytro Krasnenkov, Roman Kirilenko and Borys Mankovsky
Department for the Study of Age-Related Cardiometabolic Diseases, D. F. Chebotarev Institute of Gerontology of the National Academy of the Medical Sciences of Ukraine, Kyiv, Ukraine

Background and Aim: Chronic kidney disease (CKD) is a major complication of type 2 diabetes mellitus (T2DM), significantly impacting morbidity and mortality. The application of artificial intelligence (AI), particularly Explainable AI (XAI), offers new opportunities for predicting diabetic complications, including CKD. This study aimed to utilize XAI through H2O AutoML to identify key risk factors for CKD in T2DM patients.

Materials and Methods: Data from 133 patients with T2DM (mean age 62.7 ± 11.5 years; 36.6% female) were analyzed using H2O AutoML. Gradient Boosting Machine (GBM) models outperformed others; Stacked Ensemble and Deep Learning models were excluded. SHapley Additive exPlanations (SHAP) were used to interpret model predictions and evaluate feature importance.

Results: Peripheral neuropathy emerged as the most influential predictor of CKD, suggesting a link between microvascular damage and renal dysfunction. Age and diabetes duration were positively associated with CKD risk, reflecting physiological decline and disease progression. Chronic heart failure (CHF) and elevated low-density lipoprotein cholesterol (LDL-C) also contributed significantly, likely due to their roles in vascular impairment. Notably, historical exposure to famine, reflecting Ukraine's traumatic past, was identified as a significant risk factor, possibly due to long-term epigenetic effects on metabolic health.

Conclusions: SHAP-based analysis enabled transparent interpretation of CKD risk in T2DM patients, revealing both expected and novel predictors. These findings support the clinical utility of XAI in enhancing individualized risk assessment and informing targeted prevention strategies in diabetes care.

EP157 - ECE_2098 - Knowledge of crisis prevention strategies are highly effective, whereas vulnerability scores may elicit Addison's disease crises

Ian Ross[1], Sofia Llahana[2], Michelle Anderson[1], Belene Demeke[1], Elouise Minnie[1], John Wass[3] and Michelle Henry[4]
[1]*Division of Endocrinology, Groote Schuur Hospital, Medicine, University of Cape Town, Cape Town, South Africa;* [2]*Saint George's, School of Medical and Health Sciences, London, United Kingdom;* [3]*Department of Endocrinology, Medicine, Churchill Hospital, Oxford, United Kingdom;* [4]*Centre for Higher Education Development, University of Cape Town, Cape Town, South Africa*

Objective: The knowledge in patients with Addison's disease (AD) to prevent an adrenal crisis and the degree to which patients feel vulnerable is unknown.

Design: A telephonic interview of 47 South African patients was undertaken, determining knowledge of crisis prevention strategies and assessment of vulnerability in patients.

Methods: A score was determined in respect of knowledge of adrenal crisis (AC) and degree of vulnerability was assessed. Patients who had a crisis with those who did not. Associations with AC were evaluated and the impact of knowledge and vulnerability were determined.

Results: Two-thirds (64%) had suffered from an adrenal crisis in the previous 5 years compared with 34% who never had a crisis. Poorer knowledge prevention of an adrenal crisis was associated with an AC, especially having had a cold (31.2% vs 71%; $P = .002$), fever (44.7% vs 90.3%; $P < .001$), infection (50% vs 93.5%; $P < .001$), vomiting (50% vs 80.6%; $P = .007$) and diarrhoea (37.5% vs 71%; $P < .001$), respectively. The median proportion with vulnerability for each question was 41.5%. Disease duration was negatively correlated with vulnerability; ($r = -0.426$; $P = .003$). Number of

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

comorbidities was correlated with vulnerability ($r = 0.290$; $P = .048$). A negative correlation between knowledge score and number of crises in the previous 5 years was found ($r = -0.530$; $P < .001$). Logistic regression is showed the only predictor for crisis in the past year, or past 5 years was patients' knowledge ($P < .001$). Predictors of knowledge were younger patients, more comorbidities, patients who had AC or scored higher on vulnerability questionnaire. Variables accounted for 52% of the variance ($F = 9.751$; $P < .001$).

Conclusions: Education is critical in preventing, specifically cold fever, infection, vomiting and diarrhoea. Health-care providers should provide psychological support considering the significant vulnerability burden.

EP158 - ECE_3106 - Implementation of a cohort to analyse the health status of adults with congenital adrenal hyperplasia (CaHASE2)

Cahase2 Investigators Society for Endocrinology, UK and Aled Rees
Society for Endocrinology, Bristol, United Kingdom

Congenital adrenal hyperplasia (CAH) is the most prevalent form of primary adrenal insufficiency, affecting approximately 1 in 15 000 individuals. Suboptimal health status and care provision among adults living with CAH have been described globally. Consequently, the CaHASE2 initiative was launched in 2023 to implement a robust, prospective, longitudinal cohort study aimed at analysing the health status of adults with CAH in the UK and Ireland. Centres commenced systematic collection of real-world data utilizing the international I-CAH registry. Currently, 23 centres actively contribute, having successfully recruited 488 adults with 766 clinic visits. While the cohort predominantly comprises younger to middle-aged adults, 130 participants are aged 51 years or older, providing opportunities to investigate emerging health challenges. Preliminary analyses reveal that a considerable number of patients are overweight or obese. Assessments of 17-hydroxyprogesterone concentrations suggest significant proportions may be receiving overtreatment. Although androstenedione levels remain below 8 nmol/L in most patients, a significant fraction exhibits suboptimal hormonal control. Interestingly, findings reveal no discernible correlation between current glucocorticoid dosage and patient weight or body surface area. Seven percent of patients had type-2-diabetes. Depression was commonly observed. There are clear signals of ongoing impaired health status and signs of suboptimal control in adults with CAH. Over the subsequent 12 months, the project will focus on collaborating with principal investigators to enhance longitudinal data completeness. This improved data will be crucial for comprehensively investigating variations in healthcare provision, health status, and clinical outcomes, and facilitating the provision of anonymized benchmarking data to all participating centres.

EP159 - ECE_3314 - Megestrol acetate: a hidden glucocorticoid confounding HPA axis assessment

Anca Matei[1,2], Stefana Bilha[1,2], Viviana Adam[1], Alina-Elena Șchiopu[1,2,3], Diana Martiniuc[2], Alexandru Florescu[1,2], Ana-Maria Bârcă[2], Laura Teodoriu[4] and Cristina Preda[1,2]
[1]Universitatea de Medicină și Farmacie "Grigore T. Popa" Iași, Iași, Romania; [2]Endocrinology, Spitalul Sf. Spiridon Iași, Iași, Romania; [3]Endocrinology, Hospital Saint Spiridon, Iasi, Romania; [4]Endocrinology, Regional Institute of Oncology, Iași, Romania

Introduction: Megestrol acetate (MA) is a synthetic progestin with glucocorticoid activity that may suppress the hypothalamic–pituitary–adrenal (HPA) axis. In patients with adrenal or pituitary incidentalomas, this exposure limits the interpretability of standard endocrine testing and requires a pragmatic, clinically driven approach.

Case: A 64-year-old woman was referred for endocrine evaluation due to persistently low serum cortisol levels. Medical history included endometrial carcinoma treated by total hysterectomy with bilateral adnexectomy and she had been receiving long-term megestrol acetate therapy (160 mg/day) since 2020, with stable disease and no evidence of recurrence on oncological follow-up Imaging revealed two incidental findings: a left adrenal incidentaloma measuring 8 mm, stable on serial computed tomography examinations, with benign imaging characteristics (homogeneous, attenuation <10 Hounsfield units), and a pituitary microadenoma measuring 4 mm, without mass effect or optic chiasm involvement. Basal hormonal evaluation demonstrated HPA axis suppression (low morning serum cortisol = 1.1 µg/dL, low-normal ACTH = 11 pg/mL, DHEAS = 22.6 µg/dL). No other pituitary hormone deficiencies were identified, suggesting preserved overall pituitary function; therefore, hypocortisolism could not be interpreted in a pituitary context. Mild IGF-1 elevation was attributed to newly diagnosed type 2 diabetes rather than autonomous growth hormone secretion. Given the absence of clinical features of adrenal insufficiency (stable hemodynamics, normal electrolytes, and no hypoglycemia), ACTH stimulation testing was not pursued, as it would not have changed the course of management at this stage. On the other hand, adrenal incidentaloma workup showed normal urinary metanephrines and a normal aldosterone–renin ratio. Dexamethasone suppression testing for autonomous cortisol secretion was not performed due to MA-induced HPA axis suppression. The patient also exhibited a Cushing-like phenotype, including central obesity, facial erythema, diabetes mellitus (HbA1c 7.2%), hypertension (blood pressure 155/90 mmHg), dyslipidemia, and osteopenia. It remains difficult to ascertain whether these features are directly attributable to chronic MA exposure or represent independent metabolic disease.

Conclusions: In patients receiving long-term megestrol acetate, biochemical suppression of the HPA axis should be interpreted cautiously and primarily in clinical context. When dynamic testing is limited by pharmacological suppression, management should focus on patient safety and ongoing monitoring to reassess treatment plan if needed. In the setting of stable oncological disease without recurrence, this case raises an important multidisciplinary question: should gradual tapering and discontinuation of megestrol acetate be considered to mitigate Cushing-like adverse effects, while exploring alternative strategies for oncological disease control under close surveillance?

EP160 - ECE_1107 - Successful adrenal recovery following long-term prednisolone use: a case demonstrating the value of structured steroid withdrawal and patient education

Muna Guma[1], Hassan Bukhari[1], Harry Wilson[2], Helen Addison[1] and Elliot Crowhurst[2]
[1]Endocrinology and Diabetes, County Durham and Darlington NHS Foundation Trust, Darlington, United Kingdom; [2]County Durham and Darlington NHS Foundation Trust, Darlington, United Kingdom

Background: Prolonged corticosteroid therapy is a well-known cause of secondary adrenal suppression. The process of steroid withdrawal can be challenging, and patient anxiety or premature testing may compromise successful recovery of the hypothalamic–pituitary–adrenal (HPA) axis.

Case Summary: We report a **58-year-old female** with **Crohn's disease**, managed under gastroenterology, who was referred to endocrinology for **steroid withdrawal**. She had been on **prednisolone 8 mg daily for 21 years**, which had recently been reduced by the gastroenterology team to 5 mg. The patient was subsequently managed using the **Merran Steroid Withdrawal Protocol**. Baseline cortisol and short Synacthen testing (SST) were intentionally **not performed prior to withdrawal**, as these were deemed to have limited value and could increase patient anxiety. Instead, the patient received **comprehensive education** regarding symptoms of adrenal insufficiency and adrenal crisis, and was followed up regularly with **telephone reviews every few weeks**. An **SST performed at week 4**, when the patient had been completely off prednisolone, demonstrated the following results:

- Baseline cortisol: **539 nmol/L**
- 30-minute cortisol: **901 nmol/L**
- 60-minute cortisol: **1051 nmol/L**

This excellent cortisol response confirmed **full recovery of adrenal function** and the ability of the corticotroph axis to stimulate normal adrenal physiology following gradual weaning.

Conclusions: This case highlights the **effectiveness of a structured steroid withdrawal protocol** and the **importance of patient education and reassurance** in facilitating adrenal recovery. Minimising unnecessary testing and physician interference can reduce patient anxiety and support safe, physiological restoration of HPA axis function.

Abstract citation ID: lvag096.749

EP163 - ECE_3212 - Early-onset primary aldosteronism in a 17-year-old male: identification and reclassification of a novel CACNA1H variant

Alessandro Risio[1,2], Vittoria Favero[2,3], Carmen Aresta[2], Alessandro Maloberti[4,5], Cristina Giannattasio[4,5] and Iacopo Chiodini[2,3]
[1]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; [2]Unit of Endocrinology, ASST GOM Niguarda Hospital, Milan, Italy; [3]Department of Biotechnology and Translational Medicine, University of Milan, Milan, Italy; [4]Milan, Italy [5]School of Medicine and Surgery, University of Milano-Bicocca, Milan, Italy

Introduction: Germline mutations in *CACNA1H*, encoding the T-type voltage-gated calcium channel Cav3.2, cause familial hyperaldosteronism type 4, characterized by early-onset primary aldosteronism (PA) and hypertension. *CACNA1H* mutations can be associated with epilepsy, and additional phenotypic features such as developmental delay, autism, and immunologic and gastrointestinal involvement have been described. These patients present with normal adrenal morphology or bilateral adrenal hyperplasia rather than adenomas. These gain-of-function mutations lead to increased calcium influx, membrane depolarization, and autonomous aldosterone production in adrenal glomerulosa cells. While most reported *CACNA1H* variants are recurrent (eg, M1549V and E282K), novel variants continue to expand the genetic spectrum of this condition. Pathogenicity is established through functional studies and family segregation analyses.

Case Presentation: We describe a 17-year-old male with early-onset hypertension diagnosed at age 12 in 2019, with a family history of early-onset hypertension (maternal aunt). The patient was followed in paediatric cardiology for low-risk ventricular pre-excitation and a pericardial effusion known since 2022. Despite initiation of losartan therapy in 2023, blood pressure control remained suboptimal (mean 160/100 mmHg). Doppler ultrasound excluded renal artery stenosis. Hormonal testing revealed biochemical features of PA (aldosterone 40.1 ng/dL, renin 0.5 mIU/L, ARR 80.2, potassium 3.6 mEq/L) during treatment with alpha-1 blockers and calcium antagonists. Computed tomography showed no adrenal lesions. Adrenal vein sampling was attempted. However, right adrenal vein cannulation was unsuccessful, precluding assessment of lateralization. Hypercortisolism and glucocorticoid-remediable aldosteronism were excluded with dexamethasone tests. The most recent echocardiogram revealed early concentric left ventricular hypertrophy, which was not present in previous examinations. Low-dose spironolactone was subsequently introduced, resulting in excellent blood pressure control and increased renin (22 mIU/L) and potassium (4.5 mEq/L) levels. Given the young age at disease onset, genetic testing was performed, indentifying a c.4289T > G substitution in exon 22 of *CACNA1H*, initially classified as a variant of uncertain significance (VUS). Following family segregation studies demonstrating a de novo origin, the variant was reclassified in December 2025 as likely pathogenic (ACMG class 4: PS2, PM2, PP3).

Conclusions: This case expands the genetic spectrum of *CACNA1H*-related PA by reporting a novel de novo variant. Reclassification based on segregation analysis highlights the importance of parental testing in variant interpretation. These findings support genetic screening in patients with early-onset PA, particularly before 20 years of age, to guide clinical management and family counselling. Notably, cardiac findings in this patient have not been previously reported in association with CACNA1H mutations, unlike CACNA1D-related PASNA syndrome.

EP166 - ECE_1272 - Congenital adrenal hyperplasia—a Maltese cohort

Carol Cardona Attard[1,2], Martha Spiteri[2] and Josanne Vassallo[1,3,4]

[1]Diabetes and Endocrine Centre, Mater Dei Hospital, Msida, Malta; [2]Department of Medicine, Mater Dei Hospital, Msida, Malta; [3]Faculty of Medicine and Surgery, University of Malta Medical School, Mater Dei Hospital, Msida, Malta; [4]Molecular & Cellular Endocrinology Research Lab, Centre for Molecular Medicine and Biobanking, Room 322, Msida, Malta

Background: Congenital adrenal hyperplasia (CAH), an autosomal recessive disorder, encompasses a spectrum of phenotypes secondary to impaired cortisol and variable mineralocorticoid production, and androgen excess, depending on the type and severity of enzyme deficiency in the adrenal steroidogenesis pathway. It is associated with many long-term health sequelae, usually secondary to under- or overtreatment with glucocorticoids +/− mineralocorticoids. The aim of our study was to assess the different phenotypes and quality of care provided to these patients presenting at Mater Dei hospital, Malta.

Methods: Patients with 17-hydroxyprogesterone (17-OHP) levels >10 ng/mL, measured between January 2009 and 2023, post-infancy during the follicular phase in premenopausal women or after cosyntropin stimulation, were identified. Twenty-two consented to participate out of 29 identified patients. Data collected via questionnaire included presenting symptoms, co-morbidities, fertility, management and follow-up details. Clinical assessment included blood pressure, anthropometry, biochemical testing (17-OHP, testosterone, androstenedione) and a bone mineral density (BMD).

Results: Most patients had 21-hydroxylase deficiency (20/22, 90.9%), with 2 (9.1%) having 11β-hydroxylase deficiency. Late-onset CAH accounted for 19 cases (86.4%), while 3 (13.6%) had classic CAH (2 salt-wasting, 1 simple-virilising). Eighteen participants (81.8%) were women and four (18.2%) were men (3 adults, one <16 years). Mean age was 41.7 years (SD 16.5). At study enrolment, 11 (50%) individuals were treated with steroids, predominantly prednisolone (63.6%). Weight gain was reported by 45.5% of patients, all of whom had received steroid therapy. Six patients (28.6%) were overweight and six (28.6%) had obesity. Age- and sex-standardised overweight prevalence did not differ from the Maltese population (44.1% vs 35.3%, $P = .429$), whereas obesity was less prevalent in CAH (15.4% vs 33.2%, $P = <.001$). Among those with available BMD data, osteopenia was present in 9/18 (50.0%) and osteoporosis in 1/18 (5.6%). Nine adults (42.9%; 8 women, 1 man) reported 19 spontaneous pregnancies and 13 live births; complications occurred in half of female deliveries. Genetic counselling was undertaken in 4 patients (18.2%), with partner testing in 2 (9.5%). Only 11 patients (50%) felt their symptoms were controlled, and 12 (54.5%) had endocrinology follow-up at study enrolment.

Conclusions: Late-onset CAH seems to be still underdiagnosed/confounded with other conditions such as Polycystic ovary syndrome. Inadequate screening particularly due to the lack of neonatal screening in Malta might also be a reason. This could lead to incorrect treatments, ongoing symptoms and poor quality of life. Timely screening, genetic testing and counselling would improve diagnosis and patient outcomes.

Abstract citation ID: lvag096.751

EP170 - ECE_1830 - Minor trauma, major consequences: a subacute hypertensive crisis revealing an occult pheochromocytoma

Marjeta Kermaj[1,2], Ledia Omeri[1], Dorina Ylli[1,2], Megi Lekbello[1,2], Zgjim Gola[3] and Agron Ylli[1,2]

[1]Endocrinology, University Hospital Center "Mother Tereza", Tirana, Albania; [2]University of Medecine, Tirana, Albania; [3]Cardiology, University Hospital Center "Mother Tereza", Tirana, Albania

Background: Pheochromocytoma is a rare catecholamine-secreting neuroendocrine tumor that may remain clinically silent until exposure to physiological stress precipitates excessive catecholamine release and hypertensive crisis. While major trauma is a recognized trigger, the clinical significance of minor peripheral injuries followed by cumulative inflammatory and immune stress is rarely reported.

Case Presentation: We report a young male with no significant medical history who presented with fever, severe occipital headache, palpitations, and marked blood pressure lability. Three days after sustaining a minor penetrating nail injury to the left great toe without initial medical treatment, the patient developed localized pain and presented to the emergency department. He received intramuscular human tetanus immunoglobulin (250 IU) and antibiotic therapy and was hospitalized for two weeks for wound management. No hypertensive episodes or adrenergic symptoms were documented during hospitalization. Two days after discharge, the patient developed fever followed by acute adrenergic symptoms and labile hypertension, prompting further evaluation. Contrast-enhanced abdominal CT revealed a large adrenal mass consistent with pheochromocytoma, and biochemical testing confirmed marked catecholamine excess. The patient was stabilized with alpha-adrenergic blockade followed by beta-adrenergic blockade and subsequently underwent elective adrenalectomy, with postoperative histopathology confirming pheochromocytoma and complete resolution of hypertensive episodes.

Conclusions: This case demonstrates that minor peripheral trauma, followed by cumulative physiological, inflammatory, and immune stress, may unmask an occult pheochromocytoma and precipitate a subacute, life-threatening hypertensive crisis. The delayed onset of symptoms argues against a direct pharmacologic or immunologic trigger and instead supports a threshold-dependent stress mechanism. Clinicians should consider pheochromocytoma in patients presenting with unexplained and labile hypertension following seemingly benign injuries and prolonged inflammatory stress.

Metabolic Diseases, University Clinical Center of Serbia, Belgrade, Serbia

Introduction: Most patients with hypertension have essential hypertension, while secondary causes account for 5%-10% of cases, including endocrine disorders. Aldosterone plays a key role in electrolyte balance, and its excessive secretion may lead to unrecognized resistant hypertension.

Case Presentation: A female patient, a nurse without night shifts, has had arterial hypertension since the age of 30. During the last five years, antihypertensive therapy was changed approximately once per year. Usual blood pressure on therapy was 150/110 mmHg, with a maximum recorded value of 203/158 mmHg. Due to frequent headaches and hypertensive crises, she often presented to the emergency department. As part of the evaluation for secondary hypertension, imaging studies were performed. Computed tomography showed a normal right adrenal gland, while the left adrenal gland had a prominent medial limb. Initial testing was performed in a regional center on maximal doses of an angiotensin receptor blocker and a thiazide diuretic, and showed normal hypothalamic-pituitary-adrenal axis, while renin-angiotensin-aldosterone system testing showed elevated aldosterone levels (271 ng/L) with potassium at the lower normal range (K 3.7 mmol/L). For adequate aldosterone evaluation, therapy was switched to aldosterone-neutral medication (calcium channel blocker and alpha-blocker). At our center, 24-hour ambulatory blood pressure monitoring revealed a non-dipper pattern. Basal and confirmatory testing for hyperaldosteronism was performed. The aldosterone-to-renin ratio (ARR) was within the normal to borderline range. The captopril test showed appropriate suppression of aldosterone (aldosterone 0, 90, 120 min: 204.3, 109.6, 72.5 ng/L; plasma renin activity (PRA) 0, 90, 120 min: 0.79, 1.5, 2.2 ng/mL/h). The saline infusion test yielded borderline results (aldosterone 0, 30, 60, 120, 240 min: 208.6, 137.9, 123.7, 162.9, 119.6 ng/L; PRA 0, 30, 60, 120, 240 min: 1.10, 0.86, 1.10, 1.10, 0.84 ng/mL/h). A low-dose dexamethasone suppression test showed significant aldosterone suppression (aldosterone 206.2-82.1 ng/L; PRA 0.36-0.76 ng/mL/h).

Conclusions: This case describes a patient with early-onset hypertension and elevated aldosterone levels. Normal potassium levels, mostly negative confirmatory tests, and two normal ARR values (25.8; 18.9) make primary aldosteronism unlikely. However, significant aldosterone suppression during the low-dose dexamethasone test (60%), together with a family history of early-onset hypertension, suggests possible glucocorticoid-remediable aldosteronism. Genetic testing will be considered for further evaluation. If confirmed, treatment with low-dose glucocorticoids will be initiated.

EP173 - ECE_3630 - Marked biochemical severity of primary aldosteronism occurs across diverse adrenal CT phenotypes

Ia Kavtiashvili, Mariam Bulashvili and Nino Zavrashvili
Tbilisi Institute of Medicine, Tbilisi, Georgia

Background: Adrenal computed tomography (CT) is routinely incorporated into the diagnostic evaluation of primary aldosteronism (PA) and is frequently used to infer disease phenotype in clinical practice. Despite its widespread use, the extent to which adrenal CT findings reflect the biochemical severity of aldosterone excess remains uncertain, particularly outside of highly selected cohorts.

Aim: To determine whether adrenal CT phenotype is associated with biochemical severity in patients with primary aldosteronism.

Methods: We performed a retrospective case series of 11 patients with primary aldosteronism confirmed by an elevated aldosterone-to-renin ratio (ARR). All patients underwent systematic biochemical assessment including aldosterone concentration, renin measurement, and serum potassium evaluation. Adrenal CT findings were classified as unilateral adenoma or nodule, bilateral hyperplasia or adrenal thickening, normal adrenal morphology, or no focal lesion documented. Biochemical severity was assessed using aldosterone concentration, ARR, and serum potassium nadir. Analyses were descriptive and non-parametric due to the exploratory nature of the study.

Results: Adrenal CT findings were heterogeneous: unilateral adenoma ($n = 3$), hyperplasia or thickening ($n = 3$), normal adrenal morphology ($n = 3$), and no focal lesion documented ($n = 2$). Aldosterone concentrations ranged widely from 78.6 to 900 ng/L, with marked aldosterone excess observed across all CT phenotypes. ARR values were markedly elevated irrespective of imaging appearance. Hypokalemia (serum potassium <3.5 mmol/L) was present in 7 of 11 patients (64%) and occurred in every CT category. Importantly, severe hypokalemia (≤3.2 mmol/L) was identified in patients with normal or non-lateralizing CT findings.

Conclusions: In this real-world cohort, adrenal CT phenotype was not associated with biochemical severity in primary aldosteronism. Clinically significant aldosterone excess and hypokalemia occurred across all imaging categories, including normal and non-lateralizing CT findings. These findings reinforce the central role of biochemical testing in PA and caution against using CT phenotype as a surrogate marker of disease severity in routine clinical practice.

Table 1 Adrenal CT phenotype and biochemical characteristics of the study cohort.

Patient	CT phenotype	Aldosterone (ng/L)	Renin (ng/L)	ARR	K (mmol/L)
P1	Unilateral adenoma	214	<1	>214	3.9
P2	Bilateral hyperplasia	122	1.4	90	3.4
P3	Normal CT	118	2.53	46.6	4.33
P4	Unilateral adenoma	78.6	0.9	87.3	3.64
P5	Adrenal thickening	107	1.6	66	4.1
P6	Normal CT	105	<1	>105	3.78
P7	Normal CT	611	37	74	3.3
P8	Bilateral hyperplasia	114	<1	>114	3.4
P9	No focal lesion	183	<1	>183	3.1
P10	Unilateral adenoma	900	<1	>900	3.0
P11	No focal lesion	181	0.8	225	3.2

EP174 - ECE_3674 - Renal and metabolic heterogeneity in primary aldosteronism: a single-center experience

Ia Kavtiashvili[1], Mariam Orjonikidze[1] and Giorgi Vepkhishvili[2]
[1]*Tbilisi Institute of Medicine, Tbilisi, Georgia;* [2]*Tbilisi State Medical University, Tbilisi, Georgia*

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Background: Primary aldosteronism (PA) is a leading cause of secondary hypertension and is associated with increased cardiovascular and renal morbidity. While hypokalemia has traditionally been considered a hallmark of PA, a substantial proportion of patients present with normokalemia. As a result, renal involvement in PA may be overlooked, particularly in patients without overt electrolyte disturbances.

Aim: To describe renal and biochemical characteristics in patients with primary aldosteronism and to assess whether potassium phenotype reflects the degree of renal involvement in a real-world single-center cohort.

Methods: We conducted a retrospective single-center case series including 11 patients with confirmed primary aldosteronism, defined by an elevated aldosterone-to-renin ratio. Serum potassium and creatinine levels were analyzed in all patients. Estimated glomerular filtration rate (eGFR) was calculated using the CKD-EPI 2021 creatinine-based equation when age and sex data were available.

Results: Serum potassium levels ranged from hypokalemic to normokalemic values. Renal function demonstrated marked heterogeneity, with both preserved and mildly reduced eGFR observed across patients regardless of potassium status. Importantly, reduced eGFR was not confined to hypokalemic individuals, indicating a lack of direct correlation between potassium phenotype and renal impairment.

Conclusions: In this single-center experience, potassium phenotype alone did not adequately reflect renal involvement in patients with primary aldosteronism. Renal dysfunction was observed across both hypokalemic and normokalemic presentations, underscoring the limited utility of serum potassium as a marker of disease severity or end-organ damage. These findings are consistent with emerging evidence that aldosterone excess can exert direct deleterious effects on renal structure and function independent of potassium status. Our data support current guideline recommendations advocating comprehensive biochemical and renal assessment in all patients with suspected or confirmed primary aldosteronism. Early identification of renal impairment is particularly important, as appropriate subtype classification and targeted treatment may lead to stabilization or improvement of renal function and reduce long-term cardiovascular risk. Routine incorporation of eGFR assessment into the diagnostic evaluation of PA may therefore enhance risk stratification and inform optimal management strategies.

Table 1 Patient-level renal and biochemical characteristics.

Patient	Potassium (mmol/L)	Creatinine (μmol/L)	eGFR (mL/min/1.73 m^2)
P1	3.9	97.2	75
P2	3.4	92.0	59
P3	4.33	76	70
P4	3.64	74	104
P5	4.1	84.9	104
P6	3.78	106	83
P7	3.3	106	70

EP177 - ECE_3098 - When stress hits both sides: bilateral adrenal hemorrhage—case report and literature review

Maria Pisimisi, Maria Mathiopoulou and Mile Vidovic
Hospital of Uster, Uster, Zurich, Switzerland

Introduction: Bilateral adrenal hemorrhage (BAH) is a rare but potentially life-threatening condition that may result in acute adrenal insufficiency and adrenal crisis. Reported etiologies include severe physiological stress, sepsis, coagulopathies—particularly anticoagulant therapy and heparin-induced thrombocytopenia—antiphospholipid syndrome, and adrenal neoplasms. Mortality rates of up to 15% have been reported, with adrenal insufficiency occurring in 16%-50% of patients with bilateral involvement, underscoring the importance of early recognition and appropriate management.

Methods: An 83-year-old male was hospitalized for acute pyelonephritis and demonstrated clinical improvement under intravenous antibiotic therapy. The patient was receiving phenprocoumon and had supratherapeutic anticoagulation. Ten days into hospitalization, he developed acute-onset diffuse abdominal pain accompanied by a hypertensive crisis (204/91 mmHg). Laboratory evaluation was largely unremarkable, with no elevation of inflammatory markers and normal abdominal laboratory parameters, except for elevated lactate levels and persistent supratherapeutic anticoagulation. Initial contrast-enhanced abdominal computed tomography (CT) revealed no acute pathology. Due to persistent symptoms and rising C-reactive protein levels, repeat CT imaging performed eight days later demonstrated bilateral adrenal hemorrhage. In this case, BAH was most likely stress-induced in the context of acute infection, with concomitant anticoagulation representing an additional risk factor. The underlying pathophysiology is thought to involve adrenal vein thrombosis, vascular congestion, and subsequent hemorrhage related to increased adrenal blood flow and impaired venous drainage. Clinical presentation is frequently nonspecific, including abdominal or flank pain, hemodynamic instability, or unexplained clinical deterioration, necessitating a high index of suspicion in at-risk patients. Diagnosis relies primarily on imaging, with contrast-enhanced CT as the modality of choice, while MRI may provide further lesion characterization.

Results: Endocrine evaluation revealed serum cortisol levels in the upper normal range with normal adrenocorticotropic hormone (ACTH) concentrations, therefore, glucocorticoid replacement therapy was not initiated. BAH represents a medical emergency due to the high risk of adrenal crisis and hemodynamic instability. Prompt recognition and early management are essential, including immediate stress-dose glucocorticoid therapy in patients with suspected adrenal insufficiency, aggressive fluid resuscitation, correction of metabolic disturbances, and close

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

hemodynamic monitoring. Identification and treatment of precipitating factors, such as infection or anticoagulant-related bleeding, are critical.

Conclusions: Early recognition and multidisciplinary management are key to preventing adrenal crisis and improving outcomes. Given the nonspecific clinical presentation, a high index of suspicion is required, particularly in patients exposed to physiological stress or anticoagulation. Timely imaging and endocrine evaluation enable appropriate intervention and reduce morbidity and mortality.

EP179 - ECE_2049 - Cushing disease initially presented as macronodular adrenal hyperplasia: a case report and review of literature

Ching-Hua Tseng[1] and Chia-Hung Lin[2]
[1]National Taiwan University Hospital, Zhongzheng District, New Taipei City, Taiwan; [2]New Taipei City, Taiwan

Introduction: Cushing syndrome is characterized by elevated plasma cortisol levels resulting from exogenous exposure or endogenous overproduction. Common manifestations include central obesity, proximal myopathy, striae, and impaired glucose tolerance. We report a case of recurrent Cushing syndrome, initially presenting with adrenal involvement and later diagnosed as Cushing disease. This case illustrates the diagnostic challenges of recurrent hypercortisolism and presents the importance of identifying the primary etiology to guide appropriate treatment and long-term management.

Case: A 61-year-old male presented in 2020 with moon face, weight gain, easy bruising, and muscle weakness for six months. Physical examination revealed a buffalo hump, central obesity, and purple striae. Initial laboratory testing showed loss of the diurnal cortisol rhythm with ACTH within the normal range. Imaging demonstrated bilateral adrenal nodules, more prominent on the left. Pituitary MRI revealed no lesion. Cushing syndrome due to a primary adrenal adenoma was diagnosed, and left adrenalectomy was performed in February 2021. In May 2023, the patient developed recurrent symptoms, including progressive facial acne, oily scalp, easy bruising, and lower limb weakness. Laboratory testing showed loss of the diurnal cortisol rhythm, now with elevated ACTH. Repeat pituitary MRI identified a 4 mm microadenoma. Inferior petrosal sinus sampling (IPSS) in January 2024 confirmed Cushing disease. Transsphenoidal adenomectomy was performed in February 2024, with subsequent resolution of symptoms. Follow-up MRI in May 2024 showed postoperative changes without residual tumor.

Discussion: The patient initially presented with bilateral adrenal nodules, Cushing syndrome, and borderline ACTH levels. Imaging suggested adrenal involvement, leading to left adrenalectomy. Two years later, recurrent Cushing syndrome with elevated ACTH was diagnosed as Cushing disease. Literature review suggests the presentation is compatible with ACTH-dependent macronodular adrenal hyperplasia (MAH). This autonomous secretion suppresses pituitary ACTH, resulting in relatively low ACTH levels. We postulate that an undetectable pituitary microadenoma initially stimulated adrenal growth and cortisol secretion. Adrenalectomy removed the source of auto-suppression, possibly permitting pituitary tumor progression and subsequent recurrence. As up to 23% of Cushing disease patients have normal pituitary MRI findings, IPSS remains an important diagnostic tool. However, due to its cost and procedural risks, shared decision-making is essential.

Conclusions: Cushing disease may present as an adrenal tumor, such as MAH, making identification of the primary cause essential. When clinical findings and test results are inconsistency, the diagnosis should be reconsidered. A negative sellar MRI does not exclude Cushing disease, and IPSS remains a valuable diagnostic tool in challenging cases.

EP180 - ECE_2358 - Pheochromocytoma during pregnancy: a case report

Ghofran Shahat[1], Hatim Aljohani[2] and Ali Alenazi[3]
[1]King Faisal Specialist Hospital & Research Centre, Madinah, Saudi Arabia; [2]Prince Mohammed bin Abdulaziz Hospital, Riyadh, Saudi Arabia; [3]Royal College of Physicians of Ireland, Dublin, Ireland

Introduction: Pheochromocytoma is a rare catecholamine-secreting tumor originating from adrenal chromaffin cells. Although uncommon, its occurrence during pregnancy is associated with significant maternal and fetal morbidity and mortality. Diagnosis is often delayed due to symptom overlap with hypertensive disorders of pregnancy, emphasizing the need for heightened clinical suspicion.

Case Presentation: We present the case of a 44-year-old gravida 14 para 10 woman with chronic hypertension who presented at 24 weeks of gestation with recurrent episodes of palpitations, dyspnea, diaphoresis, and markedly labile blood pressure reaching 180/130 mmHg despite methyldopa therapy. Abdominal ultrasound revealed a right adrenal mass measuring 31 × 28 mm. Magnetic resonance imaging without contrast confirmed a well-defined right adrenal lesion (27 × 31 mm) with high T2 signal intensity. Biochemical investigations demonstrated markedly elevated plasma and 24-hour urinary catecholamines and metanephrines, confirming the diagnosis of pheochromocytoma.

Management and Outcome: Methyldopa was discontinued and alpha-adrenergic blockade with prazosin was initiated with gradual dose titration, resulting in improved hemodynamic stability. Due to the advanced gestational age at diagnosis, surgical resection was postponed. The patient underwent an elective cesarean section at 34 weeks of gestation, delivering a healthy female infant who required brief neonatal observation only. Two weeks postpartum, she underwent a successful laparoscopic right adrenalectomy without complications. Postoperatively, her symptoms resolved completely, blood pressure normalized, and follow-up biochemical testing returned to normal.

Conclusions: This case illustrates the diagnostic challenge of pheochromocytoma in pregnancy and emphasizes that refractory or labile hypertension associated with adrenergic symptoms should prompt evaluation for secondary causes. MRI without contrast combined with biochemical testing remains the diagnostic cornerstone. Individualized multidisciplinary management with appropriate alpha-blockade, planned delivery, and delayed adrenalectomy can result in excellent maternal and fetal outcomes even when diagnosis is made late in pregnancy.

EP182 - ECE_2355 - Endocrine hypertensions: from Conn's syndrome to the gut microbiome

Sanja Borozan[1,2] and Joseph Pappachan[3,4,5]
[1]*Department of Endocrinology, Clinical Centre of Montenegro, Podgorica, Montenegro;* [2]*Faculty of Medicine, Podgorica, Montenegro;* [3]*Faculty of Science, Manchester Metropolitan University, Manchester, United Kingdom;* [4]*Department of Endocrinology, Kasturba Medical College, Manipal Academy of Higher Education, Manipal, KA, India;* [5]*Department of Endocrinology, Countess of Chester Hospital NHS Trust, Cheshire West and Chester, United Kingdom*

Hypertension remains one of the most significant global health challenges even in the 21st century, affecting approximately 40% of the adult population. While most individuals with high blood pressure have essential hypertension, recent estimates indicate that secondary hypertension, mostly of endocrine origin, accounts for up to 30% in those aged <40 years. Among those with refractory hypertension, nearly 50% have an identifiable underlying cause. Although endocrine hypertension (EH) is fairly common, it is often overlooked or diagnosed late, with an average delay of 3-5 years. This delay can lead to serious complications, including irreversible damage to target organs and, ultimately, premature mortality.

From the initial descriptions of Conn's and Cushing's syndromes to modern molecular and genetic classifications, diagnostic algorithms for EH have undergone a significant transformation, enabling active case-finding, early detection, and a personalized approach to treatment. Today, EH is no longer viewed solely through the lens of classical hormonal dysfunctions but as a diverse group of disorders that include genetic predisposition, autoimmune mechanisms, and interactions with other systems. Recent advances in genetics have enabled further subclassification of the disease and the use of targeted therapies, thereby increasing the level of individualization in treatment. Alongside well-established pathophysiological mechanisms, there is growing interest in the role of the gut microbiome in EH, particularly its influence on blood pressure through the production of metabolites such as short-chain fatty acids and trimethylamine-N-oxide, and its effects on systemic inflammation and endothelial dysfunction. These mechanisms open new perspectives for the development of diagnostic biomarkers and innovative therapeutic strategies.

A multidisciplinary approach, together with new molecular and biochemical markers and advanced imaging techniques, is essential in today's clinical management of EH. Early diagnosis of the underlying condition is essential for a potential cure or optimal control of hypertension.

EP183 - ECE_3184 - Artificial intelligence in adrenal imaging: detection and segmentation of adrenal glands

Zuzanna Roszkowska[1], Malgorzata Bobrowicz[1], Radoslaw Roszczyk[2] and Urszula Ambroziak[1]
[1]*Department of Internal Medicine and Endocrinology, Medical University of Warsaw, Warsaw, Poland;* [2]*Faculty of Electrical Engineering, Warsaw University of Technology, Warsaw, Poland*

Background: Accurate visualization of the adrenal glands is crucial for the evaluation of adrenal pathology. However, their small size, variable shape, and proximity to other retroperitoneal structures make automated analysis challenging. Artificial intelligence (AI) tools capable of detecting and segmenting adrenal glands could significantly improve workflow efficiency and lay the groundwork for future tumor characterization.

Objective: At the current stage of the project, we aim to develop and validate an AI-based algorithm for automated detection and 3D segmentation of adrenal glands in non-contrast CT scans. This constitutes a foundational step for subsequent modules that will analyze adrenal lesions.

Methods: A multidisciplinary team from the Medical University of Warsaw and Warsaw University of Technology is collaborating to build a comprehensive dataset of anonymized abdominal CT scans. Using state-of-the-art deep learning architectures, we are training models to precisely identify and segment both adrenal glands, generating accurate three-dimensional reconstructions. The performance of the model is evaluated based on segmentation accuracy and anatomical consistency.

Conclusions: The AI algorithm successfully detects and segments adrenal glands in three dimensions, offering a robust and scalable tool for future applications in adrenal imaging. This stage represents a critical foundation for further development of AI systems aimed at lesion detection and classification in adrenal pathology.

EP187 - ECE_1434 - Cardiovascular events and target organ demaged in primary aldosteronism

Natasa Vujacic[1,2] and Goran Zoric[1]
[1]*Clinic of Endocrinology, Diabetes and Metabolic Disease, Kliničkі Centar Srbije, Beograd, Serbia;* [2]*Clinical Center of Serbia, Belgrade, Serbia*

Introduction: Primary aldosteronism (PA) is the most frequent secondary hypertension wich can lead to increased occurrence of cardiovascular, renal and central nervous system complications. Subjects with PA due to aldosterone-producing adenoma (APA) are diagnosed mostly due to clinical picture of hypokalaemia and hypertension.

Materials and Methods: The study group of PA included 40 patients (25 females, 15 males). The study groups (CS $n = 20$; A+HT $n = 40$) did not differ by age and sex. Standardized endocrinological testing for the diagnosis confirmation was done. The aim of this study was analyze clinical characteristics of the PA due to adenoma (PA) and to compare the frequency of many cardiovascular, renal and cerebrovascular events with those found in adrenal Cushing syndrome (CS) and adrenal tumour associated with essential hypertension (A+HT).

Results: There was no significant difference between groups related to the age, nor sex distribution, although a higher number of women in all groups was recorded ($P = .099$). Systolic and diastolic blood pressures were significantly higher in PA group ($P = .005$ and $P = .002$ respectivaly), with the lowest levels in NFA+HT group. The significanteley higher mean arterial pressure (MAP)

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

was also found in PA group ($P = .001$). The longest hypertension duration was recorded in the PA group, and was significantly longer ($P = .001$) than in CS+SCS group. PA patients had also the longest hypertension history ($P = .01$) and all had hypokalaemia. The smallest mean tumour diameter was found in PA group ($P < .001$). Atrial fibrillation is found to be twelve times more frequent in PA than in essential hypertension (EHT), but only patients older than 50 years have myocardial infarction 6.5 times and cerebrovascular infarction (CVI) 4.2 times independent of blood pressure and PA subtypes. Chronic renal failure was found in 20% of patients. Chronic renal failure was quite common in all three groups of hypertensive patients

Conclusions: It revealed that patients with aldosterone-producing adenoma have significantly higher systolic, diastolic and mean blood pressures compared to patients with nonfunctioning adrenal adenoma with hypertension. All patients with PA also had hypokalaemia, which aggravated organ damage or hypertensive emergencies.

EP189 - ECE_2854 - Adrenal function in clinically stable liver transplant candidates: an exploratory pre-transplant assessment

Daniela Cuboni[1], Elena Musso[2], Mattia Rossi[3], Letizia Meomartino[1], Valentina Gasco[1], Ezio Ghigo[1], Roberta Giordano[1,4], Gianluca Aimaretti[1] and Loredana Pagano[1]

[1]Division of Endocrinology, Diabetes and Metabolism, Department of Medical Science, University of Turin, Turin, Italy; [2]University of Turin, Turin, Italy; [3]Turin, Italy; [4]Department of Biological and Clinical Sciences, University of Turin, Turin, Italy

Background: Adrenal dysfunction has been described in advanced liver disease, particularly in critically ill patients, where it has been associated with adverse outcomes. In clinically stable liver transplant candidates, however, adrenal function is more difficult to interpret, and both the prevalence and clinical significance of hypothalamic–pituitary–adrenal (HPA) axis alterations remain uncertain. This analysis is part of a broader project investigating endocrine comorbidities in patients with liver cirrhosis.

Objective: To explore adrenal function in clinically stable liver transplant candidates undergoing pre-transplant evaluation and to assess the contribution and limitations of basal cortisol measurement and ACTH stimulation testing in this setting.

Methods: We retrospectively analyzed adult patients referred for endocrine consultation within the liver transplant pathway at a tertiary center between January 2021 and September 2024. Patients with available 08:00 AM. serum cortisol measurements, in the absence of ongoing systemic glucocorticoid therapy, were included. Basal cortisol <50 µg/L was considered suggestive of adrenal insufficiency, values >150 µg/L normal, and values between 50-150 µg/L defined a grey zone, prompting a standard 250 µg ACTH stimulation test. An adequate response was defined as a peak cortisol >180 µg/L.

Results: Twenty-five patients were included; median age was 58 years (IQR 54-66), 68% were male, median MELD score was 11.5 (IQR 8-16), and 68.2% were Child–Pugh class A. Hepatocellular carcinoma was present in 68%. Median morning cortisol was 83 µg/L (IQR 72-101). Based on basal cortisol alone, only 3/25 patients (12%) were within the normal range, whereas 21/25 (84%) fell within the grey zone and 1/25 (4%) had cortisol <50 µg/L. Of the grey-zone patients, 12/21 (57.1%) underwent ACTH stimulation testing; 7/12 (58.3%) achieved an adequate cortisol response, while 5/12 (41.7%) did not, indicating heterogeneous adrenal responsiveness despite clinical stability.

Conclusions: In clinically stable liver transplant candidates, basal total cortisol measurement was frequently inconclusive, with most patients falling into an indeterminate range. ACTH stimulation testing revealed substantial interindividual variability in adrenal responsiveness, highlighting the diagnostic challenges of adrenal assessment in this population. Alterations in cortisol-binding proteins may further confound interpretation of total cortisol measurements, supporting the need for more refined approaches to HPA axis evaluation in the pre-transplant setting. In this context, ongoing analysis of morning salivary cortisol within this cohort, although not formally validated at peak morning levels, may help to refine future approaches to HPA axis evaluation.

Abstract citation ID: lvag096.762

EP190 - ECE_2960 - Prevalence and predictors of testicular adrenal rest tumors in adults with congenital adrenal hyperplasia

Giulia Bovo, Irene Tizianel, Pierluigi Mazzeo, Giacomo Voltan, Chiara Sabbadin, Filippo Ceccato and Mattia Barbot

Ponte San Nicolò, PD, Italy

Background: Testicular adrenal rest tumors (TARTs) represent a significant complication in males with congenital adrenal hyperplasia (CAH), potentially impairing fertility and quality of life. Although TARTs are well-documented in pediatric populations, evidence regarding their prevalence and clinical significance in adult CAH patients remains limited, particularly regarding biochemical features and implications for disease management.

Aim of the Study: This study aimed to assess the prevalence of TARTs in adult males with CAH and to investigate potential associations with clinical features, biochemical parameters and indicators of disease control.

Methods: We conducted a retrospective analysis of 28 adult males with CAH (26 with 21-hydroxylase deficiency, 25 classic and 1 non-classic form, 2 with 11β-hydroxylase deficiency, median age 34 years) followed at our adult endocrinology unit. Clinical data included age at diagnosis, morphometric and biochemical parameters, and treatment regimens. TARTs were assessed via testicular ultrasonography.

Results: TARTs were identified in 12/28 patients (42.9%) with a mean age of 42 years. Patients with TARTs were significantly older at first adult endocrinology evaluation compared to those without TARTs (27.5 vs 19 years, $P = .026$) and had higher body weight (70 vs 66 kg, $P = .041$). All patients with 11β-hydroxylase deficiency developed TARTs. No significant differences were observed between patients with and without TARTs in biochemical parameters, for example 17 OHP (418 vs 398, $P = .237$) or androstenedione/testosterone ratio (1.3 vs 1.5, $P = .305$), hydrocortisone equivalent doses (median 20 mg in both groups, $P = .508$),

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

or phenotype distribution. Longitudinal evaluation between the first adult endocrinology visit and last follow-up showed that six patients experienced an increase in TART size or new TART development over time, one patient underwent surgical removal, and one showed a reduction in TART size, possibly related to improved disease control.

Conclusions: TARTs affect approximately half of adult males with CAH in our cohort, with a particularly high prevalence in those with 11β-hydroxylase deficiency. Older age and higher body weight emerge as risk factors for TART development. These factors may reflect, respectively, loss of follow-up during the transition to adult care and the effects of glucocorticoid overtreatment aimed at achieving stricter disease control in patients with TARTs. These findings pinpoint the importance of a structured transition of care from pediatric to adult endocrinology and underscore the need for long-term follow-up. Larger studies are needed to confirm these observations and define optimal screening protocols.

EP191 - ECE_3063 - Primary hyperaldosteronism

Ana Chokhonelidze
IBSU, Caucasus Medical Center, Nutrition and Metabolism Centre, Tbilisi, Georgia

Patient: 40-year-old female

Anthropometrics: Weight 89.5 kg, Height 164 cm, BMI 33, Waist circumference 120 cm

Complaints at Presentation: Recurrent hypertension (up to 200/100 mmHg), generalized weakness, dizziness, palpitations, emotional lability, imbalance.

History of Present Illness: For one year, persistent hypertension with disturbed sleep and diet, emotional stress. Diagnosed with nodular euthyroid goiter and carbohydrate metabolism disorder. One month earlier hospitalized for hypertensive crisis.

Hospital Investigations:

- **Brain CT:** No acute pathology; moderate frontal cortical atrophy.
- **Echocardiography:** Mild LV hypertrophy, diastolic dysfunction, EF 60%, mild ascending aortic dilation.
- **Vascular Duplex:** Significant stenosis of right internal carotid artery (>65%), bilateral vertebral artery deformities.
- **Laboratory:** Hypokalemia (K = 3.2 mmol/L), hyperglycemia (glucose 6.0 mmol/L).
- **Consultations:** Neurology and cardiology.

Medications at Presentation: Metformin XR 500 mg, Verapamil 80 mg, Magne-B6, Betahistine 24 mg.

Outpatient Findings:

- CBC/urinalysis: Normal.
- **Electrolytes:** Na 142, K 4.0, Ca++ 1.2 mmol/L.
- **Lipids:** Total cholesterol 192, HDL 41, LDL 109, VLDL 40, TG 206 mg/dL.
- **Creatinine:** 45 μmol/L.
- **Glucose/Insulin:** Glucose 99 mg/dL; Insulin 8.74; HOMA-IR 2.1; HbA1c 5.9%.
- **Liver function:** Tbil 0.6; Dbil 0.3; ALT 42; AST 28; GGT 41; ALP 95.
- Magnesium: 1.03.
- **Hormonal tests:** TSH 1.12; Anti-TG 16; Anti-TPO 12.6; Aldosterone 183; Renin 2.9; ARR 64; 24 h urine metanephrine 261; normetanephrine 320; cortisol 26.
- **Ultrasound:** Borderline hepatomegaly, fatty liver; right adrenal lesion 18 × 13 mm hypoechoic. Thyroid volume 20 cm^3; right lobe nodule 23 × 13 × 19 mm (FNA: colloid, BSRTC-II).
- **CT Imaging:** Bilateral adrenal nodules with fatty components, consistent with adenomas.

Main Diagnosis: Primary hyperaldosteronism (E26.0)

Comorbidities: D44.1; E74.8; E04.1; I15.2; E78.2; E66.8; K76.0; E55.9

Treatment: Spironolactone 50 mg initially controlled BP but caused menstrual irregularities. Therapy switched to eplerenone 25 mg, stabilizing BP and restoring cycle. Patient declined surgery; AVS recommended for functional assessment of bilateral adenomas.

Additional Therapy: Metformin XR 500 mg, Rosuvastatin/Ezetimibe 10/10 mg, Vitamin D3 2000 IU. Lifestyle modifications: balanced diet, physical activity, sleep hygiene.

Summary: 40-year-old female with hypertensive crisis. Imaging revealed bilateral adrenal adenomas. Outpatient labs confirmed dyslipidemia, impaired carbohydrate metabolism, and fatty liver. Hormonal studies established primary hyperaldosteronism. Medical therapy with mineralocorticoid receptor antagonists stabilized blood pressure and improved symptoms. Patient currently refuses surgical intervention and remains under endocrinology follow-up.

EP192 - ECE_3382 - Clinical, imaging and pathological features of adrenal ganglioneuromas: a series of 3 cases in a tertiary center

Danai Barlampa[1], Eirini Kaliakatsou[1], Athanasios Fountas[1], Kostis Karachalios[1], Charikleia Paschalidi[1], Chrysoula Samara[2], Dimitrios Bouklas[3], Marina Sassi[3], Giorgos Zografos[4], Chrysanthi Aggeli[4], Athina Markou[1] and Labrini Papanastasiou[1]
[1]Unit of Endocrinology, and Diabetes, Endocrinology, "G. Gennimatas" General Hospital of Athens, Athens 11527, Greece; [2]Radiology Department, "G. Gennimatas" General Hospital of Athens, Athens, Greece; [3]Surgical Pathologist Department, "G. Gennimatas" General Hospital of Athens, Athens, Greece; [4]Third Department of Surgery, "G. Gennimatas" General Hospital of Athens, Athens, Greece

Background: Adrenal ganglioneuromas are rare, benign tumors originating from neural crest cells and an uncommon cause of adrenal incidentalomas. They are typically non-functioning and often display non-specific imaging features, limiting reliable differentiation from other benign or malignant adrenal lesions. Due to non-specific radiological characteristics, definitive diagnosis is established postoperatively.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Aim: To present three cases of adrenal ganglioneuroma with heterogeneous imaging features, highlighting the diagnostic challenges and favorable outcomes after surgery.

Case Presentations: The first case is a 47-year-old woman who presented with persistent low back pain. A CT scan revealed a 4.2 cm retroperitoneal mass localized to the left adrenal bed, in contact with the adrenal gland with a non-contrast density of 20 HU. Subsequent MRI identified a 4.5 cm heterogeneous lesion characterized by high T2 signal intensity and absence of signal loss on out-of-phase T1 sequence. 123I-MIBG scintigraphy was unremarkable. Hormonal work-up excluded catecholamine, cortisol and aldosterone hypersecretion. The patient underwent left adrenalectomy and histopathological examination showed a maturing ganglioneuroma composed predominantly of Schwannian stroma (Ki-67 0.5%, S100, SOX10, synaptophysin positive). Postoperatively, the patient remains disease-free with no evidence of recurrence. The second case concerns a 34-year-old woman with a 2.8 cm left adrenal incidentaloma on CT, with a baseline attenuation of 35 HU. MRI revealed a 3 cm lesion with intermediate-to-low signal intensity on T2-weighted sequences and absence of signal loss on out-of-phase T1 images. The lesion was hormonally inactive. Due to indeterminate imaging characteristics surgical excision was performed. Histopathology confirmed an adrenal ganglioneuroma with predominant Schwannian stroma maturing subtype. The post-operative course was uneventful, and no relapse has been observed during follow-up. The third case involves a 61-year-old woman with bilateral adrenal adenomas (2.1 and 2.8 cm on the right and the left side, respectively) with evidence of cortisol autonomy. Contiguous with the right adrenal adenoma a 3.3 cm additional lesion was detected showing high T2 signal and marked contrast enhancement on MRI, raising suspicion for pheochromocytoma. While MIBG scintigraphy showed mildly increased uptake, urinary fractioned metanephrine and normetanephrine levels were within normal limits. The patient underwent right adrenalectomy and histopathological analysis revealed an adrenal adenoma adjacent to an adrenal ganglioneuroma (Ki-67:1.5%. SOX10, synaptophysin, S100 positive).

Conclusions: Adrenal ganglioneuromas may present with diverse and misleading imaging features. Despite thorough biochemical and radiological evaluation, pre-operative diagnosis remains challenging. Surgical resection allows definitive diagnosis and is associated with excellent prognosis.

EP193 - ECE_1036 - Adrenal tumors: a retrospective single-center overview of functional and histological characteristics

Tamara Dojcinovic[1,2], Jelena Malinovic Pancic[1,2] and Boris Dojcinovic[2,3]

[1]*University Clinical Center of the Republic of Srpska, Banja Luka, Bosnia and Herzegovina;* [2]*Faculty of Medicine, University of Banja Luka, Banja Luka, Bosnia and Herzegovina;* [3]*Primary Health Care Center of Banja Luka, Banja Luka, Bosnia and Herzegovina*

Introduction: Adrenal tumors are increasingly diagnosed due to the widespread use of imaging techniques, and they are often classified as incidentalomas when discovered during imaging conducted for reasons unrelated to suspected adrenal pathology. While most incidentalomas are nonfunctional, some require therapeutic intervention due to their size or functional activity.

Objective: The aim of the research is to present the most common indications for surgical treatment of adrenal tumors in one center.

Methods: This retrospective study included 74 patients with a mean age 58 years, who underwent surgical resection of adrenal tumors at the University Clinical Center of the Republic of Srpska between 2014 and 2024. Data were collected from electronic medical records.

Results: Among the 74 analyzed patients, 73% were female. The mean age at diagnosis was 57.74 ± 13.16 years (range 26-83), and the mean tumor size was 56.26 ± 22.52 mm (range 22-115 mm) Regarding hormonal activity, 51.4% of the tumors were nonfunctional. Among functional tumors, 27% ($n = 20$) of patients had Cushing syndrome, 15% ($n = 11$) had pheochromocytoma, 1.4% ($n = 1$) had paraganglioma, 2.7% ($n = 2$) had primary hyperaldosteronism, and 4.1% ($n = 3$) had adrenal cortical carcinoma. Histopathological subtypes included adenoma (48.6%), pheochromocytoma (13.5%), hyperplasia (9.5%), adrenocortical carcinoma (4.1%), and various benign lesions (ganglioneuroma, myelolipoma, cyst, paraganglioma, etc.) in smaller numbers. No statistically significant association was found between tumor size and hormonal activity ($P = .79$). Additionally, no significant difference in tumor size was observed between genders.

Conclusions: The majority of adrenal tumors surgically treated in our center were nonfunctional, consistent with data reported in the literature. Surgical intervention was mainly indicated due to tumor size.

EP194 - ECE_1654 - Primary aldosteronism with concomitant mild autonomous cortisol secretion and bilateral adrenal nodules: a management challenge

Stefania-Alexandra Bunceanu[1], Bena Andreea[2], Roxana Pui[1] and Stoian Dana[2]

[1]*Department of Doctoral Studies, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania;* [2]*Timisoara, Romania*

Background: Primary aldosteronism (PA) with concurrent mild autonomous cortisol secretion (MACS) represents a form of hormonal co-secretion that is far more common than previously appreciated, with major consequences for cardiovascular and renal morbidity, as well as substantial metabolic impact. When this co-secretion is present and imaging identifies bilateral adrenal adenomas, management becomes particularly challenging, as selecting the optimal therapeutic strategy often requires careful balancing of diagnostic uncertainty, clinical benefits, and long-term risks.

Case: A 61-year-old patient was referred for endocrine evaluation after an emergency presentation with precordial pain and palpitations, later diagnosed with paroxysmal atrial fibrillation and resistant hypertension. Severe hypokalaemia with borderline hypernatraemia prompted investigation for secondary hypertension. During the endocrine work-up, aldosterone was elevated with borderline renin, raising strong suspicion for PA. To allow accurate confirmatory testing, spironolactone was discontinued for four weeks. On reassessment, plasma renin activity was suppressed, aldosterone remained elevated, and the aldosterone-

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

to-renin ratio was markedly increased (580), confirming the diagnosis of PA. Additional hormonal evaluation showed borderline ACTH, and cortisol failed to suppress adequately after the 1 mg overnight dexamethasone test, supporting concomitant MACS. For adrenal morphology, an unenhanced CT scan was performed because of chronic kidney disease (eGFR ~32 mL/min/1.73 m^2). Non-contrast CT demonstrated bilateral, homogeneous adrenal nodules (10 mm left, 12 mm right), with an initial attenuation of 20 HU. Given the contraindication to iodinated contrast, contrast-enhanced ultrasound (CEUS) was used for further characterisation: the left lesion showed no enhancement, whereas the right showed mild enhancement with heterogeneous washout, raising concern for that nodular lesion. Although CEUS is not yet standardised in adrenal imaging guidelines, it provided clinically useful information when conventional contrast-based pathways were not feasible. The patient initially declined surgery. However, as renal function deteriorated and the right adrenal nodule showed a substantial increase in attenuation to 37 HU on follow-up CT, the patient agreed to right laparoscopic adrenalectomy eight months after the initial evaluation. Histology confirmed a 1 cm adrenal adenoma with spironolactone bodies and low proliferative activity (Ki-67 2%). Histological confirmation of cortisol secretion was not available.

Outcome: After surgery, blood pressure normalised and renin recovered from suppression, consistent with biochemical remission of aldosterone excess. Renal function improved, with a higher eGFR at three months. Reassessment of cortisol autonomy showed adequate suppression on the postoperative 1 mg overnight dexamethasone test (cortisol 1.2 µg/dL), arguing against persistent MACS. The left adrenal nodule remained radiologically stable on follow-up imaging.

EP196 - ECE_3031 - A rare case of adrenal pheochromocytoma with normal plasma and urinary metanephrine levels

Elena-Maria Pavel[1], Teodora Puscas[1], Claudiu Zaharia[1], Miruna Prie[1], Diana Stanciu[2], Mihaela Stanciu[1,2] and Codruta Lebada[1,2]

[1]Department of Endocrinology, County Clinical Emergency Hospital of Sibiu, Sibiu, Romania; [2]Department of Endocrinology, Lucian Blaga University of Sibiu, Sibiu, Romania

Introduction: Pheochromocytoma is a rare tumor originating from chromaffin cells of the adrenal medulla and is characterized by excessive catecholamine secretion. The clinical presentation varies from the classic triad of hypertension, headache, and diaphoresis to entirely asymptomatic cases. Diagnosis is based on biochemical evidence of catecholamine excess and radiological localization of the tumor. Surgical resection is the treatment of choice; however, long-term postoperative surveillance is recommended.

Case Report: We report the case of a 27-year-old male with no known comorbidities who presented with right upper abdominal pain. He denied symptoms suggestive of catecholamine excess: headaches, palpitations, diaphoresis, or hypertension. Abdominal ultrasonography demonstrated a right adrenal mass. Further abdominal computed tomography (CT) and magnetic resonance imaging (MRI) confirmed the presence of a 3 × 3 cm lesion arising from the right adrenal gland. Biochemical evaluation revealed normal 24-hour urinary metanephrine levels (135 µg/24 h; reference range <400 µg/24 h), while urinary normetanephrine levels were markedly elevated (4040 µg/24 h; reference range <500 µg/24 h). Plasma metanephrine concentrations were within the normal range; however, plasma normetanephrine levels were increased approximately eightfold above the upper limit of normal. This biochemical profile was suggestive of an extra-adrenal pheochromocytoma. Despite these findings, imaging studies localized the tumor to the adrenal gland, raising suspicion of a clinically silent adrenal pheochromocytoma. The patient underwent successful laparoscopic right adrenalectomy. Histopathological examination confirmed the diagnosis of pheochromocytoma. Postoperatively, the patient had an uneventful recovery, with complete resolution of symptoms and normalization of plasma metanephrine (25 µg/24 h; reference range <100 µg/24 h) and normetanephrine levels (32 µg/24 h; reference range <216 µg/24 h).

Conclusions: This case highlights the importance of integrating clinical presentation, biochemical evaluation, and imaging findings in the diagnosis of pheochromocytoma. Two unusual features were observed: the absence of classical clinical symptoms and the presence of normal plasma and urinary metanephrine levels in the context of markedly elevated normetanephrine concentrations. Although this biochemical pattern is typically associated with extra-adrenal pheochromocytoma, imaging confirmed an adrenal origin of the tumor.

EP197 - ECE_1768 - Effective cortisol synthesis control with markedly low-dose osilodrostat in ACTH-independent Cushing syndrome: a case report

Gabriela Handzlik[1], Anna Chudek[1], Maria Świerkot[2], Ewa Płoskonka[2], Joanna Staniszewska-Mróz[2] and Jerzy Chudek[1]

[1]Department of Internal Medicine and Oncological Chemotherapy, Medical University of Silesia, Katowice, Poland; [2]Independent Public Clinical Hospital named after Andrzej Mielęcki, Medical University of Silesia in Katowice, Katowice, Poland

Introduction: Surgical adrenalectomy is the treatment of choice in ACTH-independent Cushing syndrome (CS). However, it may be contraindicated in patients with advanced age or severe comorbidities. Pharmacological treatment options include osilodrostat, an oral 11β-hydroxylase inhibitor approved for ACTH-dependent CS, which has been used sporadically in ACTH-independent CS. We present a case of ACTH-independent CS successfully controlled with extremely low doses of osilodrostat.

Case Presentation: A 64-year-old female was admitted to the endocrinology unit for evaluation of resistant hypertension with persistent hypokalemia. The initial evaluation suggested primary aldosteronism, but subsequent hormonal work-up established ACTH-independent CS, with elevated 24-hour urinary free cortisol, loss of the diurnal cortisol rhythm, unresponsiveness to 1 mg overnight dexamethasone suppression test, and decreased plasma ACTH level. Abdominal CT imaging revealed a 17-mm adrenal tumour of the right gland with benign radiological features. The patient presented with multiple, potentially CS-

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

related comorbidities, including obesity (BMI 35.7 kg/m^2), type 2 diabetes mellitus, severe hypertension with kidney disease, osteoporosis (with low-trauma vertebral fractures), and severe obstructive sleep apnea. Her medical history was complicated by life-threatening infections, including severe COVID-19 pneumonia requiring ICU admission (2020) and septic shock in the course of necrotizing soft tissue infection of the lower extremity (2024). Due to the very high perioperative risk, adrenalectomy was contraindicated and pharmacological treatment with osilodrostat was initiated in March 2025 at a standard starting dose of 2 mg bid. This regimen resulted in a rapid decrease of cortisol secretion with serum cortisol levels below 3 µg/dL and concomitant symptoms of adrenal insufficiency, including nausea and hypotension, requiring temporary hydrocortisone substitution. After a gradual reduction of osilodrostat dose to 1 mg every 5 days, serum cortisol and free cortisol concentrations in daily urine collections remained within the reference. Treatment resulted in normalization of serum potassium levels, improved blood pressure control, and overall clinical status.

Conclusions: In clinical trials and in real-world settings, osilodrostat is typically administered in Cushing disease at daily doses of two to sixty milligrams. Published evidence on the use of osilodrostat in ACTH-independent CS is limited, and reports specifically addressing low-dose efficacy are lacking. This case demonstrates the effectiveness and tolerance of very low-dose osilodrostat as a treatment option for ACTH-independent Cushing syndrome in patients ineligible for surgery. It raises awareness of a wide range of osilodrostat dosing in Cushing syndrome.

EP198 - ECE_3472 - Pseudohyperkalaemia in thrombocytosis—a reminder

Bara Taufik and Asjid Qureshi
Department of Diabetes & Endocrinology, Northwick Park Hospital, London, United Kingdom

Introduction: Pseudohyperkalaemia is defined as a raised serum potassium with concurrent plasma potassium levels within the normal range. There is usually a slight difference between serum and plasma potassium levels, owing to release of potassium from activated platelets during clotting; pseudohyperkalaemia occurs where there is a difference greater than 0.4 mmol/L between the two values, in the absence of symptoms or ECG changes. While pseudohyperkalaemia occurs relatively frequently in primary care, owing to difficulties in storage and transportation of samples, it is far less common in the hospital setting.

Case: A gentleman with a background of ulcerative colitis, pancreatic cancer and diabetes mellitus was seen during a routine consultation while an inpatient for management of his diabetes. Routine blood tests showed a serum potassium of 6.0 mmol/L. There were no concerning ECG features; the hyperkalaemia was refractory to standard treatment. He did not take any medications that would predispose him to hyperkalaemia, and was adherent to a low-potassium diet as advised by a dietitian. Random cortisol was checked and was found to be 464 nmol/L, excluding Addison's disease. It was noted that he had significant thrombocytosis, with an apparent positive correlation between his platelet count and serum potassium levels. Repeat blood tests showed serum potassium of 5.6 mmol/L; the same sample was simultaneously run through a blood gas analyser, with a potassium of 4.8 mmol/L. Given all other causes of hyperkalaemia had been excluded, it would appear that this was a case of pseudohyperkalaemia secondary to thrombocytosis. He has since been referred onto a Haematologist for further investigation.

Conclusions: Pseudohyperkalaemia should always be considered in patients with unexplained, hyperkalaemia where the clinical context or progress is unusual. Identifying pseudohyperkalaemia may avoid subjecting patients to unnecessary investigations and potentially harmful treatments.

EP199 - ECE_1862 - Demographic and clinical characteristics of pheochromocytomas and paragangliomas at the University Hospital of the Canary Islands

Selena Rodriguez Fernandez, Kevin David Díaz Gorrín, Javier Panizo Fra, Paula Pérez, Óliver Quintero Rodríguez, Ana Paola Leon Ocando, MacArena Sánchez-Gallego Alonso, Itziar Aznar Ondoño and Juan Ignacio Márquez De La Rosa
Endocrinology and Nutrition, Hospital Universitario de Canarias, San Cristóbal de La Laguna, Spain

Introduction: Pheochromocytoma is a rare neuroendocrine tumor arising from chromaffin cells of the adrenal medulla, responsible for catecholamine production. Approximately 80%-85% of cases are adrenal, while the remainder occur at extra-adrenal sites (paragangliomas). The estimated annual incidence is 1-2 cases per 100 000 habitants, affecting men and women equally, with peak incidence between the third and fifth decades of life. In Spain, 83% of cases are sporadic and 17% hereditary, mainly associated with multiple endocrine neoplasia type 2A. The treatment of choice is surgical resection, preceded by alpha-adrenergic blockade. Recurrence occurs in approximately 10%-16% of patients and is more common in those with a family history or extra-adrenal tumors.

Objective: To study the clinical characteristics of patients with pheochromocytomas or paragangliomas at the University Hospital of the Canary Islands.

Materials and Methods: A retrospective observational study including patients diagnosed with pheochromocytoma and followed in the Endocrinology outpatient clinic between 2024 and 2025. A total of 14 patients were included, with a mean age of 63.78 years, of whom 71.43% were female.

Results:

- Median age at diagnosis was 57.5 years.
- Presentation as incidentaloma occurred in 47.05%, with hypertension present in 65% (17.6% paroxysmal). Other symptoms were reported in 52.9%.
- Catecholamines were elevated at diagnosis in 76.92%.
- Most frequent location was adrenal (76.47%), followed by carotid (17.64%) and auricular (5.88%). Laterality was left unilateral in 52.92%, right unilateral in 23.53%, and bilateral in 23.52%. Unifocal disease was present in 82.35%.
- Mean tumor size was 5.44 cm.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

- The most commonly used imaging modality for diagnostic confirmation was MRI (40.04%), followed by CT (33.3%) and MIBI scintigraphy (26.66%).
- Genetic testing was performed in 5 patients, with positive results in 3. Only one patient had disease associated with a syndrome (Neurofibromatosis type 1).
- The treatment of choice was laparoscopic surgery (82.35%), followed by medical therapy (11.7%) and radiotherapy (5.88%).
- Postoperative complications occurred in 5.88%.
- Additional treatment was required in 17.64% (mostly radiotherapy). Recurrence occurred in 23.53% (2 local recurrences and 2 paragangliomas at other sites).
- Mean follow-up duration was 10.07 years. Persistent hypertension was present in 23.53%, and 100% of patients currently have stable disease.

Conclusions: Given the severity of the disease, early diagnosis and surgical intervention are fundamental in the management of pheochromocytoma. Although rare, recurrence is not negligible, supporting the need for long-term follow-up.

EP200 - ECE_1398 - A calm before the catecholamine storm: case of normotensive pheochromocytoma

Radmila Milosheska[1,2], Risto Pejkov[3], Ivana Mickovski[4] and Daniela Buklioska Ilievska[5]

[1]*Endocrinology and Diabetes, General City Hospital "8th September", Skopje, North Macedonia;* [2]*Endocrinology, Diabetes and Metabolic Diseases, General City Hospital "8th September", Skopje, North Macedonia;* [3]*Urology, University Surgery Clinic "St. Naum Ohridski", Skopje, North Macedonia;* [4]*PZU Vasileva Kardio, Skopje, North Macedonia;* [5]*Pulmonology and Alergology, General City Hospital "8th September", Skopje, North Macedonia*

Background: Pheochromocytomas are functional tumors that originate from the adrenal medulla and extramedullary sympathetic ganglia, arising from chromaffin cells that secrete catecholamines. It is estimated that 5%-6.5% of all adrenal incidentalomas are pheochromocytomas, which are associated with a diverse array of clinical symptoms. Notably, around 8% of these cases may involve patients who are asymptomatic, with their diagnosis occurring incidentally or prompted by discomfort due to tumor mass growth.

Case Presentation: An 18-year-old female patient presented at the endocrinology outpatient clinic with a complaint of recurrent pain in the left lumbar region, accompanied by episodes of vomiting over the past two months. Prior imaging at another institution, specifically an abdominal ultrasound, indicated a notable displacement of the left adrenal gland, measuring 76 mm × 50 mm × 56 mm. A subsequent CT scan of the abdomen and pelvis confirmed this finding, confirming the presence of a heterogeneous ill-defined tumor mass in the area of the right adrenal gland, which also led to a comprehensive hormonal evaluation with the same measurements. The hormonal assessment revealed significant results: VMA levels were measured at 112.7 umol/dU (7.0-68.0 umol/dU), Metanephrines at 26.2 umol/dU (<5 umol/dU), Cortisol at 897 nmol/L (55-690 nmol/L), and ACTH at 28.7 pg/mL (7.2-63.3 pg/mL). These findings suggested a diagnosis of pheochromocytoma.

Management: She opted to commence treatment with a minimal dose of prazosin and planned to titrate to the optimal dosage while maintaining careful monitoring to prevent hypotensive episodes. During the laparoscopic surgical procedure, several hypertensive crises were encountered and subsequently managed by the anesthesiology team. Following this, the tumor was successfully excised using a traditional surgical approach, resulting in the removal of the tumor-altered adrenal gland, which weighed 99 grams and measured 9 cm × 6 cm × 2.7 cm. Pathological and immunohistochemical analyses indicated that the tumor was positive for Chromogranin and Synaptophysin, and S100 was positive in the sustentacular cells. Post-operative evaluations of VMA and metanephrine levels were conducted to verify normalization of both cortisol and ACTH levels.

Conclusions: Pheochromocytoma is a rare condition that presents significant challenges regarding timely diagnosis, particularly in cases involving normotensive patients, who may remain asymptomatic for extended periods until a compressive effect manifests. Therefore, it is essential to conduct hormonal evaluations for all adrenal incidentalomas, irrespective of clinical symptoms. This approach facilitates timely diagnosis and ensures appropriate preoperative preparation for patients, thereby minimizing potential complications during surgical intervention.

EP201 - ECE_1362 - Gender differences in adrenal disorders: a 16-year retrospective analysis of clinical and biochemical findings from Oman

Muzna AlHinai[1,2], Isa Alsalmi[1] and Ehab Abdelrazek[1]

[1]*The Royal Hospital, Bawshar, Oman;* [2]*Oman Medical Speciality Board, Muscat, Oman*

Background: Adrenal disorders are individually uncommon but clinically important. The incidence and prevalence of adrenal disorders in the active component of the Omani population have not been previously described.

Aim: To characterize the clinical, biochemical, and imaging profiles of all patients with confirmed primary adrenal disorders managed at the Royal Hospital Oman.

Methods: Retrospective cross-sectional situational analysis. Data retrieved from Alshifa system (Jan 2006-Dec 2022). Inclusion criteria were confirmed diagnoses of primary adrenal disorders. Patients with unconfirmed diagnoses or secondary adrenal disorders were excluded. Incidental adrenal findings not investigated were not included.

Results: A total of 129 patients met inclusion criteria. Mean age was 34.9 ± 22.4 years, with male predominance (63.8%). Statistical disparities included the prevalence of chronic hypokalaemia in males (14.5% of men vs 2.2% of females ($P = .026$). Another disparity noted is 17-hydroxyprogesterone levels were higher in women, with a mean ~201 ng/mL in females vs 51.8 ng/mL in males ($P = .021$). Imaging patterns showed no sex effect: computed tomography and Magnetic resonance imaging showed similar rates of adrenal mass detection. No gender disparity appeared in diagnostic imaging or tumour size. Most adrenal diagnoses were distributed similarly in males and females. Adrenal lipomas tended to be more frequent in women,

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

but this didn't reach significance ($P = .102$). Among all studied adrenal disorders, most prevalent in our cohort was congenital adrenal hyperplasia (25%) followed by adrenal adenoma (17%). The mortality was higher in adrenocortical carcinoma compared to other included adrenal disorders, regardless of gender.

Conclusions: This 16-year analysis highlights gender differences in adrenal disorders in Oman, with CAH and adrenal adenomas being predominant. While overall disease distribution was similar between both genders, important sex-specific differences emerged: chronic hypokalaemia was more common in men, women had higher 17 hydroxyprogesterone. These results support sex-sensitive diagnostic approaches and provide baseline data to guide future research. High prevalence of CAH is likely due geographical variation, sub-analysis to investigate underlying consanguinity as contributing factor is recommended.

EP202 - ECE_3249 - Connshing syndrome: a case report

Chayma Besrour[1], Hiba Bettaieb[2], Wiem Helali[3], Manel Boudokhane[4], Rim Bourguiba[5] and Syrine Bellakhel[5]
[1]*Endocrinology, Internal Security Forces Hospital Marsa, Tunis, Tunisia;* [2]*Rhumatology, Hopital de Force de Sécurité Interieure de la Marsa, Tunis, Tunisia;* [3]*Internal Medecine, Hopital de Force de Sécurité Interieure de la Marsa, Tunis, Tunisia;* [4]*Tunis, Tunisia;* [5]*Internal Security Forces Hospital Marsa, Internal Medecine, Tunis, Tunisia*

Introduction: Primary hyperaldosteronism (Conn's syndrome) is a common cause of secondary hypertension, characterized by autonomous aldosterone secretion and suppressed renin levels. Mild autonomous cortisol secretion (MACS), often detected incidentally, is associated with subtle cortisol excess without overt Cushingoid features. The coexistence of both conditions termed «Connshing syndrome»is rare but clinically significant due to its potential impact on cardiovascular and metabolic risk.

Case report: A 60-year-old male patient with a history of type 2 diabetes mellitus, hypertension, and coronary artery disease was evaluated following incidental hypokalemia discovered during hospitalization for an acute coronary syndrome. Clinical examination did not show any abnormalities.

Endocrine Findings first exluded pheochromocytoma, Then the exploration of mineralocorticoid secretion showed an elevated plasma aldosterone level at 1346 pmol/L with renin level at 6.7 mU/L and an aldosterone-to-renin ratio of 201.9 (>64), confirming primary Hyperaldosteronism (Conn's Syndrome). As for the glucocorticoid secretion an initial 1 mg overnight dexamethasone suppression test (DST)yielded to a cortisol level of 92 nmol/L > 50 nmol/l (no suppression); repeat Standard DSTs confirmed elevated cortisol level at 111.7 nmol/L and 153.8 nmol/L, with unsuppressed levels compared to a reference threshold of 50 nmol/L. ACTH was measured at 14.4 pg/ml in favour of a mild autonomous cortisol secretion (MACS).

Contrast-enhanced adrenal CT revealed bilateral adrenal nodules: two left-sided (10 mm external limb, 8 mm internal) and one right-sided (9 mm internal). A follow-up scan after one year confirmed persistence of similar bilateral nodules.

The patient exhibits primary hyperaldosteronism with concurrent mild autonomous cortisol secretion, consistent with a Connshing syndrome.

Discussion: Connshing syndrome affects approximately 20%-30% of patients with primary hyperaldosteronism and is associated with a higher cardiovascular risk profile due to the synergistic effects of aldosterone and cortisol excess on blood pressure, glucose metabolism, and vascular remodeling.

Early recognition of dual hormone secretion is crucial for optimal management and risk stratification, particularly in patients with pre-existing cardiovascular disease.

Abstract citation ID: lvag096.774

EP203 - ECE_3824 - Significance of primary aldosteronism forms not meeting syndrome's conventional criteria

Piotr Kmieć
Department of Endocrinology and Internal Medicine, Medical University of Gdańsk, Gdańsk, Poland

Significance of Primary Aldosteronism Forms Not Meeting Syndrome's Conventional Criteria

The established diagnostic work-up of primary aldosteronism (PA) has consisted of three consecutive steps: screening of at-risk populations using the aldosterone-to-renin ratio (ARR), confirmatory testing in those with a positive screen, and subtyping (between a familial form, adrenocortical carcinoma, bilateral or unilateral disease). PA has been effectively excluded if: 1) the patient did not belong to one of the risk groups, 2) screening, or 3) confirmatory test were negative.

A plethora of evidence in the last two decades has proven the inadequacy of this dichotomous approach. Like other endocrinopathies, PA encompasses a wide spectrum of clinical and hormonal presentations. It can be present in individuals with normotension and normokalemia as well as lead to life-threatening hypertensive crises and/or hypokalemia.

The 2025 Endocrine Society guideline has reframed the PA diagnostic work-up radically. It mirrored the European Society of Cardiology 2024 guideline in suggesting PA screening among all adult patients with HT (McEvoy et al., European Heart Journal, 2024(45); Adler et al., JCEM, 2025(110)). Conversely, the application of confirmatory tests is to be limited, owing to lack of/poor evidence that using them improves the management. The document repeatedly emphasizes the difficulty of defining diagnostic thresholds due to the continuous nature of hormonal parameters, which necessitates a probabilistic approach (diagnosis more or less likely). The progressive hormonal severity of mild/subclinical PA has been evidenced (Buffolo et al., Hypertension, 2024(81)).

Mild PA forms have become more relevant in light of to-date studies associating dysregulated aldosterone secretion with the development of HT, vascular, renal, and metabolic complications. Just as overt PA can be successfully managed with targeted treatment, it is necessary to consider the same therapies in its less severe forms.

Clear renin suppression justifies mineralocorticoid-receptor antagonist (MRA) therapy and warrants consideration of surgically treatable PA. However, intermediate (PRA 0.5-1.0 ng/mL/h or direct renin 6-15 mIU/L) levels that yield an ARR below overt PA criteria (2.0-2.5 ng/mIU) constitute a diagnostic gray zone. The PATHWAY-2 trial, its substudies, and a recent meta-analysis indicate MRAs are superior in low-renin HT but optimal thresholds

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

remain undefined (Shah et al., J Hum Hypertens 2024(38), Williams et al., Lancet 2015(386), Williams et al. Lancet Diabetes Endocrinol 2018(6)). The ongoing REMASTER trial may help clarify whether patients in this intermediate zone benefit more from MRA or conventional HT therapy (Shah et al., J Hum Hypertens 2024(38)).

EP205 - ECE_2162 - Clinical profile of primary aldosteronism patients attending a tertiary endocrine center in Nepal

Ansumali Joshi[1,2], Srijana Karmacharya[1], Puspa Dahal[1], Smriti Khadka[1], Radhika Tuladhar[1] and Sapana Yadav[1]
[1]*Kathmandu Diabetes and Thyroid Center, Lalitpur, Nepal;* [2]*Kathmandu Diabetes and Thyroid Centre, Kathmandu, Nepal*

Primary aldosteronism patients' data is scarce in Nepal. We retrospectively reviewed all 18 patients with Primary aldosteronism from 2010 to 2024. 10(55.56%) patients were males and 8(44.44%) were females with M: F ratio 1.25:1. Mean age was 53.66 ± 12.86 years and mean BMI was 25.26 ± 3.71 Kg/m^2. Presenting clinical features were uncontrolled hypertension in 7(38.89%), hypertension with hypokalemia in 6(33.33), incidental adrenal adenoma in 1(5.56%) and asymptomatic in 6(33.33%). Resistant hypertension was seen in 3(16.67%) patients. Mean SBP at presentation was 155.55 ± 17.2 mmHg and DBP was 98.88 ± 10.22 mmHg. Mean Potassium level was 3.67 ± 0.62 mEq/L, sodium level was 139.16 ± 2.72 mEq/L and eGFR was 83.58 ± 28.02 ml/min/1.723 m^2. Plasma aldosterone level was 103.83 ± 145.04 ng/dl and plasma renin activity was 0.59 ± 0.74 ng/ml/hr. In some patients, direct renin measurement was done and mean was 1.31 ± 1.13 mlU/l. Mean aldosterone: plasma renin activity ratio was 371.65:1 and mean aldosterone: direct renin ratio was 207.56:1. Bilateral adrenal hyperplasia was seen in 7 (38.89%) and unilateral in 1(5.56%). Adenoma was seen in 9 (50%). Right sided adrenal adenoma was seen in 3(16.67%) and left sided in 6(33.33%). Surgery for unilateral adenomas was done in 7 (38.89%) patients. Rest was put on Spironolactone. Surgery was curative with no anti-hypertensives required in 1 patient only and 1-2 anti-hypertensive in 6 (33.33%) patients at 6 months follow up. With spironolactone use, hypertension was well controlled in all patients.

EP206 - ECE_3638 - Adrenal hemorrhage: a rare diagnostic challenge

Bárbara Jesus[1], Ana Margarida Sobral[1], Adriana Duarte[1], Mariana Coelho[1], Leonor Rodrigues[2], Alice Monsanto[1], Tânia Carvalho[1], Gustavo Rodrigues[1], Mariana Lavrador[1], Dírcea Rodrigues[1] and Leonor Gomes[1]
[1]*Local Health Unit of Coimbra, Coimbra, Portugal;* [2]*Local Health Unit of Aveiro, Aveiro, Portugal*

Introduction/Background: Adrenal incidentalomas are frequently detected on cross-sectional imaging and require systematic evaluation to exclude hormonal hypersecretion and malignancy. Adrenal hemorrhage is rare, occurring in approximately 0.11% of imaging studies, and can closely mimic adrenal neoplasms, often presenting as a suspicious mass. Clinical manifestations range from incidental findings to nonspecific abdominal pain, acute adrenal insufficiency, or cardiovascular compromise. Predisposing factors include anticoagulation, trauma, neoplastic disease, infections, acute stress, coagulopathy and systemic disorders. We present a case of a left adrenal mass initially suspected to be neoplastic, ultimately diagnosed as an adrenal hemorrhage.

Clinical case: A 63-year-old male was referred to Endocrinology after incidental detection of an adrenal mass on chest CT, performed for chronic cough. A subsequent abdominal CT was requested to further characterize the lesion, revealing a 5.3 cm left adrenal nodule, slightly heterogeneous with focal calcification, with 33HU and markedly low absolute (33%) and relative (5%) washout values. Small abdominal lymph nodes were noted, the largest measuring 1 cm.

Due to the size and highly suspicious imaging features, the patient was admitted directly in the Endocrinology ward for expedited evaluation. He was asymptomatic, denying abdominal pain or symptoms suggestive of hormonal hypersecretion. Medical history included hypertension diagnosed approximately 10 years earlier, well controlled with perindopril/amlodipine; type 2 diabetes, dyslipidemia, anemia, alcohol-related chronic liver disease, peripheral arterial disease, and active smoking. Medications also included carvedilol, metformin/dapagliflozin, sitagliptin, rivaroxaban and atorvastatin/ezetimibe.

During hospitalization, a comprehensive hormonal evaluation was performed, including plasma metanephrines and 3-methoxytyramine, 24-hour urinary free cortisol, ACTH/cortisol circadian rhythm, 1mg dexamethasone suppression test, and androgens, all within the reference ranges, effectively excluding pheocromocytoma, hypercortisolism and androgen excess.

The patient subsequently underwent laparoscopic left adrenalectomy, without complications. Histopathology revealed an organized, thrombosed adrenal hematoma and no evidence of malignancy. The postoperative course was uneventful, and he was discharged from both Urology and Endocrinology follow-up.

Discussion/Conclusions: This case illustrates that adrenal hemorrhage can mimic neoplastic adrenal lesions, posing a diagnostic challenge. The combination of low washout, focal calcification and size >5 cm raised substantial concern for malignancy, justifying surgical intervention despite an asymptomatic presentation. In this patient, anticoagulation and advanced chronic liver disease likely contributed to hemorrhage risk. While most adrenal hemorrhages resolve spontaneously, surgical resection should be considered when imaging cannot reliably exclude neoplasia, particularly given that 48% of hemorrhages with associated masses harbor pheochromocytoma. Comprehensive hormonal assessment, careful imaging interpretation, and multidisciplinary management are essential for appropriate treatment decisions.

EP207 - ECE_1395 - Adrenal crisis in a 36-year-old male with pneumonia: a case report of complications leading to adrenal coma, rhabdomyolysis, and acute kidney failure

Ivana Mickovski[1,2], Radmila Milosheska[3] and Daniela Buklioska Ilievska[1,3]

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

[1]Faculty of Medical Sciences, Goce Delcev University, Stip, North Macedonia; [2]PZU Vasileva Kardio, Skopje, North Macedonia; [3]General City Hospital 8th September, Skopje, North Macedonia

Background: Adrenal crisis is a rare but life-threatening emergency caused by acute adrenal insufficiency, often triggered by infections or physiological stress. Rapid diagnosis and treatment are essential to prevent multi-organ failure.

Case presentation: We present a 36-year-old previously healthy male admitted with pneumonia who developed adrenal crisis complicated by adrenal coma, rhabdomyolysis, and acute kidney failure. The patient presented with hypotension, fever, and altered consciousness. Laboratory findings revealed hyponatremia (Na 122 mmol/L), hyperkalemia (K 6.1 mmol/L), hypoglycemia, elevated creatine kinase (12 000 U/L), and acute renal impairment (creatinine 3.8 mg/dL). Serum cortisol was critically low (2.1 µg/dL), confirming adrenal insufficiency.

Management and Outcome: Immediate treatment with intravenous hydrocortisone (100 mg bolus followed by infusion), aggressive fluid resuscitation, and broad-spectrum antibiotics resulted in rapid hemodynamic stabilization. Supportive measures for rhabdomyolysis and renal failure were implemented, leading to full recovery within one week. The patient was discharged on maintenance oral corticosteroid therapy and scheduled for endocrinology follow-up.

Conclusions: This case highlights the importance of early recognition and prompt corticosteroid replacement in adrenal crisis, particularly in patients with infection-related triggers. Rapid intervention with hydrocortisone, antibiotics, and intensive fluid therapy remains the cornerstone of successful management.

Keywords adrenal crisis, adrenal insufficiency, pneumonia, rhabdomyolysis, acute kidney failure

EP208 - ECE_1597 - Dual ectopic thyroid tissue with a eutopic thyroid gland: an unusual presentation of struma ovarii

Arshiya Dutta[1], Amal Shaharyar[2] and Pinaki Dutta[2]
[1]Medicine, Maharishi Markandeshwar University, MBBS, Solan Tehsil, India; [2]Endocrinology, Postgraduate Institute of Medical Education and Research Chandigarh, Chandigarh, India

Context: Struma ovarii is an exceptionally rare monodermal ovarian teratoma characterized by the predominance of thyroid tissue and is frequently misdiagnosed due to its nonspecific clinical and radiological features. Preoperative differentiation from other ovarian neoplasms is challenging, and definitive diagnosis is usually established only on histopathological examination.

Case description: We report a case of unilateral benign struma ovarii in a 19-year-old unmarried female, in which the tumor closely mimicked ovarian malignancy on imaging owing to its large size and complex morphology, despite normal tumor markers and thyroid function tests. The patient was successfully managed with fertility-preserving surgical excision. Postoperative endocrine evaluation confirmed a normally functioning eutopic thyroid gland and a coexisting thyroglossal duct cyst, representing a rare occurrence of dual ectopic thyroid tissue in the presence of a eutopic thyroid gland.

Conclusions: This case highlights the diagnostic challenges of struma ovarii, particularly in young patients, and underscores the importance of histopathology in establishing the diagnosis. Surgical resection remains the cornerstone of treatment and is associated with an excellent prognosis in benign cases.

Keywords struma ovarii, ovarian goitre, ovarian thyroid, euthyroid

EP1675 - ECE_1980 - CT-based radiomics for differentiation of adrenal lesions

Almaz Manaev[1,2], Natalya Tarbaeva[1], Kseniya Vysotskaya[1], Anastasia Chevais[1], Anna Roslyakova[1], Ekaterina Troshina[1], Nadezhda Platonova[1], Galina Melnichenko[1] and Natalia Mokrysheva[1]
[1]Endocrinology Research Centre, Moscow, Russia; [2]National Research Nuclear University MEPhI, Moscow, Russia

Introduction: Adrenal lesions present a significant diagnostic challenge, as their etiologies range widely from benign adenomas to aggressive malignancies. Accurate differential diagnosis is therefore critical for determining appropriate treatment and prognosis. Recent advances in quantitative image analysis, particularly radiomics, offer a promising solution by identifying subtle patterns invisible to the human eye. Integration of quantitative imaging data with machine learning algorithms provides a powerful framework for building objective diagnostic models

Objective: Development and validation of a machine learning model utilizing CT texture analysis for the differential diagnosis of adrenal lesions.

Methods: This retrospective single-center study included 570 patients with histologically confirmed adrenal tumors: 40 cases of adrenocortical carcinoma, 180 lipid-poor adenomas, 50 lipid-rich adenomas, 15 cysts, 35 myelolipomas, 15 lesions of neurogenic origin, and 235 pheochromocytomas. Radiomic features were extracted from four-phase contrast-enhanced CT images using the PyRadiomics 3.1.0 module after manual 3D segmentation.

Feature reproducibility was assessed using the intraclass correlation coefficient (ICC), and feature variability was evaluated via the coefficient of variation (CV). To mitigate technical variability, CT attenuation data were standardized using the mean aortic attenuation as an internal reference. A LightGBM gradient boosting model was implemented in Python (version 3.9.21) for classification tasks.

The study protocol was approved by the Institutional Review Board of the Endocrinology Research Centre (Protocol No. 20, dated November 13, 2024).

Results: The extracted radiomic features demonstrated high reproducibility, with 70.3%-82.3% exhibiting an ICC > 0.9 across the different CT phases. Standardization using aortic attenuation significantly reduced feature variability, increasing the proportion of stable features (CV < 0.15) from 12.9%-27.7%.

The binary classification model (malignant vs benign) achieved high diagnostic performance on the test set, with a sensitivity of 0.945, specificity of 0.932, and an area under the receiver operating characteristic curve (AUC) of 0.944. However, the multiclass model for differentiating specific tumor subtypes showed limited accuracy. Performance was particularly low for

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

lipid-rich adenomas, cysts, and lesions of neurogenic origin, with F1-scores ranging from 0 to 0.333.

The main limitations of this study include its retrospective design, the lack of a standardized CT acquisition protocol, and an imbalanced dataset.

Conclusions: The proposed CT radiomics-based model demonstrated high efficacy for the binary classification of adrenal lesions as benign or malignant, highlighting its potential utility for initial screening. However, its diagnostic value for the precise subtyping of adrenal tumors remains limited.

EP1677 - ECE_1420 - Regional and gender disparities in lipid-lowering therapy among diabetic patients: a comprehensive Spanish nationwide study 2020-2024

Jessica Ares Blanco[1,2,3], Miguel García[1,2], Alicia Martín-Nieto[3], Elías Delgado[1,2,3] and Edelmiro Luis Menéndez-Torre[1,2,3]

[1]University of Oviedo, Oviedo, Spain; [2]Instituto de Investigación Sanitaria del Principado de Asturias, Oviedo, Spain; [3]Hospital Universitario Central De Asturias, Oviedo, Spain

Introduction: Cardiovascular disease remains the leading cause of morbidity and mortality in patients with diabetes. Lipid-lowering therapy is a cornerstone of cardiovascular prevention in this population, yet treatment patterns and equity of access across different demographic groups remain incompletely characterized. With Spain's diabetes prevalence reaching 14.8% and over 5.1 million affected adults, understanding treatment distribution patterns is essential for optimizing preventive strategies.

Objectives: To analyze geographic, gender, and age-related patterns in lipid-lowering treatment among Spanish diabetic patients over a five-year period, and to identify potential disparities in treatment access and utilization.

Methods: Comprehensive descriptive analysis of lipid-lowering therapy data from 2020 to 2024 across all 19 Spanish administrative regions. Data were stratified by sex, four age groups (0-14, 15-34, 35-64, ≥65 years), and year. Regional treatment distributions were contextualized within known diabetes prevalence patterns. Temporal trends were analyzed to assess treatment expansion and consistency across demographic subgroups.

Results: Overall treatment coverage expanded from 3 440254 cases (2020) to 3 962 928 (2024), representing 15.2% growth. Based on national diabetes prevalence estimates, approximately 77%-78% of Spanish diabetic patients receive lipid-lowering therapy.

A persistent gender gap was observed throughout the study period, with men representing 54.1% of treated patients vs 45.9% women, remaining stable across all years. This disparity was most pronounced in the 35-64 age group (60.1% men vs 39.9% women) but attenuated in elderly c 46.6% women).

Age distribution revealed that elderly patients (≥65 years) comprised 64% of all treatments, with particularly high representation among women (68.4% of treated women vs 60.6% of treated-men belonged to this age group).

Geographic analysis showed substantial variation in absolute treatment numbers, with Andalusia leading (759 164 cases in 2024), followed by Catalonia (586 075) and Valencia (505 628). These patterns align with regional diabetes prevalence variations, ranging from 4.51% in Castilla-León to 9.72% in Canary Islands. However, the male-to-female treatment ratio remained consistent across all regions, suggesting systemic rather than regional gender disparities.

Conclusions: Spain demonstrates high overall lipid-lowering therapy coverage in diabetic patients with consistent expansion across regions. However, significant gender disparities persist, particularly in middle-aged populations, with women accessing treatment predominantly at older ages. These findings suggest potential undertreatment or delayed treatment initiation in women, representing a critical gap in cardiovascular prevention. Future research should investigate whether these patterns reflect differences in diabetes phenotypes, prescribing practices, patient preferences, or healthcare access barriers to inform targeted public health strategies.

EP1683 - ECE_2487 - Cardiometabolic burden and predictors of functional status in adrenal incidentalomas

Mădălina Elena Iftimie[1,2], Iulia Florentina Burcea[1,2], Ramona Dobre[1,2] and Cătălina Poiană[1,2]

[1]Endocrinology, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania; [2]Endocrinology I, "C.I.Parhon" National Institute of Endocrinology, Bucharest, Romania

Introduction: Adrenal incidentalomas (AIs) are a frequent discovery nowadays because of routine cross-sectional imaging. While functioning AIs, including mild autonomous cortisol secretion (MACS) are linked to cardiometabolic morbidity, emerging data show that non-functioning incidentalomas also carry significant metabolic risks and higher mortality than controls. We aim to characterize the clinical and epidemiological features of AIs evaluated in a tertiary endocrinology clinic.

Methods: We conducted a retrospective observational study of all patients investigated for incidentally discovered adrenal tumors at "C.I. Parhon" National Institute of Endocrinology between October 2023-October 2025. We excluded patients with tumors <1 cm and incomplete records. Demographic, imaging, hormonal and comorbidity data were collected and compared between functioning and non-functioning AI.

Results: 194 patients were included in the final analysis (83.5% female, mean age 59.68 ± 9.48 years). The majority of adrenal masses were discovered by computed tomography scans (75.3%), performed for abdominal pain or digestive complaints. Mean tumor diameter was 26.5 ± 12.4 mm. Most lesions had benign imaging characteristics (91.8%) and were unilateral (62.4%). Functional classification: non-functioning AI 51.0%, MACS 40.7%, overt Cushing's 4.1%, primary hyperaldosteronism 2.1%, pheochromocytoma 1.0% and mixed cortisol-aldosterone hypersecretion 1.0%. Cardiometabolic comorbidities were common overall (dyslipidemia 87.6%, hypertension 78.9%, diabetes mellitus (DM)/impaired glucose tolerance 51.0%, obesity 47.9%) and were similarly prevalent in functioning and non-functioning AI subgroups, irrespective of hypersecretory phenotype. Functioning AIs had larger maximum tumor diameters than non-functioning lesions (29.6 vs 23.5 mm; $P < .001$), but no significant differences were found between the two subgroups for

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

major cardiovascular events ($P = .193$) or mortality ($P = .703$). Multivariate logistic regression identified maximum tumor diameter (OR 1.049 per mm, $P < .001$), presence of DM (OR 1.598, $P = .031$) and female sex (OR 2.606, $P = .033$) as independent predictors of functioning status. Receiver Operating Characteristic (ROC) analysis of a combined prediction model showed moderate discrimination between functioning and non-functioning adrenal tumors (area under the curve 0.666).

Conclusions: In this tertiary cohort, adrenal incidentalomas carried a high burden of cardiometabolic comorbidity, regardless of their functional status, suggesting that the line between functioning and non-functioning AIs may be a false dichotomy. Maximum tumor diameter, female sex and presence of DM could predict the functional status of AI, but these findings warrant prospective validation.

EP209 - ECE_1985 - Parathyroidectomy reduces systemic inflammatory indices in patients with primary hyperparathyroidism

Jake Schembri, Simon Mifsud and Mark Gruppetta
Department of Diabetes and Endocrinology, Mater Dei Hospital, Msida, Malta

Introduction: The classical manifestations of primary hyperparathyroidism (PHPT) mainly involve skeletal and renal end-organ complications. However, a spectrum of non-classical manifestations associated with PHPT has also been described, including cardiovascular (CV) and neurocognitive sequalae.[1] Recent literature reports elevated inflammatory markers such as high-sensitive C-reactive protein and tumour necrosis factor-alpha in patients with PHPT. Since chronic low-grade inflammation is central to the pathogenesis of atherosclerosis, this may represent a mechanism underlying the increased risk of CV disease observed in PHPT patients.[2] In this study, we investigated whether systemic inflammatory indices (derived from readily available haematological parameters) change following curative parathyroidectomy in patients with PHPT.

Method: We retrospectively reviewed patients with PHPT who underwent parathyroidectomy between 2017 and 2019. Parathyroid hormone (PTH), corrected calcium, white cell count (WCC), neutrophil count, lymphocyte count, platelet count, neutrophil-lymphocyte ratio (NLR), and systemic immune-inflammation index (SII) were evaluated at baseline (pre-parathyroidectomy) and 6 months post-parathyroidectomy.

Results: 56 patients with PHPT underwent parathyroidectomy during the study period. The mean age was 60.4 years (SD 12.3), with a female predominance of 71.4% ($n = 40$). Significant pre-operative to post-operative decreases were observed in corrected calcium (median 2.80 mmol/L (IQR:2.73-2.9) to 2.30 mmol/L (IQR:2.23-2.35), $P < .001$) and PTH (median 160 ng/L (IQR:121.1-235.7) to 35.4 ng/L (IQR:27.7-54), $P < .001$).

WCC and neutrophil counts also declined significantly post-parathyroidectomy. Median WCC decreased from 7.21×10^9/L (IQR:5.97-7.96) to 6.59×10^9/L (IQR:5.36-7.82) ($P = .004$) and median neutrophil count decreased from 4.61×10^9/L (IQR:3.46-5.3) to 3.7×10^9/L (IQR:2.97-5.13) ($P = .002$). There was no significant difference between pre- and post-operative lymphocyte or platelet counts ($P = .159$ and $P = .92$, respectively).

Post-parathyroidectomy, median SII improved from 557.8 (IQR:440.8-789.4) to 540.8 (IQR:331.7-734.4) ($P = .011$), and median NLR decreased from 2.41 (IQR:1.81-2.99) to 2.13 (IQR:1.51-2.84) ($P = .037$).

Conclusions: In this retrospective cohort, curative parathyroidectomy for patients with PHPT was associated with significant improvement in systemic inflammatory indices (SII and NLR) and reductions in WCC and neutrophil counts at 6 months. Overall, the observed reduction in SII and NLR following parathyroidectomy is consistent with previous studies, suggesting that this low-grade inflammation observed in PHPT may be reduced following surgical intervention.

EP210 - ECE_1576 - Divergent roles of the vitamin D receptor in the osteoclast lineage and cathepsin K-expressing cells in bone homeostasis

Dong-Kyo Lee[1], Kyung-Hwa Kim[1], Na-Rae Park[1], Xian Jin[1], Ying Cui[1], Xiangguo Che[1], Sihoon Lee[2], Shigeaki Kato[3], Hyun-Ju Kim[1] and Je-Yong Choi[1]
[1]Department of Biochemistry and Cell Biology, Cell and Matrix Research Institute, School of Medicine, Kyungpook National University, Daegu, South Korea; [2]Department of Internal Medicine and Laboratory of Genomics and Translational Medicine, Gachon University College of Medicine, Incheon, South Korea; [3]Graduate School of Life Science and Engineering, Iryo Sosei University, Iwaki, Fukushima, Japan

Vitamin D receptor (VDR) signaling is a central regulator of bone homeostasis, yet its cell-specific function within the bone microenvironment remains controversial. Here, we show that VDR is highly expressed in early-stage osteoclastogenic cells but is barely detectable in fully mature osteoclasts. To dissect lineage-specific roles of VDR, we utilized two conditional knockout models: *LysM;Vdr$^{f/f}$*, lacking VDR in osteoclast precursors, and *Ctsk;Vdr$^{f/f}$*, lacking VDR in cathepsin K–expressing cells. In vitro, $1,25(OH)_2D_3$ suppressed osteoclastogenesis in WT cells, an effect abolished in *LysM;Vdr$^{f/f}$* cells but retained in *Ctsk;Vdr$^{f/f}$* cultures, indicating that the inhibitory action of vitamin D-VDR signaling occurs primarily at the precursor stage. Mechanistically, $1,25(OH)_2D_3$ promoted proteasome-dependent degradation of c-Fos in WT cells, a process absent in *LysM;Vdr$^{f/f}$* cells. VDR interacted with c-Fos in pre-osteoclasts, and this association was reduced following $1,25(OH)_2D_3$ treatment, consistent with ligand-induced c-Fos degradation. Despite these in vitro findings, *LysM;Vdr$^{f/f}$* mice exhibited normal bone homeostasis under

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

physiological conditions. In contrast, *Ctsk;Vdr*$^{f/f}$ mice displayed increased bone mass driven by enhanced osteoblast activity rather than altered osteoclast function. Collectively, these findings suggest that while VDR in the osteoclast lineage is not a major regulator of physiological bone homeostasis, VDR in non-osteoclastic Ctsk-expressing cells, potentially including periosteal stem cells, may act as a negative regulator of bone formation, providing a novel perspective on vitamin D action in the skeleton.

EP211 - ECE_1721 - Familial hypocalciuric hypercalcaemia with CaSR missense variant, two case reports

Alhasan Al-Saadi[1,2], Emmon Kiyani[1], Sucheeth Gowda[1], Abdullatif Farhat[1] and Ravikumar Ravindran[1]
[1]*Aneurin Bevan Health Board, Newport, United Kingdom;* [2]*The Aneurin Bevan—JD Wetherspoon, Newport, United Kingdom*

Background: Familial hypocalciuric hypercalcaemia (FHH) is a rare benign genetic condition, with an estimated prevalence of approximately 1 in 78 000 people in the general population. It displays an autosomal dominant pattern of inheritance with high penetrance, and it affects both men and women equally. FHH is caused by loss of function mutation in the CaSR gene leading to decreased receptor activity in response to serum calcium levels. CaSR in the parathyroids, senses minute changes in blood calcium and controls parathyroid hormone release and hence regulates serum calcium levels. Loss of function mutation in CaSR reduces the receptors' ability to detect high calcium levels, leading to inappropriately high calcium levels in the blood and normal to slightly elevate PTH levels in the blood. The inactivating mutation also affects the CaSR in the kidneys. In normal conditions, the CaSR in the kidneys normally sense high serum calcium levels and reduces calcium reabsorption. This defect leads to a relative over-reabsorption of calcium in the renal tubules, resulting in hypocalciuria.

Methods: 2 case studies are reported involving patients with hypercalcemia with a normal Parathyroid hormone (PTH) The clinical presentation, the investigations and the genetic test results are reviewed alongside a literature review was conducted to understand the importance of CaSR gene testing.

Case presentation: We report two cases,

The first case is one of a 60-year-old female. She was referred with High Calcium 2.86 mmol/L since November 2022. Her main symptom was fatigue with a family history of hypercalcemia. PTH was normal and Vitamin D level was corrected with no improvement in her biochemistry. Other blood tests were unremarkable.

The second case is one of a 41-year-old male who presented with nausea & fatigue. His Calcium Levels were 2.71 mmol/L with a normal PTH and corrected Vitamin D level. His mother had asymptomatic longstanding hypercalcaemia

Their Calcium Creatinine clearance ratio was calculated to be 0.00662, 0.00888 respectively.

Subsequently both cases underwent Genetic testing which confirmed the Diagnosis of FHH (Consistent with a genetic diagnosis of CaSR-related hypocalciuric hypercalcaemia)

Conclusions: We recommend a two-step diagnostic process as follows: the calcium/creatinine clearance ratio (CCCR) is measured from a 24-hour urine sample and then all patients with CCCR of 0.020 or less are tested for mutations in the CASR gene. Patients who have a family history of Hypercalcemia with Higher CCCR are also recommended for testing. The diagnostic sensitivity of this setup is 98%.

EP212 - ECE_2899 - Laser thermal ablation of the parathyroid glands in a patient with MEN1 syndrome—a case report

Dominika Kaszewska-Perka[1], Łukasz Krotowski[1], Małgorzata Wichlińska[1], Ewelina Witkowska[1], Agnieszka Domańska-Czajka[1], Monika Pacocha[1], Janusz Łuczak[1], Anna Fedorczak[1], Renata Stawerska[1,2] and Arkadiusz Zygmunt[1,2]
[1]*Department of Endocrinology and Metabolic Diseases, Polish Mother's Memorial Hospital—Research Institute, Lodz, Poland;* [2]*Department of Developmental Age and Adult Endocrinology, Medical University of Lodz, Lodz, Poland*

Introduction: Multiple endocrine neoplasia type 1 (MEN1) is a hereditary disorder caused by germline mutations in the *MEN1* gene, most commonly manifesting as multiglandular and recurrent primary hyperparathyroidism. Surgical treatment is associated with a risk of disease recurrence or the development of permanent hypoparathyroidism. Minimally invasive techniques, such as percutaneous laser thermal ablation, may represent an alternative therapeutic option in selected patients.

Case description: A case of a 38-year-old man with genetically confirmed MEN1 syndrome (c.781C > T mutation in the *MEN1* gene, detected in September 2021) and a positive family history of MEN1 was presented. The patient was diagnosed with primary hyperparathyroidism complicated by nephrolithiasis, osteopenia, and arterial hypertension. Imaging studies revealed three focal lesions corresponding to the parathyroid glands, including a dominant enlarged parathyroid gland located posterior to the middle portion of the left thyroid lobe ($15 \times 10 \times 18$ mm). Biochemical evaluation showed an elevated parathyroid hormone level (PTH 145.4 pg/mL), hypercalcemia (total calcium 2.85 mmol/L, ionized calcium 1.55 mmol/L), hypophosphatemia (0.69 mmol/L), and concomitant hypercalciuria.

Methods: Under ultrasound guidance, the patient underwent two sessions of percutaneous laser thermal ablation of the parathyroid glands using the EchoLaser system. The first procedure, performed in May 2025, was carried out with an energy of 1204 J, resulting in a partial improvement in biochemical parameters. Due to the persistence of primary hyperparathyroidism, a second procedure targeting the same lesion was performed in November 2025, using a higher energy setting (4013 J).

Results: Twenty-four hours after the second procedure, a significant reduction in PTH levels was observed (from 116 pg/mL to 69 pg/mL), accompanied by normalization of serum calcium (from 2.87 mmol/L to 2.54 mmol/L) and phosphate levels (from 0.76 mmol/L to 1.00 mmol/L). No adverse events related to the thermal ablation procedures were observed, and no hypoparathyroidism developed.

Conclusions: Percutaneous laser thermal ablation enabled effective biochemical control of hyperparathyroidism in the

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

presented patient with MEN1 syndrome, without the occurrence of complications. Given the multifocal and recurrent nature of hyperparathyroidism in MEN1, laser thermal ablation may represent a safe, repeatable, and minimally invasive therapeutic option in carefully selected patients, particularly in those at high surgical risk or who do not consent to surgical treatment.

EP214 - ECE_1803 - Type 2 diabetes control—managing bone strength and microarchitectural damage

Iustina Cosmina Mogos[1,2], Dan Alexandru Niculescu[2,3], Roxana Dusceac[3] and Catalina Poiana[2,3]
[1]*Endocrinology, Spitalul Clinic de Urgență Prof. Dr. Agrippa Ionescu, București, Romania;* [2]*Carol Davila University of Medicine and Pharmacy, București, Romania;* [3]*Institutul Național de Endocrinologie CI Parhon, București, Romania*

Introduction: The bone paradox of type 2 diabetes patients consists of the higher incidence of fracture numbers encountered despite high bone mineral density measured by X-ray osteodensitometry. One of the potential explanations is the intricated microarchitecture deterioration.

Methods: We conducted an observational, prospective, single-center study including 604 postmenopausal women and men with type 2 diabetes (281), prediabetes (197) or normal glycemic profile (126). X-ray densitometry with trabecular bone score measurement were performed measuring the lumbar spine, femur neck and distal radius. We collected data on participants' glycemic balance and vitamin D levels.

Results: Bone mineral density was higher at all sites in the prediabetes and type 2 diabetes groups. We did not find a relationship between glycemic control—glycosylated hemoglobin and bone damage reflected by bone mineral density or T-score, at any of the three investigated sites. Adjusted absolute bone mineral density after analysis of covariance showed in the control group a BMD in lumbar spine 1.056 ± 0.018, femur neck 0.832 ± 0.12 , distal radius 0.764 ± 0.009. The prediabetes cohort had a BMD in lumbar spine 1.076 ± 0.013, femur neck 0.840 ± 0.009, distal radius 0.775 ± 0.007. The type 2 diabetes patients had a BMD in lumbar spine 1.132 ± 0.011, femur neck 0.892 ± 0.007, distal radius 0.792 ± 0.006. The BMI difference between groups was not statistically significant. The trabecular bone score did not differ significantly between the three groups. The majority of patients had normal TBS 283 (55.49%), 216 patients (42.35%) had partly degraded microarchitecture, and only 11(2.6%) had degraded bone microarchitecture. The densitometry results showed that 193 (31.9%) patients had osteoporosis, 284 had osteopenia (46.94%) and 128 (21.16%) patients had normal BMD. Osteoporosis was found in 22.7% of T2DM patients and 34.8% of prediabetes patients. The diabetes cohort had a good glycemic balance, with a mean glycated hemoglobin 6.3% (5.8-6.6) and 25 OH vitamin D was in target for 64.9% of the participants-37 ng/mL (29,43) in the control group, 35 ng/mL (28,42) for prediabetes group and 33 ng/mL (25,39) in diabetics.

Conclusions: Our study emphasises that a good glycemic balance and vitamin D status can delay the bone deterioration and maybe the literature published cut-offs of 7.5% HbA1c begin to shift the balance toward bone deterioration.

EP215 - ECE_3036 - From symptoms to sequencing: a case of hypophosphatemic osteomalacia with a novel genetic variant

Smritimayee Panda[1], Pragya Kafley[1], Vaibhav Singhal[2], Kausik Mandal[1] and Preeti Dabadghao[1]
[1]*Medical Genetics, Sanjay Gandhi Postgraduate Institute of Medical Science, Lucknow, India;* [2]*Max Super Speciality Hospital Vaishali, Ghaziabad, India*

Background: Fanconi renotubular syndrome is an uncommon group of disorders characterized by proximal tubulopathies. There are five recognized subtypes of Fanconi syndrome, designated FRTS1-5.

Case presentation: A 40-year-old woman presented with bilateral hip pain ongoing for three years. She had sustained fractures in both legs from minor trauma three years earlier. Laboratory investigations revealed hypophosphatemia and a decreased TMP-GFR. Urinalysis showed proteinuria, calcinuria, and glucosuria. Whole-exome sequencing identified a novel heterozygous missense mutation in GATM, which was a VUS. Sanger sequencing of family members confirmed the same variant in affected relatives.

She was treated with phosphorus supplements and alkali therapy. After one year of follow-up, her pain improved, and she experienced no further fractures.

Conclusions: This case describes a novel GATM variant in a patient with hypophosphatemic osteomalacia. It underscores the importance of thorough evaluation for early diagnosis and targeted management to achieve better outcomes.

EP216 - ECE_1837 - Role of MEN1 genetic status on clinical phenotype of MEN1 disease: a single center cohort

Laura Pierotti[1], Elena Pardi[1], Chiara Sardella[2], Anna Dal Lago[1], Giacomo De Leo[1], Paolo Piaggi[3,4], Fausto Bogazzi[1], Liborio Torregrossa[5], Angela Michelucci[6], Maria Adelaide Caligo[6], Claudio Marcocci[1] and Filomena Cetani[1]
[1]*Department of Clinical and Experimental Medicine, Endocrine Unit, University of Pisa, Pisa, Italy;* [2]*Endocrine Unit, University Hospital of Pisa, Pisa, Italy;* [3]*NIDDK, National Institutes of Health, Phoenix, AZ, United States;* [4]*Department of Information Engineering, University of Pisa, Pisa, Italy;* [5]*Department of Surgical, Medical and Molecular Pathology and Critical Area, University of Pisa, Pisa, Italy;* [6]*Laboratory of Molecular Genetics, University Hospital of Pisa, Pisa, Italy*

Multiple Endocrine Neoplasia type 1 (MEN1) is a rare hereditary syndrome characterized by the neoplastic transformation of multiple endocrine tissues. The disease is caused by inactivating mutations of the *MEN1* gene. However, MEN1 diagnosis may also be based on clinical criteria, even in the absence of genetic confirmation. Consequently, some patients meet clinical diagnostic criteria for MEN1 despite lacking an identifiable MEN1 mutation. These MEN1-negative individuals may represent phenocopies and could display a distinct clinical behavior.

The aim of this retrospective observational study was to compare the clinical phenotype, disease progression, and outcomes of *MEN1*-positive and *MEN1*-negative patients in a large single-center cohort.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

We included 205 patients with a clinical diagnosis of MEN1 (116 index cases, 89 relatives) followed at a tertiary referral center between 1993 and 2023. Based on genetic testing, patients were classified as *MEN1*-positive ($n = 157$) or *MEN1*-negative ($n = 48$). Age at disease onset and diagnosis, number and type of MEN1-related manifestations, skeletal and renal complications, overall survival, and time to development of a third MEN1-related manifestation were evaluated in the entire cohort and in index cases.

MEN1-positive patients developed MEN1-related manifestations at a significantly younger age compared with *MEN1*-negative patients. In the overall cohort, the mean age at first manifestation was 35.8 ± 14.4 years in *MEN1*-positive vs 45.7 ± 14.4 years in *MEN1*-negative patients ($P < .001$). Comparable differences were observed for the second (39.7 ± 14 vs 50.6 ± 12, $P < .001$) and third manifestations (42.5 ± 13.7 vs 54.6 ± 11.1, $P < .001$) and for age at MEN1 diagnosis (36.9 ± 12.5 vs 45.7 ± 14.4, $P = .002$). *MEN1*-positive patients exhibited a higher disease burden, with a greater prevalence of three or more manifestations compared with *MEN1*-negative patients (40.8% vs 25.0%; $P = .048$). This difference was more pronounced in the index cases group (52.9% vs 25.0%; $P = .003$). Time to development of a third MEN1-related manifestation was significantly shorter in *MEN1*-positive patients, who showed an increased age-adjusted risk both in the overall cohort (HR 2.46, $P = .009$) and among index cases (HR 3.02, $P = .003$). In addition, *MEN1*-positive patients had a higher prevalence of nephrolithiasis and significantly lower age-adjusted Z-scores at the femoral neck and lumbar spine. Overall survival did not differ significantly between groups.

In conclusion, MEN1-positive patients exhibit earlier onset and a more aggressive and penetrant disease course than MEN1-negative patients, who appear to follow a milder clinical course. These findings support the concept of MEN1 phenocopies and highlight the clinical relevance of genetic status for risk stratification and individualized surveillance strategies.

EP217 - ECE_1222 - A systematic review and network meta-analysis of pharmacological strategies to improve bone mineral density in functional hypothalamic amenorrhoea

Agathoklis Efthymiadis[1], Konstantinos Tsikopoulos[2], Edouard G. Mills[1], Andrew Milne[3], Waljit Dhillo[1], Ali Abbara[1] and Alexander Comninos[1]

[1]Section of Endocrinology and Investigative Medicine, Imperial College London, London, United Kingdom; [2]Department of Orthopaedics, University Hospitals Bristol, Bristol, United Kingdom; [3]Hammersmith Campus Library, Imperial College London, London, United Kingdom

Background: Functional hypothalamic amenorrhoea (FHA) underlies up to 30% of secondary amenorrhoea. One of the most detrimental consequences of FHA is its impact on bone health, due to hypoestrogenaemia and nutritional deficiencies. Indeed, up to 44% of affected women have low bone mineral density (BMD) resulting in sevenfold higher risk of fractures compared with healthy women. Although first-line management of FHA typically involves a combination of psychological/dietetic interventions, over two-thirds of women remain amenorrhoeic despite one year of intensive treatment. When lifestyle measures fail to restore menses within 6-12 months, pharmacological treatments are usually required to protect bone health, but the comparative efficacy of these interventions remains uncertain.

Aim: To compare the efficacy of available pharmacological treatments for BMD in women with FHA using network meta-analysis (NMA) for the first time.

Methods: Medline/Embase/Emcare/Cochrane/CENTRAL/ISRCTN/ClinicalTrials.gov were searched until September 20, 2025. Eligible randomised-controlled trials evaluating pharmacological treatments for lumbar spine (LS), femoral neck (FN), or total hip (TH) BMD were included. PRISMA-NMA guidance was followed. Outcomes were expressed as standardised mean differences (SMDs) with 95% confidence intervals (CIs). The CINeMA (Confidence in Network Meta-Analysis) framework was employed to assess certainty.

Results: Thirteen RCTs, comprising 897 women in total, were included (LS BMD: $n = 897$; FN BMD: $n = 370$; TH BMD: $n = 750$). *Transdermal* hormone replacement therapy (HRT) (LS BMD: 77, FN BMD: 22) was more effective than control (placebo or no intervention) in increasing LS BMD with SMD 0.34 (95% CI 0.03, 0.64) and FN BMD with SMD 0.57 (0.04, 1.10) over 12-18 months. By contrast, *oral* HRT and the combined oral contraceptive pill (COCP) (LS BMD: $n = 166$, FN BMD: $n = 30$, TH BMD: $n = 54$) did not increase BMD in any of the assessed skeletal sites over 12-24 months. Furthermore, teriparatide administered for 6 months was superior to *transdermal* HRT and COCP for LS BMD with SMDs 1.48 (0.38, 2.59) and 1.75 (0.66, 2.83), but not FN or TH BMD.

Conclusions: *Transdermal* HRT and teriparatide both increase LS BMD in women with FHA, with *transdermal* HRT also improving FN BMD. By contrast, *oral* HRT and COCP do not exert benefits at any skeletal site. These differences may be partly explained by the differential effect of transdermal vs oral oestrogens on osteoanabolic insulin-like growth factor-1 (IGF-1). This is the first NMA of all available pharmacological strategies for BMD in FHA and has important clinical implications for the bone management of women with FHA.

Study registration: PROSPERO (CRD42024576872).

EP218 - ECE_1474 - Prevalence of vertebral fractures and incidental discovery of vertebral fractures using Vertebral Fracture Assessment (VFA)—a retrospective population-based study in Brasov, Romania

Oana-Maria Capraru[1], Paula Bucur[1] and Daniela Chetan[2]

[1]Endocrinology, Săcele County Hospital, Brasov, Romania; [2]Nuclear Medicine, Regional Oncology Institute, Iasi, Romania

Introduction: Vertebral fractures (VF) are a major complication of osteoporosis and are associated with an elevated risk for subsequent vertebral and nonvertebral fractures. Despite the increased morbidity, many VF are clinically silent and frequently do not come to medical attention. In this analysis we observed the prevalence of VF and the clinically silent VF discovered during VFA.

Material and Method: Data were included from 364 consecutive subjects who had measurement of BMD of posterior-anterior lumbar spine (LS), total hip (TH) and femoral neck (FN) with Hologic Horizon W® densitometer and VFA using lateral spine

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

imaging IVA™ mode in the supine position. Vertebral fractures were quantified using the Genant Semi-Quantitative Grading System for Vertebral Deformity as mild = 1, moderate = 2 and severe = 3. Standardized self-reported questionnaires were used to collect data regarding lifestyle factors influencing the risk of osteoporosis and fractures. Questionnaires included medical history, medication, and prior fracture.

Results: From the total study population, 352 were females, mean age 65.9 years and 12 males, mean age 65.3 years, mean LS BMD was 0.830 g/cm^2 and mean TH BMD was 0.798 g/cm^2. Vertebral fractures were observed in 89 patients (24%) among whom 59 patients (16%) were incidentally discovered by VFA and 30 patients had a self-reported VF. Low TH BMD and T score, advanced age, use of corticosteroids, parental hip fracture, previous fracture and years postmenopausal were observed to increase the risk of VF in our cohort. Among all patients with VF, 52.8% had osteoporosis at the LS or FN by BMD criteria and 41% (37 patients) had more than one VF. The most frequent VF were at T12, T11 and L1 and 24.7% had grade 3 VF. From the 59 patients with clinically silent VF, 40% had T scores suggestive of osteopenia, and 7% had normal BMD. 30% of patients had more than one VF and the most frequent silent VF were grade 1 and 2. Only 11% had grade 3 VF and 30% had previous pharmacological treatment for osteoporosis with or without other non-vertebral fractures. We did not find any differences in LS, TH or FN BMD between the group of patients with self-reported and silent VF but patients with clinically silent VF had a better TH T score.

Conclusions: Accurate radiographic detection of VF through VFA in addition to BMD has a substantial impact on the strategy of treatment and possible prevention of future osteoporotic fractures.

EP219 - ECE_1655 - The impact of the updated 24-hour urinary calcium excretion threshold on aPHPT management

Elena Castellano, Chiara Bona, Micaela Pellegrino, Irene Comune, Federico Arecco, Andrea Craparo, Claudia Baffoni and Anna Rosa Pia
Department of Endocrinology, Diabetes and Metabolism, Santa Croce and Carle Hospital, Cuneo, Italy

Introduction: The Fifth International Workshop on the management of asymptomatic primary hyperparathyroidism (PHPT) updated criteria for surgical indication. Specifically, the 24-hour urinary calcium excretion threshold was lowered and differentiated by sex, potentially expanding surgical eligibility. The impact of this modification, has not been yet assessed in real clinical practice.

Methods: We analyzed a consecutive series of 540 patients diagnosed with PHPT.

Among the, 70 patients did not meet any surgical criteria according to the IV International Workshop.

This subgroup included 54 women and 16 men (mean age 65 ± 9.5, being 13.2% e 12.9% of total M and F respectively).

We evaluated how many of these patients would newly fulfill surgical criteria when applying the updated, sex-specific urinary calcium thresholds (>250 mg/day for women and >300 mg/day for men).

Results: Among women without prior surgical indication, 5/54, corresponding to 9.3% of this subgroup, met the criteria for surgery. On the other hand, none of the 16 men without surgical indication met the updated hypercalciuria criterion.

Conclusions: In our consecutive PHPT series, lowering the urinary calcium threshold increased surgical eligibility among women, while no effect was observed in men. Several factors may contribute to this sex-specific finding, including the lower urinary calcium cutoff established for women and the relatively small number of men without surgical indication. Overall, these data suggest that the revised hypercalciuria criterion has an impact on surgical indication predominantly in women.

Abstract citation ID: lvag096.792

EP220 - ECE_1767 - "Determinants of osteoporosis in patients with primary hyperparathyroidism: the role of calcium–phosphate metabolism"

Sebastian Szewczyk and Michal Popow
Department of Internal Medicine and Endocrinology, University Clinical Centre of the Medical University of Warsaw, Warsaw, Poland

Background: Primary hyperparathyroidism (PHPT) is characterized by chronic parathyroid hormone (PTH) excess, leading to hypercalcemia, increased bone turnover, and an elevated risk of skeletal complications. Osteoporosis is a frequent manifestation of PHPT; however, the biochemical determinants of bone loss remain incompletely understood. In particular, the roles of active vitamin D (1,25-dihydroxyvitamin D, calcitriol) and renal phosphate handling in the pathogenesis of osteoporosis in PHPT require further clarification.

Objective: To identify biochemical determinants of osteoporosis in patients with PHPT, with a particular focus on calcitriol levels and renal phosphate handling, and to evaluate their predictive performance in discriminating osteoporotic from non-osteoporotic individuals.

Methods: We retrospectively analyzed 74 adult patients with biochemically confirmed primary hyperparathyroidism eligible for parathyroid surgery. All patients underwent comprehensive biochemical assessment, including serum total calcium, phosphate, parathormone (PTH), 25-hydroxyvitamin D, 1,25-dihydroxyvitamin D (calcitriol), and 24-hour urinary calcium excretion. Renal phosphate handling was estimated using the tubular maximum for phosphate reabsorption per glomerular filtration rate (TMP/GFR). Osteoporosis was defined according to WHO criteria based on dual-energy X-ray absorptiometry. Univariate and multivariate logistic regression analyses were performed to identify independent predictors of osteoporosis. Receiver-operating characteristic (ROC) curve analysis was used to assess diagnostic performance and determine optimal cutoff values.

Results: Osteoporosis was present in 33.8% of the study population. Patients with osteoporosis exhibited significantly higher calcitriol levels and significantly lower TMP/GFR values, indicating impaired renal phosphate reabsorption, compared with non-osteoporotic individuals. These associations remained significant in multivariate analysis. In contrast, serum total calcium, phosphate, PTH, and 25-hydroxyvitamin D levels did not differ significantly between groups. ROC analysis demonstrated clinically meaningful discriminatory performance for both calcitriol

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

and TMP/GFR, with identifiable cutoff values for osteoporosis risk stratification.

Conclusions: Elevated levels of the active form of vitamin D and impaired renal conservation of phosphate are independently associated with osteoporosis in patients with primary hyperparathyroidism, outperforming traditional biochemical markers. These findings suggest that excessive calcitriol activity and renal phosphate wasting may play a key pathophysiological role in PHPT-related bone loss. Incorporating calcitriol measurement and assessment of renal phosphate handling into routine clinical evaluation may improve identification of patients at high skeletal risk and support more individualized management strategies in primary hyperparathyroidism.

EP221 - ECE_2094 - Impact of fat and muscle mass on low bone mass in young adults: a health screening center-based study

Han Na Jang
Seoul, South Korea

Background: Compared to osteoporosis in older adults and postmenopausal women, the epidemiology and risk factors of low bone mass in young adults remain under-investigated. This study aimed to investigate the prevalence and risk factors of low bone mass in young adults using data from the Kangbuk Samsung Hospital Health Screening Center.

Methods: In this retrospective cohort study, adults <50 years who underwent bone mineral density (BMD) test between January 2012 and December 2024 were included. Low bone mass was defined as a lowest Z-score ≤ −2.0 among the lumbar spine, femoral neck, and total hip. Vitamin D deficiency was defined as total 25-hydroxyvitamin D ≤20 ng/mL.

Results: A total of 107 612 individuals underwent BMD test (37.5% men; median age 42.0 [37.0, 45.0] years; median body mass index (BMI) 22.6 [20.5, 25.1] kg/m^2). The median total vitamin D level was 19.0 [13.7, 25.7] ng/mL, and 54.5% had vitamin D deficiency. The median lowest Z-score was −0.5 [−1.1, 0.2]. Low bone mass was observed in 6 779 subjects (6.3%), affecting 11.1% of men and 3.4% of women. Prevalence in men increased in the 20s, peaked in the 30s (8.4%, 12.4%, 10.7% for 20s, 30s, 40s), whereas women showed lower but stable prevalence (1.8%, 3.4%, 3.6%). In men, subjects with low bone mass had a higher BMI (26.0 [23.8, 28.8] vs 24.5 [22.8, 26.5] kg/m^2, $P < .001$), lower skeletal muscle mass (41.7 [39.0, 44.2] vs 43.4 [41.2, 45.5]%, $P < .001$), and higher fat mass (26.1 [21.8, 31.0] vs 23.1 [19.6, 26.8]%, $P < .001$), with higher proportion of current smoker, hypertension, diabetes, and dyslipidemia. In women, subjects with low bone mass had a lower BMI (21.0 [19.1, 23.4] vs 21.3 [19.7, 23.4] kg/m^2, $P < .001$), lower skeletal muscle mass (37.0 [34.6, 39.6] vs 37.6 [35.3, 40.0]%, $P < .001$), and higher fat mass (30.9 [26.1, 35.5] vs 30.2 [25.9, 34.5]%, $P < .001$), with higher prevalence of diabetes and dyslipidemia. Skeletal muscle mass was inversely associated with low bone mass in women (OR [95% CI] 0.907 [0.885, 0.930]), while increased fat mass was associated with higher risk of low bone mass in both men (1.106 [1.087, 1.126]) and women (1.220 [1.194, 1.247]).

Conclusions: Low bone mass is not uncommon among young adults, particularly in men. Altered body composition—characterized by reduced skeletal muscle mass and increased fat mass—was associated with low bone mass. Early screening and body composition-focused interventions may help prevent low bone mass in young adults

EP222 - ECE_2766 - Ethnicity is associated with fragility fracture incidence independent of age, sex and socio-economic disadvantage: a single centre Australian study

Michael Fogarty[1,2], Tung Pham[3], Jacqueline Seiffert[1], Anna Kwok[1], Dhiraj Samarasinghe[1], Ritoo Chowdhury[1], Christopher Preston[1], Tanita Botha[4], Vivian Grill[1,5] and Hanh Nguyen[1,5,6]
[1]Endocrinology and Diabetes, Western Health, Melbourne, Australia; [2]Endocrinology and Diabetes, Northern Health, Melbourne, Australia; [3]Western Health, Performance Unit, Health Information Services, Melbourne, Australia; [4]Statistics, Deakin University, Melbourne, Australia; [5]Medicine, The University of Melbourne, Melbourne, Australia; [6]Medicine, School of Clinical Sciences, Monash University, Melbourne, Australia

Background: Western Health(WH) provides care to an ethnically diverse community. We examined the burden of minimal trauma fractures in adults aged ≥50 years presenting to WH over a five-year period and analysed the differences in incidence across the major ethnic groups.

Methods: Fracture presentations at WH in adults aged ≥50 years between 2018-2022 were identified by ICD-10AM codes from the hospital electronic database. Fractures of the skull, hands, feet, and presentations with trauma codes were excluded. Admission and demographic data were extracted. Ethnicity was defined by birth country, grouped according to Australian Bureau of Statistics(ABS) Standard Australian Classification of Countries. Cumulative fracture incidence was estimated for total fractures, hip fractures, and major osteoporotic fractures(MOF), stratified across each major ethnic group. ABS 2021 Census data for postcodes was used to calculate fracture incidence in the WH catchment. Index of Relative Socioeconomic Disadvantage(IRSAD) scores was derived from Census data, applied at the area-code level and presented in quintiles.[1] Analysis included logistic regression to assess association with ethnicity, sex age, and IRSAD.

Results: Of 251 750 adults aged ≥50 years residing in the WH catchment, majority are born in Australia-Oceania(47%), Europe(25%), and Asia(21%). Between 2018-2022, 7 943 fractures occurred in7 315 persons residing in the WH catchment. The WH fracture cohort had a median age(min-max) of 62(50-105) years, 52.3% were female, IRSAD was 4(2-5). Fracture incidence per 1000 persons for Asian-born, Australia-Oceania-born, and European-born groups was: Total Fractures—14.9, 26.1, and 43.8, respectively; MOF—7.7, 13.8, and 26.6, respectively; Hip fracture—2.3, 5.2 and 11.0, respectively.

After adjusting for differences in age, sex and IRSAD, Australia-Oceania-born and European-born cases had a significantly higher total fracture incidence than Asian-born, [OR(95%CI): 1.76(1.60-1.94) and 1.94(1.75-2.14), respectively, all $P < .001$]. This finding was also demonstrated for hip fractures [Australia-Oceania-born cf. Asian-born: 1.86(1.47-2.4), $P < .0001$; European born cf. Asian-born: 1.97(1.56-2.50), $P < .0001$] and MOF [Australia-Oceania-

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

born cf. Asian-born: 1.65(1.45-2.89), $P < .0001$; European-born cf. Asian-born: 1.96(1.71-2.24), $P < .0001$] subgroups. European-born persons had lower fracture incidence than Australia-Oceania-born when accounting for the same variables [OR 0.85(0.78-0.99), $P < .001$].

Conclusions: Asian-born cases consistently demonstrated lower fracture incidence than Australian-Oceanic and European peers at our Australian tertiary service, independent of age, sex and social disadvantage. This finding highlights ethnicity as an independent determinant of fracture risk, and supports the need to consider ethnicity when evaluating the risk-benefit of osteoporosis therapies.

Background: Chronic non-bacterial osteitis (CNO) is a heterogenous, rare, sterile inflammatory bone disorder characterized by painful, sclerotic lesions most often involving the anterior chest wall, but may affect any bone in adults. Owing to the absence of population-based studies in adults, the global prevalence of CNO is estimated to range from 1/160 000-1/200 000. CNO is likely underdiagnosed due to limited clinical awareness. Furthermore, its pathophysiology remains incompletely understood, and there is a lack of validated diagnostic criteria and standardized therapeutic approaches.

Purpose and Methods: The Core Registry within the European Registries for Rare Endocrine and Bone Conditions (EuRREB) collects mandatory Core Data Elements for ERN registries and allows for the collection a specific dataset within a condition-specific module (CSM), including clinical data (i.e., clinical manifestations, patient history, imaging results and treatment modalities) and Patient Reported Outcome Measures (PROMS).

The CNO condition-specific module was created following a consensus meeting, during which the initial initiative was launched and a proposal for the set-up was suggested. This module was then further developed over 1.5 years through the multi-stakeholder (European Calcified Tissue Society, ERN-BOND, European Society of Endocrinology) collaboration of clinicians, researchers, and a patient advocacy group (Chronic non-bacterial osteitis-sterno costoclavicular hyperostosis (CNO-SCCH) NL).

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

The aim was to create a framework supporting observational studies leading to future interventional projects elucidating the CNO phenotype, disease-course, pathophysiology, diagnosis, and treatment.This module was derived from the 2024 consensus guidelines for CNO diagnosis and treatment and refined through a 9-point Likert scale survey ($n = 29$) providing iterative feedback during testing. Variables were included if 80% of participants scored > 7 on the Likert scale.

Results: All 52 proposed variables (i.e., patient history, past/current medication, diagnostic tools, ASAS/CASPAR criteria, bone-pain, imaging, clinical follow-up, among others) were included. PROMS included EQ-5D-5L, BPI-SF, and BFI-SF questionnaires. A beta version was launched in August 2025 featuring CNO-unique variables. After incorporating revisions from the final feedback round, the completed module was officially launched on 01-12-2025.

Conclusions: This module is the first multicenter initiative to prospectively monitor and longitudinally characterize CNO patients. Addressing rare-disease research challenges via international data collection, this registry provides a powerful platform to meet patient needs and improve clinical care. As participation expands, the data will enable studies of clinical practices, disease course, treatment effects, and geographical variability. Researchers and clinicians worldwide may add patient data to the registry, and request access to the module to support collaborative CNO research.

EP225 - ECE_2995 - Bone mineral density trajectories following parathyroidectomy in patients with primary hyperparathyroidism

Simon Mifsud[1], Jake Schembri[1], Christian Camenzuli[2], Matthew Cassar[2] and Mark Gruppetta[1]
[1]*Department of Diabetes and Endocrinology, Mater Dei Hospital, Msida, Malta;* [2]*Safi, Malta*

Introduction: Parathyroidectomy is indicated in patients with primary hyperparathyroidism (PHPT) and osteoporosis. This study evaluates pre- and post-operative dual-energy X-ray absorptiometry (DEXA) findings to assess the timeframe and pattern of bone mineral density (BMD) improvement after surgery.

Method: We retrospectively reviewed DEXA scans and biochemical profiles of PHPT patients who underwent parathyroidectomy between 2017 and 2024. Femoral neck and lumbar spine BMD were evaluated at baseline (pre-parathyroidectomy) and at 1-, 2-, and 5-years post-parathyroidectomy using a linear mixed-effects model adjusting for age and gender.

Results: A total of 104 patients with PHPT underwent parathyroidectomy during the study period. The mean age was 61.6 years (SD: 12.54), with a female predominance of 76% ($n = 79$). The median serum calcium at diagnosis was 2.76 mmol/L (IQR:2.68-2.87), with a median PTH of 120 ng/L (IQR:96.5-160.5).

Following parathyroidectomy, both femoral neck and lumbar spine BMD demonstrated significant improvement over time. Femoral neck log-transformed BMD estimated marginal means (EMM) rose from −0.187 preoperatively to −0.159 at 1 year, −0.140 at 2 years, and −0.111 at 5 years. Pairwise comparisons (Bonferroni-adjusted) revealed significant improvement corresponding to approximately 4.8% at 2 years (ΔEMM 0.047, $P = .006$) and 7.8% at 5 years (ΔEMM 0.075, $P < .001$) compared with baseline. The increase observed at 1 year (2.7%) did not reach statistical significance ($P = .388$).

Lumbar spine log-transformed BMD EMM similarly increased from −0.113 preoperatively to −0.064 at 1 year and −0.025 at 2 years, with a slight decline to −0.041 at 5 years. Pairwise comparisons (Bonferroni-adjusted) demonstrated significant gains from baseline at all post-operative timepoints: +5% at 1 year (ΔEMM 0.049, $P < .001$), +9.2% at 2 years (ΔEMM 0.088, $P < 0.001$), +7.5% at 5 years (ΔEMM 0.072, $P < 0.001$). Although lumbar spine BMD remained significantly higher than baseline at 5 years, a modest non-significant decline occurred between 2- and 5-years post-parathyroidectomy ($P = 1.0$).

Age negatively impacted femoral neck log-transformed BMD ($P = .03$) but had no significant effect on lumbar spine log-transformed BMD ($P = .90$). Males exhibited higher log-transformed BMD EMM than females at both sites (both $P < 0.001$).

Conclusions: Our study revealed that both femoral neck and lumbar spine BMD increase significantly post-parathyroidectomy. Lumbar spine BMD improved more rapidly, reaching statistical significance at 1-year post-parathyroidectomy, whereas femoral neck BMD improvement became significant at 2- and 5-years post-operatively. Appreciating the trajectory of BMD improvement following parathyroidectomy in PHPT patients may guide physicians in managing persistent osteoporosis, allowing for appropriately timed intervention without premature or delayed therapy.

EP226 - ECE_1550 - Integrated clinical, genetic and histopathological analysis with long-term follow-up of nine Italian families harboring germline variants in the CDC73 gene

Anna Dal Lago[1], Laura Pierotti[1], Simone Della Valentina[1], Chiara Sardella[2], Giacomo De Leo[1], Elena Pardi[1], Angela Michelucci[3], Maria Adelaide Caligo[3], Gianluca Frustaci[4], Luigi De Napoli[4], Gabriele Materazzi[4], Liborio Torregrossa[5] and Filomena Cetani[1,2]
[1]*Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy;* [2]*Endocrine Unit 2, University of Pisa, Pisa, Italy;* [3]*Laboratory of Molecular Genetics, University of Pisa, Pisa, Italy;* [4]*Pisa, Italy;* [5]*Department of Surgical, Medical and Molecular Pathology and Critical Area, University of Pisa, Pisa, Italy*

Germline mutations of cell division cycle 73 (*CDC73*) gene are associated with Hyperparathyroidism-Jaw Tumor Syndrome (HPT-JT) and some cases of familial isolated hyperparathyroidism (FIHP). HPT-JT is a rare autosomal dominant syndrome with incomplete penetrance, characterized by the variable association of primary hyperparathyroidism (PHPT), renal lesions, jaw tumors, and uterine lesions. Atypical parathyroid tumors and carcinomas are more prevalent in HPT-JT compared to sporadic or other familial forms of PHPT. FIHP is a familial form of PHPT, it is a heterogeneous disease, which has also been related to other mutations.

We evaluated the clinical, histopathological, and genetic features of nine families carrying *CDC73*-related PHPT followed at our outpatient clinic.

The total group included 29 patients. 22 members (females: 12; males:10) were affected by PHPT, two had renal cysts, one presented with jaw tumor and one female had a uterine polyp. The

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

remaining 7 members (females: 4, males: 3) were asymptomatic carriers of the disease, with no clinical manifestations. PHPT was the first disease manifestation in all affected subjects, with a median age of 29 years (IQR: 20-39) at diagnosis. Nephrolithiasis/nephrocalcinosis affected 7 patients (63%) and osteoporosis at any site was present in 2 subjects (19%). The median value of calcium was 13,9 mg/dl (IQR: 11,9-16,6), The median parathyroid hormone (PTH) level, assessed as a fold increase, was 2,27. Genetic analysis revealed a large heterozygous deletion of all exons of the *CDC73* gene in two families, whereas the other seven families had different heterozygous frameshift mutation of the *CDC73* gene. The surgery consisted of selective parathyroidectomy in 11 patients (78%) whereas bilateral neck exploration was performed in 3 subjects (22%). Histological examination revealed chief cell adenoma in 6 cases (43%), oncocytic adenoma in 1 (7%), atypical tumor in 6 patients (43%) and carcinoma in 1 (7%). Nine patients (69%) were disease free at a median follow-up of 3,5 years (IQR: 2,75-7). Recurrent PHPT was present in 4 patients (31%) after a disease-free interval of 7 years (IQR: 3-11,25).

As regards the 7 asymptomatic carriers of the disease, none of them developed any manifestation of the syndrome during follow up.

In conclusion, family history assessment and genetic testing are essential for accurate diagnosis and proper follow-up in young PHPT patients.

EP227 - ECE_1928 - Primary hyperparathyroidism associated with multiple endocrine neoplasia type 1 in patients aged ≤21 years: results from a single-center study

Simone Della Valentina[1], Laura Pierotti[1], Chiara Sardella[2], Elena Pardi[1], Anna Dal Lago[1], Gianluca Frustaci[3], Gabriele Materazzi[3,4] and Filomena Cetani[1,2]

[1]Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy; [2]Endocrine Unit, University Hospital of Pisa, Pisa, Italy; [3]Endocrine Surgery, University Hospital of Pisa, Pisa, Italy; [4]Department of Surgical, Medical, Molecular and Critical Care Pathology, University of Pisa, Pisa, Italy

Background: In multiple endocrine neoplasia type 1 (MEN1), primary hyperparathyroidism (PHPT) is typically the earliest and most prevalent manifestation. When PHPT occurs during adolescence or early adulthood, clinically relevant renal and skeletal complications may already be present, yet data in this age group remain limited.

Methods: We conducted a single-center retrospective study including MEN1 patients aged ≤21 years, followed at the University Hospital of Pisa between 2001 and 2024 with genetically confirmed MEN1. We assessed age at PHPT diagnosis, baseline PHPT-related renal and skeletal complications (including DXA Z-scores), and longitudinal outcomes under surgery, medical therapy, or active surveillance.

Results: Among 21 MEN1 patients aged ≤21 years, 15 (71%) developed PHPT; 14/21 (67%) were diagnosed at age ≤21. Median age at PHPT diagnosis was 18 years (IQR 15-19; range 12-21), with no significant sex-related difference. At baseline, 10/15 patients (67%) exhibited at least one PHPT-related complication: hypercalciuria (>4 mg/kg/24 h) in 8/14 (57%), silent nephrolithiasis in 4/14 (29%), and reduced bone mass (DXA Z-score <−2.0) in 6/14 (43%). Reduced bone mass predominantly involved the one-third distal radius (5 patients; median Z-score −2.7), followed by femoral neck/total hip (3 patients; median Z-scores −2.4 and −2.1, respectively) and lumbar spine (2 patients; median Z-score −2.4). No morphometric fragility fractures were observed. Bone turnover markers showed osteocalcin above the age-adjusted upper limit (median 36.2 µg/L; IQR 26.9-50.8), while bone-specific alkaline phosphatase and CTX were variably elevated (median fold increase 0.72 and 0.54, respectively). Follow-up data were available for 14/15 patients over a median of 8 years (IQR 6-12). Five patients (33%) underwent parathyroidectomy at a median age of 22 years (IQR 19-25; two before age 21); histology showed multiglandular hyperplasia in 4 and an atypical parathyroid tumor in one. Postoperatively, 3/5 had persistent PHPT, 1 developed hypoparathyroidism, and 1 experienced recurrence ~10 years after surgery. During follow-up, 7/14 (50%) received cinacalcet, with overall acceptable tolerability.

Conclusions: In MEN1 patients diagnosed at ≤21 years, PHPT is common and frequently complicated by early renal involvement and reduced bone mass—particularly at cortical sites. Long-term management should be individualized, integrating careful surveillance, timely surgery when indicated, and adjunctive medical therapy to mitigate complications and recurrence.

EP228 - ECE_2697 - Analytical performance of the automated ionify vitamin D LC-MS/MS assay for the quantification of 25-hydroxyvitamin D and 24,25-dihydroxyvitamin D

Katie Weaver[1], Tom de Waal[2], Michael Vogeser[3], Sven Groesgen[4], Christina Fan[4], Elie Fux[4], Anton Hilger[4], Raymond T. Suhandynata[5], Russell P. Grant[6], Barry J. Toole[5], Pieter Vermeersch[2], William A. Clarke[1] and Dusanka Kasapic

[1]Department of Pathology, Johns Hopkins University School of Medicine, Baltimore, United States; [2]Clinical Department of Laboratory Medicine, UZ Leuven, Leuven, Belgium; [3]Institute of Laboratory Medicine, LMU University Hospital, Munich, Germany; [4]Roche Diagnostics GmbH, Mannheim, Germany; [5]Department of Pathology, University of California San Diego, San Diego, United States; [6]Center for Esoteric Testing, Labcorp, Burlington, United States

Introduction: Measurement of 25-hydroxyvitamin D [25(OH)D] is clinically important because both elevated and deficient levels are associated with disturbances in calcium and phosphorus homeostasis. The metabolite 25-hydroxyvitamin D [25(OH)D] serves as the primary clinical biomarker for establishing vitamin D sufficiency. Beyond total 25(OH)D, the measurement of 24,25-dihydroxyvitamin D [24,25(OH)2D] has gained clinical relevance for identifying patients with CYP24A1 gene mutations and overcoming limitations associated with fixed 25(OH)D cutoffs. Consensus statements highlight the important role of vitamin D metabolites, in particular of the 24,25 to 25(OH)D ratio.

Although LC-MS/MS offers superior specificity, its routine use is often limited by the need for specialized staff and complex manual workflows. This study evaluated the analytical performance of the Ionify® Vitamin D iPack on the Cobas® i 601 analyzer, a fully automated LC-MS/MS system.

Methods: Repeatability and reproducibility (CLSI EP05-A3) were assessed across three laboratories using three reagent lots over five days. Inter-laboratory accuracy was evaluated at six sites

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

using External Quality Assessment (EQA) samples (DEQAS, CAP) compared to Reference Measurement Procedures (RMPs). Additionally, a method comparison (CLSI EP09c) was performed against a validated in-house LC-MS/MS Laboratory Developed Test (LDT) using patient serum samples.

Results: The assay demonstrated robust precision across all sites and reagent lots. Coefficients of variation (%CV) for repeatability and reproducibility (lot-to-lot and site-to-site) ranged from 2.7%-4.8% for 25(OH)D and 2.3%-3.5% for 24,25(OH)2D, with nearly all %CVs remaining below 6%. Accuracy assessment revealed median recoveries ranging from 89% to 110% of expected values and 92%-109% of the reference method values. Method comparison showed high correlation with the validated LDT for both metabolites (Pearson r: 0.984-0.995; slopes: 0.913-1.027). The test duration for one sample on the system for the tested analytes was 34 minutes, respectively.

Conclusions: The Ionify Vitamin D assay on the Cobas i 601 analyzer provides precise, accurate, and reproducible measurements of 25(OH)D and 24,25(OH)2D. By combining the analytical superiority of LC-MS/MS with full automation, this system supports timely and accurate measurements of vitamin D metabolites in routine laboratory settings.

Kyriakou, Athens, Greece

Introduction: APS-1 (Autoimmune Polyendocrine Syndrome type 1) or APECED (Autoimmune Polyendocrinopathy–Candidiasis–Ectodermal Dystrophy) is a rare disease caused by biallelic genetic changes in the AIRE gene. The three most common clinical manifestations are chronic mucocutaneous candidiasis, hypoparathyroidism, and primary adrenal insufficiency (Addison's disease). More than 126 different mutations in the AIRE gene have been described. There is no clear genotype–phenotype correlation. A wide variability in the spectrum and severity of clinical manifestations has been described even among carriers with the same AIRE genetic change, even among siblings. We present the cases of two siblings (an older sister, 20 years old, and a younger brother, 17 years old) with a homozygous loss-of-function mutation in the AIRE gene.

Case presentation: The older sister was initially diagnosed at 6.5 years old with hypoparathyroidism and at 8 years with primary adrenal insufficiency. At 11 years, she remained at Tanner stage I, and biochemical evaluation revealed primary hypogonadism. She developed onychomycosis at 12 years and was also diagnosed with hypothyroidism at 16 years.

The younger brother developed onychomycosis before the age of 9. At 9 years old, he was diagnosed with hypoparathyroidism and Addison's disease. He was also diagnosed with hypothyroidism at 10 years old. At the latest biochemical evaluation, at 17 years old, his gonadotropin levels showed an increasing trend indicative of primary gonadal insufficiency.

Genetic testing revealed a homozygous AIRE variant, c.892G > A (p.Glu298Lys) in both siblings, while their parents were found to be heterozygous carriers.

Conclusions: Despite the well-known poor genotype–phenotype correlation in patients carrying the same pathogenic *AIRE* variants, herein, we describe two siblings with the same homozygous *AIRE* mutation who exhibited similar clinical manifestations, albeit with disease onset at different ages. Moreover, in the older sister, a switch from conventional therapy to palopegteriparatide was initiated upon reaching adulthood because of poorly controlled hypoparathyroidism.

Abstract citation ID: lvag096.801

EP233 - ECE_3128 - Impact of romosozumab on quality of life in women with osteoporosis: a prospective pilot study

Giacomo Voltan[1,2], Carlo Mogno[1,2], Giacomo Contini[1,2], Michela Ferrarese[1,2] and Valentina Camozzi[1,2]

[1]Endocrinology Unit, University Hospital of Padova, Padova, Italy; [2]Department of medicine—DIMED, University of Padova, Padova, Italy

Background: Romosozumab is a monoclonal anti-sclerostin antibody with a dual anabolic and antiresorptive mechanism of action and currently represents the most effective therapy in terms of bone mineral density (BMD) increase and fracture risk reduction in patients with osteoporosis. While its skeletal efficacy is well established, data on its impact on patient-reported outcomes, particularly quality of life (QoL), are currently lacking. The aim of this study was to evaluate the effect of romosozumab on QoL in women treated for osteoporosis.

Methods: This was a prospective, single-center study including 59 postmenopausal women with osteoporosis treated with romosozumab according to national reimbursement criteria (Nota 79). Quality of life was assessed using the validated ECOS-16 questionnaire at baseline, 6 months and 12 months. Biochemical parameters were collected at baseline, 6 and 12 months, while BMD at the lumbar spine and femoral sites was evaluated by DXA at baseline and after 12 months of treatment.

Results: At the time of analysis, 14 patients had completed the full 12-month course of romosozumab. After 12 months of therapy, a significant increase in BMD was observed at both the lumbar spine (0.744 vs 0.619 g/cm^2, $P = .029$) and the femoral site (0.623 vs 0.585 g/cm^2, $P = .001$). Quality of life significantly improved as early as 6 months of treatment, with a reduction in ECOS-16 score (50.0 vs 54.33, $P = .013$), which was maintained

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

at 12 months (47.17 vs 54.33, $P = .041$). Notably, the percentage increase in BMD was inversely correlated with ECOS-16 score at 12 months (Spearman's rho = −0.709, $P = .022$), indicating that greater skeletal gains were associated with better patient-reported quality of life.

Conclusions: Romosozumab confirms its efficacy as a highly effective treatment for osteoporosis and is associated with a clinically meaningful improvement in quality of life. Given that lower ECOS-16 scores reflect better QoL, the observed inverse correlation between BMD gain and QoL score suggests that skeletal improvement translates into tangible clinical benefits for patients. This pilot study provides the first prospective evidence that romosozumab therapy positively impacts quality of life in addition to its well-established effects on bone mass, supporting the inclusion of patient-reported outcomes in future osteoporosis trials.

Abstract citation ID: lvag096.802

EP234 - ECE_1656 - Cinacalcet for preoperative primary hyperparathyroidism: insights into clinical-phenotypes and surgical outcomes from real-word observational data

Cosmina Schiteanu[1,2], George Varughese[1] and Laks Varadhan[1]
[1]Stoke-On-Trent, United Kingdom; [2]Stoke-on-Trent, Diabetes and Endocrinology, Endocrinology, Stoke-on-Trent, United Kingdom

Introduction: Primary hyperparathyroidism (PHPT) can present with severe hypercalcemia. Parathyroidectomy remains the definitive treatment but medical optimization before surgery with cinacalcet may be required. Beyond its role in biochemical stabilization, the need for cinacalcet may reflect a more severe disease phenotype, potentially correlating with identifiable parathyroid pathology and higher likelihood of surgical cure.

The aim of the study was to assess the preoperative use of cinacalcet and evaluate the phenotype of patient group it represents in real-world clinical practice.

Methods: All patients with primary hyperparathyroidism (PHPT) who were given cinacalcet over last 3 years was accessed. Patients who were specifically initiated for pre-operative control of calcium and underwent surgery were identified. Demographic and clinical parameters and radiological investigations (ultrasound [US] and technetium-99m sestamibi single-photon emission computed tomography with CT[MIBI-SPECT/CT] were collated.

Results: $N = 46$ (20.5% of all cases operated for PHPT over 3 years).

Females: 69.6% ($n = 32$).

Mean age: 61.2 ± 15.5 years (median 62; 22-82).

Mean starting calcium was 3.02 mmol/L (2.74-3.71)[normal:2.2-2.6] and PTH 22.3 pmol/L (6.83-88.96) [normal:2.0-8.5]. Indication for starting cinacalcet was symptomatic hypercalcemia in 76% ($n = 35$) or severe hypercalcemia (Ca > 3.0 mmol/L) in 52.2% ($n = 24$). Evidence of end-organ damage (osteoporosis ± fractures, renal stones) was present in 30.4%. ($n = 14$).

Mean duration of usage of cinacalcet was 66 weeks (4-178). Mean cinacalcet dose required used immediately before surgery was 63 mg/day (15-240). Immediate pre-op calcium was 2.79 mmol/L (2.29-3.38). 52.2% ($n = 24$) achieved adequate control of calcium with cinacalcet alone; others required additional treatment such as hospital visit for pamidronate infusion and/or intravenous fluids when clinically indicated.

US was done in all patients and positive in 84.8% ($n = 39$); MIBI-SPECT/CT in 44 and positive in 72.7% ($n = 32/44$). 61.4% ($n = 27/44$) had positively concordant scan results; 15.9% ($n = 7$) had both scans being negative, and while the rest had one scan positive and other reported as normal.

89.1% ($n = 41/46$) were successfully operated and cured. Of these, 25/41 had concordant positive scans and 10 at least one scan positive. Histology was parathyroid adenoma ($n = 40$) or carcinoma.

In 5 patients, cure was not achieved: 2/5 had concordant scans being positive and histology was adenoma/hyperplasia. In other 3/5 no intraoperative lesion found.

Conclusions: A significant proportion of patients may need cinacalcet to optimize calcium awaiting surgery, Use of a cinacalcet, a surrogate marker of severe and symptomatic hypercalcemia, may help to identify a phenotype of patients with operable, localized disease and to predict better localisation and cure rates.

Abstract citation ID: lvag096.803

EP237 - ECE_3124 - 18F-Fluorocholine positron emission tomography/computed tomography (18F-Choline PET/CT) in localization of parathyroid adenomas: a case series

Aggeliki Kyriakou[1], Angeliki Angelidou[1], Vasiliki Antonopoulou[1], Sofia Georgiadi[1], Kalliopi Pantelia[1], Anna Louisa Chaliasou[1], Stavros Karakozis[2], Lampros Karakozis[2], Stylianos Gavriilidis[3], Nikoletta Pianou[3], Phivi Rontogianni[3], Marinella Tzanela[1] and Theodora Stratigou[1]
[1]Department of Endocrinology "D. Ikkos"- Diabetes Center- EndoERN-Evangelismos General Hospital, Athens, Greece; [2]Thyroid Surgery Clinic, Athens, Greece; [3]Department of Nuclear Medicine and PET-CT, General Hospital «Evangelismos- Polyclinic», Athens, Greece

Background: Primary hyperparathyroidism (PHPT) is a common endocrine disease, most frequently caused by solitary parathyroid adenoma. Diagnosis is established biochemically, and surgical removal of hyperfunctioning parathyroid gland is the only curative treatment. Accurate localization is therefore essential for the success of minimally invasive parathyroidectomy (MIP). Although conventional imaging modalities are effective in most cases, they yield negative or discordant results in approximately 10%-15% of cases. ^{18}F-Fluorocholine positron emission tomography/computed tomography (^{18}F-Choline PET/CT) is a promising advanced imaging technique demonstrating high sensitivity and positive predictive value in the detection of parathyroid adenomas. Herein, we report the results of ^{18}F-Choline PET/CT in a case series of nine patients ($N = 9$) with PHPT following negative or inconclusive preoperative imaging.

Case-series: ^{18}F-Choline PET/CT was performed at our hospital from 2023 to 2025. The mean age of the nine patients was 58 years old, and the female-to-male ratio was 7:2. All patients had previously undergone neck ultrasound, 6/ 9 had Sestamibi scintigraphy (99mTc-Sestamibi), 3/9 had 99mTc-Sestamibi SPECT/CT, 6/9 had 4D/CT and 1/9 had MRI.

^{18}F-Choline PET/CT was positive in six out of nine patients (6/9), revealing parathyroid adenoma. All six patients had mild hypercalcemia (mean serum calcium: 11 mg/dl) and an average parathyroid hormone (PTH) of 147 pg/ml. In 2/6 patients all conventional imaging modalities were negative, while in 4/6 the

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

findings were discordant. All six patients underwent minimally invasive parathyroidectomy, and histopathology confirmed parathyroid adenomas in all cases. Calcium and PTH levels normalized. All three patients with negative ^{18}F-Choline PET/CT (3/9) had normocalcemic PHPT and mean PTH:130 pg/ml. In 2/3, neck ultrasound was negative, while in one patient a small lesion was detected representing either atypical adenoma or hyperplasia. Although all three patients had positive 99Tcm Sestamibi scans (2/3 with SPECT/CT), the findings were not definitive for adenomas.

Discussion: 18F-Choline PET/CT is highly effective preoperative localization imaging technique for patients with PHPT, providing crucial guidance for MIP. Currently, it is available in a limited number of specialized centers and is performed when conventional imaging is negative or inconclusive. In our case-series, 18F-Choline PET/CT detected parathyroid adenomas in the majority of patients, leading to successful surgery. However, it was negative in three patients. This finding should be interpreted with caution, as these patients did not undergo surgery. Our results, in line with current literature, highlight the significance of this method as a valuable tool in the effective management of PHPT.

EP238 - ECE_3443 - Cosmetic procedure-induced granulomatous disease presenting with hypercalcemia: a case report

Tânia Fernandes[1], Filipa Barros Alves[1], Marta Castro Tomé[1], Alexandra Novais Araújo[1,2] and Rosa Maria Príncipe[1,2]
[1]*Endocrinology, Local Health Unit of Matosinhos, Matosinhos, Portugal;* [2]*Faculty of Medicine of University of Porto, Porto, Portugal*

Hypercalcemia is a disorder of calcium metabolism, often classified as parathyroid hormone (PTH)-dependent or PTH-independent. However, less common causes may explain this frequent metabolic disturbance. Polymethylmetacylate (PMMA), used as a permanent cosmetic filler, has been linked to delayed foreign-body reactions and metabolic complications.

We report a clinical case of a 55-year-old woman with hypercalcemia, admitted for acute obstructive pyelonephritis due to E. coli infection, with impaired kidney function and ureterohydronephrosis.

Initial laboratory results revealed severe hypercalcemia, with serum corrected calcium levels for albumin of 14.56 mg/dL. She presented with no symptoms typically associated with this ionic disturbance. Further workup revealed PTH 14.1 pg/mL (normal range: 15.0-68.3 pg/mL), alkaline phosphatase enzyme of 81 U/L (40-180 U/L) and phosphorus levels 4.9 mg/dL (2.3-4.7 mg/dL) and markedly elevated 1,25-dihydroxycalciferol levels (242.8 pg/mL). She presented with decreased kidney function (creatinine of 4.6 mg/dL). Previous analytic studies showed that hypercalcemia was already present three years before her hospital admission (calcium 11.8 mg/dL), as well as chronic kidney disease (creatinine 1.76 mg/dL). We actively excluded malignant and autoimmune etiologies. Our patient revealed she had done an aesthetic procedure in her glutes eight years ago with injections of PMMA, a cosmetic filler used for soft-tissue augmentation. Imaging findings revealed multiple areas of subcutaneous fat densification in her gluteal region, bilaterally, in relation to these injections. The hypercalcemia was attributed to increased extrarenal production of active vitamin D by activated macrophages within PMMA-induced granulomas. Hypercalcemia was treated with intravenous hydration, a calcimimetic agent (60 mg daily) and corticosteroid therapy (prednisolone 30 mg daily), resulting in progressive normalization of serum calcium levels and clinical improvement.

Cosmetic enhancement procedures may have delayed side effects that explain the aetiology of hypercalcemia. Removal of this permanent filler is not possible; therefore, long term treatment is necessary to avoid recurrence of hypercalcemia. This case report highlights the challenging management of hypercalcemia in a young patient with impaired kidney function and the need to carefully balance effective calcium control with renal safety.

Garofalidis', Medical School, National and Kapodistrian University of Athens, KAT General Hospital, Kifissia, Athens, Greece*

Introduction: Osteoporosis is a global health problem. Among men with osteoporosis, 50%-80% have secondary osteoporosis, which is frequently under-recognized. Male hypogonadism may represent a cause of secondary osteoporosis. Systemic mastocytosis is another uncommon but clinically significant cause and may present with severe skeletal involvement. We report a patient with known hypogonadism in whom the assessment for secondary osteoporosis revealed systemic mastocytosis.

Case presentation: A 62-year-old man with a medical history of hypertension, nephrolithiasis, previous knee arthroplasty and Y chromosome mosaicism presented with acute back pain following minimal trauma after lifting a 15-kg weight. Cytogenetic investigation due to azoospermia revealed a rare mosaic karyotype pattern of 45,X/46,XY/ 47,XY, +mar (Y).

The molecular analysis of Y-chromosome markers (DYS1, DYS222, DAZ) confirmed loss of Y chromosomal material. He had previously received testosterone replacement therapy during puberty.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

The imaging revealed a vertebral fracture at L1 and kyphoplasty was performed. Nine days later, he experienced sudden back pain and further imaging demonstrated new vertebral fractures at T12, L4, and L5. Thus, he underwent an additional kyphoplasty. Given the occurrence of multiple low-trauma vertebral fractures, the patient was evaluated for secondary causes of osteoporosis other than his partial hypogonadism (testosterone levels = 2.33 ng/ml (normal range: 1.93-7.40)). The workup revealed elevated serum tryptase levels (34.9 μg/L) and hypothyroidism. The patient underwent a bone marrow biopsy, which together with serum tryptase levels, confirmed the diagnosis of systemic mastocytosis. Treatment with levothyroxine, and midostaurin was initiated. Although bisphosphonates remain the cornerstone of therapy for mastocytosis-associated osteoporosis, the patient expressed significant concern regarding the risk of acute phase reactions when informed of bisphosphonates' side effects. Therefore, denosumab therapy was initiated, considering evidence suggesting it may also reduce serum tryptase levels.

New bone mineral density measurements will be evaluated in February 2026, one year after the treatment initiation.

Conclusions: This case highlights the importance of investigating secondary causes of osteoporosis in patients presenting with osteoporosis, as more than one contributing factors may coexist.

EP241 - ECE_3851 - Screening for MEN1 mutations in high-risk primary hyperparathyroidism: age and glandular involvement as predictors of germline status

Bogdan Radu Dițescu[1], Iulia Florentina Burcea[1,2], Dobre Ramona[1,2], Andra Caragheorgheopol[3], Elena Emanuela Braha[4] and Cătălina Poiană[1,2]

[1]*First Endocrinology Department, "C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania;* [2]*Department of Endocrinology, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, Bucharest, Romania;* [3]*Research Laboratory—Pathology Department, "C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania;* [4]*Department of Genetics, "C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania*

Introduction: Primary hyperparathyroidism (PHPT) most commonly results from single-gland disease, whereas in hereditary syndromes such as Multiple Endocrine Neoplasia type 1 (MEN1) it typically presents as multiglandular involvement, with most patients developing disease by the fifth decade of life. In accordance with current clinical practice guidelines for MEN1, the objective of this study was to evaluate the clinical and biochemical phenotypes of PHPT and to assess the utility of genetic screening in patients diagnosed before the age of 35 or those presenting with multiglandular disease.

Methods: We performed a retrospective analysis of patients diagnosed with PHPT between January 2024 and December 2025 who met at least one of the following criteria: age ≤35 years at diagnosis or evidence of multiglandular parathyroid disease. Clinical characteristics, biochemical parameters, imaging findings, and associated endocrine manifestations were reviewed. All patients underwent germline MEN1 mutation testing.

Results: A total of 13 patients were included and stratified into two groups based on clinical selection criteria. The first group included 7 patients diagnosed with PHPT prior to age 35 (29 ± 5.06 years), while the second group consisted of 6 patients (55.5 ± 10.1 years) presenting with multiglandular parathyroid disease. In the early-onset group, 85.7% of patients had a single parathyroid adenoma at diagnosis, while 14.3% presented with double adenomas. The mean serum calcium level for this subgroup was 10.41 ± 0.47 mg/dL, with a mean parathyroid hormone (PTH) concentration of 138.92 ± 63.48 pg/mL. In contrast, among patients with multiglandular involvement, 66.6% had two affected glands and 33.3% had three parathyroid adenomas. This group demonstrated higher biochemical severity, with a mean serum calcium level of 11.67 ± 0.58 mg/dL and a median PTH concentration of 220.5 pg/mL. Across the entire cohort, systemic evaluation revealed pituitary tumors in 76.9% of patients, neuroendocrine tumors in 30.7%, and adrenal tumors in 38.4%. MEN1 germline mutations were identified in 28.5% of patients diagnosed before age 35 and in 50% of those with multiglandular parathyroid disease.

Conclusions: Multiglandular parathyroid involvement appears to be a stronger clinical predictor for MEN1 mutations than isolated young age at onset. The high prevalence of associated endocrine tumors supports a MEN1-like phenotype across the cohort, underscoring the importance of genetic evaluation and raising the possibility of syndromic phenocopies.

EP242 - ECE_2607 - "Serum inflammation-based scores (SIBs) in primary hyperparathyroidism: association with biochemical severity and postoperative outcomes"

Karol Ciszek[1], Dorota Pach[1], Marta Opalinska[1], Jacek Podlewski[2], Marcin Barczynski[3], Aleksander Konturek[3] and Alicja Hubalewska-Dydejczyk[1]

[1]*Chair and Department of Endocrinology, Jagiellonian University Medical College, Kraków, Poland;* [2]*Dover Fueling Solutions, Kraków, Poland;* [3]*Department of Endocrine Surgery, Faculty of Medicine, Jagiellonian University Medical College, Kraków, Poland*

Primary hyperparathyroidism (PHPT) is a chronic endocrine disorder increasingly associated with low-grade inflammation, partly caused by persistently elevated parathyroid hormone (PTH) levels. Serum inflammation-based scores (SIBS), obtained from routine blood tests, are widely used as markers of inflammation in various clinical settings; however, their role in primary hyperparathyroidism remains poorly defined. The aim of this study was to assess the association between SIBS and the biochemical severity of primary hyperparathyroidism, to evaluate gender differences in these markers, and to analyze their changes after parathyroidectomy.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

This retrospective single-center study included patients with primary hyperparathyroidism treated between 2020 and 2025 in our clinic. Of the 279 initially identified patients, 153 with complete preoperative laboratory data were included in the analysis. The analyzed inflammation-based scores included the neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR), monocyte-to-lymphocyte ratio (MLR), and the systemic immune-inflammation index (SII: platelets × neutrophils/lymphocytes). Associations between serum calcium, PTH, and SIBS were assessed using correlation analyses and multivariable linear regression models. Postoperative follow-up data were available for 19 patients, allowing for paired pre-post comparisons using Student's t-test or the Wilcoxon signed-rank test, as appropriate. P value $< .05$ was considered statistically significant.

The final cohort consisted of 153 patients (127 females, 26 males). Due to the non-normal distribution of the data, non-parametric analyses were used. Male patients demonstrated significantly higher MLR and NLR values compared to females ($P = .0014$ and $P = .024$, respectively). Significant associations were observed between SIBS and biochemical markers of PHPT. Serum calcium levels showed positive correlations with NLR ($P < .001$), MLR ($P = .002$), and SII ($P < .001$). Similarly, PTH levels positively correlated with NLR ($P < .001$), MLR ($P < .001$), and SII ($P < .001$). In multivariate analysis, MLR was independently associated with PTH, age, and male sex. All inflammation-based scores showed a numerical decrease after parathyroidectomy; however, a statistically significant reduction was observed only for PLR (mean change −34.2, $P = .046$). Changes in MLR, NLR, and SII did not differ significantly, most likely due to the limited number of patients with available postoperative complete blood count with differential.

Serum inflammation-based scores are associated with the biochemical severity of primary hyperparathyroidism. Sex-related differences were observed, with higher MLR and NLR values in male patients. Although SIBS tended to decrease after parathyroidectomy, larger studies with bigger follow-up are needed to confirm postoperative changes and clarify their clinical relevance.

EP243 - ECE_2783 - Limited predictive performance of scoring models for sporadic multiglandular parathyroid disease in patients referred for fluorocholine PET/CT

Katerina Zajickova[1,2], Josef Vcelak[1,3], Petr Libánský[4], Dana Michalska[2] and David Zogala[5]
[1]Institute of Endocrinology, Prague, Czech Republic; [2]General University Hospital and First Faculty of Medicine, III. Internal Clinic, Endocrinology and Metabolism, Prague 2, Czech Republic; [3]First Faculty of Medicine, First Faculty of Medicine, Charles University, Prague 2, Czech Republic; [4]3rd Department of Surgery, Surgery, Motol University Hospital, Prague 5, Czech Republic; [5]General University Hospital and First Faculty of Medicine, Nuclear Medicine, Prague 2, Czech Republic

Multiglandular parathyroid disease (MGD) is a less common presentation of sporadic primary hyperparathyroidism (PHPT), occurring in approximately 10%-20% of patients compared to single gland hyperparathyroidism (SGD). Equivocal parathyroid imaging is associated with a higher prevalence of MGD in PHPT, making focused, limited parathyroidectomy challenging.

We present a cohort of 54 patients with PHPT (mean calcium 2.77 mmol/l, parathyroid hormone (PTH) 102.1 ng/l and age 64.0 years) who underwent fluorocholine PET/CT (FCH) due to inconclusive neck ultrasound, MIBI scintigraphy or persistent PHPT. Thirteen of 54 patients had MGD (24.1%) based on postoperative histology. The diagnostic performance of three preoperative MGD prediction models (CaPTHUS, the Washington University Index (WUI) and the Luo nomogram) was evaluated.

There were no differences in preoperative parameters, including serum calcium, phosphate, creatinine, and PTH levels, between patients with MGD and SGD. The CaPTHUS test correctly identified 10 patients (76.9%) with MGD and six patients (14.6%) with SGD. The WUI correctly identified three patients (23.1%) with MGD and 30 patients (73.2%) with SGD. The Luo nomogram failed to identify any cases of MGD. FCH identified 42.8% of patients with MGD, and its positive predictive value increased to 50% when combined with WUI-based stratification.

The equivocal standard parathyroid imaging and milder disease presentation were likely the reasons why the preoperative prediction scoring models could not reliably distinguish sporadic MGD from SGD in our patient cohort. The positive predictive value of FCH in diagnosing MGD was better than the three prediction models. The diagnostic value of combining FCH with selected biochemical indices for predicting MGD warrants validation in larger patient populations. Currently, the extent of parathyroidectomy in patients with equivocal imaging relies on surgeon expertise because preoperative differentiation of MGD from SGD is difficult.

EP244 - ECE_1302 - Unmasking a hereditary cause of aggressive hyperparathyroidism

Leire Perez Garcia[1], Maria del Carmen Fernandez Lopez[2], Leire Isasa Rodriguez[2] and Leire Agea Diaz[1]
[1]Hospital Universitario Araba, Vitoria-Gasteiz, Spain; [2]Hospital Universitario Cruces, Barakaldo, Spain

Background: Parathyroid carcinoma is a rare cause of primary hyperparathyroidism and may occur as part of Hyperparathyroidism–Jaw Tumor (HPT-JT) syndrome, an autosomal dominant disorder caused by pathogenic germline variants in *CDC73*.

Case presentation: A 59-year-old man presented to the emergency department in January 2019 with progressive asthenia, polydipsia and severe hypercalcemia (albumin-corrected calcium 16.02 mg/dL). Labs showed markedly elevated PTH (1363 pg/mL) and severe 25-hydroxyvitamin D deficiency (6 ng/mL). He reported constitutional symptoms since September 2018 and a history of nephrolithiasis requiring lithotripsy 10 and 20 years earlier.

Emergency management included intravenous hydration, furosemide, zoledronic acid, and calcitonin, achieving calcium levels of 8-10.6 mg/dL. Cervical computed tomography revealed a 30 × 26 × 48 mm solid mass posterior to the right thyroid lobe, suggestive of parathyroid carcinoma.

In February 2019, he underwent right hemithyroidectomy with en bloc resection of the right superior parathyroid tumor. Histology confirmed a 3-cm oncocytic parathyroid carcinoma with vascular invasion, capsular and adipose infiltration, necrosis, mitotic index 4/10 HPF, and Ki-67 index 10%. A peritumoral

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

hyperplastic parathyroid gland was also identified. Preoperative PTH was 1681 pg/mL, decreasing to 145 pg/mL postoperatively.

Persistent normocalcemic hyperparathyroidism (PTH 300 pg/mL) prompted reoperation in September 2019, excising the inferior and half of the left superior hyperplastic parathyroid glands. Post-reintervention, he achieved stable normocalcemia (8.2-9.3 mg/dL), normal phosphate, high-normal PTH (60-150 pg/mL), and adequate vitamin D status.

Genetic testing revealed a heterozygous *CDC73* frameshift variant (c.687_688delAG; p. R229Sfs*37), recently reported in association with HPT-JT syndrome. One daughter was affected and required surgery, another tested negative.

Follow-up: Despite high risk of hungry bone syndrome, only initial phosphate supplementation and monthly cholecalciferol were needed. Postoperative hypothyroidism required levothyroxine 50 µg daily since 2020. A stable 15-mm lesion in the left second rib, consistent with a brown tumor, was observed on serial magnetic resonance imaging (MRI) between 2020 and 2024. Bilateral Bosniak I renal cysts were observed (largest 3 cm in left kidney, stable 2019-2024). Serial imaging showed no local recurrence (neck ultrasound 2025; MRI 2024), and dental panoramic radiography revealed no jaw tumors (2022). Bone densitometry showed normal lumbar and femoral osteopenia (2023).

Conclusions: This case highlights the diagnostic and therapeutic challenges of parathyroid carcinoma associated with HPT-JT syndrome and underscores the importance of genetic testing and long-term multidisciplinary follow-up.

Abstract citation ID: lvag096.810

EP245 - ECE_2602 - Teriparatide as an effective treatment for refractory hypocalcemia in Autoimmune Polyglandular Syndrome Type 1

Rita Pinto Ribeiro[1], Patrícia Brito[1], Bruna Silva[2], Adriana de Sousa Lages[1], Bárbara Araújo[1], Joana Maclel[1], Diana Borges Duarte[1], Juliana Sá[1], Sara Esteves Ferreira[1] and Olinda Marques[1]

[1]Endocrinology Department, Unidade Local de Saúde de Braga, Braga, Portugal; [2]Endocrinology Department, Unidade Local de Saúde Tâmega e Sousa, Penafiel, Portugal

Introduction: Autoimmune Polyglandular Syndrome Type 1 (APS-1) is a rare inherited disorder characterized by the triad of chronic mucocutaneous candidiasis, hypoparathyroidism, and adrenal insufficiency. Management of hypocalcemia in APS-1 can be challenging, particularly when malabsorption limits oral calcium and active vitamin D efficacy. Teriparatide, a recombinant PTH (1-34) analog, is not approved for hypoparathyroidism but has been used off-label in selected refractory cases.

Case report: Female, 26-year-old, followed in the Endocrinology Department since age 18 for APS-1, comprising primary adrenal insufficiency, primary hypoparathyroidism, premature ovarian insufficiency, autoimmune hepatitis, ectodermal dystrophy of dental enamel and nails, and exocrine pancreatic insufficiency. She was on calcium, calcitriol, azathioprine, hydrocortisone, fludrocortisone, estradiol, progesterone, and pancreatin.

Since 2017, she has experienced recurrent episodes of symptomatic hypocalcemia despite high-dose calcitriol (2,25 µg/day) and calcium carbonate (4500 mg/day), typically triggered by diarrheal exacerbations. She reported a long-standing history of alternating diarrhea and constipation.

In 2024, she presented to the Emergency Room with facial and extremities paresthesias and muscle stiffness. One month earlier, she started complaining of nausea, vomiting, and diarrhea, and the subsequent symptomatic hypocalcemia was treated with intravenous calcium gluconate(IV calcium) and increased oral calcium dose.

At readmission, biochemical evaluation revealed hypokalemia, hypocalcemia, hypomagnesemia and normal serum phosphorus, and she started IV calcium and electrolyte correction. During the first 15 days of hospitalization, repeated attempts to discontinue IV calcium and maintain oral therapy alone resulted in recurrent severe hypocalcemia.

On day 16, teriparatide 20 µg once daily was initiated as an off-label treatment for refractory and severe hypocalcemia. Within two days, IV calcium supplementation was successfully discontinued, and the patient transitioned to oral therapy, with diarrhea resolution. Following discharge, oral calcium carbonate and calcitriol doses were progressively reduced.

Ten months later, she remains clinically stable with normal calcium, phosphorus, and calciuria on calcium carbonate 3000 mg/day, calcitriol 1 µg/day, and teriparatide 20 µg every other day.

Conclusions: This case supports the use of teriparatide as a potential therapeutic option for refractory hypocalcemia due to hypoparathyroidism in APS-1, especially when malabsorption limits conventional therapy. It should be reserved for selected patients under close monitoring. However, the optimal treatment duration remains uncertain, as long-term safety data are still limited.

Abstract citation ID: lvag096.811

EP246 - ECE_2850 - The therapeutic challenge of chronic hypoparathyroidism: a case report of real-life experience with palopegteriparatide

Giulia Del Sindaco[1], Angela Pagnano[1,2], Lucrezia Ghisleni[1,2], Giulia Carosi[1] and Giovanna Mantovani[1,2]

[1]Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Department of Clinical Sciences and Community Health, Dipartimento di Eccellenza 2023-2027, Università Degli Studi Di Milano, , Milan, Italy

The management of chronic hypoparathyroidism remains a therapeutic challenge. Therapy aims to prevent hypocalcemic symptoms, maintain serum calcium levels in the low-normal range, and avoid hypercalciuria, a major concern in this disease. Many patients fail to achieve biochemical control with conventional therapy and experience persistent symptoms with impaired quality of life. Moreover, even in the presence of normocalcemia, unpredictable calcium fluctuations and long-term complications, such as renal impairment, extraskeletal calcifications, and neuropsychiatric disorders, may occur. In this context, emerging therapies based on recombinant PTH or PTH agonists represent a promising approach.

We report the paradigmatic case of a patient who underwent multiple therapeutic strategies over years.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

The patient is a 47-year-old woman who underwent total thyroidectomy at the age of 20 for Graves–Basedow disease unresponsive to medical treatment. Since the diagnosis of hypoparathyroidism, she never achieved satisfactory clinical or biochemical control despite multiple treatment attempts, and she continued to experience hypocalcemic symptoms. In addition to conventional therapy with high-dose calcium supplementation and active vitamin D, up to 7-8 gr of calcium and 2-2.5 mcg of calcitriol daily, she was previously treated with PTH replacement therapy (PTH(1-34) and subsequently PTH(1-84)). Over the years, she experienced several episodes of laryngospasm and severe tetany requiring hospitalization and intravenous calcium administration. She also developed hypercalciuria, nephrocalcinosis, and nephrolithiasis, leading to the introduction of thiazide diuretics. Notably, even during PTH replacement therapy, calcium and calcitriol could never be discontinued because of inadequate biochemical and clinical control, and hypercalciuria persisted.

TransConPTH (palopegteriparatide) is a sustained-release prodrug of PTH(1-34) designed to provide physiological PTH levels over 24 h in adults with hypoparathyroidism. The patient started palopegteriparatide at a dose of 18 mcg daily in July 2025, reporting improved well-being within the first days of treatment. With progressive dose escalation, conventional therapies were gradually down-titrated, allowing complete withdrawal of calcitriol in November 2025. Serum calcium and phosphate levels remained within the low-normal range, no hypocalcemic symptoms were reported, and hypercalciuria normalized after three months of therapy. Bone turnover markers remained stable at the last biochemical assessment. The current palopegteriparatide dose is 42 mcg daily, and no adverse events have been reported to date.

In conclusion, in our experience, palopegteriparatide significantly improved the management of chronic hypoparathyroidism compared with conventional therapy and previous PTH replacement strategies. By restoring physiological PTH activity, palopegteriparatide represents a promising treatment for achieving clinical and biochemical control in chronic hypoparathyroidism.

Abstract citation ID: lvag096.812

EP248 - ECE_2437 - Skeletal lesions in prostate cancer: when primary hyperparathyroidism is the culprit

Teodora Vintilă[1], Alexandru Florescu[1,2], Irina Puscasu[1], Andra Berigoi[1], Stefana Bilha[1,2] and Cristina Preda[1,2]
[1]*Saint Spiridon County Hospital, Iași, Romania;* [2]*Iași, Romania*

Skeletal involvement is a defining feature of advanced prostate cancer (PC) and is commonly regarded as a surrogate of metastatic spread, often guiding staging and therapeutic decisions. While this assumption is frequently justified, it may obscure alternative causes of bone involvement, particularly in the presence of coexisting endocrine disorders. Emerging evidence suggests that primary hyperparathyroidism (PHPT) represents a source of diagnostic ambiguity when skeletal lesions coexist with metabolic bone disease in PC.

We report the case of a 75-year-old man with PC (Gleason score 7), treated with androgen deprivation therapy, in whom pelvic magnetic resonance imaging during oncologic follow-up revealed multiple skeletal lesions suspicious for metastatic disease. The most prominent lesion (41 × 16 mm) was located in the right inferior pubic ramus, with additional indeterminate lesions in the sacrum and iliac bones.

Subsequent evaluation revealed hypercalcemia, prompting endocrinological assessment. Biochemical testing was consistent with PHPT, with elevated PTH (1741 pg/mL), hypercalcemia (13.3 mg/dL), hypercalciuria (367.2 mg/24 h), and low–normal vitamin D levels (20.5 ng/mL). Neck ultrasound and sestamibi scintigraphy identified a large hyperfunctioning left inferior parathyroid lesion. In parallel, bone scintigraphy demonstrated extensive skeletal involvement, with multiple hyperfixating foci affecting the skull, right radius, lumbar spine, sacrum and pelvis resulting in a heterogeneous pattern. In the oncologic context, this appearance was initially interpreted as highly suggestive of widespread metastatic disease.

The patient underwent parathyroidectomy, with histopathology confirming an atypical parathyroid adenoma. One year postoperatively, biochemical parameters normalized (PTH 25.95 pg/mL, corrected calcium 8.3 mg/dL, alkaline phosphatase 58 U/L). Follow-up bone scintigraphy demonstrated marked regression of tracer uptake at previously involved sites, no new hyperfixating lesions, and persistent extra-articular uptake at the level of the hands, a scintigraphic finding consistent with brown tumors. Together with biochemical normalization, this evolution supported the retrospective diagnosis of parathyroid-related bone disease. Bone mineral density improved at axial sites (+40.1% lumbar spine, +16.7% femoral neck), with persistent cortical impairment at the distal radius.

This case illustrates how PHPT can function as a major diagnostic confounder in patients with PC, in whom skeletal lesions are frequently framed as metastatic disease. Beyond a diagnostic pitfall, it raises a clinically relevant question regarding the systematic evaluation of calcium–PTH homeostasis in this population. Proactive parathyroid assessment may be clinically justified in selected PC patients with skeletal involvement or biochemical abnormalities to prevent cancer overstaging and avoid therapeutic escalation driven by metabolically reversible bone pathology.

EP249 - ECE_2720 - The paradox of diagnosis: evaluating osteoporosis knowledge and health literacy among female patients

Birgul Genc, Berna Evranos Ogmen, Reyhan Ersoy, Oya Topaloglu and Bekir Cakir
Endocrinogy and Metabolism, Ankara Bilkent Şehir Hastanesi, Ankara, Türkiye

Objective: This study aimed to evaluate the knowledge levels and socio-demographic characteristics of female patients regarding osteoporosis and to determine whether a formal diagnosis of the disease correlates with higher health literacy.

Methods: This descriptive, cross-sectional study included 396 female participants aged 30 and over. Data were collected through face-to-face interviews using a standardised demographic questionnaire and a modified 36-item osteoporosis knowledge questionnaire. Participants were divided into two groups based on their medical history: those diagnosed with osteoporosis ($n = 66$) and those without ($n = 330$). Anthropometric measurements

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

(BMI) and laboratory findings (serum calcium and vitamin D) were also recorded.

Results: The mean age of the osteoporosis group was significantly higher (63.23 ± 14.41 years) compared to the non-osteoporosis group (50.70 ± 11.56 years, $P < .001$). Patients with osteoporosis were more likely to be from disadvantaged socioeconomic backgrounds, with significantly higher illiteracy rates (28.78% vs 10.30%, $P = .0001$). Despite their diagnosis, the mean total osteoporosis knowledge scores showed no statistically significant difference between the two groups (45.8 ± 15.8 vs 41.67 ± 16.8, $P = .066$), indicating a shared deficiency in disease awareness. Furthermore, the osteoporosis group exhibited significantly lower serum calcium levels ($P = .048$) and alarmingly low rates of calcium and Vitamin D supplementation.

Conclusions: A clinical diagnosis of osteoporosis does not inherently lead to improved disease knowledge or better health practices. Current management appears to be focused on pharmacological treatment, neglecting the essential role of patient education. There is an urgent need for structured, literacy-level-appropriate educational programs to bridge the implementation gap and improve long-term bone health outcomes, particularly among socio-economically disadvantaged populations.

EP250 - ECE_2401 - Severe refractory hypocalcaemia in a breast cancer patient—multiple concurring mechanisms

Daniel Grigorie[1,2], Diana Felicia Coles[3,4] and Alina Sucaliuc[1]
[1]*Romania, Bucharest, Romania;* [2]*"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania;* [3]*"CI Parhon" National Institute of Endocrinology, Bucharest, Romania;* [4]*"Carol Davila" University of Medicine and Pharmacy, Doctoral School, Bucharest, Romania*

Background: Hypocalcaemia, in contrast to hypercalcaemia, is a rare complication of malignancy, often multifactorial, severe and prolonged, particularly in the context of antiresorptive therapy and extensive skeletal involvement and complicates oncologic management.

Case presentation: We report the case of a 52 years old woman with metastatic hormone receptor–positive breast cancer, who developed severe, refractory hypocalcaemia following a single 120 mg dose of denosumab. She was receiving oncologic therapy with ribociclib, letrozole and goserelin. The patient had total thyroidectomy 2 years earlier and reported inconsistent supplementation with 600 mg calcium and 400 IU vitamin D, being asymptomatic. Prior to denosumab serum calcium was 8.4 mg/dL (8.6-10.6 mg/dL), PTH 37.8 pg/mL (15-65 pg/mL). Five days after denosumab administration, she presented with a severe, life-threatening tetanic crisis with opisthotonus and marked QTc prolongation, with a nadir serum calcium of 3 mg/dL (0.75 mmol/L). Despite intravenous and oral calcium (up to 3.6 g calcium carbonate daily) and alfacalcidol (3 µg/day), hypocalcaemia remained refractory for over two months, with levels reaching 6.4 mg/dL at admission in our department; normal phosphate, magnesium and renal function, elevated alkaline phosphatase (563 U/L, NR 35-105 U/L), and an inappropriately normal parathyroid hormone level (50.7 pg/mL). Imaging revealed disseminated, predominantly osteoblastic bone metastases. Reviewing the chart of the surgery we identified hypoparathyroidism—Ca 7 mg/dL, PTH 4 pg/mL, which evolved to parathyroid insufficiency, after a year Ca 7.2 mg/dL, PTH 50 pg/mL. Switching to calcitriol (1.5 µg/day) and higher calcium dose (4.2 g/day) resulted in gradual normalization of calcium levels and QTc interval, with complete recovery from hypocalcaemia after approximately 95 days. However, inconsistent outpatient monitoring later led to transient hypercalcaemia, hypercalciuria, and renal function decline.

Discussion: Denosumab-induced suppression of bone resorption represented the main precipitating factor. Extensive osteoblastic metastases are less common than osteolytic metastases in breast cancer but they acted as a major facilitating factor, promoting accelerated bone formation and mineralization with increased skeletal calcium sequestration. Parathyroid insufficiency post-thyroidectomy made a significant contribution by limiting compensatory parathyroid hormone response.

Conclusions: Although uncommon, malignancy-associated severe hypocalcaemia may be inherently life-threatening when multiple concurring mechanisms coexist: denosumab administration, osteoblastic metastases and reduced parathyroid reserve.

EP252 - ECE_3548 - Effect of denosumab on osteoporosis prevalence in simultaneous pancreas and kidney recipients

Jana Brunová and Simona Kratochvílová
Institute for Clinical and Experimental Medicine, Prague, Czech Republic

Introduction: Organ transplant recipients especially after simultaneous pancreas and kidney (SPK) are at increased fracture risk compared to general population. The recommended treatment of osteoporosis in solid organ transplant recipients includes vitamin D, calcium supplementation and bisphosphonates. Denosumab is the possible therapeutic option for patients with impaired renal function.

Aim of study: We investigated the bone mineral density (BMD) development in SPK patients, who originally started with denosumab therapy for osteoporosis in lumbar spine and/or proximal femur

Methods: Our retrospective study comprises 34 subjects after SPK, (12 M, 22 W, mean age 44 ± 9.6 y at the beginning of therapy), transplanted between 1994-2024. Dual energy X-ray absorptiometry scans (DXA) were performed with the Lunar Prodigy apparatus. The mean therapy duration was 37.2 ± 24.2 months (3.1y). Fracture history was present in 15/34 (44%) patients.

Results: L spine T score improved in the whole group from −1.4 ± 1.3 to −0.7 ± 1.5 ($P < .001$). The values of proximal femur T score increased from −2.9 ± 0.6 to −2.7 ± 0.8 after the therapy ($P < .05$). Mean increase in BMD of L-spine was 8.2 ± 6.9%, of the proximal femur raised by 3.6 ± 7.2%. The denosumab therapy decreased the prevalence of osteoporosis in all patients from 34/34 (100%) to 18/34 (53%), in L spine from 7/34 (20%) to 4/34

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

(12%), proximal femur from 32/34 (94%) to 17/34 (50%) and in neck from 28/34 (82%) to 20/34 (59%).

Summary: The denosumab treatment significantly improved the BMD values at L spine and proximal femur sites in SPK recipients treated for osteoporosis. The prevalence of osteoporosis decreased by 47% in whole group.

EP253 - ECE_3885 - Adherence to the mediterranean diet as a predictor of bone health in adults with cystic fibrosis

María Del Carmen Andreo-Lopez[1], Victoria Contreras-Bolívar[1], Francisco Casas-Maldonado[1], Silvia Merlos-Navarro[2], Casilda Olveira[3], Gabriel Olveira[3], José Manuel Vaquero-Barrios[4], Manuel García-Amores[5], Diego Becerra-García[1] and Manuel Muñoz-Torres[1]
[1]Hospital Universitario San Cecilio, Granada, Spain; [2]Hospital Universitario Virgen de las Nieves, Granada, Spain; [3]Hospital Universitario Regional de Málaga, Granada, Spain; [4]Hospital Universitario Reina Sofía, Córdoba, Spain; [5]Hospital Universitario de Jaén, Jaén, Spain

Background: Cystic fibrosis–related bone disease (CFBD) is an increasingly prevalent complication and is associated with a higher risk of fragility fractures and mortality. Beyond areal bone mineral density (aBMD) assessed by dual-energy X-ray absorptiometry (DXA), advanced imaging techniques such as trabecular bone score (TBS) and three-dimensional DXA (3D-DXA) allow a more detailed evaluation of bone microarchitecture and compartmental structure. However, the impact of modifiable nutritional factors, including adherence to the Mediterranean diet, on these advanced bone parameters in adults with cystic fibrosis (CF) remains poorly characterised.

Objective: To evaluate whether adherence to the Mediterranean diet is associated with bone structural parameters assessed by conventional DXA, TBS, and 3D-DXA in adults with CF.

Methods: A case–control study including 32 adults with CF and 70 healthy controls matched for age, sex, and body mass index was conducted. Bone health was assessed using DXA to obtain aBMD, TBS to estimate trabecular microarchitecture, and 3D-DXA to analyse cortical and trabecular compartments. Clinical and biochemical data were collected. Adherence to the Mediterranean diet was assessed using the PREDIMED questionnaire. Multivariable regression models were applied to identify independent associations.

Results: Fragility fractures were present in 22% of adults with CF. Good adherence to the Mediterranean diet was significantly lower in the CF group compared with controls (50% vs 81.2%, $P = .001$). Adults with CF showed a higher prevalence of low aBMD (28.1% vs 5.7%, $P < .001$), impaired trabecular microarchitecture assessed by TBS (31.3% vs 12.5%, $P = .002$), and lower cortical and trabecular parameters evaluated by 3D-DXA (all $P < .01$). In multivariable analyses, adherence to the Mediterranean diet emerged as an independent predictor of aBMD, TBS, and 3D-DXA–derived parameters, explaining between 14% and 60% of their variability.

Conclusions: CF-related bone disease remains highly prevalent in adults with cystic fibrosis. Individuals with CF exhibit impaired bone status across multiple imaging modalities. Higher adherence to the Mediterranean diet is independently associated with more favourable bone structural parameters, suggesting a potential role for dietary patterns in bone health optimisation in this population.

EP254 - ECE_2618 - "It is not what it seems"-a rare case of Water-clear cell parathyroid adenoma

Zehra Irshad, Dominic Oduro-Donkor and Ranganatha Rao
Coventry, United Kingdom

Background: Water-clear cell parathyroid adenoma (WCCPA) is an exceedingly rare manifestation of primary hyperparathyroidism with only five reported cases to date.[1] Here we describe an interesting case of WCCPA presenting as a stroke mimic.

Case presentation: A 64-year-old African gentleman with background of hypertension presented to Emergency department with acute presentation of slurred speech and balance issues. Initial bloods showed creatinine levels of 136 umol/L (ref 50-104). He had a CT head which did not show any acute pathology and subsequent MRI ruled out acute stroke. He developed confusion and agitation. Blood tests revealed severe hypercalcemia (serum adjusted calcium 4.81 mmol/L, ref 2.17-2.56). Parathyroid hormone was significantly raised at 311 pmol/L (ref 2.0-8.5) with inorganic phosphate levels of 1.58 mmol/L (ref 0.8-1.5), Vitamin D levels of 30 nmol/L (ref > 49) and creatinine levels of 376 umol/L. Initial management included intravenous rehydration and intravenous Bisphosphonate.

CT-TAP showed well-defined enlarged soft tissue leision at the thoracic outlet appearing separate from the right lobe of thyroid. Follow-up ultrasound neck and NM SPECT parathyroid confirmed right-sided parathyroid adenoma. He was admitted under Endocrinology and referred to ENT for parathyroid surgery. He continued to be treated with IV fluids with strict input and output fluid monitoring. Whilst awaiting surgery he was trialled with Calcitonin which did not improve his calcium levels. A right parathyroidectomy was performed, and a histopathological examination confirmed the diagnosis of WCCPA. Post-operatively, the serum calcium and PTH levels of the patient normalised, symptoms resolved and his recovery was uneventful.

Conclusions: WCCPA is a rare albeit significant cause of primary hyperparathyroidism. It is difficult to diagnose as imaging maybe non-specific. This is the first reported case of WCCPA presenting as a stroke mimic with severe hypercalcemia. WCCPA have a unique water-clear cytoplasmic appearance, due to the accumulation of glycogen and intracellular fluid. Histology is key for diagnosis and surgical management has good outcomes. More literature is required to understand lack of response to medical management. Despite their rarity WCCPA are important to understand for early diagnosis and

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

treatment to prevent end-stage complications associated with uncontrolled hypercalcemia.

EP255 - ECE_2386 - The calcium to magnesium ratio as predictor of renal lithiasis in primary hyperparathyroidism: results from a moroccan cohort

Meryem Eladla, Mohammed Amine Essafi, Zineb El Azime, Hayat Aynaou and Houda Salhi
University Hospital Center Fez Morocco, Endocrinology, Fez, Morocco

Background: Hypercalciuria plays a key role in the development of renal lithiasis in primary hyperparathyroidism, however kidney stones do not occur in all hypercalciuric patients, suggesting the involvement of additional factors . The objective of our study was to evaluate the association between the calcium-to-magnesium ratio and renal lithiasis in this population.

Methods: We conducted a retrospective descriptive and analytical study including patients with hypercalcemic primary hyperparathyroidism managed in the Department of Endocrinology, Diabetology, and Nutrition at Hassan II University Hospital, Fez, between January 2020 and January 2025. Among diagnosed cases, 85 patients met the inclusion criteria and were divided into two age- and sex-matched groups: patients without renal lithiasis (Group 1) and patients with renal lithiasis (Group 2).

All patients underwent a complete biological evaluation including serum calcium, phosphate, magnesium levels, 24-hour urinary calcium excretion, renal function, and calculation of the Ca/Mg ratio. Renal lithiasis was confirmed by renal ultrasonography. Patients with normocalcemic, secondary or tertiary hyperparathyroidism, estimated glomerular filtration rate <30 mL/min, prior medical or surgical treatment, or incomplete records were excluded. An elevated Ca/Mg ratio was defined as >6.35. Statistical analysis was performed using SPSS version 26. Multivariate logistic regression was used to identify independent predictors of renal lithiasis, with $P < .05$ considered significant.

Results: 85 patients were included: 54 in Group 1 and 31 in Group 2. Compared with Group 1, patients with renal lithiasis had higher body mass index and parathyroid hormone levels, and lower estimated glomerular filtration rate, while serum calcium and magnesium levels were comparable between groups. Multivariate analysis showed a significant association between an elevated Ca/Mg ratio and renal lithiasis (OR $\approx$ 3.2, $P < .01$), and an inverse association between serum magnesium levels and renal lithiasis (OR < 1, $P < .05$). Parathyroid hormone levels were not significantly associated with renal lithiasis ($P = .06$). The Ca/Mg ratio and 24-hour urinary calcium showed sensitivities of 78% and 75%, and specificities of 79% and 47%, respectively.

Conclusions: The calcium-to-magnesium ratio is associated with renal lithiasis in primary hyperparathyroidism and demonstrates better specificity than 24-hour urinary calcium excretion. This ratio may represent a simple and practical tool for lithiasis risk stratification in PHPT. In parallel, serum magnesium appears to be inversely associated with renal lithiasis, supporting its protective role. These findings warrant confirmation through prospective studies.

EP256 - ECE_3404 - Clinical features and treatment strategy of primary hyperparathyroidism during pregnancy

Ekaterina Bibik, Shuainat Labazanova, Tatiana Kokorina, Anna Eremkina, Svetlana Vorotnikova and Natalia Mokrysheva
Endocrinology Research Centre, Moscow, Russia

Background: Primary hyperparathyroidism (PHPT) during pregnancy remains an important clinical problem that requires management and monitoring of the multidisciplinary team. Clinical symptoms of PHPT in pregnant women are often non-specific, leading to diagnostic delays. Biochemical profile of patients correlates with an increased risk of maternal and fetal complications. Drug treatment are limited and may be prescribed based on individual risk-benefit assessment, parathyroidectomy (PTE) seems more beneficial for pregnant patients with symptomatic disease.

Aim: To describe clinical features of PHPT and treatment outcomes in pregnant women.

Results: We managed 30 women (median age 34 [30; 40] years), who were referred to our Centre, among them 28 at 20.5 [16; 24.5] week gestation (min 5, max 34) and two in the postpartum period. 3 patients had confirmed MEN1 syndrome. At initial presentation, the key biochemical parameters were as follows: iPTH 105.5 pg/ml [78.5; 145.8], albumin-adjusted serum calcium (Ca) 2.85 mmol/l [2.69; 2.95], ionized Ca 1.42 mmol/l [1.4; 1.52], phosphorous 0.76 mmol/l [0.7; 0.83], 24-h urinary Ca 10.4 mmol [8.4; 12.5]. The complications of PHPT included nephrolithiasis (50%), bone disorders (17%), non-classical features were gestational diabetes (23%) and hypertension (6%).

10 women received conservative treatment (gr1), 50% of them were operated on after childbirth and 16 underwent PTE in 2 trimester because of severe disease (gr2). A conservative management in all cases included low-calcium diet and rehydration, taking cholecalciferol. 2 patients received cinacalcet with a positive effect before delivery/PTE. One pregnancy occurred during denosumab therapy. Surgery included selective PTE with confirmed parathyroid adenomas (84%), atypical parathyroid tumor (12%) or cancer (4%).There were miscarriages in 2 women and single case of surgical abortion at 21 weeks gestation because of congenital heart defect. One patient underwent emergency C-section because of preeclamplsia,in other cases, the delivery was on time. The total frequency of fetal/newborn complications was 20% in the gr1 and 6% in the gr2, among them hypocalcemia ($n = 1$), congenital pneumonia ($n = 2$), intrauterine fetal death in twins ($n = 1$) were observed.

Conclusions: PHPT during pregnancy can present with various clinical manifestations. Optimal management should be individualized, taking into account gestational age and the

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

severity of hypercalcemia. Surgical intervention appears to offer greater benefits, particularly in symptomatic cases of PHPT.

EP257 - ECE_1892 - Hypercalcaemic crisis due to a water-clear cell parathyroid adenoma

Christina Millou, Christopher Harrold, Reshma Agrawal and David Howe
Endocrine and Diabetes, Wisdem Center, University Hospital of Coventry and Warwickshire, Coventry, United Kingdom

We report a case of water-clear cell adenoma associated with primary hyperparathyroidism. Primary hyperparathyroidism (PHPT) is a leading cause of hypercalcaemia, most commonly due to parathyroid adenomas. The typical cell type in parathyroid adenoma is the chief cell, followed by oxyphilic cell and water-clear cells are extremelly rare and often large.

Case presentation: A 64-year-old man presented with dizziness, unsteady gait and slurred speech and was diagnosed with an acute cerebrovascular event complicated by confusion and expressive aphasia. Investigations revealed severe hypercalcaemia and acute kidney injury.

Initial biochemistry showed adjusted calcium 4.81 mmol/L (ref. range 2.17-2.56 mmol/L), creatinine 395 µmol/L (ref. range 59-104 µmol/L), and PTH 311.2 pmol/L (ref. range 2.0-8.5 pmol/L), consistent with PTH-dependent hypercalcaemia. Vitamin D was low 30 nmol/L (ref. range > 49 nmo/l). Renal ultrasound was normal. Neck ultrasound demonstrated a 3.1×2.4 cm thyroid nodule, but a parathyroid adenoma could not be excluded.

Despite aggressive intravenous fluids, hypercalcaemia persisted. Denosumab 120 mg was administered, leading to biochemical improvement. Cinacalcet was commenced and the patient was discharged.

Two months later he re-presented with confusion and weakness after stopping cinacalcet. Calcium was again elevated (3.54 mmol/L) with PTH 146 pmol/L. Intravenous fluids and pamidronate produced only transient benefit. A SPECT-CT scan localized a lesion posterior to the right lower thyroid pole, consistent with a right inferior parathyroid adenoma.

The patient underwent urgent parathyroidectomy after informed consent was obtained. Post-operatively, PTH suppressed to 0.8 pmol/L and calcium rapidly normalized. At discharge, adjusted calcium was 2.18 mmol/L with PTH 8.1 pmol/L, confirming biochemical cure.

Histopathology: The resected tumor weighed 14.25 g and measured $48 \times 32 \times 21$ mm. Microscopy revealed a thinly encapsulated parathyroid neoplasm composed predominantly of water-clear cells, with focal chief and oncocytic cell population. No capsular thickening or lymphovascular invasion was identified. The morphology is diagnostic of water-clear cell parathyroid adenoma.

Discussion: Parathyroid adenomas account for 75%-80% of PHPT. Water-clear cell adenomas are rare, usually large, and may be difficult to localize on sestamibi imaging. Although often considered biochemically indolent, this case demonstrates that WCCA can present with life-threatening hypercalcaemic crisis.

EP258 - ECE_1779 - When osteoporosis is not the whole story: late-onset multiple acyl-CoA dehydrogenase deficiency in a postmenopausal woman

Sevkican Gunes, Gamze Bilik Oyman, Ümmü Mutlu, Hulya Hacisahinogullari, Meryem Karaca, Tugba Kalayci and Ayse Kubat Uzum
Istanbul, Türkiye

Background: Osteoporosis is frequently diagnosed in postmenopausal women, yet secondary etiologies account for nearly one-third of cases. Progressive myopathy or accompanying neuromuscular manifestations should prompt a systematic evaluation for underlying metabolic disorders.

Case presentation: A 57-year-old woman was referred for evaluation of osteoporosis. She was frail and wheelchair-dependent due to progressive proximal muscle weakness over three years, accompanied by diffuse musculoskeletal pain. Although inflammatory myopathy was suspected, myositis autoantibodies were negative, electromyography showed a myopathic pattern, and muscle biopsy was non-specific; nonetheless, she received intravenous immunoglobulin, rituximab, and high-dose corticosteroids.

Menopause age was 50 years, had no family history of osteoporosis, did not smoke or consume alcohol. Laboratory evaluation demonstrated normal creatinine, calcium, phosphorus, parathyroid hormone, vitamin D, thyroid function, and 24-hour urinary calcium. Creatine kinase and transaminase levels were mildly elevated. Dual-energy X-ray absorptiometry revealed a lumbar spine T-score of −1.8 and a femoral neck T-score of −3.3, with FRAX-estimated risks of 19% for major osteoporotic fracture and 6.4% for hip fracture. Vertebral imaging revealed mild height loss at L3. Denosumab therapy was initiated, but multiple vertebral fractures occurred eight months later, following a fall, prompting the addition of teriparatide.

Given the prominent myopathy, adult-onset metabolic myopathies were considered. Lactate and ammonia levels were normal. There is no ketonuria. Tandem mass spectrometry showed elevated multi-chain acyl carnitine (C4, C5, methyl-glutaryl, C14:2) levels, and urinary organic acid analysis revealed elevated ethyl-malonate, a pattern consistent with multiple acyl-CoA dehydrogenase deficiency(MADD). Pompe disease was excluded by normal alpha-glucosidase activity, while McArdle and Cori diseases were considered unlikely based on clinical features. The only manifestation attributable to MADD was proximal myopathy. Echocardiography revealed no evidence of cardiac involvement. Molecular genetic testing revealed a homozygous pathogenic ETFDH variant (c.1130T > C), thereby establishing the diagnosis of MADD.

Treatment with riboflavin, coenzyme Q10, and levocarnitine was initiated along with a low-fat, frequent-meal diet. Within one month, the patient achieved independent ambulation with a 75% reduction in ethylmalonate levels. At six months, there was a marked and sustained improvement in muscle strength and pain, accompanied by an approximately 25% increase in bone mineral density.

Conclusions: This case underscores the need for a systematic and individualized approach to osteoporosis, particularly when accompanied by progressive myopathy. Late-onset metabolic

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

disorders, including MADD, should be included in the differential diagnosis, as delayed recognition may result in prolonged diagnostic uncertainty and exposure to unnecessary treatments.

EP259 - ECE_2188 - CD4+ T cells senescence decreases bone density by changes in genes related to calcium and phosphorus homeostasis

Daniel Cabello-Rivera[1], Rosa Plaza-Clavero[1], Luna Ballesteros-Arias[1], Juan Francisco Aranda[2], Manuel Naves Díaz[3], Juan A. Ardura[1], Arancha R. Gortazar[1] and Maria Del Nogal Avila[1]

[1]*Instituto de Medicina Molecular Aplicada (IMMA) Nemesio Díez, Facultad de Medicina, Universidad San Pablo-CEU, CEU Universities, Urbanización Montepríncipe, Boadilla del Monte 28660, Spain;* [2]*Department of Genetics, Physiology and Microbiology, Faculty of Biology, Complutense University of Madrid, C. de José Antonio Novais, 12, Madrid 28040, Spain;* [3]*Bone and Mineral Research Unit, Hospital Universitario Central de Asturias, Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), Oviedo 33011, Spain*

Introduction: Bone serves as the primary reservoir of calcium and phosphorus in the body and undergoes continuous remodeling. During aging or in conditions of calcium and phosphorus imbalance caused by physiological or pathological processes, bone resorption may increase, negatively impacting bone density. Calcium and bone homeostasis are regulated by several hormones, including PTH, calcitonin, calcitriol, and FGF23, produced in different organs. Inflammaging, a state of low-grade chronic inflammation associated with aging, is considered a risk factor for age-related diseases such as osteoporosis. Accumulation of senescent cells during aging can impair tissue function through the development of a Senescence-Associated Secretory Phenotype (SASP). Mice lacking expression of the mitochondrial gene *Tfam* specifically in CD4+ T cells exhibit T cell senescence and a premature aging phenotype. In this study, we investigated how senescent CD4+ T cells influence bone remodeling.

Materials and Methods: Gene expression was analyzed by real-time PCR in tibiae from CD4-TFAM mice ($Tfam^{fl/fl}$ $Cd4^{Cre/Cre}$) and control littermates, kindly provided by Dr. Mittelbrunn's research group (Centro de Biología Molecular Severo Ochoa, Madrid, Spain). Bone morphology was assessed using micro-computed tomography (micro-CT). Additionally, MLO-Y4 cells, an osteocyte model, were treated with 1% serum from CD4-TFAM or control mice, and gene expression was analyzed by real-time PCR.

Results: CD4-TFAM mice exhibited significantly lower bone mineral density and compromised bone structural integrity compared with controls. In bone tissue, the OPG/RANKL ratio and expression of osteocyte (osteocalcin) and osteoblast markers (alkaline phosphatase and Runx2) were reduced in CD4-TFAM mice. Expression of hormone receptors such as PTH1R and VDR was also significantly lower, whereas FGF23 expression was higher in CD4-TFAM mice. MLO-Y4 cells treated with serum from CD4-TFAM mice showed significantly increased RANKL expression, while VDR expression remained unchanged compared to cells treated with control serum.

Discussion: Mice with senescent CD4+ T cells displayed reduced bone mineral density and impaired structural integrity, likely due to enhanced osteoclastic activity at the expense of osteoblast function, combined with diminished responsiveness to hormonal regulation resulting from decreased receptor expression.

EP260 - ECE_2678 - Epidemiology and clinical management of autosomal dominant hypocalcemia type 1 (ADH1): a systematic literature review

Tariq Ahmad[1], Nipith Charoenngam[2], Kelly Roszko[3], Chukwuebuka Dominic Igbelina[4], Nicholas Parr[4], James Frampton[4], Marissa Betts[4], Arun Mathew[5], Lyndsay Smith[5] and Heather Falvey[5]

[1]*University of California San Francisco, Benioff Children's Hospital, Oakland, CA, United States;* [2]*Endocrine Unit, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States;* [3]*Skeletal Disorders and Mineral Homeostasis Section, National Institute of Dental and Craniofacial Research, National Institutes of Health, Bethesda, MD, United States;* [4]*Thermo Fisher Scientific, Inc., Waltham, MA, United States;* [5]*BridgeBio Pharma, Inc., San Francisco, CA, United States*

Introduction: Autosomal dominant hypocalcemia type 1 (ADH1) is a genetic form of hypoparathyroidism in which gain-of-function variants in the calcium-sensing receptor (CaSR) gene cause low parathyroid hormone (PTH) levels, hypocalcemia, hypercalciuria and hyperphosphatemia, leading to neuromuscular symptoms and renal complications. This PRISMA-compliant systematic review identified available evidence on epidemiology, management, humanistic and economic costs of ADH1.

Methods: Studies reporting on the epidemiology, clinical management, humanistic burden, or economic costs of ADH1 were eligible. Searches covered Embase, MEDLINE, PsycInfo, EconLit, and Cochrane databases (September 24, 2025).

Results: Eight studies were identified; three on epidemiology and five on clinical efficacy and/or safety of treatments. No humanistic or economic cost studies were found. ADH1 prevalence per 100 000 people was 6.4 in UK BioBank, 3.9 in US DiscovEHR and 0.6 in Norway (any ADH). Encaleret, an investigational oral calcilytic and negative allosteric modulator of CaSR, was evaluated in a phase 2b study with two 5-day inpatient periods, a 24-week outpatient period, and long-term extension ($N = 13$; NCT04581629). Encaleret significantly increased mean albumin-corrected serum calcium and intact PTH and decreased mean serum phosphate and 24-hour urinary calcium compared with baseline (all $P < .05$). Kidney function remained stable. No serious adverse events (SAE) were reported. Findings were sustained over 42 months (open-label). In a pharmacokinetic study ($N = 5$; NCT02204579), the calcilytic NPSP795 induced dose-dependent increases in mean serum PTH concentrations at 15- and 210-minutes post-administration ($P < .05$). Symptomatic cholelithiasis was reported in one patient during the 2-week follow-up. In a retrospective cohort study ($N = 6$), patients treated with subcutaneous PTH infusion via pump over

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

0.8-5.5 years showed increases in mean serum calcium and magnesium and reduced seizures vs baseline treatment with calcium/vitamin D analogs and/or bolus PTH injection ($P < .05$), but with no significant changes in mean serum phosphate or calcium–phosphate product. No SAEs were reported. In a case series ($N = 5$; median follow-up: 5 years), patients treated with calcium carbonate, calcitriol and/or PTH injection had similar median serum calcium, phosphate and magnesium concentrations to untreated patients. In another case series, of patients treated with calcium, calcitriol, thiazide diuretics or dihydrotachysterol ($N = 25$; with any ADH; mean treatment duration: 7.1 years), one patient experienced impaired kidney function and one patient died.

Conclusions: ADH1 is a rare, serious, understudied condition. Available clinical evidence is limited, though investigational calcilytics such as encaleret are associated with promising biochemical improvements in small studies. Gaps remain regarding long-term outcomes and the humanistic and economic burden of ADH1.

EP261 - ECE_2131 - The effect of denosumab on IGF-1 and bone turnover markers in patients with severe osteoporosis

Mariana Agapito Fonseca[1,2], Marta Vaz Lopes[2,3], Teresa Alegria Neto[2], Catarina Isabel Lopes[2], Miguel António Duarte[2], Mariana De Griné Severino[2,3], Ema Lacerda Nobre[2,3], Ana Gomes[2,3], Francisca Costa[1], Eva Alves[1,3], Francisco Sampaio[1,3] and Ana Paula Barbosa[1,2,3]
[1]Fracturary Osteoporosis Multidisciplinary Clinic, ULS Santa Maria, Lisbon, Portugal; [2]Diabetes and Metabolism Department, ULS Santa Maria, Endocrinology, Lisbon, Portugal; [3]Lisbon, Portugal

Background: Insulin-Like Growth Factor-1 (IGF-1) is the main growth factor in the bone matrix and regulates the expression of receptor activator of nuclear factor kappa-B ligand (RANKL). In osteoporosis, IGF-1 declines in serum and bone, highlighting its predominant anabolic effect *in vivo*. Denosumab is a monoclonal antibody that binds RANKL, preventing osteoclast differentiation, leading to fracture risk reduction. This mechanism of action is linked to that of IGF-1, which could lead to potential alterations in serum IGF-1 levels in osteoporotic patients under denosumab. Therefore, the authors aimed to analyze the variation of IGF-1 levels in patients under denosumab and its relationship with known bone turnover markers.

Methods: Retrospective single-center analysis of female patients with osteoporosis and fragility fractures treated with denosumab. Data were obtained from electronic health records and included age at the beginning of denosumab, duration of therapy, IGF-1 and bone turnover markers (BTM) [Procollagen-1 N-terminal Propeptide (P1NP), bone alkaline phosphatase (BALP), C-terminal telopeptide (CTX) and osteocalcin] before treatment and at the time of its interruption or at the last appointment.

Results: The study included 37 female patients. The mean age at the beginning of denosumab was $71,8 \pm 11,7$ years old, with mean duration of therapy of $37,3 \pm 17,0$ months. Treatment with denosumab was associated with a statistically significant reduction in all four BTM, with CTX showing the greatest decrease (57,5%), followed by osteocalcin (53,2%), P1NP (48,1%) and BALP (34,3%). IGF-1 levels reduced by 7,5% (mean level before denosumab 100,7 ng/mL, after denosumab 93,2 ng/mL), without attaining statistical significance ($P = ,413$).

Conclusions: In this population, treatment with denosumab led to the expected decrease in all bone turnover markers, with the biggest expression in CTX, in agreement with the inhibition of bone resorption. It also led to a decrease in serum IGF-1, accompanying the BTM trend, but without statistical significance.

Although serum IGF-1 levels do not always directly represent bone IGF-1 levels, these preliminary results of a small cohort point to a lack of effect of denosumab on the bone anabolic action of IGF-1.

EP262 - ECE_2926 - Real-world clinical assessment of CKD-associated osteoporosis: a single-center experience

Nada Akad[1,2], Mihaela Baranceanu[2], Teodora Nastasa[2], Anca Matei[1,2], Alexandru Florescu[1,2], Maria-Christina Ungureanu[1,2] and Stefana Bilha[1,2]
[1]Universitatea de Medicină şi Farmacie 'Grigore T. Popa' Iaşi, Iaşi, Romania; [2]Endocrinology, Spitalul Clinic Judeţean de Urgenţă Sfântul Spiridon Iaşi, Iaşi, Romania

Chronic kidney disease (CKD) is associated with complex disturbances in mineral and bone metabolism, collectively referred to as chronic kidney disease–mineral and bone disorder (CKD-MBD). Alterations in calcium, phosphate, parathyroid hormone (PTH), and vitamin D metabolism contribute to impaired bone quality, reduced bone strength, and an increased risk of fragility fractures. Importantly, skeletal involvement in CKD may overlap with, but is not identical to, age-related or postmenopausal osteoporosis, posing diagnostic and therapeutic challenges.

Patients on maintenance hemodialysis have a markedly increased fracture risk, while kidney transplant recipients remain vulnerable despite improved kidney function, due to persistent CKD-MBD and immunosuppressive therapy. Early identification of osteoporosis in these populations is essential for fracture prevention.

We present the real-world clinical assessment of CKD-associated osteoporosis in a tertiary center in Iasi, Romania. Over the past year, we evaluated 78 patients, including 30 patients on hemodialysis (HD)**,** and 48 kidney transplant recipients (KTR)**.**

All patients underwent bone mineral density (BMD) assessment by dual-energy X-ray absorptiometry (DXA), along with evaluation of mineral metabolism parameters, including serum calcium, phosphate, and parathyroid hormone (PTH). Serum 25-hydroxyvitamin D levels and bone turnover markers were additionally assessed when available.

In the HD group (15 men, 15 women; median dialysis vintage 46 months**),** osteoporosis was identified in 13 patients (43.3%), osteopenia in 9 patients (30.0%), low BMD in 3 patients (10.0%), and normal BMD in 5 patients (16.7%). CKD-MBD alterations were observed in 29 of 30 patients. Notably, one patient had a history of multiple fragility fractures (forearm, vertebral, and ankle), and another presented with vertebral fractures at the L2-L4 level.

In the KTR group (26 men, 22 women; median time since transplantation 83.5 months), osteopenia was observed in 15 patients (31.3%), osteoporosis in 9 patients (18.8%), low BMD in 7 patients

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

(14.6%), while 17 patients (35.4%) had normal BMD. CKD-MBD alterations were noticed in 42 out of 48 patients. No fractures occurred in the KTR group prior to their evaluation.

In conclusion, our real-world data demonstrate a substantial burden of low bone mass and osteoporosis across the CKD spectrum, with the highest prevalence observed in hemodialysis patients and a persistent risk in kidney transplant recipients. These findings support the need for systematic bone health assessment and individualized management strategies in CKD-associated osteoporosis.

EP263 - ECE_2934 - Lower calcium availability may impact bone density in vegans: results from a cross-sectional study

Johana Gallova, Karolína Mrkáčková, Anna Ouřadová and Jan Gojda
Departement of Internal medicine, Královské Vinohrady University Hospital and Third Faculty of Medicine, Charles University, Prague, Czech Republic

Background: Plant-based diets have gained substantial popularity in recent years, driven by their perceived health and environmental advantages. Although robust evidence supports their beneficial effects on cardiometabolic outcomes, uncertainties persist regarding their impact on bone health. The present study aimed to compare self-identified vegans with an age- and BMI-matched group of omnivores to assess differences in calcium–phosphate metabolism, renal calcium handling, and bone density.

Methods: Czech participants from the multinational VEGANSCreener study were analysed, including self-identified vegans (VG, $n = 107$, mean age 33.63 ± 6.31 years) and omnivores (OM, $n = 55$, mean age 32.29 ± 9.79 years). Anthropometry, body composition, and resting energy expenditure measured by indirect calorimetry were recorded. Blood samples and 24-hour urine collections were obtained. Serum concentrations of calcium, phosphate, parathyroid hormone, vitamin D, creatinine, and alkaline phosphatase were measured in the institutional laboratory, along with 24-hour urinary calcium and urea excretion. Bone density was assessed using heel ultrasound densitometry. Dietary intake was evaluated using a 4-day prospective food record analysed with validated food composition databases. Between-group comparisons were performed using unpaired non-parametric Mann–Whitney tests. Associations between variables were assessed using Spearman correlation analysis. A P-value < 0.05 was considered statistically significant.

Results: The VG and OM groups were comparable in anthropometric characteristics and resting metabolic rate. Serum calcium concentrations did not differ between groups, while phosphate levels were lower in VG. Moreover, vegans exhibited significantly lower 24-hour urinary calcium excretion compared with omnivores (1.26 ± 0.88 vs 2.12 ± 1.48 mmol/day, $P < .0001$) and higher PTH concentrations (3.28 ± 1.13 vs 2.58 ± 0.83 pmol/L, $P = .0002$), accompanied by lower 24-hour urinary urea excretion (127.5 ± 60.1 vs 197.1 ± 101.6 mmol/day, $P < .0001$). No significant differences in bone density T- or Z-scores were observed between groups, though when performing sex—stratified analyses, we found significant difference in men only. Dietary records showed significantly lower calcium intake in vegans compared with omnivores (823 ± 289 vs 1026 ± 389 mg/day, $P = .0016$). Among participants with available data, calcium supplementation was reported by approximately 10% of vegans.

Conclusions: Despite lower renal calcium excretion and compensatory increased PTH, vegans did not exhibit impaired bone density compared with omnivores. These findings suggest that lower dietary calcium intake, with possible contributions of lower calcium bioavailability, is not necessarily associated with reduced bone health.

EP265 - ECE_2034 - Primary hyperparathyroidism due to abnormal giant single-gland and multigland disease: 2 case reports of a second-level endocrinological centre

Antonino Russo[1], Luca Fabris[2], Michele Zuolo[2], Giacomo Faccioli[2], Simone Zanella[3], Enzo Bonadies[3], Francesco Antonio Ciarleglio[4] and Vito Racanelli[1]
[1]*Azienda Sanitaria Universitaria Integrata del Trentino (ASUIT), Trento;* [2]*General Surgery Department, Azienda Sanitaria Universitaria Integrata del Trentino (ASUIT), "Valli del Noce Hospital", Cles, TN, Italy;* [3]*General Surgery Department, Azienda Sanitaria Universitaria Integrata del Trentino (ASUIT), "Santa Maria del Carmine Hospital", Rovereto, TN, Italy;* [4]*General Surgery Department, Azienda Ospedaliera di Perugia, Ospedale di Perugia, Perugia, Italy*

Introduction: Primary hyperparathyroidism (PHPT) is the most common cause of hypercalcemia, affecting approximately 1% of adults in the general population. The clinical history and pathway of 2 particular cases of PHPT are described below.

Observations: Case Report 1

A 57 year-old female was admitted to the emergency department in September 2023 reporting abdominal pain. Laboratory admission profile exhibited indicated PHPT (table 1). Neck ultrasound identified one suspected rounded area below the lower pole of thyroid's left lobe. Sestamibi scan, however, showed two areas of high uptake of tracer caudally to the left lobe of the thyroid. She was submitted to surgery and intraoperative-PTH assay confirmed the removal of pathological parathyroid (PTH 866→79 pg/mL, 20 min after removal). The postoperative course was regular and calcium at discharge was normal (9.2 mg/dl). Histopathology revealed the presence of a single giant left adenoma (oncocytic variant, 7 gr, 5.1 cm diameter). A second lesion adjacent to adenoma was also removed, which was histologically found to be a reactive lymph-node.

Case report 2

A 78 year-old female was admitted to the emergency department in March 2024, reporting anemia with chest discomfort. Laboratory admission profile indicated PHPT (table 1). Neck ultrasound identified two suspected areas at the middle-inferior third of thyroid's right lobe and posteriorly at the middle third of thyroid's left lobe . She further underwent Sestamibi scan, that confirmed the enlargement of the right and left lower parathyroids. Therefore, she was referred for elective surgery. Intraoperative PTH assay confirmed the removal of two pathological parathyroids (PTH 171→73 pg/mL, 20 min after removal of both lesions). The postoperative course was uneventful and calcium at discharge was normal (9.9 mg/dl). Histopathology revealed a left parathyroid adenoma (mainly

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

oxyphilic cells, 3 g, 3.5 cm diameter) and a right parathyroid adenoma (mainly chief cells; 3 g, 2.5 cm diameter).

Conclusions: These case reports emphasize the peculiarity of PHPT presentation related to abnomal single-gland (1) and multigland (2) disease. The first case highlights how preoperative instrumental assessment can be distorted by the morphological characteristics of large adenomas. The second case allows us to understand how PHPT can sometimes be sustained by double adenomas with different histopathological characteristics.

	Range	Case 1	Case 2
Creatinine (mg/dl)		*1.17*	*0.62*
Calcium (mg/dl)	*8.5-10.5*	***12.4***	***12.0***

EP267 - ECE_3686 - Normocalcemic primary hyperparathyroidism: characterization, complications, and follow-up

Joana Vinhais, Beatriz R. Pereira, Ana Cláudia Martins, David Verissimo, Catarina Ivo, Mafalda Marcelino, Dolores Passos, Luis Lopes, João Jácome de Castro and João Nunes Silva
Serviço de Endocrinologia, Hospital das Forças Armadas, Lisboa, Portugal

Background/Aims: Normocalcemic primary hyperparathyroidism (PHPT) is diagnosed by persistent elevation of PTH with normal calcium concentration and exclusion of secondary causes of hyperparathyroidism. As its incidence increases, accurate diagnosis and appropriate management are crucial to prevent complications.

Aimed to characterize patients with normocalcemic PHPT evaluated in our hospital, the incidence of complications and evolution to hypercalcemia.

Methods: We retrospectively analysed every patient with raised PTH since 2015 and a minimum follow-up of 2 years in our department. Patients with chronic kidney disease (CKD; GFR < 60 mL/min/m^2), vitamin D deficiency and hypercalcemia were excluded.

Results: Among 1337 patients with elevated PTH and normal total calcium, 812 were excluded due to CKD or vitamin D deficiency, and 487 due to incomplete data or follow-up < 2 years.

We analysed 38 patients with normocalcemic PHPT. Average age was 68.7 years; 52.6% were female. Mean PTH was 111.2 pg/mL (15-68), total calcium 9.8 mg/dL (81-10.4), phosphate 3.1 mg/dL (2.5-4.5), alkaline phosphatase 80 U/L (30-120) and 25-OH vitamin D 42 ng/mL (30-100).

Thirty patients (79%) had target organ involvement. Regarding skeletal manifestations, 12 patients had osteoporosis in densitometry (three were taking bisphosphonates before diagnosis), and seven sustained fractures. Nephrolithiasis was identified in 13 patients, and eight exhibited hypercalciuria. Five patients were diagnosed before age 50.

Regarding the number of complications: 21 patients had one complication; Eight patients had two complications, and one patient had three complications.

Average follow-up time was 5.8 years, and five patients (13%) progressed to mild hypercalcemia.

One patient was submitted to parathyroidectomy but maintained normocalcemic PHPT, although showed improvement of complications.

Conclusions: Differentiating normocalcemic PHPT from secondary hyperparathyroidism is not always straightforward. In this cohort, eight patients presented hypercalciuria, which can also represent a secondary cause of hyperparathyroidism.

In our cohort, most patients remained normocalcemic during the follow-up, consistent with an overall stable biochemical course of the disease. However, skeletal and renal complications were frequent, highlighting the importance of establishing the diagnosis and properly manage normocalcemic PHPT.

Many patients had incomplete diagnostic workup, suggesting underdiagnosis of this condition. The reduced number of surgically treated patients indicates difficulties in differential diagnosis and lesion localization.

EP268 - ECE_1875 - Effect of teriparatide on trabecular bone score

Dan Peretianu[1]
[1]*Endocrinology, Medical Center Povernei, Bucharest, Romania*

Objective: To investigate the importance of trabecular bone score (TBS) in the follow-up of anti-osteoporotic therapy with teriparatide.

Material/Method: A. DEXA: GE-Lunar Prodigy Pro # 500074. TBS: iNsight®, version 3.0.2.0.

B. Patients: 138 patients women (only one man) were analyzed correlatively with BMD and TBS before and after teriparatide, 20 microg/day, between 6 months to 4 years. 269 tests were performed. **C.** Percentage difference calculation: (x-y)*100/x, where "x" is the original score value and "y" is the current score value.

Results: Data are displayed in the order: analysis time, number, BMD score ante, BMD score post, BMD percentage increase, *P*-value, TBS score ante, TBS score post, TBS percentage increase, *P*-value:

Post teripratid	Number	Age on onset	Current age	DMO score ante-T	DMO score post T	Increase %	*P*	TBS score ante-T	TBS score post -T	Increase %	*P*
6 months	63	66.45	66.95	−1.49	−1.19	20.63	.08	−3.03	−2.75	9.35	.09
12 months—1 year	78	66.70	67.70	−1.86	−1.43	22.42	.001	−3.30	−2.61	20.6	.05
18 months—1,5 year	29	66.49	67.99	−1.58	−0.96	38.89	.02	−2.95	−2.68	9.14	.31

(*continued*)

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Continued

Post teripratid	Number	Age on onset	Current age	DMO score ante-T	DMO score post T	Increase %	P	TBS score ante-T	TBS score post -T	Increase %	P
24 months—2 years	62	65.70	67.70	−1.83	−1.20	34.14	.0000	−3.16	−2.93	7.34	.148
30 months—2,5 years	11	66.25	0.00	−1.77	−0.99	44.09	.009	−2.39	−2.02	15.66	.256
36 months—3 years	20	68.26	71.26	−1.66	−0.88	46.72	.0013	−3.31	−2.74	17.21	.037
42 months—3,5 yeras	5	69.08	72.58	−2.17	−1.27	71.15	.040	−2.76	−1.94	42.40	.073
48 months—4 years	1	52.00	56.00	−0.85	−1.18	−38.24	.33	−3.40	−3.28	3.68	.887

Observations: 1. Increase in BMD scores is much greater and statistically significant than the increase in TBS scores. This is because TBS scores were much more altered than BMD scores. **2.** The apparent decrease in TBS growth at 2 years (20.6% −1 y, 9.14%-1,5, v 7.34% at 2 y) would suggest that this would be the time to stop therapy. However, at 2.5, 3, and later at 3,5 years the TBS score increases surprisingly very much: 15.66%, 17.21% and 42.4%. **3.** No adverse effects were observed after 2 years administration.

Conclusions: 1. Although teriparatide (usual administration) does not appear to be more active on bone microarchitecture (TBS) than on bone material accumulation (BMD),

2. The administration of teriparatide over the 2-year period brings benefits, certified by the correlative increase in BMD and TBS scores.

EP269 - ECE_1912 - Post-stroke fracture risk: intracerebral haemorrhage vs ischaemic stroke—a systematic review and meta-analysis

Chrislyn Ng[1,2], Connor Burley[3], Jakub Mesinovic[4], Peter Ebeling[1], Gabrielle Stokes[3,5,6], Frances Milat[1,3,5] and Mícheál Ó. Breasail[1]

[1]Monash University, Clayton, Australia; [2]Department of Endocrinology, Monash Health, Clayton, Australia; [3]Monash Health, Clayton, Australia; [4]Deakin University, Burwood, Australia; [5]Hudson Institute of Medical Research, Melbourne, Australia; [6]Clayton, Australia

Background: Stroke can be divided into two subtypes—intracerebral haemorrhage (ICH) and ischaemic stroke (IS), of which ICH constitutes 28.8% of strokes and contributes to significant mortality and morbidity. Heightened fracture risk in stroke survivors is a well-established physical complication. The mechanisms for this are multifactorial, culminating in skeletal fragility and falls. Despite this, there is inconsistent evidence surrounding post-stroke fracture rates depending on stroke aetiology.

Objective: Examine the current literature in post-stroke fracture outcomes in both stroke subtypes.

Methods: A systematic review was conducted in accordance to PRISMA guidelines, with PROSPERO registration. We searched Ovid MEDLINE, Scopus, Cochrane Database and Embase up to November 2025 for observational studies reporting post-stroke fracture outcomes in adults with confirmed ICH, with comparisons to IS. Additionally, backward citation screening was carried out. Risk of bias was assessed using the Joanna Briggs Institute (JBI) critical appraisal checklist. A meta-analysis is currently underway.

Results: Fifteen total studies were identified through screening methods. Five analysed cumulative incident fractures, three provided sub-analysis of fracture rates at multiple fracture locations, four focused solely on hip fractures, and one focused particularly on "'low-trauma" fractures. The remaining two studies utilised stroke subtype as a co-variate only and thus did not present meaningful data. Results across the included studies were inconsistent in establishing whether IS or ICH is associated with a greater fracture risk, with only four reporting a statistically significant difference. These included three reporting increase fracture rate in the ICH cohort. Two of these studies, Zheng et al. and Lee et al., compared each stroke subtype against a matched non-stroke control group rather than conducting a direct comparison between ICH and IS. Whereas the study Lisabeth et al. reported increased overall fracture rates in the ICH with a hazard ratio of 1.93 (95% CI: 1.11-3.34) when directly compared to IS. Interestingly, one study reported higher fracture rates in the alternative stroke subtype.

Conclusions: There is some evidence suggests that ICH may be associated with higher fracture risk than IS, however a formal meta-analysis is currently pending. Based on the included studies, it is clear that both stroke subtypes are associated with increased fracture risk and in turn poor bone health outcomes. The limited number of studies comparing stroke subtypes highlights the need for more robust and well-designed studies. Overall, these results support the need for implementation of a generic approach to post-stroke bone health assessment and fracture prevention.

EP270 - ECE_2535 - Proximal humeral cortical thickness measured by MRI accurately predicts low bone mineral density in acromegaly

Sebnem Burhan[1], Yigitcan Kartal[2], Ozge Polat Korkmaz[3], Mutlu Niyazoğlu[1,4] and Esra Hatipoglu[3,4]

[1]Department of Endocrinology and Metabolism, University of Health Sciences, Basaksehir Cam and Sakura City Hospital, Istanbul, Türkiye; [2]Department of Radiology, University of Health Sciences, Basaksehir Cam and Sakura City Hospital, Istanbul, Türkiye; [3]Pituitary Disorders Research Center, University of Health Sciences, Istanbul, Türkiye; [4]Department of Neurosurgery, University of Health Sciences, Basaksehir Cam and Sakura City Hospital, Istanbul, Türkiye

Objective: In acromegaly, Dual-Energy X-ray Absorptiometry (DXA) assessed bone mineral density (BMD) is often misleading. Although it is still useful for guideline-recommended BMD monitoring, it cannot be relied on alone, so it should be complemented by other bone assessments. The aim of this study was to investigate the diagnostic value of humeral cortical thickness measured from shoulder magnetic resonance imaging (MRI) in patients with acromegaly and to determine its performance

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Materials and Methods: Twentythree patients with acromegaly followed in the endocrinology clinic were included in the study. Patients with postmenopausal status, cases with age >65 years, or known hypogonadism were excluded. A single radiologist, blinded to DXA results, measured average humeral cortical thickness (HCT). HCT was measured by calculating the difference between the outer and inner cortical margins at 10 cm and 12 cm distal to the humeral head by using T1-weighted coronal shoulder images (1.5 Tesla). DXA was also performed within one months of the MRI. Patients were divided into two groups based on lumbar spine DXA T-scores: normal BMD (T-score ≥ -1.0) and low BMD (T-score < -1.0). Data analysis included between-group comparisons, Spearman correlation and ROC curve analysis.

Results: The acromegaly cohort ($n = 23$;13 females,10 males; age 48 ± 9.4 years) had a median IGF-1 of 186 ng/mL[153-269] and median GH of 1.10 ng/mL[0.50-1.88]. Seventeen patients (70%) were in remission, and 13 (58%) were receiving medical therapy. The mean HCT of patients in the low BMD group (4.81 ± 1.23 mm) was statistically significantly lower than the normal BMD group (6.22 ± 0.99 mm) ($P = .014$). A positive correlation was found between HCT and DXA T-scores ($r = 0.54$, $P < .01$). ROC analysis demonstrated excellent diagnostic performance of CBT on MRI, with an area under the curve (AUC) of 0.988 (95% CI: 0.955-1.00, $P < .001$). The optimal cut-off point was identified; a cut-off of 5.24 yielded 100% sensitivity and 92.9% specificity.

Conclusions: Proximal HCT measured from shoulder MRI is a reliable, radiation-free biomarker for assessing BMD in acromegaly patients. It holds significant potential as a complementary tool to DXA, particularly in cases where bone structural changes due to growth hormone excess may confound DXA measurements. The opportunistic use of this technique can provide additional and valuable information about bone health in patients undergoing shoulder MRI for different indications.

Keywords acromegaly, humeral cortical thickness, dual-energy X-ray absorptiometry (DXA), osteoporosis, magnetic resonance imaging (MRI)

EP273 - ECE_3747 - Hyperphosphatemic familial tumoral calcinosis: a case report of a severe disease course

Vit Zikan[1,2], Aleš Panczak[3], Dana Michalska[1], Kateřina Hirschfeldová[3], Renata Vlasakova[1] and Ivan RaskaJr[1]

[1]First Faculty of Medicine, Third Internal Clinic, Clinic of Endocrinology and Metabolism, General University Hospital, Charles University, Prague, Czech Republic; [2]First Faculty of Medicine, Third Department of Medicine-Department of Endocrinology and Metabolism, General University Hospital, Charles University, Prague, Czech Republic; [3]Faculty of Medicine 1, Institute of Biology and Medical Genetics, General University Hospital, Charles University, Prague, Czech Republic

Hyperphosphatemic familial tumoral calcinosis (HFTC) is a rare disorder characterized by hyperphosphatemia and ectopic deposition of calcium–phosphate crystals, caused by loss of function of fibroblast growth factor 23 (FGF23). We report the case of a 50-year-old man with HFTC and a 35-year history of progressive ectopic calcifications.

Laboratory testing revealed elevated serum phosphate (1.97 mmol/L; reference range 0.65-1.61) and low plasma intact FGF23 (13.42 ng/L; reference range 23.2-95.4). Genetic analysis identified a pathogenic variant in the FGF23 gene consistent with HFTC. NaF-PET demonstrated increased osteoblastic activity predominantly in multiple extra-osseous soft-tissue calcifications (elbows, pelvis, hips, and feet), with minor subcutaneous calcifications in the lower legs. Bilateral renal calcifications, including nephrolithiasis and parenchymal calcifications, were also present.

Management included phosphate-lowering strategies (dietary restriction, phosphate binders, acetazolamide) and surgical excision of symptomatic lesions. The patient experienced repeated relapses of calcified masses, mainly around the elbows, pelvis, and hips, requiring more than 40 surgical procedures. Complications included non-healing skin defects and a high risk of infectious complications necessitating continuous wound care. Additional complications comprised recurrent bilateral nephrolithiasis with left-sided pyelolithiasis requiring ureteral stenting, occlusion of the distal left anterior tibial artery with further vascular calcifications and treated arterial hypertension.

This case highlights the importance of a multidisciplinary approach. However, treatment options remain limited, with evidence largely restricted to case reports and small cohorts, and no clearly effective causal therapy currently available.

Keywords acetazolamide, ectopic calcifications, fibroblast growth factor 23, hyperphosphatemic tumoral calcinosis, phosphate

EP275 - ECE_2017 - A rare cause of fragility fractures: tumor-induced osteomalacia due to a phosphaturic mesenchymal lesion hidden in the foot

Eider Pascual-Corrales[1], María Eugenia Reguero Callejas[2], Fausto González Lizán[3] and María del Carmen Sanz Pascual[3]

[1]Endocrinology and Nutrition, Hospital Universitario Ramón y Cajal, Madrid, Spain; [2]Pathology, Hospital Universitario Ramón y Cajal, Madrid, Spain; [3]Traumatology, Hospital Universitario Ramón y Cajal, Madrid, Spain

Introduction: Tumor-induced osteomalacia (TIO) is a rare paraneoplastic syndrome caused by fibroblast growth factor 23 (FGF23)-secreting mesenchymal tumors, leading to renal phosphate wasting, hypophosphatemia and osteomalacia. Tumor localization is often challenging, particularly when circulating FGF23 levels are within the reference range, delaying diagnosis and treatment.

Case presentation: We report the case of a 62-year-old man referred for evaluation of severe hypophosphatemia and multiple low-impact fractures. His relevant past medical history included obesity treated with sleeve gastrectomy. Since October 2024, he developed progressive generalized bone pain, proximal muscle weakness and multiple insufficiency fractures affecting the feet, calcaneus and sacrum. Laboratory evaluation revealed persistent hypophosphatemia (1.7-2.3 mg/dL; reference range 2.7-4.5 mg/dL) despite supplementation, reduced tubular phosphate reabsorption (66.7%; reference range 80%-94%), elevated alkaline phosphatase (176 U/L; reference range 53-128 U/L), normocalcemic hyperparathyroidism (PTH 121.1 pg/mL; reference range 17.3-74.1 pg/mL), 25-hydroxyvitamin D insufficiency (20.0 ng/mL), low-normal 1,25-dihydroxyvitamin D (31.8 pg/mL) and elevated bone turnover markers (β-CTX and P1NP).

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Notably, FGF23 concentrations were repeatedly within the normal range.

Bone mineral density showed osteoporosis at the lumbar spine (T-score −3.3) and osteopenia at the hip (T-score −2.0). Bone scintigraphy revealed focal uptake in the posterior right fifth rib and areas of stress-related bone remodeling in the right lower extremity, including a prior calcaneal fracture, while pelvic MRI confirmed an insufficiency fracture of the left sacral ala. Extensive imaging studies, including 18F-FDG PET/CT, neck ultrasound, parathyroid scintigraphy and CT scans, were initially inconclusive. However, 68Ga-DOTA-TOC PET/CT demonstrated a focal, intensely somatostatin receptor-avid lesion (SUVmax 8.2, Krenning 3-4) at the base of the right foot between the second and third toes. MRI of the foot confirmed a hypervascular interdigital soft tissue mass measuring approximately $20 \times 17 \times 14$ mm. Ultrasound-guided core needle biopsy revealed a benign mesenchymal neoplasm with histological and immunohistochemical features consistent with a phosphaturic mesenchymal tumor.

The lesion was surgically treated in December 2025 with wide excision and extensive margins. The pathology report of the surgical specimen confirmed the diagnosis of a phosphaturic mesenchymal tumor. Biochemical abnormalities, including hypophosphatemia, resolved after surgery, allowing discontinuation of phosphate supplementation.

Conclusions: This case highlights the diagnostic challenges of tumor-induced osteomalacia, particularly in patients with normal circulating FGF23 levels. Somatostatin receptor-based imaging using 68Ga-DOTA peptides remains the preferred modality for tumor localization. Early recognition and complete surgical resection are essential to achieve biochemical cure and prevent progressive skeletal morbidity.

EP277 - ECE_1183 - FRAX prediction with and without bone mineral density: a comparison and the factors influencing the discordant results in osteoporosis treatment decisions in Sri Lanka

Shahini Winson Gnanathayalan, Mahisha Chandrasekaran, T.G. Athukorala, Uditha Bulugahapitiya and Manilka Sumanatilleke
Endocrinology and Diabetes, National Hospital of Sri Lanka, Colombo, Sri Lanka

Background: The Fracture Risk Assessment Tool (FRAX) estimates an individual's 10-year fracture probability using clinical risk factors, with bone mineral density (BMD) as an optional contributor. Incorporating BMD may refine risk estimates, but its impact on treatment decisions in the Sri Lankan setting remains unclear. The objective of the study was to evaluate the level of agreement between treatment recommendations generated by FRAX with BMD and FRAX without BMD, using Sri Lankan intervention thresholds.

Methods: A cross-sectional analysis was conducted among adults aged 40-90 years who underwent dual-energy X-ray absorptiometry(DXA) for osteoporosis screening at a tertiary hospital in Sri Lanka in 2023-2024. FRAX probabilities were calculated using the Sri Lankan model, both with and without femoral neck BMD. Participants were categorized into treatment or non-treatment groups based on national thresholds (≥9% for major osteoporotic fracture risk[MOFR] and ≥3% for hip fracture risk[HFR]). Concordance was defined as identical treatment recommendations from both FRAX approaches. Clinical variables were compared between concordant and discordant groups.

Results: Of the 309 participants included, 88.0% were women. Treatment was recommended for 94 individuals(30.4%) using FRAX with BMD and 82 individuals(26.5%) using FRAX without BMD. Overall concordance was 82.5%(255/309). The median age was 61 years in the concordat group and 66 years in the discordant group. Discordance was significantly more frequent among older adults, particularly those aged >60 years($P <$ .001), and among individuals whose FRAX scores without BMD were close to intervention thresholds($P <$ .001). A greater proportion of patients with DXA-defined osteoporosis showed discordant classifications compared with those with osteopenia or normal BMD. Sex, BMI, and other clinical risk factors including secondary osteoporosis did not differ significantly between the two groups. In the discordant subset, treatment was suggested for 32 participants(59.3%) using FRAX with BMD compared with 22 participants(40.7%) using FRAX without BMD. These differences were not influenced by sex or BMI, but treatment recommendations based on FRAX with BMD were significantly more common among younger participants($P <$ .001) and those with osteoporosis on DXA($P <$ .001).

Conclusions: FRAX calculations with and without BMD yield consistent treatment recommendations for most patients. However, agreement diminishes in older adults and in those whose BMD-free FRAX estimates fall near intervention thresholds. These findings highlight the importance of obtaining BMD in borderline cases and in elderly patients to improve fracture-risk precision, while supporting the cost-effectiveness of using FRAX without BMD in resource-poor settings with limited DXA access.

EP280 - ECE_1881 - Chronic cholecalciferol supplementation and adequate vitamin D status are associated with reduced risk of long COVID

Luigi Di Filippo, Umberto Terenzi, Simona Bolamperti, Simonetta Bossoni, Marco Campaniolo, Licia Gifuni, Mauro Doga and Andrea Giustina
Institute of Endocrine and Metabolic Sciences, Università Vita-Salute San Raffaele, IRCCS Ospedale San Raffaele, Milan, Italy

Vitamin D deficiency has been associated with worse COVID-19 outcomes and with the persistence of post-acute sequelae, but the impact of vitamin D supplementation on Long COVID remains poorly defined. We investigated the association between chronic cholecalciferol supplementation, circulating 25-hydroxyvitamin D [25(OH)D] concentrations, and the risk of Long COVID.

This retrospective observational study included patients with confirmed COVID-19 between March 2020 and May 2021 previously followed at a tertiary Endocrine Department. Long COVID was defined according to NICE criteria as the persistence of at least two symptoms for more than 12 weeks after recovery. Patients receiving chronic cholecalciferol supplementation

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

were compared with non-supplemented individuals. A 1:1 matched analysis for age, sex, comorbidities, and acute COVID-19 severity was performed, together with dose-specific analyses for daily cholecalciferol intake ≥750 IU and ≥1000 IU.

Overall, 132 patients were included (median age 56 years; 49% male), of whom 50 (38%) were chronically supplemented with cholecalciferol for a median duration of 38 months. Long COVID was diagnosed in 30 patients (22.7%). Long COVID occurred less frequently among supplemented patients compared with non-supplemented individuals (14% vs 28%, $P = .086$). The difference became statistically significant in patients receiving ≥1000 IU/day (10.5% vs 27.6%, $P = .039$) and showed a similar trend for doses ≥750 IU/day (12.5% vs 28.6%, $P = .051$). Baseline 25(OH)D concentrations were significantly lower in patients with Long COVID (17.5 vs 24 ng/mL, $P = .023$).

In the matched cohort ($n = 86$), Long COVID occurred in 22.1% of patients and was significantly less frequent in those supplemented with cholecalciferol (11.6% vs 32.6%, $P = .036$). In this matched cohort, baseline 25(OH)D concentrations showed a strong predictive performance for Long COVID (AUROC 74.3%, $P = .005$). Similar findings were confirmed in matched analyses restricted to patients receiving ≥1000 IU/day (8.5% vs 34.2%, $P = .018$). In multivariate logistic regression analyses, chronic cholecalciferol supplementation emerged as an independent protective factor against Long COVID in both the entire cohort (OR 0.31, $P = .038$) and the matched cohort (OR 0.22, $P = .017$), while lower 25(OH)D concentrations independently predicted Long COVID occurrence. Obesity emerged as an independent risk factor only in the non-matched cohort.

In conclusion, chronic cholecalciferol supplementation, particularly at daily doses ≥750-1000 IU and associated with adequate 25(OH)D concentrations, was independently associated with a lower risk of Long COVID. These findings suggest that maintaining sufficient vitamin D status through long-term supplementation may represent a simple, safe, and low-cost strategy to mitigate post-COVID sequelae and support recovery.

Abstract citation ID: lvag096.836

EP281 - ECE_2614 - Successful management of gestational hypercalcemia due to CYP24A1 mutations with intermittent intramuscular calcitonin: a multigenerational family case

Sean Godfrey[1], Nadejda Kotlyarevska[1] and Maya Y. Peltsverger[1,2,3]

[1]Novant Health New Hanover Regional Medical Center, Wilmington; [2]Internal Medicine, Novant Health NHRMC, Wilmington, United States; [3]Novant Health New Hanover Regional Medical Center, Wilmington, United States

Background: Loss-of-function mutations in CYP24A1, encoding vitamin D 24-hydroxylase, impair vitamin D catabolism and cause vitamin D-dependent hypercalcemia. Pregnancy triggers symptomatic hypercalcemia in 81.8% of affected women, with high rates of obstetric complications including preterm delivery, preeclampsia, and fetal loss.[1] Therapeutic options are limited, as bisphosphonates are contraindicated. We report a multigenerational family demonstrating genotype-phenotype correlation and successful management with intermittent intramuscular calcitonin.

Case presentation: Two sisters with biallelic CYP24A1 pathogenic variants [c.62delC (p.Pro21Argfs8) and c.1186C > T (p.Arg396Trp)] and a variant of uncertain significance [c.1219T > A (p.Tyr407Asn)] developed pregnancy-associated hypercalcemia. The index patient presented with symptomatic hypercalcemia refractory to conservative measures. She was managed with intravenous normal saline, low-calcium diet, strict vitamin D and sunlight restriction, and intermittent intramuscular calcitonin throughout gestation. This multimodal approach maintained serum calcium within safe range (11.4 mg/dL), prevented calcitonin tachyphylaxis, and was associated with stable renal function, absence of acute kidney injury, and well-controlled blood pressure.[2]

In contrast, her older sister, treated only with intravenous fluids during both pregnancies, experienced recurrent hospital admissions for nephrolithiasis, persistent hypercalcemia (10-11.5 mg/dL), preeclampsia, and preterm delivery. Their mother, a monoallelic carrier, remained asymptomatic, demonstrating attenuated disease expression consistent with the 5.6% symptomatic hypercalcemia rate in heterozygous carriers.[1] The father, also a monoallelic carrier, had nephrolithiasis only.

The index patient's newborn developed neonatal hypercalcemia due to inherited CYP24A1 deficiency. Genetic testing revealed inheritance of a single pathogenic variant [c.62delC (p.Pro21Argfs8)], with absence of the c.1186C > T variant, confirming monoallelic carrier status. Monoallelic carriers can develop symptomatic hypercalcemia (5.6% rate) and have increased risk of nephrolithiasis (19.4%) and nephrocalcinosis (4.9%).[1,3]

Conclusions: This familial case demonstrates the autosomal recessive inheritance pattern of CYP24A1 deficiency with clear genotype-phenotype correlation. Biallelic mutations confer high risk of pregnancy-triggered hypercalcemia and obstetric complications, while monoallelic variants are associated with milder or asymptomatic phenotypes. Intermittent intramuscular calcitonin, combined with dietary and environmental vitamin D restriction and hydration, represents an effective and safe strategy for managing gestational hypercalcemia.[1,4,5] This approach may reduce maternal complications including acute kidney injury, hypertension, and preeclampsia compared to conservative management alone. Early diagnosis, family screening, and tailored perinatal management are essential for optimizing outcomes in both mothers and newborns with CYP24A1 deficiency. Neonates inheriting CYP24A1 mutations require lifelong monitoring and strict avoidance of vitamin D supplementation.[1,3]

EP282 - ECE_3085 - Management of patients with hypoparathyroidism treated with teriparatide: the long-term clinical experience of Padova's Endocrinology Department

Giacomo Contini, Giacomo Voltan, Carlo Mogno, Michela Ferrarese and Valentina Camozzi

Endocrine Disease Unit, University-Hospital of Padova, Padova, Italy

Introduction: Chronic hypoparathyroidism is traditionally managed with calcium and calcitriol supplements, but these treatments often fail to ensure adequate control of serum calcium levels and do not effectively prevent complications. In more

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

severe cases, treatment with 1-34PTH (teriparatide) can be used; in Italy, this is authorized under Law 648/1996 and reserved for patients who meet specific criteria. However, even teriparatide does not always allow for optimal disease control, requiring multiple daily administrations and failing to guarantee prevention of hypocalcemic crises. Here we report our clinical experience with four patients with postsurgical hypoparathyroidism who have been treated for years with 1-34PTH.

Patient presentation: Katy, 51 years old, with significant comorbidities including nephrocalcinosis due to medullary sponge kidney and breast cancer; despite replacement therapy, there was poor control of hypercalciuria, and the patient experienced numerous episodes of hypocalcemia requiring IV calcium infusions; she showed temporary improvement with 1-84PTH, which was later discontinued.

Rossana, 29 years old, with class II obesity, had difficulties absorbing the drug due to the thickness of subcutaneous fat, only partially resolved by using longer needles; after weight loss, she developed iatrogenic hypercalcemia.

Maria, 60 years old, initially benefited from 1-84PTH but, after switching to 1-34PTH, experienced several episodes of severe hypocalcemia.

Luana, 51 years old, with symptomatic atrophic gastritis and intolerance to calcium supplements, experienced multiple hypocalcemic crises.

Conclusions: The experiences reported highlight the complexity of managing hypoparathyroidism, with recurrent crises, a negative impact on quality of life, and difficulties related to comorbidities. 1-84PTH, which is no longer available, had provided benefits to several patients. Recently, palopegteriparatide has been approved, allowing for once-daily administration and showing excellent results in trials, but it is not yet reimbursed in Italy, limiting access and leaving 1-34PTH as the only option, which remains off-label and not fully effective.

EP283 - ECE_1620 - Outpatient parathyroidectomy for primary hyperparathyroidism in the Canadian public health care system: a safe and cost-saving practice

Camille Klotz[1], Florence Bénard[2], Dan Moldoveanu[2], Marie-Josée Bégin[3], Rondeau Geneviève[4] and Frédéric Mercier[2,5]
[1]*Faculty of Medecine, University of Montréal, Montreal, Canada;* [2]*Surgical Oncology, Surgery, Centre Hospitalier Universitaire de Montréal (CHUM), Montreal, Canada;* [3]*Endocrinology, Medecine, Centre Hospitalier Universitaire de Montréal (CHUM), Montréal, Canada;* [4]*Montréal, Canada;* [5]*Oncologic, Endocrine and Digestive Surgery, Surgery, Hôpital Privé Jean Mermoz, Lyon, France*

Primary hyperparathyroidism (PHPT) accounts for 80%-90% of outpatient-diagnosed hypercalcemia and is associated with complications like osteoporosis, nephrolithiasis and renal impairment. PHPT is caused by a single parathyroid adenoma and the preferred treatment consists in a focused parathyroidectomy. Although it can be safely performed as an outpatient procedure in selected patients, this practice remains uncommon in Canada, despite its potential for substantial cost savings for the public health care system.

The aim of this case series was to evaluate the safety and economic relevance of outpatient focused parathyroidectomy. This observational study was conducted at the Centre Hospitalier de l'Université de Montréal (Québec, Canada) between 2023 and 2025. Twenty-five patients who underwent outpatient parathyroidectomy were included. Most patients were female (76%), with a mean age of 60 years old. Patients were carefully selected preoperatively; classified II or III on the American Society of Anesthesiologists scale. All adenomas were localized preoperatively using technetium-99m sestamibi scintigraphy or 18F-choline positron emission tomographic imaging.

Mean preoperative ionized calcium and parathyroid hormone (PTH) levels were 1.46 mmol/L and 17.8 pmol/L, respectively. Patients were directly admitted to the operating room the day of surgery. Mean operative time was 35 minutes. Immediate postoperative biochemical assessment showed mean PTH of 2.67 pmol/L. PTH levels decreased by an average of 75%, consistent with biochemical cure, as a PTH reduction of 50% or more, with return to the normal range, is an established early marker of success. Two patients experienced complications that did not delay discharge: a right vocal cord paralysis and an intraoperative bleeding requiring vein repair.

Twenty patients were discharged with oral calcium supplementation according to preoperative calcium or postoperative PTH levels. One patient discharged without supplementation developed asymptomatic hypocalcemia on postoperative day one, which resolved with oral calcium by day two. At 48 h postoperatively, calcium and PTH levels had normalized in all but one patient due to a second adenoma not identified on initial imaging. Two postoperative emergency visits were recorded in the first 48 h; one for suspected acute renal insufficiency that was an erroneous laboratory and one for diffuse paresthesia despite normocalcemia.

From a health economic perspective, outpatient parathyroidectomy was associated with cost reduction estimated to thousands of dollars per patient, primarily due to avoidance of postoperative hospitalization.

In conclusion, outpatient focused parathyroidectomy is a safe approach for PHPT in carefully selected patients and offers significant cost savings for the public health care system.

EP284 - ECE_1270 - Multiple myeloma and primary hyperparathyroidism: a case of dual pathologies co-existing for the presentation of hypercalcaemia

Pei Shan Yeo[1,2]
[1]*Singapore, Singapore;* [2]*Endocrinology, Tan Tock Seng Hospital, Singapore, Singapore*

Hypercalcaemia of varying severity is a common electrolyte disturbance that can affect up to 1%-2% of the general population. Depending on its degree of elevation and symptoms, severe hypercalcaemia is considered an endocrinology emergency. These patients are often referred to endocrinologists for management in such settings.

Apart from instituting acute measures for calcium lowering, it is crucial to dissect the aetiology of hypercalcaemia to treat the underlying cause and consider multiple pathologies appropriately. A rare case of dual pathology leading to hypercalcaemia due to multiple myeloma and primary hyperparathyroidism is presented in this middle-aged Chinese man. This 52-year-old man

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

was referred to our service for the medical management of calcium lowering therapy in the context of hypercalcaemia of malignancy with the classical presentation of low back pain, anaemia, acute renal impairment and hypercalcaemia. A myeloma panel done revealed newly diagnosed multiple myeloma. However, on review of the biochemistry, an elevated serum calcium level associated with hypophosphatemia and an inappropriately elevated PTH level was not in keeping with the aetiology of multiple myeloma. Subsequent investigations revealed a left lower hyperfunctioning parathyroid adenoma on Sestamibi scan. He also suffered complications of osteoporosis from the underlying primary hyperparathyroidism. Hypercalcaemia persisted despite chemotherapy for multiple myeloma. The patient eventually underwent a focused left inferior parathyroidectomy with resolution of hypercalcaemia.

This case serves to illustrate several learning points including (a) careful interpretation of biochemistry studies for calcium metabolism; (b) consideration for alternative diagnoses and/or dual pathologies to tie in the clinical presentation, initial management and progress of the patient; (c) ordering and prioritisation of treatment with dual pathologies; and (d) multidisciplinary care. These learning points are crucial in the holistic management of our patient to diagnose the presence of both medical conditions that warrant different treatment plans to resolve the hypercalcaemia.

EP286 - ECE_3654 - Assessing bone health and factors associated with low bone mineral density in Turner and Klinefelter syndromes

Rita Pinto Ribeiro[1], Patrícia Brito[1], Eduarda Mourão Rodrigues[2], Adriana de Sousa Lages[1], Ana Margarida Monteiro[1], Catarina MacHado[1], Catarina Matos[1], Juliana Sá[1], Maria Joana Santos[1], Marta Alves[1], Maria Pereira[1], Vera Fernandes[1], Olinda Marques[1] and Sara Esteves Ferreira[1]

[1]Endocrinology Department, Unidade Local de Saúde de Braga, Braga, Portugal; [2]Escola de Medicina da Universidade do Minho, Braga, Portugal

Background: Turner Syndrome (TS) and Klinefelter Syndrome (KS) are two chromosomal disorders associated with primary hypogonadism, predisposing affected individuals to low bone mineral density (BMD) and osteoporosis. Although hormone replacement therapy (HRT) plays a central role in the management of bone health in these populations, BMD outcomes are influenced by multiple factors beyond gonadal hormone deficiency. The aim of this study was to evaluate the factors influencing BMD in TS and KS patients by analyzing the relationship between BMD outcomes and clinical, biochemical, and therapeutic variables in these populations.

Methods: We conducted a retrospective study of adult patients with TS and KS followed at our center between 2011 and 2025. Data on BMD, hormone replacement therapy, parameters of phosphocalcium metabolism, and other relevant clinical and biochemical variables were collected. Patients were classified into low and normal BMD groups based on BMD measurements. Statistical analyses were performed to assess associations between BMD status and the studied variables.

Results: We included 17 TS and 25 KS adult patients. In TS patients, delayed HRT initiation was associated with low BMD ($P = .023$). BMI showed significant positive correlations with femoral absolute BMD ($r = 0.684$, $P = .005$) and femoral T-score ($r = 0.621$, $P = .018$), whereas time from TS diagnosis to HRT initiation was negatively correlated with femoral T-score ($r = -0.551$, $P = .027$). Growth hormone therapy showed no significant impact on bone health.

In KS, low BMD patients had a later diagnosis and were older than those with normal BMD ($P = .019$ and $P = .006$, respectively). They also initiated testosterone therapy later ($P = .005$). Femoral BMD showed positive correlations with testosterone therapy dose ($r = 0.610$, $P = .035$), vitamin D ($r = 0.436$, $P = .030$), and phosphorus levels ($r = 0.763$, $P = .001$).

Conclusions: This study highlights the critical role of timely HRT initiation in preserving bone health in TS and KS. Additionally, vitamin D status appears to influence BMD in KS, underscoring the need for optimized monitoring. These findings provide valuable insights for improving BMD preservation and management strategies in these populations.

EP287 - ECE_1128 - Turner syndrome mosaicism (45,X/46,XY) presenting with severe osteoporosis and secondary hyperparathyroidism: a multidisciplinary case study

Madina Sagimbayeva, Aigul Durmanova, Diana Kurgambekova and Zhaniya Tazhigulova

Corporate Fund "University Medical Center", Department of Endocrinology, General Therapy Program 2, Astana, Kazakhstan

Introduction: Turner syndrome (TS) is a chromosomal disorder caused by partial or complete monosomy of the X chromosome, affecting 1 in 2000-2500 live female births. Mosaic forms containing Y-chromosome material (45,X/46,XY) are uncommon and frequently associated with atypical phenotypes, gonadal dysgenesis, and complex metabolic complications. Early recognition of such genetic variants is essential for preventing progressive skeletal and endocrine deterioration.

Case presentation: We report a 36-year-old woman with Turner syndrome mosaicism (45,X/46,XY) who presented with progressive skeletal deformities, chronic pain, and multiple pathological fractures. Her height was 130 cm, and she exhibited primary amenorrhea and characteristic Turner features, including short stature, webbed neck, and gonadal dysgenesis. She became wheelchair-dependent in 2023 due to progressive bone fragility. Genetic karyotyping confirmed mosaicism 45,X[12]/46,XY[13], with 48% X monosomy and 52% Y-chromosome presence.

Clinical Data Included: Endocrine investigations revealed hypophosphatemia (0.27-0.38 mmol/L), elevated parathyroid hormone levels (256.7 pg/mL), and vitamin D deficiency (28.5 ng/mL). Thyroid function tests indicated subclinical hypothyroidism (TSH 5.3 mIU/L). Imaging findings included generalized osteoporosis, multiple pelvic and femoral neck fractures in consolidation, and bilateral hip osteoarthrosis (CT and DEXA scan). Despite long-term treatment with denosumab, calcium, and vitamin D supplementation, bone mineral density showed no improvement. FISH analysis confirmed Y-chromosome mosaicism in 65% of lymphocytes, providing a genetic explanation for the severe skeletal phenotype.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Discussion: The presence of Y-chromosome material in Turner mosaicism may intensify skeletal fragility and endocrine dysfunction through disrupted gonadal steroidogenesis and mineral metabolism. Secondary hyperparathyroidism and phosphate imbalance further exacerbate bone loss. This case illustrates the diagnostic challenges of mosaic TS in adulthood, especially when initial manifestations mimic isolated metabolic bone disease. Multidisciplinary evaluation involving endocrinology, genetics, and orthopedics was crucial for accurate diagnosis and individualized management.

Conclusions: Turner syndrome mosaicism (45,X/46,XY) with Y-chromosome inclusion represents a rare but clinically significant cause of severe, treatment-resistant osteoporosis. Early cytogenetic testing should be considered in patients with unexplained osteoporosis, primary amenorrhea, and short stature. Timely initiation of hormone replacement therapy, phosphate correction, and careful surveillance for gonadal neoplasia are key to improving quality of life and reducing morbidity.

Keywords Turner syndrome, mosaicism, osteoporosis, secondary hyperparathyroidism, genetic endocrinology

EP289 - ECE_3799 - Recognizing X-linked hypophosphatemia: the role of family screening in patients with short stature

Mihaela Maria Vlad[1], Carmen Dorogi[2] and Bianca Maler[2]
[1]2nd Internal Medicine, "Victor Babes" University of Medicine and Pharmacy, Timişoara, Romania; [2]Endocrinology, "Pius Brinzeu" Emergency County Hospital, Timişoara, Romania

Background: X-linked hypophosphatemia (XLH) is a rare inherited disorder caused by pathogenic variants in the *PHEX* gene. It is characterized by increased fibroblast growth factor 23 (FGF-23) activity, leading to renal phosphate wasting, hypophosphatemia, reduced 1,25$(OH)_2$ vitamin D synthesis, and impaired bone mineralization. Clinical manifestations include growth failure, skeletal deformities, dental abnormalities, muscle weakness, and chronic pain. Diagnostic delay is frequent, particularly in adults and in patients initially evaluated for isolated short stature.

Case presentation: We report three members of the same family diagnosed with XLH, emphasizing the pivotal role of targeted family screening. The diagnostic process was initiated in **Case 1**, a 43-year-old woman with lifelong disproportionate short stature, who had previously been misdiagnosed with pituitary dwarfism and later achondroplasia. Persistent hypophosphatemia identified during routine evaluation raised the suspicion of XLH. Upon further questioning, the patient reported multiple relatives with short stature. Subsequent construction of a detailed family pedigree revealed a pattern consistent with X-linked dominant inheritance, prompting systematic family screening. **Case 2**, the nephew of Case 1, had been diagnosed at 2 years of age with familial hypophosphatemic rickets resistant to vitamin D and treated with active vitamin D analogues and phosphate supplementation until the age of 7 years. **Case 3**, the mother of Case 2, had never undergone endocrinological evaluation despite marked short stature and skeletal deformities. All three patients presented with chronic musculoskeletal pain, disproportionate short stature, waddling gait, genu varum, and poor dentition. Biochemical evaluation demonstrated persistent hypophosphatemia, normal serum calcium, low-normal 1,25$(OH)_2$ vitamin D levels, elevated or high-normal alkaline phosphatase, increased urinary phosphate excretion, and reduced tubular phosphate reabsorption. Radiological examination revealed pseudofractures in Case 2. Genetic testing confirmed a pathogenic *PHEX* mutation in all affected family members.

Management and Outcomes: Cases 1 and 3 received conventional therapy with active vitamin D analogues and oral phosphate, with limited clinical improvement. Case 2 initiated treatment with burosumab, resulting in normalization of serum phosphate levels and improvement in biochemical parameters, while clinical symptoms improved modestly.

Conclusions: This case series demonstrates that recognition of hypophosphatemia in a single patient with short stature should prompt thorough family history assessment, pedigree analysis, and targeted family screening. Early identification of XLH allows timely treatment and may prevent irreversible skeletal complications and long-term impairment in quality of life.

Abstract citation ID: lvag096.843

EP291 - ECE_3271 - Adult-onset familial hypomagnesemia with secondary hypocalcemia: an atypical presentation of a rare disorder

Ana Margarida Sobral[1], Alice Monsanto[1], Bárbara Jesus[1], Adriana Duarte[1], Mariana Coelho[1], Sofia Lopes[1], Mafalda Martins Ferreira[2], Mariana Lavrador[1], Joana Reis Guiomar[1], Carolina Moreno[1], Daniela Guelho[1] and Leonor Gomes[1]
[1]Coimbra, Portugal; [2]Serviço de Endocrinologia da Unidade Local de Saúde São José, Lisboa, Portugal

Introduction: Familial hypomagnesemia with secondary hypocalcemia (FHSH) is a rare autosomal recessive disorder (prevalence < 1/million) caused by mutations in the *TRPM6* gene (chromosome 9q22), which encodes a magnesium-permeable ion channel expressed in the renal tubules and intestine.

Clinical manifestations include seizures and neurodevelopmental delay, typically presenting in childhood. Biochemically, it is characterized by severe hypomagnesemia and consequent hypocalcemia refractory to calcium supplementation. Treatment consists of magnesium replacement.

We report an atypical case diagnosed only in adulthood, representing the first case described in the literature with these characteristics.

Case report: A 22-year-old man presented to the emergency department with abdominal pain, vomiting, diarrhea, and episodes of absence. His medical history was notable for attention deficit hyperactivity disorder (ADHD). Physical examination at admission was unremarkable.

An electroencephalogram excluded epileptic activity, and brain computed tomography revealed calcifications of the basal ganglia.

Laboratory evaluation showed: Ca^{2+} 6.3 mg/dL; albumin 5.2 g/dL; Mg^{2+} < 0.6 mg/dL (1.8-2.6); PO_4^{3-} 5.4 mg/dL (2.5-4.5); 25-hydroxyvitamin D 19 ng/mL; and inappropriately low parathyroid hormone levels (PTH 16 pg/mL [9-72]).

The patient was admitted to the Endocrinology Department and treated with calcium carbonate 1500 mg twice daily and

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

intravenous magnesium sulfate. Calcium carbonate was discontinued after normalization of serum magnesium levels. At discharge, laboratory results showed Ca^{2+} 10.1 mg/dL and Mg^{2+} 1.9 mg/dL under magnesium aspartate 1229.6 mg three times daily.

Family history revealed that his brother had epilepsy and hypomagnesemia since the age of 2 years and was on magnesium supplementation. Genetic testing for causes of hypomagnesemia identified a homozygous *TRPM6* variant, c.3179T > A p.(Ile1060Asn). Family members were referred for genetic counselling and are currently waiting for test result.

The patient is currently asymptomatic, with normal calcium levels and well-controlled magnesium levels on magnesium aspartate 1229.6 mg twice daily.

Conclusions: FHSH is a rare cause of hypomagnesemia, usually diagnosed in childhood. This case illustrates a late-onset presentation, highlighting the importance of considering a genetic etiology in adults with unexplained hypomagnesemia and hypocalcemia.

FHSH should be considered in patients with refractory hypocalcemia and neurological symptoms, as early diagnosis and treatment may prevent potentially irreversible neuromuscular and metabolic complications.

According to the literature review, this is the first reported case with adult-onset manifestations leading to diagnosis. The identified variant has been described in only one other case, also reported in Portugal, with no evidence of familial relationship or consanguinity between the two cases.

Abstract citation ID: lvag096.844

EP292 - ECE_2450 - A Rare cause of osteopenia and non-cirrhotic portal hypertension in a premenopausal breast cancer patient: gaucher disease

Ece Gül Köse Hamidi[1], Deniz Türküm Atikcan[1], Merve Şenay Özçalık[1], Ozlem Turhan Iyidir[1], Asli Nar[1], Arzu Oguz[2] and Neslihan Başçıl Tütüncü[1]
[1]*Endocrinology and Metabolism, Department of Endocrinology and Metabolism, Baskent University Faculty of Medicine, Ankara, Türkiye;* [2]*Oncology, Department of Oncology, Baskent University Faculty of Medicine, Ankara, Türkiye*

Introduction: Gaucher disease is an autosomal recessive lysosomal storage disorder caused by β-glucocerebrosidase deficiency. Although it is the most common lysosomal storage disease, adult-onset cases remain rare and are frequently diagnosed late due to heterogeneous and often subtle clinical manifestations. Skeletal involvement, including osteopenia and osteoporosis, represents one of the earliest and most prevalent features, yet is commonly misattributed to primary or secondary causes. In premenopausal women with breast cancer receiving aromatase inhibitor (AI) therapy, bone loss is expected, which may obscure the presence of underlying rare disorders. The coexistence of cytopenias and organomegaly should prompt further investigation.

Case presentation: A 43-year-old premenopausal woman was referred for evaluation of reduced bone mineral density. She had been diagnosed with early-stage, hormone receptor–positive breast cancer and treated with left mastectomy followed by ovarian suppression with goserelin and adjuvant letrozole. Dual-energy X-ray absorptiometry revealed diffuse lumbar osteopenia, with osteoporosis at L4 (T-score −2.5), and femoral osteopenia. Laboratory evaluation showed mild anemia (Hb 11.7 g/dL), leukopenia (3.82×10^3/μL) and persistent thrombocytopenia ($96\text{-}112 \times 10^3$/μL). Biochemistry was largely unremarkable, with normal calcium–phosphate balance and adequate vitamin D levels. Abdominal ultrasonography demonstrated marked splenomegaly (192 mm) and features consistent with non-cirrhotic portal hypertension, while hepatic veins remained patent and no evidence of cirrhosis was observed.

The combination of osteopenia, cytopenias, splenomegaly and portal hypertension raised suspicion for a lysosomal storage disorder. Enzymatic testing revealed markedly reduced leukocyte β-glucocerebrosidase activity (0.80 nmol/mg/h) and significantly elevated plasma chitotriosidase (452 μmol/L·h), consistent with Gaucher disease. Genetic confirmation via *GBA* mutation analysis was planned.

Discussion: While AI therapy commonly induces bone loss in premenopausal breast cancer patients, the presence of systemic features in this case indicated an alternative etiology. Gaucher disease is associated with bone marrow infiltration, increased bone resorption and impaired bone formation, predisposing patients to early osteopenia and fractures. Delayed diagnosis may result in irreversible skeletal damage and progressive organ involvement.

Conclusions: This case highlights that osteopenia in premenopausal breast cancer patients should not be attributed solely to oncological therapy when accompanied by cytopenias and organomegaly. A holistic assessment of systemic findings is essential to identify rare yet treatable conditions such as Gaucher disease, enabling timely intervention and prevention of long-term complications.

EP293 - ECE_2725 - Clinical features of long-standing postoperative hypoparathyroidism with multiple complications

Madina Bakirzhan[1,2], Anna Bazarova[1,2], Malika Kozhemzharova[1,2] and Zhannat Taubaldiyeva[1,2]
[1]*Astana Medical University, Astana, Kazakhstan;* [2]*Endocrinology, Multidisciplinary City Hospital No.1, Astana, Kazakhstan*

Relevance: Long-standing postoperative hypoparathyroidism is a rare endocrine disorder with significant clinical interest due to its chronic course and systemic complications. Prolonged use of active vitamin D metabolites carries a high risk of renal and extraskeletal complications. Renal complications, including nephrocalcinosis and nephrolithiasis, occur in 20%-40% of patients. This case demonstrates the severe consequences of conventional therapy and highlights the need for reconsideration of treatment strategies.

Aim: To analyze the clinical course of long-standing postoperative hypoparathyroidism with systemic complications, evaluate limitations and risks of standard therapy using active vitamin D metabolites, and emphasize the need for transition to parathyroid hormone therapy to prevent progression and preserve organ function.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Case description: Hypoparathyroidism affects approximately 20-40 per 100 000 population, mainly postoperative. In Kazakhstan, reliable epidemiological data are limited due to restricted access to specialized care, insufficient laboratory diagnostics, and absence of national registries.

Standard therapy with active vitamin D metabolites does not replicate parathyroid hormone effects and causes chronic hypercalciuria and elevated calcium–phosphate product, mechanisms underlying renal and extraskeletal complications.

The patient has a 20-year history of endocrine disease. At 23, she underwent total thyroidectomy for diffuse toxic goiter, complicated by persistent hypoparathyroidism and hypothyroidism, requiring lifelong hormone replacement.

Pregnancy at 32 occurred with chronic hypocalcemia, requiring careful monitoring and therapy adjustment. From age 34, she received alfacalcidol 3-5 μg/day, maintaining normocalcemia.

At 46, nephrocalcinosis and a left renal calculus were detected; at 48, nephrolithiasis exacerbation led to acute kidney injury (eGFR 24 mL/min). Surgery was performed, and alfacalcidol reduced to 2 μg/day. At 49, partial renal recovery (eGFR 58 mL/min) was observed, but recurrent hypocalcemia required an increase to 3 μg/day. At 50, a right renal calculus was identified. At 52, brain MRI revealed basal ganglia calcifications.

Conclusions: Even with normocalcemia, conventional therapy with active vitamin D metabolites does not prevent severe systemic complications. Progressive nephrocalcinosis, recurrent nephrolithiasis, renal function decline, and cerebral calcifications highlight the limited efficacy of this approach. Transition to recombinant parathyroid hormone therapy is pathogenetically justified, clinically appropriate, and may help prevent further progression of systemic complications while preserving organ function.

EP295 - ECE_1593 - The prevalence and clinical presentation of transient primary hyperparathyroidism

Yanmei Qi, Renata Marques Jones and Xiangbing Wang
Rutgers University-Robert Wood Johnson Medical School, New Brunswick, United States

Background: Primary hyperparathyroidism (PHPT) has become a common endocrine disorder and surgery is the only cure for symptomatic patients. Rarely, hypercalcemia and elevated intact parathyroid hormone (iPTH) may spontaneously normalize without intervention, a phenomenon termed transient PHPT (tPHPT). The prevalence of tPHPT remains unknown and the etiologic spectrum is evolving. We present 2 cases of tPHPT: one representing the longest reported follow-up of adenoma-associated tPHPT, and another highlighting a novel post-viral etiology.

Case presentation: Case 1: A 60-year-old man presented with new-onset hypercalcemia (11.6 mg/dL), elevated iPTH (124 pg/mL), vitaminD deficiency (15.2 ng/mL), and hypercalciuria (24-hour urine calcium 604 mg). Imaging indicated a left parathyroid adenoma. Immediately prior to planned parathyroidectomy, repeated testing revealed spontaneous normalization of calcium (9.6 mg/dL) and iPTH (64 pg/mL). Consequently, surgery was cancelled. Over a 12-year follow-up (the longest reported in literature), calcium and iPTH remained normal, with most recent calcium 9.7 mg/dL and iPTH 71 pg/mL. Imaging confirmed adenoma size reduction and subsequent stability. BMD remained normal, and the patient remained asymptomatic.

Case 2: A 60-year-old woman presented with asymptomatic hypercalcemia (serum calcium 11.4 mg/dL, ionized 6.1 mg/dl) and inappropriately high-normal iPTH (57 pg/mL). No history of malignancy or thiazide, lithium, vitamin D, and calcium supplements. Renal function, vitamin D status, and calcium-sensing receptor sequencing were normal. Imaging revealed a multinodular goiter without parathyroid findings. Notably, she had recovered from COVID-19 infection 4-6 weeks prior to calcium (11.6 mg/dL) and iPTH (110 pg/mL) peak. Without intervention, biochemical markers normalized within seven months (calcium 9.1 mg/dL, iPTH 38 pg/mL), followed by alkaline phosphatase normalization six months later. Remission has persisted for >3 years.

Discussion/Conclusions: The estimated global prevalence of tPHPT is 0.0016% (67 cases reported since 1946), markedly lower than the 0.4% (2/500) frequency identified in our center.

Proposed pathogenic mechanisms include adenoma infarction or hemorrhage (~93%), immune-mediated inflammation/injury, and possible parathyroiditis.

Case 1 strongly suggests adenoma auto-infarction; the 12-year follow-up validates a conservative approach but underscores the need for surveillance. Conversely, Case 2 lacked structural pathology but was temporally linked to SARS-CoV-2, suggesting a distinct mechanism of post-viral parathyroiditis causing transient PTH leakage. The absence of secondary causes and sustained remissions support a self-limited process. To our knowledge, this is the first documented tPHPT case with a post-viral etiology.

Recognizing tPHPT is critical to avoid unnecessary parathyroidectomy. Pre-operative biochemical re-assessment is vital, particularly in new-onset or short-duration hypercalcemic PHPT. For confirmed tPHPT, observation is appropriate, though long-term monitoring remains crucial given the potential of recurrence.

EP300 - ECE_2883 - Primary hyperparathyroidism masquerading as tertiary hyperparathyroidism in a renal transplant recipient

Huriya Siddique[1], Shahroz Azhar[1], Arfa Ahmed Assad[1], Sidra Safdar[2], Muhammad Murtaza Shafqat[1] and Hira Irfan[1]
[1]*Endocrinology, Internal Medicine & Endocrinology, Pakistan Kidney and Liver Institute & RC, Lahore, Pakistan;* [2]*Clinical Trial Unit, Department of Oncology and Radiotherapy, Mayo Hospital Lahore, Lahore, Pakistan*

Background: Persistent hypercalcaemia following renal transplantation is most commonly attributed to tertiary hyperparathyroidism, reported in approximately 17%-50% of transplant recipients. However, alternative aetiologies should be actively considered. We describe a renal transplant recipient with persistent hypercalcaemia who was ultimately diagnosed with primary hyperparathyroidism due to an ectopic mediastinal parathyroid adenoma.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Case presentation: A 48-year-old male underwent a living-related renal transplant after nine years of haemodialysis for end-stage renal disease secondary to long-standing uncontrolled hypertension. Post-transplant recovery was uneventful, and he achieved stable graft function on an immunosuppressive regimen.

Three years post-transplant, he presented with generalized bone pain and weakness. Biochemical evaluation revealed persistent hypercalcaemia (11.06 mg/dL) with elevated intact parathyroid hormone (iPTH) levels (148.9 pg/mL) and mildly elevated phosphate levels. Renal function and vitamin D levels were within normal limits. These findings initially suggested tertiary hyperparathyroidism. However, parathyroid ultrasonography was unremarkable.

The combination of persistent hypercalcaemia, elevated iPTH levels, and normal ultrasonographic findings raised suspicion for an ectopic parathyroid source. A contrast-enhanced CT scan of the neck and chest did not identify ectopic parathyroid tissue. Given the high index of suspicion, a Tc-99m sestamibi parathyroid scan with early and delayed imaging was performed, demonstrating focal tracer uptake in the superior mediastinal region, consistent with an ectopic mediastinal parathyroid adenoma. The patient was referred to thoracic surgery for resection and remains under close endocrinology follow-up.

Conclusions: This case illustrates a rare but important diagnostic pitfall in renal transplant recipients presenting with persistent hypercalcaemia. Elevated parathyroid hormone levels after transplantation should not be automatically attributed to tertiary hyperparathyroidism. Although uncommon, primary hyperparathyroidism—particularly due to ectopic parathyroid adenomas—remains a crucial differential diagnosis, especially when conventional imaging is inconclusive. Functional imaging with Tc-99m sestamibi plays a pivotal role in localising ectopic parathyroid tissue and preventing diagnostic delay, inappropriate management, and prolonged patient morbidity.

EP301 - ECE_2983 - Performance of diagnostic modalities in primary hyperparathyroidism: single-center expert experience

Fatma Nur Korkmaz
Kayseri, Türkiye

Introduction: In patients with primary hyperparathyroidism(PHPT) requiring treatment, parathyroid localization is performed using neck ultrasonography(USG), Parathormone washout(PTHW) and/or fine-needle aspiration biopsy(FNAB), parathyroid sestamibi scintigraphy(MIBI), and -dimensional contrast-enhanced neck tomography(4D-CT). Parathyroid adenomas(PA) may mimic lymph nodes or thyroid nodules on imaging; therefore, accurate localization requires combined evaluation of multimodal imaging and biopsy techniques.

Aim: The aim was to evaluate the diagnostic accuracy of imaging methods used to determine localization in patients diagnosed with PHPT.

Method: Patients with PHPT between March 2024 and January 2026 were retrospectively reviewed. The patients' demographic characteristics, laboratory parameters, imaging modalities (USG, MIBI scintigraphy, 4D-CT), vertebral radiographs, bone mineral density measurements of the femur, spine, and distal radius), indications for treatment were evaluated. The indications for surgery were determined according to the criteria defined in the Fifth International Workshop on the Evaluation and Management of Primary Hyperparathyroidism. The diagnostic algorithm is shown in Figure 1.

Results: The clinical and laboratory characteristics of the patients are presented in Table 1. Three of the four patients diagnosed with MEN belonged to the same family. Figure 2 summarizes the results of the localization studies. PTHW was not performed because one patient had a preliminary diagnosis of parathyroid carcinoma, three patients had not accepted PTHW procedure, and six patients had previously performed MIBI studies that were positive and concordant with USG. Using USG ± PTHW/FNAB or MIBI, the PA was localized in 80.5% of the patients (47 + 7 out of 67 patients). Among three patients with negative USG findings, only one underwent surgery based on MIBI uptake, confirming parathyroid adenoma on pathology (1/67 false negative USG).

The correlation of MIBI and USG results is presented in Table 2 in PTHW(+) patients. According to this, 3/3 lesions in the right upper gland, 4/5 lesions in the right lower gland, 3/7 lesions in the left upper gland, and 7/8 lesions in the left lower gland were detected. False-negative uptake was observed in 6 out of 23 cases.

One patient with negative USG was truly diagnosed with PA with MIBI. Another patient was diagnosed with PA on the neck by USG and FNAB, while MIBI revealed an ectopic PA localization. Surgery was performed in 21 patients, with 20 diagnosed with PA and 1 with parathyroid carcinoma.

Conclusions: PTH washout demonstrates high diagnostic accuracy, while FNAB and MIBI are less reliable. MIBI, however, may offer additional value in cases with multiple lesions.

Figure 1

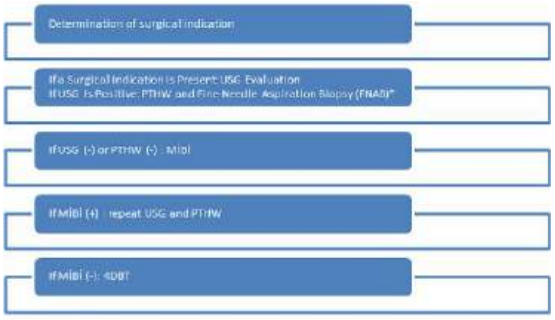

Figure 1.**Diagnostic algorithm.**
* In patients who had previously undergone MIBI imaging at an external center, PTH washout and FNAB were not performed. Note: At the stage deemed appropriate for surgery, MIBI and/or 4D-CT imaging was performed regardless of ultrasonographic or PTH washout positivity.

EP302 - ECE_3831 - A diagnostic masquerader: CYP24A1-related vitamin D–dependent hypercalcaemia presenting as recurrent nephrolithiasis over three decades

Maliha Iqbal[1], Saba[2,3,4], Al-BahraniAli[2] and Amie Thompson[2]

[1]Maidstone, Maidstone Hospital, United Kingdom; [2]Clinical Metabolism, Clinical Metabolism, Maidstone Hospital, Maidstone, United Kingdom; [3]Diabetes and Endocrinology, Maidstone and Tunbridge Wells NHS Trust, Maidstone, United Kingdom; [4]Diabetes and Endocrinology, Maidstone Hospital, Maidstone, United Kingdom

Background: Primary hyperparathyroidism (PHPT) is a common cause of hypercalcaemia and nephrolithiasis; however, rare disorders of vitamin D metabolism can mimic this presentation. Autosomal recessive infantile hypercalcaemia type 1 (ARIH1), caused by pathogenic variants in *CYP24A1*, leads to impaired degradation of active vitamin D metabolites, resulting in PTH-independent hypercalcaemia, hypercalciuria, and renal stone disease. Diagnosis is often delayed due to atypical biochemical features.

Case presentation: We describe a 63-year-old male with a history of recurrent renal stone disease since 1988. Over more than 20 years, he was reviewed multiple times in endocrine clinics for suspected PHPT. Biochemistry consistently showed mildly elevated or high-normal adjusted serum calcium (2.57-2.91 mmol/L) with parathyroid hormone (PTH) levels not suppressed but in the lower half of the reference range at 2.1-3.6 pmol/L (reference range: 1.6-6.9 pmol/L). Serum phosphate was intermittently low-normal, renal function remained preserved, and 24-hour urinary calcium was persistently elevated (10.5-11.3 mmol/24 h), with calcium-creatinine clearance ratios around 0.03, excluding familial hypocalciuric hypercalcaemia. Vitamin D levels were normal to high-normal, and extensive evaluation excluded malignancy, granulomatous disease, and paraproteinemia. There was no history of calcium or vitamin D supplementation.

Family history revealed a sister who underwent parathyroid surgery for hypercalcaemia in later life. Given long-standing PTH-independent hypercalcaemia dating back to the late 1990s, a disorder of vitamin D metabolism was suspected. Measurement of vitamin D metabolites demonstrated elevated 1,25-dihydroxyvitamin D with suppressed 24,25-dihydroxyvitamin D and markedly elevated metabolite ratios. Genetic testing confirmed a homozygous pathogenic variant in *CYP24A1*, establishing the diagnosis of ARIH1.

Management and Outcome: The patient was advised to avoid vitamin D supplementation, excessive dietary calcium, and prolonged sun exposure, with emphasis on maintaining good hydration. He was referred for genetic counselling, with discussion of cascade testing for family members. Shared care with a tertiary metabolic bone service was established, with consideration of cinacalcet as a potential future therapeutic option. Renal function remains stable.

Conclusions: This case highlights the importance of considering *CYP24A1*-related hypercalcaemia in patients with long-standing nephrolithiasis, hypercalcaemia, hypercalciuria, and low-normal PTH. Early recognition can prevent unnecessary surgery and guide appropriate long-term management and family screening.

EP303 - ECE_1917 - Management of osteoporosis in stroke patients: a systematic review of clinical practice guidelines

Chrislyn Ng[1,2], Mariam Mohammad Rahim[1,2], Jakub Mesinovic[3], Ayse Zengin[1], Anne Trinh[1,2,4], Peter Ebeling[1,5], Frances Milat[1,4,6], Gabrielle Stokes[1,2,4] and Mícheál Ó. Breasail[1]

[1]Monash University, Clayton, Australia; [2]Monash Health, Clayton, Australia; [3]Deakin University, Burwood, Australia; [4]Hudson Institute of Medical Research, Melbourne, Australia; [5]Monash Health, Melbourne, Australia; [6]Department of Endocrinology, Monash Health, Clayton, Australia

Background: Stroke is a leading cause of mortality and morbidity worldwide, with stroke survivors suffering a wide range of post-stroke complications. Osteoporosis is a well-established complication post-stroke due to accelerated bone and muscle loss. While this is a significant driver of fractures, osteoporosis post-stroke remains substantially underdiagnosed and undertreated.

Objective: To evaluate current clinical guidelines and recommendations for osteoporosis screening, prevention and treatment post-stroke.

Methods: A systematic review was conducted and reported in accordance to PRISMA guidelines, with PROSPERO registration. We searched OVID MEDLINE, Embase, Emcare and Web of Science databases up to 05/01/2026 with a complementary search for websites of major international societies, national professional bodies specialising in the care of stroke and/or osteoporosis and Guidelines International Network (GIN). Identified guidelines were appraised using the AGREE-II (Appraisal of Guidelines for Research and Evaluation) tool.

Results: Nine clinical guidelines across five countries were identified, including guidelines from the United Kingdom ($n = 3$), the United States ($n = 3$), Singapore ($n = 1$), Malaysia ($n = 1$) and South Africa ($n = 1$). Five were osteoporosis guidelines that included information on post-stroke osteoporosis, while the remaining 4 guidelines were stroke guidelines that identified osteoporosis as a post-stroke complication. All osteoporosis guidelines nested stroke as a risk factor for osteoporosis and fractures among other neurological conditions, with no additional stroke-specific information on fracture prevention and treatment of osteoporosis. Among the four stroke guidelines, fracture risk assessment was recommended as part of stroke rehabilitation but no specific details about stroke-specific fracture risk assessment. Three of four stroke guidelines recommended improving levels of physical activity and vitamin D and calcium supplementation to avert post-stroke osteoporosis. Appraisal of identified guidelines using the AGREE-II is currently underway.

Conclusions: Despite the documented high fracture rates post-stroke, health professionals do not have adequate guidance to support the management of osteoporosis in this setting. Although acknowledged as a secondary cause of osteoporosis, stroke-specific guidance remains largely lacking from osteoporosis clinical practice guidelines. While the included stroke clinical practice guidelines included offered more targeted guidance on the screening and prevention of osteoporosis, these represent a small fraction of stroke guidelines worldwide. Providing specific recommendations post-stroke related to bone health in national osteoporosis guidelines should be a priority given the high burden of fracture in the patient population.

EP304 - ECE_1814 - Tumor-induced osteomalacia of the left maxillary sinus: diagnostic challenges

Daniel Grigorie and Alina Sucaliuc

National Institute of Endocrinology, Bucharest, Romania

Background: Tumor-induced osteomalacia (TIO) is an ultrarare paraneoplastic syndrome due to overproduction of fibroblast growth factor 23 (FGF23), which produces significant patient morbidity and poses diagnostic challenges, with an initial misdiagnosis rate of more than 95%. Biochemical features of TIO are represented by hypophosphatemia, increased or inappropriately normal levels of FGF23, and low to low normal circulating calcitriol. TIO-causing tumors have been observed in soft tissue and bone in many different locations, around 10% in the head.

Case presentation: A 57-years old woman was admitted to our endocrinology department to investigate an non-suspicious thyroid nodule, reporting a 10 months history of progressive and severe bone and muscle pain, proximal muscle deficit, mobility limitation and difficult gait and upright posture, with a preliminary diagnostic of secondary bone lytic lesions, treated with zoledronate a month before admission. The medical history included: total right hip replacement for osteoarthritis seven yrs before, osteoporosis treated with risedronate (LS Z-score = −2.9 SD), bilateral sacroiliitis by RMI and positive HLA-B27, CT head, thorax and abdomen: multiple lytic lesions in the ribs, pelvis, femoral neck, and multiple hot spots on bone scintigraphy; negative tumor markers and testing for multiple myeloma. A month before, in another hospital: P 1.39 mg/dl, AlkPhos 330 U/L (35-105). At admission: P: 1.7-1.9 mg/dl; AlkPhos 345 U/L; Ca: 8.9 mg/dl; PTH 91.48 pg/ml; 25OHD 36 ng/ml; normal renal, thyroid, adrenal function. P urine 0.58 g/24 h; TmP/GFR = 0.52 mmol/l (0.80-1.35 mmol/L); FGF-23 = 153 pg/ml (23.2-95.4); calcitriol = 30.5 pg/ml (19.9-79.3). Calcitriol 3 mcg and 3 g phosphate per day were recommended with progressive improvement of clinical, biochemical and radiographic osteomalacia. After 6 mo the treatment was interrupted for 2 weeks: *P* = 1.90 mg/dl, AlkPhos = 166 U/L; P urine 0.27 g/24 h; calcitriol = 9.14 pg/ml; FGF-23 = 254.80 pg/ml; TmP/GFR = 0.5 mmol/l. LS BMD increased by 50% after 6 mo and bone scan was normal after 1 year. As SPECT-CT was negative for tumor we performed genetic testing for XLH/FGF23, but no clinically relevant variants were detected. A PET CT Ga-68 DOTATATE identified an increased uptake focus on posterior wall of the left maxillary sinus. A maxillary sinus MRI and an appointment with an oral surgeon were scheduled.

Conclusions: This case has several particularities: a rather short history, frequent misdiagnosis, good response to conventional therapy, but delayed healing of osteomalacia due to zoledronate and the necessity of genetic testing in the absence of initial tumor localization.

EP306 - ECE_1758 - Stabilization of exostotic bone lesions following bisphosphonate therapy: a small clinical case series

Michail Savvas Magklis[1,2,3], Maria Chrysoula Tatarida Palla[1,2,3], Christos Yapijakis[1], Eleni Koniari[1], Katerina Firfilioni[1,2], Eleni Papanikolaou[1,2] and George Chrousos[1,2,3]

[1]National and Kapodistrian University of Athens, Athens, Greece; [2]Clinical and Translational Research Endocrine Unit, National and Kapodistrian University of Athens, Athens, Greece; [3]National and Kapodistrian University of Athens, University Research Institute of Maternal and Child Health and Precision Medicine, University Research Institute of Maternal and Child Health and Precision Medicine, Athens, Greece

Background: Exostoses and osteochondroma-like lesions may arise in a range of bone remodeling disorders, including Paget disease of the bone and inherited osteodysplasias, leading to pain, functional impairments, and repeated surgical interventions. Currently, no established medical therapy directly targets exostosis formation or progression and the management is surgical.

Objective: To describe clinical and radiographic outcomes following bisphosphonate therapy in patients with heterogeneous bone disorders presenting with exostotic lesions.

Methods: We report an observational case series of three patients with exostosis-prone bone disorders with genetically determined osteodysplastic syndromes, who were treated with bisphosphonate therapy for pain, functional limitation, osteoporosis, and progressive exostotic burden. Clinical outcomes included pain relief, improvement of mobility and quality of life, and no further need for surgical intervention. Radiographic follow-up was assessed using routine clinical imaging.

Results: All three patients experienced substantial symptomatic improvement within months of therapy initiation, with marked reduction in pain and improved functional capacity. During follow-up of >20 y for two patients and >3 y for the third patient, no recurrence of symptomatic exostoses or emergence of new exostotic lesions was observed. Radiographic assessment suggested stabilization of exostotic bone changes compared with prior clinical course. Treatment was well tolerated, with no clinically significant adverse effects reported.

Conclusions: In this small, heterogeneous case series, bisphosphonate therapy was associated with symptomatic improvement and apparent stabilization of exostotic bone lesions. Although causality cannot be established, these observations suggest that modulation of bone turnover may influence exostosis-related manifestations across different bone remodeling disorders. Further systematic studies are warranted to define disease-specific efficacy, optimal timing, and long-term outcomes.

EP307 - ECE_2986 - Therapeutic challenges in the management of Paget's disease of bone: effectiveness of denosumab

Iulia-Alexandra Voinea[1], Eugenia Petrova[1,2], Andra Cocoloș[1,2], Gabriela Voicu[3] and Adina Ghemigian[1,2]

[1]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [2]Department of Endocrinology, C.I.Parhon National Institute of Endocrinology, Bucharest, Romania; [3]Nuclear Medicine Laboratory, C.I.Parhon National Institute of Endocrinology, Bucharest, Romania

Background: Denosumab, a monoclonal antibody that inhibits bone resorption, is approved for osteoporosis, bone metastases, and giant cell tumor of bone. This report highlights denosumab as an effective therapy option in Paget's disease of bone (PDB) with unsustained response to bisphosphonate therapy.

Methods: A 49-year-old female has been under follow-up for five years for PDB associated with a pathogenic SQSTM1 mutation. Initial laboratory assessment included serum calcium, alkaline phosphatase (ALP), and bone turnover markers (P1NP and beta-crosslaps). Disease extent was evaluated by bone scintigraphy. Sequential antiresorptive therapy with zoledronic acid and denosumab was administered, with ongoing clinical and biochemical monitoring.

Results: At diagnosis, serum calcium, ALP, P1NP, and beta-crosslaps were increased: 10.3 mg/dL (N:8.4-10.3), 392 U/L (N:35-104), 203.4 ng/mL (N:14.28-58.92), and 0.67 ng/mL (N:0.162-0.436), respectively. Bone scintigraphy revealed left ulna involvement. The first administration of zoledronic acid induced a very good clinical and biochemical response. Twelve months after the second zoledronic acid infusion, the ulna lesion enlarged and pain reappeared. Bone turnover markers rebounded. Under denosumab therapy, bone turnover was suppressed, with resolution of symptoms. Biochemical monitoring showed partial escape from denosumab suppression at six months, with recurrent pain. Calcium supplementation during the first two months was required to prevent hypocalcemia and secondary hyperparathyroidism.

Conclusions: This case underscores the need for individualized antiresorptive strategies in PDB. Denosumab effectively controlled disease activity and symptoms. Biochemical rebound suggests that shorter dosing intervals may be required. Long-term clinical and biochemical monitoring remains essential.

EP310 - ECE_2211 - Pseudohypoparathyroidism clinical puzzle: a case report

Alla Shepelkevich[1], Diana Baalbaki[1] and Zhanna Kirilenko[2]

[1]Endocrinology, Belarusian State Medical University, Minsk, Belarus; [2]Minsk City Clinic Endocrinology Center, Minsk, Belarus

Introduction: Pseudohypoparathyroidism (PHP) is a rare genetic disorder characterized by end-organ resistance to parathyroid hormone (PTH), which results in patients developing hypocalcemia and hyperphosphatemia despite increased serum PTH levels. Moreover, its association with Albright Hereditary Osteodystrophy (AHO)—a set of distinctive physical features,

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

usually contributes to a prompt diagnosis. We report the case of a patient presenting with AHO phenotype, seizures, history of metatarsal fractures, extensive cerebral calcifications and previously normal calcium-phosphorus levels.

Case report: A 15-year-old male was referred for endocrine consultation after a sudden deterioration in his condition (fatigue, seizures, tetany, facial twitching). Patient's physical features were consistent with AHO (short stature—150 cm, round face, brachydactyly and subcutaneous ossifications) and medical history was remarkable for fractures of 2nd and 3rd metatarsals in one foot and fractures of proximal phalanges in another. The patient was formerly diagnosed with Fahr's syndrome due to abnormal findings on plain CT scan of the head which revealed symmetrical linear and focal calcification in the white matter of the frontoparietal zones and in basal ganglia. There was no documented evidence of previously abnormal laboratory results and his family history was unremarkable. Laboratory testing revealed elevated PTH of 79 pg/ml (14,9-56,9 pg/ml), low serum calcium of 1.16 mmol/L (2.1-2.6 mmol/L), high phosphorus of 1.66 mmol/L (0.81-1.62 mmol/L), high TSH of 10.5 µIU/mL (0.7-4.2 µIU/mL) and low free T4 of 10.1 pmol/L (11-23 pmol/L). According to patient's DEXA, bone mineral density was lower than that of the same age group (Z-score −2.1 in L1-L4 vertebrae). Additionally, X-ray of left hand revealed epiphyseal closure. Based on the presented clinical, laboratory and radiological findings, the diagnosis of PHP was established. Confirmation of PHP with genetic testing was not performed due to its unavailability. Patient was started on a regimen of oral calcium, calcitriol and levothyroxine, leading to significant improvement. On further follow-ups, patient remained asymptomatic with adequate compensation of PHP.

Conclusions: This clinical case emphasizes the importance of repeated phosphocalcic and PTH levels assessment in patients presenting with AHO phenotype and clinical manifestations of hypocalcemia despite previously normal levels to solve the diagnostic puzzle and improve patient's long-term outcomes.

EP311 - ECE_2906 - When bones tell a genetic story: a young woman with Albright's hereditary osteodystrophy and GNAS mutation causing pseudopseudohypoparathyroidism

Adelola Adekolu-John and Muhammad Athar Iqbal Khan
Rotherham, United Kingdom

When Bones Tell a Genetic Story: A Young Woman with Albright's Hereditary Osteodystrophy and GNAS Mutation Causing Pseudopseudohypoparathyroidism

We present the case of a 22-year-old woman referred with long-standing musculoskeletal deformities and progressive pain. She reported finger and toe abnormalities since childhood, with a 2-3-year history of worsening stiffness and pain affecting the hands, wrists, back, hips, and feet. Additional symptoms included fatigue, mood fluctuation, weight gain, and reduced mobility. There was no history of joint swelling, dysphagia, hearing impairment, or significant endocrine disturbance. She sustained a low-impact ankle fracture the previous year with prolonged healing.

Examination demonstrated brachydactyly, particularly involving the 4th metacarpals and toes, enlarged distal interphalangeal joints of both thumbs, limited MCP movements, asymmetrical hypermobility, and painful restriction of hip movements. Biochemistry revealed persistently normal adjusted calcium (2.39 mmol/L) and phosphate, elevated parathyroid hormone (PTH 8.3 pmol/L), and low 25-OH vitamin D (32 nmol/L). Genetic testing identified a pathogenic GNAS mutation.

The patient exhibited classical features of Albright's hereditary osteodystrophy (AHO), including short stature, brachydactyly, joint abnormalities, and ectopic bone-related symptoms. Given normal calcium and phosphate with raised PTH (likely secondary to vitamin D deficiency), this presentation is most consistent with pseudopseudohypoparathyroidism (PPHP) rather than pseudohypoparathyroidism (PHP).

PHP is characterised by end-organ resistance to PTH, leading to hypocalcaemia, hyperphosphatemia, and elevated PTH, often with AHO features. In contrast, PPHP shows the AHO phenotype without biochemical resistance. Vitamin D replacement was initiated and repeat PTH is planned to clarify the diagnosis. Thyroid and pituitary axes are under evaluation.

This case highlights the importance of integrating genetic, biochemical, and phenotypic data in young patients with unexplained skeletal abnormalities and chronic pain.

EP313 - ECE_1755 - A case of challenging localization in primary hyperparathyroidism

Jelena Marinkovic Radosevic[1], Lora Kirigin Biloš[1], Velimir Altabas[1,2] and Gorana Mirosevic[1,3]
[1]*University Hospital Centre Sestre Milosrdnice, Department of Endocrinology, Diabetes and Metabolic Diseases "Mladen Sekso", Zagreb, Croatia;* [2]*School of Medicine, University of Zagreb, Zagreb, Croatia;* [3]*School of Dental Medicine, University of Zagreb, Zagreb, Croatia*

Preoperative localization of hyperfunctional parathyroid tissue can, in rare cases, be challenging. Cervical ultrasonography combined with [99mTc]Tc-MIBI scintigraphy typically provides a diagnostic sensitivity of 81%-95%. In patients with discordant findings, fine-needle aspiration (FNA) cytology with parathyroid hormone measurement in the aspirate (FNA-PTH) may help confirm parathyroid origin. [18F]fluorocholine PET/CT is considered a second-line modality with reported sensitivity up to 95%. Although standard CT generally has limited value in detecting enlarged parathyroid glands, it can provide diagnostic support when first-line imaging is inconclusive or negative, or when alternative imaging techniques are unavailable.

We present a case that highlights the challenges in localizing a parathyroid adenoma in a patient with primary hyperparathyroidism. A 57-year-old woman presented with several years of polyuria (4 L/24 h). Her medical history included obstructive sleep apnoea, hyperlipidaemia, osteopenia, and partial empty sella with normal anterior pituitary function. Laboratory evaluation revealed hypercalcaemia (2.7 mmol/L; ref. 2.1-2.5), normal phosphate (0.8 mmol/L; ref. 0.7-1.4), sufficient 25-hydroxyvitamin D (103 nmol/L), normal renal function (creatinine 59 µmol/L), hypercalciuria (12.2 mmol/24 h; ref. <7.9), and elevated PTH (11.4 pmol/L; ref. 1.6-6.9), confirming primary hyperparathyroidism.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Despite clear biochemical evidence of disease, all standard localization studies were negative, including cervical ultrasound with FNA cytology, [99mTc]Tc-MIBI scintigraphy, and [18F]fluorocholine PET/CT. Finally, a conventional neck CT identified a 16 × 8 mm contrast-enhancing lesion posterior and caudal to the right thyroid lobe, suspicious for an enlarged parathyroid gland. Following FNA confirmation of parathyroid tissue, the patient proceeded to surgery, where an enlarged right superior parathyroid gland was identified, together with additional parathyroid tissue adjacent to the inferior pole of the right thyroid lobe. Both lesions were removed. Histopathology confirmed a right superior parathyroid adenoma (1.5 × 0.7 × 0.4 cm) and incidentally revealed a microadenoma (of the right inferior gland (0.3 cm). Postoperatively, calcium and PTH levels normalized.

This case highlights that, in selected patients with primary hyperparathyroidism, conventional CT—despite historically limited sensitivity—may serve as a valuable adjunct when standard imaging fails to localize pathological glands.

EP314 - ECE_3852 - Unveiling McCune-Albright syndrome: polyostotic fibrous dysplasia and hyperfunctioning endocrinopathies

Natasha Petrovska[1], Cvetanka Volkanovska Ilijevska[1], Marija Zivkovic[1], Irfan Ahmet[1], Bojan Boskovski[2] and Ivica Kocevski[3]

[1]Diabetes and Metabolic Disorders, PHI University Clinic of Endocrinology, Skopje, North Macedonia; [2]University Clinic of Neurology, Skopje, North Macedonia; [3]PHI University Clinic of Neurosurgery, Skopje, North Macedonia

Introduction: Fibrous Dysplasia (FD) is a disorder characterized by the replacement of bone tissue by fibrous tissue and irregularly distributed bone trabeculae, increasing the risk of pathological fractures. It may impact either a solitary bone (monostotic) or multiple bones (polyostotic; PFD). The proximal femur, ribs, and skull base are the most often affected bones. PFD accompanied by café-au-lait skin pigmentation and hyperfunctioning endocrinopathies is identified as McCune-Albright syndrome (MAS).

Case report: We report a case of a 22-year-old male patient presenting with severe headaches, left eye ptosis, and visual field deficits. He was initially assessed at the neurology clinic. MRI scans showed a pituitary macroadenoma with suprasellar and parasellar extension and abnormally expanded bones of the skull and face. The medical history included pathological fractures of both femurs at age of 12 and several corrective surgeries for subsequent bone bowing. Skeletal radiographs showed multiple lytic lesions in the femur and tibia. A 99mTc-MDP full-body scan demonstrated radiotracer uptake in the appendicular and axial bones. The patient was treated with intravenous bisphosphonates since he was 17 years old; however, confirmatory testing for bone disease was not done. The skeletal investigations were indicative of PFD. The presence of café-au-lait skin pigmentation implied MAS. Hormonal analysis confirmed acromegaly and hypopituitarism. After transcranial surgical decompression treatment with Sandostatin LAR was initiated, however, due to an insufficient therapeutic response, a decision was made to switch to Pasireotide every 28 days. Patient remains under our care for regular follow-ups and monitoring.

Conclusions: MAS is a diagnostic challenge and a delayed diagnosis might result in significant consequences. Screening and early detection of endocrinopathies can improve the quality of life of patients with PFD.

EP315 - ECE_1462 - Effectiveness of 4DCT for preoperative parathyroid localization in undetectable parathyroid gland from conventional study in Siriraj Hospital

Anchisa Triphob[1], Pradit Rushatamukayanunt[1], Tanakorn Tarapongpun[1], Mongkol Boonsripitayanon[1], Pongthep Pisarnturakit[1], Suebwong Chuthapisith[1], Benjapa Khiewvan[2], Dittapong Songsaeng[2] and Waraporn Imruetaicharoenchoke[1]

[1]Faculty of Medicine Siriraj Hospital, Mahidol University, Head-Neck and Breast Surgery, Surgery, Bangkok, Thailand; [2]Faculty of Medicine Siriraj Hospital, Diagnostic Radiology, Radiology, Mahidol University, Bangkok, Thailand

Objective: To evaluate the effectiveness of four-dimensional computed tomography (4DCT) for preoperative localization of parathyroid glands in patients whose can't localized by conventional imaging (Tc-99m sestamibi SPECT/CT or parathyroid scintigraphy) and undergoing parathyroid surgery at Siriraj Hospital.

Materials and Methods: This retrospective study included patients diagnosed with primary, secondary, or tertiary hyperparathyroidism between 2013 and 2025 whose parathyroid lesions could not be localized by conventional imaging and underwent 4DCT, parathyroid surgery and follow up at Siriraj Hospital. Concordance between 4DCT localization, intra-operative findings, and pathological results was assessed. Clinical characteristics, surgical outcomes, and enhancement patterns based on Hounsfield unit (HU) measurements were analyzed.

Results: A total of 72 patients with total 85 4DCT detected preoperative localization of parathyroid glands were analyzed. Effectiveness of 4DCT preoperative localization, surgical resection and pathological was truly parathyroid gland were 77 of 85 glands (90.6%). No demographic or clinical patient factors were significantly associated with surgical success or failure, although body mass index $\geq$25 kg/m^2 showed trend toward unsuccessful but non-significant. The only significant factor was imaging predictor of true-positive localization was lower non-contrast HU attenuation. Ectopic glands were identified in 31.8% of cases and no significant associated with Unsuccessful surgery.

Conclusions: In this highly selected cohort with non-pre-operative localization parathyroid gland by conventional imaging, 4DCT demonstrated high clinical effectiveness imaging for pre-operative parathyroid localization. Low HU in non-contrast phase was the only significant imaging factor associated with true-positive localization, while no definitive patient-related predictors of surgical success were identified. These findings support the role of 4DCT as a valuable second-line imaging tool in

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

complex hyperparathyroidism case, particularly in resource-limited settings.

Keywords parathyroid, 4DCT, hyperparathyroidism, preoperative localization, re-operative parathyroid surgery

EP317 - ECE_2403 - Giant parathyroid adenomas mimicking parathyroid carcinoma: a case series

Humera Tabassum[1,2,3], Gowry Reddy[1,2,3], Julie Nguyen[1,2,3], Aleksandra Schriber[1,3] and Karyne Vinales[1,2]
[1]*Endocrinology, University of Arizona College of Medicine, Phoenix, United States;* [2]*Phoenix VA Healthcare System, Phoenix, United States;* [3]*Endocrinology, Medicine, Banner—University Medical Center Phoenix, Phoenix, United States*

Background: Giant parathyroid adenomas, defined as lesions weighing >3.5 g, are rare causes of primary hyperparathyroidism. Their size, biochemical derangements, skeletal involvement, and imaging raise concern for parathyroid carcinoma. Accurate diagnosis requires integration of radiologic, histopathologic, and postoperative biochemical data. Hungry bone syndrome is a recognized complication and may be delayed.

Case Series: We report two cases of severe primary hyperparathyroidism caused by giant parathyroid adenomas with biochemical, radiologic, surgical, and pathologic overlap with malignancy.

Case 1 involved a 32-year-old male presenting with left foot pain and hypercalcemia (14.6 mg/dL). Parathyroid hormone (PTH) peaked at 3019 pg/mL with elevated alkaline phosphatase (867 IU/L). Imaging demonstrated a left parathyroid mass with diffuse skeletal FDG uptake and lytic bone lesions concerning for metastatic disease. En bloc resection of a left superior parathyroid mass with hemithyroidectomy was performed due to adherence to surrounding structures. Histopathology revealed an encapsulated hypercellular parathyroid tumor measuring 3.2 cm and weighing 4.3 g, without atypia or capsular, vascular, or perineural invasion. Ki-67 confirmed a low proliferative index, consistent with a giant parathyroid adenoma. Intraoperative PTH declined from 2146 pg/mL to 190 pg/mL. Postoperatively, the patient developed hungry bone syndrome requiring intravenous and oral calcium and calcitriol. PTH decreased to 118 pg/mL at one week and 83 pg/mL at two weeks, followed by a gradual rise (173-232 pg/mL) with normocalcemia, consistent with postoperative PTH rebound. Left foot pain resolved, and alkaline phosphatase improved to 209 IU/L.

Case 2 A 54-year-old female presented with syncope, polyuria, and polydipsia and was found to have hypercalcemia (14.1 mg/dL), elevated alkaline phosphatase (1199 IU/L), and parathyroid hormone (PTH) exceeding 5000 pg/mL. Imaging demonstrated a right parathyroid mass abutting the posterior pole of the right thyroid lobe, showing tracheoesophageal mass effect. She underwent superior parathyroidectomy with intraoperative PTH decline to 36 pg/mL and postoperative normocalcemia. Pathology revealed a hypercellular adenoma weighing 19.2 g, with no evidence of atypia, increased mitoses, necrosis, or capsular, lymphovascular, or perineural invasion. One month later, she re-presented with hypocalcemia (corrected calcium 5.8 mg/dL), elevated PTH (184 pg/mL), and improving alkaline phosphatase (577 IU/L), consistent with delayed hungry bone syndrome.

Conclusions: PTH elevation, tumor size, mass effect, and skeletal imaging abnormalities do not imply malignancy. Integration of imaging, histopathology, and postoperative PTH trends is essential to distinguish giant parathyroid adenomas from carcinoma. Hungry bone syndrome may be severe or delayed, requiring anticipatory calcium management and biochemical surveillance.

EP318 - ECE_2495 - Giant parathyroid adenoma unmasked by acute pancreatitis and Osteitis Fibrosa Cystica: a case report

Octavian Alexandrescu[1], Ioana Herghea[1,2], Andrei Muresan[1], Dana Terzea[1], Dana Manda[1], Suzana Vladoiu[1], Sorina Schipor[1], Elena Braha[1] and Madalina Daniela Lucia Musat[1,2]
[1]*C. I. Parhon National Institute of Endocrinology, Bucharest, Romania;* [2]*Carol Davila University of Medicine and Pharmacy, Bucharest, Romania*

Introduction: Giant parathyroid adenomas (GPAs), defined as parathyroid adenomas weighing more than 3.5 g, are extremely rare clinical entities (approximately 1.5% of all parathyroid adenomas) and are often associated with severe bone disease, such as osteitis fibrosa cystica (OFC). While their pathogenesis remains unclear, GPA can exhibit both benign and malignant biochemical, histological and molecular features.

Case report: We present the case of a 51-year-old Caucasian woman who experienced left thigh muscle weakness and pain, along with difficulty walking, just several weeks before she was admitted to the intensive care unit with loss of consciousness. She was diagnosed with acute pancreatitis due to severe hyperparathyroidism: total serum calcium 18 mg/dL (4.49 mmol/L), serum intact PTH 1504 pg/mL (reference range: 17.3-74.1 pg/mL) and vitamin D deficiency (serum 25-hydroxyvitamin D: 13.13 ng/mL). Neck CT scan identified a $63 \times 40 \times 23$ mm tumor inferior and posterior to the right thyroid lobe, while left femur X-ray demonstrated a distal cystic lesion consistent with OFC. She underwent right inferior parathyroidectomy and histopathology revealed a giant parathyroid adenoma of $6.3 \times 4.1 \times 2.2$ cm, weighing 32.7 g, without atypical features. Immunohistochemistry showed diffuse positive expression of parafibromin/CDC73 and chromogranin A, and a Ki-67 index of 1% in tumor cells. Postoperatively, PTH levels decreased to 20.41 pg/mL and normal calcium levels were maintained with calcitriol and calcium supplements. However, left femur fracture occurred during hospitalization, requiring further orthopedic surgery.

Discussion: Although molecular studies of atypical parathyroid tumors have demonstrated several somatic mutations in cell-cycle control genes, such molecular signatures account for only a small fraction of GPAs. Next-generation sequencing (NGS) for germline and somatic mutations in MEN1, CDC73, VDR and CASR is pending. More likely, coexistent vitamin D deficiency contributed to the giant adenoma and OFC in this case, as the inverse relationship between parathyroid adenoma weight and serum 25-hydroxyvitamin D level was confirmed in a larger number of patients from different parts of the world (Rao DS et al).

Conclusions: This case is remarkable for several reasons: (1) acute pancreatitis that has unmasked the diagnosis of hyperparathyroidism, (2) giant parathyroid adenoma without atypical features coexisted with vitamin D deficiency and (3) OFC

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

complicated by femoral fracture, an otherwise rare occurrence in contemporary hyperparathyroidism.

Abstract citation ID: lvag096.861

EP319 - ECE_2847 - A patient Familial Hypocalciuric Hypercalcaemia (FHH) presenting with moderate hypercalcaemia

Ishara Ranathunga, Chandima Idampitiya and Fathima Pambinezhut
Endocrinology, North Cumbria University Hospitals Nhs Trust—Carlisle Library, Carlisle, United Kingdom

Background: Familial hypocalciuric hypercalcaemia (FHH) is a rare inherited disorder of calcium homeostasis, most commonly caused by inactivating variants of the calcium-sensing receptor (CaSR) gene. It is characterised by lifelong, usually asymptomatic hypercalcaemia, inappropriately normal or mildly elevated parathyroid hormone (PTH) levels, and low urinary calcium excretion. The condition can closely mimic primary hyperparathyroidism (PHPT), and failure to distinguish between the two may result in unnecessary investigations or parathyroid surgery.

Case presentation: A 69-year-old gentleman with persistent hypercalcaemia for 11 years was referred for further evaluation. He had a history of depression and type 2 diabetes. The patient reported long-standing polyuria with normal thirst. There was no history of nephrolithiasis, fractures, skeletal symptoms or known family history of hypercalcaemia. Examination revealed mildly elevated blood pressure but was otherwise unremarkable. Investigations were consistent with elevated adjusted serum calcium levels, with a highest value of 3.09 mmol/L. Serum phosphate levels were within the normal range and PTH levels were inappropriately normal in the context of hypercalcaemia. Vitamin D and renal function were normal. Twenty-four-hour urinary calcium excretion was low at 1.3 mmol/24 h, and fractional excretion of calcium was markedly low at 0.003, strongly suggestive of FHH. Genetic testing subsequently confirmed a pathogenic variant consistent with Familial Hypocalciuric Hypercalcaemia Type 1 (FHH1). A dual-energy X-ray absorptiometry scan and ultrasound urinary tract was arranged as part of baseline assessment.

Discussion: This case emphasises the diagnostic complexity of FHH, particularly in a symptomatic patient when serum calcium concentrations are higher than typically expected. Reliance on serum calcium and PTH levels alone may be misleading, highlighting the importance of fractional calcium excretion. Particularly in patients with acceptable vitamin D levels and retained renal function, a significantly lower fractional excretion of calcium continues to be a crucial differentiator between FHH and PHPT. Although FHH is generally asymptomatic and benign, patients may present with non-specific symptoms such as polyuria or neuropsychiatric complaints, which further complicate clinical assessment. In addition to providing a precise diagnosis, genetic confirmation has consequences for long-term care, counselling, and family screening. Importantly, parathyroidectomy is ineffective in FHH and should be avoided, highlighting the clinical significance of early and accurate diagnosis.

Conclusions: FHH should be considered even in symptomatic patients with longstanding moderate hypercalcaemia. Early recognition and genetic confirmation can prevent unnecessary interventions and ensure appropriate counselling and follow-up.

EP320 - ECE_2901 - Palopegteriparatide treatment for chronic hypoparathyroidism: a report of three cases

Karmelo Lovric[1], Anja Barac Nekic[2], Karin Zibar Tomsic[2] and Ivana Kraljevic[2,3]
[1]*Department of Endocrinology, General Hospital "Dr. Ivo Pedisic" Sisak, Sisak, Croatia;* [2]*Zagreb, Croatia;* [3]*School of Medicine, University of Zagreb, Zagreb, Croatia*

Background: Chronic hypoparathyroidism (HypoPT) may be associated with persistent hypocalcaemic symptoms and a high treatment burden despite conventional therapy with oral calcium and active vitamin D.

Case presentation: We report three patients with chronic HypoPT (two postsurgical, aged 60 and 70 years, and one autoimmune, aged 40 years) with recurrent symptoms of hypocalcaemia, including paresthesias and muscle cramps, despite long-term intensive conventional treatment. Prior to parathyroid hormone replacement, all patients required high daily doses of oral calcium and calcitriol yet remained incompletely biochemically controlled. Two patients presented with electrolyte instability (total calcium 1.3 and 1.86 mmol/L; phosphate 1.81 and 1.77 mmol/L, respectively); one of them had impaired renal function, while the third patient developed malabsorption following jejunostomy placement.

Results: Following initiation of palopegteriparatide therapy, two patients showed normalisation of serum calcium and phosphate concentrations within the first week of treatment, allowing withdrawal of oral calcium and active vitamin D supplementation. The third patient, previously treated with teriparatide, resulting in more stable calcium concentrations and reduced supplementation requirements, was recently transitioned to palopegteriparatide. Across all patients, hypocalcaemic symptoms were no longer reported during follow-up. No treatment-related adverse events were observed. Renal function improved in a patient who had pre-existing impairment.

Conclusions: This case series illustrates the clinical limitations of conventional therapy in chronic HypoPT and shows that parathyroid hormone replacement may facilitate biochemical stabilization and reduction of treatment burden in selected patients.

Unidade Local de Saúde de Almada-Seixal, Almada, Portugal

Background: Primary hyperparathyroidism (PHPT) may present with neuropsychiatric manifestations, particularly in elderly patients, and can mimic primary psychiatric disorders, potentially delaying diagnosis.

Case presentation: We report the case of a 73-year-old woman with stage G3b chronic kidney disease and a solitary kidney.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

One month prior to admission, she developed new-onset psychiatric symptoms characterized by anxiety and depressive features. She was evaluated by her primary care physician and a psychiatrist, and psychiatric medication was initiated and titrated (benzodiazepines followed by venlafaxine). Despite treatment, the patient experienced progressive cognitive and behavioural deterioration in the weeks preceding hospitalization, including disorientation, confabulation, visual hallucinations, and persecutory delusions. She denied systemic, infectious, or focal neurological symptoms. Physical examination on admission was unremarkable.

Initial laboratory evaluation revealed acute-on-chronic kidney injury (creatinine 2.2 mg/dL; eGFR 22 mL/min/1.73 m^2) and hypoalbuminemia (3.1 g/dL), and no elevation of inflammatory markers. Further investigation prompted by persistent confusional symptoms demonstrated severe hypercalcemia (corrected calcium 13.4 mg/dL) with markedly elevated parathyroid hormone (PTH 886 pg/mL), hypophosphatemia (1.9 mg/dL), and hypomagnesemia (1.3 mg/dL), establishing the diagnosis of PHPT. The patient received aggressive intravenous hydration, resulting in improved renal function and partial correction of hypercalcemia. Bisphosphonates were avoided due to CKD. Cinacalcet was initiated at 30 mg twice daily with biochemical improvement. Localization studies identified a 4 cm right inferior parathyroid lesion on 4D-CT with delayed washout on scintigraphy. Given surgical criteria including symptomatic severe hypercalcemia (>1 mg/dL above upper normal limit), hypercalciuria, and CKD, parathyroidectomy was performed. Intraoperative PTH monitoring demonstrated an appropriate decline from 628 pg/mL preoperatively to 129 pg/mL (79% reduction), predicting surgical success. Histopathology confirmed a parathyroid adenoma. Postoperatively, calcium and PTH levels normalized with complete resolution of neuropsychiatric symptoms. At one-year follow-up, calcium levels remain controlled.

Conclusions: This case highlights PHPT as a reversible cause of acute confusional and psychiatric symptoms in elderly patients. Despite specialist psychiatric evaluation and treatment, the underlying metabolic disorder was initially missed. Serum calcium measurement should be included in the initial metabolic evaluation of new-onset neuropsychiatric presentations, particularly in older adults, to avoid diagnostic delay of this treatable condition.

EP324 - ECE_1196 - Bone loss after high-dose glucocorticoid therapy in patients with non-idiopathic pulmonary fibrosis interstitial lung disease

Jeeyeun Hwang, Junghae Ko and Mikyung Kim
Internal Medicine, Inje University Haeundae Paik Hospital, Inje University College of Medicine, Busan, South Korea

Background: Interstitial lung disease (ILD) patients often require high-dose steroids, increasing osteoporosis risk. However, data on bone mineral density (BMD) changes in ILD patients from Asian populations, particularly Korea, are scarce. We aimed to evaluate longitudinal changes in BMD, body composition, and bone metabolic markers in a Korean ILD cohort before and after glucocorticoid therapy.

Methods: Eligible participants were ILD patients treated with prednisolone ≥5 mg/day for at least 3 months during the study period (August 2020 to August 2021). BMD was measured at baseline and 12 months. Body composition, bone metabolic markers were measured at baseline, 6 months, and 12 months. BMD changes were analyzed using paired t-tests or Wilcoxon signed-rank tests, and repeated-measures ANOVA was used for body composition and bone metabolic markers.

Results: Non-Idiopathic pulmonary fibrosis ILD patients ($n = 18$) were analyzed. BMD at the lumbar spine, femoral neck, and total hip decreased by 4.3%, 2.0%, and 1.8% (all $P < .05$). Body weight and muscle mass showed no change, whereas body fat percentage increased from 31.6% to 34.9% ($P < .001$). Vitamin D deficiency was 61% (67% men, 58% women).

Conclusions: In this Korean ILD cohort, glucocorticoids induce rapid, lumbar-predominant bone loss. Fat gain with preserved body weight cannot be detected without body composition assessment. The high prevalence of vitamin D deficiency, especially in men, remain a concern in Korean patients with ILD.

Abstract citation ID: lvag096.865

EP325 - ECE_1260 - Two-year outcomes in an adult with x-linked familial hypophosphatemia treated with burosumab

Maria Ponte, Andreia Pataco, Regina Medeiros, Ana Figueiredo, Carolina Chaves, Catarina Senra, Isabel Sousa, João Anselmo and Bernardo Gago Da Câmara Dias Pereira
Ponta Delgada, Portugal

Introduction: X-linked hypophosphatemia (XLH) is a rare disorder caused by inactivating mutations in the phosphate-regulating endopeptidase X-Linked (PHEX) gene, leading to increased serum fibroblast growth factor 23 (FGF23). Elevated FGF23 reduces renal tubular phosphate reabsorption (TmP/GFR), resulting in chronic hypophosphatemia and impaired skeletal mineralization. Burosumab, a new monoclonal antibody that targets FGF23, has demonstrated biochemical, radiographic and functional improvement in children with XLH, but long-term data in adults is still scarce. We report the outcomes of a 54-year-old woman with XLH after 2 years of burosumab therapy.

Case report: A 44 years-old female was referred to the Endocrinology consultation due to hypophosphatemic rickets. She had a medical history since her 3 years old of progressive lower limbs deformities, gait impairment, and growth deceleration, which resulted in severe short stature (-4SD). She also started presenting paresthesia, generalized bone pain and recurrent dental caries. She started cholecalciferol at 6 years old. Adult height was 136 cm, and she subsequently underwent 20 limb-lengthening surgeries, achieving 146 cm. A low-trauma femoral fracture occurred at the age of 26 and evolved into hypertrophic pseudarthrosis. Progressive functional decline resulted in premature retirement. At Endocrinology appointment hypophosphatemia, inappropriately high 1.,25-dihydroxyvitamin D and a TmP/GFR of 2.1 mg/dL (2.6-3.8) were found. Dual X-ray absorptiometry demonstrated a T-score of −3.2SD at the radius, and 1.7 SD to 2.7SD at the lumbar spine. Cholecalciferol was substituted by calcitriol (0.75 mcg/day). Genetic testing identified a heterozygous nonsense variant in PHEX (c.1699C > T,

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

p.Arg567*). At age 52, burosumab 60 mg monthly was initiated and calcitriol was discontinued. Biochemical improvement was evident at month 3: serum phosphate increased from 2.1 to 2.7 mg/dL (2.5-4.9) and TmP/GFR to 2.7 mg/dL. The Brief Pain Inventory also demonstrated clinical benefit by the third month, with a reduction in average pain intensity from 6/10 to 2/10. Progressive improvement continued throughout the two-year treatment period. The intensity of the worst pain decreased from 8/10 to 3/10, interference of pain with gait from 9/10 to 5/10, and impact on overall daily activity from 7/10 to 2/10. She formerly relied on crutches for most of her ambulation and is now capable of walking short distances unaided. The hypertrophic pseudarthrosis achieved complete radiographic healing after one year of burosumab therapy.

Discussion: This case illustrates the substantial benefit of starting burosumab in adults with long-standing XLH, allowing normalization of phosphate homeostasis and significant pain and functional improvement.

EP327 - ECE_3712 - Paget's disease of bone: differential diagnosis of a bone lesion suspicious of osteosarcoma

Nektarios Adamopoulos[1], Grigoris Effraimidis[1,2], Maria Apostolopoulou[1,2], Athanasios Kasotas[1], Dionysios Vrachnis[1], Maria Galani[1], Eleni Georgiou[1], Ioannis Gkountios[1], Anastasia-Konstantina Sakali[1] and Alexandra Bargiota[1,2]

[1]Department of Endocrinology and Metabolic Diseases, University General Hospital of Larissa, Larissa, Greece; [2]Faculty of Medicine, Department of Endocrinology and Metabolic Diseases, School of Health Sciences, University of Thessaly, Larissa, Greece

Introduction: Paget's disease of bone (PDB) is a chronic focal disorder of bone remodeling, often asymptomatic and usually is detected incidentally by elevated alkaline phosphatase (ALP) levels. Rarely benign pagetic lesions with atypical imaging features need to be distinguised from secondary osteosarcoma.

Case: A 63-year-old female patient was referred for evaluation of asymptomatic elevated alkaline phosphatase (ALP) levels, identified on routine laboratory testing. The patient reported progressive sensorineural hearing loss and further work up revealed disproportionately elevated bone—specific ALP, increased Procollagen Type I N-terminal Propeptide (PINP) and Beta-CrossLaps (β-CTX) and radiographic findings consistent with PDB such as mixed osteolytic and osteosclerotic changes of the long bones, a "picture-frame" vertebrae in the lumbar spine, osteosclerotic and osteolytic areas in the pelvis and hip. Bone scintigraphy showed an increased uptake in typical pagetic sites, but also a focal osteoblastic activity at the distal part of the right humerus with extension into adjacent soft tissues raising the suspicion of osteosarcoma. Subsequent cross—sectional imaging of this lesion with a CT and an MRI was non-diagnostic. A CT-guided bone biopsy was performed and the histological findings were typical pagetic bone changes with a mosaic pattern of "irregular cement lines", osteoblastic "rimming" at various spots and the presence of several multinuclear osteoclasts forming a pattern of focal "bite" mark. No histological findings compatible with osteosarcoma were present.

Discussion: Atypical presentation of PDB could be confusing and diagnostically challenging. As in rare cases a malignant transformation to osteosarcoma can be seen. The lifetime risk is low (≤1%), but still much higher compared to the general population and is usually observed in older adults with long standing, metabolically active disease. New focal pain, swelling, or presence of a destructive lytic lesion within a pagetic bone should raise suspicion for Pagetic osteosarcoma, which has a poor prognosis. Multidisciplinary collaboration among internists, radiologists, nuclear medicine physicians, and pathologists is essential for accurate diagnosis and optimal management for PDB.

EP328 - ECE_3858 - Rare case of secondary hyperparathyroidism as a manifestation of Celiac disease

Ana Pruidze[1], Tea Khurodze[2,3], Elisabed Pkhaladze[1], Vitali Vashakidze[1,4], Basa Gegeshidze[1,5] and Mariam Tevzadze[6]

[1]David Tvildiani Medical University, Tbilisi, Georgia; [2]David Tvildiani Medical Univeristy, Tbilisi, Georgia; [3]Medical House, Tbilisi, Georgia; [4]Gagua Clinic, Tbilisi, Georgia; [5]Caucasus Medical Center, Tbilisi, Georgia; [6]Tbilisi, Georgia

Background: Secondary hyperparathyroidism (SHPT) is a condition in which the parathyroid glands produce excessive amounts of hormone in response to severe hypocalcemia, rather than due to intrinsic parathyroid disease. The combination of hyperparathyroidism and severe osteoporosis in advanced age is frequently associated with parathyroid adenomas. Celiac disease represents a key underlying condition in which both of these endocrine disorders may occur simultaneously. Mainly this disease is associated with gastrointestinal symptoms, but also presents with extraintestinal manifestations, in adults this diagnosis may be delayed. Disturbances in calcium–phosphate homeostasis are a recognized consequence of chronic intestinal malabsorption, which causes parathormone elevation.

Case presentation: A 58-year-old woman presented to our clinic with severe back pain and a history of multiple recurrent fractures, the most recent involving the ribs. Bone densitometry conducted at our clinic demonstrated high-grade osteoporosis. Comprehensive laboratory investigations performed prior to initiation of therapy demonstrated elevated PTH levels, reduced urinary and serum calcium excretion, normal serum phosphorus concentrations, low levels of corrected calcium, severe vitamin D_3 deficiency, and evidence of hypothyroidism. On ultrasound, multiple thyroid nodules were revealed. Further diagnostic investigations were initiated to exclude the presence of a parathyroid adenoma, kidney dysfunction, and malabsorption syndrome. Repeated parathyroid scintigraphy performed on two separate occasions consistently revealed no scintigraphic evidence of adenoma. Laboratory and ultrasonographic evaluations excluded renal dysfunction and nephrolithiasis. Following consultation with a gastroenterologist,further invasive and laboratory studies were indicated. Laboratory investigations demonstrated markedly elevated tTG-IgA and significantly increased chromogranin

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

A levels. After serological confirmation of Celiac disease, duodenal endoscopy with biopsy was conducted, revealing histopathological evidence of villous atrophy. After correcting calcium and vitamin D3 levels with targeted supplementation and initiating a gluten-free diet, the patient was started on anti-osteoporotic therapy.

Conclusions: In patients with hyperparathyroidism and osteoporosis, this case emphasizes the need to consider secondary causes, including systemic conditions like malabsorption, that may drive persistent elevation of parathyroid hormone. Early recognition and management—including a gluten-free diet, supplementation, and appropriate osteoporosis therapy—are essential to prevent further bone complications and improve patient outcomes.

Abstract citation ID: lvag096.868

EP331 - ECE_2704 - Late diagnosis of X-linked hypophosphatemic rickets in an adult: clinical case and experience with burosumab therapy

Alina Alzhaxina, Kristina Baikadamova and Aigul Durmanova
University Medical Center, Astana, Kazakhstan

Introduction: X-linked hypophosphataemic rickets (XLH) is a rare hereditary disease caused by pathogenic mutations in the PHEX gene. It causes chronic hypophosphataemia and abnormal mineralisation of the bones, resulting in progressive skeletal deformity. XLH can be diagnosed in affected individuals early in the course of their disease. However, in some patients, diagnosis is delayed until adulthood, leading to poor functional outcomes.

Case presentation: We present a 23-year-old male patient with severe skeletal deformities, inability to walk independently, chronic lower limb pain, joint contractures, short stature, and premature tooth loss. Symptoms had been present since birth. During childhood, the patient was repeatedly treated for nutritional rickets without any clinical improvement. On physical examination: height—132 cm, body weight—54 kg, marked deformities of the upper and lower limbs, bilateral genu valgum, thoracic scoliosis, and severe functional limitation were observed, requiring wheelchair assistance. The patient had persistent hypophosphataemia (0.61-0.77 mmol/L), normal total serum calcium levels (2.23-2.32 mmol/L) and slightly decreased vitamin D levels (29.4 ng/mL). Alkaline phosphatase activity (ALP) was elevated (266-284 U/L). Whole-exome sequencing revealed a hemizygous pathogenic nonsense mutation (c.500G > A, p.Trp167Ter) in the PHEX gene. Brain MRI showed a congenital hydrocephalus and Arnold-Chiari malformation, type I. Renal ultrasound revealed no dilation of the upper urinary tract, and eGFR was 157.7 mL/min, confirming preserved kidney function.

Results: The patient started burosumab therapy-1.3 mg/kg subcutaneously every 4 weeks.

After starting burosumab, serum phosphate steadily rose from 0.61-0.70 mmol/L to 0.81 mmol/L, while ALP activity was trending downward. The serum calcium levels and the renal function have remain stable within the normal range. The patient reported an improvement in overall well-being and significant pain reduction. No adverse effects were noted.

Discussion: X-linked hypophosphatemic rickets (XLH) remains a diagnostic and therapeutic challenge due to its rarity and variable clinical presentation. Delayed recognition often leads to irreversible skeletal deformities and functional limitations. The introduction of burosumab has changed the treatment paradigm by directly targeting the underlying pathophysiology of phosphate wasting. This case contributes to the growing clinical experience demonstrating the importance of timely diagnosis and access to targeted therapies in improving long-term outcomes for patients with XLH.

Conclusions: Burosumab provides significant biochemical and clinical benefits in patients with severe phenotype of XLH in adults. Additional studies are needed to further study the effects of burosumab and optimal use in the management of adult XLH.

EP332 - ECE_3864 - Management of hypoparathyroidism in a patient with Fabry disease and advanced chronic kidney disease: a case report on the use of palopegteriparatide

Georgios Kostopoulos, Evangelia Makri, Athanasios Panagiotou and Foteini Adamidou
Endocrinology, Hippokration General Hospital, Thessaloniki, Greece

Background: The concurrence of chronic hypoparathyroidism and severe chronic kidney disease (CKD; estimated glomerular filtration rate [eGFR] < 30 mL/min/1.73 m^2) is rare. Palopegteriparatide has been used as replacement therapy for chronic hypoparathyroidism in Europe since its approval in 2023. However, it has not been studied in patients with advanced CKD. We present a case of postsurgical hypoparathyroidism in a patient with Fabry's disease and advanced CKD post-kidney transplantation, treated with palopegteriparatide.

Case presentation: A 59-year-old man with Fabry disease and a history of kidney transplantation with suboptimal graft function (eGFR 22 mL/min/1.73 m^2) was referred for management of chronic hypoparathyroidism. He had previously undergone total thyroidectomy and subtotal parathyroidectomy for multinodular goiter and parathyroid hyperplasia, respectively. Despite treatment with calcium carbonate (4.5 g/day), sevelamer carbonate (2.7 g/day), cholecalciferol (25000IU weekly) and alfacalcidol 1 mcg daily, biochemical evaluation revealed persistent hypocalcaemia (corrected serum calcium 6.8 mg/dL), hyperphosphataemia (serum phosphate 7.1 mg/dL), inappropriately normal PTH levels (27.7 pg/mL), magnesium 3 mg/dl, and 25-hydroxy-vitamin-D 60 ng/ml. Given inadequate biochemical control, high pill burden, and limited therapeutic options due to CKD, initiation of palopegteriparatide at a starting dose of 18 μg/day was undertaken. The patient achieved eucalcemia within ten days (corrected calcium 9.5 mg/dl) and phosphate levels dropped to 5.8-5.1 mg/dl), allowing discontinuation of alfacalcidol and phosphate binders, followed by calcium supplements eight weeks later. Palopegteriparatide dose remained at 18 μg/day and eGFR stabilized at around 25 mL/min/1.73 m^2 over the next four months of follow-up.

Conclusions: This case highlights that palopegteriparatide may be an effective and well-tolerated therapeutic option in select patients with hypoparathyroidism and advanced CKD when conventional therapy fails.

EP334 - ECE_1682 - Complexities in the management of multiple endocrine neoplasia syndrome type 1

Tatsiana Mokhort[1], Alena Khilko[2], Natalia Likharad[3] and Alena Atlivanchik[4]
[1]Endocrinology, Belarusian State Medical University, Minsk, Belarus; [2]Belarusian State Medical University, Minsk, Belarus; [3]1 Minsk City Hospital, Minsk, Belarus; [4]Minsk City Clinical Endocrinological Center, Minsk, Belarus

Introduction: Multiple endocrine neoplasia syndrome type 1 (MEN 1) is a group of heterogeneous inherited diseases, caused by hyperplasia or neoplastic transformation of several endocrine glands and characterized by variable combinations of endocrine disorders.

Results: Women, 45 y.o., was examined for newly registered episodes of hypoglycemia up to 1.9 mmol/L and hyperinsulinemia. According to imaging data, a mass measuring 43*52*48 mm was detected in the body of the pancreas, and a mass up to 1.7*1.1 cm with a density of up to 11 HU was detected in the left adrenal gland. Total gastro-pancreaticduodenal resection with splenectomy and cholecystectomy, left-sided adrenalectomy (morphologically—gastric and pancreatic NET's) was performed, after which malabsorption syndrome, pancreatogenic diabetes and hypercalcemia developed. Dominant parathyroid gland (left upper) and signs of activity of the remaining parathyroid glands were revealed after scintigraphy of the parathyroid gland (PTG) with pertechnetate (Tc-99m). After removal of the dominant parathyroid gland the patient continued to have malabsorption syndrome, despite the use of enzymatic drug. Genetic testing revealed a heterozygous variant (chr11: g.64804740dup, NM_001370259.2:c.1429dup, rs886041214) in exon 10 (out of 10) of the MEN1 gene, known in the literature as 1539insG. Hypercalcemia and elevated PTH levels persist. A family history includes the presence of NETs in 1st and 2nd degree relatives. Taking into account the patient's family history and the presence of genetically confirmed MEN 1 syndrome, surgical treatment with removal of active parathyroid glands and genetic testing of children are recommended.

Conclusions: One of the key issues in the management of MEN 1 is the choice of extent of surgery which is determined not only by the tumor size, invasion, and malignancy potential, but also by the presence of nonfunctioning gastroenteropancreatic NET's and manifestations of hyperparathyroidism.

EP336 - ECE_3735 - Hypopituitarism: a new risk factor for mineral and bone pathology

Miruna-Viorela Nacu[1], Oana Maria Teodora Georgescu[1], Sorina Martin[1,2], Anca Sirbu[1,2] and Carmen Barbu[1,2]
[1]Endocrinology, Diabetes Mellitus, Nutrition and Metabolic Diseases, Elias Emergency University Hospital, Bucharest, Romania; [2]Endocrinology, Diabetes Mellitus, Nutrition and Metabolic Diseases, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Neuroendocrinology of bone is an emerging domain exploring the direct impact of pituitary hormones on bone metabolism. Studies assessing bone health in patients with pituitary hyper or hypofunction are the cornerstone of understanding the in vivo effects of these hormonal disturbances. Data from clinical studies in patients with hypopituitarism are scarce and extremely heterogenous given the intricate complexities of this pathology and lack of objective biomarkers of adequate hormonal substitution. Herein we explore the relationship between hypopituitarism and bone metabolism.**Methods:** We performed a retrospective observational study between 2010-2024 in a tertiary endocrinology center with the aim of characterizing mineral and bone metabolism among patients with hypopituitarism (defined as deficiency in one or more pituitary axes).

Results: Sixty patients with hypopituitarism were included, mean age at diagnosis was 49.22 ± 17.11 years, 63.3% of them were women. In 36 cases, the etiology was a pituitary adenoma (83.34% macroadenomas). Using T-scores, 19 patients had osteopenia and 5 osteoporosis. In premenopausal women and men below 50 years, using Z-scores, 11 had low bone mineral density (BMD) for age and sex. Younger age at diagnosis was associated with lower BMD at lumbar spine ($P = .002$). 18 patients had low IGF1 levels matched for age and sex (median 76.73 ng/ml, IQR = 95.6) and these were positively correlated with serum levels of calcium ($P = .014$) and phosphate ($P = .033$), but not with BMD nor TBS (trabecular bone score). 80% of patients had central gonadal insufficiency. Testosterone levels were strongly significantly correlated with BMD at lumbar spine ($P = .008$). 60% of patients had central thyroid insufficiency (CTI), and 51.67% patients had central adrenal insufficiency (CAI). Patients with CTI were more likely to associate CAI ($P = .004$). FreeT4 levels had a median value of 1.09 ng/dl (IQR = 0.30) and were negatively correlated with BMD at lumbar spine ($P = .026$) and hip ($P = .003$) but not with TBS ($P = .355$). In our dataset, patients with thyroid insufficiency had lower levels of serum phosphate ($P = .004$) and alkaline phosphatase ($P = .021$), and higher levels of PTH ($P = .013$), BMD at lumbar spine and TBS, suggesting a possible low bone turnover state, with a possible compensatory rise in PTH. Patients with CAI also showed the same statistical significant associations but only for PTH levels and TBS.

Conclusions: More studies are needed to understand the mechanisms behind bone modeling and remodeling and their connection with pituitary hormones. First of all, awareness should be made among clinicians that hypopituitarism may be associated with disturbances in bone metabolism.

EP337 - ECE_1648 - Challenging hypoparathyroidism: two cases of poorly controlled disease

Carla Columbu, Alfredo Scillitani, Flavia Pugliese, Claudia Battista and Vito Guarnieri
Fondazione Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy

Background: Hypoparathyroidism is a rare endocrine disorder characterized by hypocalcemia and low parathyroid hormone (PTH) levels. Conventional therapy with oral calcium and active vitamin D is often biochemically effective; however, disease management can be challenging in specific clinical settings such as postsurgical hypoparathyroidism, long-standing idiopathic forms, and during pregnancy or lactation. In these contexts, calcium homeostasis may be highly unstable, resulting in recurrent

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

symptomatic hypo- or hypercalcemia along with a poor quality of life.

We report two cases of severe and poorly controlled hypoparathyroidism that required careful and individualized clinical management.

Case presentations: Case 1

A 63-year-old woman, with type 2 diabetes mellitus and arterial hypertension, developed severe postsurgical hypoparathyroidism following combined total thyroidectomy and parathyroidectomy performed for multinodular goiter and primary hyperparathyroidism. Her medical history was also notable for breast cancer, previously treated with quadrantectomy and she was still receiving aromatase inhibitor therapy. Two weeks after surgery, she presented to Emergency Department with symptomatic hypocalcemia (serum calcium albumin-adjusted 5.9 mg/dL), associated with neuromuscular irritability, dysphagia with progressive paresthesia, despite oral supplementation with calcium carbonate (1 g twice daily) and calcitriol (0.25 μg twice daily). Due to the persistence of severe hypocalcemia despite the progressive increase of conventional therapy, and despite patient's history of breast cancer, treatment with teriparatide 20 mcg/die started with complete resolution of symptom and progressive normalization of serum calcium levels.

Case 2

The second case involves a 29-year-old woman with long-standing idiopathic hypoparathyroidism, diagnosed in childhood following tetanic seizures that were misdiagnosed as epilepsy. Her clinical course was characterized by extreme variability of serum calcium levels, with recurrent episodes of symptomatic hypo- and hypercalcemia despite multiple adjustments of therapy with calcium, calcitriol and thiazides. She was referred to our Endocrinology Unit for severe hypercalcemia (serum calcium 16 mg/dL) occurring one month after delivery, during lactation. After withdrawal of therapy, eucalcemia was reached throughout the entire breastfeeding period. After cessation of lactation, the patient rapidly developed symptomatic hypocalcemia. Conventional therapy was reintroduced but for persistent serum calcium instability and increasing therapeutic requirements, treatment with recombinant human PTH (1-84) started, resulting in improved clinical and biochemical control.

Conclusions: These cases underscore the complexity of managing hypoparathyroidism in high-risk clinical scenarios. PTH analog therapy offers a valuable treatment option for patients with poorly controlled disease, improving biochemical picture and reducing symptom burden.

EP339 - ECE_2615 - Alternative treatment of hypercalcaemia caused by primary hyperparathyroidism: a clinical case of parathyroid cryoablation

Erika Bukelytė[1], Aurimas Mačionis[2], Aistė Kondrotienė[3], Diana Šimonienė[3], Rūta Dubeikaitė[2] and Birutė Žilaitienė[3]
[1]Faculty of Medicine, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Department of Radiology, Lithuanian University of Health Sciences, Kaunas, Lithuania; [3]Institute of Endocrinology, Lithuanian University of Health Sciences, Kaunas, Lithuania

Introduction: The management of severe hypercalcaemia in patients with advanced chronic kidney disease and active malignancy is challenging, as standard pharmacological and surgical treatment options are often limited or contraindicated. In such cases, minimally invasive interventional techniques may represent an alternative therapeutic option; however, data on their use remain scarce.

Case presentation: An 80-year-old female with stage IV chronic kidney disease and active lung malignancy was hospitalised due to severe hypercalcaemia. Laboratory investigations revealed hypercalcaemia (3,19 mmol/L), hypokalaemia (3,37 mmol/L), hypomagnesaemia (0,67 mmol/L), hypophosphatemia (0,51 mmol/L), and agranulocytosis. The patient was immunosuppressed due to ongoing chemotherapy. Agranulocytosis was corrected with filgrastim, and hypercalcaemia was initially treated with intensive intravenous hydration and loop diuretics, alongside correction of electrolyte disturbances. Neck ultrasound demonstrated an enlarged left inferior parathyroid gland. Due to impaired renal function, zoledronic acid was contraindicated. After consultation with an interventional radiologist and fine-needle aspiration of the parathyroid lesion, markedly elevated parathyroid hormone (PTH) levels were detected in the aspirate (210,6 pmol/L), confirming the diagnosis of a parathyroid adenoma. Given the minimal cystic component and high vascularity of the lesion, ethanol ablation was considered unlikely to be effective. Parathyroid cryoablation was therefore performed under ultrasound guidance and general endotracheal anaesthesia. Post-procedural neck computed tomography revealed no acute complications. A rapid and pronounced biochemical response was observed, with PTH levels decreasing to 1,36 pmol/L on the first day and to 0,4 pmol/L on the second day after the procedure. Serum phosphate levels showed no significant change (0,89 mmol/L). Serum calcium levels gradually decreased to 2,7 mmol/L, and treatment with alfacalcidol (0,5 μg/day) and calcium carbonate (3 g/day) was initiated. The doses were subsequently increased to alfacalcidol 0,75 μg/day and calcium carbonate 4 g/day, achieving normocalcaemia and normophosphataemia. Following discontinuation of intensive hypercalcaemia treatment with intravenous fluids and diuretics, a transient deterioration in renal function was observed (serum creatinine 190 μmol/L). Renal function improved with renewed intensive hydration, with creatinine decreasing to 149 μmol/L. The patient continues follow-up under endocrinological care.

Conclusions: Parathyroid cryoablation may represent an effective and safe alternative for the treatment of severe hypercalcaemia in patients with primary hyperparathyroidism when surgical or standard pharmacological therapies are contraindicated. This case highlights the importance of individualised decision-making and a multidisciplinary approach in complex clinical scenarios

Background: The management of thyroid and parathyroid dysfunction in geriatric patients is associated with distinct clinical

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

challenges that require careful therapeutic consideration. Conditions like parathyroid disorders and multinodular goiter can contribute to osteoporosis, particularly in older adults, especially postmenopausal women, which increases the risk of skeletal fragility and fractures. The interplay between thyroid function, calcium metabolism, and bone health is crucial, necessitating comprehensive diagnostic evaluation, careful surgical intervention, and effective postoperative management.

Case presentation: A 78-year-old female was diagnosed with a multinodular goiter 2-3 years ago and was treated with 5 mg of methimazole daily for 12 months, achieving a euthyroid state. She also underwent a DEXA scan 1 year ago that revealed a high degree of osteoporosis, particularly in the left forearm, for which she was prescribed denosumab. The past medical history was significant for arrhythmia and arterial hypertension, which were managed by bisoprolol and captopril symptomatically. Surgical history includes tonsillectomy. Social history was notable for tobacco use and a sedentary lifestyle. The assessments showed the presence of negative TSH receptor antibodies, significantly elevated LDL cholesterol levels, and high calcium, which raised concerns about primary hyperparathyroidism in the context of severe osteoporosis. A SPECT/CT scan later confirmed the existence of bilateral intrathyroidal parathyroid adenomas. The patient underwent a total thyroidectomy and subtotal parathyroidectomy. Histopathological examination confirms the presence of both a follicular thyroid adenoma and an intrathyroidal parathyroid adenoma with hyperplastic features. Postoperative results initially showed a significant decrease in PTH levels, although a gradual increase has been observed over time. Throughout this period, electrolyte levels have remained stable, and TSH levels have been suppressed. Postoperative maintenance therapy included levothyroxine, calcitriol, and calcium supplements, along with a combination of statins for cholesterol and antiosteoporotic medication for bone health.

Conclusions: The concomitant occurrence of thyroid and parathyroid dysfunctions adds significant complexity to the diagnostic and therapeutic processes, particularly in geriatric patients. A thorough evaluation, followed by surgical intervention and diligent postoperative management, is crucial in this case for achieving hormonal balance and enhancing bone health. Multidisciplinary care is essential, as the dynamic nature of endocrine disorders requires adaptive management strategies. The challenges highlighted in this case underscore the importance of ongoing research and collaboration among healthcare professionals to enhance outcomes for patients with overlapping endocrine disorders.

EP347 - ECE_2474 - Severe chronic hypoparathyroidism—when convetional therapy fails

Pietro Locantore, Alessandro Romano, Erika Motolese, Gianluca Cera, Vincenzo Grasso and Alfredo Pontecorvi
Fondazione Policlinico Gemelli IRCCS—Università Cattolica del Sacro Cuore, Fondazione Policlinico Gemelli IRCCS, Translational Medicine and Surgery, Rome, Italy

Hypoparathyroidism consists in insufficient production of PTH, resulting in hypocalcemia. Its etiology is mainly post-surgical, following central neck surgery, whereas other causes (autoimmune and genetic parathyroid disorders) are less common.

Clinical manifestations include neuromuscular symptoms like paresthesias and cramps to overt tetanic crises. Chronic complications are nephrolithiasis, renal failure, bone fractures, extraskeletal calcifications, cognitive impairment and poor quality of life (QoL).

Conventional therapy is based on calcium and calcitriol. When conventional therapy fails, PTH analogues are recommended. Teriparatide improves calcium control and QoL, but requires multiple daily administrations because of its short half-life and its use is off-label in hypoparathyroidism, with inconstant control and long-term side effects.

TransCon-PTH is a long-acting PTH prodrug that allows stable PTH levels with a single daily subcutaneous administration.

We herein present three cases that may benefit from TransCon-PTH, which is not available in Italy at present.

V.I. is a 40-year-old woman affected by post-surgical hypoparathyroidism following total thyroidectomy (2018) for papillary thyroid cancer.

She initially achieved good calcium balance with a low dose calcitriol regimen; however, in 2019 she underwent duodeno–ileal bypass for severe obesity. Malabsorptive effects of bariatric surgery caused her to progressively increase oral calcium dose up to 6 gr and calcitriol dose up to 4 mcg daily. She subsequently started teriparatide bid; however, calcium control remains so poor that she needs frequent intravenous calcium administration.

N.T. is a 55-year-old woman affected by post-surgical hypoparathyroidism, following total thyroidectomy in 2016 for multinodular goiter.

Due to comorbidities that reduced her adherence to conventional therapy, she experienced significant fluctuations in serum calcium levels, ranging from severe hypocalcemia to symptomatic hypercalcemia. She therefore started teriparatide on a two daily dose regimen, which however did not completely improve serum calcium level control.

I.P. is a 35-years-old female who underwent total thyroidectomy in 2022 for papillary thyroid cancer.

She developed severe post-surgical hypoparathyroidism, requiring high doses of oral calcium and calcitriol. Management of treatment became complex, requiring frequent monitoring of serum calcium levels and corresponding dosage adjustments. She started teriparatide bis-in-die, which did not completely improve clinical management, given the persistence of hypocalcemic crises and episodes of hypercalcemia.

When conventional therapies fail to ensure adequate management of chronic hypoparathyroidism, TransCon-PTH can be a valid alternative to improve QoL and reduce risk of complications. New health policies are warranted to ensure access to TransCon-PTH for selected patients who could most benefit from it.

EP348 - ECE_3882 - Methotrexate osteopathy treated with teriparatide: a case report

Matej Rakusa
Department of Endocrinology, Diabetic and Metabolic Disease, University Medical Centre Ljubljana, University Medical Centre Ljubljana, Ljubljana, Slovenia

Introduction: Methotrexate osteopathy (MTXO) is a rare complication of methotrexate treatment characterized by low-energy stress fractures of the lower extremities. MTXO leads to chronic

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

pain and subsequent immobility. Healing of fractures can be prolonged, with reports spanning over several years. Discontinued MTX treatment is associated with a greater chance of healing. The effectiveness of additional treatments to accelerate bone fracture healing is uncertain.

Case report: We present a case of a 66-year-old female with spontaneous, unhealed fractures of the lower limbs. She had a history of rheumatoid arthritis and leukopenia as part of Felty's syndrome. The patient was treated with methotrexate (20 mg weekly), folic acid, cholecalciferol (7000 IU weekly), and occasionally filgrastim. She experienced progressively worsening pain in both ankles and feet, left knee, without any evident injury. On the scale, pain was assessed as 8/10 and rendered the patient unable to walk. Magnetic resonance imaging (MRI) of the bones revealed stress fractures of both calcanei, the distal epiphysis of the right tibia, the second metatarsal of the right foot, the third metatarsal of the left foot, and the medial condyle of the left knee. Bone mineral density was decreased to osteoporotic levels, with the lowest T-score of −3.0 SD. Laboratory findings were in normal range as follows: corrected calcium 2.36 mmol/L, phosphate 1.02 mmol/L, alkaline phosphatase (AF) 1.89 µkat/L, creatinine 57 µmol/L, 25-hydroxyvitamin D 73.2 nmol/L, iPTH 29 ng/L, CTX 0.476 µg/L, and PINP 59.7 µg/L. Based on the fractures in typical locations and the absence of other causes, methotrexate osteopathy was confirmed. Methotrexate was discontinued, and treatment with teriparatide (20 µg daily) was initiated. One month after starting teriparatide therapy, the patient reported reduced pain, assessed on a scale of 2/10. After 1 year, PINP was 160.9 µg/L, CTX 0.144 µg/L. Only the fracture of the medial condyle of the left knee did not show signs of healing. All other healed at least partially.

Conclusions: Methotrexate osteopathy is a rare treatment complication. It is characterised by non-traumatic stress fractures of the distal and proximal tibia, calcaneus, talus, and metatarsals in patients treated with methotrexate. Discontinuation of methotrexate is critical for bone healing. Due to the rarity of methotrexate osteopathy, the optimal treatment approach is not entirely clear.

Introduction: Primary hyperparathyroidism associated with multiple endocrine syndrom type 1 in children si very rare. It is caused by overproduction of parathormone by a pathologically changed parathyroid glands.

Methods: We carried out a retrospective study in 4 patients (age 8-17 years) who had surgical treatment between 2022-2025.

Results: All these patients had positive family history. Patients were examined using sonography, MIBI-scintigraphy and MRI. Calcium was measured before and after surgery: parathormone was monitored postoperative. First surgical operation was curative in three patients: reoperation was necessary in one patient. Other major complication were not observed.

Conclusions: Surgery offers definitive and safe treatment of primary hyperparathyroidism associated with MEN1 in children.

EP351 - ECE_3534 - When hydration masks diabetes insipidus: lithium toxicity with hypernatremia and hyperparathyroidism, a case report

Beatriz R. Pereira[1], Joana Vinhais[1], David Verissimo[1], Catarina Ivo[1], Ana Cláudia Martins[1], Luis Lopes[1], Ascension Lopez[2], Dolores Passos[1], Mafalda Marcelino[1], João Jácome de Castro[1] and João Nunes Silva[1]
[1]Endocrinology, Hospital Das Forças Armadas, Lisboa, Portugal; [2]Lisboa, Portugal

Introduction: Lithium has a narrow therapeutic window and can cause endocrine and renal complications, including lithium-associated hyperparathyroidism and impaired urinary concentration.

Case report: A 61-year-old woman presented to the emergency room with one-week of tremor and dizziness. Examination was positive for psychomotor retardation and fluctuating mental status. She had previous known history of bipolar disorder, treated with lithium (1200 mg/day), bupropion (150 mg/day), paliperidone (3 mg/day) and trazodone (150 mg/day).

Initial laboratory blood tests showed lithium 4.1 mmol/L (0.6-1.2), calcium 11.2 mg/dL (8.1-10.4), sodium 130 mmol/L (135-145) and mild acute kidney injury (eGFR 48 mL/min/1.73 m^2). Lithium was immediately discontinued and intravenous 0.9% sodium chloride initiated. Within 48 hours, lithium decreased to 1.5 mmol/L and calcium to 10.5 mg/dL, while sodium increased to 139 mmol/L. PTH was markedly elevated (331 pg/mL, 15-68.3), and thyroid function within normal range (TSH 3.29 uUI/mL, 0.27-4.2).

On day four of hospitalization, intravenous fluids were stopped, resulting in marked thirst and polyuria, as well as progressive hypernatremia (peak serum sodium 166 mmol/L on day five). Complementary evaluation evidenced dilute urine (urine osmolality 195 mOsm/kg) despite hyperosmolar plasma (serum osmolality 353 mOsm/kg) and elevated copeptin (26.5 pmol/L). A desmopressin trial (0.06 mg twice daily) lead to a mild clinical response, but persistent high urine output. Hypernatremia was

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

corrected gradually with free-water replacement, normalizing by day 35.

On discharge (day forty-four), thirst and polyuria had resolved, sodium was 143 mmol/L, calcium 9.5 mg/dL, and PTH persisted elevated (189 pg/mL).

Two months after lithium discontinuation, renal function had normalized (eGFR 79 mL/min/1.73 m^2), calcium and sodium remained within the normal range (9.4 mg/dL and 144 mmol/L, respectively). However polyuria, polydipsia and elevated PTH (178 pg/mL) persisted, leading to desmopressin up-titration to 0.06 mg twice daily.

Discussion/Conclusions: Lithium suspension and intravenous fluids improved lithium toxicity and hypercalcemia. Subsequent reduction of free-water availability unmasked severe hypernatremia with inappropriately dilute urine and only partial response to desmopressin, consistent with nephrogenic diabetes insipidus.

Initial hyponatremia was most compatible with polydipsia in the setting of diabetes insipidus, with preserved thirst mechanisms. Concomitant psychotropic medications may have reduced free-water clearance, but the absence of urine volume and osmolality prior to fluid discontinuation limits confirmation of the underlying cause.

Lithium-associated endocrine complications show heterogenous reversibility timelines, ranging from normalization after cessation to persistence for weeks to months. In this patient, serum calcium normalized rapidly, while polyuria and PTH elevation persisted at two-month follow-up. This highlights the need for close monitoring and structured endocrine follow-up, even after lithium discontinuation.

EP352 - ECE_2801 - Densitometric vertebral morphometry in pseudohypoparathyroidism 1B and nonsurgical hypoparathyroidism: a case series study

Dana Michalska[1], Josef Vcelak[2,3], Dorota Baszczynska[4], Anna Kudlova[4] and Katerina Zajickova[1,2]
[1]. *Internal Clinic, Endocrinology and Metabolism, General University Hospital and First Faculty of Medicine, IIIPrague 2, Czech Republic;* [2]*Institute of Endocrinology, Prague, Czech Republic;* [3]*First Faculty of Medicine, Charles University, First Faculty of MedicinePrague 2, Czech Republic;* [4]*3rd Faculty of Medicine, Charles University, Prague 10, Czech Republic*

Pseudohypoparathyroidism (PHP) and nonsurgical hypoparathyroidism (Ns-HypoP) are rare diseases characterized by hypocalcemia. In PHP, parathyroid hormone (PTH) levels are elevated due to end-organ resistance, with variable tissue sensitivity. In PHP1B the skeletal system is believed to be spared.

Vertebral fracture assessment (VFA), bone densitometry, and bone biochemistry were evaluated in 5 patients with PHP1B and 5 patients with Ns-HypoP. There were no differences between the two groups in terms of age, body mass index, calcium and creatinine levels, 25-hydroxyvitamin D levels, lumbar spine bone mineral density, and trabecular bone score. However, individuals with PHP had significantly higher levels of parathyroid hormone (12.34 pmol/L vs 0.982 pmol/L, $P \leq .002$) and osteocalcin (34.56 vs 16.78 µg/L, $P \leq .021$). VFA detected one moderate biconcavity, one moderate wedge deformity, and two moderate compressions in patients with PHP. In contrast, only a single wedge vertebral deformity was observed in one elderly patient with Ns-HypoP.

VFA revealed morphometric changes predominantly in patients with PHP1B. Vertebral deformities have to be verified on spinal imaging. VFA may provide additional insights into trabecular bone involvement in PHP1B; however, larger studies are necessary to validate these preliminary findings.

EP353 - ECE_3703 - Pregnancy- and lactation-associated osteoporosis presenting with multiple vertebral fractures and marked bone density recovery: a case report

Ia Kavtiashvili, Ketevan Chanturishvili and Natia Shonia
Tbilisi Institute of Medicine, Tbilisi, Georgia

Background: Pregnancy- and lactation-associated osteoporosis (PLO) is a rare cause of fragility fractures in young women, most often presenting with thoracolumbar vertebral fractures in late pregnancy or early postpartum. Early recognition is critical to prevent prolonged disability and to guide future pregnancy planning.

Case presentation: A 28-year-old woman (G1P1) developed severe back pain with ~5 cm height loss during the third trimester. Delivery occurred at 37 weeks' gestation (06/2021). Postpartum spinal MRI demonstrated multiple vertebral compression fractures (Th11, Th12, L1, L2, L4). Past history included non-toxic nodular goiter (FNA Bethesda II) and vitamin D deficiency. BMI was 26.6 kg/m^2. Secondary causes of osteoporosis (including celiac disease, Cushing syndrome, hyperparathyroidism, and hyperthyroidism) were excluded, supporting the diagnosis of PLO.

Investigations (DXA): Baseline DXA (2021) showed severe osteoporosis: lumbar spine BMD 0.487 g/cm^2 with Z-score −5.1 (L4 Z-score −5.6). Hip measurements were also low (e.g., left femoral neck BMD 0.516 g/cm^2, T/Z −3.0; right femoral neck BMD 0.627 g/cm^2, T/Z −2.0).

Serial DXA demonstrated substantial improvement:

01/2023: Lumbar spine BMD 0.768 g/cm^2 (T-score −3.4), with reported gains vs baseline (lumbar + 57.7%; left femoral neck +46.5%; right femoral neck +30%).

09/2023: Lumbar spine BMD 0.784 g/cm^2 (T-score −3.3; Z-score −3.4).

03/2024: Lumbar spine BMD 0.786 g/cm^2 (T-score −3.3).

02/2025: Lumbar spine BMD 0.840 g/cm^2 (T-score −2.2; Z-score −2.2), with improved hip indices (left femoral neck BMD 0.807 g/cm^2; T/Z −1.0).

Treatment and Follow-up: Initial management included calcium 1200 mg/day and vitamin D 2000 IU/day plus denosumab 60 mg subcutaneously every 6 months. After three denosumab doses, an unplanned pregnancy was discovered. A multidisciplinary discussion addressed fetal risk and the implications of treatment interruption; ultimately, pregnancy was terminated and therapy was transitioned to annual zoledronic acid infusions with continued calcium/vitamin D supplementation. (Regulatory labeling warns denosumab may cause fetal harm and requires pregnancy exclusion prior to dosing.)

Conclusions: This case highlights severe PLO presenting antenatally with multiple thoracolumbar fractures and very low baseline lumbar BMD, followed by marked BMD recovery on

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

antiresorptive therapy with close DXA surveillance. It underscores the importance of (1) considering PLO in pregnant/postpartum women with acute back pain and height loss, (2) systematic exclusion of secondary osteoporosis, and (3) proactive counseling on medication choice and future pregnancy planning—particularly when denosumab exposure is possible.—check if it is correct for uploading?

EP354 - ECE_2745 - Atypical parathyroid adenomas—the borderline diagnosis in primary hyperparathyroidism

Mihaela Baranceanu[1], Nada Akad[2], Alexandru Florescu[1], Anca Matei[1] and Stefana Bilha[1]
[1]*Universitatea de Medicină și Farmacie 'Grigore T. Popa' Iași, Endocrinology, Iași, Romania;* [2]*Universitatea de Medicină și Farmacie 'Grigore T. Popa' Iași, Iași, Romania*

Introduction: Atypical parathyroid adenomas (APAs) represent a rare and diagnostically challenging cause of primary hyperparathyroidism (PHPT), classified as tumors of uncertain malignant potential and situated on the histopathological spectrum between benign parathyroid adenoma and parathyroid carcinoma. Their definitive diagnosis relies primarily on careful postoperative histopathological evaluation, as no preoperative clinical or biochemical features are pathognomonic.

Case presentation: We report two cases of APA in male patients presenting with severe manifestations of PHPT. The first case involved a 49-year-old man with a history of hypertension, recurrent nephrolithiasis, and a previous episode of urosepsis, who was found to have persistent hypercalcemia (serum calcium 13.2 mg/dL) and elevated parathyroid hormone (PTH 133 pg/mL), with preserved renal function. Screening for multiple endocrine neoplasia syndromes was negative. Parathyroid scintigraphy suggested a right inferior parathyroid adenoma, and surgical excision was performed. Histopathological examination revealed atypical features, including a thick fibrous capsule, trabecular growth pattern, and cellular atypia.

The second case involved a 74-year-old man with a history of prostate adenocarcinoma, who presented with markedly elevated PTH levels (1228 pg/mL), hypercalcemia (13.3 mg/dL), and hypercalciuria (367 mg/24 h). Skeletal evaluation demonstrated very low T-score of −5.9 at the forearm and multiple brown tumors on bone scintigraphy. Parathyroid scintigraphy identified a left-sided parathyroid adenoma, which was surgically removed. Histological analysis confirmed an atypical parathyroid adenoma composed predominantly of chief cells arranged in an insular and lobular pattern, with capsular adhesion, low mitotic activity, absence of vascular or perineural invasion, and a low Ki-67 proliferation index (<1%)

Conclusions:

1. APAs may present with moderate to severe biochemical abnormalities and significant renal and skeletal complications of PHPT, often overlapping clinically with parathyroid carcinoma.
2. Accurate diagnosis of atypical parathyroid adenomas relies on careful histopathological and immunohistochemical evaluation. Exclusion of absolute criteria of malignancy including-invasion of adjacent structures, vascular invasion, perineural invasion, and metastases is mandatory. Despite their limited specificity, immunohistochemical markers may provide supportive information in differentiating benign from malignant parathyroid lesions.
3. Surgical excision remains the treatment of choice, and long-term follow-up is essential due to the uncertain malignant potential and associated risk of recurrence.

Abstract citation ID: lvag096.882

EP355 - ECE_1932 - From suspected metastases to parathyroid disease: tertiary hyperparathyroidism mimicking metastatic bone disease in chronic kidney disease

Salome Kalandadze[1,2], Mariam Pailodze[1], Inga Shoshiashvili[1], Tedo Jokharidze[1], Ana Khoperia[1] and Ketevan Kankava[3]
[1]*New Hospitals, Tbilisi, Georgia;* [2]*Endocrinology, Caucasus Medical Center, Tbilisi, Georgia;* [3]*Megalab, Tbilisi, Georgia*

Introduction: A 65-year-old woman with a five-year history of advanced chronic kidney disease (serum creatinine 329 µmol/L) and type 2 diabetes presented with progressive left sacral pain over two months. Initial spine magnetic resonance imaging demonstrated infiltrative changes in the left sacrum, raising strong suspicion for metastatic bone disease. The patient was therefore referred to the oncology department with a presumed malignancy of unknown primary.

Investigations: Further imaging confirmed extensive skeletal involvement. MRI revealed multifocal infiltrative marrow changes involving S2-S3 and the left sacrum. Whole-body FDG PET/CT demonstrated multiple hypermetabolic lytic skeletal lesions, including the right scapula (SUVmax 9.2), left sacrum (SUVmax 6.6), pubic bone with an associated pathological fracture (SUVmax 16.4), left femoral shaft with cortical erosion (SUVmax 11.2), and right proximal tibia (SUVmax 9.3). Low-grade FDG uptake was noted in the cervical region (SUVmax 3.3).

Comprehensive oncologic evaluation, including gynecological assessment, failed to identify a primary tumor. Given the high metabolic activity and pathological fracture, a biopsy of the pubic bone lesion was performed. Histological and immunohistochemical analysis excluded malignancy, with differential diagnoses including giant cell tumor vs hyperparathyroidism-associated brown tumor.

In view of these findings, an endocrinologic evaluation was undertaken. Biochemical testing revealed markedly elevated parathyroid hormone levels (PTH 1139 ng/L; reference range 15-65) with concomitant borderline hypercalcemia (total calcium 11.0 mg/dL; ionized calcium 1.36 mmol/L), elevated alkaline phosphatase (211 U/L), severe vitamin D deficiency (25-hydroxy-vitamin D 9 ng/mL), low-normal phosphate (1.16 mmol/L), hypomagnesemia (0.60 mmol/L), and low 24-hour urinary calcium (1.2; reference 2.5-7.5). The patient was not receiving calcium supplements or active vitamin D at presentation.

The cervical FDG uptake observed on PET/CT was subsequently anatomically localized by targeted neck ultrasound to a 29 × 18 mm hypoechoic, hypervascular lesion in the expected anatomical location of a parathyroid gland.

Diagnosis: Based on the combination of long-standing CKD, markedly elevated PTH, hypercalcemia, extensive high-turnover

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

bone disease, and parathyroid imaging findings, a diagnosis of tertiary (autonomous) hyperparathyroidism in the context of CKD–mineral and bone disorder was established.

Management and Follow-up: Parathyroidectomy was recommended but declined. Medical therapy with cinacalcet resulted in early biochemical improvement, with reductions in both PTH and serum calcium.

Conclusions: This case highlights that severe CKD-related hyperparathyroidism may closely mimic metastatic malignancy on FDG PET/CT and underscores the critical importance of integrating histopathology, mineral metabolism, and targeted parathyroid imaging to avoid misdiagnosis and guide management.

Abstract citation ID: lvag096.883

EP360 - ECE_3562 - Tertiary hyperparathyroidism in advanced CKD: a case report

Cristina Contreras Pascual[1] and Paloma Gonzalez Lazaro[2]
[1]*Hospital Santa Bárbara, Soria, Spain;* [2]*Hospital General La Mancha Centro, Alcázar de San Juan, Spain*

Tertiary hyperparathyroidism (THPT) is an infrequent but clinically significant consequence of long-standing secondary hyperparathyroidism in patients with advanced chronic kidney disease (CKD). Persistent autonomous parathyroid hyperplasia may not resolve after kidney transplantation and can negatively impact graft function, making pre-transplant management particularly challenging.

We describe a 60-year-old male with end-stage renal disease (CKD G5) secondary to malignant hypertension and nephroangiosclerosis, on thrice-weekly hemodialysis since May 2023 and currently listed for kidney transplantation. His medical history included former heavy smoking, previous alcohol abuse, dyslipidemia, hypertensive cardiomyopathy, and grade 3 hypertensive retinopathy. The patient was referred to the Endocrinology Department for assessment of severe hyperparathyroidism prior to transplantation.

Biochemical evaluation revealed extremely elevated intact parathyroid hormone (PTH) concentrations (up to 1745 pg/mL), severe 25-hydroxyvitamin D deficiency (8.92 ng/mL), low–normal serum calcium (8.25 mg/dL), hyperphosphatemia (5.12 mg/dL), and an estimated glomerular filtration rate <15 mL/min/1.73 m^2. Cervical ultrasound suggested a small left parathyroid adenoma (7 mm), whereas parathyroid scintigraphy was negative. Choline PET imaging subsequently demonstrated hyperplasia of all four parathyroid glands, supporting the diagnosis of THPT due to prolonged uremic stimulation.

Considering the low likelihood of regression after kidney transplantation and the potential risk of post-transplant graft dysfunction, a subtotal parathyroidectomy with autotransplantation into the sternocleidomastoid muscle was performed. Within 24 hours postoperatively, the patient developed severe hypocalcemia (corrected calcium 6.79 mg/dL) associated with suppressed PTH levels (<2.4 pg/mL), consistent with postoperative hypoparathyroidism and hungry bone syndrome. One month after surgery, PTH levels normalized (31.5 pg/mL) and vitamin D status improved (34.2 ng/mL); however, persistent hypocalcemia required intensive calcium supplementation, including intravenous calcium during hemodialysis, oral calcium salts, and phosphate binders. Histopathological analysis confirmed diffuse parathyroid hyperplasia without evidence of malignancy.

This case highlights the complexity of managing tertiary hyperparathyroidism in patients with advanced CKD awaiting kidney transplantation. Although pre-transplant parathyroidectomy may reduce the risk of graft dysfunction, clinicians should anticipate severe postoperative hypocalcemia and hungry bone syndrome, even when parathyroid autotransplantation is performed.

EP361 - ECE_1723 - Screening for osteoporosis: to scan or not to scan both hips in dual energy absorptiometry (DXA)

Shahini Winson Gnanathayalan and Uditha Bulugahapitiya
Endocrinology and Diabetes, National Hospital of Sri Lanka, Colombo, Sri Lanka

Introduction: Controversy remains regarding the use of bilateral hip scanning when bone mineral density (BMD)is measured, and bilateral hip scanning is not mandatory in international guidelines for screening of osteoporosis. Scanning one hip is cost and time effective.

Objectives: This study aimed to compare the diagnostic ability of BMD assessment in one hip in comparison to both hips.

Methods: This cross-sectional study was performed in males and females (40-90 years of age), being screened for osteoporosis using DXA-scan at a tertiary hospital in Sri Lanka, in 2023. Scanning both hips in addition to lumbar spine is the usual practice in this center.

Results: In the preliminary analysis of 161 subjects screened for osteoporosis (88% females, mean age 62 years), 52% had lower BMD in the left, when comparing the femoral neck BMD in both sides. There was no significant difference in the mean femoral neck BMD of the left vs the right leg (0.685 vs 0.687 g/cm^2). Of the total 161 individuals, osteoporosis ($T \leq -2.5$) was detected in 62 (38.5%) using the lumbar spine and right hip, compared to 64 (39.8%) subjects using the lumbar spine and left hip. Using the lumbar spine and both hips identified 66 (41%) individuals with osteoporosis. Lowest T-score was detected in the lumbar spine in 68% (45/66) of osteoporotic patients. Therefore, diagnosis based on use of the lumbar spine and right hip BMD, or lumbar spine and left hip BMD failed to identify only 4 (6%) or 2 (3%) subjects with osteoporosis respectively. When FRAX (Fractur risk assessment tool) with BMD was applied to these 6 subjects in whom using lumbar spine and one hip BMD failed to detect osteoporosis, 5 were identified to have high fracture risk indicating treatment according to Sri Lankan specific intervention thresholds.

Conclusions: The results indicate that scanning only one hip in addition to lumbar spine is sufficient to screen for osteoporosis. Larger studies are required for more reliable results and to identify subgroups who would benefit from dual hip scanning.

EP362 - ECE_2136 - Method for increasing the ultrasonic conductivity of skull bone tissue in patients who are planned to be treated with magnetic resonance imaging-guided focused ultrasonic imaging

Liliya Kuzina
Chystiakove, Ukraine

The invention relates to medicine, namely to endocrinology and neurosurgery, and can be used to treat patients with altered ultrasound conductivity of bone tissue who are planned to be treated with magnetic resonance imaging-guided focused ultrasound (MR-FUS) The MR-FUS method is most often used to treat movement disorders such as Parkinson's disease, dystonia, and essential tremor. The method is based on two technologies—high-intensity focused ultrasound (HIFU) and MRI. Using heating or cavitation at a variable distance from the sensor, HIFU can cause selective thermal coagulation in a clearly defined volume.The error in the destruction of brain tissue with this method is extremely small and averages 0.50-0.75 mm, varying depending on the technical characteristics of the selected equipment. The arsenal of solutions to the problem associated with low CUPT is very limited, which in turn leads to numerous refusals to perform operations using focused ultrasound. The objective of the invention is to develop a method for increasing the ultrasound conductivity of the bone tissue of the skull for further surgical interventions in patients using MR-FUS in a short time and with a safer method. The technical result of using the invention is a significant increase in the skull UCCT in patients with an initial UCCT of less than 0.35, achieving the threshold value necessary for thalamotomy with MR-FUS.The proposed method for increasing the ultrasound conductivity of the cranial bone tissue is carried out as follows. The patient for whom MR-FUS is planned undergoes CT of the cranial bones to determine the UPCCT, as well as laboratory tests for ionized calcium and vitamin D. If the coefficient is less than 0.35, the patient is administered Bonviva (Ibandronic acid) 3 mg intravenously by bolus over 15-30 seconds once every 3 months, Aquadetrim (Cholecalciferol) at a dose of 1500-5500 IU per day and Calcium D3 Nycomed (Calcium carbonate + Cholecalciferol) at a dose of 500 mg + 200 IU 2 times a day. The course of treatment is 3-6 months. After 3 months, the patient undergoes a repeat CT of the cranial bones on the same device and with the same program to assess the ultrasound conductivity coefficient of bone tissue, and laboratory tests for vitamin D and ionized calcium. If the cranial CUPCT increases by more than 0.35, the patient is referred for surgery using focused ultrasound. If there is no effect after 3 month.

EP363 - ECE_2684 - Cushing's hidden fragility: lessons from a case of severe skeletal impairment

Praveena Vankayalapati[1], Preeshila Behary[1,2], Jeremy Cox[1,2], Alexander Comninos[1,2], Karim Meeran[1,2], Niamh Martin[1,2], Nair Ramesh[1], Debbie Papadopoulou[1] and Jacques Abella[1]
[1]*Imperial College Healthcare NHS Trust, London, United Kingdom;* [2]*Imperial College, London, United Kingdom*

Introduction: Cushing's syndrome (CS) is associated with reduced bone density and increased risk of fragility fractures. Glucocorticoid-excess suppresses osteoblast function, enhances bone resorption, and disrupts calcium and vitamin D homeostasis, leading to skeletal fragility.

We present a case of pituitary CS, illustrating severe skeletal morbidity and response to targeted anabolic bone therapy.

Case presentation: A 35-year-old man with pituitary CS underwent a trans-sphenoidal surgery in March 2022 and started prednisolone 3 mg/day post-operatively. He reported ongoing disabling back pain and chest pain. MRI spine revealed bilateral rib fractures and multi-level vertebral compression fractures of various chronicity (T3-L1) and a severe kyphotic deformity. Dual-energy X-ray absorptiometry (DEXA) confirmed markedly reduced bone mineral density (BMD) with Z-scores of −3.1 and −3.3 at the lumbar spine (LS) and total hips respectively. Vitamin D levels were adequate and dietary calcium intake was optimised. Bone turnover markers were elevated, consistent with active fracture healing.

Severe pain caused significant functional impairment, requiring strong opioid analgesia and inability to work. After discussion in our Endocrinology Bone MDT treatment with teriparatide 20 µg daily mcg daily was initiated and kyphoplasty performed. Pain gradually improved, allowing opioid withdrawal. DEXA after 18 months of teriparatide demonstrated substantial improvement in BMD: +28.1% at the LS, +34% at the hip (Z-scores −1.1 and −1.6, respectively).

Discussion: Despite the well-recognised skeletal consequences of CS, bone health evaluation and management are often overlooked. Delays in CS diagnosis are common averaging 30.6 months (1), during which substantial skeletal impairment may occur.

We recently showed[1] that only 43% of patients presenting with CS had vitamin D measured and 39% received bone health management: calcium intake and/or vitamin D optimisation and/or initiation of bone-protective agents. Fracture risk persisted despite CS remission while early bone-protective therapy accelerated LS BMD recovery.

The choice of bone protective agent should be individualised. Concerns exist regarding prolonged suppression of bone turnover with antiresorptive agents, which may theoretically blunt osteoanabolic response in the post-remission skeletal recovery.[2] Anabolic therapy may therefore be preferred.[3,4]

Conclusions: This case highlights that in patients with CS, there is a need to

1. Assess bone health alongside definitive treatment of CS
2. Optimise calcium and vitamin D status early
3. Incorporate early fracture risk assessment, a low threshold for skeletal imaging and individualised bone-protective therapy, including anabolic agents, in selected high-risk individuals.

EP364 - ECE_2791 - Primary hyperpathroidsm with negative 99mTc-sestamibi scintigraphy

Megi Lekbello[1], Dorina Ylli[2], Violeta Hoxha[2], Marjeta Kermaj[1] and Klodi Poshi[1]
[1]*Endocrinology, Internal Medicine, University Hospital Mother Tereza, Tirana, Albania;* [2]*Endocrinology, Internal Medicine, University of Medicine, Tirana, Albania*

Introduction: Primary hyperparathyroidism (PHPT) is caused by autonomous parathyroid hormone (PTH) secretion, most commonly from a single adenoma. Surgical treatment depends on accurate preoperative localization. Although 99mTc-sestamibi scintigraphy is widely used, false-negative results occur in up to 25% of cases, complicating management.

Case presentation: A 33-year-old male presented to the emergency department following a syncopal episode. On admission, he was bradycardic (heart rate 38 beats per minute) and reported fatigue and excessive sweating. Laboratory investigations revealed marked hypercalcemia (serum calcium 12.6 mg/dL). His medical history was significant for hypertension and nephrolithiasis. Biochemical evaluation demonstrated elevated serum PTH and calcium levels, low serum phosphate, and normal vitamin D levels, consistent with a diagnosis of primary hyperparathyroidism. Neck ultrasonography showed a normal thyroid gland, and the parathyroid glands were not visualized. Subsequent 99mTc-sestamibi scintigraphy was negative. Given the strong clinical and biochemical suspicion, a contrast-enhanced computed tomography (CT) scan of the neck was performed, revealing a suspected 7-mm parathyroid adenoma located in the posterior inferior cervical region. The patient's symptomatic bradycardia was attributed to severe hypercalcemia, and medical therapy with cinacalcet was initiated. He was referred for surgical evaluation; however, the patient expressed significant hesitation regarding parathyroidectomy.

Conclusions: Negative 99mTc-sestamibi scans significantly influence clinical decision-making for both endocrinologists and surgeons, often affecting referrals and recommendations for parathyroidectomy. Recognition of characteristic patterns in patients with negative MIBI scans, (such as small or single adenomas), may allow for more targeted diagnostic strategies. Discordant imaging findings are associated with lower cure rates, longer operative times, and delayed surgical referral, emphasizing the importance of integrating clinical, biochemical, and multimodal imaging data in the management of primary hyperparathyroidism.

EP365 - ECE_3692 - Rare case of Isolated Hypogonadotropic hypogonadism with concomitant osteoporosis

Tea Khurodze[1,2], Vitali Vashakidze[1], Ana Pruidze[1], Basa Gegeshidze[1] and Elisabed Pkhaladze[1]
[1]*Tbilisi, Georgia;* [2]*David Tvildiani Medical University, T'bilisi, Georgia*

Introduction: Isolated Hypogonadotropic hypogonadism(IHH) is a rare endocrine disorder with various clinical manifestations that results from impairment of the hypothalamic–pituitary–gonadal (HPG) axis and normal levels of remaining pituitary hormones. Although amenorrhea, infertility, and lack of secondary sexual characteristics are the main patient concerns, low estrogen levels enhance bone resorption, and late diagnoses can lead to irreversible bone loss and increased susceptibility to fractures.

Case report: A 21-year-old Caucasian female was referred to an endocrinologist with complaints of bone pain, weakness, hair loss, and brittle nails. At the age of 17, she was diagnosed with primary amenorrhea due to Isolated Hypogonadotropic Hypogonadism with decreased levels of LH, FSH, estrogen, hypoplastic ovaries, and uterus on ultrasound. Kallmann syndrome was excluded(no olfactory complaints). Patient did not report eating disorders, psychological stress, or strenuous physical activity during adolescence. Karyotyping revealed a normal female pattern 46. Sex hormone therapy was commenced, though the patient did not adhere to the prescribed regimen regularly. On physical examination, she had a normal habitus without congenital anatomical defects. Height:161 cm, Weight: 53 kg, BMI: 20.4. Lab tests revealed Hashimoto's hypothyroidism, normal phosphate-calcium metabolism. DEXA scan confirmed early onset osteoporosis. The patient was treated with levothyroxine, bisphosphonates, vitamin D, and calcium supplementation, resulting in both laboratory and clinical improvement. Hormone replacement therapy was restored by a gynecologist to optimize reproductive health outcomes.

Conclusions: This case illustrates the multisystemic and progressive nature of IHH. Diagnosis requires careful integration of clinical, biochemical, instrumental, and genetic investigations. Early treatment is crucial in preventing adverse endocrine, metabolic, and skeletal outcomes.

EP366 - ECE_3903 - When a fracture tells a hormonal story: unmasking primary hyperparathyroidism beyond imaging

Eni Celo[1] and Bariola Duro[2]
[1]*Trauma University Hospital, Tirana, Albania;* [2]*Poliklinika e Specialiteteve nr.4, Tirana, Albania*

Fragility fractures may be the first clinical manifestation of an underlying endocrine disorder. We report the case of a 61-year-old woman in whom evaluation following a left humeral fracture led to the diagnosis of primary hyperparathyroidism despite non-localizing imaging.

The patient presented with a traumatic fracture of the left proximal humerus. Osteoporotic changes were noted on plain radiographs, leading to subsequent assessment with dual-energy X-ray absorptiometry, which demonstrated reduced bone

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

density, with a T-score of −2.3 at the hip and −2.6 at the femoral neck. These findings led to further metabolic assessment, which revealed vitamin D deficiency (25-hydroxyvitamin D 16.6 ng/mL; reference >30 ng/mL), elevated ionized calcium (1.30 mmol/L; reference 1.12-1.30 mmol/L), and inappropriately increased parathyroid hormone (PTH) levels (86 pg/mL; reference range 10-65 pg/mL), with normal renal function. Neck ultrasonography showed a multinodular goitre without visualization of parathyroid enlargement.

Vitamin D supplementation with cholecalciferol 2000 IU daily was initiated. After one month, vitamin D levels improved to 27.8 ng/mL; however, hypercalcaemia persisted and became more pronounced (ionized calcium 1.35 mmol/L; reference 1.12-1.30 mmol/L; total calcium 11.5 mg/dL; reference 8.5-10.5 mg/dL), while PTH levels remained elevated (78 pg/mL). Technetium-99m sestamibi scintigraphy failed to localize hyperfunctioning parathyroid tissue, supporting a diagnosis of imaging-negative primary hyperparathyroidism.

Parathyroidectomy was discussed but declined by the patient. A conservative management strategy was therefore adopted, including optimization of vitamin D status, initiation of antiresorptive therapy for skeletal protection, and close biochemical and densitometric monitoring.

This case highlights the importance of considering primary hyperparathyroidism in patients presenting with fragility fractures and reduced bone density, even when localization studies are negative, and underscores the central role of biochemical assessment in guiding diagnosis and management.

EP368 - ECE_3787 - Postpartum osteoporosis as a diagnostic challenge: a case report

Marija Toshevska Stefanoska, Ivana Mladenovska, Argjent Mucha, Aleksandra Stevchevska, Elena Pavlevska and Sasha Jovanovska Mishevska
Clinic of Endocrinology, Diabetes and Metabolic Disease, Ss. Cyril and Methodius University in Skopje, Skopje, North Macedonia

Postpartum Osteoporosis as a Diagnostic Challenge: A Case ReportBackground: Postpartum osteoporosis, also referred to as pregnancy- and lactation-associated osteoporosis (PLO), is an uncommon condition characterized by substantial bone loss and an increased risk of fragility fractures in young women. As back pain is a frequent complaint in the postpartum period, the underlying diagnosis may be overlooked, contributing to delayed recognition of postpartum osteoporosis in clinical practice.

Case report: We describe the case of a 33-year-old woman, with a body mass index of 18.9 kg/m^2 who presented with acute, severe, non-traumatic back pain occurring six months after delivery**.** The patient was actively breastfeeding at the time of presentation. She had no prior fractures, chronic illnesses, or exposure to medications known to affect bone metabolism. Pregnancy and delivery were uncomplicated.

Physical examination revealed restricted spinal mobility with localized tenderness. Laboratory evaluation showed normal serum calcium, phosphate, parathyroid hormone, and 25 hydroxyvitamin D levels, with normal renal and thyroid function, excluding secondary causes of osteoporosis. Dual-energy X-ray absorptiometry demonstrated markedly reduced bone mineral density, predominantly at the lumbar spine (Z-score ≤ −2.5). Spinal magnetic resonance imaging revealed vertebral compression fractures.

Based on clinical presentation, imaging findings, prolonged lactation history, and exclusion of secondary etiologies, a diagnosis of postpartum osteoporosis was established. Discontinuation of lactation and initiation of supportive therapy with calcium and vitamin D supplementation resulted in significant clinical improvement within six months.

Conclusions: This case report underscores postpartum osteoporosis as a clinically relevant and frequently underestimated cause of severe back pain in young women.Increased clinician awareness is essential for early diagnosis, timely management, and prevention of long-term skeletal complications.

EP369 - ECE_2300 - AI-based fractal and morphometric ultrasound analysis of peripheral nerves in diabetic neuropathy: a pilot study

Rostyslav Bubnov[1,2], Zbigniew Pilecki[3], Grzegorz Pilecki[3], Lev Kalika[4] and Karol Szyluk[5]
[1]*Ultrasound, Clinical hospital `Pheophania, Kyiv, Ukraine;* [2]*Zabolotny institute of microbiology and virology, Kyiv, Ukraine;* [3]*Orthopedics, Group of City Hospitals in Chorzow, Chorzow, Poland;* [4]*New York Dynamic Neuromuscular Rehabilitation & Physical Therapy, New York, United States;* [5]*Medical University Of Silesia, Katowice, Poland*

Background: Diabetic peripheral neuropathy (DPN) is a major chronic complication of diabetes mellitus, often diagnosed late due to limited sensitivity of conventional clinical and electrophysiological methods. Ultrasound (US) enables non-invasive visualization of peripheral nerves, but standard metrics such as cross-sectional area (CSA) provide incomplete information on microstructural damage. Fractal geometry allows quantitative assessment of tissue complexity and structural disorganization.

We **aimed** to evaluate an AI-assisted fractal–morphometric ultrasound approach for the assessment of diabetic neuropathy using the patented ultrasound-based framework, integrating ultrasound morphometry and fractal image analysis.[1-5]

Methods: Twenty patients with type 2 diabetes mellitus and clinically confirmed peripheral neuropathy were prospectively analyzed. High-frequency B-mode ultrasound of peripheral nerves (ulnar and median nerves) was performed. Morphometric parameters included CSA, fascicle diameters, and fascicular heterogeneity according to a patented ultrasound neuropathy method.[3-5] Fractal analysis of nerve images was conducted using a box-counting algorithm to calculate fractal dimension (FD) and lacunarity.[1,2] An AI-assisted pipeline integrated morphometric and fractal features to generate a composite neuropathy severity index. Findings were compared with reference values from healthy nerves.

Results: Diabetic neuropathy nerves demonstrated increased CSA, enlargement of selected fascicles, and loss of normal fascicular organization. Fractal analysis revealed significantly higher FD values (mean FD 1.74-1.82) and increased lacunarity compared to healthy

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

nerve patterns (FD ~1.40-1.45), indicating increased structural complexity and microarchitectural disorganization. Greater FD and fascicular heterogeneity correlated with clinical severity of neuropathy. AI-based feature integration improved differentiation between mild and advanced neuropathy patterns.

Conclusions: AI-assisted fractal–morphometric ultrasound analysis provides a novel, quantitative, and non-invasive approach for evaluating diabetic peripheral neuropathy. This method captures microstructural nerve alterations beyond conventional ultrasound metrics and may support early diagnosis, phenotyping, and monitoring of diabetic neuropathy for personalized and predictive endocrinology care.

EP370 - ECE_2737 - Combination therapy with SGLT2i and polyethylene glycol loxenatide vs SGLT2i monotherapy for cardiovascular events in Chinese patients with type 2 diabetes: a multicenter retrospective study

Yaqian Duan[1], Peiyun Chen[1], Ke Li[1], Shengbing Li[1], Mengliu Yang[1], Shaowei Duan[2], Yale Duan[2], Zhizhen Hu[2] and Dongfang Liu[1]

[1]*The Second Affiliated Hospital of Chongqing Medical University, Chongqing, China;* [2]*Jiangsu Hansoh Pharmaceutical Group Co., Ltd., Shanghai, China*

Background: In real-world Chinese patients with type 2 diabetes (T2D), whether combining sodium-glucose co-transporter 2 inhibitors (SGLT2i) with Glucagon-like peptide-1 receptor agonists (GLP-1RAs) further reduces the risk of major adverse cardiovascular events (MACE) compared with SGLT2i monotherapy remains unclear. Therefore, this study aimed to evaluate the comparative cardiovascular effectiveness of SGLT2i plus the specific GLP-1 RA Polyethylene Glycol (PEG)-loxenatide vs SGLT2i monotherapy in this population.

Methodology: This multicenter retrospective cohort analysis used data from the Tianjin Health Care Data Platform, covering 82 hospitals in China. Adult patients with T2D and cardiovascular disease (CVD) or CVD risk factors who initiated treatment with either SGLT2i plus PEG-loxenatide or SGLT2i monotherapy for >3 months between Jan 2016 and Dec 2024 were identified. Propensity score matching (PSM, caliper = 0.1) was performed based on age, sex, diabetes duration, CVD, dyslipidemia, renal disease, and the use of antihypertensive and lipid-lowering medications. The index date was defined as the date of the first prescription of the respective treatment regimen. All analyses followed the intention-to-treat principle, from the index date until the occurrence of an outcome event, death, or last observation. The primary endpoint was 3P-MACE (all-cause mortality, nonfatal myocardial infarction, and nonfatal stroke). The Cox proportional hazards regression models were used to estimate the hazard ratios (HRs) and 95% confidence intervals (CIs).

Results: After 1:1 PSM, 4020 patients were included in each group. The median duration of medication use was 228 days (combination) and 333 days (SGLT2i monotherapy). Combination therapy was associated with a 28% lower risk of 3P-MACE (HR, 0.72; 95% CI, 0.60-0.88; $P < .001$; Table 1), including significant reductions in nonfatal myocardial infarction (HR, 0.42; 95% CI, 0.24-0.74; $P = .002$) and non-fatal stroke (HR, 0.77; 95% CI, 0.63-0.94; $P = .012$). The risks of coronary revascularization (HR, 0.52; 95% CI, 0.36-0.76; $P < .001$) and hospitalization for unstable angina (HR, 0.73; 95% CI, 0.56-0.95; $P = .021$) were also significantly lower in the combination therapy group.

Conclusions: In this real-world cohort study involving Chinese patients with T2D, combination therapy with SGLT2i and PEG-loxenatide was associated with a significant lower risk of MACE compared with SGLT2i monotherapy.

EP371 - ECE_3158 - Genetically predicted HbA1c and the risk of acute pancreatitis in a mendelian randomization study

Silvano da Silva[1], Vasiliki Lagou[2], Vinicius Ribeiro[1] and Camilly de Paiva[1]

[1]*Faculty of Medical Sciences of Santos (FCMS)—UNILUS—Lusíada University Center, Santos, Brazil;* [2]*Bioinformatics Multidisciplinary Environment, Federal University of Rio Grande do Norte, Natal, Brazil*

Introduction: Glucagon-like peptide-1 receptor agonists (GLP-1RAs) are widely used for the treatment of type 2 diabetes and obesity, but their potential association with acute pancreatitis, largely based on observational evidence, remains an area of concern. Glycated hemoglobin A1c (HbA1c) reflects long-term glycemic exposure and represents a key metabolic pathway modulated by GLP-1 receptor activation. Mendelian randomization (MR) enables causal inference between an exposure and an outcome using genetic variants as instrumental variables (IVs). In this study, we applied a two-sample MR approach to evaluate whether genetic liability to higher HbA1c levels is causally associated with acute pancreatitis risk using data from FinnGen and the UK Biobank for independent replication.

Aim: To determine whether genetically predicted HbA1c levels have a causal effect on the risk of acute pancreatitis.

Methods: Genome-wide significant variants ($P < 5 \times 10^{-8}$) for HbA1c were selected from a large European-ancestry genome-

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

wide association study (GWAS) (ieu-b-4841) and clumping was performed ($r^2 < 0.001$) to obtain independent variants as IVs. For acute pancreatitis, GWAS data from FinnGen (finn-b-K11_ACUTPANC) and UK Biobank (ukb-b-19388) were used. Exposure and outcome datasets were harmonized to align effect alleles, excluding ambiguous palindromic variants. Causal estimates were obtained using the inverse variance weighted (IVW) method, with MR-Egger, weighted median, and mode-based approaches as sensitivity analyses. Heterogeneity and directional pleiotropy were assessed using Cochran's Q statistic and MR-Egger intercept, respectively.

Results: Genetic instruments for HbA1c comprised 12 independent variants, of which nine were retained after harmonization with the FinnGen acute pancreatitis dataset. In the primary analysis, genetically predicted HbA1c levels were not causally associated with acute pancreatitis risk ($\beta_{IWV} = -0.091$, $P = .45$). Results were consistent across other MR methods, with no evidence of heterogeneity or directional pleiotropy, and leave-one-out analyses showed no influential single variant.

Similarly, in UK Biobank, no causal association between HbA1c and acute pancreatitis was observed (inverse variance weighted $\beta = -7.3 \times 10^{-4}$, $P = .36$, IVs = 5), with concordant findings across other MR methods and no evidence of heterogeneity or pleiotropy.

Conclusions: This MR study found no causal association between genetically predicted HbA1c levels and acute pancreatitis risk. From a clinical endocrinology perspective, these results indicate that glycemic dysregulation alone does not seem to contribute to pancreatitis development. Therefore, potential pancreatic adverse events related to GLP-1RAs are unlikely to be mediated by glucose-lowering mechanisms.

EP372 - ECE_2269 - Masld metabolomic staging association to atherosclerotic plaque burden beyond traditional risk factors

Belén García Izquierdo[1], Sonsoles Guadalix[2], Rebeca Mayo[3], Delia D'ávola[4], Janire Allende[3], Manuel García de Yébenes[5], Marta Mediero Benítez[2], Gorka Bastarrika Alemañ[6], Javier Escalada[7], Ainara Martínez-López[3], Carolina M. Perdomo[7], Ana Huerta[4], Fernando Hernández-Terciado[5], Sonsoles Gutierrez-Medina[2], Juan Carlos Pastrana[4] and Diego Martínez-Urbistondo[4]

[1]Endocrinology and Nutrition, Clínica Universidad de Navarra, Madrid, Spain; [2]Endocrinology and Nutrition, Clínica universidad de Navarra, Madrid, Spain; [3]Derio, Rubió Metabolomics, Vizcaya, Spain; [4]Internal Medicine, Clínica universidad de Navarra, Madrid, Spain; [5]Cardiology, Clínica universidad de Navarra, Madrid, Spain; [6]Radiology, Clínica universidad de Navarra, Pamplona, Spain; [7]Endocrinology and Nutrition, Clínica universidad de Navarra, Pamplona, Spain

Aims: Although cardiovascular prevention strategies based on traditional risk factors are effective, they may not fully capture subclinical atherosclerosis. Metabolic dysfunction–associated steatotic liver disease (MASLD) has emerged as a potential contributor to cardiovascular risk, yet its independent role in clinical risk stratification remains controversial. This study aimed to evaluate the ability of metabolomic-defined MASLD to predict coronary atherosclerotic burden beyond traditional risk factors.

Materials and Methods: A cross-sectional study was conducted in asymptomatic adults aged 40-80 years undergoing a comprehensive cardiovascular evaluation, including coronary computed tomography angiography. Patients with previous cardiovascular disease, excessive alcohol intake, or body mass index <25 kg/m^2 were excluded. Cardiovascular risk was categorized according to ESC guidelines. Hepatic status was assessed using the OWLiver® serum metabolomic test, classifying participants as healthy liver, metabolic dysfunction–associated steatotic liver (MASL), metabolic dysfunction–associated steatohepatitis (MASH), or MASH at risk (MASH with fibrosis stage ≥ 2). Coronary artery disease severity was classified using CAD-RADS.

"Cardiovascular risk excess" was defined as coronary disease exceeding that expected for each ESC risk category: CAD-RAD S ≥ 2 in low-to-moderate risk, CAD-RADS ≥ 3 in high risk, and CAD-RADS ≥ 4 in very high risk).

Results: A total of 144 participants were included (mean age 58.7 ± 8.6 years; 12.5% women). MASLD stratification showed healthy liver in 13.2%, MASL in 68.1%, MASH in 11.8%, and MASH at risk in 6.9% patients. CAD-RADS ≥2 was detected in 36.1% of individuals, and cardiovascular risk excess in 19.4%.

Advanced MASLD phenotypes (MASH and MASH at risk) were associated with a higher prevalence of cardiovascular risk excess across ESC categories, with a significant interaction between hepatic stage and baseline risk ($P < .05$). This enabled the definition of a composite phenotype termed "MASH at cardiovascular risk," representing 9% of the cohort and characterized by a markedly higher prevalence of both CAD-RADS ≥ 2 and cardiovascular risk excess, independently of age, sex, ESC risk category and coronary calcium score ($P < .01$). Inclusion of this phenotype improved discrimination and risk reclassification beyond traditional clinical models and coronary calcium. Clinically, this subgroup had substantially higher absolute risk, with an estimated number needed to screen of 2-3 to detect one case with CAD-RADS ≥ 2, and 3 to identify one individual with cardiovascular risk excess.

Conclusions: Metabolomic evaluation of MASLD using OWLiver is a potential tool to identify patients at higher risk of coronary artery disease, with potential clinical implications.

Abstract citation ID: lvag096.895

EP374 - ECE_1795 - RBC distribution width predicts progression of coronary artery calcification

Jong Suk Park[1], Jeong Kyu Kim[2] and Min Kyung Kim[3]

[1]Seoul, South Korea; [2]Yonsei University College of Medicine, Seoul, South Korea; [3]Hallym University College of Medicine, Seoul, South Korea

Background: Recent studies have reported that red blood cell distribution width (RDW) is a risk factor for cardiovascular disease; however, the relationship between RDW and coronary artery calcification (CAC) progression remains unclear. This study aimed to examine the association between RDW and CAC progression in asymptomatic Korean adults.

Methods: A total of 1166 subjects who underwent at least two CAC evaluations in a healthcare center were selected. The subjects were stratified into three groups based on RDW. CAC progression was defined as either the presence of incident CAC in

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

CAC-free subjects at the baseline or an increase of ≥2.5 units between the square root of the baseline and follow-up CAC scores (CACSs) in subjects with detectable CAC at baseline.

Results: CAC progression was observed in 305 subjects (26.2%) during the 4.2-year follow-up period. The subjects were categorized into three groups based on their RDW, the baseline CACS and prevalence of CAC (CACS > 0) increased significantly with a gradual increase in the order of the RDW tertile. The follow-up CACS and the incidence of CAC progression increased significantly in the order of increasing RDW tertiles, the $\Delta\sqrt{}$transformed CACS values ((T1, 1.19 ± 1.96; T2, 1.39 ± 2.84; T3, 1.75 ± 3.74; $P < .05$) were found to be higher in individuals with higher baseline RDW. In addition, individuals with higher baseline RDW exhibited greater increases in $\Delta\sqrt{}$transformed CACS values. The results of the multivariate logistic regression analysis indicated that age, male, BMI, LDL-C level, presence of diabetes and hypertension, and observation time were independent predictors of CAC progression. Furthermore, RDW was also identified as an independent predictor of CAC progression (AOR = 1.298, 95% CI = 1.028-1.639, $P < .01$).

Conclusions: RDW is significantly associated with CAC progression; therefore, RDW has been identified as a potential predictor of CAC progression. Further prospective large-scale studies are required to clarify the mechanism of this relationship.

EP376 - ECE_3160 - Genetically predicted expression of the SGLT2 gene (SLC5A2) and risk of diabetic ketoacidosis

Silvano Da Silva[1], Vasiliki Lagou[2], Gabriel Mendieta[1], Maria Eduarda de Santana[1] and Maria Fernanda Gonçalves[1]
[1]Faculty of Medical Sciences of Santos (FCMS)—UNILUS—Lusíada University Center, Santos, Brazil; [2]Bioinformatics Multidisciplinary Environment, Federal University of Rio Grande do Norte, Natal, Brazil

Introduction: Sodium-glucose cotransporter 2 inhibitors (SGLT2i) are widely used in type 2 diabetes treatment due to their metabolic, cardiovascular, and renal benefits. However, rare cases of diabetic ketoacidosis, including euglycemic presentations, have been reported, posing diagnostic and safety challenges in clinical practice. The mechanisms underlying individual susceptibility to ketoacidosis during SGLT2 inhibition are not fully understood. Mendelian randomization (MR) enables causal inference between an exposure and an outcome providing insights into biological mechanisms involved in disease risk in this approach, expression quantitative trait loci (eQTLs) can be used as instrumental variables (IVs) to estimate the causal effect of the expression of *SLC5A2*, which encodes the renal SGLT2, on the risk of diabetic ketoacidosis.

Aim: To evaluate the causal association between genetically predicted *SLC5A2* expression and diabetic ketoacidosis risk.

Methods: A two-sample MR study was conducted using summary-level genome-wide association data. Genetic instruments for *SLC5A2* expression were obtained from a publicly available cis-eQTL dataset of European ancestry ($N = 31\,306$) selecting genome-wide significant variants ($P < 5 \times 10^{-8}$) and performing clumping ($r^2 < 0.001$). Diabetic ketoacidosis was used as the primary outcome, with summary statistics derived from the FinnGen consortium (345 cases/183 185 controls). Causal estimates were calculated using the Wald ratio, with results expressed as odds ratios (OR) and 95% confidence intervals.

Results: After clumping, only one independent genome-wide significant eQTL (rs6565236) remained and was used as an IV in MR. Two-sample MR using this variant showed no evidence of a causal association between genetically predicted *SLC5A2* expression and diabetic ketoacidosis risk (OR 0.46, 95% CI 0.06-3.52; $P = .46$).

Conclusions: Genetically predicted *SLC5A2* expression was not causally associated with the risk of diabetic ketoacidosis. These findings suggest that the increased risk of ketoacidosis reported with SGLT2i is unlikely to be driven by inherited variation in the *SGLT2* pathway, highlighting the importance of clinical and pharmacodynamic factors in patient susceptibility.

EP377 - ECE_3691 - FABP4 and fatty liver index in obesity: insights across metabolic health categories

Barbara Bromińska, Aleksandra Krygier, Ewa Milewska-Kobos, Ewelina Szczepanek-Parulska and Marek Ruchala
Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences, Poznan, Poland

Introduction: Fatty Acid Binding Protein 4 (FABP4) is an intracellular lipid-binding protein involved in the regulation of fatty acid transport, lipid signalling, and cholesterol homeostasis. Elevated circulating FABP4 levels have been proposed as a potential biomarker for the detection and progression of liver steatosis. It represents the initial stage of non-alcoholic fatty liver disease (NAFDL), a condition strongly linked to metabolic dysregulation. Moreover, metabolic syndrome (MetS) is frequently associated with the development and severity of liver steatosis.

Objective: The goal of this study is to examine the association of FAB4 with liver steatosis in metabolic healthy obese (MHO), pre-metabolic syndrome(pre—MetS) and metabolic syndrome (MetS) patient.

Materials and Methods: We conducted a cross-sectional study including 103 treatment-naive obese patients (body mass index, BMI ≥ 30 kg/m^2). Participants were divided into three groups: MHO ($n = 18$), who did not meet any MetS criteria and were not using antihypertensive, glucose-lowering, or lipid-lowering medications; pre-MetS ($n = 32$), who met at least one MetS criterion (excluding waist circumference), but did not fulfil the full MetS definition; and MetS ($n = 53$). Multiple biochemical parameters were analysed. BMI and waist circumference (WC) were assessed. The fatty liver index (FLI) was calculated using a validated logistic regression formula. An FLI ≥ 60 was considered indicative of a high risk of liver steatosis.

Results: FABP4 levels differed significantly between the three groups ($P < .001$). Further analysis showed lower FABP4 in the MHO group compared with both METS ($P = .001$) and pre-METs ($P = .032$), while MetS and pre-METs did not differ ($P = .354$). FLI also differed significantly between groups ($P < .001$), with all pairwise comparisons showing significance. FLI was higher in the MetS group than in the other groups, and higher in the pre-MetS group than in the MHO group. FABP4 correlated with FLI ($r = 0.430$), GGTP ($r = 0.264$) and ALT ($r = 0.212$). In binary logistic regression, FABP4 was positively associated with liver steatosis (FLI ≥ 60) in both crude ($P < .001$; OR 42.530 95% CI 6.12-295.58) and adjusted models ($P < .001$; OR 1.22, 95% CI 1.078-1.378). FABP4 levels were

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

higher in patients with FLI ≥ 60 than in those with FLI < 60 ($P <$ .001).

Conclusions: Overall, our findings support FABP4 as a potential biomarker reflecting both metabolic phenotype and liver steatosis in obesity. Further studies are needed to clarify the role of FABP4 as a non-invasive indicator of NAFDL.

EP378 - ECE_2268 - Early setmelanotide treatment in a child with Bardet–Biedl syndrome type 5

Dimitrios Papadimitriou, Stavroula Kontogianni, Aspasia Michoula, Eleni Dermitzaki and Ioanna Grivea
Pediatric Endocrinology, Pediatrics, University of Thessaly, Larisa, Greece

Background: Bardet Biedl syndrome (BBS) is a rare genetic disorder classified among primary ciliopathies, characterized by multisystem involvement. Its estimated prevalence is 1 in100.000-160.000 live births. It is inherited in an autosomal recessive manner. Over 20 BBS genes have been identified. It is clinically diagnosed based on Beales criteria (>4 primary features or 3 primary and >2 secondary).

Case report: We present the case of a 4-year and 10-month-old girl with genetically confirmed Bardet-Biedl syndrome type 5 (BBS5), carrying a homozygous c.619-1G > C mutation in the BBS5 gene. The clinical phenotype included severe early-onset obesity (BMI SDS: +6.94), hypothyroidism, postaxial polydactyly of the right foot, intellectual RRoutine cardiac, renal, and ophthalmologic assessments (including echocardiogram, renal ultrasound, and fundus examination) were all normal. Marked hypothyroidism with TSH 24.5 IU/L but normal FT4 1.3 ng/dl was treated with levothyroxine 100 mcg/day to optimize thyroid function together with life style modification as possible and metformin suspension 500 mg × 2 p.o. Within 7 months BMI reduced from +6.94 to +5.81 SDS. Given the severity of obesity and the persistent hyperphagic behavior, following genetic confirmation of BBS5, the patient was considered for targeted therapy with setmelanotide, the melanocortin-4 receptor (MC4R) agonist approved for the treatment of obesity due to POMC, LEPR, and BBS-related deficiencies. BMI SDS further reduced from +5.81 to +4.64 within 5 months with marked resolution of hyperphagic behavior. This was the first pediatric case in Greece for which approval for setmelanotide treatment was granted by the National Health Organization (EOPYY). Treatment with setmelanotide was initiated under close clinical monitoring. The response was remarkable, with rapid and sustained reduction in appetite, improved satiety, and a significant decrease in body weight. After six months of therapy, the patient's BMI SDS decreased from +6.94 to +4.64, marking a clinically meaningful improvement. The only reported side effect was skin hyperpigmentation, a known class effect of MC4R agonists. However, this was well tolerated by the patient and family, particularly as the child had a naturally darker skin tone, and the change was not considered cosmetically distressing.

Conclusions: This case underscores the importance of early genetic diagnosis in syndromic obesity, as it allows for personalized therapeutic strategies. It also highlights the clinical efficacy and tolerability of setmelanotide in a young child with BBS5, contributing to the limited but growing body of real-world evidence supporting its use.

EP379 - ECE_2907 - Triglyceride-to–HDL cholesterol ratio as an independent predictor of incident diabetes in obese individuals: a KoGES-based analysis

Soo Jin Yun
Kyung Hee University, Seoul Campus, Seoul, South Korea

Background: The triglyceride-to–HDL cholesterol (TG/HDL) ratio has been proposed as a surrogate marker of insulin resistance and metabolic risk. However, its predictive value for incident diabetes mellitus (DM) among obese individuals remains unclear, particularly after accounting for baseline glycemic indices.

Methods: We analyzed data from the Korean Genome and Epidemiology Study (KoGES). Obesity was defined as a body mass index (BMI) ≥ 25 kg/m^2. Baseline TG/HDL ratio was calculated as triglycerides divided by HDL cholesterol. Incident DM was defined as the first occurrence of physician-diagnosed diabetes or use of antidiabetic medication during follow-up. Participants with diabetes at baseline were excluded. The association between log-transformed TG/HDL ratio and incident DM was evaluated using multivariable models adjusted for age, sex, fasting glucose, and HbA1c. Kaplan–Meier curves were constructed according to quartiles of TG/HDL ratio to compare cumulative DM incidence. Predictive performance was assessed using receiver operating characteristic (ROC) curve analysis by comparing the area under the curve (AUC) of a basic model (age, sex, fasting glucose, and HbA1c) with that of an extended model including TG/HDL ratio.

Results: Among obese participants without diabetes at baseline (n = 3956), 780 individuals developed DM during follow-up. Baseline log-transformed TG/HDL ratio was independently associated with incident DM after adjustment for age, sex, fasting glucose, and HbA1c (odds ratio per 1–standard deviation increase, approximately 1.32). Kaplan–Meier analyses demonstrated stepwise increases in cumulative DM incidence across increasing quartiles of TG/HDL ratio. The addition of log(TG/HDL) to a basic model including age, sex, fasting glucose, and HbA1c improved discrimination for incident DM, with the AUC increasing from 0.814 to 0.821 (ΔAUC = 0.0067).

Conclusions: In obese individuals, the TG/HDL ratio was independently associated with the risk of incident DM, even after adjustment for baseline glycemic indices. Furthermore, incorporation of TG/HDL ratio into a conventional risk model significantly improved the prediction of future DM. These findings suggest that the TG/HDL ratio may serve as a simple and clinically useful marker for diabetes risk stratification in obese populations.

EP382 - ECE_3302 - Clinical impact and long-term sustainability of advanced hybrid closed-loop systems therapy in type 1 diabetes patients in real-world settings

Ana Rocío Martínez Hartmann, Cristian Jesús Lucena Morales, Carlos López-Pereira, María Ángeles Cutilla Muñoz and Isabel Torres-Barea
Endocrinology and Nutrition Department, Endocrinology and Nutrition, Puerta del Mar Hospital, Puerta del Mar Hospital, Cadiz, Spain

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Objectives: To evaluate the real-world efficacy and safety of Advanced Hybrid Closed-Loop (AHCL) systems therapy by analyzing the evolution of glycemic parameters and insulin requirements before treatment initiation and during the first year of follow-up.

Material and Methods: An observational study was conducted on a cohort of 83 adult patients with T1D (mean age 32.7 ± 15.7 years; 66.3% female) treated at a specialized unit of Puerta del Mar Hospital. 86.7% who initiated treatment with the Minimed 780G system. 70% transitioned from multiple daily injections (MDI) therapy and 30% from open-loop therapy.

Glycemic variables and insulin doses were analyzed, comparing prior data against 1, 6, and 12 months of treatment. The Wilcoxon test was used for continuous variables and McNemar's test for analyzing changes in the proportion of patients achieving targets.

Results: Use of the AHCL system was associated with an early and significant improvement in metabolic control. Time in Range (TIR 70-180 mg/dL) increased significantly at all visits compared to baseline ($P < .001$). This improvement was achieved through a drastic reduction in Time Above Range (TAR > 180 mg/dL) and Time Below Range (TBR < 70 mg/dL) ($P < .001$).

The proportion of patients achieving the composite target (TIR ≥ 70% + TBR < 4% + CV < 36%) increased significantly from 11% at baseline to 56.6% at one year ($P < .001$).

Regarding insulin therapy, although the Total Daily Dose showed a non-significant reduction ($P = .07$), the decrease in basal insulin dose was significant ($P < .01$) compared to prior treatment. The system retention rate at one year was 87.8%.

Table 1 Evolution of metabolic parameters: Prior vs 1 year (Data expressed as Mean ± SD. *P*-value according to Wilcoxon test).

Parameter	Pre-AHCL	1 Year (AHCL)	*P*-value
HbA1c (%)	7.61 ± 1.15	6.95 ± 0.60	<.001
TIR (% 70-180)	55.9 ± 16.0	77.3 ± 10.3	<.001
TAR (% >180)	40.6 ± 17.5	20.2 ± 10.6	<.001
TBR (% <70)	4.22 ± 4.62	2.42 ± 2.12	.01
CV (% Variability)	37.0 ± 6.93	32.2 ± 4.79	<.001

Conclusions: Treatment with AHCL systems in patients with T1D proves to be highly effective and safe in real clinical practice, with early and sustained results. It optimizes glucometrics by halving time in hyperglycemia and minimizing time in hypoglycemia, alongside a reduction in glycemic variability. It notably optimizes the insulin profile, achieving these goals with a reduced need for insulin, primarily basal insulin.

EP383 - ECE_2964 - Comparison of the clinical effectiveness of three different dietary patterns in overweight and obese adults

Christina Balamoti and Alexandra Bargiota
Department of Endocrinology and Metabolic Diseases, University Hospital of Larissa, Larissa, Greece

Introduction: A large proportion of adults are overweight or obese. Digital health strategies are increasingly used for obesity management.

Objective: We studied the effectiveness of three different hypocaloric dietary interventions in overweight and obese adults, their weight-loss sustainability, adherence to the Mediterranean diet and satisfaction levels.

Methods: Randomized 5-month trial. 158 adults (mean age 49.5 ± 10.6 years) were stratified by BMI and age and allocated to a Fixed-Daily Diet (FDD), Multiple-Choice Diet (MCD), or App-Based Diet (ABD) with an energy deficit of 563 kcal/day. Effectiveness was assessed by changes in body weight (BW), percentage body weight (%BW), body fat percentage (BF%), waist circumference (WC), hip circumference (HC), and waist-to-hip ratio (WHR). Adherence to Mediterranean diet was assessed by MedDiet Score (low ≤20, moderate 21-35, high 35-55). Post-intervention dietary satisfaction assessed by the Diet Satisfaction Questionnaire (DSat-28).

Results: Baseline characteristics were similar across groups. At 5 months, the ABD group achieved greater absolute BW loss compared with the FDD and MCD groups (−8.0 ± 4.0 kg vs −4.8 ± 5.3 in FDD and −4.7 ± 3.7 in MCD; $P = .003$) and greater %BW loss (−8.3 ± 4.5% vs −5.4 ± 5.3% in FDD and −5.0 ± 3.7% in MCD; $P = .006$). ABD showed greater reductions in %BF (−4.9 ± 2.8% vs −2.8 ± 2.5% in FDD and −3.0 ± 2.0% in MCD; $P = .001$), in minimum WC (−7.6 ± 4.2 cm vs −4.5 ± 5.0 and −3.4 ± 3.4; $P < .001$), in umbilical WC (−7.1 ± 3.4 cm vs −5.3 ± 5.1 and −4.0 ± 4.4; $P = .009$), in HC (−6.4 ± 3.0 cm vs −4.1 ± 3.8 and −3.5 ± 3.5; $P = .002$), and in WHR (−0.028 ± 0.024 vs −0.012 ± 0.034 in FDD and −0.008 ± 0.026 in MCD; $P = .010$). Adherence to Mediterranean diet was moderate and comparable across groups (FDD: 26.1 ± 6.2; MCD: 27.7 ± 5.3; ABD: 28.2 ± 5.8; $P = .145$). Dietary satisfaction was higher in the ABD group compared with the FDD and MCD groups (113.0 ± 12.5 vs 100.9 ± 18.3 in FDD and 100.7 ± 20.4 in MCD; $P = .006$).

Conclusions: The ABD found to be the most effective intervention for improving the assessed anthropometric parameters with the highest satisfaction score, suggesting that mobile nutrition applications may serve as valuable tools to support dietary management and weight control.

EP385 - ECE_1876 - Dual activation of PPARα and PPARγ by Liquiritigenin attenuates hepatic lipid accumulation and insulin resistance through AMPK signaling

Hae Jin Kim, Yu Jung Heo, Jieun Park, Nami Lee, Sung-E Choi, Ja Young Jeon, Seung Jin Han, Dae Jung Kim and Kwan-Woo Lee
Ajou University School of Medicine, Institute of Medical Science, Suwon, South Korea

Metabolic dysfunction-associated steatotic liver disease (MASLD) is characterized by excessive triglyceride accumulation and chronic inflammation in the liver, driven largely by impaired fatty acid oxidation and disrupted metabolic signaling. Liquiritigenin (LQ), a flavonoid derived from licorice root, exhibits various biological properties. However, its specific role in mitigating MASLD and its associated metabolic disorders has not yet been clearly

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

elucidated. In this study, we evaluated the effects of LQ in both a high-fat diet (HFD)-induced mouse model of MASLD and HepG2 cells. C57BL/6J mice were fed a HFD for 14 weeks, and LQ (20 or 40 mg/kg) was administered daily for the final 2 weeks before sacrifice. LQ treatment significantly reduced the elevated levels of triglycerides, aspartate aminotransferase, and alanine aminotransferase observed in HFD-fed mice. Moreover, LQ alleviated the HFD-induced glucose intolerance and insulin resistance, as evidenced by intraperitoneal glucose and insulin tolerance tests. Following LQ treatment, phosphorylation of AMPK and the protein expression levels of SIRT1, PGC-1α, PPARα, and PPARγ were markedly increased. The expression of SREBP1 was significantly decreased, while the expression of fatty acid oxidation-related genes was upregulated. In FFA-treated HepG2 cells, LQ activated AMPK signaling, enhanced fatty acid oxidation gene expression, improved insulin sensitivity (p-AKT, p-IRS1), and suppressed inflammatory cytokines (IL-6, IL-1β, TNF-α). Notably, pharmacological inhibition of AMPK abolished LQ-induced enhancements in fatty acid oxidation. Collectively, these findings demonstrate that LQ ameliorates MASLD by activating the AMPK-SIRT1-PGC-1α-PPARα/γ axis to promote hepatic fatty acid oxidation, suppress lipogenesis, enhance insulin sensitivity, and attenuate inflammation, positioning LQ as a promising therapeutic candidate for MASLD.

EP386 - ECE_2716 - Perceived stigma and the impact of healthcare professionals' language on people with type 1 diabetes: a single-center study

Patrícia Brito[1], Carlos Lucas Calheno[2], Rita Ribeiro[1], Nuno Faria[1], Olinda Marques[1] and Diana Borges Duarte[1]
[1]*Endocrinology Department, Unidade Local de Saúde de Braga, Braga, Portugal;* [2]*Escola de Medicina da Universidade do Minho, Braga, Portugal*

Introduction: Type 1 diabetes mellitus (T1DM) requires intensive daily management and can generate significant emotional burden, influenced both by the stigma associated with the disease and by the language used during clinical consultations. This study evaluated the perception of stigma and the impact of clinical communication in adults with T1DM followed at our department.

Methods: This was a cross-sectional observational study involving 134 adults with T1DM. Data collection included sociodemographic and clinical variables, supplemented by a questionnaire composed of the "Guilt and judgement" and "Identity concerns" subscales from the Type 1 Diabetes Stigma Assessment Scale, the Problem Areas in Diabetes—5 scale and questions about communication experiences and linguistic perception.

Results: Despite generally good metabolic control and widespread use of technology, high levels of stigma and emotional distress were observed. "Guilt and judgement" stigma was more prevalent among women, younger individuals, those with higher education levels and those with shorter disease duration. The "Identity concerns" subscale scored higher among participants who perceived their economic situation as unfavorable and among those not native to Portugal. Distress associated with T1DM was higher among women, those in a relationship, individuals diagnosed at older ages, and participants with chronic complications, and was significantly associated with the stigma subscales evaluated. The absence of close contacts with T1DM was linked to higher stigma, while experiences of rejection or bullying due to the disease were consistently associated with higher levels of both stigma and distress. Additionally, 52.2% of participants reported a negative impact of clinical communication, and 90.3% attributed high importance to the language used during consultations.

Conclusions: Stigma and emotional distress are central elements in the experience of living with T1DM. These results reinforce the need to integrate psychosocial dimensions and person-centered communication strategies into T1DM management.

EP388 - ECE_3156 - Genetic evaluation of glycemic pathways targeted by GLP-1 receptor agonists and the risk of anterior ischemic optic neuropathy

Silvano Da Silva[1], Vasiliki Lagou[2], Vinicius Ribeiro[1] and Camilly de Paiva[1]
[1]*Faculty of Medical Sciences of Santos (FCMS)—UNILUS—Lusíada University Center, Santos, Brazil;* [2]*Bioinformatics Multidisciplinary Environment, Federal University of Rio Grande do Norte, Natal, Brazil*

Introduction: Anterior ischemic optic neuropathy (AION) is a rare but vision-threatening condition associated with vascular and metabolic risk factors. Although recent pharmacovigilance reports have suggested a possible link between glucagon-like peptide-1 receptor agonists (GLP-1RAs) and non-arthritic AION, the causal mechanisms remain unclear. GLP-1RAs exert broad metabolic effects, particularly on glycemic regulation. Mendelian randomization (MR) is a method that allows causal inference between an exposure and an outcome using genetic variants as instrumental variables (IVs).

Aim: To assess whether genetic liability to glycemic traits is causally associated with the risk of AION using a two-sample Mendelian randomization approach.

Methods: A two-sample MR study was conducted using summary-level genome-wide association data. Genetic instruments for glycemic traits (HbA1c) were obtained from two independent GWAS datasets (ieu-b-4841 and ieu-b-103) at genome-wide significance ($P < 5 \times 10^{-8}$) and clumped for clumped to obtain approximately independent signals based on linkage disequilibrium ($r^2 < 0.001$, 10 000 kb). The outcome was anterior ischemic optic neuropathy (AION) from the FinnGen consortium (finn-b-DM_AION). Causal estimates were derived primarily using the inverse variance-weighted (IVW) method, with weighted median, MR-Egger, and mode-based as additional MR methods for checking consistency. Heterogeneity and directional pleiotropy were assessed using Cochran's Q statistics and the MR-Egger intercept.

Results: Genome-wide significant instruments for HbA1c were obtained from two independent GWAS. For the first MR analysis (ieu-b-4841), nine variants were used as IVs; IVW showed no causal effects of HbA1c on AION (OR 1.53, 95% CI 0.74-3.16, $P =$ .25), with consistent null findings across other MR methods

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

and no evidence of heterogeneity (Q $P = .55$) or pleiotropy (Egger $P = .38$). Similarly, the second MR analysis (ieu-b-103) on 11 IVs revealed no significant causal estimates (IVW: OR 1.88, 95% CI 0.26-13.77, $P = .54$), with no evidence of heterogeneity (Q $P = .52$) or directional pleiotropy (Egger $P = .85$).

Conclusions: Our analyses do not support a causal effect of genetic liability to glycemic traits on the risk of AION, suggesting that a potential association between GLP-1 receptor agonists and AION might be primarily mediated by other, non-glycemic pathways.

Abstract citation ID: lvag096.905

EP389 - ECE_2263 - Comparative analysis of corneal and epithelial thickness in patients with type 2 diabetes mellitus

Iryna Havryliak[1] and Natalia Greben[2]
[1]*Ophtalmology, Bogomolets National Medical University, Kyiv, Ukraine;* [2]*Bogomolets National Medical University, Kyiv, Ukraine*

Diabetes mellitus can affect all ocular structures, from the retina to the cornea. Corneal alterations collectively referred to as diabetic keratopathy include recurrent corneal erosions, persistent corneal ulcers, severe dry eye disease, reduced corneal sensitivity, impairment of epithelial and endothelial barrier functions, and stromal edema. Central corneal thickness is an important clinical parameter used to assess the condition of the cornea prior to refractive surgery, detect corneal dystrophies and ectasias, and serve as an indicator of endothelial function, which plays a key role in maintaining the structure and function of the cornea.**Materials and Methods:** The study included 44 patients with type 2 diabetes, divided into groups with a history of more than 10 years and less than 10 years, and a control group of 10 people (healthy patients). Visometry, biomicroscopy, Schirmer's test, tear break-up time, and central corneal thickness were performed.

Results: Patients with DM were divided into two groups according to disease duration: less than 10 years (Group 1) and more than 10 years (Group 2).

Central corneal thickness (CCT) was significantly higher in patients with DM compared to the control group. The mean CCT was 556.0 ± 23.1 μm in Group 1 and 581.1 ± 24.4 μм in Group 2, compared to 534.1 ± 18.8 μм in the control group ($P < .05$). Patients with disease duration longer than 10 years demonstrated a statistically significant increase in CCT compared to those with a shorter duration ($P < .05$).

Schirmer's test values were significantly reduced in both diabetic groups compared to controls ($4{,}5 \pm 0.4$ mm and $4{,}3 \pm 0.6$ mm and $11{,}2 \pm 2{,}2$ mm, respectively; $P < .05$), with the lowest values observed in patients with longer disease duration.

Tear break-up time (TBUT) was also significantly decreased in patients with DM, particularly in Group 2 ($4{,}2 \pm 0{,}12$ s) compared to Group 1 ($3{,}8 \pm 0{,}06$ s) and the control group ($2{,}6 \pm 0{,}04$ s, $P < .05$).

Conclusions: Patients with type 2 diabetes mellitus have structural and functional changes in the cornea, including increased CCT and changes in the surface of the eye, compared to healthy individuals. The severity of these changes increases with the duration of the disease, suggesting a progression of the diabetic corneal pathology. Assessment of central corneal thickness and ocular surface parameters may be useful for early detection and monitoring of diabetic keratopathy.

EP390 - ECE_3121 - Role of FIB-4 in predicting TOAST and recurrence in diabetics with acute ischemic stroke

Pilar Pérez Reyes[1], Jerónimo Cruces Párraga[2], Pablo Doblas Ráez[2], Francisco Javier Serrano García[2], Julia Silva Fernandez[1] and Mª Rosa Alhambra Expósito[1,3]
[1]*Unidad de Gestión Clínica de Endocrinología y Nutrición, Hospital Universitario Reina Sofía, Córdoba, Spain;* [2]*Unidad de Gestión Clínica de Neurología, Hospital Universitario Reina Sofía., Córdoba, Spain;* [3]*Endocrinología y Nutrición, Hospital Universitario Reina Sofía, Córdoba, Spain*

Background and Aims: FIB-4 has been associated with a higher prevalence of atrial fibrillation (AF), increased stroke recurrence and type of stroke according to TOAST (Trial of Org 10172 in Acute Stroke Treatment). The aim of this study was to determine the prevalence of type 2 diabetes mellitus (T2DM) in patients with ischemic stroke, as well as to assess if FIB-4 levels in patients with T2DM are linked to these factors.

Materials and Methods: Prospective study of patients admitted in 2024 with acute ischemic stroke. Presence of AF and previous infarcts according to HbA1c and FIB-4 levels in diabetic and non-diabetic patients were evaluated. SPSS v.29 was used.

Results: 265 patients (64.5% men, 35.5% women) with ischemic stroke. Mean age of 68.68 ± 13.04 years. T2DM was present in 25.6% ($n = 68$), 0.75% ($n = 2$) had previously been diagnosed with type 1 diabetes (T1DM). Overall mean HbA1c level was $6.19\% \pm 1.01$, and $7.11\% \pm 1.25$ among patients with T2DM. Overall mean FIB-4 was 1.86 ± 1.07 and 1.83 ± 0.91 in patients with T2DM, with no significant differences in FIB-4 between patients with and without T2DM ($P = .201$).

In patients with T2DM, atherosclerosis stroke was the most frequent (46.6%), followed by cardioembolic stroke (27.6%). Higher FIB-4 values were significative associated with cardioembolic stroke overall ($P < .001$) and in patients without T2DM ($P = .006$). We found no significative differences between TOAST and FIB-4 in patients with T2DM ($P = .103$). No statistically significative differences were found between HbA1c and TOAST overall ($P = .105$) and in patients with T2DM ($P = .700$).

Presence of old infarcts at the diagnosis was significative higher in patients with T2DM (51.4% vs 34.71%, $P = .014$). Higher FIB-4 values were significative associated with presence of old infarcts in patients with T2DM ($P = .017$) but it was not in patients without T2DM ($P = .808$). AF was present at hospital admission in 29.95% of patients overall and 27.1% in patients with T2DM. Higher FIB-4 scores were statistically significative associated with the presence of AF at admission, regardless of T2DM status ($P = .010$ T2DM patients; $P < .001$ non-T2DM patients).

Conclusions: T2DM has a considerable prevalence among admissions due to ischemic stroke at our hospital. No significant associations were found between FIB-4 and TOAST classification in T2DM patients in this sample. Higher FIB-4 scores were associated with AF and old infarcts presence in T2DM patients, suggesting that follow-up care for T2DM patients

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

should consider AF and elevated FIB-4 scores. Further studies with larger sample sizes are warranted.

EP391 - ECE_3647 - Early endothelial dysfunction in type 1 diabetes mellitus: a multimodal assessment using flow-mediated dilation, carotid intima-media thickness, and inflammatory biomarkers

D. Amulya Reddy[1,2], Vijay Sheker Danda[1], Vivek Kyatham[1], Ann Elias[1], Venu Gopal Reddy K.[1] and Bhanusree Kalava[1]
[1]*Hyderabad, India;* [2]*Department of Endocrinology, Gandhi Medical College, Hyderabad, India*

Background: Individuals with type 1 diabetes mellitus (T1DM) are at increased risk of premature cardiovascular disease, with endothelial dysfunction representing an early and potentially reversible stage of vascular injury. Indian data integrating functional, structural, and inflammatory markers of vascular health in youth with T1DM remain limited.

Objective: To assess endothelial dysfunction in children and adolescents with T1DM and examine its association with glycemic control and duration of diabetes using flow-mediated dilation (FMD), carotid intima-media thickness (CIMT), and inflammatory biomarkers.

Methods: In this single-centre cross-sectional study, 41 patients with T1DM (median age 15 years) and 41 age- and sex-matched healthy controls were evaluated. Endothelial function was assessed using brachial artery FMD, including time-to-peak dilation and percentage peak FMD. Structural vascular changes were assessed using CIMT. Serum high-sensitivity C-reactive protein (hsCRP) and endothelin-1 (ET-1) were measured using ELISA. Correlations with HbA1c and duration of diabetes were analysed.

Results: Compared to controls, patients with T1DM demonstrated significantly reduced percentage peak FMD [6.55% (IQR 5.83-7.17) vs 8.21% (7.50-8.74); $P < .001$] and markedly delayed time-to-peak FMD [240 s (120-240) vs 30 s (30-60); $P < .001$], despite comparable baseline and peak brachial artery diameters. CIMT did not differ significantly between groups. Both hsCRP and ET-1 levels were significantly elevated in the T1DM group ($P = .003$ and $P < .001$ respectively). Percentage peak FMD correlated negatively with HbA1c ($\rho = -0.52$, $P < .001$) and duration of diabetes ($\rho = -0.33$, $P = .033$), while CIMT correlated positively with diabetes duration but not HbA1c.

Conclusions: Children and adolescents with T1DM exhibit early endothelial dysfunction characterized by impaired and delayed FMD responses, preceding structural vascular changes. Elevated hsCRP and ET-1 levels indicate early inflammatory and endothelial activation. Non-invasive vascular functional assessment may improve early cardiovascular risk stratification in youth with T1DM.

EP392 - ECE_3710 - Evaluation of diabetes related distress in adolescents with type 1 diabetes during the transition to adult care

Soukaina Lahlou, Nassim Essabah Haraj, Malak Iggar, Siham El Aziz and Asma Chadli
Clinical Neuroscience and Mental Health Laboratory, Endocrinology, Diabetology, Metabolic Diseases and Nutrition, Ibn Rochd University Hospital, Casablanca, Morocco

Introduction: The transition from adolescence to adulthood is a sensitive period characterized by major physical, psychological, and social changes. For adolescents living with type 1 diabetes (T1D), this phase involves a heavy daily treatment burden and complex self-management demands, which can lead to emotional distress and reduced adherence to care.

The aim of this study was to assess diabetes-related distress in adolescents with T1D and to evaluate its impact on glycemic control.

Materials and Methods: This was a descriptive cross-sectional study including adolescents aged 15 to 18 years with type 1 diabetes, followed in the Endocrinology Department between January 2021 and December 2024. Diabetes-related emotional distress was assessed using the Problem Areas in Diabetes (PAID) questionnaire. Clinical, biological, and therapeutic data were collected from medical records. Statistical analysis was performed using SPSS software.

Results: A total of 100 patients were included, with a female-to-male ratio of 1.5. The mean age was 16 years, and the mean duration of diabetes was 5 years. The mean HbA1c was 10.6%, reflecting poor glycemic control.

The mean PAID score was 27%, with moderate to high distress observed in 91% of patients. A significant positive correlation was found between PAID score and HbA1c ($P < .001$), indicating that higher emotional distress was associated with poorer glycemic control.

Conclusions: Diabetes-related emotional distress is common among adolescents with T1D and is associated with suboptimal glycemic control. These findings highlight the importance of integrating psychological assessment and support into routine diabetes care.

EP393 - ECE_1290 - Modulation of mitochondrial function and Ca^{2+} dynamics by semaglutide in pancreatic beta cells

Éverton Vogt[1], Eloisa Vilas-Boas[2], Debora Rocha[1], Camille Caldeira[1] and Alicia Kowaltowski[1]
[1]*Departamento de Bioquímica, Instituto de Química and Centro de Metabolismo CoMeta, São Paulo, Brazil;* [2]*Faculdade de Ciências Farmacêuticas, São Paulo, Brazil*

GLP-1 receptor agonists such as semaglutide regulate multiple stimulus–secretion coupling components in pancreatic beta cells, integrating metabolic, ionic, and secretory pathways. These agents influence mitochondrial ATP production, membrane excitability, and Ca^{2+} handling, all of which are essential for insulin secretion. Despite their clinical relevance, the mechanistic links between GLP-1 signaling, mitochondrial remodeling, and intracellular Ca^{2+} dynamics remain incompletely defined. This study aimed to determine whether semaglutide alters mitochondrial morphology and function, oxygen consumption, Ca^{2+} dynamics, and the immunocontent of ion-transport proteins in INS-1E beta cells. Cells were treated with 0-200 nM semaglutide for 24–72 h and evaluated using fluorescence microscopy for

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

mitochondrial morphology, Seahorse extracellular flux analysis for respiratory parameters, FURA-2 imaging for Ca^{2+} dynamics (in the presence or absence of extracellular Ca^{2+} and in the presence of specific inhibitors), Amplex Red assays for extracellular H_2O_2 production, and automated Western protein detection. Semaglutide did not affect cell viability. Basal and ATP-linked oxygen consumption decreased over time, whereas non-mitochondrial oxygen consumption increased in a dose-dependent manner, with no differences in glucose-stimulated H_2O_2 formation. Mitochondrial volume decreased over time, whereas sphericity and branching parameters increased independently of semaglutide concentration. Semaglutide increased cytosolic Ca^{2+} in a dose-dependent manner in the presence of extracellular Ca^{2+}; this response was abolished under Ca^{2+}-free conditions and by verapamil or glibenclamide, indicating dependence on VDCCs and upstream modulation of KATP channels. Inhibitors of mitochondrial Ca^{2+} transport (CGP and ruthenium red) eliminated the effect, and thapsigargin suppressed the signal, indicating contributions from both mitochondrial uptake and ER store mobilization. Store-operated calcium entry was reduced only at 200 nM semaglutide. MCU protein content increased exclusively at 200 nM, whereas NCLX remained unchanged. Together, these preliminary findings indicate that semaglutide integrates bioenergetic and Ca^{2+}-signaling responses in beta cells through combined modulation of mitochondrial remodeling, respiratory activity, and organelle-dependent Ca^{2+} handling.

EP394 - ECE_3560 - Effect of a 6-months culturally tailored lifestyle intervention on weight, waist circumference and HbA1c in multi-ethnic patients with type 2 diabetes

Sabrina Berti[1,2], Vania Campanella[1,2], Silvia Ricci Bitti[1], Michele Baldari[1,2], Valentina Lo Preiato[2], Flaminia Fanelli[1,2], Emmanuele Capobianco[1,2], Cristiana Cantone[1,2], Guido Di Dalmazi[1,2] and Uberto Pagotto[1,2]

[1]Department of Medical and Surgical Sciences (DIMEC), University of Bologna, Bologna, Italy; [2]Endocrinology and Diabetes Prevention and Care Unit, IRCCS Policlinico di S. Orsola, Bologna, Italy

Background and Aims: In type 2 diabetes, ethnic background can influence dietary habits and response to standard nutritional interventions. This study, part of the ongoing PLANEAT Horizon Europe Project, aims to evaluate the effectiveness of a simple culturally tailored, sustainability-oriented lifestyle intervention on body weight, waist circumference, and HbA1c in patients living in Italy with different cultural backgrounds.

Methods: All patients had Type 2 diabetes. At baseline, patients chose between a lifestyle intervention that could integrate, at their request, culturally tailored dietary advice, plus supervised weekly physical activity ("intervention group"), or general Mediterranean dietary recommendations alone ("control group"). At baseline, 3 months, and 6 months, all patients underwent medical visits with antidiabetic therapy adjustment if needed and received dietary counselling.

Results: A total of 101 patients were enrolled (South Asia $n = 27$; North Africa $n = 25$; Eastern Europe $n = 23$; Italy $n = 26$). South Asians and North Africans were younger than Italians (48 ± 7 and 51 ± 9 vs 64 ± 6 years; $P < .001$ and $P = .02$). Waist circumference was lower in South Asians than in all other groups (91 ± 9 vs 106 ± 11 cm; $P < .001$). BMI was lower in South Asians compared with Italians and Eastern Europeans (27.0 ± 4.4 vs 31.6 ± 4.6 and 31.9 ± 5.0 kg/m^2; $P = .01$ for both). HbA1c was similar across groups.

Overall, 42 (41.6%) patients chose the intervention group and 59 (58.4%) the control group. Compared with Italians (reference group), Eastern Europeans were less likely to choose the lifestyle intervention (OR 0.26, 95% CI 0.08-0.87; $P = .03$), while the other groups showed similar probabilities. In the intervention group, all patients requested culturally tailored dietary advice.

At 3 ($n = 89$) and 6 months ($n = 69$), a significant weight loss was observed (6 months: -1.7 ± 5.3% of body weight vs baseline, $P = .019$). However, the intervention was not superior to general dietary recommendations in terms of weight loss (6-month percentage weight change from baseline: -1.3 ± 4.2% in the intervention group vs -1.8 ± 6.1% in the control group; $P = .70$). No significant interaction between ethnic origin and intervention group on weight loss was found (p for interaction = 0.095).

HbA1c significantly improved from baseline to 6 months (57.1 ± 18.8 vs 50.5 ± 8.3 mmol/mol; $P = .02$), with no differences among cultural groups ($P = .106$) or between intervention or control ($P = .132$, P for interaction = 0.899). Waist circumference did not improve significantly over time or within specific ethnic groups.

Conclusions: So far, culturally tailored lifestyle intervention did not show to be superior to general dietary recommendations on weight, waist circumference, or HbA1c reduction.

EP395 - ECE_1221 - Linking stress-related behavior to adipose tissue function in vulnerable and resilient mice

Adrian Segev, Saumya Kishor Mehta, Suparna Sen, Ayala Wollman, Albert Pinhasov and Tovit Rosenzweig

Department of Molecular Biology, and The Adelson School of Medicine, Ariel University, Ariel, Israel

Chronic stress contributes to multiple morbidities, including metabolic disorders. Our previous work demonstrated that stress-coping phenotypes are closely associated with obesity-related metabolic dysfunction and white adipose tissue (WAT) impairment in mouse models of stress vulnerability and stress resilience. When challenged with a high-fat diet (HFD), stress-vulnerable mice developed obesity-associated metabolic alterations, whereas stress-resilient mice were largely protected.

Although WAT is well recognized as a central regulator of metabolic health, the bidirectional relationship between behavioral regulation and adipose tissue function remains poorly understood. The present study aimed to investigate the interplay between WAT function and mood-related behaviors, with a particular focus on stress-coping characteristics. Specifically, we examined whether pharmacological interventions targeting either mood regulation (paroxetine, an SSRI) or adipose tissue function (pioglitazone, a PPARγ agonist) exert reciprocal effects on behavioral outcomes and WAT functionality in stress-vulnerable mice. In parallel, we assessed the impact of chronic stress exposure on WAT function in stress-vulnerable and stress-resilient mice.

The study was conducted using a unique, selectively-bred mouse model. Animals were classified as dominant (Dom) or

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

submissive (Sub) based on a dominance–submissiveness relationship test, in which mice compete for access to sweetened milk. Stress-vulnerable (Sub) mice were treated for four weeks with paroxetine or pioglitazone while maintained on a standard diet (STD). Both treatments improved social behavior in the three-chamber test. Anxiety-like behavior in the open-field test was reduced only by pioglitazone, whereas exploratory activity in the hole-board test and active coping strategies in the forced swim test were enhanced by both drugs.

To assess adipose tissue responses, stromal vascular cells were isolated from WAT. Both treatments enhanced preadipocyte proliferation and adipogenic differentiation in subcutaneous depots, while impairments persisted in visceral depots.

To further examine the effects of stress on adipose tissue function, mice were subjected to an unpredictable chronic mild stress (UCMS) paradigm for three weeks. Preadipocyte proliferation and adipogenesis in subcutanous WAT were higher in Dom than in Sub mice, accompanied by a greater abundance of preadipocytes as revealed by FACS analysis. UCMS further enhanced proliferation and differentiation in Dom mice, while suppressing these processes in Sub mice.

In summary, pharmacological targeting of either mood or adipose tissue induced parallel behavioral and adipose cellular changes. Moreover, chronic stress differentially modulated adipose tissue function in stress-vulnerable vs stress-resilient mice, supporting a bidirectional link between stress-related behavior and adipose tissue plasticity.

EP396 - ECE_1460 - Impact of subclinical hypothyroidism on postprandial triglycerides and MASLD in obese individuals with and without type 2 diabetes mellitus

Lavina Patnaik[1], Sv Madhu[1], Nishant Raizada[1] and Shuchi Bhatt[2]
[1]*Endocrinology, University College of Medical Sciences, New Delhi, India;* [2]*Radiology, University College of Medical Sciences, New Delhi, India*

Introduction: Diabetes and obesity are associated with increased cardiometabolic risk, largely due to dyslipidemia, particularly postprandial hypertriglyceridemia. Postprandial hypertriglyceridemia has been associated with increased risk of Metabolic dysfunction–associated Steatotic Liver Disease (MASLD) and cardiovascular complications. Subclinical hypothyroidism (SCH) is also linked to increased postprandial triglyceride (PPTG) levels and its adverse consequences. Thus, SCH could further exaggerate the cardiometabolic risk in individuals with obesity and type 2 diabetes mellitus. Extrathyroidal effects of thyroid stimulating hormone (TSH), such as effects in adipose tissue and hepatocytes, along with modulation of bile acid metabolism and fibroblast growth factor-21 (FGF-21) levels, may be important links in this enhanced cardiometabolic risk in such patients. Hence, we conducted this study to look at the association of SCH with PPTG, total bile acid and FGF-21 levels and MASLD in obese individuals with and without type 2 diabetes mellitus.

Methodology: This cross-sectional analytical study included 212 overweight/obese participants divided into four groups: obese type 2 diabetes with and without SCH, obese non-diabetic with and without SCH. Postprandial triglyceride levels were assessed by oral fat challenge at 0, 2, 4, 6, and 8 hours. Total bile acids and FGF-21 were measured using enzymatic and ELISA methods, respectively. MASLD was graded by ultrasonography. Data were analyzed using ANOVA, Mann–Whitney and chi-square tests (SPSS v29).

Results: Participants with coexistent type 2 diabetes and SCH had the highest PPTG area under curve (AUC) and peak PPTG levels compared to other groups ($P < .05$). Individuals with SCH without diabetes had significantly lower PPTG-AUC and peak PPTG than their euthyroid counterparts. No significant differences in total bile acids or FGF-21 were observed between groups. PPTG-AUC and baseline and 2-hour post-fat challenge triglyceride levels were significantly associated with MASLD severity ($P < .05$), but bile acid and TSH levels were not.

Discussion and Conclusions: This study highlights the impact of coexistence of type 2 diabetes and SCH in obese individuals who showed highest postprandial hypertriglyceridemia, compared to obese with diabetes only, thereby indicating increased cardiometabolic risk as a result of SCH. Obese individuals without diabetes or SCH showed higher PPTG AUC and peak triglycerides than obese with SCH alone, suggesting a differential effect of TSH on lipid metabolism in individuals with and without type 2 diabetes mellitus. Thus, SCH modifies PPTG and metabolic risk in those with both obesity and type 2 diabetes, supporting consideration of treatment of SCH to reduce risk.

EP397 - ECE_1506 - Beyond BMI: obesity phenotype with sarcopenia

Sadaf Ali[1,2,3], Gabriela Da Silva Xavier[1] and Tarekegn Hiwot[4]
[1]*University of Birmingham, Birmingham, United Kingdom;* [2]*Metabolism and Systems Science, University of Birmingham, Birmingham, United Kingdom;* [3]*Institute of Metabolism & Systems Sciences, Birmingham, United Kingdom;* [4]*University Hospitals Birmingham, Birmingham, United Kingdom*

Background: Obesity is typically associated with preserved or increased lean mass; however, certain monogenic forms present with a contrasting and clinically significant phenotype characterised by **marked reductions in muscle mass alongside excess adiposity**. This **sarcopenic obesity phenotype** is recognised as one of the most dangerous body-composition profiles, conferring **higher mortality, greater functional decline and accelerated metabolic deterioration** in middle-aged and older adults. Monogenic obesity syndromes offer a unique model for understanding these mechanisms, as metabolic dysfunction arises independently of overall adiposity. Emerging evidence suggests that defects in skeletal muscle oxidative capacity and mitochondrial structure may underlie the profound insulin resistance observed in these individuals. Defining how altered body composition and muscle bioenergetics interact is therefore critical to understanding disease pathophysiology and guiding targeted treatment.

Methods: Ten adults with monogenic obesity of Alstrom syndrome were compared with ten BMI-matched obese controls. Body composition (fat-free mass [FFM], total body water [TBW], and predicted regional muscle mass) was assessed by bioimpedance. Metabolic profiling included fasting glucose, insulin, c-

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

peptide, HbA1c, lipid panels, HOMA-IR, and liver enzymes. High-resolution respirometry on freshly isolated skeletal muscle fibres quantified oxidative phosphorylation capacity. Electron microscopy (EM) assessed mitochondrial area, number, aspect ratio and form factor. Statistical significance was set at $P \leq .05$.

Results: Despite comparable BMI, participants with monogenic obesity exhibited a pronounced **sarcopenic phenotype**, with significantly lower FFM, TBW and muscle mass across trunk and limbs (all $P \leq .01$). Metabolic evaluation revealed markedly elevated fasting glucose ($P = .003$), hyperinsulinaemia and increased c-peptide ($P \leq .05$), alongside higher HbA1c and HOMA-IR ($P \leq .05$), indicating **severe insulin resistance**. Liver enzymes, including ALT and alkaline phosphatase, were significantly raised ($P \leq .05$), suggesting hepatic involvement.

High-resolution respirometry demonstrated a **global reduction in mitochondrial oxidative phosphorylation**, with significantly lower oxygen flux across all substrates. Overall mitochondrial capacity decreased **1.49 ± 0.03-fold** compared with controls. EM analyses showed no change in mitochondrial area or number; however, mitochondrial **aspect ratio** (-0.127 ± 0.0449) and **form factor** (-0.0106 ± 0.0273) were significantly reduced, indicating impaired mitochondrial shape, branching and network complexity.

Conclusions: This study identifies a **high-risk sarcopenic obesity phenotype** in monogenic obesity, characterised by low lean mass, severe insulin resistance, impaired mitochondrial oxidative capacity and altered mitochondrial structure. These findings emphasise the need to move **beyond BMI** when defining obesity phenotypes and highlight skeletal muscle mitochondrial dysfunction as a key driver of metabolic disease in this population.

EP398 - ECE_1825 - Early childhood adiposity assessed by waist-to-height ratio and its impact on later obesity

Markéta Vaňková[1], Tereza Svobodová[1], Josef Vcelak[1], Radka Taxová Braunerová[2] and Tereza Metelcová[2]
[1]*Molecular Endocrinology, Institute of Endocrinology, Prague, Czech Republic;* [2]*Obesity Management Centre, Institute of Endocrinology, Prague, Czech Republic*

Rapid weight gain and changes in body composition during early childhood are strongly associated with an increased risk of obesity and cardiometabolic diseases later in life. Early-life exposures play a critical role in obesity development. Although body mass index (BMI) is widely used to assess normal body weight, alternative indices such as waist-to-height ratio (WHtR) may better reflect cardiometabolic risk by capturing central adiposity.

This study investigated the risk of increased adiposity in early childhood and its association with excess weight in adolescence and young adulthood.**Methods:** Three study populations were analyzed: (1) 11 307 children aged 6.5-7.9 years from the WHO Childhood Obesity Surveillance Initiative (COSI) collected between 2008 and 2025; (2) a longitudinal subsample of 613 children assessed at ages 6.5-7.9 years in the 5th round of COSI (2019) and re-evaluated at ages 11-13 years (2022-2024); and (3) 253 young adults (mean age 23.3 ± 2.04 years) with available WHtR data from adolescence (mean age 15.3 ± 1.88 years). In children, waist circumference, height, weight, and BMI were measured, and overweight and obesity were classified according to WHO criteria. In adults, BMI and waist circumference were assessed. Abdominal obesity was defined as WHtR ≥ 0.5 in all participants. Statistical analyses included chi-square tests (NCSS 2019) and multivariate regression using O2PLS (SIMCA).

Results: Adiposity risk was identified in 94% of children with severe obesity, 72% with obesity, 26% with overweight, and 2.7% of normal-weight children. Modifiable factors associated with higher adiposity risk included parental underestimation of child weight, shorter breastfeeding duration, insufficient sleep, low physical activity, sedentary behavior, unhealthy diet, family history of metabolic disease, and lower parental education. While overweight and obesity were more prevalent in boys, sex was not associated with adiposity risk. During the 4-year follow-up, 78.7% of children maintained a healthy WHtR, whereas 6.4% exhibited persistently elevated WHtR. In young adulthood, 63% of individuals with elevated WHtR had already shown increased adiposity in childhood.

Conclusions: Early identification of children at high risk of adiposity and targeted intervention on modifiable factors may be more effective than treating obesity at later stages. While BMI remains useful for population surveillance, direct assessment of adiposity provides a clearer link to obesity-related risk factors and long-term outcomes.

Funding: Supported by the Ministry of Health of the Czech Republic in cooperation with the Czech Health Research Council under project No. AZV NU23-09-00252 and project MH-CZ-DRO (EU00023761).

EP399 - ECE_1918 - A/J male mice resist obesity-driven bone loss through increased antioxidant enzyme capacity compared to obesity-prone C57Bl/6J male mice

Michaela Ferencakova[1], Martina Dzubanova[1], Andrea Benova[1], Dung Nguyen[1], Jan Prochazka[2], Frantisek Spoutil[2], Tomas Cajka[1], Marek Vrbacky[1], Kristina Bardova[1], Martin Rossmeisl[1], Jan Kopecky[1] and Michaela Tencerova[1]
[1]*Prague, Czech Republic;* [2]*Czech Centre for Phenogenomics & Laboratory of Transgenic Models of Diseases, Institute of Molecular Genetics of the Czech Academy of Sciences, Prague, Czech Republic*

Background: Obesity-associated bone fractures are not manifested in all obese individuals. However, the underlying mechanism behind this phenomenon has not been well described. Thus, we investigated the effect of obesity on bone and bone marrow stromal cell (BMSCs) metabolism in obesity-prone C57BL/6J (B6) mice and obesity-resistant A/J mice under obesogenic condition.

Methods: Eight-week-old B6 and A/J male mice were either fed with normal diet (ND) or high-fat-diet (HFD) (60% kcal from fat) ($n = 10$/group) for 3 months and examined for metabolic and bone parameters. Primary BMSCs were obtained from treated mice for cellular analyses. Proteomic and metabolomic analysis of bone marrow (BM) was performed using LC-MS. siRNA transfection of selected targets from proteomics in primary B6 and A/J BMSC was performed followed by measurements of osteogenic and adipogenic potential and cellular metabolism.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Results: After 3 months of HFD, B6 mice gained body weight (+1.5-fold, $P < .001$) and impaired glucose tolerance (+1.3-fold, $P < .05$) comparing to A/J mice. HFD impaired trabecular and cortical bone in B6 mice, while HFD A/J mice did not manifest trabecular bone loss ($P > .10$) and increased cortical thickness and decreased porosity ($P < .001$). These obesity-induced changes were accompanied by lower bone marrow adiposity in A/J vs B6 mice ($P < .01$). Further, primary BMSCs isolated from A/J mice manifested higher glycolytic profile compared to respiratory profile in B6 BMSCs ($P < .001$) correlating with higher osteogenic potential of A/J BMSCs under HFD. Proteomic analysis revealed increased levels of antioxidant enzymes (e.g. GLO1, DPP7) in A/J compared to B6 mice. siGlo and siDpp7 BMSCs showed lower osteogenic capacity suggesting its important role for bone homeostasis.

Conclusions: Our data show that obesity induced worse impact on bone and fat metabolism in B6 compared to A/J mice associated with lower BMSC glycolytic capacity in B6 mice. These changes were accompanied by increased levels of antioxidative enzymes in A/J HFD BM suggesting protection from HFD-induced oxidative stress.

EP400 - ECE_2249 - Benefits of a short-term Mediterranean Diet (MD) intervention on circadian expression profile of the clock gene BMAL1 and of TLR4 in Peripheral Blood Mononuclear Cells (PBMC) of patients with obesity

Claudia Pivonello[1], Nunzia Magnacca[2], Chiara Graziadio[1], Mariarosaria Negri[3], Feliciana Amatrudo[4], Elisabetta Vozza[5], Guendalina Del Vecchio[1], Claudia Vetrani[3], Sabrina Tini[6], Flavia Prodam[6], Rosario Pivonello[2] and Annamaria Colao[2]
[1]Department of Public Health, Federico II University, Naples 80131, Italy; [2]Department of Clinical Medicine and Surgery, Federico II University, Naples 80131, Italy; [3]Department of Psychology and Health Sciences, Pegaso Telematic University, Napoli, Italy; [4]Pegaso Telematic University, Napoli, Italy; [5]Department of Experimental Medicine, La Sapienza University of Rome, Rome, Italy; [6]Department of Health Sciences, University of Piemonte Orientale, Novara, Italy

A low-grade chronic inflammatory condition characterises obesity, with a dominant infiltration in adipose tissue of activated macrophages expressing high levels of Toll-like receptor 4 (TLR4), whose exaggerated and uncontrolled pro-inflammatory signalling induced by infection can lead to septic shock and death. Circadian rhythm-related gene expression patterns in PBMC exhibited marked variation in subjects with obesity compared to controls, often associated with the upregulation of certain clock genes, such as BMAL1, contributing to metabolic comorbidities. Moreover, BMAL1 regulates time-dependent inflammatory responses following TLR4 activation by modulating enhancer activity.

The current study investigated the effect of a short-term MD intervention (STMD) on the circadian gene and TLR4 profiles in PBMC of 38 obese patients (24 F (63%), 14 M (37%)) and 7 obese diabetic patients (2 F (29%), 5 M (71%)), enrolled at AOU Federico II of Naples and University of Piemonte Orientale, respectively. Anthropometric and biochemical parameters were assessed before (T0) and after six weeks of MD intervention (T1). Blood samples for PBMC extraction were collected in the morning (8AM) and in the afternoon (4PM) in fasting conditions, both at T0 and T1. Clock genes (BMAL1, PER1, PER2, CRY1, CRY2) and TLR4 were evaluated in PBMC by RT-qPCR. At T0, only BMAL1($P = .036$) and TLR4 ($P = .0004$) expression at 4PM were significantly higher than 8AM. After normalization on weight and BMI, BMAL1 and TLR4 expression significantly correlated in both the morning ($r = 0.530$, $P < .001$) and the afternoon ($r = 0.579$, $P < .001$).

Although STMD only a slight but non-significant improvement of the anthropometric and biochemical parameters, it was sufficient to modulate the expression of some clock genes (PER1 $P = .002$, PER2 $P = .012$ and CRY1 $P = .027$) that resulted in significantly lower in the afternoon (T1 4PM) compared with the morning (T1 8AM). However, compared to T0 4PM, STMD significantly decreased the clock genes (BMAL1 $P = .03$, PER1 $P = .002$, CRY1 $P = .001$, CRY2 $P = .017$) and TLR4 ($P < .0001$) expression at T1 4PM, thus restoring gene levels to normal values at T1 compared to T0. After normalization on weight and BMI, BMAL1 and TLR4 expression significantly correlated both the morning ($r = 0.384$, $P = .036$) and the afternoon ($r = 0.936$, $P < .001$) at T1. In conclusion, patients with obesity display higher expression of BMAL1 and TLR4 in PBMC during the afternoon, increasing inflammation susceptibility. STMD restores a more physiological BMAL1 gene profile in PBMC and consequently reduces the expression and activation of TLR4 and thus macrophages' immune activity and inflammatory response.

EP401 - ECE_2274 - Prevalence and impact of first-trimester obesity on maternal and fetal outcomes in a South Asian population

Minuri Fernando[1], Indunil Piyadigama[2,3], Dulani Samaranayake[4,5] and Prasad Katulanda[6,7]
[1]National Hospital—Sri Lanka, University Medical Unit, Colombo, Sri Lanka; [2]Faculty of Medicine, University of Colombo, Sri Lanka; [3]Gynaecology and Obstetric Department, De Soysa Maternity Hospital- University Gynaecology and Obstetric Clinic, Colombo, Sri Lanka; [4]Faculty of Medicine, University of Colombo, Sri Lanka; [5]Community Medicine Department, Colmbo, Sri Lanka; [6]Faculty of Medicine, University of Colombo, Sri Lanka; [7]University Medical Unit-Endocrine Clinic, University Medical Unit, Colombo, Sri Lanka

Background: Obesity is an epidemic that has now invaded the low and middle-income countries. This is common among females of the reproductive age group, which paves the way to obesity in pregnancy, resulting in increased risk of pregnancy-related adverse outcomes, even at a lower pre-pregnancy BMI among Asians, due to their differences in body fat compositions compared to the non-Asian population. South Asian data is limited.

Methods: This is a retrospective descriptive cross-sectional study, among postpartum mothers aged ≥16 years, with a singleton pregnancy, having a first-trimester BMI on records, and delivered at De Soyza Maternity Hospital, Colombo, Sri Lanka, during July 2024 to September 2024. An interviewer-administered questionnaire was used for data collection. Data analysis was done using SPSS 26 software. Asian BMI cut-offs were used. Overweight and obesity were combined to assess the risk of complications. Bivariate analysis using the chi-square test was done

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

to determine the significance of maternal and fetal/neonatal outcomes with the combination of overweight-obesity.

Results: Four hundred mothers participated in the study. According to Asian cut-offs, the prevalence of first-trimester obesity was 41.8% (95%CI 36.92-46.58), overweight was 17.5% (95%CI 13.78-21.22), and underweight was 11.8% (95%CI 8.59-14.91). The first-trimester overweight-obesity combination was significantly associated with maternal complications: gestational diabetes mellitus [OR = 1.66 (95% CI 1.06—2.60; $P = .025$)], pregnancy-induced hypertension [OR = 3.73 (95% CI 1.40—9.95; $P = .005$)], premature labor [OR = 2.2 (95% CI 1.01—4.81; $P = .044$)], emergency cesarean section [OR = 1.71 (95% CI 1.06—2.77; $P = .028$)], and the presence of one or more maternal complication [OR = 1.80 (95% CI 1.18—2.72; $P = .006$)]. None of the fetal/neonatal complications had any significant association with the overweight-obesity combination.

Conclusions: According to Asian BMI cut-offs, South Asians have a higher prevalence of obesity in pregnancy, which is significantly associated with maternal adverse outcomes. This highlights the importance of using Asian BMI cut-offs for Asian patients and the importance of preconception BMI optimization to prevent maternal morbidity.

EP402 - ECE_2635 - Circulating humanin is inversely associated with obesity in patients with acromegaly

Dorota Filipowicz[1], Daniela Dadej[1], Marianna Cemel[1] and Marek Ruchala[1]

[1]*Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences, Poznań, Poland*

Introduction: Cardiovascular complications are the leading cause of premature mortality in patients with acromegaly and are linked to metabolic disturbances driven by prolonged exposure to elevated IGF-1 levels. Humanin, a mitochondria-derived peptide with protective properties against cellular stress and regulatory effects on insulin and IGF signalling, may influence pathways underlying metabolic and cardiovascular risk; however, its role in acromegaly remains unclear. The aim of this study was to evaluate circulating humanin concentrations in patients with acromegaly and to assess their associations with disease activity, anthropometric, and inflammatory parameters.

Materials and Methods: This cross-sectional study included 130 participants (55% women): patients with active ($n = 52$) and inactive acromegaly ($n = 37$), and a control group without acromegaly ($n = 41$). Serum humanin concentrations were measured using a commercial Human Putative Humanin Peptide (MT-RNR2) ELISA kit (Cusabio). Anthropometric (body weight, BMI), hormonal (IGF-1, GH, SAGIT score), and inflammatory parameters (CBC, CRP, Fe, TIBC, ferritin) were collected. Statistical analyses were performed using Statistica 13 (TIBCO Software Inc.), with $P < .05$ considered statistically significant.

Results: Serum humanin concentrations did not differ between patients with active acromegaly, inactive acromegaly, and controls (Kruskal–Wallis: $H(2) = 1.69$, $P = .43$). In patients with acromegaly, humanin levels were inversely correlated with BMI (Spearman's $\rho = -0.21$, $P < .05$). Acromegaly patients with BMI $\geq$ 30 kg/m^2 (62%) had significantly lower humanin concentrations than patients with BMI < 30 kg/m^2 (median 1046 [IQR 750-1680] vs 1498 [998-2446] pg/mL; Mann–Whitney $P = .011$). In multivariable linear regression adjusted for age and sex, obesity remained independently associated with lower log-transformed humanin concentrations ($b = -0.38$, $P = .038$), corresponding to around 30% lower levels. Results were consistent in sensitivity analyses excluding values above the 95th percentile ($b = -0.33$, $P = .045$).

Conclusions: Circulating humanin concentrations are not associated with acromegaly presence or activity but decline with increasing obesity in this high cardiometabolic risk population. This finding may suggest attenuation of humanin's mitochondrial-related protective effects with excess adiposity and highlights the potential importance of weight-reduction strategies in acromegaly. These findings support further evaluation of humanin as a potential biomarker of metabolic risk in acromegaly; further studies are warranted to clarify its role in obesity.

Objectives: To evaluate the efficacy and safety of synthetic semaglutide injection (Test drug) compared with Wegovy® (Reference drug) 2.4 mg subcutaneously for weight management in patients with waist circumference <112 cm (Subgroup 1[S1]) and ≥112 cm (Subgroup 2 [S2]).

Materials and Methods: A phase III, multicentre, randomized, open-label, active-controlled clinical study (CTRI/2025/04/085487) was conducted across 22 study sites in India after

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

receiving regulatory and ethics committee approvals. In this study, 267 adult patients with (BMI) ≥ 30 kg/m^2 or ≥27 kg/m^2 with the presence of at least one co-morbidity of hypertension, dyslipidaemia and/or type 2 diabetes mellitus were included. Patients were randomized to receive either test drug or reference drug weekly for 24 weeks. Secondary endpoints included change in BMI, waist circumference, SF-36, and glycaemic measures in diabetic and non-diabetic patients. Safety assessments included incidence of TEAEs and anti-drug/neutralizing antibody.

Results: At baseline, 132 patients were included in S1 and 135 patients were included in S2. Mean (±SD) percentage reduction in weight from baseline to week 24 was −14.0 (±3.97) with test drug and −13.6 (±3.80) with reference drug in S1 ($P = .4116$) and −13.7 (±4.59) with test drug and −14.5 (±4.36) with reference drug in S2 ($P = .3244$) respectively. Proportion of patient achieving ≥ 5% and ≥10% body weight reduction was comparable between test and the reference drug in both S1 and S2 ($P = .3217$ and $P = .1152$ for S1 and $P = .4703$ and $P = .3423$ for S2 respectively). Mean (±SD) change in waist circumference with test and the reference drug was −9.62(±3.53) cm and −8.81 (±4.03) cm respectively in S1 ($P = .0790$) and −11.8 (±7.17) cm and −14.1(±11.66) cm respectively in S2 ($P = .1483$) at week 24. In diabetic patients there was decrease in glycaemic parameters (HbA1c, FBG and PPBG) from baseline to week 24 in both S1 and S2 and was comparable between arms ($P > .05$). In non-diabetic patients decrease in glycaemic parameters (HbA1c, FBG and PPBG) from baseline to week 24 was not clinically relevant compared to diabetic patients and was comparable between arms ($P > .05$). Study medications were well tolerated.

Conclusions: Semaglutide injection is effective in weight management irrespective of baseline waist circumference and can be a treatment of choice in weight management with or without co-morbidities

EP404 - ECE_3547 - Effect of CPAP and testosterone replacement on serum testosterone in obese men with obstructive sleep apnea and varying degrees of glucose metabolism disorders

Violetta Yuzvenko, Tetiana Yuzvenko, Oleksandr Tovkai, Volodymyr Pankiv, Olena Tretyak, Dmytro Kogut and Vadym Ischuk
Kiev, Ukraine

Background/Objectives: Obstructive sleep apnea (OSA) is associated with hypogonadism in obese men and is frequently accompanied by disorders of glucose metabolism. In men with prediabetes and type 2 diabetes mellitus, OSA may further aggravate insulinresistance and glycemic control, contributing to hormonal imbalance. This study aimed to evaluate the impact of continuous positive airway pressure (CPAP) and testosterone replacement therapy (TRT) on serum total testosterone and metabolic parameters in obese men with OSA and impaired glucose metabolism.

Methods: Seventy-seven men aged 24-72 years (mean 47.8 ± 11.4) with overweight or obesity were studied. Patients were categorized as having type 2 diabetes ($n = 37$), prediabetes ($n = 16$), or insulin resistance without glucose impairment ($n = 24$). All participants underwent anthropometric assessment and measurement of fasting plasma glucose, insulin, HbA1c, lipid profile, and total testosterone. Baseline HbA1c levels were 8.1 ± 2.2% in patients with type 2 diabetes, 6.6 ± 1.3% in those with prediabetes, and 6.9 ± 1.5% in patients with insulin resistance. Obstructive sleep apnea was diagnosed using SOMNOtouch RESP eco monitoring. Patients were stratified by apnea-hypopnea index (AHI): ?15 ($n = 11$), 15-29.9 ($n = 23$), and ≥30 events/hour ($n = 43$). After 6 months of treatment, HbA1c significantly decreased in all groups, with the greatest improvement in patients receiving combined CPAP and TRT ($P < .05$). Treatment groups were: Group 1—CPAP ($n = 26$); Group 2—TRT ($n = 25$); Group 3—CPAP + TRT ($n = 17$). Statistical analysis was performed using Kruskal-Wallis ANOVA; $P < .05$.

Results: Baseline testosterone and anthropometric parameters were similar across groups. Post-treatment, all groups showed significant BMI reduction and increased serum testosterone ($P < .001$). Group 3 exhibited the largest increase, with most patients experiencing more than a twofold rise.

Conclusions: OSA significantly reduces serum testosterone in obese men. CPAP therapy increases testosterone levels, and combination with TRT provides the greatest effect. OSA should be considered a factor affecting hormonal balance and male reproductive health, beyond sleep-related breathing disturbances.

EP405 - ECE_3803 - Muscle mass, cellular integrity, and physical function after bariatric surgery: a Longitudinal Study in Severe Obesity

María Garcia Olivares[1], Rocío Fernández Jiménez[1], Cristina Navas-Moreno[1], Nerea Ruiz-Campos[1], Ángela Martínez-Martínez[1], José Ignacio Martínez Montoro[1], Carolina Gutiérrez-Repiso[1], Ángela Núñez-Morales[1], Rocío Soler-Humanes[2], Luís Ocaña-Wilhelmi[2], Diéter Morales-García[1], Francisco J. Tinahones[3], Jose Manuel Garcia-Almeida[1,4] and Lourdes Garrido-Sánchez[1]
[1]Instituto de Investigación Biomédica de Málaga-Plataforma en Nanomedicina (IBIMA Plataforma BIONAND), Málaga, Spain; [2]Instituto de Investigación Biomédica de Málaga-Plataforma en Nanomedicina (IBIMA Plataforma BIONAND), Virgen de la Victoria University Hospital, Surgery, Málaga, Spain; [3]Instituto de Investigación Biomédica de Málaga-Plataforma en Nanomedicina (IBIMA Plataforma BIONAND), Virgen de la Victoria University Hospital, Endocrinology and nutrition, Málaga, Spain; [4]Málaga, Spain

Introduction: Bariatric surgery in patients with severe obesity leads to substantial weight loss and marked metabolic improvements. However, its effects on muscle mass, cellular integrity, and physical function remain a matter of debate.

Objectives: To evaluate longitudinal changes in muscle mass, cellular integrity, and physical function in patients with severe obesity before and one year after bariatric surgery.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Materials and Methods: This longitudinal study included patients with severe obesity assessed preoperatively and at 12 months after bariatric surgery. Anthropometric and biochemical parameters were collected. Body composition was evaluated using bioelectrical impedance vector analysis (BIVA) and thigh nutritional ultrasound. Physical function was assessed by handgrip dynamometry and the Timed Up and Go test.

Results and Conclusions: At 12 months post-surgery, significant reductions were observed in body weight (−29.0%), BMI (−28.9%), and fat mass (−43.1%) ($P < .001$). These changes were accompanied by marked metabolic improvements, including significant decreases in glucose, insulin, HOMA-IR, and triglyceride levels (all $P < .001$).

Concurrently, significant reductions in fat-free mass (−12.4%), body cell mass (BCM; −16.6%), and body cell mass index (BCMI; −16.9%) were observed. Phase angle declined significantly (−8.4%; $P < .001$), suggesting impaired cellular integrity. In multivariate analysis, higher baseline BCM was independently associated with lower relative muscle mass loss ($\beta = 1.06$; $P < .001$), whereas older age and female sex were associated with greater muscle loss. Regarding physical performance, baseline phase angle ($\beta = .36$; $P = .026$) and baseline BCM ($\beta = .54$; $P = .033$) independently predicted improvement in Timed Up and Go performance.

Conclusions: Despite significant metabolic benefits and improvements in functional performance, bariatric surgery is associated with substantial loss of muscle mass and deterioration in muscle quality. Baseline BCM and phase angle emerge as key markers to identify patients at higher risk of muscle loss and may help guide targeted preoperative nutritional and exercise interventions.

EP406 - ECE_1369 - Impact of ethnicity and antihyperglycemic medications on dementia incidence in older adults with type 2 diabetes

Elena Chertok Shacham[1,2], Sireen Sharif[1], Muhammad Kadah[1] and Snait Ayalon[3]
[1]*Emek Medical Center, Internal Medicine B, Afula, Israel;* [2]*Technion, Israel institute of Technology, Medical Faculty, Haifa, Israel;* [3]*Emek Medical Center, Research Authority, Afula, Israel*

Background: Type 2 diabetes increases the risk of cognitive decline and dementia. Data on ethnic differences in dementia prevalence among patients with diabetes remain limited.

Methods: We conducted a retrospective matched case–control study of Clalit Health Services members aged 60 or older. Matching (1:3) was based on age, sex, language, and socioeconomic status. Ethnicity was determined by spoken language or place of birth. Prescriptions and refills for antidiabetic medications were recorded for the two years preceding the index date. Clinical, anthropometric, and comorbidity data were analysed.

Results: Our final cohort consisted of data from 150 237 patients. During up to 20 years of follow-up, 39% of participants developed dementia (crude proportion); however, when accounting for death as a competing risk, the 10-year cumulative incidence was approximately 9-10%, and ethnic differences were attenuated after multivariable adjustment. The use of SGLT-2 and DPP-4 inhibitors was associated with a lower probability of dementia. Specifically, SGLT-2 inhibitors (HR, 0.40; 95% CI, 0.38-0.41), GLP-1 agonists (HR, 0.64; 95% CI, 0.62-0.67), and DPP-4 inhibitors (HR, 0.67; 95% CI, 0.65-0.68 were associated with a reduced risk of dementia-related mortality.

Conclusions: SGLT-2 inhibitors, DPP-4 inhibitors, and GLP-1 receptor agonists were associated with reduced dementia-related mortality in older adults with type 2 diabetes. The effect was robust across ethnic groups, supporting their potential role in mitigating neurodegenerative outcomes.

EP408 - ECE_2828 - In vivo overexposure to non-esterified fatty acids increases circulating basal and postprandial androgen levels in normal female mongrel dogs

Christophe Richer dit Laflèche[1], Joanie Faubert[1], Foued Naimi[1], Sylvain Bellanger[1], Marie-Claude Battista[1], Ouhida Benrezzak[2], André Carpentier[1,2] and Jean-Patrice Baillargeon[1,2]
[1]*Sherbrooke, Canada;* [2]*Centre de recherche du Centre hospitalier universitaire de Sherbrooke, Sherbrooke, Canada*

Background: The etiology of the polycystic ovary syndrome is poorly understood, but studies suggest that lipotoxicity may be an important contributor.

Aim: To evaluate the effects of an in vivo overexposure to non-esterified fatty acids (NEFA) on changes in circulating androgen levels.

Methods: Female mongrel dogs underwent a 17.5-hour metabolic protocol. During the first 8 hours (night period), dogs ($n = 6$/group) received either a Intralipid-heparin 20% (IH; 0.02 ml/kg/min + 0.5 U/kg/min) or a saline infusion (control group), followed by a standard meal at 08h30. Blood samples were drawn every 60 minutes during the night period (8h) and for 9 hours post-meal (day period). Only 2 dogs (1/group) were in estrus. Changes from baseline were calculated as the incremental area under the curve (iAUC) of the fold increase from baseline and were compared between groups using t tests, unadjusted or adjusted for potential confounders or mediators. Correlations between parameters were done using linear regressions.

Results: In the 12 dogs studied (27.6 ± 2.9 kg), baseline androgen levels were comparable between experimental groups. NEFA levels more than doubled within one hour of infusion in the IH group. NEFA iAUC was significantly higher in response to the nocturnal IH infusion compared to the saline group (461 vs −47.7, $P = .001$) and rapidly returned to normal after discontinuation. The 17-hydroxyprogesterone (17-OHP) iAUCs were significantly higher in the IH group than in the saline group both at night (−73.0 vs −255, $P = .024$) and during the day (−49.6 vs −329, $P = .015$). No statistically significant changes in other androgens were detected. In multivariate analyses, the effects of IH on 17-OHP iAUCs were independent from night or day iAUCs of insulin, ACTH, and cortisol, and of day NEFA iAUC. Nocturnal NEFA, and cortisol iAUCs correlated with both the nocturnal and diurnal 17-OHP iAUCs ($R^2 = 0.49$, $P = .011$, and $R^2 = 0.35$, $P = .044$ for NEFA; and $R^2 = 0.42$, $P = .022$, and $R^2 = 0.33$, $P = .049$ for cortisol). Interaction analyses suggested a modifying effect of NEFA iAUC on the association between night 17-OHP, and insulin iAUC. The slope of the association tended to be more pronounced with higher NEFA exposure, though subgroup analyses underpowered.

Conclusions: An acute in vivo elevation of circulating NEFA using an IH protocol induces a significant increase in fasting and insulin-stimulated, postprandial androgen precursor production in normal female dogs.

EP411 - ECE_1500 - Non-invasive blood glucose measurement using visible light photoplethysmography signals in subjects with diabetes

Hyeong-Kyu Park[1] and Chul Sik Kim[2]
[1]*Soonchunhyang University, Seoul, South Korea;* [2]*Yonsei University, Yongin, South Korea*

The global diabetic population is expected to reach 800 million by 2035, increasing the need for continuous blood glucose monitoring. Conventional methods, like finger-prick glucometers and invasive continuous glucose monitors, are burdensome due to pain, infection risks, and consumable costs. Several non-invasive devices measuring glucose via fingertip tissue have been developed but lack the required accuracy for commercialization. This study was aimed to investigate a non-invasive optical glucose meter that accounts for fingertip thickness, skin condition, and body mass index. Blood glucose was measured by analyzing photoplethysmography signals from 660 nm light irradiated onto the fingertip, with venous blood glucose levels used for calibration. Individual characteristics were incorporated during calibration by determining baseline values and applying an appropriate feature extraction algorithm to derive the final formula. A total of 28 subjects with diabetes (13 males, 15 females; 3 with type 1 and 25 with type 2 diabetes) had their fasting and postprandial glucose levels measured using both the non-invasive device and venous blood sampling. The device's accuracy was evaluated with the mean absolute relative deviation (MARD), which was 8.8%, showing superior accuracy compared to previous studies. Consensus Error Grid (Type 1) analysis revealed 100% of data in zones A and B, confirming clinical reliability. ISO 15197 requires 99% of glucose values to fall within these zones, and this clinical trial confirmed 100% compliance. In summary, our results have demonstrated the feasibility of non-invasive glucose measurement with accuracy comparable to venous blood glucose levels in subjects with diabetes. To commercialize our novel device, further studies to address the wider ranges of blood glucose levels in various subjects, such as individuals with anemia, chronic kidney or liver diseases will be needed.

EP413 - ECE_2894 - Development of a rabbit model for type 2 diabetes mellitus

Denis Visotskii[1,2], Dmitrii Popov[2], Kseniya Vysotskaya[1] and Gleb Kosovsky[2]
[1]*Endocrinology Research Centre, Moscow, Russia;* [2]*Afanas'ev Institute of Fur-bearing Animal Breeding and Rabbit Breeding, Rodniki, Russia*

Introduction: The domestic rabbit (*Oryctolagus cuniculus*) is a classic model in biomedical research. However, all existing diabetic models in this species rely on beta-cytotoxic agents to induce a state of absolute insulin deficiency, mimicking type 1 diabetes mellitus (T1DM). A model capturing the pathogenesis of type 2 diabetes mellitus (T2DM), with its characteristic insulin resistance and compensatory hyperinsulinemia, has yet to be developed in rabbits.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Aim: To develop and validate a reproducible model of T2DM in rabbits that replicates its characteristic metabolic disturbances

Materials and Methods: The experiment was performed on eight female soviet chinchilla rabbits aged 6 weeks, which were divided into an experimental group ($n = 4$) and a control group ($n = 4$). The T2DM model was induced through a two-stage protocol: a 12-week high-fat diet (HFD, 17% fat) followed by a 2-week course of intramuscular dexamethasone injections (0.5 mg/kg) to simulate glucocorticoid-induced insulin resistance. Weekly monitoring included body weight, morphometry (body length and waist circumference), and fasting blood glucose. Metabolic assessments was performed via intravenous glucose tolerance tests (IVGTT) and comprehensive biochemical profiling (lipid panel, insulin).

Results: The combined HFD and dexamethasone protocol successfully induced a sustained metabolic syndrome consistent with T2DM. Key features included: persistent hyperglycemia (IVGTT: 0 min: 8.1 ± 0.4 vs control 6.97 ± 0.83 mmol/L; 120 min: 9.1 ± 0.9 vs 7.93 ± 0.77 mmol/L), hyperinsulinemia (1.06 ± 0.5 vs 0.61 ± 0.3 μU/mL), abdominal obesity, and atherogenic dyslipidemia (elevated triglycerides, LDL, VLDL, and atherogenic index). These metabolic alterations persisted for at least two weeks after dexamethasone withdrawal. Notably, traditional markers of chronic hyperglycemia (HbA1c, fructosamine) did not show significant elevation.

Conclusions: We have developed the first easily reproducible rabbit model that reflects fundamental pathophysiological features of of T2DM: abdominal obesity, insulin resistance, chronic hyperglycemia, and atherogenic dyslipidemia. However, the absence of significant differences in chronic hyperglycemia markers (glycated hemoglobin A1c and fructosamine) in animals from the diabetes model group highlights the importance of species-specific considerations in preclinical research and the necessity of identifying adequate species-specific markers for assessing chronic hyperglycemia in rabbits.

Funding: This study was supported by the Ministry of Science and Higher Education of the Russian Federation (state grant № 075-00504-26-00).

EP414 - ECE_3498 - Variants in the NME7 gene contribute to impaired fasting glucose in adolescents

Tereza Svobodová[1,2], Daniela Vejrazkova[1], Josef Vcelak[1], Tereza Metelcová[3] and Markéta Vaňková[1]

[1]Institute of Endocrinology, Molecular Endocrinology, Prague, Czech Republic; [2]Faculty of Science, Charles University, Anthropology and Human Genetics, Prague, Czech Republic; [3]Institute of Endocrinology, Obesitology, Prague, Czech Republic

Background: Genetic susceptibility to impaired glucose metabolism is shaped by complex metabolic pathways that may act differently across developmental stages. While many diabetes-associated genetic variants exert their effects through obesity and insulin resistance, alternative adiposity-independent mechanisms remain insufficiently explored, particularly in paediatric populations. Impaired fasting glucose (IFG) in adolescence may represent an early manifestation of dysregulated glucose homeostasis and a precursor of later metabolic disease. Variability in the *NME7* gene, encoding nucleoside diphosphate kinase 7, has previously been linked to glucose tolerance dynamics, including oral glucose tolerance test curve shape in adults, suggesting a potential role in glucose regulation. This study aimed to investigate whether selected variants in the *NME7* gene are associated with IFG in adolescents and whether these associations are related to adiposity.

Methods: Selected single-nucleotide polymorphisms within the *NME7* genomic region were analysed in a case–control study including 2129 adolescents (mean age 15.4 ± 1.73 years). Cases ($n = 159$) were defined by impaired fasting glucose (fasting plasma glucose > 5.6 mmol/L), while controls had normal fasting glucose levels. Associations with IFG were assessed using logistic regression under dominant genetic models adjusted for sex. To evaluate adiposity, linear regression analyses were performed for SDS BMI and waist-to-height ratio. In addition, categorical obesity phenotypes were analysed using three definitions: (i) overweight + obesity + severe obesity vs normal weight, (ii) obesity + severe obesity vs normal weight, and (iii) severe obesity vs normal weight. Obesity categories were defined using SDS BMI thresholds: overweight (≥1 to <2), obesity (≥2), and severe obesity (≥3 SDS BMI).

Results: Two *NME7* variants (rs4656659 and rs2157597) were associated with increased risk of IFG in adolescents (OR = 1.53 [1.08-2.15] and OR = 1.47 [1.06-2.05], respectively). These associations were not accompanied by differences in general or central adiposity, as no significant relationships were observed with SDS BMI, waist-to-height ratio, or categorical obesity phenotypes.

Conclusions: Genetic variability in the *NME7* region is associated with impaired fasting glucose in adolescents independently of adiposity. These findings suggest that *NME7* may influence early glucose dysregulation through non-obesity-mediated mechanisms and highlight the importance of paediatric genetic studies for identifying pathways relevant to early metabolic disease development.

EP415 - ECE_1409 - LETM-domain containing 1 (LETMD1) as a key player in adipocyte energy dissipation

Hannah Hui

Hong Kong, Hong Kong

Obesity is characterized by excessive accumulation of body fat and is now becoming a major public health issue. Beige adipocyte is a special type of adipocyte that is capable of burning energy in the form of heat and therefore has been a new therapeutic target for weight control and metabolic diseases. By Tandem Mass Tag-based quantitative proteomics analysis of the purified mitochondria from inguinal white adipose tissue (iWAT), we previously identified LETMD1 protein as a potential candidate contributing to energy dissipation in mouse beige adipocyte. However, the function of LETMD1 in human beige adipocytes as well as how the expression of LETMD1 is regulated

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

remain to be elucidated. In this project, we cultured the human induced pluopotent stem cell (hiPSC)-derived beige adipocyte, and demonstrated that overexpression of LETMD1 enhanced mitochondrial respiration. Furthermore, such an effect was still present when uncoupling protein 1 (UCP1), the classical thermogenic gene was knocked-out, demonstrating that LETMD1 engages a non-classical energy dissipation pathway. Further, we established a fluorescence-based LETMD1 reporter hiPSC line, which can reflect endogenous LETMD1 expression in a high-throughput manner. This LETMD1 reporter cell line enabled us to screen a preclinical compound library in which several potential hits have been identified. An unbiased CRISPR-Cas9-based transcription factor knockout library screening will also be performed to identify key regulators and pathways controlling LETMD1 expression in human beige adipocytes. Meanwhile we are currently also examining the anti-obese, anti-diabetes function of LETMD1 in the animal model, where we will transfer the LETMD1 overexpressing beige adipocytes to immune-deficient mice and examine whether enhancing the expression of LETMD1 in beige adipocytes could improve the whole-body metabolism of the recipient mice. Collectively, the work of the current project will provide valuable insight into LETMD1-targeted approaches for the management of obesity, diabetes, and metabolic diseases.

EP416 - ECE_1411 - Risk of incident chronic obstructive pulmonary disease in type 2 diabetes treated with SGLT2 inhibitors or GLP-1 receptor agonists vs DPP-4 inhibitors: a Real-World Cohort Study

Wei-Chuan Chang[1], Alice Yi-Yun Chan[2], Wan-Ting Huang[3], Ching-Hui Loh[2,4] and Huei-Kai Huang[2,3,5]
[1]Hualien County, Taiwan; [2]School of Medicine, Tzu Chi University, Hualien, Taiwan; [3]Center for Clinical Epidemiology and Biostatistics, Hualien Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Hualien, Taiwan; [4]Center for Aging and Health, Hualien Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Hualien, Taiwan; [5]Department of Family Medicine, Hualien Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Hualien, Taiwan

Background: Patients with type 2 diabetes (T2D) have a higher risk of developing chronic obstructive pulmonary disease (COPD), which is associated with substantial morbidity and mortality. Although sodium–glucose cotransporter-2 inhibitors (SGLT2is) and glucagon-like peptide-1 receptor agonists (GLP-1 RAs) have demonstrated pleiotropic cardiometabolic effects and potential pulmonary benefits, their associations with incident COPD risk remain unclear.

Objective: To evaluate the associations of SGLT2is and GLP-1 RAs, using dipeptidyl peptidase-4 inhibitors (DPP4is) as an active comparator, with the risk of incident COPD in patients with T2D.

Method: We conducted a retrospective cohort study using the TriNetX Global Collaborative Network (2015-2024), emulating a target trial with a new-user, active-comparator approach. Adults with T2D initiating SGLT2is or GLP-1 RAs were compared with DPP4i users. Propensity score matching was used to balance baseline demographics, comorbidities, medication use, and laboratory data. Cox proportional hazards models were used to estimate hazard ratios for incident COPD.

Results: After propensity score matching, 329,987 matched pairs were included in the SGLT2is vs DPP4is comparison, and 303,020 matched pairs were included in the GLP-1 RAs vs DPP4is comparison. Compared with DPP4is, SGLT2i use was associated with a lower risk of incident COPD (HR, 0.86; 95% CI, 0.84-0.87), and GLP-1 RA use was associated with a similar risk reduction (HR, 0.86; 95% CI, 0.85-0.88). These associations were consistent across age and sex subgroups. In the direct comparison between GLP-1 RAs and SGLT2is (301 664 matched pairs), no significant difference in incident COPD risk was observed (HR, 0.98; 95% CI, 0.96-1.01).

Conclusions: SGLT2is and GLP-1 RAs were associated with a significantly lower risk of incident COPD compared with DPP4is in patients with T2D. These findings support the potential respiratory-protective pleiotropic effects of these agents and may inform treatment selection for patients with T2D at risk for chronic lung disease.

EP417 - ECE_2075 - Hepatoprotective benefits of gliflozins in patients with type 2 diabetes and nonalcoholic steatohepatitis

Iryna Kostitska[1], Nadiia Protas[2], Yurii Protas[1], Daryna Hrychyniuk[1] and Myroslav Lehun[1]
[1]Ivano-Frankivsk National Medical University, Endocrinology, Ivano-Frankivsk, Ukraine; [2]Ivano-Frankivsk National Medical University, Endocrinology, Ivano-Frankivska miska hromada, Ukraine

Background and Aims: Type 2 diabetes mellitus (T2D) is frequently associated with metabolic comorbidities that substantially increase the risk of nonalcoholic steatohepatitis (NASH). Fetuin-A, a liver-derived hepatokine, plays a pivotal role in the pathogenesis of insulin resistance (IR), dyslipidemia and hepatic fibrogenesis in patients with NASH. Despite growing evidence of pleiotropic metabolic benefits, the effects of sodium–glucose cotransporter-2 inhibitors (SGLT2i, gliflozins) on hepatokine regulation and liver fibrosis remain controversial. This study aimed to compare the hepatoprotective effects of dapagliflozin and empagliflozin in patients with T2D and NASH.

Materials and Methods: 42 patients with T2D and NASH were enrolled (60.2% males; mean age 59.2 ± 8.5 years; T2D duration 15.2 ± 4.3 years; body mass index (BMI) 38.1 ± 6.6 kg/m^2; waist circumference 121.4 ± 4.6 cm; glycated hemoglobin (HbA1c)- 8.23 ± 0.16%; index HOMA 6.32 ± 1.25; FIB-4 index 1.39 ± 0.28; METAVIR score at liver elastography—8.59 ± 0.58 kPa). Clinical, laboratory and instrumental assessments were performed at baseline and after 12 weeks. Serum fetuin-A and insulin were measured by ELISA. Patients were allocated into three groups (Grs): Gr 1 ($n = 14$) received basic medical therapy (BMT), including metformin (MET-2000 mg/day), alpha-lipoic acid (600 mg/day), rosuvastatin (10 mg/day); Gr 2 ($n = 14$) received dapagliflozin (DAPA-10 mg/day) in addition to BMT; Gr 3 ($n = 14$) received empagliflozin (EMPA 10-25 mg/day) plus BMT.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Results: After 12 weeks of treatment the greater reduction in WC were observed in Gr 2 (−3.08 ± 0.02 cm, $P < .01$) and Gr 3 (−2.99 ± 0.04 cm, $P < .01$) vs compared to Gr 1 (−0.69 ± 0.08 cm), concurrently BMI decreased significantly in the subjects receiving DAPA (−1.96 ± 2.58 kg/m^2, $P < .05$) and EMPA (−1.74 ± 2.72 kg/m^2, $P < .05$). HbA1C level was lowered by 0.48% (Gr 1); 0.96% (Gr 2) and 0.94% (Gr 3). Index HOMA was lowered by 0.25% (Gr 1); 1.02% (Gr 2) and 0.99% (Gr 3). FIB-4 decreased significantly in patints of Gr 2 (1.29 ± 0.14 to 0.59 ± 0.04, $P < .01$) and Gr 3 (1.28 ± 0.15 to 0.60 ± 0.08, $P < .01$) that in the Gr 1 (1.21 ± 0.11-1.16 ± 0.09). Due to the positive result of METAVIR score was higher in subjects of Gr 2 (8,58 ± 1,31 vs 5.43 ± 0.25 kPa, $P < .01$) and Gr 3 (8.54 ± 1.62 vs 5.22 ± 0.62 kPa; $P < .01$) compared with Gr 1 (8.51 ± 1.64 vs 7.76 ± 1.06 kPa). As regards to effect gliflozins on fetuin-A positive effect (0.6 time) in both groups. SGLT2i therapy resulted in a greater reduction of hepatic fibrosis and serum fetuin-A levels compared with Gr1.

Conclusions: Gliflozins exert hepatoprotective and metabolic benefits, supporting their potential as an innovative therapy for patients with NASH.

EP418 - ECE_2665 - Epigenetic inhibition of class I histone deacetylases by MS-275 attenuates diabetic skeletal muscle atrophy via Akt/ARK5–FoxO and myostatin–Smad signaling

Tae Ho Kim[1], Youngho Son[2,3], Suji Choi[2,3], Sung-E Choi[2], Youngha Kim[2], Seung Jin Han[2], Ja Young Jeon[2], Hae Jin Kim[2], Dae Jung Kim[2], Nami Lee[2] and Kwan-Woo Lee[2]
[1]*Division of Endocrinology and Metabolism, Seoul Medical Center, Seoul, South Korea;* [2]*Department of Endocrinology and Metabolism, Ajou University School of Medicine, Suwon, South Korea;* [3]*Department of Biomedical Sciences, Graduate School of Ajou University, Suwon, South Korea*

Background: Sarcopenia is highly prevalent in individuals with diabetes and is associated with impaired physical function and increased mortality. Diabetes-associated skeletal muscle atrophy is driven by chronic inflammation, dysregulated anabolic–catabolic signaling, and activation of ubiquitin–proteasome–mediated protein degradation. Emerging evidence suggests that histone deacetylases (HDACs) act as epigenetic regulators of metabolic and inflammatory pathways; however, their role in diabetic sarcopenia remains incompletely understood.

Methods: Male *db/db* mice were used as a model of diabetes-associated muscle atrophy and treated with MS-275 (entinostat), a selective class I HDAC inhibitor, for 4 weeks. Skeletal muscle mass and fiber cross-sectional area were assessed by magnetic resonance imaging and histological analysis. Inflammatory responses, myostatin signaling, and Akt/ARK5–FoxO–mediated catabolic pathways were evaluated using immunohistochemistry, quantitative PCR, ELISA, and western blotting.

Results: MS-275 treatment significantly restored skeletal muscle mass and myofiber size in *db/db* mice. These effects were accompanied by marked reductions in macrophage infiltration, pro-inflammatory cytokine expression, and NF-κB activation. MS-275 also suppressed circulating myostatin levels and attenuated downstream Smad2/3 signaling. Furthermore, MS-275 restored Akt and ARK5 phosphorylation and promoted FoxO1/3 phosphorylation, resulting in decreased expression of the muscle-specific E3 ubiquitin ligases MuRF1 and atrogin-1.

Conclusions: Our findings demonstrate that epigenetic inhibition of class I HDACs by MS-275 attenuates diabetes-associated skeletal muscle atrophy by coordinately suppressing inflammatory signaling and myostatin-driven catabolic pathways while restoring Akt/ARK5–FoxO signaling. Targeting HDAC-mediated epigenetic regulation may represent a promising therapeutic strategy for preserving skeletal muscle mass in diabetic sarcopenia.

EP419 - ECE_2284 - Real-world glycaemic outcomes of advanced hybrid closed-loop insulin pump therapy in adults with Type 1 diabetes in a regional centre in Ireland

Hafiz Muhammad Sohail[1,2], Nehan Shakeel[1,2], Georgina Doyle[1], Lorraine Kelly[1], Michelle McCormack[1], Catherine McGarry[1], Ciara O'brien[1], Meadhbh Ní Ghallchóir[1], Jayant Sharma[1] and M.A. Pyeh Kyithar[1,3]
[1]*Diabetes & Endocrinology Department, Midland Regional Hospital, Portlaoise, Ireland;* [2]*College of Physicians and Surgeons of Pakistan, Karachi, Pakistan;* [3]*Dublin, Ireland*

Background: Advanced hybrid closed-loop (AHCL) insulin pump systems combine continuous glucose monitoring with automated insulin delivery and are increasingly used in management of Type 1 diabetes(T1D). While randomised trials demonstrate improved glycaemic outcomes, real-world audit data are essential to assess whether these benefits are sustained in routine practice and whether internationally recommended targets are achieved.

Methods: We conducted a retrospective analysis of adults (≥18 years) with T1D commenced on AHCL insulin pump therapy at a regional diabetes centre, with a median age of 37.3 years (IQR 25.8-48.1), comprising 56 females and 32 males. Continuous glucose monitoring (CGM) and clinical data were collected from Dexcom Clarity platform, Medtronic CareLink system and medical records. Pre-AHCL data were compared with the most recent available post-AHCL data. Outcomes included time-in-range (TIR), time-above-range (TAR), time-below-range (TBR), glucose management indicator (GMI), glycaemic variability expressed as coefficient of variation (CV), HbA1c and sensor utilisation. Results are presented as medians and interquartile ranges (IQR). Paired t-tests were used for matched pre- and post-AHCL comparisons, with $P < .05$ considered statistically significant.

Results: 88 adults with T1D were included, all of whom used the MiniMed™ 780G AHCL system. The median duration of AHCL use at the time of study was 9.6 months (IQR 5.6-17.7). Median TIR improved from 46.0% (IQR 30.5-63.0) prior to AHCL initiation to 74.5% (IQR 66.0-82.3) on AHCL. In paired analyses ($n = 53$), median TIR increased by 27.8% ($P < .001$), with a significant reduction in TAR (−28.3%, $P < .001$). Importantly TBR remained low and did not change significantly (median TBR pre-AHCL 0.4% vs on AHCL 0.47% ($P = .64$) indicating that improvements in glycaemic control were not achieved at the expense of increased hypoglycaemia. Median GMI improved from 7.9% (IQR 7.35-

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

8.70) pre-AHCL to 6.9% (IQR 6.7-7.2) on AHCL. Among individuals on AHCL, 65% achieved the recommended target of TIR ≥70%.There was also a significant improvement in HbA1c after initiation of AHCL system 61(IQR 52.8-71.3) mmol/mol vs 54 mmol/mol (IQR 52.8-71.3) ($P = .0097$). 32% of the cohort did not consistently share or upload their AHCL data. No pump-related hospital admissions or emergency department attendances were recorded.

Conclusions: AHCL insulin pump therapy is associated with clinically meaningful improvements in glycaemic ranges and variability in adults with T1D without an increase in hypoglycaemia. While median glycaemic outcomes exceeded international guideline targets, a proportion of patients remained below target highlighting the need for ongoing optimisation and structured follow-up.

EP420 - ECE_3669 - Pancreatic transplantation in monogenic vs type 1 diabetes: insights from a Spanish Referral Center

Mariana Jesús Gomes Porras[1,2,3], Virginia Morillas Jiménez[1], Carmen Bautista Recio[1], Marta Elena Domínguez-López[1], Raquel Niddam Sanchez[4], José Antonio Pérez Daga[5], Verónica López Jiménez[6], Elena Gutierrez Vilchez[6] and María Soledad Ruiz de Adana Navas[1,2]

[1]Endocrinology and Nutrition, Regional University Hospital of Málaga, Malaga, Spain; [2]Institute of Biomedical Research of Málaga (IIBIMA), BIONAND Platform, Málaga, Spain; [3]Biomedical Research Networking Center for Diabetes and Associated Metabolic Diseases (CIBERDEM), group CB07/08/0019, Málaga, Spain; [4]Endocrinology and Nutrition, Príncipe de Asturias University Hospital, Madrid, Spain; [5]General Surgery, Regional University Hospital of Málaga, Málaga, Spain; [6]Nephrology, Regional University Hospital of Málaga, Málaga, Spain

Objective: To compare the sociodemographic characteristics and post-transplant outcomes of patients with type 1 diabetes mellitus (T1D) and monogenic diabetes (MoD) who underwent pancreas transplantation at a Spanish national referral center.

Materials and Methods: This retrospective descriptive study included 224 patients with T1D and 8 with MoD who underwent pancreatic transplantation since 1992 at a single Spanish referral center. A comprehensive, specialized multidisciplinary clinical follow-up was conducted both pre- and post-transplantation.

Results: Of 248 pancreatic transplants, 217 (87.5%) were simultaneous pancreas–kidney (SPK) procedures, including 209 in T1D (84.3%) and 8 in MoD (3.2%); 13 (5.2%) were pancreas-after-kidney (PAK) transplants, all in T1D; 2 (0.8%) were pancreas transplant alone (PTA), all in T1D; and 16 (6.4%) were pancreatic retransplants, including 15 in T1D (6.0%) and 1 in MoD (0.4%). Of the patients with MoD, seven (87.5%) had MODY, including HNF1A-MODY ($n = 4$), HNF4A-MODY ($n = 1$), and two digenic forms (GCK+HNF1A-MODY and HNF4A+HNF1A-MODY), while one patient (12.5%) had mitochondrial diabetes (m.3243A>G variant in the *MT-TL1* gene). The median delay to genetic diagnosis was 27 years (P25-P75: 15.5-34). Male predominance was observed in both groups (MoD 62.5% vs T1D 65%). Patients with MoD were slightly older at transplantation than those with T1D (mean age 44.6 vs 41 years) and had a longer duration of diabetes prior to transplantation (median 30.5 vs 25 years). All patients had microvascular complications, particularly advanced chronic kidney disease (ACKD). At the time of pancreatic transplantation, a similar proportion of patients were on dialysis in both groups (MoD 75% vs T1D 78%). Most patients also had macrovascular complications of diabetes (MoD 62.5% vs T1D 57%), especially peripheral arterial disease and ischemic heart disease. Pancreatic graft survival was higher in T1D than in MoD patients (70% vs 55.5%), with graft loss mainly due to early postoperative complications (MoD 44.5% vs T1D 30%). Graft vascular thrombosis was the most common complication, and one MoD patient developed peripancreatic necrosis secondary to a pancreatic fistula. Ninety-day perioperative mortality was higher in MoD than in T1D (12.5% vs 2.6%).

Conclusions: Pancreatic trasplantation may be an effective therapeutic option for selected patients with T1D and MoD, particularly when endocrinological evaluation is performed promptly before the initiation of dialysis. Delayed genetic diagnosis (median of 27 years) and lack of personalized treatment may contribute to higher perioperative risk, increased mortality, and lower pancreatic graft survival in MoD, highlighting the importance of applying precision medicine.

EP423 - ECE_1970 - Anti-inflammatory & anti-fibrotic effects of semaglutide in a rat model for metabolic kidney disease

Felix Wiegand[1], Simon Kloock[1], Palina Zytner[1], Thorsten Bischler[2], Panagiota Arampatzi[2], Max Kurlbaum[3], Elion Hoxha[4], Martin Fassnacht[1], Kerstin Amann[5], Christoph Daniel[5] and Ulrich Dischinger[1]

[1]Department for Internal Medicine, Division of Endocrinology and Diabetes, University of Wuerzburg, University Hospital of Wuerzburg, Wuerzburg, Germany; [2]Core Unit Systems Medicine, University of Wuerzburg, Wuerzburg, Germany; [3]Core Unit Clinical Mass Spectrometry, University of Wuerzburg, University Hospital Wuerzburg, Wuerzburg, Germany; [4]Department of Internal Medicine, Division of Nephrology, University of Wuerzburg, University Hospital Wuerzburg, Wuerzburg, Germany; [5]Department of Nephropathology, Friedrich-Alexander University Erlangen-Nuremberg, University Hospital Erlangen, Institute of Pathology, Erlangen, Germany

Introduction: The metabolic syndrome is a major risk factor for chronic kidney disease (CKD). Clinical trials show nephroprotective effects of Glucagon-like peptide (GLP)-1 receptor agonists, eg, semaglutide. In order to elucidate the mechanism of action of semaglutide in CKD, we investigate molecular kidney effects of semaglutide in a “two-hit” rat model for metabolic-induced CKD.

Methods: Renal impairment was induced by high-fat/fructose “Western” diet and chronic NO-synthase inhibition (L-NAME) in male Wistar rats. After 8 weeks, rats were randomized to either semaglutide injections ([sema], $n = 6$) or to saline sham intervention (kidney damage [KD], $n = 6$). A healthy control group received standard chow ([ctrl], $n = 6$) for 16 weeks. After 8 weeks on treatment, blood biomarkers, steroid hormone profiling (LC/MS), urinary protein/creatinine ratio quantification (UPCR, mg/mg), histology, qPCR and RNA-seq of the kidneys were performed.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Results: Kidney damage was confirmed by elevated blood creatinine levels (ctrl 28.2 ± 6.2 µmol/L, KD 55.8 ± 32.4 µmol/L, n.s.), urea (ctrl 8.4 ± 0.6 mmol/L, KD 10.2 ± 2.3 mmol/L, $P = .065$) & UPCR (ctrl 1.9 ± 1.2 g/g; KD 19.1 ± 11.1 g/g, $P < .01$). Compared with ctrl, KD showed significantly elevated aldosterone concentrations (ctrl 1.55 ± 0.1 ng/L, KD 2.54 ± 0.7 ng/L, $P < .01$). In sema, aldosterone concentrations showed a trend toward lower levels compared with KD, although statistical significance was not reached (sema 1.9 ± 0.2 ng/L, $P = .093$). Histology showed tubulo-interstitial damage with tubular dilatation, tubular atrophy & interstitial inflammation in KD. qPCR revealed significantly elevated gene expression of KIM-1, OPN, Tgfb and PAI-1 in KD vs ctrl. Sema contributed to favorable kidney function, as indicated by reduced urea (sema 6.0 ± 0.4 mmol/L, $P < .01$) and UPCR (sema 2.2 ± 2.4, $P < .01$). Sema exhibited lower expression of KIM-1, OPN, Tgfb, PAI-1 (all $P < .5$). RNA-seq showed upregulation of TNF-, PI3K/Akt- and NFκB signaling in KD compared to ctrl (adj.$P < .001$), which was reversed by sema treatment (all adj.$P < .001$).

Conclusions: The reduction of proteinuria and serum urea confirms nephroprotection under semaglutide. Semaglutide exerts anti-inflammatory & anti-fibrotic effects in this model of metabolic CKD. The PI3K/Akt axis may serve as a central integrator of inflammatory, fibrotic, and structural pathways, potentially mediating nephroprotection and warranting further investigation.

EP424 - ECE_1984 - Reversal of metabolic dysfunction-associated steatohepatitis by galectin-3 inhibition

Anne Raissa Melo Santos[1], Alessandra Gonçalves Da Cruz[1], Felipe Nunes de Camargo[1], Jessica Denielle Matos Dos Santos[1], Helena Gaspar Monteiro[1], Sandro Leão Matos[1], Jorge Felipe Argenta Model[1], Layanne Cabral Da Cunha Araujo[2] and João Paulo Camporez[1]

[1]Department of Phisiology, Faculdade de Medicina de Ribeirão Preto, Clinic, Ribeirão Preto, Brazil; [2]Superior Institute of Biomedical Sciences, State University of Ceara, Biomedical Sciences, Fortaleza, Brazil

Metabolic dysfunction–associated fatty liver disease (MAFLD) is characterized by excessive accumulation of triglycerides in the liver and is strongly associated with hepatic insulin resistance and type 2 diabetes mellitus. MAFLD may progress to metabolic dysfunction–associated steatohepatitis (MASH), a severe condition marked by hepatic inflammation and fibrosis, which can lead to hepatocellular carcinoma. Galectin-3 (Gal-3), a β-galactoside–binding lectin, has been implicated in inflammatory and fibrotic diseases and has emerged as a mediator in liver injury. Thus, strategies targeting Gal-3 inhibition represent a promising therapeutic approach for MASH. This study evaluated the effects of oral treatment with modified citrus pectin (MCP), a potential Gal-3 inhibitor, on metabolic and hepatic alterations associated with MASH. Male ApoE knockout mice ($n = 15$) were divided into four experimental groups: control diet (CTL), control diet supplemented with MCP (CTL+MCP), Western diet (WD), and Western diet with MCP (WD+MCP) (CEUA 1376/2024R2). After 11 weeks of dietary intervention, glucose metabolism was assessed by glucose tolerance test (GTT), and body composition was evaluated by magnetic resonance imaging. Hepatic triglyceride content and lipid droplet accumulation were determined using colorimetric assays and Oil Red O staining. Inflammatory signaling pathways were assessed by quantifying JNK protein levels, and insulin sensitivity was evaluated by Western blotting for total and phosphorylated AKT2. Total Gal-3 protein levels were quantified, and macrophage infiltration was assessed by F4/80 immunohistochemistry. Serum alanine aminotransferase (ALT) and aspartate aminotransferase (AST) activities were measured using kinetic kits. The WD and WD+MCP groups exhibited a significant increase in fat and lean mass compared to the CTL group. In the GTT, CTL, and WD+MCP mice, a significant reduction in the area under the glucose curve was observed compared to the WD mice. Hepatic triglyceride content and lipid droplet accumulation were increased in the WD group relative to CTL and reduced in the WD +MCP group. Also, the WD+MCP group showed a significant reduction in JNK phosphorylation compared with the WD group, accompanied by decreased F4/80 staining, indicating lower macrophage infiltration. Insulin signaling was improved in WD +MCP mice, as evidenced by increased AKT2 phosphorylation. ALT and AST levels were elevated in WD mice and reduced by MCP treatment. Furthermore, collagen deposition and Gal-3 protein levels were increased in the WD group and reduced in WD +MCP mice. Overall, our data suggest that Gal-3 inhibition shows promise as a potential therapeutic approach to partially reverse MASH.

Introduction: Nutrient availability and amino acid homeostasis are central regulators of metabolic and endocrine function in the liver. Alterations in amino acid sensing and utilization contribute to metabolic reprogramming in metabolic dysfunction–associated steatotic liver disease (MASLD), a major driver of liver-related morbidity. Increasing evidence suggests that protein synthesis and translational control link nutrient excess to cellular dysfunction. Aminoacyl-tRNA synthetases (ARSs), which connect amino acid metabolism with translation and exert additional regulatory roles, may act as key mediators of disease progression. Therefore, we aimed to characterize the expression landscape and functional relevance of ARSs during chronic liver disease progression to hepatocellular carcinoma (HCC).

Materials and Methods: We performed an extensive transcriptomic analysis encompassing 27 cytosolic and mitochondrial

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

ARSs across 16 independent *in silico* cohorts. These datasets included a wide spectrum of chronic liver disease stages and HCC. Following the identification of the most consistently dysregulated genes, mitochondrial *HARS2* and *PARS2* were selected as top candidates for functional characterization due to their robust expression patterns. For functional studies, we employed CRISPR/Cas9-mediated gene editing to generate knockout (KO) models in two distinct HCC cell lines: Hep3B and SNU-387. The functional impact of these ARSs on the malignant phenotype was rigorously assessed through a battery of assays, including cell proliferation, wound-healing migration, colony formation, and tumorsphere formation to evaluate their role in HCC.

Results: Transcriptomic analysis revealed a widespread significant dysregulation of ARSs in HCC. Mitochondrial ARSs, specifically *HARS* and *PARS2*, emerged as the most robust biomarkers, significantly discriminating between tumor and adjacent non-tumoral tissue across multiple cohorts. In the Hep3B cell line, a *HARS2*-KO was successfully generated with 95% efficiency. Functional assays demonstrated that *HARS2* depletion led to a significant reduction in cell proliferation, migratory capacity, colony-forming units, and tumorsphere volume, suggesting a protumorigenic role in HCC.

Conclusions: Our findings reveal a profound dysregulation of ARSs in the progression from chronic liver disease to HCC. Specifically, mitochondrial *HARS2* acts as a key driver of tumorigenicity, highlighting its potential as a novel therapeutic target and diagnostic biomarker within the metabolic-oncological axis.

EP426 - ECE_2457 - High-fat diet disrupts intestinal crypt homeostasis by modulating epithelial proliferation and immune cell dynamics in mice

Maja Antolić[1], Sanja Srakočić[2], Mirela Janjić[2], Vuk Milutinović[2], Anja Ognjenović[2], Anesa Ivić[2], Sonja Vidović Iviš[2], Hrvoje Brzica[2], Ines Glojnarić[2] and Snježana Čužić[2]
[1]*In vivo Pharmacology and Toxicology, Selvita Ltd., Zagreb, Croatia;* [2]*Selvita Ltd., Zagreb, Croatia*

Obesity and pre-diabetes are major global public health challenges, with a high-fat diet (HFD) serving as a key contributor to obesity, insulin resistance, and metabolic inflammation. HFD-induced metabolic stress can disrupt intestinal homeostasis, affecting both epithelial proliferation and immune cell composition. Mice fed a high-fat diet are commonly used to model these conditions in vivo. Among immune cells, M2-polarized macrophages are known to support epithelial regeneration and promote the resolution of intestinal inflammation. However, the effects of HFD on the interplay between intestinal epithelial proliferation and immune cell dynamics within small intestinal crypts remain incompletely understood.

In this study, 5-6-week-old C57BL/6J male mice were fed either control chow or an HFD for 20 weeks. Blood glucose and insulin levels were measured in fasted animals. Small intestine sections were analyzed using hematoxylin and eosin (H&E) staining for morphometric assessment, while immunohistochemistry (IHC) was employed to evaluate epithelial proliferation (Ki67), crypt intraepithelial T lymphocytes (CD3), and M2 macrophages (CD206) in the lamina propria surrounding mucosal crypts. Morphometric parameters included mucosal thickness, crypt depth, villus length and width. Digital image analysis was used to quantify Ki67 expression as the percentage of positive cells, the number of intraepithelial CD3-positive cells, and the CD206-positive area within the lamina propria adjacent to crypts.

HFD-fed mice exhibited significantly increased body weight, hyperinsulinemia, and hyperglycemia compared to controls. In small intestinal crypts, the percentage of Ki67-positive cells showed a decreasing trend in HFD-fed animals, whereas the number of intraepithelial CD3-positive T lymphocytes was significantly increased. In contrast, the CD206-positive area, representing M2 macrophages, was significantly reduced in the HFD group.

These findings indicate that HFD induces systemic metabolic dysfunction and disrupts small intestinal crypt homeostasis. Reduced epithelial proliferation, increased T-cell infiltration, and decreased M2 macrophage presence suggest that HFD-induced immune dysregulation may impair intestinal epithelial regeneration. The observed association between epithelial proliferation and M2 macrophages highlights the potential role of macrophage-mediated support in maintaining intestinal epithelial integrity under metabolic stress. Overall, this study demonstrates that HFD not only drives metabolic disturbances but also alters the cellular composition and regenerative capacity of small intestinal crypts, providing mechanistic insight into the gut-related consequences of obesity and pre-diabetes.

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) remains a major global health challenge, driven by a complex interplay of lipid dysregulation and mitochondrial failure. Thiostrepton (TST), while traditionally known as a thiopeptide antibiotic, has emerged as a potent modulator of inflammation and mitochondrial homeostasis. This study explores the novel therapeutic potential of TST in reversing the core pathological hallmarks of MASLD.

Methods: To simulate chronic metabolic stress, male C57BL/6J mice were challenged with a 15-week high-fat diet (HFD). Following disease establishment, TST (2.5 mg/kg) was administered intraperitoneally for 5 weeks. We performed a comprehensive evaluation integrating systemic metabolic profiling (IPGTT, IPITT), serum biochemistry (ALT, AST), and molecular/histological analysis of hepatic lipogenesis and fibrotic remodeling.

Results: TST treatment led to a profound restoration of metabolic health, significantly enhancing glucose disposal and insulin

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

sensitivity. These systemic improvements were accompanied by a sharp decline in liver injury markers. At the molecular level, TST effectively silenced the pro-steatotic program by downregulating *Srebp1c* and *Fasn*, while simultaneously inhibiting fibrogenic gene expression. Histological scoring confirmed a marked reduction in both lipid vacuoles and collagen deposition, validating the robust anti-steatotic and anti-fibrotic efficacy of TST.

Conclusions: Our study identifies Thiostrepton as a high-potential therapeutic agent that multi-targets the metabolic and structural facets of MASLD. By coordinating lipid metabolism and attenuating fibrosis, TST offers a promising multifaceted strategy for treating progressive liver disease.

EP429 - ECE_3518 - Adipose-derived stem cells and monocyte/macrophage interactions drive inflammatory responses in obesity

Davide Masi[1], Mariaignazia Curreli[1], Michele Avventaggiato[1], Serena Recalchi[1], Stefania Morrone[1], Matteo Russo[1], Mikiko Watanabe[1], Stefania Mariani[1], Daniele Gianfrilli[1], Andrea Isidori[1], Giovanni Casella[2], Elisa Petrangeli[1], Marco Tafani[1] and Carla Lubrano[1]

[1]*Department of Experimental Medicine, Section of Medical Pathophysiology, Food Science and Endocrinology, Sapienza University, Rome, Italy;* [2]*Department of Surgical Sciences, Sapienza University, Rome, Italy*

Background: Obesity-associated adipose tissue (AT) dysfunction is driven by chronic low-grade inflammation, particularly within visceral adipose tissue (VAT), where hypoxia profoundly alters stromal–immune interactions. Adipose-derived stem/stromal cells (ASCs) are key regulators of the AT microenvironment and, in obesity, may actively promote inflammatory macrophage responses.

Objective: To define how ASCs derived from subcutaneous (SAT) and visceral (VAT) fat of individuals with obesity modulate monocyte/macrophage activation and polarization under normoxic and hypoxic conditions, and to elucidate the contribution of NF-κB signaling to this crosstalk.

Methods: ASCs were isolated from paired SAT and VAT samples of patients with obesity undergoing bariatric surgery. Human THP-1 monocytes were differentiated into M0 macrophages and polarized toward M1 or M2 phenotypes, then cultured alone or co-cultured with SAT- or VAT-derived ASCs under normoxia or hypoxia (1% O_2). Macrophage proliferation, adhesion, and polarization were evaluated by cell counts, microscopy, flow cytometry (CD14, CD80, CD206), western blotting (HIF-1α, NF-κB, RAGE), and immunofluorescence. TNF-α secretion was quantified by ELISA. NF-κB involvement was assessed using the pharmacological inhibitor parthenolide.

Results: Hypoxia alone increased THP-1 proliferation and induced HIF-1α, NF-κB, and RAGE expression, enhancing inflammatory activation across macrophage phenotypes. Co-culture with ASCs markedly amplified macrophage activation, with VAT-derived ASCs exerting stronger effects than SAT-derived ASCs. VAT-ASCs significantly increased CD14, CD80, and CD206 expression in THP-1 cells and potentiated hypoxia-driven responses. Functionally, VAT-ASCs promoted elevated TNF-α secretion, particularly in M1-polarized macrophages, an effect further enhanced by hypoxia. In contrast, SAT-ASCs attenuated TNF-α release in several polarization states, even under hypoxic conditions. Hypoxia induced robust NF-κB activation and nuclear localization predominantly in M1 macrophages. Parthenolide effectively inhibited NF-κB activation, reduced inflammatory marker expression, and significantly decreased adhesion of M1 macrophages to both SAT- and VAT-derived ASCs.

Conclusions: Hypoxia and visceral ASCs synergistically drive macrophage activation and inflammatory polarization in obesity through NF-κB–dependent mechanisms. The enhanced pro-inflammatory crosstalk between VAT-ASCs and macrophages identifies a pathogenic axis contributing to adipose tissue inflammation and dysfunction, highlighting NF-κB as a potential therapeutic target in obesity-related metabolic disease.

EP430 - ECE_3900 - Early changes in circulating immune cell populations following GLP-1 receptor agonist therapy in obesity

Kleopatra Alexiadou[1], Mona Xia[1], Rajalakshmi Valaiyapathi[1], Anna Kowalka[1], Irene Guo[1], Lara Jimenez-Pacheco[1], Julia Kenkre[1], Saira Hameed[2], Chioma Izzi-Engbeaya[1], Harvinder Chahal[2], Sirazum Choudhury[2] and Tricia Tan[1]

[1]*Imperial College London, London, United Kingdom;* [2]*Imperial College Healthcare NHS Trust, London, United Kingdom*

Background: Obesity is a multisystem disease associated with numerous complications, including type 2 diabetes, cardiovascular disease and at least 13 types of cancer. Pre-clinical data and randomised controlled trials suggest that glucagon-like peptide-1 receptor agonists (GLP-1RAs) exert pleiotropic effects beyond weight reduction and glycaemic control, including cardiovascular benefits occurring prior to substantial weight loss. This observation suggests the presence of weight-independent mechanisms, which remain incompletely understood but may involve immunomodulatory effects. The aim of this study was to investigate the impact of GLP-1 receptor agonism on circulating immune cell populations. We hypothesised that GLP-1RA therapy would be associated with a shift away from a pro-inflammatory immune phenotype.

Methods: In this observational study, 19 adults with obesity initiating treatment with either semaglutide 1 mg weekly or liraglutide 3 mg daily were recruited. In addition, 12 adults with obesity commencing a low-calorie diet were recruited as a control group. Participants were assessed at baseline, 6-8 weeks and 12-16 weeks after treatment initiation. Anthropometric measurements and biochemical analyses, including fasting glucose, insulin, lipids, high-sensitivity C-reactive protein (hsCRP) and HbA1c, were performed. Peripheral blood mononuclear cells were isolated by gradient centrifugation and immunophenotyped using a comprehensive antibody panel targeting lymphoid and myeloid surface markers. Samples were analysed using a Cytek Aurora spectral flow cytometer, with downstream analysis performed using FlowJo software. We present a preliminary analysis of the GLP-1RA treatment group.

Results: Body weight decreased significantly over the study period, with a mean reduction of 4.2% (95% CI −5.3 to −3.1) at 6-8

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

weeks and 6.3% (95% CI −8.0 to −4.6) at 12-16 weeks. No significant changes were observed in fasting glucose, insulin, or hsCRP levels. Flow cytometric analysis demonstrated a significant reduction in circulating B cells and a shift in natural killer cell subsets at 6-8 weeks, characterised by an increase in $CD56^{+}CD16^{Hi}$ cells and a reduction in $CD56^{Bright}CD16^{Dim}$ cells. At 12-16 weeks, an increase in $CD3^{+}$ T cells and a reduction in neutrophils were observed.

Conclusions: GLP-1 receptor agonist therapy is associated with early dynamic changes in circulating immune cell populations, detectable within weeks of treatment initiation and preceding significant metabolic improvements. Ongoing analysis of the dietary intervention group will help determine whether these immunological changes are independent of weight loss. These immunological alterations may contribute to the pleiotropic benefits of GLP-1RAs and support their potential therapeutic applications beyond obesity and diabetes.

EP431 - ECE_2430 - Body fat (%) change thresholds predicting LDL cholesterol progression to treatment levels

Kyoung Min Kim and Su Jin Kwon
Endocrinology, Internal Medicine, Yongin Severance Hospital, Yonsei University College of Medicine, Yongin, South Korea

Background: Dyslipidemia represents a critical cardiovascular risk factor. While body composition changes influence lipid metabolism, sex-specific thresholds for body fat percentage changes that predict progression to treatment-requiring LDL levels remain undefined.

Methods: We conducted a retrospective longitudinal analysis of 30 159 adults (15 235 men, 14 924 women) who underwent repeated health screenings at Severance Hospital Health Screening Center between 2010-2023. Participants had ≥2 measurements of LDL cholesterol and body composition. Mean follow-up was 4.3 years. Multivariate logistic regression models incorporating baseline LDL-C, body fat percentage change, age, sex, and follow-up interval identified the body fat percentage change associated with ≥50% probability of reaching LDL-C ≥160 mg/dL across baseline LDL strata.

Results: Baseline characteristics showed mean age of 43.7 years, BMI 23.2 kg/m^2, and LDL-C 112.8 mg/dL. Men exhibited higher baseline LDL-C (116.8 vs 108.6 mg/dL) and triglycerides (126.9 vs 80.9 mg/dL) compared to women. Body fat percentage change correlated positively with LDL-C progression in both sexes. Critical thresholds varied markedly by baseline LDL, age, and sex. For men aged <50 years with baseline LDL 120-129 mg/dL, a 9.7% body fat increase conferred 50% risk of reaching LDL ≥160 mg/dL, decreasing to 3.2% and 0.9% for higher baseline LDL 140-149 and 150-159 mg/dL respectively. Men ≥50 years demonstrated lower thresholds: 6.7%, 3.1%, and 1.4% for respective baseline categories. Women showed distinct patterns. Those aged <50 years reached 50% risk with 13.3%, 9.2%, 5.5%, 2.5%, and 0.03% body fat increases for baseline LDL 110-119, 120-129, 130-139, 140-149, and 150-159 mg/dL respectively. Women ≥50 years required smaller increases: 10.5%, 5.0%, 2.1%, and 0.4% for baseline LDL 120-129 through 150-159 mg/dL.

Conclusions: Changes in body fat percentage are significantly associated with the risk of reaching clinically high LDL levels. Our model provides specific BF% change "cut-off" values that can be used in clinical settings to provide personalized weight management targets for preventing the progression to hyperlipidemia, particularly in patients with borderline-high baseline LDL levels.

EP432 - ECE_1355 - From fatty liver to adipokines: converging pathways linking insulin resistance to early atherosclerosis in obese children and adolescents

Ashraf Soliman, Manal Musallam, Fawziya Alyafei, Nada Alaaraj, Noor Hamed, Shayma Ahmed and Noora Alhemaidi
Pediatric Endocrinology, Hamad Medical Center, Doha, Qatar

Background: Childhood obesity is increasingly complicated by early vascular remodeling, measurable as increased carotid intima–media thickness (cIMT). Beyond excess adiposity per se, disturbances in carbohydrate metabolism and adipose derived signaling molecules appear to play a central role. Two phenotypic clusters—nonalcoholic fatty liver disease (NAFLD) and adipocytokine dysregulation—have emerged as key intermediates linking insulin resistance to subclinical atherosclerosis in pediatric obesity.

Objectives: To synthesize evidence from the past 25 years examining the associations between increased cIMT, carbohydrate metabolism abnormalities, and adipocytokines in obese children and adolescents, with particular focus on NAFLD-heavy and adipokine-heavy phenotypes.

Methods: A structured narrative synthesis was performed using validated studies summarized in Table A (NAFLD-focused) and Table B (adipokine-focused). Included evidence comprised cross-sectional studies, interventional weight-loss studies, and systematic reviews/meta-analyses published between ~2000 and 2025. NAFLD was defined by ultrasound or liver biopsy, while metabolic assessment included fasting glucose, insulin, HOMA-IR, OGTT-derived indices, and adipocytokines (eg, resistin, adiponectin subfractions, chemerin). Outcomes of interest were mean or maximal cIMT and its metabolic determinants.

Results: Across NAFLD-heavy studies, obese children with NAFLD consistently exhibited higher cIMT than obese peers without NAFLD and normal-weight controls. This association was evident even in childhood and adolescence and strengthened with greater hepatic disease severity, including biopsy-proven steatosis and steatohepatitis. NAFLD-associated increases in cIMT closely paralleled markers of insulin resistance (elevated fasting insulin, HOMA-IR) and adverse lipid profiles, supporting NAFLD as a vascular “risk amplifier” within pediatric obesity. Interventional data further demonstrated that weight loss and metabolic improvement were accompanied by reductions in cIMT, indicating partial reversibility of early vascular changes. Adipokine-heavy studies revealed that specific adipocytokines are directly and indirectly linked to cIMT. Resistin showed robust positive associations with cIMT, acting both directly and via insulin resistance and systemic inflammation (hsCRP). Alterations in adiponectin subfractions, rather than total adiponectin alone, were

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

associated with preatherosclerotic phenotypes. Chemerin levels correlated with metabolic syndrome determinants and early vascular pathology, even in obese children without overt hypertension. Collectively, these findings demonstrate that adipokine dysregulation integrates adipose inflammation with carbohydrate metabolism to drive vascular remodeling.

Conclusions: Evidence from NAFLD-heavy and adipokine-heavy pediatric studies converges on a common pathway: insulin resistance–centered metabolic dysfunction linking obesity to increased cIMT. NAFLD identifies a particularly high-risk subgroup, while adipocytokines provide mechanistic insight into early atherosclerosis. These findings support early metabolic screening, including assessment of NAFLD and adipokine-related risk, to prevent progression of cardiovascular disease in obese youth.

EP433 - ECE_1386 - Emotional and psychological dimensions of living with type 1 diabetes: a qualitative study of adolescents, parents, and healthcare providers in Nepal

Binaya Bhattarai[1,2]
[1]Endocrinology, Hams Hospital, Hams Hospital, Kathmandu, Nepal; [2]Endocrinology, HAMS Hospital, Kathmandu, Nepal

Background: Type 1 diabetes mellitus (T1DM) presents not only a chronic physical burden but also a significant psychological challenge, particularly among adolescents and young adults. Despite increasing recognition of the emotional toll of diabetes, mental health care remains inadequately integrated into routine diabetes management.

Objective: This qualitative study explores the lived psychological experiences of adolescents and young adults living with diabetes (AYALD), their parents, and healthcare professionals to identify key emotional stressors, coping mechanisms, and systemic gaps in psychosocial support.

Methods: A phenomenological design was employed using five focus group discussions (FGDs): two with AYALD, two with their parents ($n = 20$ per group), and one with healthcare professionals ($n = 15$). Discussions were audio-recorded, transcribed verbatim, and thematically analyzed using NVivo software following a six-step framework that included data familiarization, coding, theme development, and synthesis.

Results: Three major themes emerged: (1) Emotional Burden, characterized by fear, isolation, and stigma at diagnosis and during daily management; (2) Diabetes and School, highlighting inadequate institutional preparedness and experiences of stigmatization; and (3) Diabetes and Depression, revealing prevalent depressive symptoms and gaps in mental health referral and integration. Subthemes included emotional masking, parental overprotection, and the pivotal role of peer support and diabetes camps. A key finding was the disconnect between increased mental health referrals by medical professionals and low patient uptake, suggesting structural barriers within pediatric mental health care pathways.

Conclusions: Living with T1DM extends beyond metabolic regulation; it is a deeply emotional experience shaped by social, familial, and institutional factors. Effective diabetes care requires systemic reforms to integrate psychological support into routine management, strengthen peer-support networks, enhance school-level awareness, and improve interdisciplinary communication. Further research is warranted to validate emotional masking as a potential clinical indicator and to examine long-term psychosocial outcomes among youth living with diabetes.

Abstract citation ID: lvag096.943

EP434 - ECE_1489 - Hidden metabolic risk in erectile dysfunction: prevalence of undiagnosed diabetes mellitus, prediabetes, and metabolic syndrome

Emre Hepşen[1], Samet Kıpık[1], Mustafa Köse[1], Hüseyin Mert Durak[1], Neslihan Koray Fedai[2] and Sema Hepşen[2]
[1]University of Health Sciences, Ankara Etlik City Hospital, Urology, Ankara, Türkiye; [2]University of Health Sciences, Ankara Etlik City Hospital, Endocrinology and Metabolism, Ankara, Türkiye

Background: This study aimed to determine the prevalence of undiagnosed impaired glucose metabolism (IGM) and metabolic syndrome (MetS) in men presenting with erectile dysfunction (ED) and to assess whether ED severity is associated with specific IGM subgroups.

Methods: 605 consecutive men aged ≥18 years presenting with ED were evaluated for inclusion. Patients with known IGM, chronic diseases, antiandrogen use or prior testicular, pituitary, or prostate surgery were excluded. ED severity was assessed using the 5-item International Index of Erectile Function (IIEF-5). Diabetes mellitus (DM) and prediabetes were diagnosed based on the 2025 American Diabetes Association, while MetS was defined according to the revised NCEP–ATP III criteria. Clinical data, anthropometrics, and laboratory measurements were obtained.

Results: Of the 310 patients included, the mean age was 52 ± 13.3 years, the median body mass index was 27.7 kg/m^2 (19.6-42.9), and the median waist circumference was 93 cm (73-127). Hypertension was present in 84 patients (27.1%), and obesity in 49 (15.8%). Median fasting plasma glucose was 91 mg/dL (63-568), median HbA1c was 5.4% (4.2-11.7), and median 2-hour oral glucose tolerance test glucose was 192 mg/dL (124-275). MetS was identified in 94 patients (30.3%), and IGM in 82 (26.4%), including 28 newly diagnosed cases of DM (9.0%) and 54 cases of prediabetes (17.4%). Among patients with prediabetes, impaired fasting glucose (IFG) was observed in 53.7%, combined IFG and impaired glucose tolerance in 7.4%, and elevated HbA1c in 38.9%. The prevalence of IGM differed significantly across ED severity categories ($P = .042$). Testosterone were significantly lower in patients with MetS (median, 331 ng/dL; $P < .001$). The IIEF-5 score showed a moderate negative correlation with age ($r = -0.368$, $P < .001$) and weak negative correlations with HbA1c ($r = -0.192$, $P = .001$) and fasting glucose ($r = -0.180$, $P = .001$). ROC analysis showed that IIEF-5 score had a modest but statistically significant ability to discriminate IGM (AUC, 0.599; $P = .008$), with sensitivity and specificity of 0.512 and 0.639 at a cut-off of 14.5. Similarly, its discriminatory performance for MetS was limited (AUC, 0.571; $P = .047$), with sensitivity of 0.505 and specificity of 0.606.

Conclusions: Newly diagnosed IGM and MetS were detected in nearly one out of every three patients presenting with ED. These findings emphasize that patients with ED, particularly

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

those with mild or moderate symptoms, should be carefully evaluated for underlying metabolic risk, as ED may serve as an early clinical indicator of otherwise unrecognized metabolic disturbances.

EP435 - ECE_1726 - Prediabetes stage and kidney function decline in non-diabetic adults: a metabolic liver-kidney link?

Josep León Mengíbar[1,2], Rafael Simo Canonge[1], Cristina Hernandez[1], Olga Simó[1], Pedro Gil[1], Angel Michael Ortiz[1], Aaron Switzer[1] and Albert Lecube[1]
[1]Hospital Universitari Vall d'Hebrón, Barcelona, Spain; [2]Vall d'Hebron University Hospital, Barcelona, Spain

Introduction: Metabolic dysfunction-associated steatotic liver disease (MASLD) has been linked to chronic kidney disease (CKD), with fibrosis as the potential pathogenic factor shared by both diseases. The Fibrosis-4 (FIB-4) index is a widely used non-invasive fibrosis marker; however, its association with renal outcomes remains uncertain. We evaluated the relationship between FIB-4, estimated glomerular filtration rate (eGFR) decline and albuminuria in the ILERVAS cohort.

Methods: We included 3,940 adults aged 45-70 years from the ILERVAS study, all free of diabetes, CKD and chronic liver disease. FIB-4 was analysed categorically (<1.30 vs ≥1.30) and continuously in regression models. Renal outcomes were eGFR and albuminuria (albumin-to-creatinine ratio ≥30 mg/g) at baseline and 4 years. Multivariable linear and logistic regression models were adjusted for age, sex, hypertension, presence of prediabetes, adiposity, lipids and smoking.

Results: At baseline, 78.3% of participants were classified as low FIB-4 risk and 21.7% as indeterminate-high risk; the latter were older and had lower eGFR, whereas albuminuria prevalence was similar. At 4 years ($n = 1593$), eGFR remained lower in the indeterminate-high group, with no differences in albuminuria prevalence. In multivariable analyses, higher FIB-4 values and prediabetes independently predicted greater eGFR decline ($\beta = -1.15$ and -1.57; $P = .013$ and .023, respectively). Age, female sex, baseline eGFR and hypertension also emerged as independent predictors of eGFR decline.

Conclusions: In adults at low-to-moderate cardiovascular risk without diabetes or established liver/kidney disease, both higher FIB-4 values and prediabetes were independently associated with faster eGFR loss. FIB-4 may help to capture systemic metabolic factors related to fibrosis, suggesting its potential role in renal risk stratification.

EP436 - ECE_1798 - Irisin ameliorates low-dose endotoxemia-induced muscle atrophy via integrin αVβ5-mediated suppression of TLR4 signaling pathway

Muhammad Arif Aslam[1] and Joo Young Huh[2]
[1]Chonnam National University, Gwangju, South Korea; [2]Seoul, South Korea

Metabolic endotoxemia, defined as the chronic low-grade elevation of circulating lipopolysaccharide (LPS), is increasingly being recognized as a driver of systemic inflammation, metabolic dysfunction, and age-related muscle atrophy. However, the molecular pathways linking endotoxemia to muscle atrophy and the potential protective role of irisin, a myokine derived from fibronectin type III domain-containing protein 5 (FNDC5), remain poorly understood. This study addressed the gap between metabolic endotoxemia and muscle atrophy and investigated whether irisin could serve as a muscle-protective factor. Male C57BL/6J mice received low-dose LPS administration (300 μg/kg for 1, 3, 7, and 14 days). Muscle mass, fiber cross-sectional area, and expression of genes and proteins were analyzed. FNDC5 knockout mice were used to assess the contribution of endogenous irisin. Recombinant irisin (0.1 mg/kg/day) was administered to LPS-treated mice, with or without integrin αVβ5 blockade by cilengitide. Repeated low-dose LPS treatment induced significant muscle wasting, as reflected by reduced muscle mass, impaired physical performance, and upregulation of atrogin-1 and MuRF1. LPS activates TLR4/MD2 signaling pathway and NLRP3-mediated pyroptosis, as indicated by elevated caspase-1 and cleaved gasdermin D (GSDMD) levels while simultaneously suppressing FNDC5/irisin expression. FNDC5 deficiency further aggravated LPS-induced muscle atrophy and pyroptotic signaling. In contrast, recombinant irisin restored muscle mass and improved physical function. Mechanistically, irisin directly bound MD2, limiting TLR4/MD2 complex formation, and the muscle-protective effects of irisin were abolished by integrin αVβ5 blockade with cilengitide, confirming receptor dependence. Collectively, these findings identify the TLR4/caspase-1/GSDMD axis as a key driver of endotoxemia-induced muscle atrophy and establish irisin as a protective myokine that counters endotoxemic muscle loss through MD2 binding and integrin αVβ5 signaling, supporting its therapeutic potential for inflammation-associated muscle wasting.

EP437 - ECE_1836 - Bidirectional associations between FIB-4 severity and cardiovascular autonomic neuropathy in type 2 diabetes

Chan-Hee Jung[1], Hyun-Ju Lee[1], Yoon Young Cho[1], Bo-Yeon Kim[1], Chul-Hee Kim[1] and Ji-Oh Mok[1]
[1]Soonchunhyang University College of Medicine, Bucheon Hospital, Endocrinology and Metabolism, Diabetes Center, Internal Medicine, Bucheon-si, South Korea

Background and Aim: To our knowledge, studies examining the association between the fibrosis-4 (FIB-4) index and cardiovascular autonomic neuropathy (CAN) in patients with type 2 diabetes (T2DM) are very limited. In this study, we explored the bidirectional relationship between FIB-4 categories and the presence of CAN in T2DM, with particular interest in whether liver fibrosis indices might correspond to autonomic dysfunction.

Methods: A total of 434 T2DM patients were enrolled in this cross-sectional study. CAN was assessed using five tests according to Ewing's protocol and was defined as the presence of autonomic neuropathy points ≥2.0. FIB-4 index categories were defined using age-adjusted cut-off values. For participants <60 years, FIB-4 was categorized as low risk (<1.30), intermediate risk (1.3-2.67), and high risk (>2.67). For participants aged ≥60, FIB-4 ≤2.0 was defined as low risk, while FIB-4 >2.0 indicated elevated fibrosis risk.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Results: The mean age of participants was 55.9 years and 55.8% were male. The median duration of diabetes was 5 years (IQR 0-12), with 35.0% having diabetes for ≥10 years. The mean FIB-4 index was 1.28 ± 0.99, and autonomic function testing revealed a mean CAN score of 2 ± 1.3, with 61.3% meeting the criteria for CAN. Participants with CAN had significantly higher FIB-4 values compared with those without CAN (1.4 ± 1.2 vs 1.2 ± 0.7, P = .01). FIB-4 severity categories showed a trend toward higher proportions of high-risk FIB-4 in subjects with CAN than those without CAN (6.8% vs 1.8%, P = .06). The prevalence of CAN increased markedly across categories, from 40.3% in the low group to 85.7% in the high FIB-4 group (P < .001). In the bivariate correlation analyses, FIB-4 showed significant positive correlations with both parasympathetic (r = 0.164, P < .001) and sympathetic autonomic scores (r = 0.110, P < .05), and CAN total score (r = 0.168, P < .001). In multivariable logistic regression, High-risk FIB-4 severity was associated with significantly greater odds of CAN (OR 8.9, 95% CI 1.1-76.8), while CAN presence was also independently associated with High-risk FIB-4 status (OR 11.1, 95% CI 1.1-107.7).

Conclusions: FIB-4 severity and CAN presence demonstrated a bidirectional association, although estimates were modest. These findings suggest that liver fibrosis markers may reflect broader multisystem vulnerability related to autonomic dysfunction and highlight the need for larger longitudinal studies to determine clinical significance.

EP438 - ECE_1851 - Differential associations of FIB-4 index with dynapenia in younger and older patients with type 2 diabetes mellitus

Ji-Oh Mok, Chan-Hee Jung, Hyun-Ju Lee, Yoon Young Cho, Bo-Yeon Kim and Chul-Hee Kim
Soonchunhyang University College of Medicine, Bucheon Hospital, Endocrinology and Metabolism, Diabetes Center, Internal Medicine, Bucheon-si, South Korea

Background and Aim: Dynapenia is an important predictor of adverse health outcomes and may be influenced by metabolic dysfunction. The fibrosis-4 (FIB-4) index, a non-invasive marker of liver fibrosis, has been associated with systemic metabolic abnormalities; however, its relationship with dynapenia and the potential mediating role of insulin resistance remain unclear, particularly across different age groups.

Methods: We conducted a cross-sectional analysis of 582 adults with T2DM stratified by age (<60 and ≥60 years). Dynapenia was defined based on handgrip strength criteria. FIB-4 index categories were defined using age-adjusted cut-off values. For participants <60 years, FIB-4 was categorized as low risk (<1.30), intermediate risk (1.3-2.67), and high risk (>2.67). For participants aged ≥60, FIB-4 ≤2.0 was defined as low risk, while FIB-4 >2.0 indicated elevated fibrosis risk.

Results: The mean age of all participants was 5.9 years and duration of DM was 8 years. The prevalence of dynapenia was 19.1% in all subjects (11.8% in aged <60 and 28.1% in aged ≥60). When stratified by age, participants aged <60 years showed a higher prevalence of the low-risk category (71.4%), with 25.2% as intermediate risk, and 3.4% as high risk. Among participants aged ≥60 years, the proportion of low risk was lower (55.2%) while the prevalence of intermediate- and high-risk was higher (35.1% and 9.7%). FIB-4 showed significant inverse correlations with HGS and the HGS/ASMI ratio, but not with ASMI. Multivariable logistic regression analysis was performed to examine the association between FIB-4 severity and dynapenia. Among age <60 years, high FIB-4 severity was significantly associated with dynapenia (OR 13.24, 95% CI 1.7-103.6) after adjustment for covariates. After further adjustment for HOMA-IR as marker of insulin resistance attenuated the association, although effect sizes remained elevated (High risk OR 4.9). In contrast, among aged ≥60 years, the association between FIB-4 severity and dynapenia was weaker and not statistically significant.

Conclusions: Our study showed the association between FIB-4 severity and dynapenia appears to differ by age. These findings suggest that FIB-4 may serve as an early metabolic risk marker for dynapenia, particularly in younger populations. The attenuation of the association after adjustment for HOMA-IR suggests that insulin resistance may represent an important mechanistic link between liver fibrosis burden and muscle strength decline in younger adults. In contrast, the association was weaker and more heterogeneous in adults aged ≥60 years, consistent with multifactorial aging-related mechanisms.

EP439 - ECE_2035 - Association between perceived psychological stress and eating disorders in adolescent and young adults with type 1 diabetes

Ruta Navardauskaite[1,2], Vika Jaskeviciute[3], Virginija Bulikaite[1,4] and Lina Lašaitė[5]
[1]*Department of Endocrinology, Lithuanian University of Health Sciences, Kaunas, Lithuania;* [2]*Department of Endocrinology, Lithuanian University of Health Sciences, Kaunas, Lithuania;* [3]*Pediatric Department, Lithuanian University of Health Sciences, Kaunas, Lithuania;* [4]*Department of Nursing, Lithuanian University of Health Sciences, Kaunas, Lithuania;* [5]*Institute of Endocrinology, Lithuanian University of Health Sciences, Kaunas, Lithuania*

Introduction: Adolescents and young adults with type 1 diabetes mellitus (T1DM) are at an increased risk of developing eating disorders (ED) compared to their healthy peers. ED in T1DM patients ranges from 7.0% to 39.3% and is associated with poor glycemic control and impaired psychosocial well-being.

Objectives: To assess the relationship between eating disorder severity and perceived stress in adolescents and young adults with T1DM attending a specialised transition-age diabetes camp.

Methods: Levels of perceived stress and ED were assessed in 29 adolescents and young adults with T1DM (age: 17.1 ± 2.0 years; T1DM duration: 8.9 ± 4.5 years; age at diagnosis: 8.1 ± 4.1 years; HbA1c: 7.5 ± 1.4%; BMI: 23.7 ± 3.9 kg/m^2) attending the diabetes camp for transition-age patients. The Perceived Stress Scale (PSS) was used to measure stress levels (higher scores indicate greater perceived stress), and the Eating Disorder Examination Questionnaire (EDE-Q) was used to assess ED severity (higher scores indicate more severe ED symptoms).

Results: Participants were divided into two groups based on PSS scores: low perceived stress (<20, n = 14) and high perceived

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

stress (≥20, $n = 15$). Those with high perceived stress had significantly higher EDE-Q scores in restraint ($P = .004$), eating concern ($P < .001$), shape concern ($P < .001$), weight concern ($P = .002$), and global score ($P < .001$). Additionally, they reported more binge eating episodes with loss of control per month ($P = .016$). BMI was correlated with EDE-Q restraint (r = 0.377, $P = .048$), eating concern (r = 0.581, $P = .001$), global score (r = 0.447, $P = .017$), and number of compulsive exercise episodes per month (r = 0.389, $P = .041$). PSS scores were correlated with EDE-Q restraint (r = 0.470, $P = .012$), eating concern (r = 0.628, $P < .001$), shape concern (r = 0.628, $P < .001$), weight concern (r = 0.567, $P = .002$), and global score (r = 0.652, $P < .001$).

Conclusions: Adolescents and young adults with T1DM and high perceived stress exhibit higher levels of eating disorder symptoms compared to those with low perceived stress.

EP441 - ECE_2338 - The insulin-like growth factor system and the progression ofrenal complications of type 2 diabetes

Adrian Heald[1], Yasitha Illangasekera[2,3], Andreas Matheou[4], Ram Prakash Narayanan[5], Steve White[6], Hellena Habete-Asres[7], Abigail Lay[4], Liliana Shalamanova[8], William Ollier[8], Graham Hitman[9], Ritwika Mallik[9], Philip Kalra[4], Martin Whyte[10] and Martin Gibson[1]

[1]Department of Diabetes and Endocrinology, Salford Royal Hospital, Salford, United Kingdom; [2]Sheffield Hallam University, Sheffield, United Kingdom; [3]University of Peradeniya, Peradeniya, Sri Lanka; [4]University of Manchester, Manchester, United Kingdom; [5]Whiston Hospital, Prescot, Merseyside, United Kingdom; [6]University of Newcastle, Newcastle, United Kingdom; [7]Kings College Hospital, London, United Kingdom; [8]Manchester Metropolitan University, Manchester, United Kingdom; [9]Queen Mary University of London, London, United Kingdom; [10]University of Surrey, Guildford, United Kingdom

Introduction: Insulin-like growth factors (IGFs), including IGF-I and IGF-II, are members of a family of growth promoting peptides and are some of the most abundant growth factor polypeptides found in humans. The IGF family contains at least seven exclusive high-affinity IGF binding proteins (IGFBPs). In recent years, the biological role of IGFBPs within kidney disease has been increasingly recognised.

Methods: Baseline IGF/IGFBP profile was related to 2 primary outcomes: (i) change in albumin-to-creatinine ratio over time (urine ACR trend slope) and (ii) change in serum creatinine over time (creatinine trend slope) and to all-cause mortality. Trend slopes were derived for each participant using repeated measures over follow-up. IGF-I, IGF-II, IGFBP-1 and IGFBP-2 were measured by immunoassay.

Results: At baseline, 59.3% of patients were male and 40.7% were female. Mean age at baseline was 56.6 ± 9.4 years. The mean follow-up period was 17.4 ± 5.2 years. IGF-II and IGFBP-3 were found to be strongly correlated with each other (Spearman rho = 0.80), and were therefore not included simultaneously in the multivariate linear regression model to avoid co-linearity. Baseline IGF-II, IGFBP-1 and IGFBP-2 levels were both significant and independent predictors of urine ACR increase. The predictive strength of these factors remained even when adjusted for covariates. Higher IGFBP-2 was independently associated with steeper rate of ACR progression (B = 0.007, $P = .002$), while IGFBP-1 showed an inverse association (B = −0.057, $P = .009$). IGF-II also remained positively associated with ACR trend (B = 0.005, $P = .013$), whereas IGF-I showed no association. IGFBP-1 showed a significant inverse association with serum creatinine change (B = −0.038, $P = .04$). Survival analysis revealed that higher circulating IGFBP-2 levels were independently associated with higher all-cause mortality (hazard ratio [HR] per 1 standard deviation (SD) increase 1.306, 95% CI 1.151-1.483 $P = .0001$)

Conclusions: In conclusion, this longitudinal study with up to 23 years follow-up, indicated that higher IGF-II, lower IGFBP-1 and higher IGFBP-2 levels, all associated with a greater likelihood of ACR progression over time, while lower IGBFP-1 also associated with a greater change in serum creatinine over time. This was independent of standard risk factors. Higher baseline IGBFP-2 also associated with higher all cause mortality. This highlights the relevance of the IGF/IGFBP system to our understanding of renal complications in diabetes and suggests that further exploration of these associations is merited.

EP443 - ECE_3246 - Morphofunctional assessment using bioelectrical impedance vector analysis, nutritional ultrasound and handgrip strength in severe anorexia nervosa

Aida Elhadri-Egea[1], Víctor Siles-Guerrero[2], Rosa Natalia García Pérez[3] and José Manuel Romero-Márquez[4]

[1]Endocrinology and Nutrition Department, Hospital Universitario Virgen de las Nieves, Granada, Spain; [2]Endocrinology and Nutrition Department, Hospital Universitario Virgen de las Nieves, Granada, Spain; [3]Endocrinology and Nutrition Department, Hospital Universitario Virgen de las Nieves, Granada, Spain; [4]Hospital Universitario Virgen de las Nieves, Granada, Spain

Background: Monitoring physical recovery in anorexia nervosa (AN) requires functional assessment tools beyond body weight. Phase angle (PhA), nutritional ultrasound (NU) and handgrip strength provide a comprehensive and reproducible evaluation of true nutritional status.

Methods: A prospective cohort of 43 women (mean age 28.7 ± 13.5 years) admitted for severe AN to a specialized inpatient unit was evaluated. Anthropometric data, multifrequency bioelectrical impedance analysis, NU of the rectus femoris muscle and abdominal adipose tissue, and handgrip strength measured with a Jamar® dynamometer were collected. Two complementary analyses were performed: (1) stratification by PhA tertiles at admission and assessment of associations with morphofunctional parameters and length of hospital stay; (2) comparison of variables between admission and discharge.

Results: Higher PhA at admission was associated with greater body cell mass, rectus femoris muscle area and handgrip strength (all $P < .001$), as well as shorter hospital stay (41 vs 58 days; $P < .05$) and lower estimated hospital costs (€25 829 vs €36 523), calculated according to the diagnosis-related group daily cost for eating disorders. During hospitalization, significant increases were observed in body weight, fat-free mass, fat mass, handgrip strength and abdominal subcutaneous fat, while no

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

relevant changes were detected in PhA or serum protein levels.

Conclusions: The combined use of bioelectrical impedance vector analysis, nutritional ultrasound and handgrip strength enables precise monitoring of functional recovery in severe AN and helps anticipate length of stay and economic impact. Integrating these tools into clinical protocols may optimize inpatient management, support individualized decision-making and provide objective outcome measures in patients with extreme malnutrition.

EP444 - ECE_3605 - Female sexual function following glp-1 receptor agonist therapy in women with obesity: a prospective observational study

Sara Odalovic[1], Kristina Saravinovska[1,2], Dijana Jankovic[1], Antoan Stefan Sojat[1,2], Natalija Antic[1], Jana Vujnovic[1], Boban Stepanovic[1], Neda Delic[2], Ilija Gunjic[3], Mina Hagen[4], Lana Durutovic[2], Miomira Ivovic[1,2], Svetlana Vujovic[1,2] and Ljiljana Marina[1,2]

[1]Clinic of Endocrinology, Diabetes and Metabolic Diseases, University Clinical Centre of Serbia, Belgrade, Serbia; [2]Belgrade, Serbia; [3]Faculty of Pharmacy, University of Belgrade, Belgrade, Serbia; [4]Faculty of Media and Communications, Singidunum University, Psychology Department, Belgrade, Serbia

Introduction: Available evidence shows that women with obesity treated with glucagon-like peptide-1 receptor agonist (GLP-1 RA) exert decreased sexual function following the treatment. Moreover, compared with men, data on sexual function in women treated with GLP-1 RAs are particularly limited.

Aim: To evaluate changes in sexual function in women with obesity before and three months after initiation of GLP-1 RA therapy, and to investigate potential associations with weight loss, mental health and body image.

Methods: This prospective observational study included 25 women with obesity initiating GLP-1 RA therapy—semaglutide or liraglutide. Sexual function was assessed using the Female Sexual Function Index (FSFI). Symptoms of depression and anxiety were evaluated using the Patient Health Questionnaire-9 (PHQ-9) and Generalized Anxiety Disorder-7 (GAD-7), respectively, while body self-perception was assessed with the Body Shape Questionnaire (BSQ). All questionnaires were distributed at two time points: baseline and after 3-months of GLP-1 RA treatment initiation. Participation in clinical and psychological interventions, including weight loss-associated hospitalization and motivational interviewing with group psychological support, was assessed.

Results: 25 women completed the questionnaires, mean age 44.8 ± 6.1, mean baseline BMI 40.7 ± 8.5 kg/m^2, mean BMI after three months—34.8 ± 8 kg/m^2. 22/88% women were on liraglutide, and 3/12% on semaglutide. The mean percentage of initial BMI lost after 3 months was $11.6 \pm 6.5\%$ kg/m^2. 13/52% of women were hospitalized for weight loss, and 17/68% underwent motivational interviewing and were part of the psychological support group. Overall FSFI scores significantly increased after 3 months of GLP-1 RA treatment ($P < .001$). The type of GLP-1 RA did not affect weight loss ($P > .05$). Weight loss, type of GLP-1 RA, hospitalization, motivational interviewing with group psychological support, total GAD-7, PHQ-9 nor BSQ scores did not affect FSFI score changes ($P > .05$). Mental health indicators were overall improved after 3 months of GLP-1 RA treatment ($P < .001$). In multiple linear regression models, we found no significant predictors of weight reduction or sexual function changes.

Conclusions: Improvement of sexual function in our cohort was independent of the weight loss and was not statistically explained by clinical and psychological interventions, nor by changes in depression, anxiety or body shape perception scores. However, mental health and body shape self-perception scores were improved over the same period, which suggests an overall positive impact of the GLP-1 RA treatment. Studies with longer follow-up are needed to elucidate the long-term effects and underlying mechanisms.

EP445 - ECE_3599 - The role of endocrine disruptors and steroid hormones in gestational diabetes mellitus

Michaela Svojtková[1], Lucie Kolatorova[1], Tereza Skodova[1], Daniela Vejrazkova[1], Katerina Anderlova[2], Patrik Simjak[2], Karolina Adamcova[2], Antonin Parizek[2] and Jana Vitku[1]

[1]Department of Steroids and Proteofactors, Institute of Endocrinology, Praha 1, Czech Republic; [2]Department of Gynecology, Obstetrics and Neonatology, General University Hospital in Prague, Praha, Czech Republic

Introduction: During pregnancy, insulin resistance increases, compensated by increased insulin secretion. In predisposed pregnant women, insulin secretion is insufficient and gestational diabetes mellitus (GDM) develops. The growing use of substances that affect the endocrine system (endocrine disruptors, EDs), together with evidence of their role in the development of type 2 diabetes (DM2), has led to the hypothesis that EDs may contribute to the rising incidence of GDM.

Objectives: to describe exposure to selected EDs in women diagnosed with GDM compared to a control group and to identify changes in the steroid spectrum in relation to ED exposure and GDM.

Methods: We included 97 pregnant women from that 55 with diagnosed GDM (fetus: 30 male and 25 female) and 42 healthy controls (fetus: 15 male and 27 female). Women taking medications or having diseases affecting steroidogenesis were excluded. Maternal blood was collected two times during pregnancy, at delivery, three days and six months after delivery. Mixed fetal cord blood after delivery was collected. In all samples, steroids (nine C21 steroids, nine androgens, three estrogens and their conjugates) and EDs (bisphenols A, S, F, P, AF, AP, methylparaben, ethylparaben, propylparaben, butylparaben, benzylparaben and their conjugates) were analysed using LC MS/MS. Data were statistically analysed using the Mann–Whitney test, with fetal sex considered.

Results: No changes in ED and steroids were found in women (GDM) with a female fetus compared to controls. In women (GDM) with a male fetus, a lower level of conjugated ethylparaben and butylparaben was found compared to controls, as well as lower conjugated androstenedione, conjugated progesterone, conjugated and free 5α-dihydroprogesterone, pregnenolone, 11-deoxycortisol, 11-deoxycorticosterone and higher 11-

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

ketotestosterone. Other changes were found in cord blood, where we demonstrated the occurrence of some EDs. In cord blood of girls (offspring of GDM), there were higher levels of conjugated butylparaben and lower levels of dehydroepiandrosterone and estradiol. In cord blood of boys (offspring of GDM), there were higher levels of bisphenol A and bisphenol S.

Conclusions: We demonstrated the occurrence of ED not only in pregnant women, but also in their offspring, where a higher level was found in offspring of women with GDM. We also observed alterations in steroid levels in women with GDM carrying male fetus, some of which have been described in the literature in male patients with DM2.

EP447 - ECE_1385 - Associations between DXA-derived parameters of body composition and bone mass density in patients with T2DM and metabolic dysfunction-associated steatotic liver disease

Martin Kasko[1], Emil Fraenkel[1], Tomas Koky[2], Jana Figurova[1], Slavka Pacakova[2] and Ivica Lazúrová[1]

[1]Faculty of Medicine, 1st Department of Internal Medicine, Pavol Jozef Safarik University in Kosice, Kosice, Slovakia; [2]Stryn, Norway

Introduction: Metabolic dysfunction-associated steatotic liver disease (MASLD) appears to be associated with changes in bone mineral density (BMD) and fracture rate; however, the current data are ambiguous. The relationship between MASLD and bone metabolism remains controversial regarding the protective effect of mechanical loading vs the detrimental effects of insulin resistance and chronic inflammation. This study aimed to clarify the effects of MASLD on bone health in the setting of obesity and type 2 diabetes mellitus (T2DM) in a European population.

Methods: This cross-sectional observational study enrolled 156 patients with T2DM and MASLD (95 females, 61 males; mean age 62.85 ± 10.73 years), compared against a control cohort of 40 T2DM patients without hepatic involvement. Hepatic steatosis was rigorously quantified using vibration-controlled transient elastography (FibroScan®), with a Controlled Attenuation Parameter (CAP) threshold of >238 dB/m. BMD and detailed body composition (fat/lean mass, android/gynoid ratio) were evaluated via DXA. The biochemical profile focused on the GH/IGF-1 axis, insulin resistance (HOMA-IR), and a comprehensive panel of bone turnover markers (BTMs), including Osteocalcin, P1NP, and bCTX.

Results: Patients with MASLD exhibited significantly higher BMI (Body Mass Index), visceral adiposity, and HOMA-IR compared to controls. In the overall cohort, CAP positively correlated with total BMD ($r = 0.21$, $P = .001$). Sex-stratified analysis revealed this association was significant only in females ($r = 0.29$, $P = .004$). Conversely, in males, CAP showed a significant negative correlation with BTMs (Osteocalcin: $r = -0.35$, $P = .006$; bCTX: $r = -0.26$, $P = .04$). Multivariable ROC analysis revealed that traditional BMI-based assessments are suboptimal. The most robust diagnostic performance was achieved in females (Figure 1), where a model integrating CAP, age, and android fat % yielded an AUC of 0.746 (Sensitivity 76.4%, Specificity 71.4%). In the overall cohort, the inclusion of AGR (Android-to-Gynoid fat Ratio) (Figure 2) and ALMI (Appendicular Lean Mass Index) (Figure 3) significantly improved the identification of reduced total BMD and BMD of the hips, respectively.

Conclusions: In T2DM, the MASLD-bone relationship is sexually dimorphic: while liver steatosis correlates with higher BMD in women via android fat distribution, it impairs bone remodeling in men. Clinical screening for fracture risk in MASLD patients would benefit from evolving beyond BMI to incorporate sex-specific algorithms and DXA-derived soft tissue metrics to optimize diagnostic accuracy.

EP449 - ECE_1258 - Association between obstructive sleep apnea risk and type 2 diabetes among Emirati adults: results from the UAE Healthy Future Study

Manal Taimah[1,2]

[1]Abu Dhabi, United Arab Emirates; [2]Public Health Research Center, New York University Abu Dhabi, Abu Dhabi, United Arab Emirates

Background: Obstructive sleep apnea (OSA) is increasingly recognized as a cardiometabolic risk factor, yet its relationship with type 2 diabetes (T2DM) remains insufficiently explored in Middle Eastern populations despite high regional burdens of obesity and diabetes. Understanding this association in the United Arab Emirates (UAE), where rates of metabolic disease continue to rise, is essential for informing screening and prevention strategies.

Objective: To examine the association between OSA risk and T2DM among Emirati adults and to identify sociodemographic and anthropometric predictors of diabetes across OSA risk categories.

Methods: This cross-sectional analysis used baseline data from the UAE Healthy Future Study, collected between 2016 and 2023. A total of 4578 Emirati adults aged 18-71 years completed the STOP-BANG questionnaire and underwent standardised anthropometric measurements and blood sampling. OSA risk was categorised into low, intermediate, and high groups. T2DM was defined using American Diabetes Association diagnostic criteria, including fasting glucose, HbA1c, random glucose, and self-reported diagnosis with medication use. Logistic regression models (unadjusted and adjusted) estimated the association between OSA risk and T2DM, controlling for education, marital status, waist circumference, and smoking.

Results: Participants were young (mean age 27.5 ± 8.35 years), and 55.8% were male. High OSA risk was identified in 16.6% of the cohort, with men showing substantially higher prevalence than women. T2DM prevalence was 4.63%. In unadjusted models, intermediate (OR 2.44; 95% CI 1.78-3.35) and high OSA risk (OR 6.44; 95% CI 4.32-9.59) were strongly associated with T2DM ($P < .0001$). After adjustment, associations remained significant: intermediate OSA risk (OR 1.65; 95% CI 1.18-2.32) and high OSA risk (OR 3.44; 95% CI 2.23-5.33). Higher waist circumference, lower educational attainment, and being married or previously married were additional predictors of T2DM. Gender differences were evident, with men showing higher rates of snoring and elevated

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

neck circumference, while women reported greater daytime fatigue.

Conclusions: Among Emirati adults, higher OSA risk is independently associated with increased odds of T2DM, even after adjusting for established sociodemographic and anthropometric factors. These findings underscore the importance of incorporating OSA screening into diabetes risk assessment and suggest that targeted interventions addressing obesity and central adiposity may help mitigate dual disease burden in this high-risk population.

Note: Preferred presentation as a poster.

EP450 - ECE_2040 - Youth- and young adult–onset type 1 and type 2 diabetes: long-term complications and mortality in a Nationwide Korean Claims Cohort

Ja Young Jeon[1], Kyounghwa Ha[1], Seung Jin Han[1], Hae Jin Kim[1], Kwan-Woo Lee[1] and Dae Jung Kim[1]
[1]*Department of Endocrinology and Metabolism, Ajou University School of Medicine, Suwon, South Korea*

Background: We compare long-term risks of diabetes-related complications and mortality between T1DM and T2DM diagnosed at ages 0-39 years in South Korea.

Methods: This retrospective cohort of individuals aged 0-39 years newly diagnosed with diabetes between 2003 and 2006 was constructed from nationwide claims data and followed through 2023. Idividuals were categorized into 4 groups based to diabetes types (T1DM and T2DM) and ages at diagnosis (0-19 years [youth-onset diabetes] and 20-39 years [young adult-onset diabetes]). Outcomes included acute complications, severe microvascular complications, cardiovascular complications, and all-cause mortality. Time-to-event analyses used cumulative incidence functions with competing risks and Cox proportional hazards models.

Results: A total of 72 917 participants newly diagnosed with diabetes between 2003 and 2006 were included in the study. Among youth-onset diabetes, T1DM was associated with a much higher burden of acute complications, with cumulative incidence reaching 30% at 10 years and 40% at 20 years, whereas the corresponding risk in T2DM remained below 10% even after 20 years. Severe microvascular complications rose to around 20% over 20 years in both groups, with a steeper increase in T1DM, while cardiovascular complications were rare and all-cause mortality remained relatively low and similar between T1DM and T2DM. Among young adult-onset diabetes, differences between T1DM and T2DM were even more pronounced. T1DM was associated with markedly higher cumulative incidences of acute and severe microvascular complications, approximately twofold higher risk of cardiovascular complications, and more than double the risk of all-cause mortality compared with T2DM.

Conclusions: Our findings indicate that youth- and young adult-onset T1DM remains a highly vulnerable condition despite advances in diabetes management. Given the particularly elevated risks of complications and mortality observed in young adult–onset T1DM, this subgroup needs heightened clinical attention and targeted preventive strategies.

EP453 - ECE_3084 - Two cases of immunotherapy-induced type 1 diabetes: clinical characteristics, presentation and the role of technology

Vasiliki Antonopoulou, Aggeliki Kyriakou, Dimitra Sinni, Anna Louisa Chaliasou, Sofia Georgiadi, Chrysoula Koukoula, Marinella Tzanela and Theodora Stratigou
Department of Endocrinology "D. Ikkos"- Diabetes Center- EndoERN-Evangelismos General Hospital, Athens, Greece

Background: Immune checkpoint inhibitors (ICIs), widely used in the treatment of cancer, have been associated with endocrine adverse events. Although Type 1 Diabetes Mellitus (T1DM) is a rare adverse event, its abrupt onset and rapid progression may lead to life-threatening conditions, such as diabetic ketoacidosis (DKA). Herein, we describe two cases of ICI-induced T1DM, focusing on clinical characteristics and the role of technology in diabetes management.

Case 1: A 42-year-old woman with mesothelioma, treated with chemotherapy followed by nivolumab, who was diagnosed with T1DM presenting as DKA three years ago. She reported ~10 kg weight loss and catabolic symptoms prior to diagnosis. Initial therapy included basal insulin, dapagliflozin, and dulaglutide. She experienced recurrent DKA three months later. On her first visit to our department, she was on a basal-bolus regimen plus dulaglutide. BMI was 23.4 kg/m^2 and HbA1c 8.1%, with frequent glycemic fluctuations. Islet cell autoantibodies were negative and C-peptide undetectable. Autoimmune thyroiditis was also diagnosed. Dulaglutide was stopped. The patient received basal-bolus insulin treatment, carbohydrate-counting education and continuous glucose monitoring (CGM) was initiated, improving glycemic control (TIR 59%, GMI 7.3%). Nivolumab was discontinued 10 months after diabetes mellitus (DM) onset without improvement of glycemic control. An automated insulin delivery system (AID) was later initiated, resulting in marked improvement: TIR 78%, TAR 20%, TBR: 2%, GMI 6.7%. Glycemic control remains stable nearly one year later (HbA1c:6.1%). Notably, her son was diagnosed with type1 DM with positive autoantibodies one year after her diagnosis.

Case 2: A 71-year-old man with a history of mesothelioma treated with ICIs, who presented with new-onset DM and DKA. Initial management included a basal-bolus insulin regimen. One month later, he experienced severe hypoglycemia, prompting admission for intensive diabetes education and management. Laboratory evaluation revealed negative islet autoantibodies, C-peptide 0.42ng/mL, and HbA1c 10%. During the first year, glycemic control remained suboptimal with significant glucose variability (60-220mg/dL) despite degludec (15 IU) and lispro therapy. Introduction of CGM and structured carbohydrate counting education resulted in a substantial improvement of HbA1c (7%). One and a half years later, an advanced AID was initiated, further reducing glucose fluctuations.

Discussion: Our cases indicate that early detection and intensive diabetes education are crucial for the management of ICI-induced T1DM and for minimizing acute and chronic complications. The role of technology including CGM and AID can result in optimal glycemic control and enhance safety in these patients.

EP456 - ECE_2472 - Insulin autoimmune syndrome in a caucasian male: a rare cause of recurrent hypoglycemia

Kevin Veerasamy, Najmi Mohd Noor, Therese Dunleavy, Audrey Melvin and Anne Marie Hannon
University Hospital Limerick, Limerick, Ireland

Insulin autoimmune syndrome (IAS), or Hirata disease, is a rare cause of hypoglycemia mediated by insulin autoantibodies (IAA). We report a 76-year-old Caucasian male with hypertension, ischemic heart disease, and benign prostatic hyperplasia who presented with recurrent syncope and seizure-like activity over two months, necessitating his third hospital admission.

Initial workup, including CT/MRI brain, EEG, echocardiogram, and Holter monitoring, was unremarkable. During the third admission, hypoglycemia was confirmed (serum glucose 2.2 mmol/L), with markedly elevated insulin (>6945 pmol/L), C-peptide (2.48 nmol/L), and IAA titers (75%, normal <5.5%). Pancreatic imaging and endoscopic ultrasound excluded neuroendocrine tumours, and negative sulfonylurea screen confirmed IAS. The patient received intravenous hydrocortisone for two days, followed by oral prednisolone, dietary counselling for frequent low-carbohydrate meals, and continuous glucose monitoring. Rituximab was initially considered for severe, refractory hypoglycemia but was not administered due to rapid clinical and serological improvement. Follow-up revealed declining IAA titers and no further hypoglycemic episodes by five months. Historically prevalent in Japan (0.017/100 000), IAS is associated with HLA-DR4 (DRB1*0406) and triggers including sulphydryl drugs or viral infections. Rising global cases among Caucasians likely reflect increased medication use and wider IAA assay availability. IAS involves high-capacity, low-affinity IAA causing glycemic fluctuations through insulin- IAA complex dynamics. Symptoms range from mild to severe (seizures, syncope). Management is complex given an 82% spontaneous remission rate. This case highlights recognising IAS in non-Asian populations and demonstrates the efficacy of corticosteroids and dietary interventions. Recurrence is rare (<5%).

EP457 - ECE_1429 - Determinants of achieving optimal time in tight range with automated insulin delivery systems

Luís Silva Gadelho, Margarida Gonçalves, Nuno Jesus, Henrique Alexandrino, Ana Sousa, Patrícia Tavares, Gustavo Rocha and Mariana Martinho
Unidade Local de Saúde Gaia e Espinho, E.P.E., Serviço de Endocrinologia, Vila Nova de Gaia, Portugal

Background: The management of type 1 diabetes (T1D) has advanced substantially with the advent of novel technologies, such as automated insulin delivery (AID) systems, enabling more precise glycaemic control. In this context, time in tight range (TITR; glucose 70-140 mg/dL) has emerged as a clinically relevant metric, as it better reflects physiological glycaemic profiles, with commonly accepted targets above 50%. This study aimed to identify factors associated with achieving optimal TITR in adults with T1D using AID systems.

Methods: All adults with T1D followed at a tertiary centre and using AID systems for at least six months were retrospectively included. Data were collected from the visit prior to AID initiation and from the most recent follow-up visit. Patients were divided into two groups according to post-AID TITR: those achieving TITR>=50% and those with TITR<50%. Baseline and post-AID variables were compared between groups, and logistic regression analysis was performed.

Results: Fifty-six patients were included; 26 (46.4%) were female, with a median age of 27.5 years and a mean diabetes duration of 17.5 years. Most patients (85.7%) had prior experience with conventional insulin pumps (median 7 years). During follow-up, 32 (57.1%) used the t:slim X2 and 24 (42.9%) the MiniMed 780G. After AID initiation, 22 (39.3%) achieved a TITR>=50% (TITR(%), mean ± SD 57.0 ± 7.1 vs 36.6 ± 8.4; $P < .001$), without an increase in time in hypoglycaemia (TBR<70mg/dL(%), median[IQR] 1,5[1-3] vs 1[0-2]; $P = .068$; TBR<54 mg/dL(%), median[IQR] 0[0-0] vs 0[0-1]; $P = .626$). Those achieving the target were older (age, median[IQR] 33.0[26.0-41.0] vs 24.0[19.0-39.0]; $P = .027$) and had better baseline glycaemic control (TIR(%), mean ± SD 62.6 ± 16.3 vs 49.3 ± 18.0; $P = .011$). They also demonstrated higher CGM use (%, median[IQR] 97.1[95.0-99.9] vs 94.9[90.9-97.9]; $P = .011$), more time spent in automated mode (%, median[IQR] 97.5[95.0-100.0] vs 95.5[90.0-97.0]; $P = .009$), a greater number of carbohydrate entries (mean ± SD 5.5 ± 1.9 vs 3.9 ± 1.3; $P < .001$), and a lower proportion of automated boluses (%, median[IQR] 14.5[8.0-21.0] vs 22.0[15.0-34.0]; $P = .001$). Logistic regression analysis identified CGM use (OR = 1.23 [95% CI: 1.03-1.47]; $P = .0246$), number of carbohydrate entries (OR = 1.98 [95%CI: 1.25-3.15]; $P = .004$), percentage of automated boluses (OR=1.11 [95%CI: 1.03-1.19]; $P = .005$), and baseline TIR (OR=1.05 [95%CI: 1.01-1.09]; $P = .016$), TAR (OR = 1.04 [95%CI: 1.01–1.08]; $P = .024$), and HbA1c (OR=2.56 [95%CI: 1.20-5.26]; $P = .015$), as predictors of achieving the TITR target.

Conclusions: Patients with better baseline glycaemic control were more likely to achieve optimal TITR following AID initiation. Achievement of the TITR target was not associated with increased hypoglycaemia and was accompanied by higher CGM use, more frequent carbohydrate entries, and reduced reliance on automated boluses.

EP458 - ECE_2173 - Glycemic control in children and adolescents with type 1 diabetes before, during, and after attending a diabetes camp: an observational cohort study

Arshia Beigi, Shadan Ashrafi, Rui (Rachel) Huang, Huaying (Helen) Zhao, Nada Al Mahmeed and Joseph Leung
University of British Columbia, Vancouver, Canada

Background and Aims: Glycemic variability often increases during diabetes camps due to increased physical activity, social interactions, and camp-based nutrition. Careful glucose monitoring is essential to minimize fluctuations. While continuous glucose monitoring (CGM) provides valuable insight into time in range and glycemic patterns, few studies have examined these outcomes before, during, and after camp in children and adolescents with type 1 diabetes, particularly comparing those on vs not on automated insulin delivery (AID). The aim of this study was to evaluate changes in glycemic control associated with diabetes camp attendance and to assess whether these changes differed by AID.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Methods: Eighty-eight children and adolescents aged 7 to 17 years with type 1 diabetes attending the 2025 Diabetes Canada Camp Khakhamela in Vancouver, British Columbia were included in the final analysis. All participants used a CGM system and were managed with either insulin pump therapy (with or without AID) or multiple daily injections. CGM data were collected for four predefined periods: two weeks before camp, during camp, and two post-camp intervals (weeks 0-2 and weeks 2-4). Participants with less than 60% active CGM time during any interval were excluded to ensure data reliability. Demographic and treatment characteristics, including insulin delivery modality and AID use, were recorded. Paired comparisons were performed across time periods, with subgroup analyses conducted based on AID use.

Results: The mean age was 12.3 ± 2.5 years, with a mean diabetes duration of 5.8 ± 3.9 years. Of the 88 participants, 29 (33%) were boys and 59 (67%) were girls. Forty-nine (56%) used AID, including open-source (39%) and commercial systems (17%). Most participants (89%) were on insulin pump therapy. AID users consistently demonstrated a higher time in range (TIR) compared to those not using AID across all study periods. Among non-AID users, TIR increased significantly during camp compared with the pre-camp period ($P = .037$). In contrast, no significant change in TIR was observed among AID users during camp ($P = .656$).

Conclusions: Diabetes camp attendance was associated with improved glycemic control particularly among children and adolescents not using AID systems, highlighting the positive impact of structured camp environments in supporting diabetes self-management. Participants using AID maintained stable glycemic control across all periods, suggesting resilience of automated systems during periods of increased variability.

EP459 - ECE_3466 - A bioimpedance analysis of body composition and advanced glycation end-product evaluation in patients using advanced hybrid closed-loop systems, patch pumps, or multiple daily injections

Michele Baldari[1,2], Sabrina Berti[1,2], Enrico Saudelli[1,2], Simona Moscatiello[1], Sara Flamigni[1], Uberto Pagotto[1,2] and Guido Di Dalmazi[1,2]

[1]Endocrinology and Diabetes Prevention and Care Unit, IRCCS Policlinico di S. Orsola, Bologna, Italy; [2]Department of Medical and Surgical Sciences, Alma Mater Studiorum Università di Bologna, Bologna, Italy

Background and Aims: The effect of advanced hybrid closed-loop (AHCL) systems on body composition in individuals with type 1 diabetes mellitus (T1DM) remains unclear. This cross-sectional study aimed to compare body composition and, secondly, to evaluate AGEs, among patients using AHCL systems (MiniMed 780G® or t X2 Control-IQ®), multiple daily injections (MDI), or patch pumps without advanced insulin delivery algorithms.

Methods: Patients who had been using the same AHCL system for at least one year ($n = 30$) were compared with individuals using MDI ($n = 35$) or patch pumps ($n = 13$) in combination with a continuous glucose monitoring (CGM) sensor. Body composition was assessed by bioelectrical impedance analysis (BIA). Three-site skinfold thickness and handgrip strength were also measured. A sub-group of patients ($n = 39$, 21 MDI, 12 AHCL and 6 patch pump) underwent AGEs evaluation using skin autofluorescence.

Results: A total of 78 patients (mean age 39 ± 12 years) were enrolled. No significant differences were observed among the AHCL, MDI, and patch pump groups with respect to diabetes duration, sex distribution, body mass index (BMI), or waist circumference. HbA1c levels were also comparable across groups. Patch pumps users were younger ($P = .028$) than MDI users. Physical Activity did not differ among groups according to International Physical Activity Questionnaire (IPAQ). No significant differences in BIA-derived body composition parameters were detected. However, patch pump users showed a non-significant trend toward lower fat mass percentage(mean 19.7 ± 8.4% in MDI; 18.8 ± 5.8% in AHCL; 15.3 ± 5.2% in patch-pump users, $P = .086$), with corresponding trends toward higher fat free mass percentage and higher body cell mass percentage ($P = .086$). Total body water percentage was similar across groups ($P = .138$). Skinfold thickness and handgrip strength did not differ significantly among groups. Daily insulin dose per kilogram was significantly lower in MDI users compared with AHCL users (0.57 vs 0.68 U/kg; $P = .04$; 0.62 U/kg for patch-pump users). AGEs levels did not differ significantly among groups ($P = .113$). AHCL users showed glycemic control compared to MDI and patch pumps, with higher Time in Range(mean TIR 72 ± 7% vs 51 ± 18% vs 56 ± 18%, respectively), higher Time in Tight Range, lower Time Above Range and Time Below Range, lower GMI and glycemic variability.

Conclusions: Body composition assessed by BIA did not differ significantly among treatment groups. AHCL users had superior glycemic control compared with MDI and patch pumps, albeit with higher insulin requirements than MDI. AGEs levels were comparable across study groups.

EP461 - ECE_1119 - Dual-etiology diabetes associated with mitochondrial m.961T>C variant: A mother–son case

Azad Duman[1], Murat Alay[1] and Julide Ekici Duman[2]

[1]Endocrinology and Metabolism, Department of Internal Medicine, Yuzuncu Yil University, Van, Türkiye; [2]Department of Family Medicine, Van Yuzuncu Yil University, Van, Türkiye

Objective: The *m.961T>C* variant in the 12S rRNA (*MT-RNR1*) gene of mitochondrial DNA is commonly associated with sensorineural hearing loss due to aminoglycoside sensitivity. However, its association with a diabetic phenotype is extremely rare. Mitochondrial gene mutations may impair pancreatic β-cell function by disrupting energy production, oxidative stress balance, and insulin secretion. Here, we discuss the clinical significance of the *m.961T>C* variant identified in a family presenting with both autoimmune diabetes and neurosensory manifestations.

Case Report: A 19-year-old male patient was diagnosed with insulin-dependent diabetes in 2021. At diagnosis, the C-peptide level was 0.1 ng/mL, and pancreatic autoantibodies were positive. The patient had a history of bilateral sensorineural hearing loss and epilepsy since childhood. There was no known history of aminoglycoside exposure, and his body mass index was within normal limits. The patient's mother, aged 53, was diagnosed with diabetes in 2015 with HbA1c 6.5% and C-peptide 1.83 ng/mL. Oral antidiabetic therapy was initiated, followed by insulin

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

treatment in 2016, when autoantibody positivity was also detected. The mother has no hearing loss or neurological symptoms. Genetic analysis in both individuals revealed a homoplasmic *m.961T>C* variant in the mitochondrial 12S rRNA (*MT-RNR1*) gene.

Discussion: The coexistence of autoimmune diabetes, sensorineural hearing loss, and epilepsy in the son at an early age suggests a clinical expression of mitochondrial dysfunction. Although diabetes developed through an autoimmune mechanism in both individuals, the presence of neurological and auditory findings only in the son indicates that the *m.961T>C* variant may act as a phenotype-modifying factor. The mother's asymptomatic status supports the concept of variable phenotypic expression (incomplete penetrance) of this variant. As the association between this variant and diabetes has been rarely reported, this case represents a unique example of mitochondrial and autoimmune mechanisms coexisting in the same family.

Conclusions: This case highlights that the mitochondrial *m.961T>C* variant may contribute to the neurological and auditory phenotype in a family predominantly affected by autoimmune diabetes. In diabetes cases presenting with neurosensory features, incorporating mitochondrial genetic analysis alongside autoimmunity testing may strengthen diagnostic evaluation and enhance understanding of phenotypic diversity.

Keywords autoimmune diabetes, mitochondrial DNA, *m.961T>C*, epilepsy, hearing loss, phenotypic variation

EP463 - ECE_1541 - In-depth analysis of metabolic hormones and inflammatory markers following Roux-en-Y gastric bypass in humans and rodents: similarities and differences

Simon Kloock[1], Lukas Scheller[2], Julia Hasinger[1], Ilja Balonov[3,4], Max Kurlbaum[1], Martin Fassnacht[1], Ann-Cathrin Koschker[1], Florian Seyfried[5] and Ulrich Dischinger[1]
[1]Department of Internal Medicine, Division of Endocrinology and Diabetes, University of Wuerzburg, University Hospital Wuerzburg, Wuerzburg, Germany; [2]Department of Internal Medicine, Division of Haemato-Oncology, University of Wuerzburg, University Hospital Wuerzburg, Wuerzburg, Germany; [3]Department of General, Visceral and Transplantation Surgery, LMU University Hospital, Munich, Germany; [4]Comprehensive Cancer Center (CCC Munich LMU), LMU University Hospital, Munich, Germany; [5]Department of General, Visceral, Transplant, Vascular and Paediatric Surgery, University of Wuerzburg, University Hospital Wuerzburg, Wuerzburg, Germany

Background: Bariatric surgery induces alterations in metabolically active hormones that regulate energy balance. The objectives of this study were to validate a Roux-en-Y gastric bypass (RYGB) rat model by comparison with RYGB-treated humans and to examine associations between circulating amino acids and the incretin hormones GLP-1 and PYY in both species.

Methods: Fasting plasma samples were obtained from participants of the randomized controlled WAS trial (Koschker et al., Metabolism, 2023; RYGB $n = 20$, controls $n = 17$) at baseline and 12 months post-surgery, as well as from male Wistar rats with diet-induced obesity seven weeks after RYGB ($n = 12$) or sham surgery ($n = 12$). Concentrations of 18 peptide hormones and 21 amino acids were quantified using multiplex assays, ELISA, and LC–MS/MS.

Results: In humans, fasting GLP-1 and PYY3-36 levels were significantly reduced 12 months after RYGB (both $P < .001$), whereas rats showed a tendency toward increased levels. Fasting insulin concentrations declined after RYGB in both humans ($P < .001$) and rats ($P < .01$). Leptin levels were markedly decreased in humans ($P < .001$) and rats ($P < .05$). The inflammatory markers IL-6 and MCP-1 were significantly reduced in humans following RYGB ($P < .01$ and $P < .05$, respectively) but remained unchanged in rats. Notably, preoperative GLP-1 concentrations in humans correlated positively with weight loss 12 months after surgery (Pearson's $r = 0.733$; $P < .05$). In addition, leucine levels were positively associated with GLP-1 concentrations at 12 months post-RYGB in humans (Pearson's $r = 0.588$; $P < .05$), an association not observed in rats.

Conclusions: Baseline GLP-1 levels in humans are associated with postoperative weight loss after RYGB and may serve as a predictive marker. Overall, the rat RYGB model recapitulates key changes in incretin and adipokine profiles observed in humans, supporting its suitability for preclinical testing of pharmacological strategies targeting anorexigenic hormones in the treatment of severe obesity.

EP464 - ECE_2010 - Hyperphagia severity in adult patients with Bardet-Biedl Syndrome—a mixed-methods cross-sectional study in the United Kingdom

Jean Mossman[1], Sarah Flack[2], Elise Gamertsfelder[3], Nicolas Touchot[4], Eric Low[3] and Phil L. Beales[5]
[1]Department of Health Policy, Medical Technology Research Group, London School of Economics, London, United Kingdom; [2]Great Ormond Street Hospital for Children, London, United Kingdom; [3]Eric Low Consulting Ltd, East Lothian, United Kingdom; [4]Rhythm Pharmaceuticals, Inc, Boston, United States; [5]Genetics and Genomic Medicine Research and Teaching Department, UCL GOS Institute of Child Health, London, United Kingdom

Background: Bardet-Biedl Syndrome (BBS) is a rare genetic disease frequently associated with hyperphagia, an insatiable feeling of hunger, persistent food-seeking behaviours and abnormal food intake. This can have behavioural, emotional, social and health consequences, and may lead to early-onset obesity. Quantifying the severity of hyperphagia in adult patients with BBS remains challenging due to the limited availability of assessment tools.

Objective: To assess the level of severity of hyperphagia in adult patients with BBS and obesity living in the UK using an exploratory mixed-method approach.

Methods: This sub-analysis of a non-interventional, cross-sectional study included 39 adult patients with BBS and obesity. Patients were excluded if they were currently prescribed or had previously taken setmelanotide or if they had a BMI <30 kg/m^2. Patients were 41% male, 56% were aged 18-34 years and 82% were of white ethnicity. Patients had a mean (SD) age at diagnosis of BBS of 8.7 (8.1) years. Patients completed a 14-item hyperphagia questionnaire combining multiple-choice and open-ended questions; a subset ($n = 13$) participated in follow-up semi-structured interviews. Interview transcripts were systematically coded by a qualitative researcher and jointly reviewed with a BBS clinical expert to assign severity ratings. Interviews were designed to contextualise and overcome known limitations of

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

self-reporting in this population, including the disability paradox, stigma, and cognitive difficulties.

Results: Based on the interviews, 69% (9/13) of patients were classified as having severe hyperphagia, 31% (4/13) as moderate, and none as mild. Questionnaire data classified 8% of patients as having severe hyperphagia, 51% as moderate, and 41% as mild. Notably, 92% (12/13) of patients were assigned a higher severity level via interviews than by questionnaire responses, while only 1 patient had the same severity classification across both methods.

Conclusions: This study reveals a high prevalence of severe hyperphagia in adult patients with BBS and obesity, and suggest substantial underreporting with self-reported questionnaires. The findings highlight the limitations of questionnaire-based assessments in estimating hyperphagia severity and support the incorporation of expert-led interviews as a more accurate mixed-method approach to better capture the true burden of hyperphagia in adult patients with BBS.

Abstract citation ID: lvag096.964

EP465 - ECE_2085 - Cognitive training as an adjunct to intensive health behaviour and lifestyle treatment in childhood obesity: sleep and neurobehavioural outcomes

Deny Menghini, Gabriele Scozia, Valentina Russo, Nicoletta Gianni, Elena Madonna, Maria Rea, Francesco D'aniello, Stefano Cianfarani, Danilo Fintini and Melania Manco
Ospedale Pediatrico Bambino Gesù, Roma, Italy

Background: Paediatric overweight and obesity are frequently accompanied by sleep disruption, sedentary behaviours, and emotional-behavioural difficulties, factors that can undermine adherence to lifestyle change. Growing evidence also links excess weight with weaknesses in executive and memory functions that are central to self-regulation, suggesting that cognitive training may represent a useful adjunct to Intensive Health Behaviour and Lifestyle Treatment (IHBLT). Objective: To test whether adding computerized cognitive training (CT) to an 8-week multidisciplinary Intensive Health Behaviour and Lifestyle Treatment (IHBLT) improves sleep and neurobehavioural outcomes beyond IHBLT alone.

Methods: Eighty-four children aged 6-11 years with overweight/obesity (mean age 8.97 ± 1.70; 49 females) were assessed at baseline (T0) and post-intervention (T1). Families received caregiver-inclusive dietary and physical-activity education and an individualized Mediterranean-style diet. Using age- and gender-stratified block randomisation, participants were assigned to IHBLT (online physical-activity training twice weekly; $n = 19$) or CT+IHBLT (IHBLT plus adaptive Cogmed training, 3×25 minutes/week; $n = 24$). A parallel education-only cohort (Educational group; $n = 41$) participated when training was not feasible. Outcomes included sleep (Sleep Disturbance Scale for Children), quality of life (PedsQL), emotional-behavioural symptoms (CBCL), social functioning (ABAS-II; SRS), and neuropsychological measures of learning, attention, and working memory.

Results: Sleep disturbance improved overall, with a significant Time×Group interaction driven by larger reductions in CT+IHBLT ($F(2,81) = 4.83$, $P < .010$). Quality of life increased and CBCL symptoms decreased over time without differential group effects. CT+IHBLT showed greater gains in verbal immediate learning ($F(2,82) = 3.16$, $P = .047$) and visuospatial short-term memory (Corsi forward: $F(2,82) = 8.51$, $P < .001$); both training arms improved visuospatial working memory (Corsi backward: $F(2,82) = 4.62$, $P = .012$) relative to education only.

Conclusions: A brief, largely remote, family-centred IHBLT improved psychosocial outcomes in paediatric overweight and obesity, while adding CT yielded incremental benefits for sleep and selected memory domains relevant to self-regulation.

EP466 - ECE_3529 - Physical Activity analysis in Patients with Diabetes in Lithuania

Deimante Paskeviciene[1], Rasa Verkauskiene[1], Lina Radzeviciene[1] and Diana Simoniene[2]
[1]*Institute of Endocrinology, Lithuanian University of Health Sciences, Kaunas, Lithuania;* [2]*Department of Endocrinology, Hospital of Lithuanian University of Health Science Kauno Klinikos, Kaunas, Lithuania*

Background: Physical activity (PA) is widely recommended to improve glycemic control in diabetes, whereas prolonged sedentary behavior is linked to adverse cardiometabolic risk. Regular daily activity is critical to healthy aging and reducing risk for falls, maintaining function, and reducing premature morbidity. Multiple national guidelines recommend a multimodal exercise as the single most beneficial intervention to improve health in older adults. Regular PA enhances β-cell function, insulin sensitivity, and vascular function, which leads to better diabetes and health management as well as disease risk reduction. This study aimed to analyze physical activity and sitting time assessed by the IPAQ short questionnaire (IPAQ-SF) and their associations with key demographic and clinical factors in adults with diabetes.

Methods: In this cross-sectional study of 137 adults with diabetes (type 1, $n = 69$, type 2, $n = 68$), physical activity was assessed using the IPAQ-SF, with total MET-min/week calculated according to standard scoring rules. Participants were classified into low (<600 MET-min/week), moderate (600-3000 MET-min/week), or high (>3000 MET-min/week.) PA level. Sitting time was grouped as <6 or ≥6 hours/day. PA and sitting metrics were compared across sex, BMI group, diabetes type, education level, HbA1c, complications status, and age. Data on patients' clinical characteristics were collected from medical records.

Results: The median diabetes duration was 15 years, age—55 years. 57.7% of participants were women. By IPAQ classification, 10.9% of participants had low, 45.3% moderate, and 43.8% high PA level. A progressive decrease in BMI with increase in PA level was found ($P < .05$). In subgroup analyses, PA category did not differ significantly by sex ($P = .70$), diabetes type ($P = .13$), HbA1c level ($P = .98$), complication status ($P = .67$), or age group ($P = .71$). However, significant differences were apparent when analyzing social status: patients with higher education were more often in the moderate/high PA groups compared to patients with lower education ($P < .05$). 54.7% of participants reported sitting time <6h/day. Median sitting time was 300 (180-360) min/day with no differences by any subgroup.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Conclusions: In this cohort of people with diabetes, most patients achieved at least moderate IPAQ-defined activity levels. PA level varied significantly only by education level and BMI. Higher-educated individuals are more likely to engage in moderate or high levels of PA. Nearly half of patients reported prolonged sitting time. These findings highlight the need to promote greater PA and reduce sedentary behavior in diabetes care, especially targeting individuals with lower education.

EP467 - ECE_3687 - Mesenteric adipose tissue in Crohn's disease increases angiogenesis and fibrosis

Fernando Gutiérrrez-Martínez[1], Carlos Lopez-Gomez[1], Imane Kentaoui-Bousellam[1], Marina Herraiz-Vilela[1], Guillermo Alcain Martinez[1], Raquel Camargo Camero[1], Juan Victor Martos Vandussen[1], Alejandra Fernandez Castañer[1], Francisco Rodríguez González[1], Laura Camacho Martel[1], Cristina Rodríguez Díaz[1] and Eduardo García-Fuentes[1,2]

[1]Instituto de Investigación Biomédica de Málaga (IBIMA)-Plataforma Bionand, UGC Aparato Digestivo, Hospital Universitario Virgen de la Victoria, Malaga, Spain; [2]Malaga, Spain

Background: The presence of "creeping fat" (CrF), a specific type of mesenteric adipose tissue (MAT) that infiltrates and envelops inflamed intestinal segments, is one of the key factors underlying the Crohn's disease (CD) pathogenesis. It is associated with small intestinal transmural fibrosis and stricture formation. MAT is also an endocrine organ that appears to be a significant risk factor for the severity of intestinal fibrostenosis. It secretes a considerable number of adipokines (secretome), which appear to exert an influence on the pathogenesis of CD.

Aim: To conduct a study with the objective of examine the impact of this MAT secretome on the angiogenic and fibrosis processes.

Material and Methods: Twelve patients with CD undergoing ileocecal resection were included. The hypertrophic MAT adjacent to stenotic ileum (CD-CrF) and from the resection margin (ileal segments from non-affected area (CD-NA)) were obtained. MAT from non-CD subjects (control group (Control-MAT)) were obtained from 10 patients who underwent laparoscopic cholecystectomy. The MAT was immediately placed in DMEM and cultured for 24 hours at 37°C. This MAT-conditioned media (MAT secretome) was collected and frozen at −80°C. After, we analyzed the effect of the MAT secretome on fibrosis in intestinal myofibroblasts by the wound healing and cell proliferation assays. The effect on angiogenesis was analized in HUVECs cells by the endothelial cell cord and cell proliferation assays.

Results: Treatment with CD-NA substantially increased the wound healing ($P < .05$) and the proliferation of myofibroblasts ($P < .05$). Meanwhile, CD-CrF secretome increased the wound healing ($P < .05$) and the proliferation of myofibroblast, althought not significantly. But the analysis of soluble collagen into the culture medium showed a significant decrease after the incubation of miofibroblasts with CD-NA and CD-CrF ($P < .05$, respectively). Treatment with CD-NA and CD-CrF secretomes substantially increased the endothelial cell tube formation ($P < .05$). However, only CD-CrF secretome increased HUVECs proliferation ($P < .05$).

Conclusions: The present study highlights the association between MAT and the pathogenesis of CD. The MAT secretome from CrF may exhibit greater angiogenic and profibrotic effects than the MAT from a non-affected area, and particularly than MAT from control subjects.

Drug-induced liver injury (DILI) is a major in clinical and drug development challenge due to its unpredictable nature. While most of the research focus on direct hepatotoxicity, the role of the endocrine signaling in DILI susceptibility remains largely underexplored. As the liver is a central metabolic and endocrine organ, understanding how steroid receptor modulators interact with hepatic metabolism is critical for elucidating individual susceptibility to liver injury. Taken the advantage of using the selective progesterone receptor modulator (SPRM) ulipristal acetate (UA), a clinically effective drug for uterine leiomyomas (ULs) that carries a hepatotoxicity risk, hereby, we investigated the molecular mechanisms underlying steroid-related DILI.

We employed a patient-derived xenograft (PDX) mouse model, where human ULs transplanted into NOD.CB17-Prkdc^{scid} mice,

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

uterine leiomyomas were treated with UA to assess DILI. Hepatic effects were evaluated through histopathology, serum biochemistry, and transcriptomic profiling. Complementary *in vitro* cytotoxicity assays were performed in HepaRG cells with UA alone or in combination with steroid hormones.

In the PDX model, UA treatment induced a spectrum of liver injury (mild, 2.5%; moderate, 5%; to severe 5%) of animals, characterized by necrosis, cholestasis, and systemic inflammation. Transcriptomic analysis revealed dysregulation of xenobiotic metabolism, impaired bile acid homeostasis, and activation of stress- and injury-associated pathways. Namely, *Pgrmc1* expression remained unchanged, whereas *Tgfβ-1*, *Tgfβ-3*, *TgfβR2*, and *Eng* were upregulated, accompanied by upregulated *Smad1* and downregulated *Smad2*, *Smad3*, and *Smad8* expression. Notably, we observed zonal enhancement of progesterone receptor membrane component 1 (PGRMC1) protein localization in injured livers and a dysregulated hepatic TGF-β/Smad signaling axis. *In vitro*, UA's cytotoxicity in HepaRG cells was potentiated by co-treatment with estradiol and progesterone in a time- and dose-dependent manner.

Our results suggest that UA-associated liver injury DILI was mediated, in part, by PGRMC1, acting as a zonal integrator of steroid signaling and cellular stress. These findings provide a novel mechanistic framework for SPRM-induced DILI mechanisms, highlighting endocrine context as a critical determinant of individual susceptibility and informing the development of safer therapeutics.

EP469 - ECE_1901 - Acute and long-term impact of tight vs liberal blood glucose control in corticosteroid-treated critically ill patients

Eline Vanderwegen[1], Ilse Vanhorebeek[1], Fabian Güiza[2], Dominique D. Benoit[3], Eric Hoste[3], Alexander Wilmer[4], Björn Stessel[5], Jasperina Dubois[5], Greet Van den Berghe[6] and Jan Gunst[2]

[1]Laboratory of Intensive Care Medicine, KU Leuven, Leuven, Belgium; [2]Clinical Division and Laboratory of Intensive Care Medicine, KU Leuven, Leuven, Belgium; [3]Department of Intensive Care Medicine, Ghent University Hospital, Ghent, Belgium; [4]Medical Intensive Care Unit, KU Leuven, Leuven, Belgium; [5]Department of Anesthesiology and Intensive Care Medicine, Jessa Hospital, Hasselt, Belgium; [6]Leuven, Belgium

Introduction: Iatrogenic severe hyperglycemia by early parenteral nutrition (PN) was shown harmful in critical illness. We hypothesized that corticosteroids in ICU are another iatrogenic cause of severe hyperglycemia, increasing vulnerability for its acute and long-term harmful effects.

Methods: The hypothesis was tested in a secondary analysis of the multicenter TGC-Fast trial, in which patients not receiving early PN were randomized to tight (TGC) or liberal (LGC) glucose control.[1] We assessed whether baseline corticosteroids, defined as systemic corticosteroids initiated on ICU d-1 or 2, statistically interacted with randomization for impact on acute and 2-year outcomes via multivariable regression. The effect of TGC vs LGC was reported for patients with and without baseline corticosteroids, unadjusted and adjusted for baseline risk factors. $P < .05$ and interaction-$P < .1$ were considered significant.

Results: Of 9230 randomized patients, 2293 (24.8%) received baseline corticosteroids. Patients with baseline corticosteroids had higher blood glucose concentrations and insulin needs than patients without corticosteroids. There was significant interaction between baseline corticosteroids and randomization to TGC vs LGC on occurrence of in-ICU delirium, reduced from 33.1% to 27.5% in the first week ($P = .005$) with TGC for patients on corticosteroids only. At 2-year follow-up, significant interaction was present for mortality and mental health outcomes. For patients on corticosteroids only, TGC reduced 2-year mortality from 32.8% to 28.7% ($P = .03$), improved SF-36 mental component scores from 44.5 ± 12.8 to 46.0 ± 12.8 ($P = .02$), and improved subscores for vitality ($P = .03$) and mental health ($P = .03$). Similar results were obtained after adjustment for baseline risk factors.

Conclusions: Corticosteroids in ICU increased the severity of hyperglycemia and TGC in corticosteroid-treated patients reduced in-ICU delirium and improved long-term survival and mental health outcomes.

EP470 - ECE_2727 - Secretome and exosomes from conditioned medium of human adipose-derived mesenchymal stem cells (hAMSCs) acutely treated with dexamethasone (Dex) reduce atrophic signals in C2C12 myocytes

Nunzia Magnacca[1], Mariarosaria Negri[2], Feliciana Amatrudo[2], Francesco Cecere[3], Maria Anna Marciano[4], Bruno Hay Mele[5], Cristina De Angelis[1], Chiara Simeoli[1], Erminio M. Crescenzo[1], Raffaella Crescenzo[4], Annamaria Colao[1,6], Rosario Pivonello[1,6] and Claudia Pivonello[7]

[1]Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Diabetologia, Andrologia e Nutrizione—Università Federico II di Napoli, Naples, Italy; [2]Dipartimento di Psicologia e Scienze della Salute, Università Telematica Pegaso, Naples, Italy; [3]UOS Laboratori di Ricerca e Biobanca, UOC Ricerca Clinica e Traslazionale, AORN Santobono-Pausilipon, Naples, Italy; [4]Department of Biology, Federico II University, Naples, Italy; [5]Department for the Promotion of Human Science and Quality of Life, San Raffaele Open University, Rome, Italy; [6]UNESCO Chair for Health Education and Sustainable Development, Federico II University, Naples, Italy; [7]Dipartimento di Sanità Pubblica, Università degli Studi di Napoli Federico II, Naples, Italy

While chronic glucocorticoids (GC) exposure is associated with skeletal muscle (SM) atrophy and increased adiposity, the effects of acute GC treatment on the adipose-muscle axis remain poorly understood. The current study investigated whether acute Dex exposure (48h) modulates the secretome and the profile of miRNAs cargo in released exosomes of hAMSCs with a consequent impact on SM homeostasis.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Following acute Dex exposure, hAMSCs, differentiated into white adipocytes, exhibited a significant reduction in lipid droplet accumulation (−15.64%, $P < .0001$) quantified by Oil-Red-O staining, indicating suppression of lipogenesis. Cell miRNAs analysis, evaluated by miRNAs arrays, revealed an interesting upregulation of miR-103a-3p ($P = .008$), miR-130b-3p ($P = .04$), and miR-204-5p ($P = .01$), consistent with bioinformatic predictions linking these miRNAs to SM homeostatic pathways. miRNAs expression levels were also evaluated by RT-qPCR in exosomes released by Dex-treated (Exo Dex) and not-treated (Exo) hAMSCs. Accordingly, miR-103a-3p ($P = .03$), miR-130b-3p ($P = .04$) and miR-204-5p ($P = .04$) were upregulated in Exo Dex hAMSCs. hAMSCs secretome, evaluated by proteome profiler human adipokine array, showed decreased levels of several adipokines (Angiopoietin-1 ($P = .0003$), Angiopoietin-2 ($P = .004$), Cathepsin D ($P = .02$), Cathepsin L ($P = .002$), CRP ($P = .01$), IGFBP-3 ($P = .0005$), IGFBP-6 ($P = .007$), MIF ($P = .01$)), with a consequent shift toward a muscle-supportive environment.

To evaluate the functional impact of these changes on SM, C2C12 myotubes were exposed to conditioned medium (CM) or Exo Dex. Both exposure conditions ameliorated SM catabolic signalling, by reducing the protein levels of Atrogin-1 (CM: -11.1%, $P = .04$; CM+Dex: −17.3%, $P = .04$; Exo Dex: −33.9%, $P = .03$ vs control) and MuRF1 (CM: −36.25%, $P = .02$; CM+Dex: −28.5%, $P = .02$; Exo: −16.4%, $P = .0006$; Exo Dex: −44.16%, $P = .0006$ vs control; Exo vs Exo Dex: −27.7%, $P = .014$), evaluated by western blot. To directly assess the contribution of exosomal identified miRNAs to these findings, C2C12 cells were transfected with mimics or inhibitors. Consistently, immunofluorescence revealed that mimics transfection reduced Atrogin-1 (miR-204-5p $P < .0001$) and MuRF1 (miR-103a-3p $P = .009$, miR-130b-3p $P = .003$ and miR-204-5p $P = .05$) protein expression as observed with Exo Dex, while inhibitors transfection reversed it, confirming the impactful contribution of these exosomal miRNAs in modulating muscle catabolism.

Overall, the results of the study reveal that acute Dex treatment elicits adipose tissue responses distinct from those induced by the well-known chronic GC exposure. This in vitro study highlights a previously unrecognised mechanism by which the acute Dex exposure generates an exosomal miRNAs cargo release by differentiated hAMSCs that mitigates SM catabolic pathways, emphasising the functional importance of the adipose-muscle crosstalk in modulating SM homeostasis in conditions of acute GC treatment.

EP473 - ECE_1731 - Diabetic retinopathy after liver transplantation: impact of diabetes type

Keren Kaminer[1], Mor Atlas[2], Gloria Tsvetov[1], Amit Akirov[1] and Talia Diker Cohen[1]
[1]*Rabin Medical Center, Petah Tikva, Israel;* [2]*Ono Academic College, Kiryat Ono, Israel*

Objectiveראש הטופס: Diabetic retinopathy (DR) is a microvascular complication of diabetes mellitus (DM). Among liver transplant recipients, DM may be present prior to transplantation or may develop post-transplant. Despite the well-recognized burden of diabetes in this population, data on the incidence, progression, and management of diabetic retinopathy after liver transplantation remain limited.

Design: A retrospective study of patients who underwent liver transplantation between 1996 and 2020 and were followed for at least one year post-transplantation in a tertiary referral center. All patients had no evidence of retinopathy at baseline.

Methods: Patients with less than one year of follow-up and/or without an ophthalmologic examination were excluded. Participants were classified into two groups according to diabetes type—type 2 diabetes mellitus (DM2) or new-onset diabetes after transplantation (NODAT)—and were assessed for diabetic retinopathy at baseline and at 1, 3, 5, 10, 15, 20, and 25 years following transplantation.

Results: Eighty-eight patients were included (mean age 53 ± 11 years; 33% female). Pre-transplant diabetes mellitus was present in 50% of patients, while the remaining 50% developed NODAT. Diabetic retinopathy developed in 13.6% of the cohort (n = 12). Patients who developed retinopathy had a higher prevalence of neuropathy (30% vs 6.8%, $P = .06$) and hypertension (50% vs 19.1%, $P = .08$) at baseline, as well as higher baseline HbA1c levels (8.6 ± 2.5 vs 7.0 ± 2.3, $P = .09$). Patients with DM2 exhibited more than a sixfold increased risk of developing diabetic retinopathy during follow up compared with those with NODAT (HR = 6.527; 95% CI: 1.62-26.27; $P = .008$). Notably, retinopathy in patients with NODAT occurred only 15 years post-transplantation. The incidence rate of developing retinopathy was 1600 per 100 000 person-years. When stratified by diabetes type, patients with NODAT had a markedly lower incidence rate (628 per 100 000 person-years) compared with those with pre-transplant diabetes (3296 per 100 000 person-years).

Conclusions: In liver transplant recipients, the risk of developing diabetic retinopathy among patients with NODAT is low, with retinopathy occurring only after prolonged follow-up, beyond 15 years post-transplantation.

EP474 - ECE_3126 - Diabetic striatopathy- a clinical conundrum

Huma Razzaqe and Julia Ioana
Diabetes and Endocrinology, Our Lady of Lourdes, Drogheda, Ireland

Diabetic Striatopathy, also known as Non-ketotic hyperglycaemic hemichorea-hemiballismus is an uncommon complication of hyperglycaemia with an estimated prevalence of 1 in 100 000 individuals which can occur in patients with long-standing, poorly controlled diabetes or may present as an initial manifestation of diabetes. Patients usually present with unilateral ballismus or choreiform movements. Biochemical findings show significant hyperglycaemia following altered signal intensities in the basal ganglia on brain imaging.

The case report describes this rare presentation of hyperglycaemia in a non-compliant diabetic patient. A 53 years old woman with a one year history of poorly controlled type 2 diabetes mellitus and hypertension presented with 2 weeks history of ataxic gait and involuntary right sided jerky movements. Biochemical investigations revealed near HHS(Hyperosmolar Hyperglycaemic State) levels of serum glucose (32 mmol/l) and osmolality (295 mOsm/kg) followed by HBa1c of 173 mmol/mol.

Brain imaging included CT showed hyper dense changes in left striatum, mimicking left striatal infarction; however later T1-

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

weighted MRI brain showed hyper intensity in the basal ganglia contralateral to the choreiform movements. This finding together with the clinical picture pointed towards the diagnosis of hyperglycaemic chorea.

Patient was started on an aggressive fluid and electrolyte replacement therapy along with basal and short-acting insulin. Neurology input was sought, and tetrabenazine was commenced.

The patient's symptoms began to improve as blood glucose levels decreased to 12-14 mmol/l and completely resolved once euglycaemia was achieved. Her gait returned to normal following stabilization of blood glucose levels to 8-10 mmol/L.

This case highlights the importance of recognising hyperglycaemia as a cause of acute hyperkinetic movement disorder. Prompt recognition and stringent glycaemic control, play a crucial role in symptom reversal.

EP476 - ECE_1100 - Adalimumab-associated hypertriglyceridemia in clinical practice

JeeHee Yoon[1,2], Hee Kyung Kim[1], Jungmin Kim[3], Heung Yong Jin[4] and Ho-Cheol Kang[1]

[1]Division of Endocrinology and Metabolism, Department of Internal Medicine, Chonnam National University Medical School, Chonnam University Hwasun Hospital, Hawsun, South Korea; [2]Chonnam National University Medical School, Hawsun, South Korea; [3]Division of Endocrinology and Metabolism, Department of Internal Medicine, St. Carollo Hospital, Suncheon, South Korea; [4]Division of Endocrinology and Metabolism, Department of Internal Medicine, Jeonbuk National University Medical School, Jeonju, South Korea

Background: Adalimumab, a tumor necrosis factor-alpha (TNF-α) inhibitor monoclonal antibody, is widely used to reduce systemic inflammation in chronic inflammatory diseases. Unlike other biologics, it has not been linked to significant increases in LDL cholesterol. However, data on adalimumab-associated triglyceride changes are limited. This study investigated real-world lipid profile patterns, focusing on triglyceride dynamics during adalimumab therapy.

Method: We retrospectively analyzed patients with ankylosing spondylitis or rheumatoid arthritis who had been treated with adalimumab at Bitgoeul Chonnam National University Hospital between 2007 and 2023. Changes in lipid parameters before and during adalimumab treatment, as well as the use of lipid-lowering therapy, were analyzed.

Results: After excluding patients with incomplete data, no follow-up lipid profiles, or early discontinuation of adalimumab (eg, pregnancy), 581 patients were included in the final analysis. The mean duration of lorlatinib treatment was 144.3 months. Among 341 patients with baseline lipid profiles available prior to adalimumab initiation, total cholesterol (36.4 ± 2.0 vs 196.4 ± 43.8, $P < .001$) and triglyceride (108.6 ± 70.9 vs 249.5 ± 262.3, $P < .001$) levels increased after treatment, whereas HDL (48.5 ± 12.4 vs 49.3 ± 12.2, $P = .398$) and LDL cholesterol(101.7 ± 30.4 vs 106.6 ± 32.6, $P = .112$) levels showed no significant changes. Hypertriglyceridemia (triglycerides >200 mg/dL) was observed in 41.4% of patients, and severe hypertriglyceridemia (>500 mg/dL) occurred in 37 patients (6.3%). In 113 patients who underwent lipid testing after discontinuing adalimumab, total cholesterol (190.0 ± 33.7 vs 183.0 ± 33.5, $P < .001$) and triglyceride (198.9 ± 164.9 vs 116.7 ± 68.3, $P < .001$) levels showed a significant decline compared with levels during treatment.

Conclusions: Although the lipid alterations observed during adalimumab therapy were generally mild and reversible, severe hypertriglyceridemia may develop in certain cases. Therefore, careful monitoring and timely management are essential to mitigate the potential risk of pancreatitis.

Keywords adalimumab, lipid, triglyceride, reversible

EP477 - ECE_1350 - The impact of hyperinsulinemia on short-term prognosis in patients with hypertriglyceridemia induced acute pancreatitis: A Single-Center Retrospective Analysis

tianke Li

Chongqing, China

Purpose: The short-term prognosis of hyperinsulinemia in patients with hyperlipidemia resulting in acute pancreatitis remains uncertain, so this research explores the correlation between them.

Material and Methods: This study retrospectively analyzed patients treated for hypertriglyceridemic acute pancreatitis at XX Hospital between January 2020 and April 2023. Patients were divided into two groups based on laboratory diagnosis: the hyperinsulinemia group(HINS) and the non-hyperinsulinemia group (NHINS). The study aims to evaluate the short-term effects of hyperinsulinemia on acute pancreatitis.

Results: A total of 92 patients with hypertriglyceridemic pancreatitis were included in the study before receiving lipid-lowering therapy, with 44 in the HINS group and 48 in the NHINS group. Significant differences were observed between the two groups in terms of white blood cell count (WBC), hypersensitive C-reactive protein (CRP) levels, and fasting blood glucose at 2, 3-4, and 5-7 days after initiation of lipid-lowering intervention ($P < .05$). Following admission, patients received symptomatic interventions. However, there was a significant difference in the rate of decrease compared to the baseline between the fifth and seventh days ($P < .05$). Additionally, the groups showed significant differences in the readmission rates for recurrent pancreatitis within 30 days post-ICU transfer and discharge ($P < .05$). No statistically significant distinctions were noted in the length of hospital stay or quality of life scores fifteen days post-discharge.

Conclusions: Hyperinsulinemia adversely affects the recovery process of patients with Hypertriglyceridemia-induced acute pancreatitis.

Keywords acute pancreatitis, hypertriglyceridemia, hyperinsulinemia, short-term prognosis, endocrine

EP478 - ECE_2212 - Enhanced ER–Mitochondria Contacts as Early Drivers of Hepatic Steatosis under Protein Undernutrition

Thiago Araujo[1,2,3,4], Mariana Muniz[1], Joel Junior[1], Lohanna Barreto[1] and Everardo Carneiro[1]

[1]Universidade Estadual de Campinas, Campinas, Brazil; [2]Instituto de Biologia, Campinas, Brazil; [3]Instituto de Biologia, Campinas, Brazil; [4]IB, Campinas, Brazil

Undernutrition remains a persistent nutritional challenge in low-income countries. Metabolic adaptive responses to protein

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

undernutrition are well-established contributors to the development of metabolic dysfunction–associated fatty liver disease (MAFLD). However, the molecular mechanisms underlying MAFLD onset in this context remain incompletely understood. This study aimed to investigate the role of endoplasmic reticulum (ER)–mitochondria contacts in the initiation and progression of MAFLD during protein undernutrition. To address this objective, the human hepatoma cell line HepG2 was cultured under control (C; 100% amino acids) or amino acid restriction (AaR; 10% amino acids) conditions for up to 48 hours. Additionally, thirty-day-old male C57BL/6J mice were fed for 30, 60, or 90 days with diets containing either 14% protein (control, C) or 6% protein (protein-restricted, R). Statistical analyses were performed using Student's *t*-test or the Mann–Whitney test, with significance set at $P < .05$. It was demonstrated that HepG2 cells subjected to AaR exhibited increased lipid accumulation (87%) relative to C cells. This was accompanied by a marked increase in ER–mitochondria contacts, with a 400% increase detected by proximity ligation assay and a 250% increase measured by Mitotracker/PDI colocalization. In AaR cells, the enhanced ER–mitochondria coupling was accompanied by a 200% increase in intramitochondrial calcium influx and an 89% rise in reactive oxygen species (ROS) production. Moreover, AaR cells displayed significantly reduced basal oxygen consumption (−38%), ATP-linked respiration (−42%), and maximal respiratory capacity (−59%) relative to C cells. Notably, increased ER–mitochondria contact (550%) was detected early, after 24 hours of AaR exposure, whereas elevated ROS production, impaired mitochondrial respiration, and increased lipid accumulation were observed only after 48 hours. Confirmatory analyses revealed that livers from R mice exhibited increased ER–mitochondria contact as early as 30 days of low-protein diet intake (39%), whereas a significant increase in hepatic triglyceride content (51%) was observed only after 90 days of dietary intervention. Collectively, these findings demonstrate that alterations in ER–mitochondria contacts precede the cellular disturbances induced by AaR. Therefore, enhanced ER–mitochondria coupling promotes oxidative stress, impairs mitochondrial function, and reduces fatty acid oxidation in hepatocytes under protein undernutrition. Elucidating these early molecular events may facilitate the development of targeted therapeutic strategies to prevent or attenuate MAFLD in undernourished populations.

Background/Aim: Metabolic dysfunction-associated steatotic liver disease (MASLD) is highly prevalent among patients with type 2 diabetes mellitus (T2DM) and is increasingly acknowledged as a multisystem disorder with significant extrahepatic implications, including chronic kidney disease (CKD). Increased Fibrosis-4 (FIB-4), a marker used to evaluate liver fibrosis, has been associated with a higher risk of CKD in patients with MASLD. However, its role in broader patient populations with T2DM remains less clearly defined. We aimed to investigate the association between FIB-4 and CKD in patients with T2DM.

Methods: We retrospectively analyzed data from consecutive patients aged ≥18 years with a history of T2DM admitted to our diabetes center. Epidemiological and somatometric characteristics, as well as baseline blood tests, were recorded. A diagnosis of CKD was established with a CKD-EPI score of ≤60 ml/min/1.73 m^2. We also evaluated the Hellenic score II, the FIB-4 index, and the Aspartate Aminotransferase (AST)-to-Platelet Ratio Index (APRI) score at enrollment.

Results: Two hundred fourteen consecutive patients were enrolled—158 (73.8%) males and 56 (26.2%) females. The mean age was 67.6 ± 10.3 years. The mean duration of T2DM before recruitment was 10 ± 8.1 years. Nighty six (44.8%) patients had normal kidney function, and 54 (25.2%) had CKD at enrollment. For the remaining 64/29.9% patients, the GFR could not be calculated due to missing data. Patients with CKD were significantly older ($P < .001$), had a higher Hellenic score II ($P = .007$), higher AST levels ($P = .011$), lower platelet counts ($P = .007$), higher APRI ($P = .006$), and higher FIB-4 ($P < .001$). Additionally, they had a FIB-4≥1.3, a history of hypertension, and a history of cardiovascular disease more frequently than the non-CKD group ($\chi^2 = 18.8$, $P < .001$; $\chi^2 = 13.5$, $P < .001$; $\chi^2 = 14.2$, $P < .001$, respectively). In the multivariate analysis, sex (male: OR: 0.14, 95%CI: 0.03-0.7, $P = .022$), hypertension (OR: 4.6, 95%CI: 1.06-19.7, $P = .042$), and FIB-4 (≥1.3 vs <1.3: OR: 8.4, 95%CI: 1.9-36.2, $P = .004$) were independently associated with the presence of CKD. The area under the receiver operating characteristic (AUROC) curve for FIB-4 in identifying the presence of CKD was 0.769 (95% CI: 0.668-0.869).

Conclusions: Elevated FIB-4 is associated with a higher prevalence of CKD in patients with T2DM.

EP480 - ECE_2629 - Can glucagon-like peptide (GLP)-1 agonists and dual glucose-dependent insulinotropic polypeptides (GIP/GLP-1) agonists assist in managing hyperphagia and obesity in Prader-Willi syndrome?

Magdalena Goralska[1,2,3], Urszula Ambroziak[1], Beata Rak-Makowska[4], Jerzy Malek[1] and Agnieszka Stańczyk[1]

[1]Endocrinology and Internal Medicine Department, Warsaw Medical University, Warsaw, Poland; [2]Endocrinology and Internal Medicine, Warsaw Medical University, Warsaw, Poland; [3]Endocrinology,

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Medical University of Warsaw, Warszawa, Poland; [4]Centrum Medyczne Kształcenia Podyplomowego, Warszawa, Poland

Introduction: Prader-Willi syndrome (PWS) is a complex genetic disorder characterized by a constellation of phenotypic features and hypothalamic dysfunction, including multiple endocrine abnormalities, short stature, and severe hyperphagia associated with satiety center dysfunction that leads to morbid obesity. Hormone deficiencies diagnosed and managed in childhood necessitate lifelong continuation and monitoring into adulthood.

Material and Methods: This retrospective observational study included 14 young adult patients with Prader-Willi syndrome (aged 18-30 years) who received GLP-1 receptor agonist therapy (semaglutide; $n = 10$) or dual GLP-1/GIP receptor agonist therapy (tirzepatide; $n = 4$) over 12 months. Semaglutide treatment was initiated at a dose of 0.25 mg once weekly and gradually escalated every 4 weeks up to a maximum dose of 1.7 mg/week, whereas tirzepatide treatment was started at 2.5 mg/week and maintained at 5 mg/week (without dose escalation due to economic constraints). None had type 2 diabetes mellitus. Body weight, BMI, and body fat percentage were evaluated in all patients, while fasting glucose, insulin, lipid profile, glycated hemoglobin, and hormone levels were measured and statistically analyzed with between-group comparisons.

Results: The mean age in the tirzepatide-treated group was 21.25 years (±SD 4.7; range 18-28 years), whereas in the semaglutide-treated group it was 23.9 years (±SD 3.03; range 20-30 years). Mean baseline BMI in the tirzepatide group was 40.68 kg/m^2 (±SD 0.98; range 39.47-41.86) compared to 42.3 kg/m^2 (±SD 9.49; range 27.2-54.68) in the semaglutide group. After 12 months of treatment, no significant between-group differences were observed in ΔBMI ($P = .945$; mean ΔBMI −2.59 in the tirzepatide group vs −2.66 in the semaglutide group), potentially attributable to the small sample size in the tirzepatide cohort and the low doses administered (due to economic constraints). Both treatment groups demonstrated improvements in metabolic control, including reductions in HbA1c, fasting glucose, and lipid profile parameters. Caregivers reported better appetite regulation, with decreased active food-seeking behavior—particularly at night. No serious adverse effects were reported.

Conclusions: The main aim of PWS clinical management in adulthood is prevention of obesity and its comorbidities, treatment of hormonal disorders and mental health stabilization. GLP1 receptor agonist (semaglutide) and dual GLP-1/GIP receptor agonist (tirzepatide) therapy appears safe in PWS patients and may have potential benefits for weight, metabolic and appetite control. Further research and long-term clinical studies are essential to confirm these benefits and refine therapeutic strategies.

EP483 - ECE_3415 - From early-onset diabetes to a progeroid syndrome: a case of werner syndrome

Filipa Barros Alves[1], Marta Castro Tomé[1], Tânia Fernandes[1], Rosa Maria Príncipe[1,2], Ana Rita Soares[3], Isabel Serra Nunes[3] and Francisco Simões de Carvalho[1,2]

[1]Local Health Unit of Matosinhos, Matosinhos, Portugal; [2]Faculty of Medicine, University of Porto, Porto, Portugal; [3]Local Health Unit of Santo António, Porto, Portugal

Introduction: Werner syndrome (WS) is a rare autosomal recessive progeroid disorder caused by biallelic pathogenic variants in the *WRN* gene, which encodes a helicase involved in DNA repair and genomic stability. WS is characterized by premature aging and a high prevalence of metabolic and endocrine abnormalities. Diabetes mellitus (DM), hypogonadism, thyroid dysfunction and osteoporosis are among the most frequently reported endocrinopathies.

Case Presentation: We report a 37-year-old man with diabetes mellitus diagnosed at 18 years of age during routine laboratory testing. He had a normal BMI (21 kg/m^2) and no family history of diabetes. Autoimmune markers were negative and C-peptide levels were preserved. At 24 years of age, he was diagnosed with primary hypothyroidism of unknown etiology, adequately controlled with levothyroxine. At 33 years, he developed Achilles tendinopathy and underwent surgical osteosynthesis for a calcaneal fracture, which was complicated by chronic ulceration and secondary infection, requiring repeated surgical debridement, prolonged antibiotic therapy and adjunctive hyperbaric oxygen therapy, with complete healing achieved only after 20 months. During follow-up, additional endocrine abnormalities were identified, including hypogonadotropic hypogonadism, with low total testosterone levels (108 ng/dL) and inappropriately normal gonadotropins (LH 0.56 mIU/mL; FSH 2.59 mIU/mL). Physical examination revealed short stature, premature graying, alopecia, skin atrophy with sclerodermiform changes and normal-to-low body weight, raising suspicion of a progeroid syndrome. He denied a history of ocular abnormalities or malignancy. Whole-exome sequencing identified compound heterozygosity in the WRN gene (c.1105C>T and c.3879dup), confirming the diagnosis of Werner syndrome. Metabolic evaluation revealed marked insulin resistance and severe hypertriglyceridemia, consistent with the lipodystrophy-like phenotype described in WS. Bone mineral density was within the normal range. Pituitary MRI showed a 5mm microadenoma. Therapeutic management was adapted to the pathophysiology of the disease, prioritizing insulin sensitivity with metformin and pioglitazone, resulting in sustained improvement in glycemic control. Levothyroxine replacement and testosterone therapy were initiated according to endocrine deficits, and cardiovascular surveillance was implemented.

Conclusions: This case highlights Werner syndrome as a multisystemic endocrine disorder in which diabetes, thyroid dysfunction, hypogonadism and impaired tissue repair may serve as early clinical clues. Early recognition enables a pathophysiology-based therapeutic approach and allows timely cardiac and cancer surveillance in young patients with atypical endocrine presentations.

EP484 - ECE_1094 - Physical activity and liver fibrosis: a stratified analysis by obesity and diabetes status

Sunghwan Suh[1], Jung-Hwan Cho[1], Ji Min Han[1] and Ji Cheol Bae[1]

[1]Division of Endocrinology and Metabolism, Samsung Changwon Hospital, Sungkyunkwan University School of Medicine, Changwon, South Korea

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) represents a hepatic manifestation of metabolic syndrome. We investigated the association between leisure-time

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

physical activity (LTPA) and liver fibrosis, and whether this relationship differs by obesity and diabetes status.

Methods: We conducted a cross-sectional analysis using data from the National Health and Nutrition Examination Survey (NHANES) 2017-March 2020 cycle. LTPA was assessed using the Global Physical Activity Questionnaire (GPAQ) and classified as physically active if engaging in ≥600 metabolic equivalent (MET)-minutes per week of moderate-to-vigorous activity, or inactive. Clinically significant liver fibrosis was defined as liver stiffness measurement (LSM) ≥ 8.0 kPa on transient elastography. Multivariable logistic and linear regression models estimated adjusted odds ratios (ORs) for significant liver fibrosis, with additional subgroup analyses according to obesity and diabetes status.

Results: In 7,662 U.S. adults, physically active participants ($n = 2721$) had a lower prevalence of significant fibrosis than inactive individuals (5.4% vs 11.4%, $P < .001$). In multivariable analysis, Participants who were physically active were associated with 42% lower odds of having fibrosis (OR 0.58, 95% confidence interval [CI] 0.41-0.82; $P = .004$). This association remained consistent in subgroup analyses stratified by obesity and diabetes status, even in the non-obese subgroup with body mass index (BMI) <30 kg/m^2 (OR 0.54, 95% CI 0.32-0.91; $P = .022$) and the non-diabetic subgroup (OR 0.59, 95% CI 0.39-0.90; $P = .016$).

Conclusions: Regular moderate-to-vigorous LTPA was independently associated with lower likelihood of clinically significant liver fibrosis. This beneficial association was significant regardless of obesity or diabetes status, suggesting that LTPA may play a clinically meaningful role in populations at high risk for progressive liver disease.

EP486 - ECE_1707 - Body mass index and discharge destination after major elective orthopedic surgery: a retrospective cohort study

Dana Kagansky[1,2], Ofir Vinograd[1], Hitam Hagog Natour[3], Michal Bitan[4] and Orna Tal[1]

[1]Shamir Medical Center (Assaf Harofeh), Endocrine Institute, Affiliated to the Gray Faculty of Medical & Health Sciences, Tel Aviv University, Beer Yaakov, Israel; [2]Shamir medical Center, Endocrine Institute, Affiliated to the Gray Faculty of Medical & Health Sciences, Tel Aviv University, Beer Yaakov, Israel; [3]Meir Medical Center, Institute of Endocrinology, Diabetes and Metabolism, Kfar Saba, Israel; [4]The College of Management Academic Studies, School of Computer Science, Rishon LeZion, Israel

Background: Discharge destination after elective major orthopedic surgery influences health system capacity, costs, and post-acute care utilization. Although body mass index (BMI) is routinely documented in preoperative risk assessment, it is not a formal criterion for discharge planning, and evidence regarding its independent association with discharge destination remains limited. This study examined the association between BMI and discharge destination following major orthopedic surgery.

Methods: We conducted a retrospective cohort study of adult patients undergoing major elective orthopedic surgery at a tertiary medical center between 2015 and 2025. Eligible procedures included spine surgery, total knee replacement, and total hip replacement. BMI was calculated at admission and analyzed both categorically and continuously. The primary outcome was discharge destination, classified as home or institutional rehabilitation. Multivariable logistic regression was used to evaluate the association between BMI and discharge to institutional rehabilitation, adjusting for age, sex, type of surgical procedure, and length of hospital stay.

Results: The final cohort included 3617 patients (mean age 65 years; 55% female), of whom 22% were discharged to institutional rehabilitation. Discharge to rehabilitation increased across BMI categories, from 20% among patients with BMI <25 kg/m^2 to 25% among patients with BMI >30 kg/m^2 ($P <$ .001). In multivariable analysis, higher BMI was independently associated with discharge to rehabilitation (OR 1.03 per kg/m^2; 95% CI 1.01-1.04), after adjustment for age, sex, surgical procedure, and length of hospital stay.

Conclusions: Higher BMI was independently associated with discharge to institutional rehabilitation following major elective orthopedic surgery, beyond differences explained by hospitalization duration and procedural factors. These findings suggest that discharge destination represents a consequential and potentially system-influenced outcome, highlighting the need for more standardized, function-based discharge criteria.

EP487 - ECE_2748 - Preoperative GLP-1 receptor agonist therapy and body composition outcomes in bariatric surgery: a real-world study

Sonsoles Gutierrez-Medina[1], Isabel Higuera[1], Gloria Velasco[2], Isabel Yagüe[1], Elena Sánchez[1], Belén García Izquierdo[1], Marta Mediero Benítez[1], Fernando Lapuente[2], José María Lopesino2, Sonsoles Guadalix[1], Javier Escalada[3] and Magdalena De la Higuera[1]

[1]Endocrinology and Nutrition, Clínica Universidad De Navarra, Universidad de Navarra, Madrid, Spain; [2]Surgery, Clinica Universidad de Navarra, Madrid, Spain; [3]Endocrinology and Nutrition, Clinica Universidad de Navarra, Pamplona, Spain

Background: Glucagon-like peptide-1 receptor agonists (GLP-1 RA) are increasingly used in obesity management and are often combined with bariatric surgery (BS). While their role as adjuvant therapy after surgery is well established, evidence regarding their preoperative use and its impact on body composition remains limited, particularly in clinical practice.

Aims: To evaluate the effects of preoperative GLP-1 RA therapy on weight loss and body composition in patients undergoing BS, compared with patients managed without pharmacological treatment before surgery.

Methods: We conducted a retrospective observational study including adults undergoing BS at Clínica Universidad de Navarra between 2017 and 2023. Patients were classified according to exposure to GLP-1 RA therapy before surgery. Anthropometric parameters and body composition, assessed by bioelectrical impedance analysis, were evaluated at baseline, pre-surgery, and at 1 and 6 months post-surgery. Multivariable analyses were performed adjusting for baseline body mass index, age, and type of surgery.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Results: A total of 86 patients were included (mean age 46.6 ± 12 years; 66% women); 80.2% underwent sleeve gastrectomy and 19.8% gastric bypass. Preoperative GLP-1 RA therapy was prescribed in 34.8% of patients (63.4% liraglutide, 36.6% semaglutide) for a mean duration of 21.7 ± 15.9 weeks. Due to drug availability during the study period, semaglutide dosing reached a maximum of 1 mg weekly. Patients receiving GLP-1 RA achieved significantly greater pre-surgical weight loss compared with controls (5.1 ± 4.9% vs 2.4 ± 3.7%; $P = .005$). This difference persisted at 1 month post-surgery (15.4 ± 5.2% vs 13.0 ± 3.8%; $P = .03$), but was no longer significant at 6 months. At the time of surgery, fat mass was significantly lower in the GLP-1 RA group [53.3 kg (95% CI 50.7-56.0) vs 58.6 kg (95% CI 56.6-60.5); $P = .01$]. No significant differences in lean mass were observed, and no between-group differences in body composition parameters were detected at 6 months post-surgery. Adverse events were mild and mainly gastrointestinal (nausea 6.9%, dyspepsia 2.3%, constipation 1.1%).

Conclusions: In this real-world study, preoperative GLP-1 RA therapy was associated with greater pre-surgical weight loss and reduced fat mass at surgery, without additional lean mass loss. Although the early weight loss benefit was not sustained at 6 months, the favorable body composition profile supports a potential role for GLP-1 RA as a neoadjuvant strategy. Prospective studies with optimized dosing regimens and longer follow-up are needed to define the long-term clinical value of this approach.

EP488 - ECE_2506 - Renal function in patients with type 2 diabetes mellitus and ischemic heart disease with and without obstructive coronary atherosclerosis

Yanina Rebrova[1,2,3], Yanina Saienko[1] and Borys Mankovsky[1]
[1]*D. F. Chebotarev Institute of Gerontology of the National Academy of Medical Sciences of Ukraine, Kyiv, Ukraine;* [2]*The Scientific and Practical Medical Center of Pediatric Cardiology and Cardiac Surgery of the Ministry of Health of Ukraine, Government Institution, Kyiv, Ukraine;* [3]*Shupyk National Healthcare University of Ukraine, Kyiv, Ukraine*

Background: Type 2 diabetes mellitus (T2DM) is associated with a high risk of both ischemic heart disease and chronic kidney disease (CKD). In addition to obstructive coronary artery disease (CAD), increasing attention has been paid to ischemia with non-obstructive coronary arteries (INOCA), particularly microvascular angina, which is considered a manifestation of systemic microvascular dysfunction. However, data on renal function according to different forms of ischemic heart disease in patients with T2DM remain limited.

Aim: To compare renal function and markers of chronic kidney disease in patients with T2DM with INOCA and obstructive CAD.

Methods: The study population consisted of 80 patients with type 2 diabetes mellitus, who were categorized into INOCA ($n = 30$) and obstructive coronary artery disease ($n = 50$) groups. Age, duration of T2DM, fasting glucose, glycated hemoglobin (HbA1c), plasma creatinine, estimated glomerular filtration rate (eGFR, CKD-EPI), urine albumin-to-creatinine ratio (ACR), and plasma potassium levels were assessed. Data are presented as mean ± standard deviation. Between-group comparisons were performed using Student's t-test, and correlations were analyzed using Pearson's method.

Results: Patients with obstructive CAD were older than those with INOCA (66.8 ± 8.3 vs 58.9 ± 11.3 years). Glycemic control parameters did not differ significantly between groups (HbA1c: 6.9 ± 1.4% vs 6.7 ± 1.7%). Renal impairment was more pronounced in the obstructive CAD group, with significantly lower eGFR (51.2 ± 15.8 vs 74.3 ± 16.8 ml/min/1.73 m^2; $\mathbf{P < .001}$) and higher ACR (82.3 ± 115.8 vs 32.7 ± 34.3 mg/g; $\mathbf{P = .028}$) compared with the INOCA group. An inverse association between eGFR and ACR was observed in both INOCA and obstructive CAD groups, with a stronger correlation in patients with obstructive disease, indicating a consistent link between renal dysfunction and albuminuria across subgroups.

Conclusions: In patients with type 2 diabetes mellitus, obstructive coronary artery disease is associated with more severe renal dysfunction compared with INOCA, despite similar glycemic control. The inverse relationship between eGFR and albuminuria highlights shared cardiorenal mechanisms underlying target organ damage in T2DM

EP490 - ECE_1508 - Real-world comparison of the effects of loxenatide with other GLP-1RAs on renal outcomes in patients with type 2 diabetes: a subgroup analysis of the fighting-1 cohort study (fighting-3)

Hong Wu[1], Lianyong Liu[1], Yale Duan[2], Shaowei Duan[3], Zhizhen Hu[3] and Dajin Zou[1]
[1]*Punan Hospital, Shanghai, China;* [2]*Department of Medical Affairs, Jiangsu Hansoh Pharmaceutical Group Co., Ltd., Shanghai, China;* [3]*Jiangsu Hansoh Pharmaceutical Group Co., Ltd., Shanghai, China*

Background: Glucagon-like peptide-1 receptor agonists (GLP-1RAs) have demonstrated renoprotective effects in clinical trials. However, real-world evidence comparing the renal outcomes of different GLP-1RAs remains limited. FIGHTING-3 is a subgroup analysis of the FIGHTING-1 cohort study. FIGHTING-3 aimed to evaluate the real-world effectiveness of loxenatide vs other GLP-1RAs on renal outcomes in patients with type 2 diabetes (T2D).

Methodology: This multicentric retrospective, real-world study, was conducted using data from the Tianjin Health Care Data Platform, which includes records from 82 hospitals in China. Adults with T2D who started and continued treatment with different GLP-1RAs for at least 12 months were included. Propensity score matching (caliper = 0.1) was used to balance 10 baseline covariates, including age, sex, diabetes duration, history of cardiovascular disease, dyslipidemia, hypertension, renal disease, use of sodium-glucose co-transporter-2 inhibitors, and antihypertensive and lipid-lowering therapies. The composite renal outcome defined as a 50% sustained decline in estimated glomerular filtration rate (eGFR), onset of renal failure, or all-cause mortality. The cox proportional hazards regression model was applied to estimate hazard ratio (HR) along with their 95% confidence intervals (CIs).

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Results: In the cohorts, the median follow-up duration was 29.5 months for patients receiving loxenatide, 22.9 months for semaglutide, 27.2 months for liraglutide, and 27.8 months for dulaglutide. The proportion of days covered (PDC) was 69.5%, 47.7%, 46.7%, and 51.6%, respectively. The proportion of patients receiving high-dose treatment was 100.0% (loxenatide 0.2 mg), 52.3% (semaglutide 1.0 mg), 32.1% (liraglutide 1.8 mg), and 3.8% (dulaglutide 1.5 mg). Loxenatide was matched 1:1 with semaglutide ($N = 974$), liraglutide ($N = 798$), and dulaglutide ($N = 501$). Loxenatide was associated with a reduction of composite renal endpoint vs semaglutide (HR: 0.69, 95% CI: 0.07-7.29), liraglutide [HR: 0.15, 95% CI: 0.02-1.34], and dulaglutide (HR: 0.53, 95% CI: 0.05-5.99). However, these differences were not statistically significant (all $P > .05$).

Conclusions: Loxenatide exhibits comparable renal protection to other GLP-1RAs in T2D, aligning with the class's established benefits. However, low event rates highlight the need for larger trials to validate these findings.

EP491 - ECE_2116 - Prevalence of additional autoimmune diseases in adults with Type 1 diabetes and thyroid and/or celiac disease: a real-world cross-sectional study

Valerio Velardi, Lidiana Sanson, Barbara Toffoli, Federico Favaro, Fabio Fischetti, Bruno Fabris and Stella Bernardi
University of Trieste, Trieste, Italy

Aims: Type 1 diabetes mellitus (T1DM) is a chronic autoimmune disease that is often associated with other autoimmune conditions, mostly autoimmune thyroid disease (AITD) and celiac disease. Guidelines recommend screening subjects with T1DM for thyroid and celiac disease. Nevertheless, in case of their positivity, indicating the presence of an autoimmune polyendocrine syndrome, there is a lack of guidance on how to proceed. In other words, should we screen these patients for other autoimmune diseases? The aim of our study was to evaluate the number of additional autoimmune conditions in a cohort of T1DM patients with AITD and/or celiac disease.

Methods: This is a real-world cross-sectional study. Adult patients with T1DM followed in the ASUGI Diabetes Center (Trieste, Italy) were identified with the use of electronic medical records. Among them, we selected those who had a diagnosis of AITD or celiac disease and prescribed further exams to exclude other autoimmune conditions.

Results: 639 T1DM patients were identified and 198 of them had AITD or celiac disease. A total of 139/198 (70%) agreed on performing further analyses. In the end, 65/139 (47%) patients presented a previously unknown autoantibody positivity, which led us to diagnose 16 new pathological conditions in 15/139 patients (11%). Taking into account the newly diagnosed autoimmune conditions, as well as those that were already known, 43/139 (31%) patients had at least 3 autoimmune diseases.

Conclusions: Our data show that 31% of patients with T1DM and AITD or celiac disease have at least another (ie, a third) autoimmune disease. These data shed light on the fact that once thyroid and celiac disease screening are positive in patients with T1DM, patients should receive the diagnosis of APS, which should prompt for a broader evaluation of additional autoimmune diseases and raise medical awareness during patient follow-up.

Abstract citation ID: lvag096.984

EP492 - ECE_3018 - Impact of the Dexcom G7-Tandem t:slim X2 with Control-IQ system on glycemic control in patients with type 1 diabetes: a retrospective real-world study

Javier Panizo Fra[1], Selena Rodriguez Fernandez[2], Kevin David Díaz Gorrín[1], Paula Pérez[1], MacArena Sánchez-Gallego Alonso[1], Óliver Quintero Rodríguez[1], Ana Paola Leon Ocando[1], Orvelindo Rodríguez Hernández[1], Elena Rodríguez Sosa[1], Laura Mesa Suárez[1] and Juan Ignacio Márquez De La Rosa[1]
[1]San Cristóbal de La Laguna, Spain; [2]Endocrinology and Nutrition, Hospital Universitario de Canarias, San Cristóbal de La Laguna, Spain

Introduction: Optimal glycaemic control is essential to reduce complications in type 1 diabetes mellitus (T1DM). Hybrid closed-loop systems allow automatic insulin adjustment to optimise glycaemic control. The Dexcom G7–Tandem t:slim X2 with Control-IQ system integrates an insulin pump, a continuous glucose monitoring (CGM) sensor, and an automated control algorithm.

Objective: To retrospectively evaluate the effect of using the Dexcom G7–Tandem t:slim X2 with Control-IQ system on glycaemic control parameters (HbA1c and CGM metrics) in 15 patients with T1DM during the first 6 months of use, followed in the outpatient Endocrinology and Nutrition clinics at the Hospital Universitario de Canarias.

Materials and Methods: The variables analysed included age, sex, duration of diabetes, HbA1c, total daily insulin dose, time in range (TIR), time in hypoglycaemia, time in hyperglycaemia, coefficient of variation (CV), and percentage of time with Control-IQ activated. Data were collected for the month prior to system initiation (Dexcom Clarity) and at 6 months after starting system use (Glooko).

Statistical Analysis: Paired Student's *t*-test was used for variables with normal distribution (TIR, CV, hypoglycaemia), while the Wilcoxon signed-rank test was applied for HbA1c comparisons due to non-normal distribution.

Results: HbA1c: A significant reduction of 0.6 percentage points was observed (7.32% at baseline vs 6.63% at 6 months, $P = .010$). TIR (70-180 mg/dL): Mean increase of 11% (54.07% ± 20.67% at baseline vs 65.13% ± 7.11% at 6 months, $P = .0295$). Hypoglycaemia (<70 mg/dL): Slight reduction (2.07% ± 1.22% at baseline vs 1.47% ± 1.36% at 6 months, $P = .228$). CV (%): Mild, non-significant reduction (36.65% ± 6.03% at baseline vs 35.49% ± 5.29% at 6 months, $P = .509$).

Conclusions: This study demonstrates a significant improvement in TIR and HbA1c without an increase in hypoglycaemia. These findings support the effectiveness of hybrid closed-loop systems in real-world clinical practice, improving glycaemic control in patients with T1DM.

EP493 - ECE_3056 - Management of corticosteroid-induced hyperglycemia in hospitalized patients with Type 2 diabetes mellitus treated by the Endocrinology Department

Javier Panizo Fra, Selena Rodriguez Fernandez, Kevin David Díaz Gorrín, Paula Pérez MacHín, MacArena Sánchez-Gallego Alonso, Óliver Quintero Rodríguez, Ana Paola Leon Ocando, Laura Mesa Suárez, Elena Rodríguez Sosa, Patricia León González and Juan Ignacio Márquez De La Rosa
San Cristóbal de La Laguna, Spain

Introduction: The use of glucocorticoids in hospitalised patients with type 2 diabetes mellitus (T2DM) frequently triggers severe glycaemic decompensation, complicating clinical course and patient management. These patients often require basal–bolus insulin therapy to achieve optimal glycaemic control.

Objective: To evaluate glycaemic control and therapeutic strategies used in hospitalised patients with T2DM treated with systemic corticosteroids who were assessed by the Endocrinology service.

Materials and Methods: A prospective, observational study was conducted. Twenty-six patients with T2DM receiving corticosteroid therapy and admitted to different departments of the Hospital Universitario de Canarias (HUC) were included. All patients were assessed and followed through endocrinology consultation over a 6-month period. Glycaemic values before and after intervention, corticosteroid dose (prednisone equivalent), and the need for insulin therapy according to prior diabetes treatment were analysed.

Results: Of the 26 patients included, 57.7% were male and 42.3% female, with a mean age of 70.1 years. Mean glycated haemoglobin (HbA1c) was 7.52%. The mean daily corticosteroid dose (prednisone equivalent) was 34.8 mg. A statistically significant reduction in mean capillary blood glucose was observed, from 289.2 ± 62.1 mg/dL at the start of the intervention to 156.4 ± 29.8 mg/dL at discharge ($P < .001$). When stratified by prior treatment, patients previously treated with insulin had higher HbA1c levels (7.95% vs 6.9%, $P = .028$) and a greater number of severe hyperglycaemic episodes (>250 mg/dL) during hospitalisation (5.4 vs 2.3 episodes, $P = .005$) compared with those treated with oral antidiabetic drugs (OADs). No statistically significant differences in final glycaemic control were observed between patients treated with prednisone or dexamethasone. The incidence of hypoglycaemia was negligible. A statistically significant positive correlation was found between corticosteroid dose and insulin requirements at discharge ($r = 0.62$; $P < .005$). After stratification by prior treatment, insulin-treated patients exhibited greater glycaemic variability (mean of 5.4 episodes >250 mg/dL) compared with those treated with OADs (2.3 episodes; $P = .005$). No cases of severe hypoglycaemia were observed, with a mean of 0.4 events per patient.

Conclusions: Endocrinology follow-up of hospitalised patients with T2DM receiving corticosteroid therapy resulted in significant improvement in glycaemic profile. A direct and significant relationship exists between glucocorticoid dose and insulin requirements. Patients with previously insulin-treated T2DM show poorer glycaemic control and a higher number of hyperglycaemic episodes, representing the subgroup that benefits most from endocrinological intervention.

EP494 - ECE_3857 - Preliminary six-month prospective analysis of glycemic control and lipid profile changes following automated insulin delivery initiation in adults with type 1 diabetes

Mafalda Canudas Costa, Helena Urbano Ferreira, Ines Pereira, João Menino, Ana Rita Leite, Patricia Ferreira, Ana Luísa Barbosa, Anabela Costa, Carmo Redondo, Sílvia Monteiro, Sandra Belo, João Neves, Celestino Neves, Joana Queirós and Juliana Gonçalves
Department of Endocrinology, Diabetes and Metabolism, São João Local Health Unit, Oporto, Portugal

Background: Automated insulin delivery (AID) systems improve glycemic control in adults with type 1 diabetes (T1D), but their impact on lipid metabolism remains unclear.

Methods: Baseline, 3-, and 6-month data were analyzed from a prospective cohort of adults with T1D followed at a tertiary center who initiated either Tandem t:slim X2™ Control-IQ (CIQ) or MiniMed™780G (MM780G) since July 2023. Participants without baseline and at least one follow-up measurement of lipid profile or glycemic control were excluded. Associations between glycemic metrics and lipid parameters were evaluated using linear regression models—cross-sectional at baseline and longitudinal for within-person changes—and a linear mixed-effects model including repeated measures at 0, 3, and 6 months. Analyses were unadjusted and adjusted for age, sex, BMI, and statin therapy. Continuous variables were summarized as mean ± SD or median (IQR) according to distribution.

Results: Seventy-three adults were included (37.30 ± 11.80y; 34.30% male), 38.40% under statin therapy, 49.00% using MM780G. Baseline HbA1c was 7.60 ± 1.00%, TIR 55.13 ± 14.23%, LDL-C 86.00 (63.50-104.00) mg/dL, BMI 24.60 (22.51-27.41) kg/m^2. Higher TIR correlated with lower ApoB at baseline ($\beta = -.39$, 95%CI−0.77;−0.01, $P = .048$), not sustained after adjustment. Cross-sectionally, higher TIR associated with lower triglycerides ($\beta = -.01$, 95%CI–0.02; 0.00, $P = .049$); higher TAR showed no baseline association but was positively associated with triglycerides longitudinally ($\beta = .01$, 95%CI 0.00; 0.02, $P = .040$). BMI independently predicted higher triglycerides ($\beta = .05$, 95%CI 0.02; 0.08, $P = .001$) and LDL-C ($\beta = 1.18$, 95%CI 0.07; 2.29, $P = .040$), while statin use correlated with lower LDL-C ($\beta = -14.50$, 95%CI−23.30; −5.70, $P = .002$) and total cholesterol (TC) ($\beta = -11.70$, 95%CI −23.00;−0.40, $P = .046$). Longitudinally, increases in TBR were associated with higher LDL-C ($\beta = 1.31$, 95%CI 0.20; 2.43, $P = .022$), TC ($\beta = 1.57$, 95%CI 0.31; 2.84, $P = .020$), and non-HDL-C ($\beta = 1.50$, 95%CI 0.39; 2.60, $P = .008$). Mixed-effects models confirmed these trends: modest inverse association between TIR and triglycerides ($\beta = -.01$, 95%CI −0.01; 0.00, $P = .050$), borderline positive association between TAR and triglycerides ($\beta = .01$, 95%CI 0.00; 0.02, $P = .058$), and significant positive association between TBR and non-HDL-C ($\beta = .96$,

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

95%CI 0.02; 1.90, $P = .046$), with positive but non-significant associations with LDL-C and TC. No significant associations were observed with HDL-C or ApoA.

Conclusions: In this preliminary 6-month analysis, improved CGM-derived glycemic control—particularly higher TIR—was modestly associated with lower triglycerides, whereas higher TAR and TBR correlated with less favorable lipid profiles. Lipid metabolism may reflect short-term glycemic improvement after AID initiation, warranting confirmation at 12 months.

EP495 - ECE_1400 - Mendelian randomization identifies no causal relationship of insulin resistance on hippocampal volume

Silvano da Silva[1], Vasiliki Lagou[2], César Pórpora[1] and João Silva[1]

[1]*Faculty of Medical Sciences of Santos (FCMS)—UNILUS—Lusíada University Center, Santos, Brazil;* [2]*Bioinformatics Multidisciplinary Environment, Federal University of Rio Grande do Norte, Natal, Brazil*

Introduction: Insulin resistance is a systemic condition associated with altered brain metabolism and increased risk of cognitive and neurodegenerative disorders. Observational and neuroimaging studies suggest links between peripheral insulin resistance and structural brain changes, but these findings are limited by confounding. Mendelian randomization (MR) provides a genetic approach to determine whether insulin resistance causally influences brain structure, with important implications for endocrine mechanisms and metabolic therapies.

Aim: To assess the causal relationship between genetically predicted systemic insulin resistance and hippocampal volume (HV) using two-sample MR.

Methods: A two-sample Mendelian randomization study was performed using publicly available data to assess the causal effect of fasting insulin (FI)/glycated hemoglobin (HbA1c) on brain structure. Independent genome-wide significant variants ($P < 5 \times 10^{-8}$) selected from large-scale FI/HbA1c GWAS meta-analyses in individuals of European ancestry were used as instrumental variables. HV based on magnetic resonance imaging (MRI) GWAS data were available from UK Biobank Causal estimates of FI/HbA1c on HV were derived using inverse variance weighted (IVW) analysis and compared to those from weighted median and MR-Egger methods for consistency. Heterogeneity and horizontal pleiotropy were evaluated using Cochran's Q statistic and MR-Egger intercept, respectively, and leave-one-out analyses were conducted to assess result robustness.

Results: Genetically predicted FI was not causally associated with HV. The IVW analysis showed a non-significant effect estimate ($\beta = -.07$, $P = .71$), which was directionally consistent across other MR methods ($\beta_{\text{weighted median}} = -.11$, $P_{\text{weighted median}} = .58$; $\beta_{\text{MR-Egger}} = -0.17$, $P_{\text{MR-Egger}} = 0.88$). Cochran's Q test indicated no heterogeneity among instrumental variables (IVW Q $P = .052$) or evidence of directional horizontal pleiotropy as assessed by the MR-Egger intercept ($P = .93$). Consistent with these findings, no causal effects of genetically predicted HbA1c levels on HV were observed. Leave-one-out analyses demonstrated that no single variant disproportionately influenced the overall causal estimates.

Conclusions: This MR study provides genetic evidence that systemic insulin resistance related traits do not have a direct causal effect on HV, a structural MRI-derived trait. These findings indicate that glucose homeostasis may not directly influence hippocampal anatomy, but other, non-glycemic, mechanisms might be driving the associations between insulin resistance and central nervous system outcomes.

EP496 - ECE_1903 - Incidence and prevalence of type 1 diabetes, celiac disease and autoimmune thyroid disorders in Spain, 2018-2025

Mariana Haeberer[1], Jordi Aparici-Espot[2], Maria Alamillo[3], Yesika Díaz[3], Virginia Bellido[4], Luis Castaño[5] and Fernando Gomez-Peralta[6]

[1]*Sanofi, Madrid, Spain;* [2]*Sanofi, Barcelona, Spain;* [3]*Telomera, Madrid, Spain;* [4]*Hospital Universitario Virgen del Rocío, Sevilla, Spain;* [5]*Hospital Universitario Cruces, Bilbao, Spain;* [6]*Hospital General de Segovia, Segovia, Spain*

Introduction: We aimed to estimate incidence and prevalence of Type 1 Diabetes (T1D), celiac disease and autoimmune thyroid disorders in Spain during 2018-2025.

Methods: Retrospective observational cohort study using secondary data from Telotrón® database. Indirect standardization rates were estimated using National Statistics Institute population denominators. ICD-9/ICD-10 codes used were: T1D 250.*1,250.*3/E10; celiac disease 579.0/K90.0; Hashimoto hypothyroidism 245.2/E06.3; Graves hyperthyroidism 242.0/E05.0.

Results: As of 31-Dec-2025, the prevalences of T1D, celiac disease, Hashimoto and Graves were 0.30% ($N = 148\,688$), 0.56% ($N = 276\,548$), 0.30% ($N = 146\,508$) and 0.30% ($N = 146\,071$), respectively. Between 2018-2025, the incidence of T1D, celiac disease, Hashimoto and Graves ranged from 10.2-14.0, 26.3-43.5, 17.8-27.9 and 16.5-25.9 per 100,000, respectively. T1D incidence was higher in those aged <35 and increased over time between 0-7 and 18-35 years old. Incidence of celiac disease also increased in those aged <45 years, while incidences of Hashimoto and Graves increased in those aged >18 and between 18-45 years, respectively (Table 1). Among celiac disease, Hashimoto and Graves population, 1.71%, 1.34% and 0.81% also had T1D diagnosis, respectively. Among T1D population, 11.5% had at least one autoimmune comorbidity (2.7% celiac disease, 1.3% Hashimoto and 0.8% Graves).

Conclusions: Estimations of T1D are consistent with few previous studies. Celiac, Hashimoto and Graves diseases appear to be underdiagnosed. All conditions increased over time, T1D and celiac disease among children and adults and thyroiditis among adults, this may be partially attributed to improved diagnosis. Comorbidity between these conditions is frequent. Enhanced screening is needed.

Table 1 Incidence rates (100 000 population).

Disease	Age-group	2018	2022	2023	2024	2025

EP497 - ECE_3829 - Evaluating steroid profiles through sexual dimorphism to define metabolic phenotypes and identify advanced fibrosis in patients with MASLD

Mirko Parasiliti Caprino[1], Chiara Rosso[2], Federico Ponzetto[3], Laura Leoni[3], Giovanni Birolo[4], Grazia Pennisi[5], Gianpaolo Caviglia[2], Giulio Mengozzi[3], Salvatore Petta[5], Piero Fariselli[4], Gianluca Aimaretti[1], Tuulia Hyotylainen[6], Mauro MacCario[1], Matej Orešič[7] and Elisabetta Bugianesi[2]

[1]Endocrinology, Diabetes and Metabolism, Department of Medical Sciences, University of Turin, Turin, Italy; [2]Liver Unit, Department of Medical Sciences, University of Turin, Turin, Italy; [3]Clinical Biochemistry Laboratory, Department of Medical Sciences, University of Turin, Turin, Italy; [4]Department of Medical Sciences, University of Turin, Turin, Italy; [5]Liver Unit, University of Palermo, Palermo, Italy; [6]School of Science and Technology, Örebro University, Örebro, Sweden; [7]Turku Bioscience Centre, University of Turku and Åbo Akademi University, Turku, Finland

Aim: Sex-related differences in metabolic dysfunction-associated steatotic liver disease (MASLD) are increasingly recognised, but the endocrine mechanisms underlying disease heterogeneity and progression remain poorly understood. Given the pivotal role of steroid hormones in metabolic regulation and inflammation, we aimed to investigate sexual dimorphism in MASLD through a targeted steroidomic approach and to develop a non-invasive model for the prediction of advanced hepatic fibrosis.

Methods: In this multicentre cross-sectional study, we enrolled 463 patients with biopsy-proven MASLD from two tertiary Liver Units in Italy. Steroid profiling was performed using a newly validated liquid chromatography–tandem mass spectrometry (LC-MS/MS) method, quantifying both glucocorticoids and phase II androgen metabolites. Associations with sex, metabolic comorbidities (obesity, type 2 diabetes mellitus, and hypertension), PNPLA3 rs738409 genotype, and histological fibrosis stage were evaluated. A predictive model for advanced fibrosis (F≥3), named the FaSter model (Fibrosis and Steroid), was developed in the Turin cohort ($n = 313$) using multivariable logistic regression and internally validated with 10-fold cross-validation. External validation was performed in an independent cohort from Palermo ($n = 150$). A subgroup of 32 patients underwent hepatic transcriptomic analysis for selected steroidogenic and conjugating enzymes.

Results: Steroidomic analysis revealed marked sex- and age-specific differences in circulating steroid profiles. In men, advanced fibrosis was associated with decreased sulfation and glucuronidation of androgens, suggesting impaired hepatic inactivation. In women, steroid alterations varied according to menopausal status and metabolic phenotype, with postmenopausal women showing elevated testosterone and reduced androgen sulfate levels in advanced disease. The FaSter model, incorporating clinical parameters and ten steroid biomarkers, showed excellent diagnostic accuracy for advanced fibrosis (AUC 0.88 in the training cohort; 0.82 in the validation cohort), outperforming FIB-4 and NAFLD fibrosis score (NFS), and approaching the performance of Vibration-Controlled Transient Elastography (VCTE). Combining the FaSter model with liver stiffness measurement further improved predictive performance (AUC up to 0.91). Transcriptomic data supported a pathophysiological role for impaired hepatic steroid metabolism in the development of advanced fibrosis.

Conclusions: Steroid metabolism is closely linked to sexual dimorphism and fibrosis progression in MASLD. The FaSter model represents a novel, non-invasive, and reproducible tool for fibrosis risk stratification, with potential application in personalised hepatology. Further validation in prospective and ethnically diverse populations is warranted to confirm its generalisability and clinical utility.

EP499 - ECE_1517 - Gut microbiome differences between stress-resilient and stress-vulnerable mice parallel metabolic health status

Yonatan Karban[1], Mayalee Weissman Rosenfeld[1], Ayala Wollman[1], Oshrit Rahimi[1], Oryan Agranyoni[2], Sarven Sabunciyan[2], Albert Pinhasov[1] and Tovit Rosenzweig[1]

[1]Department of Molecular Biology, and The Adelson School of Medicine, Ariel University, Ariel, Israel; [2]Johns Hopkins University, Baltimore, United States

Obesity is a prevalent health condition that substantially increases the risk of cardiometabolic diseases, typically manifesting as metabolically unhealthy obesity (MUO). Nevertheless, a subset of individuals remains relatively metabolically healthy despite excess adiposity, a phenotype termed metabolically healthy obesity (MHO). Multiple factors have been implicated in this divergence, including adipose tissue function, gut microbiome composition, and stress responsiveness.

Accumulating evidence suggests that resilience to stress influences susceptibility to obesity and its metabolic complications. In previous work, we demonstrated that mice selectively bred

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

for differential stress-coping phenotypes exhibit distinct metabolic profiles. Stress-resilient dominant (Dom) mice displayed features consistent with MHO, whereas stress-vulnerable submissive (Sub) mice developed MUO.

The gut microbiome is a critical regulator of host metabolism and has been strongly linked to obesity-related morbidity. Dysbiosis, defined as an imbalance in gut microbial communities, has been associated with metabolic dysfunction. The current study aimed to determine whether differences in gut microbiome composition contribute to the distinct metabolic phenotypes observed in stress-vulnerable and stress-resilient mice.

Gut microbiome profiles of Sub and Dom mice maintained on a standard diet (STD) or challenged with a high-fat diet (HFD) were analyzed using 16S rRNA sequencing. HFD significantly reduced alpha diversity in Sub mice, while Observed and Shannon diversity indices were preserved in Dom mice. Phylogenetic diversity (PD) was reduced by HFD in both strains. Principal component analysis revealed distinct clustering of Sub and Dom microbiomes at baseline and following HFD exposure, indicating inherent strain-specific microbial signatures.

Differential abundance analysis using ANCOM-BC revealed a higher relative abundance of Bacteroidetes in Dom mice, whereas Sub mice exhibited increased Proteobacteria and Firmicutes. Under STD conditions, Sub mice showed enrichment of bacterial taxa previously associated with unfavorable metabolic health, including Desulfovibrionaceae, Lachnospiraceae, Ruminococcus, and Proteobacteria, alongside reduced Bacteroidales and S24-7. Accordingly, the microbiome profile of Sub mice under STD resembled that reported in metabolically unhealthy states. HFD induced microbiome shifts in both strains, including increased Desulfovibrionaceae and Proteobacteria and reduced Betaproteobacteria and S24-7; however, strain-specific differences persisted, with Sub mice maintaining higher Proteobacteria and Dom mice higher Bacteroidetes.

This study demonstrates that stress-coping phenotypes are linked to distinct gut microbiome compositions, which may contribute to differential metabolic outcomes under standard and high-fat diets.

EP500 - ECE_1831 - Semaglutide rewires thyroid transcriptional programs in obesity through sex-specific modulation of adiponectin signaling and mTOR–RET pathways

Niklas Geiger, Simon Kloock, Palina Zytner, Martin Fassnacht and Ulrich Dischinger
Division of Endocrinology and Diabetes, Department of Internal Medicine, University Hospital Würzburg, Würzburg, Germany

Background: Obesity disturbs endocrine homeostasis and reshapes thyroid-specific transcriptional programs. Recent data show a higher prevalence of thyroid dysfunction and atypical TSH profiles in obese individuals, highlighting the clinical relevance of metabolic–thyroid crosstalk. Given the widespread use of semaglutide, this study investigates its sex-specific impact on thyroid gene regulation in obese rats.

Methods: Male and female Wistar rats were exposed to an eight-week high-fat/fructose diet combined with L-NAME to induce obesity ($n = 6$ per group). Animals were subsequently randomized to semaglutide (Sema) or saline, while lean controls received standard chow without L-NAME. After additional eight weeks, thyroid tissue was analyzed by qRT-PCR for metabolic and thyroid-specific marker genes. Serum adiponectin and leptin were quantified.

Results: The adiponectin receptor emerged as an obesity-sensitive target, with males showing significant upregulation in mRNA expression vs controls ($P < .05$) and a trend toward Sema-mediated downregulation ($P = .09$). In females, Sema significantly suppressed adiponectin receptor expression ($P < .05$). In males, obesity downregulated mTOR, Cxcl10 and Foxe1 ($P < .01$), key regulators of thyroid hormone synthesis and metabolic signaling. Sema restored these transcripts ($P < .05$), suggesting a reversal of obesity-induced thyroid dysfunction. Sema also reduced Rps6ka4 expression in males ($P < .05$), pointing to a positive modulation of stress-responsive pathways. In contrast, obese females exhibited a significant upregulation of RET ($P < .05$). In males, adiponectin/leptin ratio was significantly higher in obese compared to lean rats, reduced in Sema, but without effects in females.

Conclusions: Semaglutide reprograms thyroid transcriptional networks in obesity via sex-specific modulation of adiponectin signaling and metabolic stress pathways, revealing a previously underappreciated endocrine interface between semaglutide and thyroid regulation.

EP501 - ECE_3796 - Epicardial adipose tissue shows selective associations with non-invasive hepatic fibrosis and metabolically-driven steatosis indices, revealing phenotypic heterogeneity beyond BMI in obesity

Davide Masi, Vittoria Strinati, Giorgia Maria Baldazzi, Maria Elena Spoltore, Rebecca Rossetti, Lucio Gnessi, Stefania Mariani, Mikiko Watanabe, Andrea Isidori, Daniele Gianfrilli and Carla Lubrano
Department of Experimental Medicine, Section of Medical Pathophysiology, Food Science and Endocrinology, Sapienza University, Rome, Italy

Background: Obesity is associated with substantial variability in cardiometabolic and hepatic risk that is not fully explained by body mass index (BMI). Epicardial adipose tissue (EAT) is a visceral-like fat depot with metabolic and inflammatory activity, but whether it reflects hepatic fat accumulation or more advanced, metabolically driven liver injury remains unclear.

Objective: To determine whether EAT is differentially associated with non-invasive indices of hepatic steatosis and fibrosis, independent of overall adiposity, and to assess whether epicardial fat burden contributes to the identification of obesity-related phenotypes beyond BMI.

Methods: We conducted a retrospective observational study in adults with overweight and obesity evaluated at a tertiary obesity care centre. Epicardial adipose tissue thickness was assessed by echocardiography together with measures of visceral adiposity, anthropometric variables and metabolic parameters. Hepatic steatosis and fibrosis risk were estimated using established non-invasive indices. Associations between EAT and hepatic indices

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

were examined using correlation analyses and multivariable linear and logistic regression models adjusted for demographic variables and measures of overall and central adiposity. To explore heterogeneity beyond conventional adiposity metrics, unsupervised phenotyping was performed using dimensionality reduction followed by model-based clustering.

Results: A total of 1076 individuals were included (mean age 52 ± 12 years; ~60% women), with a mean BMI of 36.1 ± 6.4 kg/m^2 and a mean EAT thickness of 8.1 ± 2.3 mm. Epicardial adipose tissue increased in parallel with visceral adiposity and insulin resistance. EAT was positively associated with fibrosis risk assessed by FIB-4 ($r \approx 0.25$, $P < .001$) and with Fatty Liver Index ($r \approx 0.40$, $P < .05$), whereas no significant association was observed with composite liver fat indices. After multivariable adjustment, EAT remained independently associated with FIB-4 ($\beta \approx 2.4$, $P \approx .03$) and Fatty Liver Index ($\beta \approx 2.2$, $P < .001$), but not with the Hepatic Steatosis Index or NAFLD Liver Fat Score. In models predicting clinically relevant steatosis, overall adiposity measures accounted for most of the variance and EAT did not retain independent significance. Unsupervised clustering identified four phenotypes characterized by different combinations of epicardial fat burden, insulin resistance, sex distribution and hepatic risk, largely independent of BMI.

Conclusions: Epicardial adipose tissue is selectively associated with non-invasive indices reflecting hepatic fibrosis and metabolically driven steatosis, rather than with liver fat accumulation alone. These findings highlight clinically relevant heterogeneity in hepatic risk among individuals with obesity and support the use of epicardial adiposity as a complementary marker in risk stratification.

EP502 - ECE_3251 - Deficient glucagon like peptide-1 (GLP-1) secretion following oral glucose stimulation as a metabolic trait in insulin resistant polycystic ovarian syndrome (PCOS) patients: A case control study

Ayan Roy[1,2], Shinjan Patra[1], Somdatta Giri[1], Kalyan Goswami[1], Sayanti Paul[1], Sampriti Gayen[3] and Pratisruti Hui[1,3]
[1]*All India Institute of Medical Sciences, Kalyani, India;* [2]*Endocrinology and Metabolism, All India Institute of Medical Sciences, Kalyani, India;* [3]*Radiodiagnosis, All India institute of Medical Sciences, Kalyani, India*

Background: Polycystic ovarian disease (PCOS) is one of the most common Endocrinologcal diseases carrying significant risk of metabolic diseases and cardiovascular risk. Though insulin resistance and beta cell functions have been investigated extensively, data related to glucagon or GLP-1 is limited. Insulin resistance is the hallmark of PCOS but its relationship with glucagon or GLP-1 is limited can be an interesting crosstalk. Though earlier studies have shown obesity can impair GLP-1 secretion, this is not studied in this high risk group. Interestingly, medicines acting on either increasing GLP-1 levels or augmenting its effects (GLP-1 analogues) have been trialled in PCOS.

Aims/Objective: The aim of the study was to explore the metabolic relationship of insulin resistance, beta cell functional with glucagon and incretins in PCOS patients. The main objective was to see the difference between various insulin indices, beta cell function measurements, glucagon and GLP-1 responses between PCOS and healthy controls.

Participants and Methodology: A total of 100 participants were screened as per Rotterdam criteria and were recruited for the project. Age matched healthy controls were also recruited. Patients and controls underwent 4 point oral glucose tolerance test (OGTT). Glucose, insulin, glucagon and GLP-1 was measured at each time point. Various beta cell functional and insulin resistance indices were calculated. GLP-1 and glucagon were compare using area under curve methods.

Results: Total 41 participants were recruited including 24 PCOS and 17 age matched controls. PCOS patients had higher BMI and waist circumference compared to controls. PCOS patients had significantly higher insulin resistance indices (HOMA IR and Matsuda index). There was no difference in various beta cell functional indices including oral disposition index or ISSI-2. There was slightly elevated fasting glucagon levels in PCOS compared to controls. All PCOS patients adequately suppressed glucagon following glucose load in the face of very high insulin secretion. Fating GLP-1 was not different between the groups but GLP-1 secretion at each time point (30, 60, 120 minutes) after glucose load were significantly lower in PCOS compared to controls. The AUC GLP-$1_{0\text{-}120}$ were lower in PCOS group (1311 ± 705 pM.min vs 2009 ± 640 pM.min). In multiple linear regression analysis, obesity, age, free androgen index or Matsuda index were not related to lower AUC GLP-$1_{0\text{-}120}$.

Conclusions: Insulin resistance is intrinsic to PCOS phenotype and lower GLP-1 secretion following oral glucose is a distinct metabolic feature in PCOS. Glucagon is adequately suppressed following glucose load in PCOS.

EP503 - ECE_1588 - Peripartum insulin delivery for type 1 diabetes pregnancies, keeping autonomy while optimizing care

Anna Emanuel[1], Misja Sprengers[1], Richard Ijzerman[1], Rebecca Painter[2] and Sarah Siegelaar[1]
[1]*Amsterdam, The Netherlands;* [2]*Erasmus MC, Rotterdam, The Netherlands*

Background: In pregnant women with type 1 diabetes, optimal glucose management during the intrapartum period is essential to reduce neonatal hypoglycaemia. Historically, many hospitals switched women to an intravenous insulin–glucose infusion during labour and delivery. However, current evidence indicates that continuation of subcutaneous insulin delivery is at least as safe. With the increasing use of hybrid closed-loop (HCL) therapy during pregnancy, continuation of automated insulin delivery during childbirth has emerged as a relevant and promising option.

Aim: To review current evidence and guideline recommendations on peripartum diabetes management in women with type 1 diabetes, with a specific focus on the feasibility, safety and effectiveness of continuing hybrid closed-loop insulin delivery during labour, delivery and the immediate postpartum period.

Methods: A structured literature search was performed in PubMed (September 2025) using the terms “peripartum OR intrapartum OR postpartum”, “type 1 diabetes”, and “hybrid

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

closed-loop OR automated insulin delivery". Randomised controlled trials, relevant observational studies and international guidelines were included. In addition, outcomes from women with type 1 diabetes who delivered in our tertiary care centre between January 2021 and June 2025 were analysed.

Results: Evidence from recent trials, including CRISTAL trial and preliminary data from the AiDAPT study, demonstrates that continuation of HCL therapy during labour and delivery is associated with a higher pregnancy-specific time in range, without an increased risk of hypoglycaemia, diabetic ketoacidosis or adverse neonatal outcomes compared with standard insulin therapy. Patient-reported satisfaction and perceived autonomy were consistently higher among women who continued their own insulin delivery system. In our centre, 23 of 26 women continued HCL therapy during the intrapartum period. No episodes of severe maternal hypoglycaemia or hyperglycaemia occurred, and no neonates experienced severe hypoglycaemia requiring prolonged intensive care admission. The rate of neonatal hypoglycaemia was 12 out of 23 (52%), consistent with previously published data.

Conclusions: Continuation of hybrid closed-loop insulin delivery in women with type 1 diabetes during the peripartum period appears to be safe and effective, provided that predefined safety conditions are met, including adequate patient education, proper device functioning and familiarity of healthcare professionals with HCL systems. Maintaining automated insulin delivery supports glycemic stability, reduces the need for intravenous insulin infusion, and preserves patient autonomy during childbirth. Transition to intravenous insulin should be reserved for situations in which patient safety cannot be guaranteed, such as technical failure or inability to self-manage.

EP507 - ECE_2514 - From bioimpedance to compliance: body composition changes during nutritional interventions

Roxana Pui[1], Stefania-Alexandra Bunceanu[2] and Stoian Dana[3]
[1]*Department of Doctoral Studies, Victor Babes University of Medicine and Pharmacy, Timişoara, Romania;* [2]*Department of Doctoral Studies, Victor Babes University of Medicine and Pharmacy, Timisoara, Discipline of Endocrinology, Second Department of Internal Medicine, University of Medicine and Pharmacy "Victor Babes", Timişoara, Romania;* [3]*Timişoara, Romania*

Introduction: Long-term adherence is one of the main challenges in obesity management. In routine care, engagement with monthly nutritional follow-up often declines rapidly after the initial consultation. Identifying early attendance trajectories may enable timely supportive strategies. This study aimed to describe follow-up attendance patterns and dropout during a 6-month nutritional intervention in adults with overweight or obesity, managed without anti-obesity pharmacotherapy.

Methods: This retrospective observational study included 2195 adults (1631 women; 564 men) with BMI ≥25 kg/m^2 evaluated between 2010 and 2020 at a specialized endocrinology and nutrition center in Timişoara, Romania. Patients received an individualized, hypocaloric, high-protein nutrition plan with scheduled monthly follow-up visits over 6 months and serial bioimpedance monitoring (Tanita BC-418). Patients treated with anti-obesity pharmacotherapy or with prior bariatric surgery were excluded. Attendance was summarized across visits from baseline (P0) to month 6 (P6).

Results: Follow-up attendance declined over the 6-month program, with most dropouts occurring within the first month after the baseline evaluation. Of the 2195 patients assessed at baseline (P0), 1747 returned for P1, 1116 attended P2, and 395 completed the final scheduled visit (P6). Overall, 68.75% attended only the baseline visit, whereas 31.25% returned for at least one follow-up. Attendance remained consistently higher in women than in men across all visits. According to the program's end-of-intervention classification, 159/2195 patients (7.2%) met the completion target, with lower proportions observed in older age groups. Among participants with paired baseline and final bioimpedance assessments, body fat percentage decreased significantly in both sexes across all age decades ($P < .001$). To illustrate the magnitude of change, in participants aged 18-30 years, median body fat declined in women (39.9% to 38.5%) and in men (30.15% to 28.6%) ($P < .001$).

Conclusions: In this substantial cohort managed exclusively through nutritional intervention, dropout after the initial visit was substantial and completion of the planned 6-month follow-up schedule was low, indicating that sustained follow-up is a major limiting factor of lifestyle-based interventions. Importantly, participants who remained engaged and attended monthly visits achieved consistent, statistically significant reductions in body fat percentage. Early, structured engagement strategies focused on the first follow-up period may reduce dropout and improve outcomes in non-pharmacological obesity care.

Maternity Center, Varanasi, India; [21]Chettinad Hospital & Research Institute, Chengalpattu, India; [22]Mumbai, India

Objectives: To evaluate the effect of synthetic semaglutide injection (Test drug) in comparison with Wegovy® (Reference drug) 2.4 mg in in physical function when used in weight management

Materials and Methods: This phase III, multicentre, randomized, open-label, active-controlled clinical study (CTRI/2025/04/085487) was conducted across 22 study sites in India after receiving regulatory and ethics committee approvals. Total 267 adult patients with BMI ≥ 30 kg/m^2 or ≥27 kg/m^2 with the presence of at least one co-morbidity of hypertension, dyslipidaemia and/or type 2 diabetes mellitus were included. Patient were randomized to receive either test drug or reference drug every week subcutaneous for 24 weeks. The primary endpoint was body-weight change at Week 24. Change in Quality of life was evaluated by total SF-36 (36-Item Short Form Health Survey) questionnaire score which was one of the secondary endpoints. This post-hoc analysis was conducted to evaluate the effect of semaglutide on physical function component of SF-36 questionnaire.

Results: At baseline, the mean (±SD) SF-36 Physical Functioning scores were similar between the two treatment groups [Test: 53.21 (±23.90); Reference: 54.81 (±23.44), $P = .6214$]. The SF-36 physical function score and change from baseline in SF-36 physical function score to week 12, and 24 are presented in below table (Table 1)

Table 1 Change in SF-36 Physical function Score.

		Semaglutide injection (test) ($N = 165$)		Wegovy (semaglutide) solution for injection (comparator) ($N = 80$)		Test Vs comparator

There was gradual improvement in SF-36 physical function score from baseline to week 24. The improvement in in SF-36 physical function score was comparable between test and the reference drug at each week ($P > .05$).

Conclusions: Semaglutide injection used in weight management also leads to improvement in SF-36 Physical Functioning scores in obese or overweight patients.

EP511 - ECE_3932 - Diabetic ketoacidosis associated with SGLT2 inhibitor therapy for alpelisib-induced hyperglycaemia: reconsidering second-line management

Lora Kirigin Biloš[1], Marina Andrešić[1], Lea Ledinsky[2], Ana Uroš[1], Jelena Marinkovic Radosevic[1] and Gorana Mirosevic[1]

[1]Klinički bolnički centar Sestre Milosrdnice, Endocrinology, diabetes i metabolic diseases, Zagreb, Croatia; [2]Department of Medical Oncology, University Hospital Centre Sestre Milosrdnice, Clinic for Tumors, Zagreb, Croatia

Background: Alpelisib is the first approved phosphatidylinositol-3-kinase alpha (PI3Kα) inhibitor for hormone receptor (HR)–positive, human epidermal growth factor receptor 2 (HER2)–negative, *PIK3CA*-mutated advanced breast cancer. Although it improves progression-free survival, hyperglycaemia is a common adverse effect, with diabetic ketoacidosis (DKA) being a rare but serious complication. PI3Kα inhibition increases hepatic gluconeogenesis, reduces peripheral glucose uptake, and induces compensatory hyperinsulinaemia, resulting in acute iatrogenic insulin resistance and hyperglycaemia. Current guidelines recommend metformin as first-line therapy, followed by sodium-glucose cotransporter-2 inhibitors (SGLT2 inhibitors) or pioglitazone as second-line agents.

Case presentation: A 64-year-old woman with metastatic HR-positive, HER2-negative, *PIK3CA*-mutated breast cancer developed DKA two months after commencing alpelisib. Baseline investigations demonstrated previously undiagnosed diabetes (HbA1c 5.8%, fasting plasma glucose 8.1 mmol/L, 2-hour OGTT 11.4 mmol/L), normal renal function, and a BMI of 22 kg/m^2. She had a family history of type 2 diabetes. Metformin and sitagliptin were initiated pre-emptively. Following alpelisib commencement, she developed grade 2 hyperglycaemia, requiring the addition of dapagliflozin. Two months later, she presented to the emergency department with dyspnoea, nausea, and altered mental status. Imaging revealed left-sided lobar pneumonia. Biochemical investigations demonstrated severe hyperglycaemia (19.6 mmol/L), metabolic acidosis (arterial pH 7.00, base excess −26.9), normal lactate, and ketonuria (+++), consistent with severe DKA. Alpelisib and dapagliflozin were discontinued. She was admitted to the intensive care unit and treated with intravenous fluids, insulin infusion, and electrolyte replacement, with rapid clinical and glycaemic improvement. Further testing showed low-normal C-peptide (0.78 nmol/L), negative diabetes autoantibodies, and an HbA1c of 9.0%. She was discharged 12 days later on basal insulin, sitagliptin, and

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

pioglitazone. Given the severity of DKA, alpelisib and SGLT2 inhibitors were permanently discontinued. At one-month follow-up, HbA1c had improved to 7.0%; however, due to disease progression with leptomeningeal spread, alpelisib was not reinitiated. Unfortunately, she died two months later.

Conclusions: This case demonstrates the rare but serious risk of DKA associated with alpelisib therapy. Despite guideline recommendations supporting SGLT2 inhibitors for glycaemic management, their use may potentiate ketoacidosis, particularly during acute illness. Enhanced surveillance, proactive patient education, close glucose and ketone monitoring, and individualized risk assessment are essential to optimize patient safety.

EP512 - ECE_3467 - Glucometabolic impact of Freestyle Libre 1 and 2 use in a large Type 1 Diabetes cohort, a retrospective study

Enrico Saudelli[1,2], Anna Malaguti[1,2], Simona Moscatiello[2], Sara Flamigni[2], Sabrina Berti[1,2], Michele Baldari[1,2], Laura Tribotti[1,2], Sara Capra[1,2], Ilenia Schillaci[1,2], Laura Agostini[1,2], Uberto Pagotto[1,2] and Guido Di Dalmazi[1,2]
[1]Department of Medical and Surgical Sciences (DIMEC), Alma Mater Studiorum University of Bologna, Bologna, Italy; [2]Division of Endocrinology and Diabetes Prevention and Care, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy

Background and Aims: The introduction of continuous glucose monitoring represents a major advancement in managing Type 1 Diabetes (T1D). In this study we aimed to assess: 1) longitudinal trends of glycated hemoglobin (HbA1c) and predictors of improved glycemic control in adults with T1D transitioning from self-monitoring of blood glucose (SMBG) to FreeStyle Libre 1 (FS1) and, subsequently, to FS2; 2) the impact of alarm use on HbA1c and ambulatory glucose profile (AGP) data.

Methods: We conducted a retrospective longitudinal analysis on adults with T1D followed at the Endocrinology Unit of IRCCS Sant'Orsola (Bologna, Italy). Exclusion criteria were: patients lacking complete HbA1c data covering the transition from SMBG to FS2, patients who hadn't used both FS1 and FS2 for at least 12 months, pump users, subjects with HbA1c >86 mmol/mol at any time. Our final cohort was composed of 355 individuals. Clinical data, AGP, and alarm use were evaluated before each upgrade, after 6 and 12-months, and at the last available follow-up.

Results: Transition from SMBG to FS1 was associated with a significant reduction in HbA1c of approximately 3 mmol/mol within the first 6 months, with sustained improvement over a mean follow-up of 45 ± 15 months. Mean HbA1c decreased from 59.8 ± 10.5 mmol/mol to 56.2 ± 10.1 at 6 months, 57.8 ± 9.7 at 12 months, and 57.2 ± 10.1 at the final follow-up ($P < .001$ for all timepoints vs baseline). In contrast, switching from FS1 to FS2 resulted in stable glycemic control over a mean follow-up of 19 ± 3 months, without significant change in HbA1c (baseline 56.6 ± 10.2 mmol/mol vs final 56.6 ± 10.1; $P = .486$). No differences were observed in mean HbA1c ($P = .821$) among alarm users ($n = 199$; HbA1c 56.4 ± 8.7 mmol/mol) vs non-alarm users ($n = 93$; HbA1c 57 ± 8.6) vs those with alarms for either hypo- or hyperglycemia ($n = 63$; HbA1c 57.4 ± 8.8). However, alarm users had significantly lower Time Below Range evaluated at each patient's last available visit (3.5 vs 5.2%, $P = .027$). Higher baseline HbA1c predicted greater HbA1c reduction for both transitions (FS1: β .455 per 1 mmol/mol increase, 95%CI 0.344-0.545, $P < .001$; FS2: β .290, 95%CI 0.196-0.384, $P < .001$). Age <65 years was associated with greater HbA1c improvement after FS1 initiation ($P = .012$).

Conclusions: Initiation of glucose monitoring with FS1 leads to significant and durable improvements in glycemic control. Upgrading to FS2 does not provide additional HbA1c benefits, regardless of alarm use, although active alarms could help reduce the time spent in hypoglycemia. Patients with higher baseline HbA1c derive the greatest glycemic improvement from sensor placement.

EP517 - ECE_1793 - Trend in the prevalence of diabetes among Korean adults with normal body mass index, 2011-2021

You-Cheol Hwang, Hyun Jin Ryu, Ji Eun Jun, In-Kyung Jeong, Kyu Jeung Ahn and Ho Yeon Chung
Seoul, South Korea

Aims: With the global increase in the prevalence of obesity, the prevalence of diabetes has increased worldwide. However, little is known about the trend in the prevalence of diabetes in people without obesity. Therefore, we aimed to investigate the trend in the prevalence of diabetes among Korean adults with normal body weight.

Methods: This study used data from the Korea National Health and Nutrition Examination Survey V-VIII from 2011 to 2021. Approximately, 38-42 million participants (weighted) per year aged ≥20 years were included in this analysis.

Results: The prevalence of diabetes has increased among adults with normal body mass index (BMI) of 18.5 to 22.9 kg/m^2 from 7.13% in 5th survey to 8.46% in 8th survey, representing a 18.7% increase (odds ratio 1.064; $P = .025$) during 10 years of follow-up periods. The increasing trend was significant in women (odds ratio 1.095; $P = .013$); however, showed only a tendency in men. According to age groups, the prevalence showed an increasing tendency in adults aged ≥40 years but, the prevalence has decreased in adults aged 20 to 39 years (odds ratio 0.560; $P = .002$).

Conclusions: The prevalence of diabetes has increased among adults with normal BMI during 10 years of follow-up and the trend was more evident in women than in men. However, the trend was different depending on age groups and rather, it showed a decreasing trend in younger adults.

[1]Faculty of Medicine and Life Sciences, University of Latvia, Riga, Latvia; [2]Research Institute of Pauls Stradins Clinical University Hospital, Riga, Latvia; [3]Institute of Applied Computer Systems, Riga Technical University, Riga, Latvia; [4]Institute of Human Movement Science, Sport & Health, Exercise Physiology, Training & Training Therapy Research Group, University of Graz, Graz, Austria; [5]Interdisciplinary Metabolic Medicine Trials Unit, Division of Endocrinology and Diabetology, Medical University of Graz, Graz, Austria

Background and Aims: Type 1 diabetes mellitus (T1DM) is a heterogeneous condition in which distinct glycaemic patterns may coexist with the development of metabolic abnormalities in a subset of individuals. These abnormalities may include alterations in lipid profiles, electrolyte balance, and liver-related biomarkers, contributing to increased cardiometabolic risk. In this study, we investigated the distribution of metabolic parameters across continuous glucose monitoring (CGM)-derived phenotypes.

Methods: CGM data from individuals with and without T1DM included in the longitudinal LatDiane project ($n = 95$) were used to derive CGM-based phenotypes. A data-driven unsupervised clustering approach was applied, using UMAP for dimensionality reduction followed by K-means clustering. Seven glycaemic phenotypes (P0-P6) were identified, reflecting distinct combinations of time spent in normoglycaemia, hypoglycaemia, and hyperglycaemia: normo-hypoglycaemic (P0), normoglycaemic with predominant time in normoglycaemia (P1), normoglycaemic (P2), hyper-normolycaemic (P3), normo-hyperglycaemic (P4), hyperglycaemic (P5), and hyper-hypoglycaemic (P6).

The derived phenotypes were subsequently applied to an independent cohort of individuals with T1DM from the T1Diabetes Granada database[1] ($N = 731$), with each participant assigned to a dominant phenotype based on weekly CGM profiles. Biochemical parameters, including triglycerides (TG), HDL cholesterol, alanine aminotransferase (ALT), and gamma-glutamyl transferase (GGT), were measured using standard laboratory methods. Differences across glycaemic phenotypes were assessed using the Kruskal–Wallis test with Dunn–Holm post-hoc correction.

Results: T1Diabetes Granada database participants were included and distributed across phenotypes as follows: P0, $n = 19$; P1, $n = 5$; P2, $n = 165$; P3, $n = 287$; P4, $n = 159$; P5, $n = 41$; and P6, $n = 55$. Due to the small sample size, P1 was excluded from biomarker analyses. Significant differences across phenotypes were observed for sodium ($P = 3.03 \times 10^{-6}$) chloride ($P = .00427$), TG ($P = 5.99 \times 10^{-5}$), HDL cholesterol ($P = .03133$), ALT ($P = .00449$), and GGT ($P = .0052$). Post-hoc analysis confirmed that P5 differed significantly from most other phenotypes in TG, HDL cholesterol and sodium. TG levels in P5 were significantly ($P < .05$) higher than in all other phenotypes and HDL cholesterol levels in P5 were significantly lower ($P < .05$) than in all other phenotypes except P6 ($P = .50$). Sodium levels in P5 were significantly lower than in all other phenotypes, while chloride levels were significantly lower ($P < .05$) in P5 compared with P2 ($P = .011$). P0 exhibited a more favorable hepatic profile, with significantly lower ($P < .05$) ALT and GGT levels compared with all other phenotypes.

Conclusions: CGM-based phenotypes in T1DM are associated with distinct lipid, electrolyte and metabolic profiles.

EP519 - ECE_2959 - IGF-2–mediated hypoglycemia in a patient with skull base chondrosarcoma: a case report

Kalliopi Pantelia[1], Vasiliki Antonopoulou[1], Angeliki Angelidou[1], Aggeliki Kyriakou[1], Panagiotis Mouchtouris[1], Georgios Kyriakopoulos[2], Marinella Tzanela[1] and Georgia Ntali[1]

[1]Department of Endocrinology "D. Ikkos"- Diabetes Center-EndoERN-Evangelismos General Hospital, Athens, Greece; [2]Department of Pathology, Evangelismos General Hospital, Athens, Greece

Introduction: Non–islet cell tumour hypoglycemia (NICTH) is a rare paraneoplastic syndrome, most commonly caused by tumour overproduction of insulin-like growth factor 2 (IGF-2) or its precursor forms (pro-IGF-2), which bind to IGF receptors and insulin receptors. Patients with IGF-2-mediated hypoglycemia present fasting hypoglycemia characterized by suppressed endogenous insulin, ketones, growth hormone, and IGF-1.

Case presentation: A 49-year-old woman developed diplopia and headache during the third month of pregnancy, followed by progressive left-sided ptosis, ophthalmoplegia, and tongue deviation. Brain MRI revealed a large, well-demarcated lobulated mass (maximum diameter 6.8 cm) located at the left skull base, in the area of petrous apex and trigeminal ganglion, in contact with the optic chiasm, causing stalk deviation. The patient underwent an uneventful caesarean section but five days postpartum, was admitted in the emergency ward in hypoglycemic coma. Her medical history included Roux-en-Y gastric bypass surgery, epileptic seizures 20 years earlier and primary hypothyroidism. She had a brother with glycogen storage disease type 1a but the rest of her family history was not notable. Laboratory evaluation during spontaneous hypoglycaemia demonstrated low plasma glucose with suppressed insulin and C-peptide levels, adequate cortisol response and low IGF-1 concentrations. Her lipid profile was normal. Hypoglycemia occurred predominantly in the fasting state. The patient underwent subtotal surgical resection of the lesion. Histopathology revealed chondrosarcoma, grade 1 (Ki-67 $\leq$2%). One month postoperatively, biochemical evaluation showed an elevated IGF-2/IGF-1 ratio (>10), supporting the diagnosis of IGF-2–mediated hypoglycemia. Immunohistochemical staining for IGF-2 was negative. A brain MRI 3 months after surgery demonstrated a residual tumor of 4.5 cm. Due to persistent hypoglycemic episodes, glucocorticoid therapy was initiated, resulting in clinical improvement. The patient subsequently was scheduled for adjuvant radiotherapy.

Conclusions: IGF-2–mediated hypoglycemia is a rare but important cause of fasting hypoglycemia in patients with large mesenchymal tumours. A high IGF-2/IGF-1 ratio is a key diagnostic marker. Definitive treatment relies on management of the underlying malignancy, while glucocorticoids represent an effective therapeutic

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

option when complete tumour resection is not feasible. To our knowledge, this is the first reported case of IGF-2–mediated hypoglycemia associated with skull base chondrosarcoma.

Table 1 Laboratory workup of hypoglycemia.

Glucose (mg/dL)	52
Insulin (μU/mL)	<2
C- peptide (ng/mL)	0.17
Insulin Auto-Abs (U/mL)	0.04

EP521 - ECE_3243 - β-Arrestin 2 deficiency attenuates hyperglycemia but exacerbates systemic and neuroinflammation in streptozotocin-induced diabetes

Anna Volkova[1,2,3], Anastasiia Gladkova[3] and Kseniya Vysotskaya[1]
[1]*Endocrinology Research Centre, Moscow, Russia;* [2]*Pirogov Russian National Research Medical University, Moscow, Russia;* [3]*Lomonosov Moscow State University, Moscow, Russia*

Diabetes mellitus (DM) is a major global health challenge of the 21st century, characterized by a steadily increasing prevalence and a high burden of complications. Elucidating the molecular mechanisms underlying DM pathogenesis is essential for the development of novel therapeutic strategies. Among emerging regulatory proteins, β-arrestin 2 has attracted considerable interest as a multifunctional modulator of GPCR signaling. β-Arrestin 2 enhances insulin secretion, regulates p38 MAPK–dependent glucose metabolism, and exerts anti-inflammatory effects by inhibiting NLRP3 inflammasome assembly and suppressing pro-inflammatory cytokine production.

This study investigated the impact of β-arrestin 2 deficiency on metabolic parameters and inflammatory responses in a murine model of type 1 diabetes.

Experiments were performed on male C57BL/6J mice and a genetically related β-arrestin 2 knockout strain (Arrb2$^{-/-}$). Animals were randomly assigned to four groups: wild-type control (WT), knockout control (KO), and diabetic groups of both genotypes (WTd and KOd). Diabetes was induced by intraperitoneal administration of streptozotocin (55 mg/kg) for five consecutive days. Blood glucose levels, body weight, and circulating neutrophil proportions were monitored longitudinally. Systemic inflammation was additionally assessed by measuring plasma nitric oxide metabolites. Neuroinflammation was evaluated by real-time PCR analysis of mRNA expression of IL-6, IL-1β, TNF-α, and protease-activated receptors PAR1 and PAR4 in the cerebral cortex and hippocampus.

Streptozotocin administration induced persistent hyperglycemia in both genotypes; however, the onset and severity of hyperglycemia were significantly attenuated in KOd mice compared with WTd controls. Despite this milder metabolic phenotype, Arrb2$^{-/-}$ mice exhibited a pronounced pro-inflammatory profile. Systemically, KOd mice displayed a significantly increased proportion of circulating neutrophils. Plasma nitric oxide levels were elevated in both KO and KOd mice relative to wild-type animals. In the central nervous system, Arrb2$^{-/-}$ mice demonstrated increased expression of IL-6, IL-1β, TNF-α, PAR1, and PAR4 mRNA in the cortex and hippocampus under basal conditions, with further amplification of this inflammatory signature in diabetic knockout mice.

These findings demonstrate a dual role of β-arrestin 2 in diabetes, combining modulation of glucose dysregulation with a critical anti-inflammatory function, particularly within neuroimmune pathways. β-Arrestin 2 may represent a promising therapeutic target for reducing inflammation-associated endocrine and neurological complications of diabetes.

EP523 - ECE_3833 - A case of diabetes mellitus secondary to dorsal pancreatic agenesis

Gayathri Bhaskaran[1], Rishi Iyer[1], Eleni Armeni[1], Sarah Ali[1] and Martin Dumskyj[1]
[1]*Diabetes and Endocrinology, Royal Free Hospital, London, United Kingdom*

Introduction: Dorsal pancreatic agenesis is a rare congenital anomaly characterized by the absence of the pancreatic body and tail, potentially leading to diabetes mellitus due to reduced beta-cell mass. This case report discusses diabetes mellitus secondary to dorsal pancreatic agenesis, highlighting diagnostic considerations.

Case Presentation: A 39-year-old male was referred to the diabetes clinic with HbA1c 81 mmol/mol. He was diagnosed with type 1 diabetes mellitus four years previously after presenting with a viral illness and hyperglycaemic ketosis, and was being managed on a basal bolus regime. An incidental CT scan for abdominal pain and haematuria revealed absence of the pancreatic body and tail, consistent with dorsal pancreatic agenesis. Diabetes autoantibodies were negative. The C-peptide was 263 pmol/L when blood glucose was 10.9 mmol/L, indicating limited residual insulin production. Other tests showed raised cholesterol, total 8.2 mmol/L, LDL 6.5 mmol/L (normal triglycerides) and transient polycythaemia (haemoglobin 192 g/L, haematocrit 0.5447 L/L), with negative genetic testing for haematological mutations, suggesting polycythaemia was probably due to chronic hyperglycaemia. Thyroid function, testosterone and renal function were normal. There was no history of alcohol use or other history to suggest pancreatitis. Imaging identified renal cysts. The patient's father had type 2 diabetes diagnosed in his 50s/60s, and nil else significant family history. MODY4 was also considered as a differential.

Management: The patient was counselled on consistent insulin administration and referred to a diabetes specialist dietitian for carbohydrate counting and insulin dose adjustment. An MRCP and faecal elastase test were arranged to evaluate the pancreas further, with plans for genetic testing for dorsal pancreatic agenesis.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Discussion: Dorsal pancreatic agenesis, with fewer than 100 reported cases, is linked to diabetes due to reduced beta-cell mass and may be associated with pancreatitis, renal, and cardiac anomalies. Negative diabetes autoantibodies in this patient support dorsal pancreatic agenesis as the cause of his diabetes. This case highlights the importance of considering unusual aetiologies of diabetes even in typical presentations.

EP525 - ECE_2601 - Real-world glycemic outcomes in pediatric type 1 diabetes after automated insulin delivery initiation

Beatriz Tavares Da Silva, Joana Queirós, João Oliveira, Catarina Figueiredo, Catarina Mendes, Joana Freitas, Maria João Oliveira, Carla Rocha, Maria José Ramos and Teresa Borges

Unidade Local de Saúde de Santo António, Porto, Portugal

Background: Automated insulin delivery (AID) systems are increasingly used in the management of type 1 diabetes mellitus (T1DM) and are fully funded for eligible patients in Portugal. We aimed to assess longitudinal changes in glycemic control following AID initiation in a pediatric T1DM cohort.

Methods: Retrospective longitudinal study of children and adolescents with T1DM using AID for at least 3 months. Data were collected at baseline and during follow-up (median follow-up: 11.8 months; range 3.0-52.4). International consensus targets were evaluated: HbA1c <6.5% for advanced technology users (ISPAD 2024), Time In Range (TIR 70-180 mg/dL) ≥70% and Time Below Range (TBR <70 mg/dL <4%) when available.

Results: Of 200 patients assessed, 157 were included (51.6% female; median age at diagnosis: 5.78 years). Median HbA1c decreased significantly from 7.5% at baseline to 6.8% at 3 months ($P < .001$) and remained stable at 12 months (median 6.7%; paired $n = 26$). Regarding the stringent ≤ 6.5% target, attainment increased nearly fourfold, from 12.1% (19/157) at baseline to 42.3% (11/26) at 12 months. The proportion of patients achieving the standard HbA1c < 7.0% goal rose from 27.4% to 84.6% at one year. Regarding CGM metrics, median TIR increased from 60% to 70% at 12 months ($P < .001$), with 51.7% of participants achieving the ≥ 70% target. Low exposure to hypoglycemia was maintained, with Time Below Range remaining <4% throughout follow-up. Safety was further demonstrated by the low incidence of acute complications: 3 episodes of moderate diabetic ketoacidosis and one episode of severe hypoglycemia (with loss of consciousness) were recorded during the observation period.

Conclusions: In this real-world pediatric T1DM cohort, AID initiation was associated with rapid and sustained improvements in glycemic control. Notably, the use of these systems allowed a substantial proportion of patients to reach the optimized HbA1c ≤ 6.5% goal without increasing hypoglycemia, supporting the effectiveness of AID in achieving the most recent clinical targets in pediatric T1DM.

EP526 - ECE_3731 - CAPTAIN-T2D: A Bayesian Response-Adaptive Randomization (RAR) Dose Range-Finding (DRF) Trial of Clofutriben (CLO) as add-on treatment in patients with Type 2 Diabetes (T2D) and Elevated Cortisol (EC)

Frank Czerwiec[1], Lindsay Berry[2], Nathan James[2], Jennifer Smith[3], Karisse Roman-Torres[4], Guohua An[5], Todd Berner[1], Sarah Hooper[1], Dora Ferrari[1], Vivian Fonseca[6], John Buse[7] and David A. Katz[1]

[1]Sparrow Pharmaceuticals, Portland, United States; [2]Berry Consultants, LLC., Austin, United States; [3]Smith Biostatistics, LLC., Menlo Park, United States; [4]CIAS Corp, Seattle, United States; [5]University of Iowa, Iowa City, United States; [6]Tulane University School of Medicine, New Orleans, United States; [7]University of North Carolina, Chapel Hill, United States

Introduction: Many patients with T2D who exhaust typical treatment options also have EC, which impedes achieving glycemic control. CLO, a selective 11β-hydroxysteroid dehydrogenase type 1 inhibitor that reduces intracellular cortisol, was associated with improved HbA_{1c} and fasting glucose in a prior diabetes clinical trial. This Phase 2 trial in patients with T2D and EC will evaluate the dose-response relationship of CLO and identify the dose(s) suitable for Phase 3 evaluation.

Methods: CAPTAIN-T2D is a double-blind, placebo-controlled, RAR DRF trial. Adults with T2D, HbA_{1c} ≥7.5%, treated with ≥2 antidiabetic medications (ADMs), and with ≥1 EC risk factor (eg, ≥3 ADMs, diabetic complication, hypertension requiring ≥2 antihypertensive medications) will undergo an overnight dexamethasone suppression test (DST). Those with post-DST cortisol >1.8 and ≤5.0 mcg/dL will be screened further for eligibility, including by pre-enrolment in-clinic and at-home monitoring for risk of hypoglycemia or hypotension. Neoplastic etiologies of EC will be screened for using medical history, exam, repeated DST cortisol >5.0 mcg/dL, and adrenal imaging to guide therapy decisions; participants with repeated DST cortisol >5.0 mcg/dL may be eligible with further evaluation. Up to 210 participants will receive oral CLO (no titration) or placebo QD for 24 weeks. The first 60 will be randomized equally to placebo and 4 CLO doses. Thereafter, a RAR algorithm will adjust dose allocations at pre-planned enrolment intervals based on the posterior probability that each dose has ≥90% maximum effect (ED_{90}) on HbA_{1c} at Week 24 or is the minimal effective dose. The algorithm will stop enrolment if a dose has >80% probability of being the ED_{90}. Safety will be reviewed regularly by an independent safety committee.

Outcomes: The prevalence of EC in the screened population and safety will be reported. The primary analysis will be a Bayesian hierarchical E_{max} model for dose-response relationship on change in HbA_{1c} at Weeks 4, 12, and 24. A supportive analysis will be a mixed model for repeated measures (MMRM) of HbA_{1c} change from baseline. Changes in other glycemic, lipid,

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

anthropometric, and BP measures will be estimated using MMRM.

Conclusions: CAPTAIN-T2D aims to define the dose-response relationship and therapeutic potential of CLO in patients with T2D and EC. By reducing excess intracellular cortisol that exacerbates T2D without impairing the HPA axis, adrenal cortisol synthesis, or its interaction with the glucocorticoid receptor, CLO might provide a targeted therapeutic option for patients with difficult-to-control T2D and EC that avoids complex monitoring or dose modifications.

EP527 - ECE_3785 - Associations between sleep quality, weight, and body composition among patients with type 2 diabetes

Solomiia Shykula and Alina Urbanovych
Danylo Halytsky Lviv National Medical University, Lviv, Ukraine

As the prevalence of diabetes and obesity continues to rise, it is crucial to find new ways of preventing and treating metabolic diseases. Disturbances in sleep patterns may be a significant risk factor for both diabetes and obesity. The purpose of this study was to determine the relationships among sleep quality, weight, and body composition in patients with type 2 diabetes.**Methods:** The study sample of 77 participants, whose ages ranged from 32 to 69 years (M = 54.3, SD = 8.27). Among the participants, 41 (53%) identified as female. The average HbA1c level was 9.28 ± 2.14%. The duration of diabetes was 7[5; 10.25] years. All patients have confirmed diabetes mellitus type 2 and were screened for sleep disorders with the Pittsburgh Sleep Quality Index (PSQI) questionnaire. Body composition was evaluated through bioelectrical impedance analysis. Statistical analysis was conducted using Microsoft Office Excel.

Results: The study revealed a correlation between sleep quality and both weight (r = 0.15) and body mass index (r = 0.25). Additionally, a negative correlation was found between sleep quality and muscle mass (r = −0.24). Furthermore, a correlation was observed between sleep quality and bone mass (r = −0.23). No other significant correlations were identified.

Conclusions: Sleep quality influences diabetes and obesity; however, further research is needed to fully understand the direction of the relationship between these factors.

EP529 - ECE_2402 - COVID-19 in pediatric patients and the risk of type 1 diabetes mellitus: a systematic review and meta-analysis

Lara Alves Tavares[1], Alexandre Rossini Murakami[2], Ana Paranzini Miguita[1], Bruno Hidalgo Molina[1], Melissa Pistori Floriano Gerardi[1] and Paulo Bignardi[1]
[1]*Pontifícia Universidade Católica do Paraná, Londrina, Brazil;* [2]*Universidade Estadual de Londrina, Londrina, Brazil*

Background: SARS-CoV-2 infects host cells via the angiotensin-converting enzyme 2 (ACE2) receptor, expressed in pancreatic endocrine tissue. Evidence suggests the virus may infect β-cells, inducing dysfunction, apoptosis, and inflammatory responses. In susceptible individuals, this may accelerate autoimmune β-cell destruction via $CD8^+$ T-cell–mediated mechanisms. While increased pediatric new-onset type 1 diabetes mellitus (T1DM) has been reported during the pandemic, findings remain conflicting.

Objective: To quantify the risk of new-onset T1DM following laboratory-confirmed SARS-CoV-2 infection in children and adolescents.

Methods: This systematic review and meta-analysis followed Cochrane and PRISMA 2020 guidelines. The protocol was registered on PROSPERO (CRD420261278565). Searches were conducted in MEDLINE/PubMed, Embase, Scopus, LILACS, and medRxiv for studies from 2020 onward. Eligible studies included patients aged 0-18 years with laboratory-confirmed SARS-CoV-2 infection (RT-PCR, antigen, or serology) compared with controls, reporting incident T1DM diagnosed by international criteria. Two reviewers performed study selection and data extraction independently. Pooled relative risks (RR) were calculated using a random-effects model (DerSimonian–Laird). Heterogeneity was assessed via I^2 statistic. Sensitivity and publication bias analyses were performed.

Results: A total of 10 studies were included, involving over 20 million pediatric patients. Prior SARS-CoV-2 infection was associated with a significantly increased risk of new-onset T1DM compared with unexposed controls (pooled RR = 1.61; 95% CI: 1.22-2.00). Substantial heterogeneity was observed (I^2 = 75%). Sensitivity analyses (leave-one-out) confirmed the robustness of the estimate. No evidence of small-study effects or publication bias was identified (Egger's test: z = 1.28; P = .20).

Conclusions: SARS-CoV-2 infection is associated with an increased risk of new-onset T1DM in children and adolescents. Despite substantial heterogeneity, the association remained consistent across sensitivity analyses. These findings support enhanced metabolic surveillance following pediatric COVID-19 and underscore the need for further high-quality studies to clarify underlying immunopathological mechanisms.

EP530 - ECE_1725 - Predictors of sarcopenic obesity in patients with diabetes mellitus

Elena Makhlina[1], Yana Navmenova[2] and Tatiana Mokhort[3]
[1]*Educational Institution "Gomel State Medical University", Gomel, Belarus;* [2]*Research Center for Radiation Medicine and Human Ecology, Research Center For Radiation Medicine And Human Ecology, Endocrinology, Gomel, Belarus;* [3]*Endocrinology, Educational Institution "Belarusian State Medical University", Minsk, Belarus*

Objective: To evaluate predictors of sarcopenic obesity (SO) in patients with diabetes mellitus (DM).

Materials and Methods: The study included 92 patients (45 men and 47 women) with DM. The average age of the patients was 55.90 ± 14.18 years, and the duration of DM was 16.80 ± 9.34 years. Muscle strength (MS) was assessed using handgrip dynamometry, which measures arm strength. Muscle function (MF) was assessed using the 4-meter walking speed test. Muscle mass (MM) and fat mass (FM) were estimated using dual-energy X-ray absorptiometry (DXA) (lunAR prodigy) as the ratio of

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

appendicular muscle mass (AMM) to weight (AMM/weight) and FM to height squared (FM/m2). Anthropometric parameters included body mass index (BMI), waist circumference (WC), and waist-to-height ratio (WC/height) and calculated MS/weight, MS/BMI, MS/WC/height ratios. Statistical analysis was performed using Statistica 10.0.

Results: Correlation analysis revealed a significant relationship between MS/ BMI and FM/m^2 (rs = −0.70; $P < .05$), AMM/weight (rs = 0.70; $P < .05$) and MF (rs = 0.51; $P < .05$). A significant relationship between MS/weight and FM/m2 (rs = −0.71; $P < .05$), AMM/weight (rs = 0.70; $P < .05$), MF (rs = 0.51; $P < .05$). A significant relationship between MS/WC/height and FM/m2 (rs = −0.76; $P < .05$), AMM/weight (rs = 0.69; $P < .05$), MF (rs = 0.57; $P < .05$). Using the ROC analysis, the cutoff value of MS/WC/height corresponding to SO was less than 39.54 kg/cm/cm (AUS 0.826; $P < .001$; sensitivity 100.00% [95% CI 71.5;100.0], specificity 61.76% [95% CI 43.6;77.8], Youden index 0.61; $P = .001$). The cutoff value of MS/BMI for diagnosing SO was less than 0.690 kg/kg/m^2 (AUS 0.844; $P < .001$; sensitivity 100.00% [95% CI 71.5; 100.0], specificity 68.57% [95% CI 50.7;83.1], Youden index 0.68; $P = .001$). The MS/weight cutoff value corresponding to SO was less than 0.214 kg/kg (AUS 0.852; $P < .001$; sensitivity 100.00% [95% CI 75.1; 100.0], specificity 77.14% [95% CI 59.9; 89.6], Youden Index 0.77; $P = .001$).

Conclusions: We propose using MS/WC/height, MS/BMI, or MS/weight as predictors of SO, as a strong correlation between these parameters and MF, MM, and FM has been demonstrated. A MS/weight cutoff value of <0.214 kg/kg is the most sensitive and specific predictor of SO in patients with DM.

EP531 - ECE_1992 - Subclinical HFpEF in diabetes: the role of NT-proBNP, BMI and inflammatory activation

Anastasiia Sokolova[1,2]
[1]*Diabetology, Institute of Endocrinology and Metabolism of the National Academy of Medical Sciences of Ukraine, Kyiv, Ukraine;* [2]*Institute of Endocrinology and Metabolism of the National Academy of Medical Sciences of Ukraine, Kyiv, Ukraine*

Background: Heart failure with preserved ejection fraction (HFpEF) is the most prevalent heart failure phenotype in patients with type 2 diabetes mellitus (T2DM) and is increasingly considered an immune-metabolic disorder driven by obesity, chronic low-grade inflammation, and metabolic stress. Subclinical HFpEF frequently remains unrecognized due to preserved left ventricular ejection fraction and absence of overt symptoms. Identification of early biomarkers reflecting myocardial stress and inflammatory activation is essential for timely risk stratification. NT-proBNP is a well-established marker of heart failure; however, its role in detecting subclinical HFpEF and its association with inflammatory pathways in T2DM remains insufficiently characterized.

Aim: To evaluate the associations between NT-proBNP levels, body mass index (BMI), and IL-17A–mediated inflammatory activation in patients with T2DM without clinically overt heart failure.

Methods: This cross-sectional observational study included 57 patients with type 2 diabetes mellitus and preserved left ventricular ejection fraction, without clinical signs or history of heart failure. All participants underwent comprehensive clinical and anthropometric assessment. Laboratory evaluation included measurement of serum NT-proBNP and IL-17A concentrations using standardized immunoassays. Transthoracic echocardiography was performed with a focus on left ventricular systolic and diastolic function. Patients were stratified according to NT-proBNP levels. Associations between NT-proBNP, BMI, inflammatory markers, and echocardiographic parameters were analyzed using correlation and comparative statistical methods.

Results: Elevated NT-proBNP levels were identified in 78% of patients with T2DM despite preserved ejection fraction and absence of overt heart failure. Patients with elevated NT-proBNP demonstrated a significantly higher BMI compared with those with normal NT-proBNP values (30.1 vs 27.2 kg/m^2), indicating a greater burden of adiposity. NT-proBNP concentrations showed a positive association with IL-17A levels, suggesting a link between myocardial stress and Th17-related inflammatory activation. In addition, higher NT-proBNP levels were associated with echocardiographic features consistent with early diastolic dysfunction, while left ventricular ejection fraction remained within the preserved range across the cohort.

Conclusions: Subclinical HFpEF is highly prevalent among patients with type 2 diabetes mellitus and is characterized by elevated NT-proBNP levels in the absence of clinical heart failure. The associations of NT-proBNP with increased BMI and IL-17A-driven inflammatory activation support the concept of HFpEF as an immune-metabolic disorder in T2DM. Combined assessment of NT-proBNP, adiposity, and inflammatory biomarkers may improve early identification of patients at risk for HFpEF and inform preventive strategies in diabetes management.

EP535 - ECE_3274 - Clinical profile of severe hypoglycaemia in adults with type 1 diabetes: real-world data from emergency care

Aida Elhadri-Egea, Víctor Siles-Guerrero, Rosa Natalia García Pérez and Martín López de la Torre-Casares
Hospital Universitario Virgen de las Nieves, Granada, Spain

Introduction: Severe hypoglycaemia remains a major complication in type 1 diabetes mellitus (T1DM) and continues to be associated with significant clinical consequences, including emergency care utilisation and impaired quality of life. This persists despite advances in diabetes education, glucose monitoring technologies, and insulin delivery systems. Real-world descriptive data are essential to better characterise patients presenting with severe hypoglycaemia and to identify common clinical features associated with persistent vulnerability.

Objective: To describe the clinical characteristics of adults with T1DM requiring emergency care for severe hypoglycaemia in a real-world setting.

Methods: A retrospective, observational, descriptive study was conducted including 66 adult patients with T1DM who required pre-hospital emergency assistance for severe hypoglycaemia between 2018 and 2022 in a tertiary hospital. Collected variables included demographic data, diabetes-related characteristics, history of severe hypoglycaemia, hypoglycaemia awareness

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

status, nocturnal occurrence of events, and recurrence after the index episode during follow-up. Data were analysed using descriptive statistics.

Results: The median age of the cohort was 42.5 years, and 65.2% of patients were male. A history of previous severe hypoglycaemia was documented in 54.5% of cases, indicating frequent prior exposure to severe events. Hypoglycaemia unawareness was reported in 43.9%, reflecting impaired recognition of early symptoms. Nocturnal hypoglycaemia was experienced by 53.0% of patients, highlighting the relevance of events occurring during periods of reduced monitoring. Following the index episode, 22.7% of patients presented at least one new severe hypoglycaemic event requiring emergency intervention during follow-up. These clinical features tended to cluster in patients with long-standing T1DM, suggesting a persistent vulnerability profile rather than isolated episodes.

Conclusions: n this cohort of 66 adults with T1DM, severe hypoglycaemia frequently occurred in the context of prior severe episodes, impaired hypoglycaemia awareness, and nocturnal occurrence, with a substantial proportion of patients experiencing recurrence after the index event. These real-world descriptive findings underscore the importance of focused post-event clinical reassessment following severe hypoglycaemia, with particular attention to awareness status and nocturnal risk, to reduce recurrent emergency episodes.

EP542 - ECE_1523 - Clinical and immunological profile of latent autoimmune diabetes in youth

Nataliia Pashkovska and Iryna Tsaryk
Bukovinian State Medical University, Chernivtsi, Ukraine

Background: Latent autoimmune diabetes in youth (LADY) is underdiagnosed form of autoimmune diabetes mellitus (DM) that combines features of type 1 (T1DM) and type 2 (T2DM) diabetes. In contrast to classical T1DM, LADY is characterized by a slowly progressive autoimmune destruction of pancreatic β-cells, leading to a gradual loss of insulin secretion, and usually manifests before the age of 30 years.

The objective: of the study was to determine the clinical and immunological characteristics of patients with LADY compared with LADA and classical T1DM.

Methods: Under our observation were 106 patients with autoimmune diabetes, who were divided into three clinical groups according to the phenotype of the disease: 40 (37.7%) had classical T1DM, 36 (34%)—LADA, 30 (28.3%)—LADY. We study complaints, history, objective examination data, laboratory tests (blood glucose and glycated hemoglobin, C-peptide, levels of antiGAD and IA-2 ab). The diagnosis of LADY was established based on a comprehensive assessment of clinical, laboratory and immunological data.

Results: Patients with LADY had a mean age of onset of 20 years, as like as classical T1DM patients, mild hyperglycemia, no ketoacidosis at diagnosis, and a high frequency of positive autoantibodies (GAD65 in almost all, IA-2 in half). The level of C-peptide in patients with LADY was 0.62 [0.29; 0.82] (ng/mL)—more than 6 times higher compared to classical T1DM ($P = .000$), indicating slower destruction of β-cells, but almost the same like in LADA group without intergroup difference. Compared to patients with LADA, patients with LADY had a younger age of onset, lower BMI, more often a multiple positive antibody profile and progressed more quickly to insulin dependence. Most patients with LADY had normal weight and no pronounced insulin resistance. Approximately a quarter of patients with LADY were initially misdiagnosed with T2DM due to the similarity of clinical manifestations. Further laboratory examination allowed to clarify the diagnosis. Treatment at the initial stage was mainly based on oral therapy (mainly metformin) with a gradual transition to insulin therapy in case of worsening control and a decrease in C-peptide. Patients who were immediately diagnosed with T1DM began basal-bolus insulin therapy with low daily doses of insulin, which was sometimes accompanied by hypoglycemia and weight gain.

Conclusions: LADY is a separate clinical and immunological variant of autoimmune DM with a young age of onset, preserved β-cell function, a high frequency of autoantibodies and rapid progression to insulin dependence, which requires early comprehensive examination and individualized treatment.

EP544 - ECE_1466 - Ten-year change in insulin injection technique knowledge and self-reported practices after the "Diabetes school" educational program implementation in Armenia: repeated cross-sectional survey

Karineh Sharian[1,2,3], Meri Danielyan[1], Gayane Bayburdyan[1], Lusine Arakelyan[1], Arthur Melkonyan[1], Naira Zohrabyan[1], Sona Hakobyan[1], Irina Muradyan[1], Shogher Grigoryan[1], Vrej Issa[1] and Yelena Aghajanova[1]
[1]Yerevan State Medical University after M. Heratsi, Endocrinology Clinic of "Muratsan" University Hospital Complex, Yerevan, Armenia; [2]American University of Armenia, Turpanjian College of Health Sciences, Yerevan, Armenia; [3]Noncommunicable Diseases, National Center for Disease Control and Prevention, Yerevan, Armenia

Background: Correct insulin injection technique is essential for safe and effective diabetes care. Armenia scaled up structured diabetes education ("Diabetes school"), but long-term changes in patients' injection-technique knowledge and related practices have not been described.

Methods: We conducted a repeated cross-sectional study comparing two independent samples of insulin-treated people with type 1 and type 2 diabetes surveyed in 2015 (paper) and 2025 (paper and electronic). Patients were recruited at Endocrinology Clinic of "Muratsan" university hospital complex in Yerevan; 2015's participants were enrolled during routine visits from January to July 2015 and were trained in insulin therapy techniques by a nurse, while the 2025 sample included patients who had previously attended the "Diabetes school". A questionnaire (based on existing injection-technique tools) captured demographics, self-reported practices, and knowledge; evidence-based responses were scored as 1 to generate a total knowledge score. Group comparisons and multivariable linear regression (gender, age, diabetes type, HbA1c, insulin therapy duration) were used.

Results: Valid total score data were available for 199 participants (2015) and 198 participants (2025). Mean total score (calculated from the score distributions) increased from 12.9 (SD 2.5) in

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

2015 to 15.0 (SD 2.4) in 2025 (mean difference 2.15 points). Marked improvements were observed in key safety-related practices: holding the needle for at least 10 seconds rose from 28.6% (2015) to 66.2% (2025), while "immediate" needle removal fell from 38.7% to 0.5%. Mixing different insulin types in one syringe decreased from 54.3% to 0.5%. Syringe/needle disposal in a special container increased from 8.6% to 38.6%. The proportion reporting shaking long-acting insulin decreased from 88.3% to 28.1%. In 2025 regression, higher scores were associated with older age (B 0.755, $P = .043$) and were lower in type 2 vs type 1 diabetes (B −1.977, $P < .001$) and with longer insulin-therapy duration (B −0.362, $P = .021$); in 2015 predictors were not statistically significant.

Conclusions: Across a decade, insulin injection technique knowledge and several high-impact self-reported practices improved substantially in Armenia. Remaining gaps (safe disposal and other technique elements) support continued reinforcement within diabetes education, with attention to groups at risk of lower knowledge (type 2 diabetes and longer insulin exposure). Education in diabetes school remains the main method of informing patients about the correct technique of insulin therapy.

EP545 - ECE_2695 - Development of personalized postprandial glucose prediction models using machine learning: integrating clinical, metabolic, and nutritional variables

Doohwa Kim[1,2,3], Hajin Park[1,2], Kyeongjun Lee[4], Jinmi Kim[2,5] and Sang Soo Kim[1,2,3]

[1]Division of Endocrinology and Metabolism, Pusan National University Hospital, Busan, South Korea; [2]Biomedical Research Institute, Pusan National University Hospital, Busan, South Korea; [3]Department of Internal Medicine, Pusan National University School of Medicine, Yangsan, South Korea; [4]Department of Mathematics and Big Data Science, Kumoh National Institute of Technology, Gumi, South Korea; [5]Department of Biostatistics, Clinical Trial Center, Biomedical Research Institute, Pusan National University Hospital, Busan, South Korea

Background & Objectives: Personalized dietary management is crucial for preventing and managing metabolic disorders, including diabetes. Individual glycemic responses to food vary greatly, despite the existence of basic dietary guidelines. This study aimed to develop and validate machine learning (ML) models to predict personalized postprandial glucose responses (PPGR), specifically focusing on the incremental Area Under the Curve (iAUC), peak glucose (Peak), and glucose slope (Slope) after meals.

Methods: We analyzed 5361 meal records from 274 subjects collected at Pusan National University Hospital. The dataset integrated 3 categories of features: 14 clinical variables, 8 nutritional variables, and 17 glucose metabolism variables (derived from CGM and insulin assays, eg, disposition index). Additionally, 30 derived variables were generated to account for nutrient ratios, interactions, and glucose-mitigating factors. Four ML algorithms—Random Forest, XGBoost (XGB), LightGBM (LGB), and CatBoost—were employed, with hyperparameter tuning performed using FLAML. Model performance was evaluated using 5-fold cross-validation on an 80/20 train-test split. We also compared models with and without glucose metabolism variables.

Results: In our evaluation, LGB and XGB consistently emerged as the top-performing models, showing not only superior predictive accuracy but also high stability across all target variables. Our analysis demonstrated distinct determinants for each PPGR metric. For iAUC and Peak prediction, factors such as meal start time, carbohydrate intake, and the fiber-to-carbohydrate ratio were identified as primary predictors. The oral disposition index (oDI) and postprandial glucose at 30 minutes (oglu30) showed high feature importance among metabolic variables. Interestingly, lipid-related variables acted mainly as secondary mitigating factors. For the slope prediction, carbohydrate-fiber interactions and HbA1c were dominant drivers. When we excluded metabolic variables to reflect a more practical, non-invasive clinical setting, basic clinical features such as fasting glucose and HDL-cholesterol showed increased importance, though predictive accuracy was slightly lower. In addition, using an ensemble approach that integrates multiple models resulted in a notable improvement in recall compared to using a single model.

Conclusions: This study shows that machine learning models can effectively predict key aspects of postprandial glycemic response by using detailed nutritional and clinical information. We found that while carbohydrate and fiber dynamics alongside meal timing are universally critical, the inclusion of specific glucose metabolism markers significantly enhances prediction precision. Our ensemble modeling provided a strong basis for developing personalized precision nutrition platforms.

EP546 - ECE_1252 - Mechanistic pathways linking maternal diabetes to offspring obesity and metabolic syndrome: quantitative synthesis of impact

Fawziya Alyafei, Ashraf Soliman, Ahmed Elawwa, Noora Alhemaidi, Nada Alaaraj, Noor Hamed and Shayma Ahmed

Hamad Medical Center, Pediatric Endocrinology, Doha, Qatar

Background: Children born to mothers with diabetes—both gestational and pregestational—are at increased risk for obesity and metabolic syndrome later in life. This association is mediated by a complex interplay of prenatal and postnatal mechanisms, which have been increasingly elucidated through clinical and experimental research. Understanding the relative impact of each mechanism is critical for early identification and risk stratification of vulnerable offspring.

Objective: To systematically evaluate and quantify the mechanisms by which maternal diabetes predisposes offspring to obesity and metabolic syndrome, and to determine their relative contributions based on published data.

Methods: A comprehensive review was conducted of 40 studies published between 2000 and 2024 that addressed the biological and developmental mechanisms linking maternal diabetes to obesity and metabolic disorders in offspring. Mechanisms were grouped into five main categories: fetal programming via hyperglycemia and insulin exposure, altered adipose tissue development, endocrine and hormonal alterations, epigenetic

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

imprinting, and postnatal influences including feeding behavior and microbiome changes. Quantitative synthesis and impact estimates were derived by pooling reported effect sizes or proportions across studies.

Results: Among the five categories of mechanisms identified, fetal programming emerged as the most impactful, accounting for approximately 30% of the total mechanistic contribution. This includes intrauterine hyperglycemia leading to beta-cell hyperplasia, hyperinsulinemia, and permanent alterations in energy regulation. Altered adipose tissue development contributed an estimated 25%, associated with increased fetal adiposity and adipocyte hyperplasia. Hormonal disruptions—including impaired leptin and adiponectin signaling—were responsible for approximately 20% of the effect, followed by epigenetic mechanisms such as DNA methylation of metabolic genes (15%). Postnatal factors, including altered infant feeding patterns, taste preferences, and gut microbiome dysbiosis, were estimated to contribute 10% to the total impact. These proportions reflect data synthesized from observational birth cohort studies, epigenomic analyses, and animal models.

Conclusions: The predisposition to obesity and metabolic syndrome in offspring of diabetic mothers arises from a multifactorial process rooted in both prenatal and postnatal exposures. Quantitative analysis reveals that fetal programming and adipose tissue development are the predominant mechanisms, but endocrine, epigenetic, and environmental factors also play significant roles. These findings underscore the need for mechanistic-based risk assessments in clinical practice to guide early interventions in at-risk children

Abstract citation ID: lvag096.1015

EP550 - ECE_3432 - Impact of nutritional status on bone mineral density in hospitalized patients with eating disorders

Rosa Natalia García Pérez, Víctor Siles-Guerrero, Aida Elhadri-Egea and Araceli Munoz-Garach
Hospital Universitario Virgen De Las Nieves, Granada, Spain

Introduction: Eating disorders (EDs), particularly anorexia nervosa, are associated with a significant impairment of bone health as a result of prolonged malnutrition and disease-related hormonal disturbances. This study evaluates the association between nutritional status, body composition parameters, and bone mineral density (BMD) in patients hospitalized for EDs.

Materials and Methods: A total of 12 women older than 16 years with severe EDs and a body mass index (BMI) ≤ 14 were included. All patients were admitted to the Eating Disorders Inpatient Unit of Virgen de las Nieves University Hospital between 2020 and 2024. Anthropometric, biochemical, body composition, and bone densitometry variables (Z-score) were collected. A descriptive and correlational statistical analysis was performed.

Results: Ninety-three percent of the patients presented some degree of bone alteration, including osteopenia or osteoporosis. Patients with lower BMD values showed reduced body cell mass (BCM), poorer nutritional index, and lower phase angle (PA) values, along with a higher degree of dehydration. Clinically relevant differences were observed between patients with osteopenia and those without bone disease in terms of BCM (17.6 ± 1.2 kg vs 19.9 ± 1.0 kg), fat mass (FM) (5.0 ± 2.1 kg vs 7.5 ± 0.8 kg), PA (4.6 ± 0.4 vs 4.8 ± 0.2), and skeletal muscle index (SMI) (6.3 ± 3.3 kg/m^2 vs 6.4 ± 1.2 kg/m^2). In densitometric assessment, lumbar spine Z-scores were -3.36 ± 0.79 in patients with osteoporosis, -1.83 ± 0.29 in those with osteopenia, and -0.3 ± 0.99 in patients without bone pathology. Clinically relevant correlations were identified between total body Z-score and SMI ($r = 0.89$), nutritional status ($r = 0.94$), and BCM ($r = 0.58$). Negative associations were also observed with body fat and hydration status. Although not all associations reached statistical significance, the observed patterns demonstrate clear clinical relevance for a multidisciplinary management approach.

Conclusions: Alterations in bone health are highly prevalent in patients with severe eating disorders. Variables such as muscle mass, hydration status, nutritional status, and body composition show clinically meaningful associations with bone mineral density. Early identification of these factors may be key to preventing bone deterioration in this patient population.

Abstract citation ID: lvag096.1016

EP551 - ECE_1112 - Amylin as a metabolic marker of latent autoimmune diabetes

Iryna Tsaryk[1] and Nataliia Pashkovska[2]
[1]*Bukovinian State Medical University, Chernivtsi, Ukraine;* [2]*Clinical Immunology, Allergology and Endocrinology, Bukovinian State Medical University, Chernivtsi, Ukraine*

Background: Amylin is thought to play a role in the development of diabetes mellitus (DM), hypertension, hyperlipidemia, and other problems in non-PCOS patients. If these findings can be extrapolated to women with PCOS, hyperamylinemia may contribute to their high risk for developing DM and its comorbidities.

The objective of the study was to determine the features of the level of amylinemia in fertile women with different types of DM.

Methods: A study of 60 patients was carried out as well as 15 individuals of control group. The patients were divided into four groups by the types of DM (15 patients in each group—classical T1DM, LADA, LADY, T2DM). The LADA group included patients with LADA1 and LADA2 phenotype (7 and 8 respectively). We study complaints, history, objective examination data, laboratory tests (blood glucose and glycated hemoglobin, C-peptide, antiGAD and serum amylin).

Results: In patients with classical T1DM the level of amylinemia did not change compared to control, whereas in T2DM it was 13.3 times significantly higher compared to the control and 7.6 times higher than in classical T1DM ($P < .05$). In LADA the amylin content was 8.6 times higher than in control and 4.9 times higher compared to classical T1DM ($P < .05$). In LADY group the amylin content was 5.3 times higher than in control and 3 times higher compared to classical T1DM, but 38% lower than in LADA patients ($P < .05$). In patients with LADA1, the serum level of amylin was 5.2 times higher relative to the control ($P < .01$), 3 times higher than in classical T1DM ($P < .05$), but 2.5 times as low as in T2DM ($P < .05$) and practically the same as in LADY group. In LADA2 the above indicator exceeded that in the control group by 12.8 times, in the group of classical T1DM—by 7.3 times, LADY—by 2.4 times, and in patients with LADA1—by 2.4 times ($P < .05$). In patients with LADY, an interdependence was found between the content

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

of amylin and insulin (r = 0.348; $P < .05$), HbA1c (r = 0.418; $P < .05$).

Conclusions: Serum amylin level significantly increase in fertile women with LADA (especially in LADA2), LADY and T2DM, which indicates the role of hyperamylinemia in the development and progression of this types of diabetes. Because amylin receptors are present in the ovarian tissue, amylin may play a role in ovarian dysfunction in PCOS. Future studies are needed to determine the role that amylin plays in metabolic abnormalities and ovarian dysfunction in PCOS.

Abstract citation ID: lvag096.1017

EP553 - ECE_2761 - Interaction between type 1 diabetes mellitus and gender-affirming hormone therapy: impact on glycemic control and clinical decision-making. A case series

Kevin David Díaz Gorrín, Selena Rodriguez Fernandez, Javier Panizo Fra, Paula Pérez, Elena Rodríguez Sosa, Patricia León González, Óliver Quintero Rodríguez, Itziar Aznar Ondoño, Juan Ignacio Márquez De La Rosa, Laura Mesa Suárez and Patricia Cabrera García
Endocrinology and Nutrition, Hospital Universitario de Canarias, San Cristóbal de La Laguna, Spain

Objectives: To analyze the interaction between type 1 diabetes mellitus (T1DM) and gender-affirming hormone therapy (GAHT), assessing its impact on glycemic control and on clinical decision-making related to GAHT, gender-affirming surgery, and therapeutic management of T1DM.

Material and Methods: Retrospective descriptive study of a case series of transgender individuals with T1DM followed in a specialized gender identity clinic. Five patients with longitudinal follow-up were included (four trans women and one trans man). Demographic and clinical variables, transition-related data, glycemic control parameters (HbA1c and basic continuous glucose monitoring metrics), and use of diabetes technology were collected. The temporal relationship between GAHT initiation, glycemic control, and clinical decision-making was analyzed using descriptive methods.

Results: Mean age was 28.4 years (range 19-41), with a mean age at T1DM diagnosis of 11.6 years. Four patients were receiving GAHT, initiated at a mean age of 19.8 years. Mean baseline HbA1c was 8.7%, increasing to 9.0% at 6 months and 8.9% at 12 months. T1DM did not influence the indication, initiation, or intensity of GAHT in any case. However, in two patients, gender-affirming surgery (vaginoplasty) was postponed due to the need for preoperative optimization of glycemic control. Only one patient was treated with continuous subcutaneous insulin infusion (CSII); this patient showed a clinically relevant improvement in glycemic control after pump initiation, with HbA1c decreasing from 8.2% to 6.1% at 6 months. In the remaining four cases, CSII was not initiated: in three patients due to poor treatment adherence and difficulties attending nursing follow-up (currently awaiting pump initiation), and in one patient due to adequate glycemic control without advanced technology. No systematic deterioration in glycemic control attributable to GAHT initiation was observed.

Conclusions: In this case series, T1DM did not represent a barrier to access to or intensity of GAHT. Glycemic control did influence the planning of gender-affirming surgery, requiring prior metabolic optimization in some cases. GAHT was not associated with a systematic worsening of glycemic control. The improvement observed in the single patient using insulin pump therapy suggests that access to diabetes technology, together with adequate adherence, may play a key role in metabolic control among transgender individuals with T1DM.

EP554 - ECE_3268 - Keeping an ear out for diabetes—to hear what is seen

Mukhopadhyay Babulayeb[1,2], Mari-Anne Scott[1] and Ross Cairns[1]
[1]*University Hospital Hairmyres, NHS Lanarkshire, Diabetes Clinic, Diabetes and Endocrinology, Glasgow, United Kingdom;* [2]*East Kilbride, Diabetes & Endocrinology, East Kilbride, United Kingdom*

The NHS Right Care Pathway for Diabetes outlines some key criteria for diagnostic uncertainty in patients with new onset diabetes. However there are no validated criteria for diagnosis of monogenic diabetes, although disease probability scoring systems are available. In the UK 90% patients with monogenic diabetes are mistakenly diagnosed with type 1 or type 2 diabetes at first.[1] We describe two young patients with a rare form of monogenic diabetes, misdiagnosed initially; we suggest features that should trigger appropriate diagnostic testing.

Patient 1: A 34 year old female, with history of gestational diabetes, presented with osmotic symptoms, HbA1c 83 mmol/mol and mild ketosis, she was commenced on gliclazide. Her BMI was 27, she had a strong maternal family history of deafness. She was found to have mild sensorineural deafness, Her genetic testing for monogenic causes confirmed MT-TL1 m.3243A>G pathogenic mutation, associated with maternally inherited diabetes and deafness (MIDD). She remains well controlled on metformin monotherapy.

Patient 2: A 33 year old male, with sensorineural hearing loss since aged 4, and cardiac conduction abnormalities (WPW syndrome), presented with osmotic symptoms and HbA1c 89 mmol/mol. His BMI was 16, and he was commenced on insulin as type 1 diabetes was suspected. His type 1 Diabetes autoantibodies were negative, C-peptide levels were high, there was a strong family history of diabetes and deafness. His MODY probability score was 15% and genetic testing confirmed MT-TL1 m.3243A>G pathogenic variant. His insulin was discontinued, his HbA1c is 47 mmol/mol on sulphonylurea monotherapy.

MIDD is a monogenic mitochondrial disorder, most commonly caused by the m.3243A>G variant of the *MT-TL1* gene, presenting with diabetes, and sensorineural hearing loss. It may also be associated with a range of other abnormalities[2]—phenotype is variable depending on the level of heteroplasmy. This disorder is under recognised and often mis-diagnosed as type 2 or type 1 diabetes. The genetic diagnosis is important for counselling (maternal transmission), identification of other affected family members and screening for associated complications like cardiomyopathy, deafness and neurological problems. The presence of sensorineural deafness in a patient or kindred with diabetes should prompt one to consider this diagnosis.

EP558 - ECE_2046 - Impact of caloric restriction with or without time-restricted eating on ambulatory blood pressure, renin, and aldosterone: exploratory analysis of a randomised controlled trial

You Jin Chang[1,2], Laurent Turner[1,2], Xiao Tong Teong[1,2], Lijun Zhao[1,2], Athena Variji[1,2], Morag Young[3,4], Gary Wittert[1,2], Leonie Heilbronn[1,2] and Amy Hutchison[1,2]
[1]*South Australian Health and Medical Research Institute, Adelaide, Australia;* [2]*School of Medicine, Adelaide University, Adelaide, Australia;* [3]*Baker Heart and Diabetes Institute, Melbourne, Australia;* [4]*Baker Department of Cardiometabolic Health, University of Melbourne, Melbourne, Australia*

Background: Time-Restricted Eating (TRE), in which food intake is limited to a 6- to10-hour window, and caloric restriction (CR) independently improve cardiovascular risk factors. Whether combining TRE with CR provides additional cardiovascular benefits is unknown. Furthermore, blood pressure (BP) and its regulators, renin and aldosterone, exhibit circadian variation, but remains unclear whether the meal timing affects these rhythms.

Aim: This study examined whether early (eCR) or delayed (dCR) CR differentially impacted BP and its regulators compared with un-restricted CR, in adults at-risk of hypertension.

Methods: This study included 114 adults (mean ± SD; age 59 ± 9 years; BMI 32.1 ± 4.6 kg/m^2; 80% female), with overweight/obesity and elevated fasting glucose. Participants were stratified by sex and fasting blood glucose (≤6.0 mmol/L; >6.0 mmol/L) and randomised (1:1:1) to a 30% energy restricted diet with all foods provided, as either eCR (eating between 0800-1600), dCR (1200-2000), or un-restricted CR for eight weeks. A 24-hour ambulatory BP monitor was worn from ~0800, including overnight sleep (~0000 to ~0730), and blood samples were collected every four hours during a 26-hour ward visit at baseline and week 8. Linear mixed models analysed day- and night-time systolic (SBP) and diastolic (DBP) BP, nocturnal SBP dipping, SBP average real variability, and plasma renin and aldosterone, adjusting for stratification factors, age, antihypertensive medication classifications, and BMI. Sensitivity analyses by dipping status (dipper ≥10%, non-dipper <10%) were conducted for nighttime BP. The cosinoRmixedeffects R package was used to analyse the MESOR (Midline Statistic Of Rhythm), amplitude, and acrophase of SBP, DBP, renin, and aldosterone. Participants with <70% successful BP readings ($n = 16$) or who withdrew ($n = 3$) were excluded.

Results: Daytime and nighttime SBP and DBP and fasting renin were significantly reduced ($P < .05$) after eight weeks, with no changes in other parameters. There were no significant interactions between study group and week or weight for any parameter ($P > .05$). Sensitivity analyses showed nighttime SBP and DBP reductions over time in both dippers and non-dippers ($P < .05$), with no differences between groups. For circadian analysis, the MESOR of SBP, DBP, renin, and aldosterone were significantly reduced within all groups. Only the DBP MESOR significantly decreased between groups. Amplitude and acrophase did not significantly change between groups in any parameter.

Conclusions: Early, or delayed CR are potential strategies to CR to improve BP vs CR alone. However, over eight weeks, neither provided additional benefits for BP measures.

EP559 - ECE_2082 - Effects of a multidisciplinary lifestyle program on muscle strength and body composition in children with excess weight

Nicoletta Gianni[1], Maria Rea[1], Danilo Fintini[1], Francesco D'aniello[1], Alessia Aureli[1], Elena Madonna[1], Gabriele Scozia[1], Valentina Russo[1], Stefano Cianfarani[1], Deny Menghini[1] and Melania Manco[1,2]
[1]*Ospedale Pediatrico Bambino Gesù, Roma, Italy;* [2]*Bambino Gesù Children's Hospital Capital, Rome, Italy*

Introduction: Sarcopenic obesity, marked by high fat mass and reduced fat-free mass, is increasingly recognized in children and may predispose them to metabolic and functional complications. This study assessed whether an intensive lifestyle intervention could improve early sarcopenic traits in pediatric patients with overweight or obesity.

Methods: Within the RESILIENT Project at Bambino Gesù Children's Hospital, children aged 6-12 years underwent an Intensive Health Behavior and Lifestyle Treatment (IHBLT) combining nutritional counseling and Adapted Physical Activity. Anthropometric measures (weight, BMI-SDS, waist circumference, waist-to-height ratio), body composition (fat mass, fat-free mass, total body water via bioelectrical impedance), and muscle strength (handgrip test) were evaluated at baseline (T0), 2 months (T1), and 5 months (T2). Associations between handgrip strength (absolute and relative), body composition, and age were explored.

Results: BMI-SDS, waist indices, and fat mass decreased, while fat-free mass and total body water increased. Absolute handgrip strength improved in both hands (dominant: 14.31 ± 3.95 to 15.12 ± 3.77 kg; non-dominant: 13.76 ± 3.37 to 14.38 ± 3.41 kg). The proportion of children above the 50th percentile for relative strength rose from 17.6% to 39.2%. Strength correlated positively with age, weight, and fat-free mass, and inversely with fat mass. Normalized strength declined with age and adiposity, suggesting early sarcopenic patterns.

Conclusions: Multidisciplinary lifestyle intervention enhances body composition and muscle strength in children with excess weight. Early strategies are essential to counteract sarcopenic obesity.

[1]Laiko University Hospital, Medical School, National and Kapodistrian University of Athens, First Department of Propaedeutic Internal Medicine, Joint Academic Rheumatology Program, Endocrinology Unit, Athens, Greece; [2]First Department of Propaedeutic Internal Medicine, Endocrinology Unit, Laikon General Hospital, Athens, Greece; [3]1st Respiratory Medicine Department, Sotiria Chest Disease Hospital, Athens, Greece; [4]Diabetes and Obesity Unit, Athens Medical Center, Athens, Greece; [5]First Department of Propaedeutic Internal Medicine, Laikon General Hospital, Athens, Greece

Introduction: GLP-1 receptor agonists and the dual GIP/GLP-1 receptor agonist, tirzepatide, induce substantial weight loss. However, concern exists that rapid weight reduction may adversely affect skeletal muscle and increase the risk of sarcopenia, while data on muscle strength and physical performance remain scarce. This prospective observational study compared the 3-month effects of liraglutide vs tirzepatide on screening tools for sarcopenia in adults with class III obesity.

Methods: Adults with a BMI >40 kg/m^2 without diabetes received liraglutide ($n = 14$, administered once daily starting at 0.6 mg with weekly dose escalation of 0.6 mg to the target dose of 3 mg) or tirzepatide ($n = 15$, administered once weekly starting at 2.5 mg with monthly dose escalation of 2.5 mg to the target dose of 7.5 mg), over a 3-month follow-up period. Demographic and anthropometric data were collected, body composition was assessed by bioelectrical impedance analysis, and sarcopenia-related functional tests (handgrip strength, gait speed, and chair-stand test) were evaluated at baseline and at 3 months. Statistical analysis was performed using SPSS version 26.

Results: At baseline, no participant met diagnostic criteria for sarcopenia. The mean age was 47 years, mean body weight 129 kg, and mean BMI 44 kg/m^2. At 3 months, weight loss was similar between the liraglutide and tirzepatide group (11.5 vs 11.9 kg, $P = .83$), as was percentage weight loss (10% vs 9%, $P = .75$). Reductions in fat percentage (−2.3% vs −2.6%, $P = .76$), fat mass (−7.3 vs −7.6 kg, $P = .86$), and fat-free mass (−4.2 vs −3.9 kg, $P = .79$) were comparable. Between-group differences were not significant for either handgrip strength (+2.0 vs −0.2 kg, $P = .29$) or chair-stand test (−2.9 vs −1.7 sec, $P = .21$), with the latter improving in both groups, and a statistically significant increase in gait speed observed in the liraglutide group compared with tirzepatide (+0.2 vs +0.0 m/s, $P = .01$).

Conclusions: Despite concerns that pharmacologically induced weight loss with incretin-based therapies may exacerbate sarcopenia, real-world data from adults with class III obesity demonstrated preserved muscle function after 3 months of treatment with liraglutide 3 mg once daily or tirzepatide 7.5 mg once weekly, despite a concomitant reduction in muscle mass.

The study protocol was prospectively registered at ClinicalTrials.gov (NCT07094568).

EP561 - ECE_2786 - Skeletal muscle function in men with obesity-related functional hypogonadism

Alicja Stańska[1], Krzysztof Kusy[2], Joanna Gorwa[3], Monika Ciekot-Sołtysiak[2], Maja Maćkowiak-Tadyszak[2], Aleksandra Derwich-Rudowicz[1], Marek Ruchala[1] and Nadia Sawicka-Gutaj[1]

[1]Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences, Poznań, Poland; [2]Poznań, Poland; [3]Department of Biomechanics, Poznan University of Physical Education, Poznań, Poland

Introduction: Obesity and its complications—metabolic, hormonal, and sexual dysfunction have become a serious public health concern. Not only is obesity a risk factor for functional hypogonadism in men, but functional hypogonadism causes increased fat accumulation and reduced muscle mass, creating a vicious circle.

Aim: The aim of the study was to compare hormonal parameters and muscle function between men with obesity-related hypogonadism, eugonadal obese men, and healthy controls.

Methods: Men aged 18-60 years, with diagnosed functional hypogonadism (a serum testosterone level 8-12 nmol/L and sexual dysfunction) and obesity (BMI ≥ 30 kg/m^2), were prospectively enrolled in the study. Eugonadal men with obesity and healthy controls (HCs) were also included. Each participant filled the International Physical Activity Questionnaire (IPAQ) and the WHOQOL-BREF questionnaire for quality of life. Hormonal parameters (total testosterone, LH, FSH, SHBG, and prolactin concentration) and biochemical parameters were assessed. Physical capacity was measured using a cardiopulmonary exercise test (CPET) and grip strength with a hand dynamometer.

Results: A total of 107 participants were included in the analysis (hypogonadal obese $n = 51$, eugonadal obese $n = 17$, and healthy controls $n = 39$). In hypogonadal group, mean age was 36.37 years, median BMI 32.29 kg/m^2, and median total testosterone 9.26 nmol/L. The most pronounced difference was observed in quality of life, revealing a median gradient pattern (HCs (93), hypogonadal obese (83), and eugonadal obese (71)). Although the total time spent sitting did not differ significantly between the HCs and hypogonadal group, participants with hypogonadism spent less time participating in vigorous and moderate physical activity ($P = .021$ and $P = .002$, respectively). There were also significant differences in physical capacity between healthy controls and obese participants (VO2 max/kg: 33.13 ± 6.07, 23.75 ± 5.81, and 21.35 ± 5.76 ml/min/kg in HCs, eugonadal obese, and hypogonadal obese, respectively) and relative strength (1.54 ± 0.10 vs 1.43 ± 0.10 and 1.41 ± 0.11 kg/kg), with healthy controls demonstrating markedly superior performance compared to obesity groups.

Conclusions: In the hypogonadal group, we observed a typical clinical picture of sarcopenic obesity, which may have significant functional and metabolic consequences. Reduced muscle strength and lower physical capacity may further reduce patients' motivation for regular physical activity and hinder effectivity of non-pharmacological treatment. These findings underscore the need for a comprehensive therapeutic approach and for optimizing the management of obesity-related hypogonadism, especially regarding quality of life and physical performance.

EP562 - ECE_2924 - Reduced weight loss response to semaglutide in patients with hypothyroidism: a real-world study

Patricia Oriol Ocejo, Jersy Cardenas, Victor Pérez de Arenaza Pozo, Alvaro Fernandez Sanchez, Blanca Timón, Beatriz Baraia Etxaburu Astigarraga, Cristina Luengo Alvarez de Buergo and Clotilde Vazquez Martinez

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Endocrinology, Fundación Jiménez Díaz University Hospital, Madrid, Spain

Background: Currently, limited data are available evaluating whether the weight-loss response to glucagon-like peptide-1 receptor agonists (GLP-1 RA) differs between patients with hypothyroidism and euthyroid individuals. Given the key role of thyroid hormones in body energy metabolism, hypothyroidism could potentially influence the effectiveness of obesity pharmacotherapy. The aim of this study was to assess whether hypothyroidism is associated with a reduced weight-loss response to semaglutide in real-world clinical practice.

Methods: A retrospective observational study was conducted including patients prescribed semaglutide between May and August 2024 in two specialised obesity clinics from two public hospitals in Madrid. All patients participated in a structured lifestyle modification programme. Patients with type 2 diabetes mellitus ($n = 32$), type 1 diabetes mellitus ($n = 2$), or incomplete data ($n = 121$) were excluded. A total of 123 patients were included in the final analysis, of whom 23 (18.7%) had a diagnosis of hypothyroidism. Weight loss during follow-up was the primary outcome. Multivariable linear regression analysis was performed, including 18 baseline demographic, anthropometric, analytical, comorbidity-related and treatment-related variables.

Results: After a mean follow-up of 6.5 ± 1.2 months, the mean achieved semaglutide dose was 1.31 ± 0.74 mg/week. Mean weight loss in the overall cohort was -5.7 ± 0.3 kg (95% CI −6.3 to −5.1). Weight loss was significantly greater in euthyroid patients compared with those with hypothyroidism: -6.3 ± 6.1 kg (95% CI −7.5 to −5.1) vs -3.2 ± 3.9 kg (95% CI −4.9 to −1.5), with a mean difference of −3.0 kg (95% CI −5.7 to −0.4; $P = .025$). No significant changes in thyroid-stimulating hormone (TSH) levels were observed in either group during follow-up. In the multivariable model, higher baseline body mass index (β −.28, $P = .02$), prediabetes (β −3.20, $P = .02$), and GLP-1–naïve status (β −2.96, $P = .02$) were associated with greater weight loss, whereas hypothyroidism (β +3.10, $P = .041$) was independently associated with reduced weight loss.

Conclusions: In this real-world cohort, hypothyroidism was independently associated with a reduced weight-loss response to semaglutide. These findings indicate that thyroid status may represent an important modulator of the effectiveness of GLP-1 receptor agonist therapy. Consideration of thyroid function may be relevant when evaluating suboptimal response to obesity pharmacotherapy.

EP563 - ECE_3136 - Exploring MASLD-associated features in women with PCOS: a subset analysis from a broader gut microbiota-focused study

Bojana Mićić[1], Sofija Ignjatović[1], Miloš Vratarić[1], Ivana Bozic-Antic[2,3,4], Uroš Gašić[1], Jelena Brkljačić[1], Mark Davids[5], Amir Bahmani[5], Max Nieuwdorp[5], Jelica Bjekic MacUt[6], Ana Djordjevic[1], Nataša Veličković[1] and Danijela Vojnović Milutinović[1]

[1]*Institute for Biological Research "Siniša Stanković"—National Institute of Republic of Serbia, University of Belgrade, Belgrade, Serbia;* [2]*Department of Endocrinology, Euromedik General Hospital, Belgrade, Serbia;* [3]*Department of Endocrinology, Faculty of Stomatology, University Business Academy, Novi Sad, Serbia;* [4]*Euromedik General Hospital, Belgrade, Serbia;* [5]*AmsterdamUMC, University of Amsterdam, Amsterdam, The Netherlands;* [6]*Department of Endocrinology, UMC Bežanijska kosa, Faculty of Medicine, University of Belgrade, Belgrade, Serbia*

Introduction: Metabolic dysfunction–associated steatotic liver disease (MASLD) is highly prevalent worldwide and frequently coexists with endocrine and metabolic disorders. Polycystic ovary syndrome (PCOS), often characterized by insulin resistance and metabolic dysregulation, has been associated with an increased risk of MASLD. However, the extent to which this association defines a distinct metabolic phenotype within PCOS remains to be explored. Within a broader multi-omics clinical study of MASLD patients from Serbia, we identified a subset of women with PCOS and investigated whether MASLD is associated with distinct metabolic, hormonal or gut microbiota features within an age-matched PCOS patients.

Patients and Methods: Exploratory subset analysis included age-matched women with PCOS stratified by ultrasound-defined MASLD (non-MASLD group, $n = 9$ and MASLD group, $n = 5$). Anthropometric, metabolic and hormonal parameters were assessed using routine clinical methods. Gut microbiota composition was analysed based on 16S rRNA gene sequencing, using diversity metrics and genus-level comparisons, while fecal short-chain fatty acids (SCFA) were measured as functional readouts of gut microbial activity. Given the small sample size and distributional characteristics of several variables, non-parametric statistical methods were applied.

Results: Age-matched PCOS women with and without MASLD showed largely overlapping anthropometric, lipid, hepatic, and hormonal profiles. Among parameters of glucose metabolism, only HbA1c was modestly higher in women with MASLD, indicating mild sustained metabolic alteration associated with MASLD within PCOS. Beta diversity analysis indicated higher heterogeneity in MASLD-PCOS women, although without clear group separation. At the genus level, MASLD-PCOS women more frequently exhibited higher abundance of taxa commonly associated with metabolic disturbances (*Rothia*, *Streptococcus*, *Lachnoclostridium*). Fecal SCFA concentrations and composition did not differ between groups, suggesting that, in our cohort, these microbial metabolites do not show an apparent association with MASLD in PCOS.

Conclusions: Within an age-matched women with PCOS, MASLD was not associated with a distinct metabolic or functional microbial signature, but rather with higher gut microbiota heterogeneity and consistent directional shifts at the genus level. Higher HbA1c, suggesting modest variation in cumulative glycaemic exposure, may reflect early metabolic divergence associated with the MASLD–PCOS phenotype.

EP564 - ECE_3229 - Post-bariatric hypoglycaemia—a case series from a large surgical bariatric centre

Aparna Chaudhary, Stephanie Miles and Foteini Kavvoura

Diabetes and Endocrinology, Royal Berkshire Hospital, Reading, United Kingdom

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Introduction: Post-bariatric hypoglycaemia (PBH) is a post-operative complication attributed to exaggerated post-prandial hyperinsulinaemia. It is defined by Whipple's triad: hypoglycaemic symptoms, low glucose levels, and symptom resolution with euglycemia. PBH typically occurs 1-4 hours post-prandially and develops 1-3 years post-operatively.

Methods: We audited patients referred between 2019 and 2025 with symptoms of PBH against 2024 Society for Endocrinology guidelines. Cases were identified from clinician worklists. Electronic records were reviewed for clinical characteristics, method of diagnosis, and interventions.

Results: Of 21 patients referred with typical symptoms, 19 were diagnosed with PBH.

Cohort characteristics:

Median age at presentation	43 years
Sex	Female 18/19 (95%)
Type of surgery	Roux-en-Y 13/19 (68%) Sleeve gastrectomy 3/19 (16%) Mini gastric bypass 3/19 (16%)
Median time from surgery to presentation	26 months
Pre-existing diabetes	4/19 (21%)
Median BMI at presentation	26.4
Median excess weight loss	82%

Mixed meal test (MMT) was performed in 16/19 patients, capillary blood glucose (CBG) in 15/19, venous glucose in 13/19 and continuous glucose monitoring (CGM) in 11/19. The median number of confirmatory tests was 3.

Rates of glucose detection <3.0 mmol/L were: MMT 44% (7/16), CBG 73% (11/15), venous glucose 38% (5/13), and CGM 90% (10/11).

All patients received information on controlled portions of carbohydrates; 79% were reviewed by a dietician (15/19).

Pharmacotherapy was used in 68% (13/19). Acarbose was used first line in all patients (13/13). GLP-1 analogues were used second line (7/13); diazoxide was used four times, verapamil and octreotide twice, and tirzepatide once. Six patients on GLP-1 analogues reported symptomatic improvement (86%).

Transoral outlet reduction was performed in three patients (16%), all remained symptomatic; two patients (67%) returned to GLP-1 analogues with improvement of symptoms.

Six patients achieved symptom resolution and were discharged (32%), two patients were lost to follow-up, and 11 patients are receiving ongoing appointments (58%). Two patients needed hospitalisation due to hypoglycaemia.

Conclusions: This cohort confirmed suggested PBH risk factors include female sex and higher weight loss post-surgery. The diagnostic challenges are reflected in the number of confirmatory tests required.

Dietary advice, dietician review and acarbose use complied with audit standards. Octreotide, pasireotide and diazoxide use is limited by convenience, funding restrictions, and tolerability. GLP-1 analogues are accessible and well tolerated; 86% of patients reported an improvement in symptoms, highlighting the importance to further consider their role in management. PBH remains challenging to manage in a considerable proportion of patients.

Objectives: To evaluate the correlation between weight loss and reduction in waist circumference in patients treated with Semaglutide injection for weight management

Materials and Methods: This phase III, multicentre, randomized, open-label, active-controlled clinical study (CTRI/2025/04/085487) was conducted across 22 study sites in India after receiving regulatory and ethics committee approvals. Total 267 adult patients with BMI $\geq$ 30 kg/m^2 or $\geq$ 27 kg/m^2 with the presence of at least one co-morbidity of hypertension, dyslipidaemia and/or type 2 diabetes mellitus were included. Patients were randomized to either test arm to receive synthetic semaglutide injection or reference arm to receive Wegovy® every week subcutaneously for 24 weeks. The primary endpoint was change in body-weight from baseline to week 24. Secondary endpoints included change in BMI, waist circumference, SF-36, and glycaemic measures in diabetic and non-diabetic patients. Safety assessments included incidence of TEAEs and anti-drug/neutralizing antibody. This post-hoc analysis was conducted to evaluate the correlation between weight loss and reduction in waist circumference.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Results: The Pearson's correlation coefficient between decrease in weight loss and decrease in waist circumference was 0.2753 with *P* value = .0003 in test arm. The Pearson's correlation coefficient between decrease in weight loss and decrease in waist circumference was 0.2753 with *P* value = .0134 in reference arm. There is positive co-relation between weight loss and reduction in waist circumference in both test and reference arm indicating greater reduction in weight is associated with more decrease in waist circumference. The correlation between weight loss and reduction in waist circumference was statistically significant in both test and reference arm. The statistical significance observed in the Pearson correlation analysis in both the arms supports the robustness of this association.

Conclusions: This post-hoc analysis demonstrated that there is greater reduction in weight is associated with grated reduction in waist circumference demonstrating favourable effect in central adiposity along with overall weight reduction

EP571 - ECE_2552 - The evolution and management of type V familial hypertriglyceridemia during pregnancy

Fatma Ben Abdessalem, Taieb Ach, Imen Halloul, Wiem Saafi, Hamza Fekih, Ghada Saad and Yosra Hasni
Endocrinology, Hôpital Farhat Hached, Sousse, Tunisia

Introduction: Pregnancy triggers profound metabolic adaptations characterized by hormonal shifts that can increase lipid levels by up to fourfold. While often physiological, this rise poses significant risks for patients with pre-existing dyslipidemia. We present a case of severe hypertriglyceridemia further complicated by the onset of gestational diabetes. This report highlights the clinical challenges of managing extreme lipid elevations to prevent life-threatening maternal and fetal complications.

Observation: We report the case of a 31-year-old primigravida referred at 25 weeks of gestation following a pathological oral glucose tolerance test. Her medical history includes familial mixed hypertriglyceridemia, diagnosed at age 19 after an acute pancreatitis episode (triglycerides: 23.4 mmol/L; total cholesterol: 8 mmol/L). Fenofibrate therapy was discontinued at the start of pregnancy. Clinical examination was unremarkable, specifically showing no eruptive xanthomas or hypertension. Upon admission, lipase levels were normal, but labs revealed severe hypercholesterolemia (18.41 mmol/L) and hypertriglyceridemia (14.12 mmol/L). Following a strict low-fat diet and omega-3 supplementation (3 g/day), levels adjusted to 16.11 mmol/L and 13.11 mmol/L by week 27. While glycemia was controlled via lifestyle changes, third-trimester ultrasound suggested a trend toward fetal macrosomia.

Conclusion: Hypertriglyceridemia was exacerbated by pregnancy, gestational diabetes, and glucose provocations, with acute pancreatitis remaining the primary risk. Furthermore, high triglyceride levels are linked to hyperviscosity syndrome and pre-eclampsia. Because therapeutic options are restricted during pregnancy, omega-3 fatty acids are the preferred treatment due to their safety and efficacy. They function by decreasing hepatic triglyceride secretion and enhancing lipoprotein lipase activity.

EP575 - ECE_1616 - Metabolic dysfunction–associated steatotic liver disease and testosterone serum levels: converging evidence from real-world observational data and meta-analysis

Giorgia Spaggiari[1,2,3], Leonardo Dalla Valentina[1], Cristina Felicani[4], Filippo Gabrielli[4,5], Simonetta Lugari[4], Antonio Granata[2,3], Manuela Simoni[1,2], Paolo Ventura[4,5], Fabio Nascimbeni[4,5] and Daniele Santi[1,2,3]
[1]Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; [2]Unit of Endocrinology, Department of Medical Specialties, Azienda Ospedaliero-Universitaria of Modena, Modena, Italy; [3]Unity of Andrology and Sexual Medicine of the Unit of Endocrinology, Department of Medical Specialties, Azienda Ospedaliero-Universitaria of Modena, Modena, Italy; [4]Unit of Internal Medicine and Metabolism, Azienda Ospedaliero-Universitaria of Modena, Modena, Italy; [5]Department of Maternal-Infantile and Adult Medical and Surgical Sciences, University of Modena and Reggio Emilia, Modena, Italy

Background: Low testosterone has been increasingly associated with metabolic dysfunction–associated steatotic liver disease (MASLD), yet the strength, direction, and clinical relevance of this relationship remain incompletely defined, particularly with respect to liver fibrosis.

Aim of the study: To investigate the association between male hypogonadism and MASLD through a dual approach, combining a real-world observational study with a systematic meta-analysis of the available literature, and to explore the potential impact of testosterone replacement therapy (TRT).

Methods: A prospective, cross-sectional, case–control observational study was carried out, including 75 men referred for sexual dysfunction or infertility, stratified into hypogonadal ($n = 59$) and eugonadal ($n = 16$) groups according to baseline testosterone serum levels. MASLD was assessed using indirect indices (Hepatic Steatosis Index, Fatty Liver Index), qualitative ultrasound, and controlled attenuation parameter (CAP), while liver fibrosis was evaluated by transient elastography and 2D shear-wave elastography. Hypogonadal men were further classified according to TRT status. The testosterone/MASLD relationship was subsequently assessed in a meta-analysis of 28 cross-sectional and longitudinal studies available in the literature.

Results: MASLD prevalence was significantly higher in hypogonadal men than in controls when combining ultrasound and biochemical criteria (85.5% vs 50.0%, $P = .023$). Liver fibrosis, assessed by imaging techniques, was detected exclusively in hypogonadal patients (18.6% vs 0%, $P = .057$). Body mass index (BMI) emerged as the strongest predictor of both MASLD and fibrosis ($P < .001$ and $P = .011$), particularly in testosterone-naïve men ($P < .001$ and $P = .033$), whereas this association was attenuated in patients receiving TRT ($P = .166$ and $P = .130$). The meta-analysis (1636 hypogonadal vs 4587 eugonadal men) confirmed a significantly higher prevalence of MASLD among hypogonadal men compared with eugonadal controls ($P = .001$), independent of age ($P = .274$) and BMI ($P = .219$).

Conclusions: This dual-approach study confirms a bidirectional association between male hypogonadism and MASLD. Real-world data support meta-analytic evidence and suggest

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

that testosterone deficiency contributes to hepatic steatosis and fibrosis mainly through increased adiposity, while TRT may mitigate liver risk by modulating body composition and metabolic dysfunction.

EP576 - ECE_1353 - Linking pediatric obesity to youth-onset type 2 diabetes: integrated longitudinal and cross-sectional evidence from population-based studies worldwide

Ashraf Soliman, Manal Musallam, Fawziya Alyafei, Nada Alaaraj, Noor Hamed and Shayma Ahmed
Pediatric Endocrinology, Hamad Medical Center, Doha, Qatar

Background: Youth-onset type 2 diabetes mellitus (T2DM) has emerged as a major global public health concern over the past two decades, paralleling the rapid rise in childhood and adolescent obesity. Although pediatric obesity surveillance is widely available across countries, population-based data on youth-onset T2DM are largely confined to regions with established registries and national audits.

Objective: To synthesize longitudinal and cross-sectional epidemiological evidence examining the association between pediatric obesity prevalence and youth-onset T2DM incidence across countries, using validated population-based studies published over the past 20 years.

Methods: A structured synthesis of PubMed-indexed literature published between 2005 and 2025 was conducted, restricted to children and adolescents younger than 20 years. Longitudinal data were obtained from population-based youth T2DM registries and national audits, including SEARCH (USA), Manitoba (Canada), the England/Wales National Paediatric Diabetes Audit, Israel, Australia, and New Zealand. These data were paired with national and global pediatric obesity surveillance sources (NCD-RisC, WHO, and national health surveys). Cross-sectional evidence was derived from national audits, cohort studies, and systematic reviews reporting obesity prevalence among youth with T2DM. Associations and trends were evaluated qualitatively and through comparative visualization.

Results: Longitudinal analyses consistently demonstrated parallel increases in pediatric obesity prevalence and youth-onset T2DM incidence within individual countries. In the United States, pediatric obesity prevalence increased from approximately 17% to over 20% between 2005 and 2018, while youth-onset T2DM incidence rose from about 3.8 to 6.8 per 100 000 youth per year. In Canada (Manitoba), youth-onset T2DM incidence nearly doubled (from 16.0 to over 30 per 100 000 per year) within less than a decade, coinciding with rising childhood obesity, particularly among Indigenous populations. Similar upward, though lower-magnitude, trends were observed in England/Wales ($\approx$1.2 to $\approx$2.6 per 100 000 per year), Israel, Australia, and New Zealand, all mirroring national increases in pediatric obesity. Cross-sectionally, the obesity–T2DM association was striking: across countries, 75-95% of children and adolescents with T2DM were overweight or obese. A global meta-analysis confirmed that approximately three-quarters of youth with T2DM have obesity.

Conclusions: Integrated longitudinal and cross-sectional evidence demonstrates a robust and consistent association between rising pediatric obesity and the expanding burden of youth-onset T2DM. Obesity precedes increases in T2DM incidence over time and is present in the majority of affected youth worldwide, underscoring pediatric obesity as the principal upstream driver of youth-onset T2DM and highlighting the urgent need for coordinated obesity prevention and strengthened international diabetes surveillance.

EP577 - ECE_1784 - High prevalence of insulin resistance and its association with cardiovascular risk in adults with type 1 diabetes

Mohd Idris Diah[1], Hwee Ching Tee[2] and Hui Chin Wong[1]
[1]*Endocrinology and Diabetes, Internal Medicine, Hospital Tengku Ampuan Rahimah Klang, Klang, Malaysia;* [2]*Endocrinology and Diabetes, Internal Medicine, Queen Elizabeth II Hospital, Kota Kinabalu, Malaysia*

Background: Insulin resistance (IR), traditionally associated with type 2 diabetes, is increasingly recognised in individuals with type 1 diabetes mellitus (T1DM) and may contribute to excess cardiovascular disease (CVD) risk. Data on the burden and cardiometabolic implications of IR in Southeast Asian adults with T1DM remain limited. This study aimed to determine the prevalence of IR using the estimated glucose disposal rate (eGDR) and to examine its association with cardiovascular risk in a multi-ethnic Malaysian cohort.

Methods: This cross-sectional study recruited 127 adults with T1DM from two tertiary centres in Malaysia. Insulin resistance was assessed using eGDR, with values <8 mg·kg^{-1}·min^{-1} indicating IR. Ten-year CVD risk was estimated using the Steno Type 1 Risk Engine (ST1RE). Clinical, anthropometric, and biochemical data, including renal function and microvascular complications, were collected. Associations with IR were explored using univariable and multivariable logistic regression analyses.

Results: The prevalence of insulin resistance was 43.3%. Participants with IR were older and had significantly higher body mass index, waist circumference, systolic blood pressure, HbA1c, and triglyceride levels, alongside lower estimated glomerular filtration rate (eGFR), compared with those without IR (all $P < .05$). Insulin resistance was strongly associated with higher predicted CVD risk, with progressively lower mean eGDR values across low-, moderate-, and high-risk ST1RE categories ($P < .001$). In multivariable analysis, waist circumference (adjusted OR 1.27 per cm; 95% CI 1.15-1.40), systolic blood pressure (OR 1.11 per mmHg; 95% CI 1.05-1.18), HbA1c (OR 4.91 per 1%; 95% CI 2.63-9.14), and eGFR (OR 0.96 per mL/min/1.73 m^2; 95% CI 0.94-0.99) were independently associated with insulin resistance.

Conclusions: Insulin resistance is common among adults with T1DM and is independently associated with adverse metabolic and cardiorenal profiles, correlating with elevated predicted cardiovascular risk. Early identification of IR using eGDR and targeted intervention addressing central adiposity, blood pressure, glycaemic burden, and renal health may help reduce long-term cardiovascular complications in people living with T1DM.

EP578 - ECE_1958 - A web-based screening tool for identifying metabolic risk in adults with type 2 diabetes

Alina Urbanovych and Nadiia Sidelnyk
Department of Endocrinology, Lviv National Medical University, Lviv, Ukraine

Background: Metabolic Health Check is a web-based tool that automatically calculates metabolic indices (BMI, waist-to-height ratio [WHtR], waist-to-hip ratio [WHR], the TyG index and FIB-4), performs a screening assessment of metabolic syndrome and excess body fat based on the 2025 Lancet Diabetes & Endocrinology Commission criteria for clinical obesity, and generates a standardised PDF report. To assess clinical relevance, a retrospective analysis of patients with type 2 diabetes mellitus (T2DM) was performed, as BMI does not always reflect true cardiometabolic risk in this population.

Aim: To evaluate the clinical value of the Metabolic Health Check, assess consistency between BMI and the TyG index, and examine the association between the TyG index and MASLD.

Materials and Methods: We performed a retrospective analysis of 129 adults with type 2 diabetes mellitus (T2DM). Patients were divided into two groups: without obesity (BMI <30 kg/m^2) and with obesity (BMI ≥30 kg/m^2), and stratified by TyG index categories (<8.5, 8.5-8.8, and ≥8.8). The prevalence of MASLD was assessed in BMI groups and TyG index categories. The TyG index was calculated using the formula TyG = ln[(TG (mmol/L) × 88.57) × (FPG (mmol/L) × 18)/2].

Results: The study included 129 patients. Mean BMI was 25.87 ± 0.37 kg/m^2 in the group without obesity ($n = 63$) and 35.13 ± 0.45 kg/m^2 in the obesity group ($n = 66$). High TyG index (≥8.8) was observed in 107/129 (82.9%) patients and occurred with similar frequency in patients with BMI <30 and ≥30 kg/m^2 (82.5% vs 83.3%; Fisher's exact $P = 1.000$). MASLD was present in 40/63 (63.5%) patients with BMI <30 kg/m^2 and in 57/66 (86.4%) patients with BMI ≥30 kg/m^2 ($P = .004$). The prevalence of MASLD increased across TyG index categories: 35.7% for TyG <8.5, 62.5% for TyG 8.5-8.8, and 81.3% for TyG ≥8.8 ($P = .001$). TyG ≥8.8 was associated with significantly higher odds of MASLD compared with TyG <8.5 (OR = 7.83; 95% CI 2.37-25.9; Fisher's exact $P < .001$).

Conclusions: The results indicate a substantial prevalence of hidden metabolic risk, as high TyG index (≥8.8) was found with similar frequency in patients without obesity and in those with obesity by BMI. The high prevalence of MASLD in the BMI <30 kg/m^2 group (63.5%) underscores the need for rapid digital metabolic screening tools based on available clinical and laboratory parameters.

EP579 - ECE_1636 - Serum Galectin-3 level alteration in type 2 diabetes mellitus and its relation to diabetes complications

Samir Assaad[1], Eman Zaky Ahmed Abdelaziz Azzam[1], Raghda Taleb[2], Aisha Thabet[1] and Ahmed Abdelhameed Osman[1]
[1]*Endocrinology Unit, Department of Internal Medicine, Alexandria Faculty of Medicine, Alexandria, Egypt;* [2]*Alexandria, Egypt*

Introduction: Galectin-3 (Gal-3) is a beta-galactosidase-binding lectin implicated in the regulation of inflammation, fibrosis, and oxidative stress. While its role in heart failure is well-recognized, its association with the broad spectrum of diabetic complications remains under investigation. This study aimed to evaluate serum Gal-3 levels in patients with Type 2 Diabetes Mellitus (T2DM) compared to healthy controls and to assess the relationship between Gal-3 levels and specific microvascular and macrovascular diabetic complications.

Methods: A cross-sectional study was conducted at Alexandria Main University Hospital involving 40 patients with T2DM and 40 age- and sex-matched healthy controls. All participants underwent detailed clinical assessment and laboratory investigations, including fasting blood glucose, HbA1c, lipid profile, renal function tests (urea, creatinine, albumin-creatinine ratio), and serum Gal-3 measurement via enzyme-linked immunosorbent assay (ELISA). Diabetic complications, including chronic kidney disease (CKD), ischemic heart disease (IHD), heart failure, diabetic retinopathy, and history of amputation were documented.

Results: Serum Gal-3 levels were significantly higher in the T2DM group (mean 5.93 ± 1.97 ng/mL) compared to the control group (2.45 ± 0.45 ng/mL; $P < .001$). Within the T2DM group, significantly elevated Gal-3 levels were observed in patients with CKD ($P = .04$), IHD ($P < .001$), heart failure ($P = .041$), and amputation ($P < .001$). No significant correlation was found between serum Gal-3 levels and HbA1c, lipid profile parameters, or the total number of comorbidities per patient. However, renal function markers (urea, creatinine, and ACR) were significantly correlated with the number of comorbidities.

Conclusions: Serum Gal-3 is significantly elevated in T2DM patients and is associated with the presence of major complications, particularly CKD and cardiovascular disease. These findings suggest that Gal-3 may serve as a biomarker for fibrosis-related organ damage in diabetes, independent of glycemic control. Further large-scale studies are warranted to validate its prognostic value in monitoring disease progression.

EP581 - ECE_1176 - Diabetes distress in adults with type 1 diabetes: The role of structured education, technology satisfaction and hypoglycaemia fear

Niamh Moloney, Kate Murphy and James Ryan
Cork, Ireland

Background: Diabetes distress is a common but underrecognised psychological burden in people with type 1 diabetes mellitus (T1DM). We examined the relationship between structured education, technology satisfaction, and fear of hypoglycaemia with diabetes distress.

Methods: A cross-sectional study of 62 adults with T1DM was conducted. Participants completed the 17-item Diabetes Distress Scale (DDS17) and surveys assessing technology satisfaction (1-5), fear of hypoglycaemia (1-5), and completion of structured education (eg, DAFNE). Clinical data included HbA_1c, age, complications, insulin regimen, and monitoring method. Elevated distress was defined as DDS17 ≥2. Independent-samples t-tests and Pearson correlations assessed associations. A decision tree model identified key predictors of elevated distress.

Results: Thirty-seven percent of patients reported elevated distress. Completion of structured education was associated with

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

significantly lower mean DDS17 scores compared to non-completers ($P = .029$). Technology satisfaction ($r = +0.06$, $P = .67$) and fear of hypoglycaemia ($r = -0.10$, $P = .42$) were not significantly associated with distress. The decision tree model achieved 68.8% accuracy, with HbA_1c, age, and structured education as the strongest predictors.

Conclusions: Structured diabetes education appears protective against elevated distress in adults with T1DM. In this cohort, technology satisfaction and fear of hypoglycaemia did not independently predict distress. These findings support incorporating structured education and routine psychosocial screening into T1DM care. Larger studies are needed to refine predictive models of distress.

EP582 - ECE_1344 - Experience with alpelisib in a secondary care hospital

Paloma Gonzalez Lazaro, Juan Antonio Mascuñana Calle, María Sanchez Crespo Juarez, María Lizano Sanchez Villacañas, Gerogina Vela Florensa and Ines Gomez García
Hospital General La Mancha Centro, Alcázar de San Juan, Spain

Introduction: Alpelisib is an alpha-selective PI3K (phosphatidylinositol 3-kinase) inhibitor, which activating mutation is present in patients with advanced breast cancer. Its main adverse effect and cause of treatment discontinuation is hyperglycemia; this is a class effect related to its mechanism of action, mediated by increased glycogenolysis and decreased peripheral glucose uptake.

Objectives: To review cases of patients treated with alpelisib, the treatment they received, and whether treatment discontinuation was necessary.

Materials and Methods: A retrospective descriptive study of 4 patients with advanced breast cancer treated with alpelisib at Mancha Centro Hospital from September 2024 to September 2025.

Results: The mean age of the patients was 61.34 years. None had a prior diagnosis of diabetes mellitus (DM). The mean BMI was 24.62 kg/m^2, and baseline HbA1c prior to treatment initiation was 5.5%. All patients developed hyperglycemia, and all required non-insulin antidiabetic treatment (2 with metformin and sitagliptin, 1 with dapagliflozin, and 1 with pioglitazone). In 3 patients, long-acting insulin was also required. The initial dose of alpelisib was 300 mg/day, and in 3 cases the dose was reduced due to grade 3 hyperglycemia (>250 mg/dL). The mean duration of treatment was 6.2 months. Two patients discontinued treatment due to disease progression, 1 patient died, and 1 patient is currently continuing treatment. There were no cases of diabetic ketoacidosis, and in all patients who discontinued treatment, blood glucose levels returned to the normal range.

Conclusions: It is necessary to monitor blood glucose levels in all patients starting alpelisib treatment, as most will develop hyperglycemia. It is important to establish management protocols and a multidisciplinary approach to avoid discontinuing a treatment with promising outcomes.

Abstract citation ID: lvag096.1035

EP583 - ECE_3374 - Features of neurotransmitter supply in patients with type 2 diabetes mellitus with polymorphisms of folate cycle genes in the post-covid state

Kateryna Komisarenko[1,2,3]
[1]*Kyiv, Ukraine;* [2]*The State Institution «V.P. Komisarenko Institute of Endocrinology and Metabolism», Kyiv, Ukraine;* [3]*The State Institution «V.P. Komisarenko Institute of Endocrinology and Metabolism», Kyiv, Ukraine*

Background: The folate cycle plays a key role in one-carbon metabolism, providing methyl groups for DNA synthesis, epigenetic regulation, and neurotransmitter production. Dysregulation of this pathway, particularly in the presence of genetic polymorphisms of folate cycle enzymes, may lead to elevated homocysteine levels and impaired serotonergic activity. Patients with type 2 diabetes mellitus (T2DM) recovering from COVID-19 frequently report persistent neurocognitive and affective symptoms, suggesting underlying neuro-metabolic disturbances.

Objective: To investigate features of neurotransmitter metabolism (serotonin and homocysteine) in post-COVID patients with T2DM carrying polymorphisms of folate cycle genes and to assess the impact of different antidiabetic treatment strategies on these parameters.

Methods: A total of 127 individuals aged 40-70 years were examined: 43 post-COVID patients with T2DM, 34 post-COVID patients without diabetes, and 50 healthy controls. Serum levels of serotonin, homocysteine, and folic acid were measured at baseline and six months after recovery from COVID-19. Genotyping for MTHFR (C677T, A1298C), MTR (A2756G), and MTRR (A66G) polymorphisms was performed using PCR-based methods. Patients with T2DM were subdivided according to therapy: subgroup 1a (metformin + SGLT2 inhibitors, $n = 25$) and subgroup 1b (metformin and/or sulfonylureas, $n = 18$). Statistical analysis included correlation, regression, and ANOVA.

Results: Six months after COVID-19, patients with T2DM demonstrated a significant reduction in homocysteine levels (mean decrease 5-10 µmol/L), an increase in serum serotonin (approximately +30 ng/mL), and normalization of folic acid concentrations. The proportion of patients with normal homocysteine levels increased from 30% to 86% in subgroup 1a and from 38% to 83% in subgroup 1b. Changes in homocysteine strongly depended on baseline values ($R^2 = 0.92$). Baseline serotonin levels correlated with body mass index ($R^2 = 0.697$). The MTRR A66G polymorphism was associated with lower serotonin levels and more pronounced post-COVID neurocognitive symptoms. Regression analysis confirmed a significant influence of both therapy type and folate cycle gene variants on serotonin dynamics ($F = 11.31$, $P < .05$).

Conclusions: Genetic polymorphisms of folate cycle enzymes contribute to neurotransmitter imbalance in post-COVID patients with T2DM. Combination therapy with metformin and SGLT2 inhibitors provides more effective normalization of homocysteine and serotonin levels compared with conventional treatment and may support neurocognitive recovery. These findings highlight the importance of personalized metabolic strategies in post-COVID diabetes management.

EP585 - ECE_2757 - Heterogeneous fatty acid–binding protein 4 (FABP4) responses after Roux-en-Y gastric bypass reveal adipokine remodeling dissociated from weight loss, inflammation, and incretin dynamics

Bedia Fulya Calikoglu[1], Handan Hanım Orskaya[2], Gulsah Yenidunya Yalin[3], Umut Barbaros[4], Ilknur Bingul[5] and Fatih Aydin[5]

[1]*Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Endocrinology and Metabolism, Istanbul University, Istanbul, Türkiye;* [2]*Department of Medical Biology, Istanbul Health and Technology University, Istanbul, Türkiye;* [3]*Istanbul Medical Faculty, Department of Internal Medicine, Division of Endocrinology and Metabolism, Istanbul University, Istanbul, Türkiye;* [4]*Istanbul Medical Faculty, Department of General Surgery, Istanbul University, Istanbul, Türkiye;* [5]*Istanbul Medical Faculty, Department of Medical Biochemistry, Istanbul University, Istanbul, Türkiye*

Background: Fatty acid–binding protein 4 (FABP4) is an adipokine closely linked to adipose tissue mass, low-grade inflammation, and cardiometabolic risk. Following bariatric surgery, FABP4 is generally expected to decrease in parallel with weight loss and improvements in inflammation. However, whether postoperative FABP4 dynamics uniformly reflect these changes or exhibit heterogeneous patterns independent of anthropometric and hormonal adaptations remains unclear.

Methods: Twenty-eight adults undergoing Roux-en-Y gastric bypass (RYGB) were prospectively followed at baseline, 3 months, and 6 months. Anthropometric measures, body composition, metabolic indices, hsCRP, IL-6, fasting GLP-1 and PYY, and serum FABP4 were assessed. The 3-month time point was included to capture early postoperative metabolic and adipokine dynamics, whereas primary analyses focused on baseline-to-6-month changes to reflect more stable biological adaptations. Patients were classified as FABP4 responders (decrease from baseline to 6 months) or rebound/non-responders. Longitudinal changes were analyzed using Friedman tests, and between-group comparisons were performed using nonparametric methods.

Results: RYGB induced early and progressive anthropometric improvement, with BMI decreasing from 51.5 [48.1-55.2] kg/m^2 at baseline to 42.8 [39.6-46.9] at 3 months and 35.6 [32.4-38.9] at 6 months ($P < .001$). Systemic inflammation improved in parallel: IL-6 declined from 3.18 [2.27-4.44] pg/mL at baseline to 2.95 [2.31-3.82] at 3 months and 1.68 [0.96-2.95] at 6 months ($P = .00015$), while hsCRP decreased significantly over time ($P < .001$). In contrast, FABP4 trajectories demonstrated marked inter-individual variability. At 3 months, FABP4 changes showed no consistent directional pattern, despite early weight loss and improvement in inflammation. By 6 months, 46% of patients exhibited no decrease or a rebound in FABP4 levels. FABP4 responders experienced less pronounced BMI reduction compared with rebound/non-responders (ΔBMI −14.2 [−16.8 to −11.9] vs −18.6 [−21.4 to −15.1] kg/m^2; $P = .03$). Changes in FABP4 were not significantly correlated with changes in BMI, fat mass, hsCRP, or IL-6 (all $P > .05$). Fasting GLP-1 and PYY levels did not differ between FABP4 response groups.

Conclusions: Despite expected improvements in weight and systemic inflammation after RYGB, FABP4 responses are heterogeneous and only weakly related to anthropometric, inflammatory, or fasting incretin changes. These findings suggest that FABP4 reflects individualized adipose tissue–specific adaptive remodeling rather than a simple surrogate of weight loss or of improvements in inflammation following bariatric surgery.

EP586 - ECE_1480 - AI-enhanced ultrasound for early detection of diabetic nephropathy

Rostyslav Bubnov[1,2]

[1]*Zabolotny Institute of Microbiology and Virology, Kyiv, Ukraine;* [2]*Ultrasound, Clinical Hospital 'Pheophania', Kyiv, Ukraine*

Background: Diabetic nephropathy (DN) is a leading cause of chronic kidney disease (CKD) and a major contributor to cardiovascular and metabolic morbidity. Conventional renal ultrasound is widely available but remains operator-dependent and insufficiently standardized for detecting early metabolic and microvascular renal changes. A structured ultrasound-based framework integrating morphological, vascular, and biomechanical features may improve early identification of diabetic renal injury.[1-3] Artificial intelligence (AI) offers potential to enhance standardization while preserving expert-driven interpretation.

Objectives: To evaluate the feasibility of AI-assisted renal ultrasound analysis for detecting and stratifying diabetic nephropathy using a structured, patented ultrasound-based framework, with human expert control over anatomical sign validation and final diagnosis.

Methods: Renal ultrasound examinations were analyzed in 40 patients with type 2 diabetes mellitus and suspected diabetic nephropathy. Imaging was performed using B-mode ultrasound, intrarenal Doppler, and shear-wave elastography (SWE), following a structured ultrasound framework integrating predefined anatomical and functional criteria. Assessed features included cortical echogenicity and texture, corticomedullary differentiation, renal contour, parenchymal thickness, intrarenal resistive index (RI), and SWE-derived stiffness distribution. An AI-assisted analytical layer quantified image features, highlighted candidate pathological signs, and proposed pattern probabilities. Each detected feature and overall diagnostic classification were verified or corrected by an expert operator. Ultrasound patterns were differentiated from other metabolic CKD phenotypes, including hypertensive and obesity-related nephropathy, using combined structural, vascular, and biomechanical criteria.

Results: AI-assisted analysis consistently identified ultrasound features characteristic of diabetic nephropathy, including diffuse cortical echogenicity increase, gradual loss of corticomedullary differentiation, elevated intrarenal RI, and relatively homogeneous cortical stiffness on SWE. Human–AI synthesis improved consistency of feature recognition and supported classification of diabetic nephropathy as a distinct metabolic renal phenotype. Expert oversight was essential for correct anatomical interpretation, particularly in patients with overlapping metabolic comorbidities.

Conclusions: AI-assisted renal ultrasound analysis, applied within a structured ultrasound-based framework, enhances reproducibility and standardization of diabetic nephropathy assessment. This human-controlled AI approach supports early detection and differentiation of diabetic renal injury within the spectrum of

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

metabolic CKD, offering a noninvasive tool for precision stratification in patients with diabetes.

Introduction: Metabolic dysfunction-associated steatotic liver disease (MASLD) is one of the most common causes of chronic liver disease. Osteoporosis is a prevalent disease characterized by decreased bone density and disrupted bone structure, resulting in bone fragility and increased fracture risk. Denosumab is a monoclonal IgG 2 antibody used as a treatment of osteoporosis, since it binds to RANKL, inhibiting RANK activation. Recent research has shown that the increase of RANKL expression in hepatocytes may be related to inflammation and fatty infiltration, and thus, denosumab may offer an additional therapeutic option for the treatment of MASLD. The aim of this study is to assess the effects of certain approved anti-osteoporotic treatments (denosumab and alendronate) on MASLD and on the body composition.

Methods: We included 38 patients (mean age 63.61 ± 8.06) with osteoporosis and MASLD. Twenty patients received anti-osteoporotic treatment with denosumab and 18 with alendronate. Patients were evaluated at baseline and after 1 year of treatment. Liver transient elastography was performed to assess hepatic steatosis using controlled attenuation parameter (CAP) and to estimate the stage of fibrosis through liver stiffness measurements (FIB). Body composition and bone mineral density (BMD) were evaluated by dual-energy X-ray absorptiometry (DXA). We performed paired t-tests within each treatment group to compare baseline and one-year follow-up measurements and P-value < .05 was considered statistically significant.

Results: There was no statistically significant change regarding CAP either among patients treated with denosumab or alendronate. Moreover, no statistically significant change was observed in FIB in either group. However, regarding patients treated with denosumab paired t-test analysis showed a statistically significant reduction in body fat percentage after one year of treatment ($P = .039$), while there was no statistically significant change in patients treated with alendronate.

Conclusions: In this study, treatment for osteoporosis with denosumab and alendronate demonstrated a comparable profile regarding hepatic steatosis and fibrosis as assessed by transient elastography. The reduction in body fat percentage in patients treated with denosumab may suggest a potential metabolic effect of this drug and the absence of significant differences regarding MASLD may be related to the small sample size and the relatively short follow-up period.

Background: Lipoprotein(a) [Lp(a)] is a genetically determined lipoprotein primarily implicated in cardiovascular risk. Lipodystrophy syndromes are rare disorders characterized by adipose tissue deficiency and severe metabolic complications, including insulin-resistant diabetes, dyslipidemia, and a high prevalence of metabolic dysfunction–associated steatotic liver disease (MASLD). Recent studies have reported an inverse association between Lp(a) and MASLD. However, data on Lp(a) levels and their relationship with liver disease in lipodystrophy are lacking.

Methods: Cross-sectional study including 32 patients with partial lipodystrophy (PLD; 90.6% females, median [IQR] age 49 [25]

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

years) and 67 patients with obesity and type 2 diabetes (T2D; 50.7% females, age 57 [10] years). Hepatic steatosis prevalence was assessed by abdominal ultrasound. In a subset of patients ($n = 19$ PLD, $n = 21$ T2D), controlled attenuation parameter (CAP) and liver stiffness (LS) were also assessed by transient elastography. Lp(a) levels were measured using a standardized assay.

Results: Compared with T2D patients, PLD individuals were younger ($P = .02$), predominantly female ($P < .001$), with a worse metabolic profile (HbA1c 7.6 [2.5] vs 6.5 [1], $P = .003$; triglycerides 159 [169] vs 132 [121] mg/dL, $P < .01$), and a higher prevalence of ultrasound-detected hepatic steatosis (81 vs 64%, $P = .011$). Median [IQR] Lp(a) levels did not differ significantly between PLD and T2D (9.5 [28.5] vs 19 [56] nmol/L, $P > .10$) with more than 80% of individuals in both groups falling into the low-risk Lp(a) category (<75 nmol/L). However, PLD patients showed a higher prevalence of very low Lp(a) concentrations (≤10 nmol/L, $P < .02$). In T2D, Lp(a) levels were inversely associated with hepatic steatosis severity as assessed by CAP ($P = .003$). This association remained significant in multivariable models adjusting for age, lipids, HbA1c, lipid-lowering and antidiabetic therapies ($P < .01$). A moderate inverse correlation between Lp(a) and LS was also observed, particularly in patients aged ≥50 years and in those with hypertension ($P < .05$). No association between Lp(a), leptin, and hepatic parameters was observed in PLD.

Conclusions: Higher Lp(a) levels were associated with lower hepatic steatosis severity in patients with T2D, but not in lipodystrophy. The enrichment of very low Lp(a) levels in PLD, potentially reflecting their distinct metabolic milieu, may limit the utility of Lp(a) as a biomarker of cardiovascular and liver disease in this setting. Further studies are needed to clarify the role of Lp(a) in metabolic liver disease across different insulin-resistant phenotypes.

EP591 - ECE_3116 - Coexistence of multiple sclerosis and Grave's disease in a patient with type 1 diabetes mellitus: a rare case with challenging management

Vasiliki Antonopoulou, Aggeliki Kyriakou, Kalliopi Pantelia, Olga Papalou, Panagiotis Karageorgiou, Marinella Tzanela and Theodora Stratigou
Department of Endocrinology "D. Ikkos"- Diabetes Center-EndoERN-Evangelismos General Hospital, Athens, Greece

Background: Type 1 diabetes mellitus (T1DM) is an autoimmune chronic disease which is characterized by autoimmune destruction of pancreatic β-cells. Patients with T1DM are at increased risk of additional autoimmune diseases, most commonly autoimmune thyroid disease, reflecting shared genetic factors and immunopathogenic mechanisms. In contrast, the coexistence of T1DM and multiple sclerosis (MS) is less frequent, despite suggesting evidence of overlapping immune pathways. The simultaneous presence of T1DM, Graves' disease (GD), and MS in the same patient represents a rare but clinically significant manifestation.

Case presentation: We report a case of a 49-year-old patient with a history of T1DM diagnosed at the age of 4 years old initially treated with multiple daily insulin injections, with suboptimal glycemic control and recurrent hypoglycemic episodes. At the age of 26 years old she was diagnosed with MS with optic neuritis and right upper extremity weakness. Brain MRI revealed demyelinating lesions. She was initially treated with Interferon beta. Due to multiple relapses, she received fingolimod and later repeated courses of intravenous corticosteroids and is currently treated with cladribine. At the age of 47, the patient developed clinical and biochemical features of hyperthyroidism. Laboratory evaluation confirmed GD (TSH 0.01 μU/mL, T3 443 ng/dL, FT4 6.1 ng/dL, TSH receptor antibodies 18.7 U/L). Treatment with thiamazole was initiated, followed by radioactive iodine (RAI) therapy. One month after RAI, she developed overt hypothyroidism (TSH 38 μU/mL) and levothyroxine replacement was started. Six months later, she presented symptoms of hyperthyroidism and developed Graves' orbitopathy. Laboratory tests showed suppressed TSH (<0.004 μU/mL) with normal FT4 and T3 levels, with markedly elevated thyroid-stimulating immunoglobulins (TSI 29.79 U/L). Thyroid ultrasound demonstrated increased vascularity. Despite discontinuation of levothyroxine, hyperthyroid symptoms persisted and TSH suppression remained. Low dose thiamazole was re-introduced with thyroid function showing marked fluctuations thereafter. Regarding her diabetes, glycemic control significantly improved after initiation of an automated insulin delivery system. Notably, from her family history, mother has also MS.

Conclusions: This case describes a rare coexistence of multiple autoimmune diseases with an unstable course of Graves' disease following RAI therapy. It highlights the complex interplay of autoimmune processes across endocrine and other systems and indicates the challenges in management of patients with overlapping autoimmune conditions. Long term monitoring, close follow up and individualized multidisciplinary therapeutic approach are essential for the management of these complex, clinically significant cases.

EP593 - ECE_3589 - Therapeutic challenges of immune checkpoint inhibitor-induced type 1 diabetes within polyendocrinopathy: two case reports

Gergő Csitári
DBC-SZIEOK, Budapest, Hungary

Immune checkpoint inhibitors (ICIs) are increasingly used, highly effective antineoplastic agents that can induce a broad spectrum of immune-mediated endocrine adverse events involving multiple glands. Among these, hypophysitis, autoimmune thyroiditis and primary adrenal insufficiency are the most frequently reported entities, occurring either in isolation or as part of complex polyendocrinopathies. Development of endocrine toxicities has been associated with improved cancer outcomes, yet autoimmune insulitis with new-onset type 1 diabetes mellitus (T1DM) remains a relatively rare but clinically demanding complication.

This abstract presents two patients treated with combined anti-CTLA-4 and anti-PD-1 therapy who developed ICI-induced T1DM as the first immune-mediated endocrine event, followed by additional endocrinopathies, creating major challenges in glycaemic management.

The first case is a 52-year-old man with stage IV malignant melanoma treated with ipilimumab plus nivolumab. Before the fourth

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

treatment cycle, routine testing revealed asymptomatic but marked hyperglycaemia without ketoacidosis. Under multiple daily human insulin injections, glycaemic control initially stabilised, allowing ambulatory follow-up. Within one month, he was additionally diagnosed with adrenal insufficiency and hypothyroidism, necessitating glucocorticoid and levothyroxine replacement. Concomitant hormone substitution was accompanied by highly labile glycaemia at home, prompting transition to analogue basal–bolus insulin therapy. On maintenance nivolumab, his melanoma exhibits substantial regression and glucose control is acceptable, although he repeatedly declines insulin pump therapy and continuous glucose monitoring.

The second case is a 55-year-old woman with malignant pleural mesothelioma who also received ipilimumab plus nivolumab. Following the second cycle, severe multisystem immune-related toxicity with prominent urticarial manifestations led to discontinuation of immunotherapy. She was subsequently admitted repeatedly for diabetic ketoacidosis and painful oesophageal candidiasis. Under empiric systemic glucocorticoid treatment, glycaemic control proved extremely unstable with frequent hypoglycaemic episodes, which improved after tapering and switching methylprednisolone to hydrocortisone in the absence of clear clinical adrenal insufficiency. Autoimmune thyroiditis with hypothyroidism was diagnosed and treated with levothyroxine, while an ACTH stimulation test off steroids ultimately excluded primary adrenal insufficiency. Because of severely impaired metabolic control (HbA1c 11.6%), she was transitioned to analogue basal–bolus insulin in an inpatient setting, resulting in marked attenuation of glucose excursions and resolution of hypoglycaemia, though further basal insulin titration and planned CGM are required.

These cases illustrate that ICI-induced T1DM, particularly when embedded in evolving polyendocrinopathy, demands intensive, dynamically adjusted insulin therapy and close interdisciplinary follow-up to balance oncological benefit and endocrine safety.

Objectives: To evaluate the efficacy and safety of Synthetic Semaglutide Injection manufactured by Sun Pharma (Test arm) with Ozempic® Injection (Reference arm) in Indian patients with Type 2 Diabetes Mellitus in three subgroups based on Age: <40 years (Subgroup 1 [S1]), 40 to <50 years (Subgroup 2 [S2]), ≥50 years (Subgroup 3 [S3])

Materials and Methods: This was a phase III, multicentre, randomized, open-label, active controlled study. Total 314 adults (18-65 years) with T2DM (HbA1c: 7.0-10.5%) on diet/exercise uncontrolled with stable metformin dose (≥1500 mg or maximum tolerated dose) for ≥12 weeks were enrolled. Eligible patients were randomized in a 1:1 ratio and received Test product or Reference product, subcutaneous injections in a weekly dose of 0.25 mg to 2 mg for 24 weeks. [CTRI Registration number: CTRI/2025/02/080592]

Results: At baseline, distribution of patients was as follows: 54 patients aged <40 years *(S1)*, 107 patients aged 40 to <50 years *(S2)* and 153 patients aged ≥50 years *(S3)*. HbA1c reduction (±SD) from baseline to Week 24 in Test arm was comparable to Reference arm across all 3 age subgroups: *S1*: −1.85 ± 0.70% vs −2.20 ± 0.80% ($P = .2220$), *S2*:−2.05 ± 0.87% vs −1.92 ± 0.96% ($P = .4542$), *S3*: −2.10 ± 0.83% vs −1.88 ± 0.90% ($P = .1557$). Significant reduction from baseline in HbA1c was observed across all three sub-groups at Week 24 in both the study arms. Significant reductions in post-prandial and fasting blood glucose levels at Week 24 were seen in both study arms and the changes were comparable across all three age subgroups. Proportion of patients achieving HbA1c <7.0% were comparable between the Test and Reference arms, *S1*: 19 (86.4%) vs 24 (82.8%) ($P = .3426$), *S2*: 36 (72.0%) vs 34 (70.8%) ($P = .8843$), *S3*: 51 (72.9%) vs 50 (72.5%) ($P = .6315$) across all three age subgroups. Three patients experienced hypoglycaemia. None of the patients required rescue medication. The incidence of treatment-emergent adverse events (TEAEs) was similar in both arms. Most common TEAEs were gastrointestinal events (Diarrhoea, Nausea, Vomiting) in all three subgroups. Study medications were well tolerated.

Conclusions: Semaglutide injection (Test Product) demonstrated comparable glycaemic control to Reference product in T2DM patients uncontrolled on metformin monotherapy across all age groups.

EP597 - ECE_3330 - Hybrid closed-loop system in elderly people with diabetes; a center's experience

Dimitra Pappa, Maria Apostolopoulou, Stefanos Tamouridis, Eleftheria Barmpa, Anastasia-Konstantina Sakali and Alexandra Bargiota
Department of Endocrinology and Metabolic Diseases, University Hospital of Larissa, Larissa, Greece

Background and Aims: Hybrid closed-loop systems (HCLS) are widely used in diabetes management and are recommended in all ages. The question is how easy and convenient is for elderly people to use technology to improve their glycemic control and quality of life. Here we present the effect of HCLS on elderly patients in the real world setting of our clinic.

Methods: 14 patients with T1DM, older than 55 years old (mean age 62.85 ± 5.21 years old) (GroupA) attending our outpatient clinic participated in the study and six of them (42.85%) were older than 65 years (mean age 67.83 ± 3.31 years old) (Group B). CGS metrics such as time in range (TIR), time above range (TAR; 180-250 mg/dl, TAR250; >250 mg/dl) and below range (TBR; 54-70 mg/dl, TBR54; <54 mg/dl) at baseline and six months after the initiation of HCLS were studied in all participants.

Results: In GroupA (6/14 males, 8/14 females) mean diabetes duration was 29.11 ± 14.18 years. 7/14 were on multiple daily insulin injections (MDI) and 7/14 on subcutaneous continuous insulin infusion (SCII) before the initiation of HCLS. At baseline they had mean HbA1c 6.53 ± 3.02%, mean TIR 65.73 ± 13.46%, TAR 28.6 ± 10.43%, TAR250 6.9 ± 6.89%, TBR 1.59 ± 2.69% and TBR54 0.45 ± 0.96%. Six months post HCLS initiation the mean HbA1c was 6.81 ± 0.73% (r = −0.303, $P = 0.508$), mean increase in TIR 10.72 ± 15% (r = 0.563, $P = .045$) and mean decrease in TAR, TAR250, TBR and TBR54 were 11.12 ± 12.26% (r = 0.176, $P = 0.564$), 4.4 ± 5.89% (r = 0.534, $P = .06$), 0.83 ± 2.36% (r = 0.569, $P = .043$) and 0.35 ± 0.96% (r = 0.240, $P = .429$) respectively. In GroupB (5/6 males, 1/6 females) mean diabetes duration was 37 ± 10.27 years and 4/6 were on MDI and 2/6 on SCII before the initiation of HCLS. At baseline they had mean HbA1c 6.31 ± 3.25%, mean TIR 69.36 ± 10.97%, TAR 28.18 ± 9.85%, TAR250 4.8 ± 6.32%, TBR 0.45 ± 0.50% and TBR54 0.01 ± 0.04%. Six months post HCLS the mean HbA1c was 7.15 ± 0.82% (r = −0.277, $P = .723$) and had mean increase in TIR 14.15 ± 12.26% (r = 0.099, $P = .852$), and mean decrease in TAR, TAR250, TBR and TBR54; 13.15 ± 12.01% (r = −0.024, $P = .964$), 3.28 ± 5.45% (r = 0.617, $P = .192$), 0.00 ± 0.63% (r = 0.216, $P = .681$) and 0.01 ± 0.04% respectively.

Conclusions: HCLS seem to improve glycemic control and CGS metrics in all patients by increasing TIR and decreasing TAR, TAR250, and especially TBR and TBR54, eliminating hypoglycemic episodes, which is important regarding the comorbidities that they have. The same results were noted on GroupB as well, showing that with good training use of technology in elderly patients can be beneficial.

EP600 - ECE_2544 - Metabolic-reproductive restoration in obese women with polycystic ovary syndrome treated with tirzepatide: a one-year single-arm interventional study

Valentina Gavazova[1,2], Sylvia Pashkunova[1,2], Vesela Mihneva[1,2] and Tzvetelina Totomirova[1,2]
[1]Military Medical Academy, Sofia, Bulgaria; [2]Clinic of Endocrinology and Metabolic Diseases, Sofia, Bulgaria

Introduction: Polycystic ovary syndrome (PCOS) is a common endocrine disorder in women of reproductive age and is frequently associated with obesity, insulin resistance, hyperandrogenism, and ovarian dysfunction, leading to chronic anovulation and menstrual irregularities. Obesity further exacerbates both metabolic and reproductive abnormalities in PCOS and increases long-term cardiometabolic risk. Metformin is widely used to improve insulin sensitivity in PCOS, however, a substantial proportion of patients are unable to tolerate this treatment due to gastrointestinal or other adverse effects. Alternative therapies that provide sustained metabolic and reproductive benefits are therefore needed. Tirzepatide, a dual glucose-dependent insulinotropic polypeptide and glucagon-like peptide1 receptor agonist, induces significant weight loss and improves insulin sensitivity and may represent a novel therapeutic option for women with obesity-related PCOS who are intolerant to metformin.

Aim: To evaluate the effects of one year of tirzepatide treatment on body weight, metabolic parameters, and ovarian function in women with obesity and PCOS-associated ovarian dysfunction who were intolerant to metformin.

Materials and Methods: This one-year, single-arm interventional study enrolled 35 women of reproductive age diagnosed with PCOS according to established criteria, with a body mass index ≥30 kg/m^2 and intolerance to metformin. Participants received once-weekly subcutaneous tirzepatide with dose escalation according to standard clinical protocols. Assessments at baseline and during follow-up visits over 12 months included anthropometric measurements, fasting glucose and insulin levels, indices of insulin resistance, and reproductive hormone profiles, including total testosterone and sex hormone-binding globulin (SHBG). Ovarian function was evaluated based on menstrual cycle regularity and available ovulatory markers. Safety and tolerability were monitored.

Results: After one year, participants showed significant reductions in body weight and BMI. Metabolic parameters improved, with reduced fasting insulin levels and enhanced insulin sensitivity. Reproductive endocrine assessment revealed decreased androgen levels and increased SHBG concentrations. Clinically, many women experienced improved menstrual cycle regularity, with evidence suggestive of restored ovulatory function in those anovulatory at baseline. Improvements in ovarian function were associated with the magnitude of weight loss and metabolic improvement. Tirzepatide was generally well tolerated, with gastrointestinal symptoms being the most common adverse events and no serious treatment-related safety concerns observed.

Conclusions: One year of tirzepatide treatment was associated with significant weight loss, improved metabolic health, and favorable effects on ovarian function in women with obesity and

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

PCOS who were intolerant to metformin. These findings support tirzepatide as a potential therapeutic alternative and warrant confirmation in randomized controlled trials evaluating long-term reproductive outcomes.

EP601 - ECE_3403 - Morphofunctional assessment in patients undergoing allogeneic transplantation: clinical application of biva, nutritional ultrasound and dynamometry in prehabilitation programs

Rosa Natalia García Pérez, Víctor Siles-Guerrero, Aida Elhadri-Egea and Martín López de la Torre Casares
Hospital Universitario Virgen De Las Nieves, GRANADA, Spain

Introduction: Patients who are candidates for allogeneic hematopoietic stem cell transplantation (allo-HSCT) are at high risk of nutritional deterioration due to intensive treatment regimens, gastrointestinal toxicity, and systemic inflammatory response. Conventional nutritional assessment methods may underestimate this risk, particularly in individuals with excess body weight or altered body composition. In this context, emerging tools such as bioelectrical impedance vector analysis (BIVA), nutritional ultrasound, and handgrip dynamometry enable a more accurate evaluation of body composition and muscle function, providing information with potential prognostic value.

Objectives: To assess the nutritional and functional status of patients undergoing allo-HSCT using advanced techniques such as BIVA, rectus femoris nutritional ultrasound, and dynamometry, and to analyze the relationship between these variables and clinically relevant outcomes, including hospital admissions and survival.

Materials and Methods: : A prospective observational study was conducted in adult patients undergoing allo-HSCT at the Virgen de las Nieves University Hospital. Nutritional assessment was performed at different time points before and after transplantation, including anthropometric measurements, BIVA, nutritional ultrasound, and evaluation of muscle strength by dynamometry. Associations between morphofunctional parameters and clinical outcomes were subsequently analyzed.

Results: : A total of 31 patients were included, with a mean age of 44.3 years, of whom 45% were male. Significant sex-related differences were observed in body weight, body cell mass (BCM), and fat-free mass index (FFMI) ($P < .001$). Rectus femoris nutritional ultrasound parameters, including cross-sectional area (RF-CSA) and Y-axis, as well as handgrip strength, were significantly higher in male patients. Early initiation of nutritional prehabilitation was significantly associated with improvements in body weight ($r = 0.423$) and FFMI ($r = 0.409$). RF-CSA showed strong correlations with body weight, body circumferences, BCM, and FFMI ($r > 0.5$; $P < .001$). Phase angle correlated with handgrip strength, FFMI, body circumferences, and ultrasound parameters. Survival was significantly associated ($P < .05$) with higher values of Y-axis ($r = 0.633$), BCM ($r = 0.816$), and FFMI ($r = 0.833$).

Conclusions: The incorporation of advanced nutritional assessment tools such as BIVA, nutritional ultrasound, and dynamometry allows the identification of morphofunctional alterations with prognostic relevance in patients undergoing allo-HSCT. Their integration into nutritional prehabilitation programs may improve risk stratification and contribute to better clinical outcomes.

EP602 - ECE_3977 - Beyond waist circumference: the metabolic significance of preperitoneal circumference

Estefanía Chumbiauca[1,2], Adrián Gil Korilis[1], Lucia O. Connor[1], Javiera Concha[1], Patricia Yárnoz[1], Elena Martín[1], Camilo Silva[1], Nerea Varo[3], Gema Fruhbeck[1], Javier Escalada[1] and Carolina M. Perdomo[1]
[1]Pamplona, Spain; [2]Clinica Universidad de Navarra, Endocrinology, Pamplona, Spain; [3]Clínica Universidad de Navarra, Biochemistry Department, Pamplona, Spain

Background and Aims: Adiposopathy is characterized by metabolic dysfunction with progressive ectopic fat accumulation and lipotoxicity. Compared to subcutaneous adipose tissue (SAT), visceral adipose tissue (VAT) is more inflammatory and metabolically active, contributing more directly to systemic inflammation, metabolic syndrome (MS), and cardiovascular risk. Traditional measurements, such as waist circumference (WC) and waist-to-height ratio (WHtR), assess metabolic risk, but their performance relative to direct ultrasound measurement of specific fat compartments remains unclear. This study aims to compare conventional and emerging adiposity parameters for predicting MS.

Method: Evaluation of a cohort of 169 patients living with obesity (PlwO) between 20 and 78 years of age without anti-obesity pharmacological or surgical treatment, who attended the outpatient clinic of the Endocrinology Unit at Clínica Universidad de Navarra. MS criteria were defined according to the modified ATP III criteria. Adiposity assessment included: a) anthropometric measurements (BMI, neck circumference, hip circumference, WC, and WHtR); b) body-fat% (assessed through bioelectrical impedance analysis [BIA], and CUN-BAE); c) Visceral adipose tissue (assessed through BIA and abdominal fat ultrasound examination [SAT, preperitoneal adiposse tissue [PAT], and preperitoneal circumference [PC]). PC was calculated as = WC – ($2\pi \times$ SAT).

Results: In PlwO, PC showed the highest correlation with the number of fulfilled MS criteria, followed by WC ($r = 0.33$ [$P < .001$] and $r = 0.26$ [$P < .01$], respectively). No correlation was found with SAT ($r = -0.06$; $P = .46$) nor PAT ($r = -0.09$; $P = .23$). PC accounted for 9.90% of the variability in the number of fulfilled MS criteria, whereas the WC, SAT, and PAT accounted for 6.88%, 0.22%, and 0.98%, respectively. After adjusting for age and sex, a higher risk of fulfilling three metabolic criteria was observed across PC tertiles (T2: OR 1.61, 95% CI 0.68-3.81 [$P = .28$]; T3: OR 2.48, 95% CI 1.02-6.05 [$P < .05$]). Patients with a PC above the median had a higher prevalence of dyslipidemia and prediabetes/diabetes, higher glucose levels, and a greater proportion of men ($P < .05$).

Conclusions: In PlwO, PC is a meaningful indicator of metabolic risk, underscoring its potential clinical value. Its positive correlation with the number of fulfilled MS criteria, stronger than that observed for conventional validated measurements (WC and WHtR), suggests that PC may more accurately reflect metabolic burden. Abdominal fat ultrasound is an accessible, cost-effective, non-invasive screening tool that may enhance the identification of metabolic risk in PlwO.

EP603 - ECE_1189 - Effectiveness of a smartphone-assisted lifestyle intervention program on weight reduction: a retrospective study

Stanislav Kravchuk and Mykola Bychkov
Danylo Halytsky Lviv National Medical University, Department of Therapy No. 1, Medical Diagnostics, Hematology and Transfusion Medicine, Faculty of Postgraduate Education, Lviv, Ukraine

Background and Aims: Overweight, obesity, and metabolic dysfunction-associated steatotic liver disease (MASLD) remain major public health challenges, particularly among women of reproductive and working age. Mobile health (mHealth) programs that integrate nutritional, psychological, and behavioral components offer a scalable approach to support sustainable lifestyle change. This study aimed to evaluate the effectiveness of *The Body School*—a 3-month, smartphone-assisted lifestyle intervention combining dietary counseling, health education, guided cooking, and psychological support—in improving anthropometric outcomes among women with overweight and obesity.

Methods: A retrospective analysis was conducted using data from 101 women who completed the program between 2023 and 2024. The intervention included nutrition support delivered via a mobile app, educational modules, psychological guidance, and physical activity recommendations. Primary outcomes were changes in body weight, body mass index (BMI), and waist-to-hip ratio (WHR), self-recorded by participants within the app. The Wilcoxon signed-rank test was used for statistical analysis ($P < .001$).

Results: The program resulted in statistically significant improvements across all primary anthropometric parameters: median weight loss was 4.0 kg (–5%), BMI decreased by 1.83 kg/m^2, and WHR decreased by 0.016.

Discussion: These results are consistent with evidence supporting mHealth interventions for weight reduction, where modest (≈5%) weight loss yields meaningful metabolic benefits. Effectiveness may be driven by the program's multicomponent, personalized structure. Limitations include retrospective design and absence of a control group.

Conclusions: *The Body School* smartphone-assisted lifestyle intervention led to significant reductions in body weight, BMI, and WHR among women with overweight, with a mean participant age of 36.9 years. These findings highlight the program's potential as an effective digital tool for multidisciplinary weight management across various metabolic conditions, including MASLD.

EP605 - ECE_1324 - Acute pancreatitis and insulin-dependent diabetes Miletus following growth hormone therapy in a patient with Kearns–Sayre syndrome: a case report

Omar Alluhayyan[1], Abdullah Alshamrani[2], Ali Alqaraishi[2], Tarek Al-Dabbagh[2], Faisal Alrashed[3] and Sultan Alotaibi[3]
[1]*King abdulaziz medical city, Riyadh, Saudi Arabia;* [2]*KAMC, Riyadh, Saudi Arabia;* [3]*KSAU-HS, Riyadh, Saudi Arabia*

Background: Kearns–Sayre syndrome (KSS) is a rare mitochondrial disorder that could present with endocrine dysfunction, including diabetes mellitus and growth hormone deficiency. Recombinant growth hormone (rGH) is frequently prescribed to address short stature; however, its potential role in precipitating severe metabolic and pancreatic complications remain underappreciated.

Case Presentation: We describe a 16-year-old female with KSS receiving long-term recombinant growth hormone therapy who presented with acute deterioration characterized by polyuria, polydipsia, severe abdominal pain, vomiting, and altered mental status. She had no prior diagnosis of diabetes mellitus. Initial evaluation revealed profound high–anion gap metabolic acidosis (pH 7.08, bicarbonate 6.7 mmol/L), marked hyperglycemia (20.2 mmol/L), positive ketones, and striking elevation of pancreatic enzymes (lipase 2963 U/L, amylase 1665 U/L). Imaging confirmed acute pancreatitis without biliary pathology or pancreatic necrosis. The patient was diagnosed with severe diabetic ketoacidosis complicated by acute pancreatitis and acute kidney injury, requiring intensive care admission, intravenous insulin infusion, aggressive fluid resuscitation, and electrolyte correction. Growth hormone therapy was suspected to be the offending cause and discontinued. Further endocrine evaluation demonstrated elevated HbA1c (10.7%), undetectable C-peptide, and persistently negative pancreatic autoantibodies, supporting the diagnosis of insulin-deficient. She improved clinically and was transitioned to basal–bolus insulin therapy. Following up after discharge, she demonstrated excellent glycemic stability with low insulin requirements and a significant improvement in HbA1c (7.1%).

Conclusions: This case illustrates a severe and uncommon metabolic disorder in a patient with KSS, where insulin-dependent diabetes and acute pancreatitis presented simultaneously while on recombinant growth hormone therapy. It highlights the vulnerability of mitochondrial patients to abrupt beta-cell failure and pancreatic injury under metabolic stress. Clinicians should maintain a high index of suspicion for pancreatitis and dysglycemia in KSS patients receiving growth hormone, particularly when gastrointestinal or osmotic symptoms emerge, and consider closer metabolic surveillance in this high-risk population.

EP608 - ECE_3077 - Phosphocalcic profile and risk of calcium nephrolithiasis in patients with metabolic syndrome

Dhouha Ben Salah[1], Dana Jalouli[2], Mariam Mestiri[1], Khouloud Boujelben[1], Fatma Gargouri[2], Mouna Elleuch[1], Nadia Charfi[1], Faten Haj Kacem Akid[1], Mouna Mnif[1], Ayadi Fatma[2] and Nabila Rekik Majdoub[1]
[1]*Hedi Chaker University hospital, endocrinology, Sfax, Tunisia;* [2]*Habib Bourguiba University hospital, Biochemstry laboratory, sfax, Tunisia*

Background: Metabolic syndrome (MetS) is a major public health concern due to its high prevalence and associated complications. Beyond well-known metabolic and cardiovascular consequences, MetS has increasingly been linked to renal involvement, particularly urinary stone formation. Identifying early urinary risk factors in patients with MetS may help prevent future stone formation.

Methods: A descriptive cross-sectional study was conducted over a 13-month period in adult patients followed for metabolic syndrome according to the NCEP-ATP III criteria at the

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Endocrinology-Diabetology Department of Hedi Chaker University Hospital, Sfax.Clinical, nutritional, biochemical, and 24-hour urinary parameters were collected. Univariate and multivariate logistic regression analyses were performed to identify factors associated with lithogenic abnormalities.

Results: A total of 85 patients were included, median age was 54.04 ± 0.88 years , a female predominance was noticed (male-to-female ratio: 0.25),median body mass index (BMI) was 37.4 kg/m^2; 82.4% of patients were obese and 64.7% had morbid obesity. Thirty-three patients (38.8%) met three MetS criteria, while 23.5% met all five criteria.

Biochemically, hypo-HDL cholesterolemia was present in 51.8%, hypertriglyceridemia in 36.5%, and dysglycemia in 77.6%. Vitamin D deficiency was observed in 88.2% of patients. The median urinary pH was 5.45 . Lithogenic urinary abnormalities included hyperuricosuria (36.5%), hypomagnesuria (34.1%), hyperphosphaturia (28.2%), hypercalciuria (16.5%), and hyperoxaluria (2.4%). Crystalluria was detected in 17.6% of cases.

Univariate analysis of predictors of lithogenic risk associated with hypercalciuria showed that, in terms of social factors, patients with hypercalciuria had significantly lower age compared with those without hypercalciuria ($P = .01$). Concerning clinical factors, hypercalciuria was significantly more frequent in patients with higher BMI, morbid obesity, and excessive salt intake ($P = .001$ for each). Biological parameters showed no significant association between hypercalciuria and serum lipids profile, or fasting glucose levels. In multivariate analysis, BMI and excessive salt intake were independently associated with hypercalciuria, with adjusted odds ratios of 1.13 (95% CI: 1.03-1.24) and 14.8 (95% CI: 2.96-74.52), respectively. No significant association was found between the number of metabolic syndrome components and lithogenic factors; however, a non-significant increase in urinary oxalate ($P = 0.07$) were observed as the number of metabolic syndrome criteria increased.

Conclusions: Metabolic syndrome is a recognized risk factor for calcium nephrolithiasis, underscoring the need for targeted preventive measures. Systematic metabolic assessment and lifestyle interventions are recommended, with intensified evaluation and annual follow-up for patients with risk factors as Obesity and high sodium intake or biochemical abnormalities

EP609 - ECE_3125 - Hypoglycaemia awareness, nocturnal events and recurrence after severe hypoglycaemia in type 1 diabetes

Víctor Siles-Guerrero, Rosa Natalia García Pérez, Aida Elhadri-Egea and José Manuel Romero-Márquez
Hospital Universitario Virgen De Las Nieves, Granada, Spain

Introduction: Impaired hypoglycaemia awareness and nocturnal hypoglycaemia are well-recognised clinical features associated with an increased risk of severe hypoglycaemia in individuals with type 1 diabetes mellitus (T1DM). Despite advances in diabetes education and monitoring technologies, these factors continue to contribute substantially to emergency care utilisation and recurrent severe episodes. Real-world descriptive data may help to better characterise patients at particularly high risk.

Objective: To describe hypoglycaemia awareness status, nocturnal hypoglycaemia, and recurrence patterns in adults with T1DM attended for severe hypoglycaemia requiring emergency medical care.

Methods: A retrospective, descriptive study was conducted including 66 adults with T1DM who required pre-hospital emergency assistance for severe hypoglycaemia between 2018 and 2022. Clinical variables analysed included hypoglycaemia awareness status, presence of nocturnal hypoglycaemia, documented history of previous severe hypoglycaemia, and occurrence of new severe episodes after the index event during follow-up. Data were analysed using descriptive statistics.

Results: Hypoglycaemia unawareness was present in 43.9% of patients, indicating a high prevalence of impaired symptom recognition at the time of emergency attendance. Nocturnal hypoglycaemia was reported in 53.0% of cases, highlighting the frequent occurrence of events during periods of reduced supervision and delayed detection. More than half of the cohort (54.5%) had a documented history of previous severe hypoglycaemia prior to the index episode. During follow-up, 22.7% of patients experienced at least one new severe hypoglycaemic episode requiring emergency intervention. The coexistence of hypoglycaemia unawareness and nocturnal hypoglycaemia was common, defining a subgroup with particularly high vulnerability and recurrent exposure to severe events.

Conclusions: Among 66 adults with T1DM attended for severe hypoglycaemia, hypoglycaemia unawareness and nocturnal hypoglycaemia were highly prevalent, and recurrence after the index episode was frequent. These descriptive findings suggest that emergency attendance often identifies patients with persistent risk factors that may not be adequately addressed by routine diabetes care. Targeted strategies focusing on restoration of hypoglycaemia awareness and prevention of nocturnal events may be crucial following a severe episode.

EP610 - ECE_3132 - The impact of diabetes mellitus in community-acquired pneumonia. Retrospective study

Elona Xhardo Hysenbelli[1,2], Bledar Hysenbelli[3], Sofiela Telo[4], Suada Velo[5] and Dorina Ylli[6]
[1]Tirana, Albania; [2]University Hospital Tirana, Internal Medicine, Tirana, Albania; [3]University Hospital "Mother Teresa", Tirana, Albania; [4]University Hospital :Shefqet Ndroqi", Tirana, Albania; [5]University Hospital "Shefqet Ndroqi", Pulmonology, Internal Medicine, Tirana, Albania; [6]University Hospital :Mother Teresa", Endocrinology, Internal Medicine, Tirana, Albania

Background: Diabetes mellitus (DM) increases the risk of infections such as Pneumonia due to the toxic effects of hyperglycemia and imune system dysfunction.The association with Community-Acquired Pneumonia (CAP) remains underexplored. Hyperglycaemia on admission and during hospital stay, is a major risk factor for poor outcomes in diabetics with CAP.

Objective: This study aimed to evaluate the impact of new onset or previously diagnosed DM ,on clinical severity and outcomes of hospitalised patients with CAP.

Methods: In our retrospective study we included a total of 150 patients, hospitalised in e tertiary Hospital Center in Albania

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

during 2025 with a confirmed CAP diagnosis.The study population consisted of adults patients with evidence of new pulmonary infiltrates on chest computed tomography (CT).

Diabetic patients were classified in two groups, pre-existing and new onset diabetes. The outcomes were compared with non-DM patients with CAP. Data on demography, laboratory test results, hospital stays were recorded in a specific questionnaire. One variable and mulvariable logisc regression analysis was done with 95% confidence interval and p-value < 0.05 considered significant.

Results: A total of 150 patients were enrolled. The mean age was 64 years. 92 patients(62%) were men.The risk of acute respiratory failure and need of O2 therapy is higher in the group of known diabetes 63% vs 59% in new onset diabetes. Diabetics patients with CAP had on average 1.4 days longer hospital stay as compared to patients without DM ($P = .002$) . There was a significant higher ICU admission and mortality rate in diabetes patients ($P < .001$).

Conclusions: Our results show that Diabetes is not only a relevante risk factor for Community-Acquired Pneumonia but also it is associated with a severe clinical presentation, longer hospitalization time and higher mortality rates.

EP611 - ECE_3247 - Diabetic foot MRSA-naries: the utility of nasal swab MRSA rule-out in moderate-to-severe diabetic foot infection

Gustavo Rodrigues, Alice Monsanto, Tânia Carvalho, Ana Margarida Sobra, Bárbara Jesus, Cristina Ribeiro and Leonor Gomes
Unidade Local de Saúde de Coimbra, Department of Endocrinology, Diabetes and Metabolism, Coimbra, Portugal

Introduction: Methicillin-resistant *Staphylococcus aureus* (MRSA) is a relevant etiological agent in diabetic foot infections, being associated with greater therapeutic complexity and limited options for empirical antibiotic therapy. In this context, exclusion of MRSA colonization through nasal swab screening—widely used in hospital protocols—has been proposed as an indirect method to rule out infection by this microorganism. The rapid availability of results allows for narrowing of the initial antibiotic spectrum without the need to wait several days for culture results.

Goals: The aim of this study was to evaluate the clinical utility of nasal MRSA screening in excluding this microorganism as the infectious agent in patients with diabetic foot infection.

Materials and Methods: All patients hospitalized for diabetic foot infection who were assessed or admitted by the Endocrinology Department between January 2025 and January 2026 were included. Results of nasal MRSA swab screening were systematically recorded and compared with microbiological isolates obtained from wound exudate, tissue biopsy, or blood cultures.

Results: Thirty-five hospitalizations for diabetic foot infection were identified, with a median length of stay of 15.0 days (IQR 12.3-20.0). The mean age was 69.6 ± 12.7 years, and 77.1% of patients were male. Infection severity was classified as PEDIS IV in 27 cases (77.1%) and PEDIS III in 8 cases (22.9%). Microbiological isolation was obtained in 24 episodes, with the most frequently identified microorganisms being *E. faecalis* (28.5%), *M. morganii* (17.1%), and *S. agalactiae* (14.2%). Only one MRSA isolate was identified (2.9%).

Thirty-one patients (88.6%) had a negative nasal MRSA swab, and no MRSA was isolated in cultures from these patients (zero false negatives). Four patients (11.4%) had a positive nasal screening result, of whom only one had microbiological isolation of MRSA (ie, three false positives). Accordingly, nasal screening showed a sensitivity of 100% and a specificity of 91.18%; given the observed prevalence, the positive predictive value was 25.29% and the negative predictive value was 100%.

Conclusions: Despite limitations related to the small sample size and the low prevalence of MRSA, this study suggests the exclusion of MRSA colonization by nasal swab screening may represent a useful tool for optimizing empirical antibiotic therapy in patients with diabetic foot infection

EP612 - ECE_2277 - Changes in serum leptin levels during the insulin tolerance test in children with short stature

Katarzyna Majewska[1], Joanna Budzulak[1], Maria Buczyńska-Górna[1], Monika Naskręcka[2], Dominik Majewski[3] and Andrzej Kędzia[1]
[1]*Poznan University of Medical Sciences, Department of Pediatric Diabetes, Auxology and Obesity, Poznan, Poland;* [2]*Poznan, Poland;* [3]*Poznan University of Medical Sciences, Department of Internal Medicine, Poznan, Poland*

Introduction: Insulin is an important regulator of leptin secretion. However, its effects may vary depending on the duration of exposure, energy availability, or the body's metabolic status. The insulin tolerance test (ITT) is used in children with short stature to diagnose growth hormone deficiency (GHD). During this test, the body is exposed to a unique metabolic situation, when insulin is administered without food intake. ITT induces hypoglycemia, which in turn activates a counterregulatory response, including increased secretion of growth hormone (GH), as well as catecholamines, glucagon, and cortisol. This mechanism is supposed to restore normal blood glucose levels but may also affect leptin secretion. The aim of this study was to evaluate serum leptin response during ITT in children with short stature.

Methods: The study included 21 children and adolescents with short stature, aged 5 to 17 years, who were eligible for ITT due to suspicion of GHD. The control group consisted of 21 healthy children matched for age, gender, and BMI. In children with short stature, serum leptin was measured after an overnight fast (at baseline), and 60 minutes after intravenous insulin administration, along with serum glucose and GH concentrations. In the control group, only fasting leptin was assessed.

Results: Fasting leptin levels were significantly higher in children with short stature than in the control group ($P = .010$). During the ITT in children with short stature, mean leptin levels before and after 60 minutes of the test were similar ($P = .903$). However, detailed analysis revealed significant differences in leptin responses depending on baseline levels. Patients with lower baseline leptin concentrations (below 10 ng/mL) showed further

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

decrease, while those with higher baseline leptin concentrations (above 10 ng/mL) showed further increase. Differences in these patterns were statistically significant ($P = .001$).

Conclusions: Regulation of leptin secretion during the insulin tolerance test seems to differ depending on baseline leptin concentrations. In children with short stature and suspected GHD, lower fasting leptin levels may reflect energy deficiency and lead to a further decrease in leptin in response to insulin administration and hypoglycemia. In contrast, in children with higher baseline leptin levels, usually associated with greater fat mass, a further increase in leptin following insulin administration may reflect a higher overall energy status. In children with short stature, leptin may be a useful marker of energy balance and perhaps also a modulator of the somatotropic axis.

EP613 - ECE_2026 - Changes in β1 adrenergic receptor and tyrosin hydroxylase expression in the pancreas of male rats in a metabolic syndrome model

Abigail Hernández-Munive[1,2], Dania Pérez-Ricardo[1], Marcia Hiriart[1] and Myrian Velasco Torres[1]
[1]*Ciudad de México, Mexico;* [2]*Instituto de Fisiología Celular, Neurociencia cognitiva, 04510, Mexico*

Metabolic syndrome (MS) is a cluster of interconnected metabolic abnormalities that significantly increases the risk of developing cardiovascular diseases, type 2 diabetes (DM2), and other health problems. Characterized by insulin resistance, abdominal obesity, dyslipidemia, and hypertension, metabolic syndrome is a growing global health concern. Within this context, autonomic dysregulation, particularly sympathetic overactivity, emerges as a critical factor in the progression of islet dysfunction and impaired glucose homeostasis. Tyrosine hydroxylase (TH) is a rate-limiting enzyme in catecholamine synthesis and a key marker of sympathetic activity. Also, alterations in the expression of adrenergic receptors (AdRe), such as β1, may reflect dysfunction of pancreatic innervation under chronic metabolic stress. Therefore, we investigated these neural-endocrine markers, which are essential to understand how the sympathetic-islet axis is reorganized during the transition from insulin resistance to pancreatic failure. Aim: Analyze the abundance of β1- AdRe and TH in pancreatic islets of male rats in a MS model. Methodology: Two-month-old male Wistar rats were divided into control (tap water) and MS (20% sucrose in drinking water) for 2 (2M) and 6 (6M) months, respectively. Measurements included body weight, body length, abdominal circumference, and quantification of fat mass. An insulin resistance test was performed by measuring peripheral glucose levels after an ip insulin bolus. After 2 or 6 M treatment, the animals were anesthetized with sodium pentobarbital, the pancreas was extracted, embedded in paraffin, and sectioned (40 µm) for immunofluorescence of β1-AdRe, insulin, and TH of β in consecutive slices of the pancreas. Results: animals in the MS model showed increases in body weight, abdominal circumference, peripancreatic fat, and peripheral insulin resistance. This increase was more pronounced in those animals with 6M treatment. There was a decrease in β1- AdRe fluorescence in the islets of animals with 2M, which was not observed in the 6M treatment animals. As for insulin, there was a decrease in fluorescence in the 2M animals, which was more pronounced in the animals that spent 6 months drinking sugary water. Finally, TH abundance increased in the islets with 6 M treatment. In conclusion, our findings demonstrate that chronic sucrose consumption induces a progressive reduction in pancreatic insulin content, likely reflecting sustained hypersecretion and an early downregulation of adrenergic receptors, indicating a neural-endocrine effort to modulate pancreatic function. The significant increase in TH abundance at six months suggests a sympathetic hyperinnervation of the islets in response to sustained metabolic stress.

EP614 - ECE_3590 - Liver receptor homolog-1 regulates aldehyde dehydrogenase 1 family member B1 in hepatic ethanol metabolism

Min-Hee Seo[1] and Seung-Soon Im[1,2]
[1]*Keimyung University School of Medicine, Physiology, Daegu, South Korea;* [2]*Keimyung University School of Medicine, Physiology, Daegu, South Korea*

Ethanol is metabolized and detoxified by multiple enzymes in the liver. Previous research has shown that ethanol consumption promotes lipid accumulation in hepatic tissue. Liver receptor homolog-1 (LRH-1) participates in controlling lipid and bile acid metabolism; however, its contribution to ethanol metabolism is not well defined. Thus, this study sought to clarify the relationship between ethanol-induced hepatic lipid accumulation and LRH-1. To investigate the role of LRH-1 in hepatic ethanol metabolism, LRH-$1^{f/f}$ and liver-specific LRH-$1^{f/cre+}$ mice were given a liquid ethanol diet for three weeks. LRH-$1^{f/cre+}$ mice displayed increased liver mass, higher neutral fat content, and elevated total cholesterol levels. Serum markers of liver injury, as well as acetaldehyde concentrations, were also higher in LRH-$1^{f/cre+}$ mice receiving ethanol. Furthermore, ethanol-fed LRH-$1^{f/cre+}$ mice showed reduced fatty acid oxidation, compromised mitochondrial function, and elevated reactive oxygen species. To identify LRH-1 targets in ethanol metabolism, RNA-sequencing was performed, revealing marked alterations in fatty acid metabolism-regulating genes between the control and ethanol-treated groups. Under LRH-1 deficiency, genes involved in ethanol metabolism showed a pronounced reduction in Aldehyde Dehydrogenase 1 Family Member B1 (ALDH1B1) expression. Conversely, LRH-1 overexpression in HepG2 cells increased ALDH1B1 levels, and ChIP-sequencing confirmed LRH-1 binding peaks within the ALDH1B1 promoter region. In summary, this study reveals that LRH-1 depletion downregulates ALDH1B1 expression, leading to acetaldehyde accumulation and enhanced intrahepatic fat deposition.

Keywords LRH-1, ALDH1B1, ethanol metabolism, liver

Ukraine; [2]State Scientific Institution "Center for Innovative Medical Technologies of the National Academy of Sciences of Ukraine", Department of Surgery, Kyiv, Ukraine; [3]State Scientific Institution "Center for Innovative Medical Technologies of the National Academy of Sciences of Ukraine", Department of Laboratory diagnostic, Kyiv, Ukraine

Background: Cardiovascular autonomic neuropathy (CAN) is a serious risk factor for cardiovascular disease and mortality in patients with diabetes mellitus and obesity. Glucagon-like peptide-1 (GLP-1) is a pleiotropic incretin with numerous functions besides glucose control. However, an association between CAN and level of GLP-1 in obesity was not fully investigated.

Aims: The aim of this study was to investigate the correlation of CAN and level of GLP-1 in obesity

Materials and Methods: We examined 62 patients with obesity (aged 49.2 ± 1.77 years, BMI – 35.03 ± 0.75 kg/m^2) (data are presented everywhere as mean±SEM). All patients were performed cardiovascular autonomic reflex tests (CARTs) by Ewing and investigated level of fasting GLP-1 and GLP-1 one hour after meal. The diagnosis of CAN was confirmed in patients with two or more positive tests. The statistical analysis was performed using SPSS statistical package version 25.0 for Windows.

Results: We found positive correlation between levels of fasting GLP-1 and the total score of CARTs, B (95% CI) 1.11(0.28/1.94), $P = .01$ and levels of GLP-1 one hour after meal B (95% CI) 0.76(0.16/1.35), $P = .015$. The blood pressure response to standing up have positive correlation with levels of fasting GLP-1 B (95% CI) 0.12 (0.009/0.24), $P = .035$ and with levels of GLP-1 one hour after meal B (95% CI) 0.087 (0.006/0.168), $P = .035$.

Conclusions: We investigated correlation between the total score of CARTs by Ewing with the levels of GLP-1, GLP-1 one hour after meal, the blood pressure response to standing up which could suggest the possible effect incretin GLP-1 in the development of CAN and sympathetic autonomic dysfunction in patients with obesity.

EP619 - ECE_3041 - Challenging diagnosis in endogenous hyperinsulinism: a case of islet cell hyperplasia mimicking insulinoma

Madalina-Bianca Stan[1,2,3], Ioana Herghea[1,2], Cristina Andreea Bordeianu[1,2], Ana-Teodora Enache[1,2], Cristian Mugur Grasu[4,5], Octav Ginghina[6,7] and Madalina Musat[1,2]
[1]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [2]C.I. Parhon Romanian National Institute of Endocrinology, Bucharest, Romania, Endocrinology, Bucharest, Romania; [3]National Institute of Endocrinology "C.I. Parhon", Endocrinology, Bucharest, Romania; [4]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [5]Fundeni Clinic Institute Romania, Department of Radiology, Bucharest, Romania; [6]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [7]Oncology Institute Bucharest Romania, Department of Surgery III, Bucharest, Romania

Introduction: Endogenous hyperinsulinism is most commonly caused by insulinoma. However, rare non-neoplastic conditions such as diffuse or focal islet cell hyperplasia (nesidioblastosis) can present with a similar clinical and biochemical picture. Differentiating between insulinoma and islet cell hyperplasia is crucial, as it impacts surgical planning and long-term outcomes. Preoperative localization is often challenging, and imaging findings may be misleading.

Case Report: We present the case of a 43-year-old woman with a 7 month history of severe hypoglycemia (30 mg/dL), accompanied by profuse sweating, dizziness, and transient dyslexia. The initial episode occurred during hospitalization, while she was diagnosed with a urinary tract infection and treated initially with ciprofloxacin, which led to acute kidney injury. Over the subsequent months hypoglycemic events reoccurred. While liver, kidney, thyroid and adrenal function tests were normal, markedly elevated insulin levels (>300 μIU/mL) and increased C-peptide (2.51 ng/mL) during a spontaneous hypoglycemic episode confirmed endogenous hyperinsulinism. As diazoxide was not available, methylprednisolone was initiated to aid glycemic control, resulting in partial improvement of hypoglycemic episodes. Imaging studies showed conflicting results: abdominal CT revealed a cephalic pancreatic lesion, while endoscopic ultrasound identified a lesion in the body-tail region, which was biopsied but without histopathological confirmation. Octreoscan was negative for somatostatin receptor-positive lesions and MRI/MRCP revealed a small nodular lesion 8/5mm, non-characteristic for insulinoma, at the border between the pancreatic body and tail. Laparoscopic surgery was performed; due to poor intraoperative localization, a corporal-caudal pancreatectomy with splenectomy was carried out. Histopathology revealed islet cell hyperplasia without evidence of a neuroendocrine tumor. Postoperatively, the patient's glycemic status normalized, and she remained asymptomatic.

Conclusions: This case highlights the diagnostic and localization challenges in endogenous hyperinsulinism. Despite biochemical and imaging findings suggestive of insulinoma, histopathology demonstrated a non-neoplastic cause.

EP620 - ECE_1681 - Dynamics of Incidence and Prevalence of Type 2 Diabetes in the Republic of Belarus

Tatsiana Mokhort[1] and Olga Salko[2]
[1]Belarusian State medical University, Minsk, Belarus; [2]Republican Center for Medical Rehabilitation and Balneotherapy, Minsk, Belarus

Objective: To assess the dynamics of the incidence and prevalence of type 2 diabetes (T2D) in the Republic of Belarus in the period from 1993 to 2024.

Materials and Methods: Data from the official statistics of the Ministry of Health were used for the analysis.

Results: For more than 30 years in the Republic of Belarus, since 1993, there has been a steady increase in the incidence of T2D from 60.55 to 382.18 per 100,000 population, with a natural decline in the pandemic period 2020-2022. During analyzed period, the incidence increased 6.3 times. The noted increase in the incidence of diabetes mellitus 2 is the result of active detection of the disease in risk groups and popularization in the media in accordance with the state program. At the same time, there is an increase in the prevalence of T2D (from 185.3 to 4418.81 per 100,000 population), which is due to an increase in life expectancy with type 2 diabetes. The World Health Organization has set a goal of detecting T2D in 80% of patients suffering from

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

this disease. The estimated detection targets for T2D for 2025 are 5.8%, with an increase to 7.6% in 2030. Currently, the proportion of patients with DM is 4.45%, which indicates that this goal has not been achieved. When building an exponential trend based on primary morbidity data, an estimated indicator was obtained, which should reach 660.55 per 100,000 population in 2030.

Conclusions: It is necessary to step up measures to detect T2D through further screening and expansion of risk groups, as well as raising awareness about this in the media. The projected increase in primary morbidity requires management decisions to optimize the provision of care to this category of patients.

EP621 - ECE_1794 - High prevalence of comorbid insomnia and sleep apnea in type 2 diabetes: a novel AI-wearable diagnostic approach

Ka Shing Yan[1], Pui Sze Grace Hui[2], Chak Yan Isaac Kwok[3], Hai Ka Betty Young[2], Yin San Florence Wong[2], Man Chi Wong[2], Lydia Leung[4], Cynthia Cheung[4] and Chih-Wei Tsai[4]
[1]*Tung Wah Eastern Hospital, Hong Kong, Hong Kong;* [2]*Hong Kong, China;* [3]*Tung Wah Eastern Hospital, Department of Clinical Psychology, Hong Kong, Hong Kong;* [4]*Belun Technology Company Limited, Hong Kong, Hong Kong*

Introduction: Sleep disorders, common in type 2 diabetes (T2DM), exacerbate health outcomes but are rarely screened for systematically in routine diabetes care, particularly in Asia where data remain limited. Comorbid insomnia and obstructive sleep apnea (COMISA) carries the highest cardiovascular burden, yet its prevalence and characteristics in Chinese patients with T2DM are poorly understood. This study estimated the prevalence of sleep disorders in a T2DM cohort and evaluated the utility of an artificial intelligence (AI)-powered wearable device, the Belun Ring (BR), in a novel diagnostic workflow for identifying sleep disorders.

Methods: An interim analysis included 29 adults with T2DM from a diabetes center in a community hospital. Screening used the STOP-BANG questionnaire for obstructive sleep apnea (OSA) and the Insomnia Severity Index (ISI). Those with ISI $\geq$8(indicating sub-threshold insomnia) or STOP-BANG $\geq$3 underwent $\geq$3 nights of BR assessment. The device generated objective data on sleep efficiency (SE), sleep onset latency (SOL), wake after sleep onset (WASO), apnea-hypopnea index based on 3% oxygen desaturation (AHI3%), and heart rate variability (HRV). Diagnostic thresholds were AHI3% $\geq$15 events/h for OSA and SE $\leq$85% for insomnia; COMISA was defined when both were present.

Results: Suspected sleep disorders were nearly universal (97%, 28/29). COMISA was most common (52%), followed by insomnia (24%) and OSA (21%). OSA-only patients were younger (median 51 years) versus COMISA or insomnia (63-64 years). Subjective ISI scores poorly distinguished groups ($P = .4$). In contrast, BR-derived objective metrics revealed clinically meaningful distinctions: SE was highest in OSA (86%), intermediate in COMISA (73%), and lowest in insomnia (69%) ($P < .01$). Insomnia showed prolonged SOL and WASO, while COMISA and OSA displayed elevated AHI3% (27 events/h and 31 events/h vs 11 events/h in insomnia; $P < .001$ and $P < .05$). HRV indices, including the standard deviation of NN intervals and root mean square of successive differences, were significantly higher in COMISA than in either condition alone ($P < .05$).

Conclusions: This interim analysis reveals a near-universal presence of sleep disorders, especially COMISA, among Chinese patients with T2DM. The BR provided objective insights that enhanced diagnostic precision beyond questionnaires. A stepped workflow—initial STOP-BANG and ISI screening (with ISI $\geq$8) followed by BR confirmation—offers a scalable, resource-efficient approach that reduces reliance on polysomnography while maintaining accuracy. Larger studies are needed to validate this AI-wearable-assisted pathway and support its integration into T2DM care for earlier detection and improved outcomes.

EP627 - ECE_3175 - Pathway to treatment of pediatric patients with type 1 diabetes mellitus diagnosed in Philippine Children's Medical Center

Melissa Joyanne Tolosa[1,2,3]
[1]*Bacolod City, Philippines;* [2]*Corazon Locsin Montelibano Memorial Regional Hospital, Bacolod, Philippines;* [3]*Dr. Pablo O Torre Memorial Hospital, Bacolod City, Philippines*

Objectives: This study aims to describe the pathway to treatment of children diagnosed with type 1 diabetes mellitus (T1DM) in a pediatric tertiary government hospital, to determine the intervals between symptom onset and treatment and to compare these intervals between patients with mild and severe presentations of T1DM.

Materials and Methods: This cross-sectional study, conducted from November 2024 to January 2025, involved direct participant interviews using an interview guide. Participants included children aged 1-18 with T1DM and their caregiver. They were classified as "mild" or "severe" based on their initial presentation. Using Walter's Pathway to Treatment, intervals were analyzed and classified as prolonged if exceeding two standard deviations from the mean. Descriptive statistics summarized demographic data, while mean and standard deviation were used to analyze intervals. An independent sample t-test compared intervals between mild and severe presentations, and a chi-square test assessed differences in the proportion of "prolonged" versus "not prolonged" intervals.

Results: Among the 66 participants, most were 6-12 years old (51.52%) and female (62.12%). The pathway to treatment takes an average of 60.46 + 63.52 days, exceeding durations reported in foreign studies. Appraisal interval (41.95 $\pm$ 58.74 days) was the longest, and the help-seeking interval (4.04 $\pm$ 8.57 days) the shortest. While total duration was comparable between groups, diagnostic ($P = .035$) and treatment ($P = .002$) intervals were significantly shorter in severe cases. Despite these differences, most participants fell into the "not prolonged" category across all intervals.

Conclusions: To reduce the alarmingly long pathway to treatment, public health interventions must prioritize improving early symptom recognition among caregivers. Simultaneously, healthcare systems should be strengthened to ensure timely diagnosis and treatment for all children, regardless of symptom severity at presentation.

EP630 - ECE_1981 - Ketogenic diet in adult refractory epilepsy: experience from Reina Sofía University Hospital, Córdoba

Carmen Zurera Gomez[1,2], Pilar Pérez Reyes[3], Concepción Muñoz[3], Ana María Moyano-Sánchez[3], Jose Carlos Estevez[3], Nazaret Pelaez[1], Isabel Martorell Ferrer[1], Maria Angeles Galvez Moreno[1] and Alfonso Jesús Calañas Continente[1]

[1]Hospital Universitario Reina Sofía, Endocrinology and Nutricion, Córdoba, Spain; [2]Hospital Reina Sofía, Endocrinology, Córdoba, Spain; [3]Hospital Universitario Reina Sofia-Resonancia Magnética y Tac, Córdoba, Spain

Background: The ketogenic diet (KD) is a high-fat, very low-carbohydrate dietary therapy that induces nutritional ketosis and may reduce neuronal excitability. We describe clinical/dietary characteristics and evaluate efficacy, safety and adherence in adults with drug-resistant epilepsy treated at our centre.

Methods: Observational, descriptive, prospective study of adults with drug-resistant epilepsy treated with KD between 2023 and 2025. We recorded epilepsy aetiology, KD modality, caloric prescription and ketogenic ratio, seizure response (>=50% reduction; seizure freedom), changes in anti-seizure medications, adverse events, and reasons for treatment discontinuation.

Results: Twenty-two patients were included (14 women, 8 men), median age 29 years (IQR 21-36). The most frequent aetiologies were genetic/structural epileptic encephalopathies (36%), post-infectious epilepsy (23%) and symptomatic focal epilepsies (18%). KD modalities were modified Atkins diet (41%), classical KD (3:1/4:1) (27%), medium-chain triglyceride (MCT) KD (23%) and low glycaemic index treatment (9%). Median caloric intake was 1800 kcal/day (IQR 1650-2200) with a mean KD ratio of 1.9:1; mean active follow-up was 8.6 months. Ten patients (45%) achieved >=50% seizure reduction; three (14%) became seizure-free; nine (41%) had no response. Seven patients (32%) reduced the dose and/or number of anti-seizure medications. Lennox-Gastaut syndrome and GLUT1 deficiency showed the best responses (>90% seizure reduction). Mild-to-moderate adverse events occurred in 12/22 (54%), most frequently weight loss >5% (n = 9), gastrointestinal symptoms (n = 5) and dyslipidaemia (n = 3); mild hypoglycaemia (n = 1) and hypercalciuria (n = 1) were also observed. No severe metabolic complications were reported. Seven patients discontinued the diet; reported reasons included adherence barriers (failure to achieve ketosis, difficulty maintaining dietary restrictions or unwillingness to change dietary habits), lack of efficacy, and gastrointestinal intolerance (persistent constipation or MCT-related diarrhoea).

Conclusions: In adults with drug-resistant epilepsy, ketogenic dietary therapy was effective and generally safe, with clinically relevant seizure improvement in 45% and seizure freedom in 14%, and allowed anti-seizure medication reduction in about one third of patients. Adherence remains the main challenge.

EP632 - ECE_3944 - Acute endocrine dysfunction following Immune checkpoint inhibition

Nuno Faria, Rita Ribeiro, Patrícia Brito, Olinda Marques, Catarina MacHado and Vera Fernandes

Unidade Local de Saúde de Braga, Endocrinology department, Braga, Portugal

Immune checkpoint inhibitors (ICI) are increasingly used in the treatment of advanced-stage malignancies. Among their adverse effects, autoimmune manifestations are notable, with endocrinopathies being among the most frequently reported.

We describe the case of a 46-year-old woman with a history of autoimmune thyroiditis (not requiring replacement therapy) and triple-negative breast carcinoma, who initiated neoadjuvant chemotherapy combined with pembrolizumab. One week after the first pembrolizumab cycle, she presented to the emergency department with three days of persistent vomiting and costochondral pain. Laboratory evaluation was compatible with diabetic ketoacidosis (glucose 607 mg/dL; ketone bodies 6.8 mmol/L; pH 7.09; HCO_3^- 4.2 mEq/L; anion gap 27 mEq/L) and thyrotoxicosis (TSH 0.025 mIU/L [reference range 0.55-4.78]; free T3 2.35 pg/mL [reference range 2.3-4.2]; free T4 1.87 ng/dL [reference range 0.89-1.76]). She denied any classical symptoms of hyperglycemia or thyrotoxicosis. She required intravenous insulin, fluid resuscitation and beta-blockade, with rapid improvement of metabolic parameters.

During recovery, she developed overt hypothyroidism (TSH 32.47 mIU/L; free T4 0.54 ng/dL; free T3 1.62 pg/mL), a pattern consistent with destructive thyroiditis, prompting levothyroxine initiation. Further evaluation showed low C-peptide levels (0.09 ng/mL; glucose 249 mg/dL), HbA1c of 7.5%, and positivity for anti-GAD and anti-ZnT8 antibodies, supporting the diagnosis of pembrolizumab-induced type 1 diabetes mellitus. She was discharged with plans for continued pembrolizumab therapy and endocrinology surveillance.

Currently, the patient presents acceptable glycemic control on a basal-bolus insulin regimen (total daily dose of 42U), is euthyroid on 150 ug/day of levothyroxine, and remains in remission from breast cancer after completing immunotherapy.

This case illustrates the rare occurrence of dual autoimmune endocrinopathies induced by ICI therapy within a short time frame, presenting with minimal clinical warning signs. It reinforces the importance of close endocrine monitoring during immunotherapy, as early recognition and prompt management are essential to ensure metabolic stability and safe continuation of oncologic therapy.

EP633 - ECE_2052 - Effects of time-restricted eating on glycemic control in type 2 diabetes: A 12-week quasi-experimental single-arm study

Kun Yang[1], Wei Fu[1], Rongsong Tang[1], Jingpin Wang[1] and Tianpei Hong[2]

[1]Peking University Third Hospital, Beijing, China; [2]Beijing, China

Background & Aims: Time-restricted eating (TRE) is a newly emerging dietary strategy that reduces body weight and

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

improves glucose tolerance in individuals with overweight or obesity. However, whether TRE is effective in improving glycemic control in individuals with diabetes remains unexplored. Herein, we aimed to investigate the effects of TRE intervention on glycemic control in patients with type 2 diabetes.

Methods: In this single-center, open-label, self-controlled trial, 32 overweight or obese adults with type 2 diabetes inadequately controlled on lifestyle modification alone or in combination with metformin and/or a-glycosidase inhibitors were enrolled to receive a 10-hour TRE for 12 weeks. The effects of TRE on glucose metabolism, body weight, body composition and other metabolic parameters were evaluated in these participants following the intervention.

Results: The 12-week TRE intervention not only significantly reduced body weight (-3.37 ± 2.74 kg, $P < .001$), but also remarkably improved glycemic control, with reduced glycated hemoglobin (HbA1c; $-0.83\% \pm 0.59\%$, $P < .001$) and fasting blood glucose (-1.38 ± 1.62 mmol/L, $P < .001$) levels. In addition, TRE also significantly reduced triglyceride level (−0.24 mmol/L [−0.58 to 0.01 mmol/L], $P < .001$) after 12 weeks of intervention.

Conclusions: TRE can improve glycemic control in individuals with type 2 diabetes. Our findings indicate that TRE may represent a novel diet management option for patients with type 2 diabetes.

EP634 - ECE_2287 - The role of Multidisciplinary team in the management of Metabolic dysfunction-associated steatotic liver disease (MASLD) in Obese individuals

Thaw Htet[1,2], Brooke Hughes[3], Julia Gordon[3], Judy Chen[1], Martina Preda[4] and Veronica Preda[1,2]
[1]*Macquarie University Hospital, Endocrine department, Sydney, Australia;* [2]*Macquarie University, Faculty of Medicine Health and Health Sciences, Sydney, Australia;* [3]*Macquarie University, Sydney, Australia;* [4]*I-MED Radiology, Sydney, Australia*

The diagnostic criteria for MASLD have evolved to incorporate the definition of hepatic steatosis with inclusion of cardiometabolic risk factors. Current management guidelines recommend lifestyle interventions, such as dietary changes and increased physical activity, supported by a multidisciplinary team (MDT). However, real-world data on the effectiveness of MDT-led care for MASLD remains limited, despite the growing prevalence of MASLD alongside rising obesity rates. This study aimed to evaluate the impact of multidisciplinary input, including dietetics and an exercise physiologist support, on MASLD and its associated biochemical markers.

A retrospective cohort study was conducted on patients presented for weight management under care of endocrinologists, with access to multidisciplinary care. Inclusion criteria required evidence of hepatic steatosis and at least one cardiometabolic risk factor (elevated BMI, HbA1c, hypertension, or dyslipidaemia) and two serial liver ultrasonograms. Outcomes were assessed before and after a minimum of six months of MDT involvement, focusing on changes in liver ultrasonograms, weight, HbA1c, fasting lipid profile, and FIB-4 scores.

In a total of 75 patients, more than 50% of the patients were managed by MDT input. Diet advice was based on principles of the Mediterranean diet and patients were encouraged to practice mindful eating, control portion servings and self-monitor their caloric intake. Exercise regimens were tailored to the individual preference including increasing incidental activity, engaging in moderate intensity aerobic exercise, and incorporating 2 resistance training sessions per week.

Participants with MDT input experienced greater weight reductions with a mean reduction of 15 kg (14%) in the MDT group compared to 6 kg (6%) in the non-MDT group. The mean reduction in BMI was also greater in the MDT group, with a 5.5 kg/m^2(13%) compared to 2 kg/m^2(6 %). Mean hepatic steatosis severity grade had improved from 1.87 to 1.23 in the MDT group, with a mean reduction of 0.65(33 %) compared with negligible improvement of 0.07(8.82%) in non-MDT group. However, the changes in FIB-4 scores was not significantly different in the two. In the type 2 diabetes patients, no significant difference in HbA1c reduction in between MDT and non-MDT groups.

Our findings support the value of structured MDT care in achieving meaningful clinical improvements in MASLD. Longitudinal patient engagement appears to be the key, highlighting the importance of integrating MASLD management into the broader obesity and metabolic health strategies.

EP635 - ECE_2659 - Shorter smartGuard™ warm-up duration is associated with better early glycaemic control in medtronic minimed™ 780G users

Ivana Dora Vodanović[1], Antonia Precali[2], Maja Baretić[1,3], Karin Zibar Tomsic[1] and Ivana Kraljevic[1,3]
[1]*University Hospital Centre Zagreb, Department of Endocrinology, Zagreb, Croatia;* [2]*Oxivita Hyperbaric Medicine Polyclinic, Zagreb, Croatia;* [3]*School of Medicine, University of Zagreb, Zagreb, Croatia*

Background: Manufacturer guidance specifies a 48-hour warm-up period (starting at the first midnight after insulin delivery begins) before SmartGuard™ (SG) activation. In clinical practice, some centres extend manual mode beyond this period.

Aim: To assess whether the duration of SG warm-up period is associated with differences in glycaemic control.

Methods: This retrospective observational study included all nonpregnant adult patients with type 1 diabetes who initiated 780G treatment for the first time from April 2021 to November 2024 in University Hospital Centre Zagreb. Baseline patient characteristics and continuous glucose monitoring data extracted from CareLink™ Clinic software were analyzed.

Glucoregulation parameters (time in/above/below range—TIR/TAR/TBR; glucose management indicator—GMI; average glucose—AG) were analyzed at baseline (P0, prior to 780G initiation), two weeks after SG initiation (P1), and three months after SG initiation (P2).

Participants were stratified into two cohorts: SGWU1 (SmartGuard warm-up ≤ 4 days) and SGWU2 (SmartGuard warm-up > 4 days). Between-group comparisons were adjusted for baseline glycaemic control and prior use of an insulin pump.

Results: We analyzed 98 participants (age 31.4 ± 10.4 years, diabetes duration 16.7 ± 7.8 years; 62.2% female) and compared data across three periods between SGWU groups. Overall, SGWU1 showed more favorable glycaemic profiles than SGWU2: higher TIR (≈71.0% vs 66.2%; $P = .0094$), lower TAR (≈25.4% vs 30.5%, $P = .0044$), lower GMI (6.92 vs 7.08, $P =$

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

.0363), and lower AG (8.29 vs 8.74 mmol/L, $P = .0068$). No significant difference emerged for TBR.

Between-group differences were most prominent for P1 (TIR 75.7% vs 69.8%, $P = .0080$; TAR 21.8% vs 28.1%, $P = .0065$; GMI 6.79 vs 7.00, $P = .0117$; AG 8.06 vs 8.54 mmol/L, $P = .0107$), whereas findings for P2 were borderline for TIR (78.1% vs 74.9%, $P = .0606$) and TAR (19.7% vs 23.1%, $P = .0725$), with no impact on GMI, AG, or TBR.

Within-group analyses showed significant improvements from P0 to P1 and P0 to P2 in both groups, with no significant change from P1 to P2.

Conclusions: Earlier SG activation is associated with better early glycaemic profiles, while differences attenuate by 3 months. These findings do not support prolonged manual-mode warm-up beyond the manufacturer's 48-hour requirement.

Objectives: To evaluate the efficacy and safety of Synthetic Semaglutide Injection manufactured by Sun Pharma (Test arm) with Ozempic® Injection (Reference arm) in Indian patients with Type 2 Diabetes Mellitus (T2DM) in three subgroups based on BMI: <23 kg/m^2 (Subgroup 1 [S1]), 23 to <25 kg/m^2 (Subgroup 2 [S2]), ≥25 kg/m^2 (Subgroup 3 [S3]).

Materials and Methods: This was a phase III, multicentre, randomized, open-label, active controlled study. Total 314 adults (18-65 years) with T2DM (HbA1c: 7.0-10.5%) on diet/exercise uncontrolled with stable metformin dose (≥1500 mg or maximum tolerated dose) for ≥12 weeks were enrolled. Eligible patients were randomized in a 1:1 ratio and received Test product or Reference product, subcutaneous injections in a weekly dose of 0.25 mg to 2 mg for 24 weeks. [CTRI Registration number: CTRI/2025/02/080592].

Results: At baseline, distribution of patients was as follows: 38 patients with BMI <23 kg/m^2 *(S1)*, 72 patients with BMI 23 to <25 kg/m^2 *(S2)* and 204 patients with BMI ≥25 kg/m^2 *(S3)*. HbA1c reduction from baseline to Week 24 in Test arm was comparable to comparator arm: *S1*: $-2.26 \pm 0.91\%$ vs $-1.89 \pm 0.87\%$ ($P = .2028$), *S2*: $-2.21 \pm 0.76\%$ vs $-2.25 \pm 0.74\%$ ($P = .9033$), *S3*: $-1.95 \pm 0.82\%$ vs $-1.85 \pm 0.95\%$ ($P = .4848$). Significant reduction from baseline HbA1c was observed across all three sub-groups at Week 24 in both the study arms. Significant reductions in post-prandial and fasting blood glucose levels at Week 24 were seen in both the study arms and the changes were comparable across all three BMI subgroups. Proportion of patients achieving HbA1c <7.0% were comparable between the Test and Comparator arms, *S1*:15 (88.2%) vs 13 (76.5%) ($P = .3697$), *S2*: 23 (74.2%) vs 27 (75.0%) ($P = .7267$), *S3*: 68 (72.3%) vs 68 (73.1%) ($P = .9184$) across all three BMI subgroups. Three patients experienced hypoglycaemia. None of the patients required rescue medication. The incidence of treatment-emergent adverse events (TEAEs) was similar in both arms. Most common TEAEs were gastrointestinal events (Diarrhoea, Nausea, Vomiting) in all three subgroups. Study medications were well tolerated.

Conclusions: Semaglutide injection (Test product) demonstrated comparable glycaemic control to Reference product in T2DM patients uncontrolled on metformin monotherapy across all three BMI subgroups of normal weight, overweight and obese patients.

Background: Polycystic ovary syndrome (PCOS) is a heterogeneous endocrine disorder among women of reproductive age, often linked to obesity, yet how body mass index (BMI) and waist-hip ratio (WHR) vary across PCOS phenotypes in unselected populations remains unclear. Therefore, this study aimed to examine BMI and WHR patterns in a large multiethnic cohort of women with and without PCOS.

Methods: A community-based study from eight countries across four continents was included. The primary outcomes were BMI and WHR. Correlations between variables were assessed using Spearman's rank correlation coefficient, and multicollinearity was evaluated using the variance inflation factor (VIF). Clinical features were compared between non-PCOS and PCOS, and stratified across PCOS phenotypes: classic (hyperandrogenism [HA], ovulatory dysfunction [OD], and/or polycystic ovary morphology [PCOM]), phenotype C (HA and PCOM), and phenotype D (OD and PCOM). Multiple linear and logistic regression analyses were used.

Results: This study comprised 9240 women representing 11 ethnic groups, of whom 45.2% were Asian Chinese (Han), followed by 22.2% Persians. Overall, 11.4% of participants were women diagnosed with PCOS, with nearly half exhibiting the classic phenotypes (48.4%). Among women with PCOS, 58.0% had normal BMI, 18.5% were overweight, and 11.7% were obese, while 12% had WHR defined central obesity. Classic and phenotype C were statistically associated with higher BMI, whereas the odds of central obesity were higher in women with classic and phenotype D subtypes.

Conclusions: Our findings indicate that in unselected populations, the majority of women with PCOS exhibit a normal BMI, in contrast to clinic-based cohorts, where obesity is markedly overrepresented. Classic and phenotype C were characterized with increased overall adiposity, whereas classic and phenotype D were distinguished by central fat accumulation, highlighting distinct patterns of body fat distribution across PCOS phenotypes. Longitudinal, population-based studies integrating multi-omic data are essential for unraveling BMI-related heterogeneity to advance precision diagnosis and management in PCOS.

Background: While alterations of the gut microbiome and its pathophysiological role in the context of obesity have been extensively studied, the role of the nasal microbiome remains unexplored.

Methods: 50 participants with obesity and 50 age- and sex-matched lean individuals at the age 18-55 years were enrolled in the study. Each participant was assessed for olfactory function using the Burghart (ODOFIN) Sniffin' Sticks Test. Anthropometric parameters, vital signs and systemic metabolic and inflammation blood parameters were assessed. Nasal swabs were obtained from the anterior nares. Nasal swab microbiome analysis was performed using 16S rRNA gene sequencing targeting the V3–V4 region. Sequence data were processed in QIIME2 using DADA2 for denoising and taxonomic assignment against the Greengenes2 reference database. Associations were evaluated using regression and correlation analyses with adjustment for body mass index.

Aim: To assess if the nasal microbiome composition is altered in individuals with obesity compared to sex- and age-matched lean controls and to elucidate if the nasal microbiome is associated with alterations in olfactory sensory perception and systemic markers on metabolism and inflammation.

Results: In total, 50 participants with obesity with a mean age of 36.2 ± 10.73 and a BMI 37.06 ± 4.96 kg/m^2 and 50 lean participants with a mean age of 36.02 ± 10.69 and a BMI 22.68 ± 1.98 kg/m^2 were enrolled. Olfactory function and olfactory threshold was impaired in the obesity compared to the lean group. Alpha diversity analyses of the nasal microbiome revealed significantly higher microbial diversity in the obesity group compared to the lean group, as assessed by Shannon entropy ($\chi^2 = 10.562$, $P = .001$) and species richness ($\chi^2 = 12.232$, $P = .0005$). Beta diversity analysis further demonstrated a significant difference in microbial community composition between the groups (PERMANOVA: $R^2 = 0.055$, $F = 4.46$, $P = .001$). The differential abundance analysis of sequence variants between the groups revealed that the presence of *Staphylococcus hominis* was associated with an obesity phenotype and, independent of BMI, with low HDL levels ($P = .004$*), while the presence of *Dolosigranulum pigrum* was associated with a lean phenotype and low LDL levels. Alterations in olfactory function were not associated with alterations in the nasal microbiome composition.

Conclusions: The diversity and composition of the nasal microbiome are associated with BMI and differ between lean individuals and individuals with obesity. The abundance and presence of

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Staphylococcus hominis are associated with an obesity phenotype and lower HDL level.

[1]Chellaram Diabetes Institute, Pune, India; [2]Bhaktivedanta Hospital and Research Institute, Thane, India; [3]Amrita institute of Medical Sciences and Research Centre, Kochi, India; [4]G.S.V.M medical College, Kanpur, India; [5]Jawahar Lal Nehru Medical College, Ajmer, India; [6]King George Hospital, Visakhapatnam, India; [7]Moti Lal Nehru Medical College, Prayagraj, India; [8]Mandya Institute of Medical Science, Mandya, India; [9]M.L.B Medical college, Jhansi, India; [10]Pulse Multispecialty Hospital, Pune, India; [11]KIDS Hospital, Bhubaneswar, India; [12]Vincare Hospital, Bathinda, India; [13]Citizen Hospital, Bangalore, India; [14]Sahyadri Super Speciality Hospital, Pune, India; [15]Supe Heart and Diabetes Hospital and Research Centre, Nashik, India; [16]OJAS Multispeciality Hospital, Pune, India; [17]Medstar Speciality Hospital, Bangalore, India; [18]Panacea Hospital, Nashik, India; [19]MMFHA Joshi Hospital, Pune, India; [20]Janta Hospital and Maternity Center, Varanasi, India; [21]Chettinad Hospital & Research Institute, Chengalpattu, India; [22]Sun Pharma Laboratories Limited, Mumbai, India

Objectives: To evaluate the efficacy and safety of synthetic semaglutide injection (Test drug) compared with Wegovy® (Reference drug) dosage up to 2.4 mg subcutaneously for weight management in mild renal impairment patients (eGFR 60 to <90 mL/min/1.73 m^2).

Materials and Methods: A phase III, multicentre, randomized, open-label, active-controlled clinical study (CTRI/2025/04/085487) was conducted across 22 study sites in India after receiving regulatory and ethics committee approvals. In this study, 267 adult patients with (BMI) ≥ 30 kg/m^2 or ≥27 kg/m^2 with the presence of at least one co-morbidity of hypertension, dyslipidaemia and/or type 2 diabetes mellitus were included. Patients were randomized to receive either test drug or reference drug weekly subcutaneously for 24 weeks.

Results: Total 101 patients with eGFR 60 to <90 mL/min/1.73 m^2 at baseline were included in this study. In this group mean (±SD) percentage reduction in weight from baseline to week 24 was −14.2 (± 3.17) with test drug and −13.7 (± 2.82) with reference drug. The decrees in weight with the test and the reference drug was comparable ($P = .6248$).

The proportion of patients achieving ≥ 5% weight loss was 98.6% with test drug and 100% with reference drug ($P = .5403$) at week 24. The proportion of patients achieving ≥10% weight loss was 88.7% with test drug and 86.7% with reference drug ($P = .6028$) at week 24 At Week 24, Mean (± SD) change from baseline in BMI with test and the reference drug was − 4.76 (± 1.14) kg/m^2 and −4.67 (± 1.12) kg/m^2 respectively ($P = .5494$). Mean (± SD) change in waist circumference with test and the reference drug was −10.2 (± 4.59) cm and −9.57 (± 3.50) cm respectively ($P = .5098$) at week 24. The change in BMI and waist circumference was comparable between the test and the reference drug at week 24

In diabetic patients there was decrease in glycaemic parameters (HbA1c, FBG and PPBG) from baseline to week 24 in both S1 and S2 and was comparable between arms ($P > .05$). In non-diabetic patients decrease in glycaemic parameters (HbA1c, FBG and PPBG) from baseline to week 24 was not clinically relevant compared to diabetic patients and was comparable between arms ($P > .05$).

Study medications were well tolerated.

Conclusions: Semaglutide injection is effective in reducing weight in mild renal impairment patients and can be a treatment of choice in management of weight in patients with mild renal impairment.

Objectives: To evaluate the correlation between weight loss and quality of life as assessed by SF-36 (36 item shoer form survey) questionnaire in patients treated with Semaglutide injection for weight management

Materials and Methods: This phase III, multicentre, randomized, open-label, active-controlled clinical study (CTRI/2025/04/085487) was conducted across 22 study sites in India after receiving regulatory and ethics committee approvals. Total 267 adult patients with BMI ≥ 30 kg/m^2 or ≥ 27 kg/m^2 with the presence

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

of at least one co-morbidity of hypertension, dyslipidaemia and/or type 2 diabetes mellitus were included. Patients were randomized to either test arm to receive synthetic semaglutide injection or reference arm to receive Wegovy® every week subcutaneously for 24 weeks. The primary endpoint was change in body-weight from baseline to week 24. Secondary endpoints included change in BMI, waist circumference, SF-36, and glycaemic measures in diabetic and non-diabetic patients. Safety assessments included incidence of TEAEs and anti-drug/neutralizing antibody. This post-hoc analysis was conducted to evaluate the correlation between weight loss and improvement in quality of life as assessed by SF-36 physical function score.

Results: The Pearson's correlation coefficient between change in weight loss and SF-36 physical functioning score was −0.155 with *P* value = .0467 in test arm.

The Pearson's correlation coefficient between change in weight loss and SF-36 physical functioning score was -0.046 with *P* value = .6831 in reference arm.

There is negative correlation between weight loss and change in SF-36 physical functioning score in both test and reference arm indicating greater reduction in weight loss is associated with more increase in SF-36 score signifying improvement is SF-36 total score. The correlation between weight loss and improvement in SF-36 physical functioning score was statistically significant in test arm. The statistical significance observed in the Pearson correlation analysis in test arm supports the robustness of this association.

Conclusions: This post-hoc analysis demonstrated that there is improvement in quality of life as measured by SF-36 physical function score with reduction in weight, in patients treated with semaglutide injection for weight management.

EP641 - ECE_2044 - Transition from autoantibody-negative to autoimmune type 1 diabetes following COVID-19 infection and vaccination: a report of four cases with delayed onset

Nurcan Ince[1], Berna Evranos Ogmen[2,3], Oya Topaloglu[2], Reyhan Ersoy[2] and Bekir Cakir[2]

[1]Trabzon Legal Training And Research Hospital, endocrinology and metabolism diseases, Yomra, Türkiye; [2]Ankara Yıldırım Beyazit Üniversitesi Tip Fakültesi, endocrinology and metabolism diseases, Ankara, Türkiye; [3]Ankara yildirim beyazit university, endocrinology and metabolism, Ankara, Türkiye

Introduction: Type 1 diabetes mellitus(T1DM) is an autoimmune disorder characterised by the destruction of pancreatic β-cells, typically identified through markers such as glutamic acid decarboxylase(GAD65) antibodies.While environmental triggers for T1DM are well-documented, the emergence of COVID-19 and its vaccines has introduced new concerns regarding their potential role in triggering autoimmune responses.This study reports four cases where patients previously diagnosed with non-autoimmune(antibody-negative) diabetes transitioned to autoimmune T1DM following COVID-19 infection and/or vaccination.

Methods: We retrospectively evaluated patients at Ankara Bilkent City Hospital whose anti-GAD levels were measured and were positive between September 2020 and August 2022. Four patients(two males, two females; age range 42-52 years) with a confirmed history of autoantibody-negative diabetes were identified.Clinical and laboratory data, including C-peptide levels, HbA1c, and vaccination/infection timelines, were extracted from electronic medical records.

Results: At the time of initial diabetes diagnosis, all four patients tested negative for GAD65 antibodies and urine ketones.Following COVID-19 infection or vaccination, all four patients developed high GAD65 antibody titres(ranging from 595 to >2000 IU/mL) and low C-peptide levels(0.16 to 0.36 ng/mL).Notably, Cases 3 and 4 also had pre-existing Hashimoto's disease. Unlike many cases in existing literature, the onset of autoimmunity in these patients was delayed; the time from infection to antibody measurement ranged from 171 to 619 days, and from vaccination to measurement ranged from 5 to 704 days(Table 1).None of the patients experienced a "honeymoon phase" or diabetic ketoacidosis at the time of antibody positivity. All four patients eventually required intensive multiple insulin therapy to maintain glycaemic control.

Discussion: These findings suggest that SARS-CoV-2 and its vaccines may act as triggers for autoimmune T1DM, even in patients with a multi-year history of non-autoimmune diabetes.The delayed presentation in these cases highlights the complexity of post-COVID autoimmunity and suggests that β-cell destruction may be progressive in some individuals.Further research and global registries are essential to clarify the long-term impact of COVID-19 on the incidence and pathogenesis of autoimmune diabetes.

Table 1

Feature	Study Cases(n = 4)	Typical Literature Cases
Initial Diabetes Status	Known autoantibody-negative (non-autoimmune)	Often, new-onset or unknown prior antibody status
Onset Timing	Delayed: 171-619 days post-infection; up to 704 days post-vaccine	Acute: Typically within 3 days to 8 weeks post-vaccination
Ketoacidosis (DKA)	None observed at the diagnosis of autoimmunity	Common:~41.7% in some vaccine-related reviews
Clinical Symptoms	Absence of overt/acute hyperglycemic symptoms	Often present with acute clinical symptoms
Honeymoon Phase	None observed; required immediate intensive insulin	Possible; some cases managed with diet or OADs temporarily

Abstract citation ID: lvag096.1072

EP642 - ECE_3992 - The first case of insulin autoimmune syndrome (Hirata's Disease) in A Qatari female: a case report

Shafik Mansour[1,2] and Shaimaa Arroub[1]

[1]Doha, Qatar; [2]Hamad Medical Corporation, Qatar Metabolic Institute, Doha, Qatar

Background: Insulin Autoimmune Syndrome (IAS), also known as Hirata's disease, is a rare cause of insulin-mediated hypoglycemia, mostly reported in East Asian populations. This condition is characterized by circulating autoantibodies that bind to endogenous insulin, creating large complexes that act as a reservoir, releasing high amounts of "free" insulin unexpectedly, causing hypoglycemia. Fewer than 10 cases have been reported

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

in Arab nationals, and to date, no cases have been documented in Qatari national. Herein, we report the first case of IAS in a Qatari woman.

Case Presentation: A 39-year-old Qatari woman presenting with a three- week history of recurrent symptomatic hypoglycemia occurring approximately two weeks after discontinuing a short course of prednisolone therapy prescribed for recurrent pregnancy loss. The hypoglycemic episodes are mainly 2-4 hours after meals. Continuous glucose monitoring revealed a characteristic pattern of postprandial hyperglycemia (200-220 mg/dL) followed by severe hypoglycemia (40-50 mg/dL). She has normal liver, renal, and adrenal functions. Laboratory evaluation during a documented hypoglycemic episode (plasma glucose 59 mg/dL) revealed markedly elevated insulin levels (760 μU/mL; reference 2.6-24.9 μU/mL) and C-peptide levels (21 ng/mL; reference 1.1-4.4 ng/mL) with an insulin-to-C-peptide molar ratio of 1.1. Cross-sectional imaging excluded pancreatic lesions. Insulin autoantibody testing confirmed the diagnosis with markedly elevated titers at 84 nmol/L (reference <0.4 nmol/L). Treatment with prednisolone 20 mg daily resulted in complete symptom resolution and progressive normalization of antibody titers to 0.62 nmol/L after eight weeks of therapy. At three months post-steroids discontinuation, the patient remained free of hypoglycemia evident by normal continuous glucose monitoring.

Conclusions: This represents the first documented case of IAS in a Qatari national, highlighting the importance of recognizing this condition outside the traditionally affected East Asian populations to avoid unnecessary invasive diagnostic procedures or pancreatic surgery.

Abstract citation ID: lvag096.1073

EP645 - ECE_3285 - A comprehensive analysis of significant muscle loss associated with weight loss after sleeve gastrectomy

Ie Byung Park[1], Seung Joon Choi[2,3] and Dae Ho Lee[4]
[1]*Gachon University Gil Medical Center, Department of Endocrinology and Metabolism, Incheon, South Korea;* [2]*Incheon, South Korea;* [3]*Gachon University Gil Medical Center, Department of Radiology, Incheon, South Korea;* [4]*Shihwa Medical center, Department of Endocrinology and Metabolism, Siheung-si, South Korea*

Background and Purpose: Changes in body composition after bariatric surgery, particularly skeletal muscle alterations, are important determinants of metabolic health during weight loss. This study evaluated post-sleeve gastrectomy (SG) changes in body composition, focusing on skeletal muscle parameters and their metabolic associations.

Materials and Methods: This prospective cohort study included 83 morbidly obese patients undergoing SG. Clinical and metabolic variables, including 101 plasma metabolites, were measured preoperatively and at six months postoperatively. Body composition was assessed using dual-energy X-ray absorptiometry (DXA) for appendicular skeletal muscle mass (ASM), lean body mass, and total body fat, and magnetic resonance imaging (MRI) for abdominal adipose tissue, intramuscular fat, skeletal muscle index (SMI), contractile mass index (CMI) at the L3 level, and proton density fat fractions of skeletal muscle, liver, and pancreas. Statistical analyses were performed to identify factors associated with skeletal muscle loss after SG.

Results: After SG, significant reductions were observed in total body fat (−37.0%) and muscle fat (−21.1%) with a dramatic reduction in liver fat (−70.5%), which was accompanied by muscle loss (ASM −12.4%, SMI −23.9%, CMI −21.0%).Changes in SMI were positively correlated with changes in body weight and total body fat. Of note, SMI changes were negatively correlated with 3-hydroxybutyric acid ($r = -0.465$) and 3-hydroxyoctanoic acid ($r = -0.400$).

Conclusions: Weight loss after SG causes significant skeletal muscle loss, potentially impairing metabolic health, underscoring the need for muscle preservation strategies postoperatively.

Abstract citation ID: lvag096.1074

EP646 - ECE_3942 - A comparative study of the well-being of patients with varicose disease of the subcutaneous veins of the lower extremities and type 2 diabetes during treatment with various thermal ablation methods

Khrystyna Moskva, Taras Kikhtiak and Olesya Kikhtyak
STATE NON-PROFIT ENTERPRISE "DANULO HALYTSKY NATIONAL MEDICAL UNIVERSITY IN LVIV", Lviv, Ukraine

Objective: To evaluate the efficacy of endovenous laser ablation (EVLA, 1470 nm wavelength) and radiofrequency ablation (RFA) in the management of patients with varicose vein disease (VVD) and type 2 diabetes mellitus (T2DM), utilizing both individualized and standardized questionnaires.

Materials and Methods: The study involved 82 patients with VVD and T2DM from Lviv between 2022 and 2024, with no prior treatment history. Patients were divided into two groups: Group I with VVD and Group II with VVD plus T2DM. Each group was further split into two subgroups: EVLA-I, RFA-I, and EVLA-II, RFA-II. Follow-up assessments were conducted before treatment (Visit 1), on day 3 (Visit 2), and 1 month post-treatment (Visit 3). At each visit, patients were assessed using the VCSS (Varicose Clinical Severity Score), VAS (Visual Analogue Scale), and a self-administered questionnaire (SAQ).

Results: VCSS scores dropped significantly ($P < .05$) after 1 month in all subgroups of VVD and VVD + T2DM, showing both thermal ablation techniques are effective. Comparing the pain intensity on the VAS scale between EVLA-I and RFA-I, and EVLA-II and RFA-II, a significant difference ($P < .05$) was found during control examination Visit 1 (4.3 ± 0.43 and 2.7 ± 0.36 for EVLA-I; 4.5 ± 0.41 and 2.4 ± 0.33 for RFA-I) and Visit 2 (3.6 ± 0.25 and 2.4 ± 0.17 for EVLA-II; 3.1 ± 0.27 and 2.1 ± 0.2 for RFA-II), indicating a higher pain intensity under the influence of ELA regardless of the study group (VCH or VCH+CD-2). At Visit 1, 46% of patients in EVLA-I and 67% in RFA-I reported no complaints. After one month (Visit 3), these numbers rose to 92% and 97%, respectively. The choice of thermal technique didn't significantly affect the "no complaints" rate between Visits 1 and 3. The VVD + T2DM group showed a smaller increase, indicating that carbohydrate metabolism disorders impact recovery, seen in more frequent and longer neurological symptoms (numbness, tingling).

Conclusions: Total VCSS scores dropped after one month in both groups, regardless of the ablation method. RFA caused less pain than EVLA during and three days post-treatment. According to a

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

self-questionnaire, RFA led to fewer complications like numbness and tingling after a month, although paresthetic symptoms were worse in VVD + T2DM patients, no matter the method.

EP647 - ECE_3971 - Impact of anthropometric measures and obesity on left ventricular remodeling

Cvetanka Volkanovska Ilijevska, Irfan Ahmeti, Valentina Velkoska Nakova, Natasha Nedeska Minova, Ljubica Georgievska Ismail, Valnetina Andova and Marija Zivkovic
Medical Faculty, Ss. Cyril and Methodius, University Clinic for Endocrinology, Diabetes and Metabolic Disorders, Endocrinology, Skopje, North Macedonia

Obesity is a major risk factor for heart failure, causing structural and functional myocardial changes. This study evaluated whether obesity independently predicts alterations in myocardial structure and function in overweight and obese individuals and assessed correlations of obesity severity and duration with myocardial remodeling and deformation.

In this cross-sectional study, 126 participants (mean age 45 ± 9.6 years; 58.7% female) with BMI > 25 kg/m² were classified into four BMI groups. Mean BMI was 35 kg/m², waist circumference was 111.9 cm, and hip circumference was 118.4 cm; 74% had obesity for >10 years. Cardiac structure and function were assessed by 2D transthoracic echocardiography, and myocardial deformation by speckle tracking echocardiography (GLS%, GRS%, GCS% for LV; PALS%, PACS% for LA). Correlations were analyzed using Pearson and/or Spearman coefficients, and stepwise linear regression identified independent predictors of remodeling.

LV and LA structural and functional changes significantly correlated with obesity degree and duration. Increased interventricular septal and posterior wall thickness correlated with waist circumference ($r = 0.216$, $P = .015$; $r = 0.385$, $P = .0001$) and waist-to-hip ratio ($r = 0.208$, $P = .02$; $r = 0.293$, $P = .001$), particularly in females. Reduced LVEF correlated with obesity duration ($r = -0.201$, $P = .040$). GLS% correlated with BMI ($r = -0.410$, $P = .000$), waist circumference ($r = -0.430$, $P = .0001$), waist-to-hip ratio ($r = -0.241$, $P = .007$), and duration ($r = -0.290$, $P = .001$). GCS% showed similar correlations (BMI: $r = -0.322$, $P = .0001$; waist: $r = -.284$, $P = .002$; waist-to-hip: $r = -0.203$, $P = .031$; duration: $r = -0.309$, $P = .001$).Indexed LV mass (LVMh, LVMh²) correlated with BMI and waist circumference, stronger in females (BMI: $r = 0.489$, $P = .0001$ vs $r = 0.352$, $P = .010$; waist: $r = 0.396$, $P = .0001$ vs $r = 0.380$, $P = .006$). LV end-diastolic volume correlated with BMI ($r = 0.182$, $P = .041$); MAPSE changes with waist circumference ($r = 0.202$, $P = 0.024$); lower LA PALS% with waist circumference ($r = -0.232$, $P = .009$).Regression analysis showed obesity duration and BMI independently predicted increased LV mass, LA volume, and reduced GCS %; waist circumference independently predicted higher relative wall thickness, lower GLS%, and decreased PALS% (all $P < .05$).

Obesity promotes structural and functional myocardial remodeling, with anthropometric parameters serving as key independent predictors of left heart changes.

EP649 - ECE_2874 - Setmelanotide treatment in severe hypothalamic obesity: report of two cases

Dimitra Sinni, Panagiotis Karageorgiou, Maria Zotou, Marinella Tzanela and Dimitra Argyro Vassiliadi
Department of Endocrinology "D. Ikkos"- Diabetes Center-EndoERN-Evangelismos General Hospital, Athens, Greece

Background: Hypothalamic obesity is a rare, severe, and treatment-resistant condition caused by genetic or acquired hypothalamic damage. It is characterized by hyperphagia, impaired satiety, rapid weight gain, and high cardiometabolic risk. Conventional lifestyle and pharmacological treatments are largely ineffective, and bariatric surgery shows limited benefit due to impaired central satiety signaling. Setmelanotide, a selective melanocortin-4 receptor (MC4R) agonist, may bypass disrupted hypothalamic pathways and represent a targeted therapeutic option.

Patients and Methods: We report two patients with severe hypothalamic obesity treated with setmelanotide. The first patient is a 22-year-old male who developed hypothalamic dysfunction after surgical resection of a craniopharyngioma, with complete loss of satiety and rapid weight gain of approximately 50 kg within four months. At baseline, body mass index (BMI) was 42.1 kg/m². Weight gain persisted despite optimized pituitary hormone replacement, dietary intervention, and off-label semaglutide. Setmelanotide was initiated and titrated to the maximum recommended dose. The second patient is a 19-year-old female with hypothalamic obesity associated with a possible hypothalamic amartoma. She gained 30 kg within a year, reaching a BMI of 50.2 kg/m². She was recently initiated on setmelanotide.

Results: In the first patient, treatment resulted in a weight loss of 16.5 kg over seven months, with BMI decreasing from 42.1 to 37.5 kg/m². In the second patient, body weight decreased by 10.5 kg after 1.5 months of therapy, with BMI reducing from 50.2 to 46.7 kg/m².

Safety: Setmelanotide was generally well tolerated. The first patient experienced skin hyperpigmentation, transient nausea, and episodes of prolonged erections, none requiring discontinuation. Despite reduced thirst perception in the context of central diabetes insipidus, serum sodium remained stable under desmopressin therapy. No significant adverse effects were observed in the second patient.

Conclusions: These cases support the potential efficacy and acceptable safety of setmelanotide in severe hypothalamic obesity of acquired or idiopathic origin. Early targeted therapy may help limit progressive weight gain when conventional treatments fail. Further prospective studies are warranted.

[1]Endocrinological Ambulatory Care, Turek, Poland; [2]Department of Endocrinology, Diabetes and Isotope Therapy, University Clinical Hospital, Wroclaw, Poland; [3]Department of Endocrinology, Diabetes and Isotope Therapy, Wroclaw Medical University, Wroclaw, Poland; [4]CodeAI, Poznan, Poland; [5]2nd Department of Gynecology and Obstetrics, University Clinical Hospital, Wroclaw, Poland; [6]Wroclaw University of Science and Technology, Faculty of Medicine, Wroclaw, Poland

Introduction: Muscle tissue is being investigated as an endocrine active organ that secretes signaling molecules known as myokines. Numerous studies have evaluated myokines concentrations in a range of disorders, including polycystic ovary syndrome (PCOS) and metabolic syndrome. Among these myokines, irisin and meteorin-like protein (Metrnl) have been suggested to play important roles in promoting adipose tissue browning and enhancing insulin sensitivity.

Material and Methods: The study population included a total of 49 women, 31 diagnosed with PCOS and 18 healthy controls; all patients were between 18 and 40 years old. PCOS was diagnosed based on revised 2003 Rotterdam criteria.

Multiple anthropometrical, hormonal and biochemical parameters were assessed, including body composition with dual energy X-ray absorptiometry. Metrnl and irisin levels were measured with commercially available immunoassays.

Results: PCOS individuals and healthy controls do not differ in terms of age, BMI, WHR, fasting glucose, HOMA-IR, or body mass composition.

Assessment of Meteorin-like protein and irisin concentrations revealed no significant differences between PCOS and healthy women. Simultaneously, comparison of patients with BMI equal or greater than 25 to normal weight women showed significantly higher concentrations of irisin in the second group and no differences in Metrnl levels (11.53 ± 4.95 vs 15.96 ± 5.01, $P < .05$ and 16.73 ± 15.41 vs 18.0 ± 20.43, $P = .77$, respectively). Additionally, irisin level was negatively correlated with BMI, body fat mass, fasting glucose and insulin concentrations. No association between myokines levels was found.

Conclusions: Although irisin seems to be a promising biomarker, inconsistent research limits its value in clinical use in the assessment or treatment of obesity. Taking into consideration the similarity in physiological functions of irisin and Metrnl, no relationship between circulating levels of those particles suggests individual roles rather than synergetic actions in physiological adaptation to metabolic disease.

EP653 - ECE_1285 - Global patterns and determinants of diabetic ketoacidosis at diagnosis of type 1 diabetes in children and adolescents: a 10-year global perspective

Ashraf Soliman[1], Noor Hamed[1], Manal Musallam[1], Fawziya Alyafei[1], Shayma Ahmed[1], Nada Alaaraj[1] and Nada Soliman[2]

[1]Hamad Medical Center, Pediatric Endocrinology, DOHA, Qatar; [2]Alexandria Health Directorate, MOH, Public Health, Alexandria, Egypt

Background: Diabetic ketoacidosis (DKA) remains a significant and potentially life-threatening complication at the onset of type 1 diabetes (T1D) in children and adolescents. Despite global improvements in diabetes awareness and care, DKA incidence at diagnosis continues to vary widely across regions. Understanding these disparities is essential for developing targeted prevention strategies.

Objective: To evaluate the global incidence of DKA at T1D diagnosis in children and adolescents over the past 10 years, and to explore the sociodemographic and health system factors contributing to this variability.

Methods: A review of epidemiological studies published between 2013 and 2023 was conducted using PubMed, Scopus, and global diabetes registries. Included studies reported DKA incidence at diagnosis in youth populations. Data were extracted on incidence rates, healthcare access, public health campaigns, and population-level characteristics across countries in Africa, Asia, the Americas, Europe, and Oceania.

Results: The DKA incidence at T1D diagnosis showed wide international variation:

- Middle East: UAE (80%), Saudi Arabia (59%)—Cultural and healthcare system barriers play significant roles.
- Asia: Malaysia (54-75%), China (50%), India (39%), Thailand (6.2%)—Wide range due to variable healthcare infrastructure and public education efforts.
- Europe: Romania (67%), Luxembourg (67%), Italy (58%), Germany (30%), Sweden and Denmark (15%)—Low rates in Northern Europe attributed to universal healthcare and early detection initiatives.
- Americas: United States (35%)—Increasing trend; disparities exist by ethnicity and insurance status.
- Oceania: Australia (26%)—Moderate incidence, reflecting robust healthcare systems but room for improvement.

Key Determinants:

- Age <5 years is consistently associated with higher DKA risk due to diagnostic delays.
- Lower socioeconomic status correlates with higher DKA prevalence.
- Public health infrastructure, national screening policies, and education campaigns significantly influence early recognition.
- Countries with widespread pediatric care and diabetes awareness campaigns (eg, Sweden, Denmark, Australia) report lower DKA rates.

Conclusions: The global burden of DKA at T1D diagnosis remains substantial, especially in low- and middle-income countries. Efforts to reduce DKA incidence must prioritize early detection through improved public awareness, training of primary care providers, and expansion of pediatric diabetes services. Tailored strategies are essential for addressing the socioeconomic and systemic gaps contributing to DKA disparities worldwide.

[1]Endocrine Unit and Diabetes Centre, Department of Clinical Therapeutics, Alexandra Hospital, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece; [2]Department of Hygiene and Epidemiology, School of Medicine, University of Ioannina, University Campus, Ioannina, Greece; [3]Department of Endocrinology and Diabetes Centre, Alexandra Hospital, Athens, Greece; [4]1st Department of Obstetrics and Gynecology, Alexandra Hospital, National and Kapodistrian University of Athens, Athens, Greece; [5]Unit of Reproductive Endocrinology, 1st Department of Obstetrics and Gynaecology, Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece

Aim: To identify ethnic differences among women with gestational diabetes mellitus (GDM) in a multiethnic cohort.

Methods: This observational study included pregnant women with GDM (IADPSG criteria) attending a tertiary centre between January 2020-December 2023, classified according to their ethnic group as White, Black, Asian, or Other. Multivariable logistic and linear regression analyses were performed.

Results: A total of 633 women (513 White, 64 Black, 32 Asian, and 24 Other/Middle Eastern) were considered eligible for inclusion. Asian women had higher HbA1c than White, Black, and Other (5.5% (37 mmol/mol) vs 5.1% (32 mmol/mol), 5.2% (33 mmol/mol), and 5.1% (32 mmol/mol), respectively, $P < .001$). At the same time, Asian women had the lowest body mass index (BMI) compared to the other groups both pre-pregnancy (25.7 ± 3.6 kg/m^2 vs 27.1 ± 6.7 kg/m^2, 28 ± 5.9 kg/m^2, and 28.1 ± 5.6 kg/m^2, respectively, $P = 0.574$) and at OGTT (28.3 ± 4.2 kg/m^2 vs 30.2 ± 6.3 kg/m^2, 30.6 ± 5 kg/m^2, and 30.4 ± 4.9 kg/m^2, respectively, $P = .525$). Insulin therapy during pregnancy was more common in Asian and Other/Middle Eastern than White and Black women (71% and 79.2% vs 54.5% and 52.4%, respectively, $P = .03$). The percentage of women who were ex-smokers was significantly higher in White compared to Asian, Black, and Other groups (9.4% vs 3.1%, 1.6%, and 0%, $P = .04$), and the difference was even higher for White women who were actively smoking during pregnancy (15.7% vs 3.1%, 3.1%, and 0% $P = .002$). Pre-existing hypothyroidism was more common in White women compared to Black, Asian, and Other (17.4% vs 6.3%, 9.4%, and 0%, $P = .01$). A proportion of total cohort delivered in the Obstetric unit of our hospital (n = 271). Neonatal birth weight was higher in the Asian group compared to White, Black, and Other groups [(3429 ± 368 g) vs (3102 ± 488 g), (3279 ± 526 g), and (3159 ± 352 g), $P = .05$]. In the multivariable analysis, Middle Eastern ethnicity (aOR 6.73, 95% CI 1.31-34.46, $P = .02$), history of GDM in previous pregnancy (aOR 2.09, 95% CI 1.35-3.24, $P < .01$) and history of macrosomia (aOR 2.53, 95% CI 1.11-5.75, $P = .03$) were independently associated with an increased risk of insulin therapy requirement during pregnancy.

Conclusions: The study confirmed the presence of ethnic differences in pregnancies complicated by GDM. The results indicate a higher metabolic burden in Asian and Middle Eastern populations. Future research should focus on implementing ethnic-specific strategies for GDM prevention and early GDM screening.

EP656 - ECE_2458 - Uric acid/albumin ratio as a marker of prediabetes and OGTT-derived glycemic abnormalities

Irem Sonmezoglu Kutuk, Sabri Engin Altıntop, Ethem Turgay Cerit, Altinova Alev, Mehmet Muhittin Yalcin, Mujde Akturk, Fusun Toruner and Ayhan Karakoc
Gazi University Faculty of Medicine, Department of Internal Medicine, Division of Endocrinology and Metabolism, Ankara, Türkiye

Background: Prediabetes and early glucose dysregulation during oral glucose tolerance testing (OGTT) represent early stages of metabolic impairment that may not be fully captured by conventional glycemic thresholds. The uric acid–to–albumin (UA/Alb) ratio reflects the balance between metabolic burden and antioxidant capacity and may serve as a practical biomarker for early metabolic risk. This study evaluated the association of the UA/Alb ratio with prediabetes, OGTT-derived dynamic abnormalities, and intermediate OGTT glycemic load.

Methods: Individuals undergoing OGTT were analyzed in this cross-sectional study. Glycemic status was defined according to ADA/WHO criteria. The UA/albumin ratio was compared between normoglycemic and prediabetic individuals. In participants classified as OGTT-normal (fasting <100 mg/dL and 120-minute <140 mg/dL), mid-OGTT glucose values at 30, 60, and 90 minutes were evaluated. A glucose threshold of ≥155 mg/dL was used to define mid-OGTT glycemic burden, and individuals were further categorized according to the timing of glucose elevation. Non-parametric tests, age-adjusted logistic regression, and ROC analyses were performed.

Results: The UA/albumin ratio was associated with metabolic risk independently of conventional OGTT criteria. The UA/albumin ratio was significantly higher in individuals with prediabetes compared with normoglycemic participants ($P < .001$). After adjustment for age, the UA/albumin ratio remained independently associated with prediabetes, conferring approximately a 2.5-fold increased odds ($P < .01$). ROC analysis demonstrated a modest but significant discriminative ability for identifying prediabetes (AUC ≈ 0.62).

Importantly, among individuals considered OGTT-normal by conventional criteria, those exhibiting mid-OGTT glucose elevations ≥155 mg/dL had significantly higher UA/albumin ratios than those without such excursions ($P = .002$). Furthermore, a stepwise increase in UA/albumin ratio was observed according to the timing of glucose elevation, with the highest values seen in individuals whose glucose peaked at later OGTT time points (Kruskal–Wallis $P = 0.002$).

Conclusions: The UA/Alb ratio is associated with metabolic dysregulation across the glycemic spectrum, including prediabetes and early OGTT-derived abnormalities not captured by conventional thresholds. These findings underscore the clinical value of dynamic OGTT assessment and suggest that the UA/Alb ratio may serve as a simple adjunctive biomarker for identifying individuals at early cardiometabolic risk.

EP657 - ECE_2738 - On the road to type 2 diabetes: metabolomic profiling for early detection, risk stratification, and complementary assessment of metabolic trajectories

Diana Drettwan[1,2], Franziska Beitz[1], Tobias Ameismeier[1], Ali Tinazli[1] and Ronny Baber[3]
[1]*lifespin GmbH, Regensburg, Germany;* [2]*lifespin GmbH, Customer Management, Regensburg, Germany;* [3]*Leipzig Medical Biobank, Leipzig, Germany*

Prediabetes represents a major and growing global health burden, affecting hundreds of millions of individuals worldwide and substantially increasing the risk of progression to type 2 diabetes mellitus (T2D). As metabolic dysfunction precedes overt hyperglycemia by several years, improved characterization of early systemic metabolic alterations is critical for timely risk stratification and prevention.

In this study, we analyzed large-scale quantitative metabolomic profiles from more than 8,000 participants of the LIFE Adult Study using high-resolution H-NMR–based metabolomics. Over 250 metabolites and metabolic features per sample were quantified to characterize metabolic states associated with normoglycemia, prediabetes, and manifest T2D. Emphasis was placed on metabolite patterns reflecting insulin resistance, altered lipid and amino acid metabolism, and early disturbances in glucose and energy homeostasis.

Integration of metabolomic data with clinical phenotypes enabled the identification of distinct metabolic signatures associated with increased future T2D risk. These signatures extend beyond single biomarkers and capture system-level metabolic dysregulation, supporting metabolomics-based risk stratification as a complementary approach to conventional glycemic markers. The findings underline the potential of metabolomic profiling to improve early detection of prediabetes and to support targeted preventive interventions before irreversible disease progression occurs.

Beyond risk assessment, metabolomics-based measures of insulin resistance may also provide a complementary framework for assessing longitudinal metabolic response trajectories in the context of emerging antidiabetic therapies, including incretin-based treatments such as GLP-1 receptor agonists. While GLP-1 therapies exert pleiotropic effects extending beyond insulin resistance—such as glucose-dependent insulin secretion, appetite regulation, gastric emptying, and weight reduction—metabolomic insulin resistance markers may offer additional system-level insight into metabolic adaptation over time. Such approaches are intended to complement, rather than replace, established clinical endpoints including glycemic control, body weight, and treatment tolerability.

In summary, large-scale quantitative metabolomics combined with digital analytics provides valuable insights into early metabolic trajectories from health to prediabetes and type 2 diabetes, with implications for prevention, risk stratification, and complementary assessment of metabolic responses.

EP658 - ECE_2900 - Pre-conception care in women with pre-gestational diabetes in a multi-ethnic population

Zi Jin[1], Naeemah Khalisadar[1], Isata Barrie[1], Gideon Mlawa[2] and Godwin Simon[2]
[1]*London, United Kingdom;* [2]*Barking, Havering and Redbridge University Hospitals NHS Trust, Internal Medicine and Diabetes and Endocrinology, London, United Kingdom*

Background: An increasing number of pregnancies are complicated by pre-gestational diabetes mellitus, especially Type 2 diabetes. Data from some studies and the UK National Pregnancy in Diabetes Audit reported poorer pregnancy preparation and higher adverse outcome rates in women with Type 2 diabetes compared with Type 1 diabetes. Potential barriers to pre-conception care include limited patient awareness, language and cultural factors, and restricted access to specialist services. The UK NICE guidelines recommend optimisation of HbA1c to <48 mmol/mol (6.5%) prior to conception, renal assessment, and retinal assessment. This audit aimed to assess glycaemic control and the completion of pre-conception assessments in a multi-ethnic population.

Methods: We retrospectively reviewed women with pre-gestational diabetes attending the antenatal services at Queen's Hospital and King George Hospital between August and October 2025. We retrieved data on patient demographics including age, ethnicity, primary language, and deprivation index, as well as BMI, pre-conception HbA1c (defined as the most recent value within 6 months prior to conception), early pregnancy HbA1c, pre-conception urine albumin-and-creatinine ratio (uACR), and diabetic retinopathy status.

Results: Of the 32 females included, 29 (90.6%) had Type 2 diabetes and 3 (9.4%) had Type 1 diabetes. The mean age was 33.9 years (range 20-47) and mean BMI was 31.4 kg/m^2. The cohort was predominantly of Asian (65.6%), followed by White British (21.9%), and Black African or Caribbean (15.6%) ethnicity, with a high proportion residing in areas of socioeconomic deprivation. Preconception HbA1c was recorded in 24/32 (75%) women. Only 6/32 (22.2%) achieved the recommended target of <48 mmol/mol (6.5%) prior to pregnancy. While HbA1c improved between pre-conception and early pregnancy in 18/32 (56.3%) women, less than half achieved target glycaemic control by the first trimester (46.9%). Recent uACR was recorded in 4/32 (12.5%) individuals.

Conclusions: In this multi-ethnic, socioeconomically deprived population, a large proportion of women with pre-gestational diabetes have inadequate metabolic optimisation and a low rate of pre-conception assessments. There is a need for a structured pre-conception diabetes service to improve pregnancy preparedness and to reduce avoidable maternal and fetal complications.

EP664 - ECE_3183 - Clinical significance of DM phenotype differentiation via digital algorithm in predicting retinopathy onset

Kateryna Ukrainets[1,2,3], Natalija Pashkovska[1] and Oleh Ukrainets[4]
[1]Chernivtsi, Ukraine; [2]Central City Clinical Hospital of Chernivtsi City Council, Chernivtsi, Ukraine; [3]Bukovinian State Medical University, Chernivtsi, Ukraine; [4]Yuriy Fedkovych Chernivtsi National University, Chernivtsi, Ukraine

Relevance: Clinical experience suggests that the phenotypic diversity of diabetes often leads to diagnostic errors in daily practice. Many cases of LADA or pancreatogenic diabetes are misclassified as Type 2 (T2DM), while MODY can be confused with Type 1 (T1DM). This directly impacts ophthalmological care, as screening schedules are often based on the initial diagnosis. Since diabetic retinopathy (DR) is a major cause of vision loss, precise classification is vital. We aimed to see if a Telegram-based diagnostic algorithm could help identify these atypical cases and better predict the risk of eye complications.

Materials and Methods: We re-evaluated the clinical data of 151 patients using a custom-developed Telegram bot. The algorithm analyzed parameters such as age of onset, BMI, C-peptide levels, GAD antibodies etc. Based on the digital verification, we grouped the patients into: T1DM (n = 40), LADA (n = 32), T2DM (n = 52), MODY (n = 12), and pancreatogenic DM (n = 15). Ophthalmological evaluation included fundoscopy for all participants, with Optical Coherence Tomography (OCT) utilized as an additional diagnostic tool where clinically indicated. Statistical analysis was performed using standard descriptive and comparative methods.

Results: The digital check led to a diagnostic shift in 21.8% of the total cohort. Some patients previously labeled as T2DM were found to have LADA or markers of pancreatic insufficiency. Additionally, n = 5 patients previously treated for T1DM were identified as MODY cases.

The most significant finding for ophthalmological practice was in the LADA group. These patients showed signs of DR on average 3.0 ± 0.3 years earlier than those with classic T2DM ($p < 0.01$). On the other hand, patients reclassified as MODY had a very low risk of microangiopathy, with 91.7% of them showing no signs of DR. For pancreatogenic DM, we observed that while proliferative DR was less common than in T1DM, early changes in the pigment epithelium occurred more frequently.

Conclusions: Our study indicates that a simple digital algorithm can be an effective tool for differential diagnosis in a clinical setting. Identifying the specific phenotype–especially LADA–is crucial because it predicts a much earlier onset of retinopathy (3 years earlier than T2DM). This supports the need for personalized ophthalmological monitoring instead of a "one-size-fits-all" approach, allowing for earlier intervention in high-risk patients.

EP667 - ECE_1254 - Comparative Impacts of Maternal Obesity with Normoglycemia, Impaired Glucose Tolerance, and Gestational Diabetes on Offspring Growth and Metabolic Outcomes: A Systematic Review

Ashraf Soliman, Fawziya Alyafei, Manal Musallam, Noora Alhemaidi, Noor Hamed, Shayma Ahmed, Nada Alaaraj and Ahmed Elawwa
Hamad Medical Center, Pediatric Endocrinology, DOHA, Qatar

Background: Maternal obesity is an established risk factor for adverse fetal programming. When combined with abnormal glucose metabolisms such as impaired glucose tolerance (IGT) or gestational diabetes mellitus (GDM)offspring are at elevated risk for early and lifelong growth and metabolic disorders. Differentiating these risks is vital for precision-targeted antenatal and postnatal care.

Objectives: To compare the short- and long-term impacts of maternal obesity with normal glycemia, IGT, and GDM on offspring growth (weight, BMI) and metabolic parameters (insulin resistance, lipid profile, blood pressure), and to estimate the magnitude of these effects from published data (2000-2025).

Methods: A systematic search of PubMed, Embase, and Web of Science identified 20 studies (n > 18,000 total offspring). Data were stratified into three exposure groups:

1. Obese mothers with normal glucose tolerance (NGT)
2. Obese mothers with IGT
3. Obese mothers with GDM

Outcomes were categorized as:

- Short-term: birth weight, neonatal adiposity, early weight gain
- Long-term: childhood obesity, BMI z-score, insulin resistance (HOMA-IR), systolic BP, lipid abnormalities

Effect sizes were extracted or calculated where possible.

Results:

- Obese-NGT:
  - 18-22% increased risk of childhood overweight compared to non-obese controls
  - Birth weight +150-250 g on average
  - Mild rise in insulin levels and HOMA-IR by adolescence (12-15%)
- Obese-IGT:
  - 38-45% increased risk of obesity in school-age children
  - 1.4-1.7× increase in HOMA-IR and fasting insulin
  - Increased triglycerides (+18%) and LDL cholesterol (+11%) at 8-12 years
- Obese-GDM:
  - 55-70% prevalence of overweight/obesity by adolescence
  - Macrosomia (>4 kg) in up to 30-35% of neonates
  - 2.5× increase in childhood metabolic syndrome risk

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

- Insulin resistance and impaired fasting glucose in 40-55% by mid-adolescence
- Hypertension (≥90th percentile) in 22-28% by 14-18 years

Dose-response trends were consistent across cohorts, showing the greatest burden among GDM-exposed offspring.

Conclusions: The severity of maternal glucose dysregulation modulates the magnitude of offspring metabolic risk. Children of obese GDM mothers experience the most pronounced growth acceleration and metabolic dysfunction. Those obese-IGT mothers are an intermediate-risk group, highlighting the need for early detection and targeted interventions.

Public Health Implications: This evidence reinforces the need for aggressive glycemic monitoring in obese pregnancies, not only for maternal outcomes but for offspring health. Public health policy should integrate tailored prenatal counseling, early postnatal screening, and long-term growth/metabolic follow-up for at-risk children to break the intergenerational cycle of metabolic disease.

EP668 - ECE_1495 - Galectin-3 and obesity in patients with type 2 diabetes mellitus: a prospective case–control study

Danijela Radojković[1,2], Milica Pesic[1,2], Saša Radenković[1,2], Vojislav Ćirić[1,2], Milena Velojić Golubović[1,2], Milan Radojkovic[1,2], Valentina Nikolic[2], Aleksandra Ignjatovic[2], Petra Popovic[1] and Jovana Zlatkovic[1]

[1]University Clinical Center, Nis, Serbia; [2]Medical Faculty, University of Nis, Nis, Serbia

Introduction: Obesity plays a central role in the development of metabolic disturbances in type 2 diabetes mellitus (T2DM). Galectin-3, a β-galactoside-binding lectin involved in inflammation and fibrosis, has been implicated in obesity-related metabolic disorders; however, its role in T2DM patients with different nutritional status remains insufficiently defined.

Objective: To investigate the role of galectin-3 in obese and normal-weight patients with type 2 diabetes mellitus and to evaluate its association with glycemic control, insulin resistance, and anthropometric parameters.

Patients and Methods: A prospective case–control observational study was conducted at the Clinic of Endocrinology, Diabetes and Metabolic Disorders, University Clinical Centre Niš, Serbia. The study included 42 patients with type 2 diabetes mellitus (T2DM), classified according to body mass index (BMI) into two groups: obese patients (group O, BMI ≥30 kg/m^2; n = 21) and normal-weight patients (group N, BMI 18.5-24.9 kg/m^2; n = 21). All participants underwent detailed medical history assessment and clinical examination, including anthropometric measurements (waist and hip circumference). Laboratory investigations included fasting blood glucose (FBG), glycated hemoglobin (HbA1c), insulin, C-peptide, calculation of HOMA-IR, renal function tests (urea, creatinine), estimated glomerular filtration rate (eGFR), albumin-to-creatinine ratio (ACR), lipid profile (total cholesterol (Hol) triglycerides (Tg), high density lipoproteins (HDL) and low density lipoproteins (LDL)), and serum galectin-3 levels. Diabetes duration was recorded. Multivariate regression analysis was performed to identify independent predictors of waist circumference.

Results: Patients in group O had significantly higher HbA1c ($P = .012$), HOMA-IR ($P < .001$), insulin ($P < .001$), and C-peptide levels ($P < .001$) compared with group N. Waist and hip circumferences were also significantly greater in obese patients ($P < .001$ for both). Diabetes duration was significantly shorter in group O compared with group N ($P = .042$). In the multivariate model, galectin-3 levels ($P = .021$) and HbA1c emerged as independent predictors of waist circumference.

Conclusions: Galectin-3 is independently associated with central adiposity in patients with T2DM, suggesting a potential role as a biomarker linking obesity, glycemic control, and metabolic dysfunction in type 2 diabetes.

EP669 - ECE_2029 - Impact of pre-pregnancy obesity on metabolic control and perinatal outcomes in gestational diabetes

Franco Nicolas Lopez Lopez, Rocio Villar Taibo, Eva Gomez Vazquez, Ana Canton Blanco and Miguel Angel Martinez Olmos

Hospital Clínico Universitario de Santiago de Compostela, Santiago de compostela, Spain

Objectives: To compare maternal–fetal variables in women with gestational diabetes (GD) according to the presence of pre-pregnancy obesity (PPO); to analyze HbA1c levels and their relationship with macrosomia (M); and to evaluate the association between PPO and insulin requirement (IR).

Materials and Methods: A retrospective observational study including pregnant women diagnosed with GD between 2022 and 2023. Participants were classified according to the presence of PPO (BMI ≥30 kg/m^2). Clinical and biochemical variables at the time of GD diagnosis were recorded.

Results: A total of 300 women were included. Table 1 summariezes the clinical, biochemil charecteistics and complications. Women with PPO were diagnosed with GD at an earlier gestational age and showed significantly higher HbA1c levels compared with non-obese women. Receiver operating characteristic (ROC) curve analysis identified HbA1c as a predictor of macrosomia, with an area under the curve (AUC) of 0.845. The optimal cut-off value was HbA1c >5.4%, yielding a sensitivity of 90% and a specificity of 61%. PPO was associated with higher HbA1c levels OR 1.095, 95% CI 1.047-1.145; $P < .001$). Insulin therapy was required in 54.5% of women with PPO compared with 21.5% of non-obese women (OR 4.38; $P < .001$). In multivariate analysis, PPO was independently associated with macrosomia (OR 3.36, 95% CI 1.34-8.98; $P = .01$), whereas insulin requirement was not independently associated (OR 0.65; $P = .38$).

Conclusions: Pre-pregnancy obesity was associated with higher insulin requirements, poorer glycemic control, and an increased

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

risk of macrosomia in women with gestational diabetes. An HbA1c value >5.4% demonstrated good discriminative capacity for predicting macrosomia. PPO remained an independent risk factor, highlighting the importance of strict metabolic control and individualized follow-up in this population.

EP670 - ECE_2372 - Liraglutide versus tirzepatide: real-world effects on lipid and carbohydrate metabolism in adults with class III obesity

Maria Evangelia Koloutsou[1], Maria Yavropoulou[1], Maria Mateniadou[1], Evanthia Kassi[1], Georgia Argyrakopoulou[2], Kyriaki Cholidou[3], Polyzois Makras[4], Nikolaos Tentolouris and Alexander Kokkinos

[1]Laiko University Hospital, Medical School, National and Kapodistrian University of Athens, First Department of Propaedeutic Internal Medicine, Joint Academic Rheumatology Program, Endocrinology Unit, Athens, Greece; [2]Athens Medical Center, Diabetes and Obesity Unit, Athens, Greece; [3]Sotiria Chest Disease Hospital, 1st Respiratory Medicine Department, Athens, Greece; [4]251 Hellenic Air Force & VA General Hospital Athens, LCH Adult Clinic, Department of Endocrinology and Diabetes and Department of Medical Research, Athens 11525, Greece; 5Laikon General Hospital, First Department of Propaedeutic Internal Medicine, Athens, Greece

Introduction: Obesity is a global health challenge associated with cardiometabolic morbidity and mortality. GLP-1 receptor agonists, such as liraglutide, and the dual GIP/GLP-1 receptor agonist tirzepatide are used in obesity and glycaemic control. Although randomized clinical trials have demonstrated efficacy, real-world head-to-head comparative data remain limited. This study aimed to compare the short-term effects of liraglutide versus tirzepatide on lipid and glycaemic parameters in adults with class III obesity, without changes in concomitant pharmacological treatment.

Methods: This prospective observational study included adults with BMI >40 kg/m^2 without diabetes who received liraglutide (n = 14; once daily, up-titrated to 3 mg) or tirzepatide (n = 15; once weekly, up-titrated to 7.5 mg) over a 3-month follow-up period. Demographic and anthropometric data were collected, body composition was assessed using bioelectrical impedance analysis, and laboratory measurements (HbA1c, glucose, insulin, total cholesterol, LDL-C, HDL-C, triglycerides) were obtained at baseline and at 3 months. Insulin resistance and sensitivity were estimated using HOMA-IR and HOMA-S. Statistical analyses were performed using SPSS version 26.

Results: A total of 29 adults with class III obesity were included (mean age 47 years, mean body weight 129 kg, mean BMI 44 kg/m^2). After 3 months of treatment, weight loss was comparable between the liraglutide and tirzepatide groups (11.5 vs 11.9 kg, $P=.83$), as was percentage weight loss (10% vs 9%, $P=.75$). Reductions in fat percentage (−2.3% vs −2.6%, $P=.76$), fat mass (−7.3 vs −7.6 kg, $P=0.86$), and fat-free mass (−4.2 vs −3.9 kg, $P=0.79$) were also similar comparable.

In the liraglutide group, total cholesterol decreased significantly (194.0 ± 33.7 to 173.3 ± 32.6 mg/dL, $P=.022$), whereas changes in LDL-C, HDL-C and triglycerides were not significant. HbA1c decreased significantly ($P=.003$), while glucose, insulin, HOMA-IR and HOMA-S showed no significant changes.

In the tirzepatide group, total cholesterol also decreased significantly (219.2 ± 55.3 to 191.7 ± 38.9 mg/dL, $P=.034$), without statistically significant changes in LDL-C, HDL-C or triglycerides. Tirzepatide induced significant decreases in fasting glucose ($P<0.001$), insulin ($P=.030$) and HbA1c ($P<.001$). HOMA-IR declined and HOMA-S increased, indicating enhanced insulin sensitivity.

Conclusions: Both incretin-based therapies improved lipid and carbohydrate metabolism over three months. Tirzepatide (up to 7.5 mg weekly) demonstrated greater short-term glycaemic control compared with liraglutide (3 mg daily), while weight loss was comparable. These findings support the real-world cardiometabolic effectiveness of incretin-based therapies beyond obesity management.

The study protocol was prospectively registered at ClinicalTrials.gov (NCT07094568).

EP673 - ECE_1193 - Sleep disorders in polycystic ovary syndrome a comparative study In Pakistani women

Shahina Ishtiaq

Ziauddin university hospital, South city hospital, Obstetrics and gynecology, Karachi, Pakistan

Background: Polycystic Ovary Syndrome (PCOS) is a prevalent endocrine disorder associated with metabolic and psychological co morbidities. While reproductive and metabolic features are well studied, sleep disturbances remain underappreciated.

Objective: To compare sleep quality and emotional distress in women with and without PCOS, and contextualize findings using metabolic data from a MASLD (Metabolic Dysfunction-Associated Steatotic Liver Disease) cohort.

Methods: In a case-control design, 200 women (100 PCOS, 100 age-matched controls) were evaluated using structured questionnaires and the CES-D 10 depression scale. Latent Class Analysis was used to cluster sleep symptom patterns. A secondary MASLD dataset (n=172) was analyzed for BMI, liver enzyme levels, and lipid profiles.

Results: Women with PCOS reported significantly more restless sleep ($P=.015$, d = 0.35), fatigue ($P=.041$, d = 0.29), and higher depression and anxiety symptoms ($P<.05$). MASLD participants showed elevated BMI (29.5 ± 5.0), ALT (31.3 IU/L), GGT (74.7 IU/

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

L), and borderline-high LDL and triglycerides.

Conclusions: Sleep issues in PCOS are closely associated with emotional distress and metabolic stress. Findings from the MASLD cohort support a systemic mechanism involving liver-related oxidative stress. Interventions must address metabolic and psychological domains to improve sleep in PCOS.

Keywords PCOS, sleep disturbances, depression, MASLD, metabolic stress, liver enzymes

EP674 - ECE_2456 - Clinical characteristics and prognostic factors of malnutrition in patients with diabetes: diades project

Víctor Simón-Frapolli[1,2,3] and Raquel De la Iglesia Arnaez[4]
[1]*Hospital Universitario Virgen De La Victoria, Endocrinology and Nutrition, Málaga, Spain;* [2]*Ibima Plataforma Bionand, Málaga, Spain;* [3]*Facultad de Medicina-UMA, Málaga, Spain;* [4]*Laboratorios Ordesa, Barcelona, Spain*

Diabetes mellitus (DM) is associated with a high prevalence of disease-related malnutrition (DRM), which worsens patients' health status. Clinical guidelines recommend medical nutrition therapy as an essential complement to the treatment of the disease.**Objective:** To understand the attitude of healthcare professionals toward DRM in patients with DM, their diagnostic methods, and their clinical practices.

Method: An online questionnaire on the general profile of diabetic patients was sent to healthcare specialists on the clinical management of patients with DM in the Spanish healthcare context. In addition, a retrospective online questionnaire for patients with DRE who were treated with oral nutritional supplementation (ONS) was sent to these specialists.

Results: A total of 235 specialists from the public and private sectors participated in the study, representing various specialties and regions and providing information on the treatment of 927 hospitalized patients at nutritional risk. 90.6% of specialists reported performing nutritional screening, with the Mini Nutritional Assessment (MNA) being the most widely used tool (65.3%).

Among patients with DM, most were type 2 (96.0%), with a mean age of 70.6 years. Most physicians (81%) reported that the diagnosis of DM had been made more than 12 months prior to the nutritional assessment. For 64.8% of specialists, the nutritional status of patients with DM at the time of diagnosis was classified as "malnourished."

Regarding the retrospective study of patients with DRM, ONS was recommended for more than 2 months in 80.9% of cases, and to improve adherence, frequent follow-up with the patient (92.8%) and better communication (92.5%) were highlighted. Unintentional weight loss was the main reason for recommending ONS (43.0%). 66.6% of patients with DRM had a previous diagnosis of DM. In terms of communication with patients, aspects such as understanding when and how to take ONS and highlighting their importance were highlighted. Almost unanimously, face-to-face consultations are the preferred channel of communication for patients, followed by telephone consultations.

In those patients who were prescribed complete oral nutrition, an average of 2 daily doses was recommended, and nutritional improvement was observed after an average of 31.0 days, with a high degree of satisfaction with the treatment.

Conclusions: The results indicate the high incidence of DRM in patients with DM and the delay in its diagnosis. Oral nutritional supplementation can improve the DRE condition of these patients at an early stage.

EP676 - ECE_1786 - Ketamine induced Hyponatremia

Huma Humayun Khan[1] and Jeremy Tomlinson[2]
[1]*Oxford Centre for Diabetes, Endocrinology and Metabolism, Oxford University Hospital, Oxford, United Kingdom;* [2]*NIHR Oxford Biomedical Research Centre, Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom*

Ketamine is a dissociative anaesthesia which also has analgesic properties and is also used in pain management and depression[1]. As it produces an out-of-body and rewarding experience, there is a potential danger for abuse of this medication[2].Cystitis and cholangiopathy are recognized side effects of ketamine use[3],however, published data on ketamine-induced hyponatremia is scarce.The exact pathophysiology is not clear though it has been postulated that ketamine stimulates the release of antidiuretic hormone from the hypothalamus.

Here, we describe an unusual case of acute hyponatremia likely induced by ketamine recreational use.

A 25-year-old malnourished gentleman presented with 1-week history of progressive lethargy and global weakness, having used ketamine recreationally for several years. He did not have recent GI losses (vomiting or diarrhoea) and did not ingest excessive amount of water or alcohol. The initial biochemistry revealed profound hyponatremia (Na 100 mmol/l). The paired serum (205 mosm/kg) and urine osmolality (313 mosm/kg) and urine sodium 93, suggested SIADH, however clinically patient appeared dehydrated and malnourished. The cortisol level was sufficient (561 nmol/l). It was unclear if hyponatremia was acute or subacute-on-chronic with last normal sodium level noted five years earlier.

Given the neurological symptoms of acute confusion and unsteadiness, the patient was treated with half the usual volume hypertonic saline (75 ml of 2.7% NaCl) over 20 minutes. A cautious approach was implemented due to the potential risk of overcorrection given his apparent malnourishment.

He was admitted to ICU and treated with slow intravenous fluid (0.9% NaCL 80 ml/hr). His Na level overcorrected by 11 mmol/l in 24-hours with polyruia, and was halted by stat 1 mcg dose of desmopressin. The patient went on to develop acute kidney injury with polyuria needing repeat administration of desmopressin which had minimal effect, suggesting ADH resistance and possible tubular injury.

It was deemed that hyponatremia was multifactorial, secondary to ketamine-induced renal salt-wasting (likely tubular damage) and an element of inappropriate ADH secretion in the context of critical illness. The sodium level steadily improved with slow IVF and by day-8 of admission, the patient had full recovery.

This case uniquely highlights ketamine as a rare cause of hyponatremia which was severe enough to warrant use of hypertonic saline and ITU admission.

EP677 - ECE_3643 - Reactive hypoglycaemia: challenges in clinical practice

Zaynah Islam[1], Naychi Kyaw Kyaw[2], Carmela Therese Chan[2], Raj Tanday[2], Anna Hawkins[2] and Khash Nikookam[2]
[1]Queen Mary University of London, Main Medical School Campus, London, United Kingdom; [2]Barking, Havering and Redbridge Hospitals NHS Foundation Trust, Diabetes and Endocrinology, Ilford, London, United Kingdom

Background: Reactive hypoglycaemia is an under-recognised condition that can significantly compromise patients' quality of life. The diagnostic process is often intricate, necessitating comprehensive evaluations to rule out alternative differential diagnosis. This not only demands considerable time and resources from clinicians and the multidisciplinary care team but also imposes psychological and physical burdens on patients in search of diagnostic clarity which may be delayed for years. Nevertheless, with appropriate therapeutic strategies, symptom control is achievable.

This is the case of a 38-year-old lady presented with a long-standing history of postprandial episodes of intermittent tremors, excessive sweating, profound fatigue, and occasional tachycardia lasting at least 15 minutes. These episodes occurred one to three times per week, primarily 2 to 3 hours post meal. During one severe episode, her blood glucose level fell to 2.1 mmol/L, resulting in transient aphasia and necessitating external assistance for oral intake.

Extensive investigations were undertaken to exclude other endocrinological and metabolic disorders. These included assessments of serum basal cortisol, a 72-hour inpatient fasting, IGF-1, 24-hour urinary metanephrines, 5-HIAA, and a short Synacthen test with normal results. 5 hours oral glucose tolerance test (OGTT) confirmed the diagnosis of reactive hypoglycaemia.

Subsequent lifestyle modifications including proportionate balanced protein, carbohydrate and fat, weight reduction advice and adherence to a high-protein, low-carbohydrate diet and fat resulted in marked symptomatic relief and stabilisation of glycaemic control. Repeat OGTT demonstrated a return to normoglycaemia.

Conclusions: Reactive hypoglycaemia is a rare and diagnostically challenging condition that may present with non-specific or atypical symptoms. A high index of clinical suspicion is essential. This case underscores the diagnostic value of OGTT and MMTT and highlights the critical role of early dietary intervention in mitigating symptom progression and reducing the risk of long-term metabolic sequelae.

EP682 - ECE_1914 - Increased collagen IV protein in renal proximal tubular epithelial cells under high-glucose condition was enhanced by dickkopf-1 but attenuated by brain-derived neurotrophic factor

I-Te Lee and Junyi Wu
Taichung Veterans General Hospital, Division of Endocrinology and Metabolism, Department of Internal Medicine, Taichung, Taiwan

Background: In addition to glomerular injury, tubulointerstitial fibrosis is one of the pathophysiological mechanisms in the diabetic kidney disease. Brain-derived neurotrophic factor (BDNF), a member of neurotrophin family, promotes cell growth and survival mainly through tropomyosin receptor kinase B (TrkB). Previously we have reported that serum BDNF level was positively correlated with renal function. Moreover, Wnt/β-catenin signaling is involved in the repair and regeneration after kidney injury. The circulating dickkopf-1 (DKK-1), a Wnt signaling inhibitor, is inversely correlated with renal function. In the present study, we aimed to examine the effects of BDNF and DKK-1 on the expression of collagen IV protein, an indicator of fibrosis.

Methods: This study included three parts: [1] We pretreated human renal proximal tubular epithelial cells with different doses of BDNF (0, 1, 10, 50 and 100 ng/mL) for 24 hours and cultured in high-glucose (HG, 33 mM) medium for another 24 hours. [2] We blocked BDNF signaling using Trk inhibitors, followed by treating the cells with BDNF (50 ng/mL) for 24 hours and cultured in HG medium for another 24 hours. [3] We pretreated the cells with BDNF (50 ng/mL) and/or DKK-1 (50 or 500 ng/mL) for 24 hours and cultured in HG medium for another 24 hours. Total protein from each experimental group was extracted and subjected to western blot analysis. Collagen IV protein intensity was normalized to total protein and compared to normal-glucose (NG, 5.6 mM) condition.

Results: First, HG condition resulted in a 1.63-fold increase in collagen IV level compared to the NG condition, and a dose-depend suppression was observed by BDNF (1.55-, 1.45-, 1.23-, 1.08-fold with 1, 10, 50, and 100 ng/mL of BDNF; respectively). Second, the HG-increased collagen IV (2.05-fold) was suppressed by BDNF (1.78-fold), but the BDNF effect was abolished (2.68-fold) after adding pan-Trk inhibitor (K252a, 200 nM). Finally, the HG-increased collagen IV (1.87-fold) was augmented (2.74-fold) by high-dose (500 ng/mL) of DKK-1, and the augmentation was attenuated (1.98-fold) by BDNF (50 ng/mL).

Conclusions: We showed a dose-depend effect of BDNF on the suppression of collagen IV protein expression, and the BNDF effect was abolished by pan-Trk inhibitor. In addition, BDNF attenuated the overexpression of collagen IV protein induced by DKK-1. Our results shed light on the roles of BDNF and Wnt/β-catenin signaling in the regulation of tubulointerstitial fibrosis. Further in vivo investigations for the synergistic effects between BDNF and Wnt/β-catenin signaling on renal tubular protection are warranted.

EP683 - ECE_3959 - The importance of integrating FIB-4 and transient elastography in detecting advanced liver fibrosis among patients with type 2 diabetes

Marin Pecani[1] and Paola Andreozzi[2]
[1]Sapienza University of Rome, Department of Experimental Medicine, Rome, Italy; [2]Policlinico Umberto I University Hospital, Sapienza University of Rome, Rome, Italy

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) with advanced liver fibrosis is highly prevalent among patients with cardiometabolic risk factors, particularly in those with type 2 diabetes, but is often asymptomatic. With normal or mildly elevated liver enzymes, it is frequently underdiagnosed in primary care and endocrinology settings. Although liver biopsy remains the gold standard for diagnosis,

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

it is not feasible for population-level screening. Current clinical guidelines recommend a stepwise approach: initial non-invasive fibrosis assessment with a simple serum-based score, such as FIB-4, followed by imaging with vibration-controlled transient elastography (VCTE). This case report underscores the value of this approach in routine clinical practice.

Case Presentation: During a routine endocrinology visit, a 58-year-old man (body mass index [BMI] 31.1 kg/m^2) with a two-year history of type 2 diabetes treated with metformin and a history of hypertension was noted to have a FIB-4 score of 1.56, corresponding to an indeterminate risk for advanced hepatic fibrosis. He reported no significant alcohol consumption and had no known history of liver disease. Physical exam showed no signs of chronic liver disease. Laboratory results were within normal limits for GGT, ALP, bilirubin, albumin, PT, and INR, and the patient's hemoglobin A1c was 7.8%. Serologic testing was negative for viral hepatitis. Given the elevated FIB-4 score, VCTE was performed, revealing a liver stiffness of 9.6 kPa, indicating significant fibrosis, and a controlled attenuation parameter of 324 dB/m, confirming hepatic steatosis. Lifestyle counseling was provided, focusing on dietary modification, alcohol avoidance, and increased physical activity. Consequently, semaglutide was initiated to improve glycemic control, promote weight loss, and address MASLD. The patient was referred to a hepatologist for further evaluation and follow-up.

Conclusions: Even in seemingly low-risk patients, combining FIB-4 with VCTE can uncover moderate to advanced fibrosis, supporting its use in routine MASLD evaluation. This case highlights the value of a stepwise, non-invasive assessment strategy in enabling earlier identification of advanced fibrosis and timely referral and surveillance in patients with metabolic risk factors. Without this approach, recognition of advanced fibrosis would likely have been delayed.

EP684 - ECE_1028 - Characteristics of cases of body weight rebound after metabolic /bariatric surgery

Bunzo Matsuura[1], Norio Horiike[2], Kojiro Michitaka[2], Hironobu Nakaguchi[1], Teruki Miyake[1] and Shinya Furukawa[1]
[1]*Ehime University Graduate School of Medicine, Toon, Japan;* [2]*Saiseikai Imabari daini Hospital, Imabari, Japan*

Background & Aim: Since 2006 at our hospital, lifestyle modification for obese patients has been provided through a team approach with a physician, dietician, nurse, physical therapist and psychologist. From 2016, a surgeon and anesthesiologist were added to the team for metabolic/bariatric surgery (laparoscopic sleeve gastrectomy: LSG). The aim of this study is to clarify the characteristics of cases of body weight rebound after LSG.

Subjects and Methods: Of 51 patients who were received LSG between January 2017 and May 2024, 40 patients (19 males and 21 females, mean age 44 years) who had been followed for more than 2 years were included. Rebound cases were defined as those in whom postoperative weight loss had increased to 90% or more of the preoperative weight. Comorbidities and the rate of change in preoperative weight loss rate, postoperative weight loss rate, and postoperative body composition were compared. We examined their body composition using InBody 720 or 770.

Results: There were 13 rebound cases and 27 non-rebound cases. There were significantly more rebound cases among women and cases with diabetes mellitus, low preoperative weight, low 6-month postoperative weight loss, weight gain from 6 months to 1 year after surgery, and postoperative muscle mass loss. There were no differences in age or preoperative weight loss rate.

In summary: Women with diabetes mellitus and those with little postoperative weight loss should be visited frequently for diet and exercise modification to detect rebound early.

EP685 - ECE_1281 - Public concern about GLP-1 analogues: a google trends analysis of global search patterns

Vasiliki Tsiama[1], Stella Proikaki[1], Konstantinos Belis[1], Efthymia Kallistrou[1], Dimitra Ragia[1], Dimitra Motsiou[1], Ioannis Ilias[1], Lina Zabuliene[2] and Christos Savvidis[1]
[1]*Hippocration General Hospital of Athens, Department of Endocrinology, Athens, Greece;* [2]*Vilnius University, Faculty of Medicine, Vilnius LT-03101, Lithuania*

Introduction: GLP-1 receptor agonists, notably semaglutide (Ozempic) and tirzepatide (Mounjaro), are increasingly used for type 2 diabetes and weight loss. Despite a favorable safety profile, rare adverse effects such as pancreatitis and vision loss have raised concern. Internet search data offer insights into public health anxieties and can inform clinical and regulatory communication.

Aim: To assess global public interest in GLP-1 analogues using Google Trends data, focusing on pancreatitis, vision loss, diet, and exercise.

Methods: Weekly Relative Search Volumes (RSVs) were obtained from Google Trends for "Mounjaro," "Ozempic," "Diet," "Exercise," "Pancreatitis," and "Blindness," from Dec 26, 2021, to Jun 22, 2025 (183 weeks). Trends were analyzed using the Mann-Kendall test, Loess smoothing, and autocorrelation functions. Synchrony was assessed via cross-approximate entropy (Cross-ApEn), with normalized RSVs. Temporal relationships were evaluated with cross-correlation analysis using differenced series to ensure stationarity.

Results: Search interest rose significantly for Mounjaro ($\tau = 0.30$, $P < .001$) and Ozempic ($\tau = 0.38$, $P < .001$), peaking at RSVs of 31 and 41. Diet showed a mild downward trend ($\tau = -0.05$, $P = .001$), with seasonal peaks; Exercise was stable but also seasonal. Searches for Pancreatitis and Blindness remained low and stable, with occasional spikes (eg, Pancreatitis RSV = 21). Cross-ApEn indicated high synchrony between Mounjaro and Ozempic (0.85), moderate with Diet and Exercise (1.22-1.32), and low with Blindness and Pancreatitis (1.35-1.45). Cross-correlation analysis showed strong contemporaneous correlation between Mounjaro and Ozempic ($r = 0.68$), weak inverse correlations with Diet and Exercise (r: −0.3), and non-significant positive correlations with Blindness and Pancreatitis (r: 0.15-0.20).

Discussion: Public interest in GLP-1 agonists is rising, likely reflecting expanding use and media coverage. Stable interest in

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

traditional methods (Diet, Exercise) with weaker associations suggests a shift toward pharmacological weight loss. Limited correlation with side-effect terms implies that public concern about adverse events is event-triggered rather than sustained. Limitations include the relative nature of RSVs and possible influence of unmeasured events. Future work should focus on media-driven search spikes to enhance real-time pharmacovigilance.

EP686 - ECE_3423 - Multidisciplinary approaches in weight management clinic: weight and psychological outcomes

Conor Bentley, Gavita Kaur, Anna Hawkins and Khash Nikookam

Barking, Havering and Redbridge University Hospitals NHS Trust, King George Hospital, Department of Endocrinology, London, United Kingdom

Obesity is a complex chronic disease frequently associated with depression and anxiety, which may adversely affect quality of life, treatment engagement and long-term outcomes. NICE guidance recommends specialist multidisciplinary weight management services incorporating dietetic, psychological, lifestyle and medical input. However, early psychological outcomes are infrequently reported alongside weight change, despite their importance to patient-centred care and service evaluation.

This service included adults attending a specialist NHS weight management clinic (November 2024 and March 2025). Participants met NICE criteria for specialist weight management and received a multidisciplinary intervention comprising lifestyle modification, at least six individual dietetic and psychological support sessions, including medical assessment. A pilot programme which combined dietetic and psychological group intervention was offered to all participants. Weight, depression (Patient Health Questionnaire-9; PHQ-9) and anxiety (Generalised Anxiety Disorder-7; GAD-7) were assessed at baseline and at interim follow-up of up to four months. Analyses were conducted on a pairwise basis using paired non-parametric tests for within-participant comparisons. Weight outcomes are reported using both median and interquartile range (IQR) and mean ± SD to aid interpretability. Clinically meaningful change was defined as a ≥5-point reduction in PHQ-9 or GAD-7 scores and ≥5% weight loss. Ethical approval was not required as this was registered as a service evaluation.

Of the twenty-four participants enrolled, thirteen had paired weight data. Median weight change at interim follow-up was −0.8 kg (IQR 3.5), with a mean reduction of −1.2 ± 2.6 kg. Weight change ranged from −7.5 kg to +1.3 kg. This change was not statistically significant ($P = .24$), and one participant (7.7%) achieved ≥5% weight loss.

In contrast, significant improvements were observed in psychological outcomes. Median PHQ-9 scores improved by −9 points (IQR −15 to −4; $P = .002$), with 69% of participants achieving clinically meaningful improvement. Median GAD-7 scores improved by −7 points (IQR −11 to −3; $P = .009$), with 62% achieving clinically meaningful improvement. Participants with severe baseline psychological symptoms demonstrated greater benefit, with those scoring ≥15 on PHQ-9 or GAD-7 showing substantially larger median reductions compared with those with lower baseline scores. No significant correlation was observed between changes in weight and changes in PHQ-9 or GAD-7 scores.

Early engagement with a multidisciplinary team in NHS weight management service was associated with clinically meaningful improvements in depression and anxiety at interim follow-up, while changes in weight were modest and variable.

Objectives: To evaluate the efficacy and safety of synthetic semaglutide injection (Test drug) with Wegovy® (Reference drug) 2.4 mg in weight management in two subgroups of patients based on BMI <35 kg/m^2 (Subgroup 1 [S1]) and BMI ≥ 35 kg/m^2 (subgroup 2 [S2])

Materials and Methods: This phase III, multicentre, randomized, open-label, active-controlled clinical study (CTRI/2025/04/085487) was conducted across 22 study sites in India after receiving regulatory and ethics committee approvals. Total 267 adult patients with BMI ≥ 30 kg/m^2 or ≥ 27 kg/m^2 with the presence of at least one co-morbidity of hypertension, dyslipidaemia and/or type 2 diabetes mellitus were included. Patients were randomized to receive either test drug or reference drug every week subcutaneously for 24 weeks. The primary endpoint was change in body-weight from baseline to week 24. Secondary endpoints included change in BMI, waist circumference, SF-36, and glycaemic measures. Safety assessments included incidence of TEAEs and anti-drug/neutralizing antibody.

Results: At baseline, 159 patients in S1 and 108 patients in S2 were included. Mean (±SD) percentage reduction in weight from baseline to week 24 was -14.6 (±4.10) with test drug and

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

-14.1 (±3.87) with reference drug in S1 ($P = .5173$) and -12.6 (±4.32) with test drug and -14.0 (± 4.50) with reference drug in S2 ($P = .1232$) respectively.

Proportion of patients achieving ≥ 5% and ≥10% body weight reduction was comparable between test and the reference drug in both S1 and S2 ($P = .3741$ and .5587 for S1 and $P = .4795$ and $P = .7910$ for S2 respectively).

Mean (± SD) change in BMI with test and the reference drug was -4.66 (±1.32) kg/m^2 and -4.53 (±1.24) kg/m^2 respectively in S1 ($P = .5808$) and -4.83 (±1.64) kg/m^2 and -5.57 (±1.72) kg/m^2 in S2 ($P = .0982$) respectively at week 24.

Mean (±SD) decrease in waist circumference with test and the reference drug was -10.3 (±3.06) cm and -10.9 (±11.27) cm respectively in S1 ($P = .5098$) and -11.4 (± 8.28) cm and -12.7 (±5.12) cm respectively in S2 (0.6749) at week 24.

In both subgroups decrease in glycaemic parameters (HbA1c, FBG and PPBG) from baseline to week 24 was comparable ($P > .05$) between test and reference drug in both diabetic and non-diabetic patients. In non-diabetic patients decrease was not clinically relevant.

Study medications were well tolerated.

Conclusions: Semaglutide injection is effective in weight management irrespective of baseline BMI and can be a treatment of choice in weight management with or without co-morbidities

Dipeptidyl peptidase-4 (DPP4) disrupts glucose homeostasis by degrading glucagon-like peptide-1 (GLP-1), thereby reducing insulin secretion and contributing to the development of type 2 diabetes mellitus; **YU-25-NC01** was identified through an in silico screening approach as a natural compound targeting this enzyme. The compound potently inhibited DPP4 enzymatic activity, and its direct interaction with the target protein was confirmed by a cellular thermal shift assay. In DPP4-expressing Caco cells, both mRNA and protein levels of DPP4 were significantly reduced, indicating regulation at transcriptional and translational levels. In a high-fat diet–induced hyperglycemic mouse model, treatment restored circulating GLP-1 levels and improved glycemic control, accompanied by increased expression of GLUT4 in skeletal muscle and GLUT2 in the liver. In addition, skeletal muscle development was enhanced, as evidenced by elevated myosin heavy chain expression and increased muscle fiber diameter. Collectively, these findings demonstrate that **YU-25-NC01** improves glucose metabolism while simultaneously promoting skeletal muscle growth, highlighting its therapeutic potential for both type 2 diabetes mellitus and diabetes-associated muscle atrophy.

EP693 - ECE_1396 - Double Diabetes in a Newly Diagnosed 18-yearl-old female with Obesity: Diagnosis, Treatment Strategies, and Lifestyle Interventions

Ivana Mickovski[1,2], Radmila Milosheska[3] and Daniela Buklioska Ilievska[1,3]
[1]*Faculty of Medical Sciences, Goce Delcev University, Stip, North Macedonia;* [2]*PZU Vasileva Kardio, Skopje, North Macedonia;* [3]*General City Hospital 8th September, Skopje, North Macedonia*

Background: Double diabetes, a hybrid form of diabetes combining autoimmune β-cell destruction with insulin resistance, is increasingly recognized among adolescents and young adults due to rising obesity rates. It presents diagnostic ambiguity and therapeutic complexity requiring both insulin replacement and insulin sensitization strategies.

Case Presentation: A 18-year-old female presented with fatigue, polyuria, polydipsia, and a 10-kg weight loss over three months. Despite weight loss, she remained obese (BMI 35.8 kg/m^2). Laboratory results revealed fasting glucose 240 mg/dL, HbA1c 10.3%, fasting insulin 22 µU/mL, and C-peptide 3.0 ng/mL. Both GAD-65 and islet cell antibodies were positive, confirming autoimmunity, while an elevated HOMA-IR (6.1) indicated marked insulin resistance. Lipid profile showed dyslipidemia, and acanthosis nigricans was present.

Diagnosis and Management: Double diabetes was diagnosed based on concurrent autoimmune and insulin-resistant features. Treatment included a basal-bolus insulin regimen (glargine and lispro) combined with metformin (up-titrated to 1000 mg twice daily). Intensive lifestyle modification focused on calorie restriction, low glycemic index nutrition, and structured exercise (150 minutes of aerobic activity weekly plus resistance training). At six months, HbA1c improved to 7.1%, weight reduced by 10 kg, and insulin requirements declined by 30%, reflecting enhanced insulin sensitivity.

Discussion: This case underscores the growing prevalence of double diabetes in young obese individuals and highlights the importance of early recognition and multidisciplinary management. The integration of insulin therapy with metformin and lifestyle interventions can significantly improve metabolic outcomes and reduce cardiometabolic risk.

Conclusions: Double diabetes requires a tailored approach addressing both autoimmune and metabolic components. Early combination therapy with insulin, metformin, and structured lifestyle modification is effective in achieving glycemic and weight control in young adults with this emerging phenotype.

EP695 - ECE_1041 - Components of a collaborative hybrid primary–specialty integrated diabetes care model leveraging CGM technology platforms to optimize outcomes: a pilot community-based quality improvement initiative

Pendar Farahani
NFMPC - Endocrinology Clinic, Milton, Canada

Background: The rising prevalence of diabetes and its associated complications demands innovative care models that bridge

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

gaps between primary and specialty care. Continuous Glucose Monitoring (CGM) technologies have transformed diabetes management, offering real-time insights that can enhance clinical decision-making and patient engagement.

Objective: This community-based quality improvement initiative aims to pilot a Hybrid Primary–Specialty Integrated Diabetes Care Model in Milton, Ontario, Canada, leveraging CGM platforms to optimize glycemic outcomes, streamline care coordination, and improve access to multidisciplinary support.

Methods: Eligible patients are enrolled through family medicine clinics based on clinical discretion. Upon enrollment, patients receive structured education on CGM use, data sharing, and self-monitoring. Lab results and medication reconciliation are integrated via provincial health data systems by care coordinators. Within two weeks, patients are evaluated by a multidisciplinary team—including endocrinologists, diabetes educators, and if it is indicated by mental health professionals—either virtually or in person. Longitudinal follow-up is conducted using CGM data and digital platforms, modeled after the "Get With The Guidelines" framework.

Results: So far, we conducted outreach to assess interest and feasibility among primary care stakeholders. Early engagement efforts have yielded promising results: Ongoing outreach is underway with family medicine clinics and health teams across the Milton region, Ontario, Canada. Multi-physician family health team clinics and solo-practice family physicians have expressed interest in joining the network. Clinics are proactively establishing shared CGM accounts, enabling collaborative data review and care coordination. This reflects a growing appetite for integrated, technology-enabled diabetes care among community-based providers. In next steps, we will proceed to formalize the onboarding process, including the development of shared protocols, training resources, and clearly defined roles within the pilot cohort. This will ensure consistency, accountability, and scalability as the program evolves.

Conclusions: This pilot will demonstrate the feasibility and potential impact of a hybrid care model that integrates CGM technology into community-based diabetes management. It will lay the groundwork for broader implementation and future research into technology-enabled chronic disease care.

EP696 - ECE_1437 - Efficacy and safety of finerenone in adults with diabetic kidney disease: insights from a retrospective cohort study

Ana Luísa Barbosa, Ana Rita Leite, Mafalda Canudas Costa, Juliana Gonçalves, Diana Alexandra Festas Silva, Sílvia Monteiro, João Neves and Joana Queirós
São João Local Health Unit, Department of Endocrinology, Diabetes and Metabolism, Porto, Portugal

Introduction: Finerenone, a non-steroidal selective mineralocorticoid receptor antagonist, has been shown to reduce albuminuria and the risk of chronic kidney disease (CKD) progression in patients with type 2 diabetes (T2D). Evaluating its safety and efficacy in real-world clinical practice, including in patients with other types of diabetes, remains essential.

Methods: We conducted a retrospective cohort study at a tertiary center including adults with diabetic kidney disease (DKD) who initiated finerenone. Participants who started/modified renoprotective therapies other than finerenone were excluded. We collected clinical and laboratory parameters, including blood pressure (BP), serum potassium levels (mEq/L), estimated glomerular filtration rate (eGFR; mL/min/1.73 m^2) and urinary albumin-to-creatinine ratio (UACR; mg/g), before finerenone initiation and after 1, 3-6 and 10-15 months. Changes in these parameters over the follow-up period were evaluated using paired t-tests or Wilcoxon signed-rank tests. Correlations between the variations in these parameters at 3-6 months were assessed using Spearman´s rank correlation.

Results: We included 38 patients (aged 64.6 ± 10.0 years; 73.6% male; 22 with T2D, 6 with type 1 diabetes (T1D) and 10 with other or unknown type; median follow-up duration of 6 months). Serum potassium levels showed a statistically significant increase after 1 month of finerenone initiation (4.51 ± 0.33 at baseline vs 4.68 ± 0.33 at 1 month, $P = .004$, $n = 37$), with no significant differences at 3-6 and 10-15 months. eGFR showed a significant decrease after 1 month (73.3 ± 23.2 at baseline vs 70.9 ± 24.8 at 1 month, $P = .040$, $n = 33$) and 3-6 months (69.9 ± 22.8, $P = .040$, $n = 27$), with no significant differences at 10-15 months. UACR decreased significantly from 146.7 (83.3-399.3) at baseline to 47.1 (30.2-92.9) at 3-6 months ($n = 25$, $P < .001$) and 72.9 (28.7-185.5) at 10-15 months ($n = 16$, $P = .003$), with no statistically significant differences between the latter two time points. No significant differences were observed in BP between baseline and 3-6 months. Hyperkalemia and finerenone discontinuation did not occur in any patient. Greater K+ increases between baseline and 3-6 months were associated with greater UACR reductions in the same period ($\rho = -0.597$, $P = .003$).

Conclusions: Finerenone was safe and effective in reducing UACR in adults with DKD. Greater serum potassium increases were associated with a stronger effect of finerenone on albuminuria.

Abstract citation ID: lvag096.1102

EP697 - ECE_2662 - Effect of Glucagon like Peptide-1 Receptor Agonist therapies on metabolic dysfunction-associated steatotic liver disease in overweight and obese adults

Thaw Htet[1,2], Julia Gordon[3], Brooke Hughes[3], Judy Chen[1], Juliana Chen[4] and Veronica Preda[1,2]
[1]Macquarie University Hospital, Endocrine department, Sydney, Australia; [2]Macquarie University, Faculty of Medicine Health and Health Sciences, Sydney, Australia; [3]Macquarie University, Sydney, Australia; [4]University of Sydney, Department of Nutrition and Dietetics, Sydney, Australia

Metabolic dysfunction-associated steatotic liver disease (MASLD) affects one in three adults globally and is currently considered the leading cause of chronic liver disease. However, it still remains substantially underdignosed. Its burden lies in the risk of progression to decompensated cirrhosis and hepatocellular carcinoma. While GLP-1 receptor agonists (GLP-1 RAs) show promising metabolic and hepatoprotective effects in trials, real-world data in overweight and obese populations remain limited. The aim of this study is to evaluate the effect of incretin analogues (semaglutide, liraglutide, tirzepatide) on hepatic steatosis in overweight or obese adults (BMI $\geq$ 25 kg/m^2) with a diagnosis of MASLD established by ultrasonography or elastography at baseline and after $\geq$ 12 months of pharmacotherapy.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

We reviewed the records and serial imaging data from 45 patients with MASLD and BMI ≥ 25 kg/m^2 who attended a multidisciplinary obesity clinic at Macquarie University Hospital, Sydney, Australia. The degree of hepatic steatosis was reported using a semi-quantitative ordinal scale (mild = 1, moderate = 2, severe = 3) to facilitate statistical analysis. The mean follow up duration was 18 months. The results of a paired t-test demonstrated a statistically significant reduction in hepatic steatosis, with a mean difference of 0.55 (95% CI [0.19, 0.93], $P = .001$). The mean pre-treatment steatosis grade was 2.04 which decreased to 1.48 post-treatment, suggesting hepatic steatosis improved in severity by approximately two-thirds of one steatosis grade, on average, following drug therapy. Greater improvements in hepatic steatosis severity were seen with larger reduction in body weight following incretin analogue therapy. A mean reduction in total body weight by 12% ± 6.7% was associated with a 2-grade improvement in steatosis, while reductions of 5% ± 0.1% and 4% ± 2.1% corresponded to a 1.5-grade and 1-grade improvements, respectively.

Our findings showed that the use of GLP-1 RAs and dual GLP-1/GIP receptor agonists was associated with an improvement in hepatic steatosis in over-weight and obese adults with MASLD. The findings of this study support the use of GLP-1 RAs and dual GLP-1/GIP receptor agonists as a part of the future clinical practice guidelines for MASLD management in over-weight and obese individuals.

Multidisciplinary prehabilitation and postoperative programs (PPP), combining physical activity, nutritional optimization and psychological support, are increasingly implemented to improve outcomes in oncology. In colon cancer, one of the most prevalent tumors in Europe, unhealthy lifestyle behaviors markedly increase the risk of postoperative complications following surgery, the first-line treatment. Within the ONCOFIT study (4-week prehabilitation plus 12-week postoperative program), perioperative participation resulted in reduced postoperative complications and improved clinical and functional outcomes in patients with colon cancer ($n = 90$). However, the systemic biological mechanisms underlying these benefits remain insufficiently characterized.

This translational study aimed to determine whether patient-derived serum obtained during ONCOFIT modulates tumor-related functional properties in vitro and to characterize associated systemic metabolic signatures. A mechanistic sub-cohort of patients receiving usual care ($n = 12$) or the PPP ($n = 12$) provided serum at three time points: baseline (T0, at diagnosis), after the prehabilitation phase (T1, 1-3 days before surgery), and after the postoperative program (T2, 3 months after surgery). Serum was applied to three human colon cancer cell lines (DLD1, HCT-116, and SW620) to assess key tumor functional properties (cell proliferation, colony formation, and cell invasion). In parallel, serum metabolic profiling was performed using nuclear magnetic resonance (NMR).

Across cell lines and functional assays, exposure to serum from PPP patients resulted in lower proliferative capacity, reduced clonogenicity, and decreased invasiveness compared with serum from usual care patients. Metabolomic profiling revealed a distinct signature in the PPP, characterized by lower LDL cholesterol and circulating fatty acids, alongside higher levels of glucose, several amino acids (Leu, Ile, Val, Lys, Thr, Phe, His, Gln, Cit, Gly, and Tyr), nitrogen-related metabolites (urea and creatinine), relative to usual care. Collectively, these findings are consistent with an intervention-associated shift toward a less pro-tumorigenic circulating milieu, potentially linking lifestyle-driven systemic remodeling to tumor cell behavior.

In conclusion, our PPP appears to modify serum-mediated regulation of colon-cancer cell proliferation, colony formation, and invasion compared with the usual care. Further research should determine the specific circulating mediators driving these effects and their clinical relevance.

EP699 - ECE_2343 - Mature onset of diabetes of young in paediatric patients - case series presentation

Milica Jakovljevic, Sandra Stankovic, Vesna Cvetkovic, Milica Ignjatović and Tatjana Stankovic

University Clinical Centre Nis, Pediatric Clinic, Endocrinology, Nis, Serbia

Introduction: Maturity-Onset Diabetes of the Young (MODY) is a group of rare, inherited types of diabetes caused by a single gene mutation, typically appearing before age of 25, characterized by positive family history and lack of autoantibodies.

Case series: The genetic testing for MODY was requested for patients with hyperglycaemia, positive family history and lack of antibodies. Out of 6 suspected patients, 4 were diagnosed with MODY, 3 boys and 1 girl. First patient, a boy aged 12 years in his annual checkup had fasting glucose levels 8 mmol/L. During oral glucose test (OGTT), glycaemia in 120. minute was 8.3mmol/L, HbA1c was 7.5%, C peptide 1.57 ng/mL. He was

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

started with Metformin. After 2 years, current HbA1c is 5.4% and C peptide is 2.53 ng/mL. A heterozygous pathogenic variant in the HNF4A gene (c.734G>A; (p.Arg245His)) associated with MODY type 1 was detected. Second patient, a 4 year old boy was diagnosed with systemic juvenile idiopathic diabetes (JIA) and received systemic corticosteroid and immunosuppressive therapy. During therapy, fasting glucose levels were above 7mmol/L, C peptide 1.2 ng/mL and HbA1c 5.9%. Dietary changes were advised. The therapy for JIA lasted for 2 years. At the age of 11 years, fasting glycaemia was 7.3 mmol/L, glycaemia after 2 hours in OGTT was 8.4 mmol/L, HbA1c was 6.5%, C peptide 1.3 ng/mL. Metformin was started. Current laboratory findings at the age of 13 years are HbA1c 6.3%, C peptid 1.41 ng/mL. A heterozygous pathogenic variant in the GCK gene (missense type c.763A>G) associated with MODY type 2 was detected. A 7 year old twins, a boy and girl were referred because of fasting hyperglycaemia, 7.3 and 6.3 mmol/L respectively. OGTTs were in reference range, with HbA1c 5.7% and 5.3% and C peptides 1.37 and 1.4 ng/mL. Dietary changes were advised. A heterozygous pathogenic variant in the GCK gene (nonsense type c.1261G>T) associated with MODY type 2 was detected in both twins. At the age of 13 years the boy had HbA1c 7.0%, while the girl had HbA1c 6.6%. Dietary change was advised.

Conclusions: Glucose intolerance in MODY starts in early childhood, so annual checkups for fasting blood glucose and urine samples should be advised in patients with positive family history. Although MODY has relatively slow progression and mild complications, early diagnosis with dietary and life style modifications and treatment can slow down progression of disease. Genetic counseling and testing should also be advised.

EP701 - ECE_3570 - Synergistic effect of vitamin D deficiency and cold season on mortality in hospitalized adults

Juraj Smaha, Martin Kužma, Peter Jackuliak and Juraj Payer
Comenius University Faculty of Medicine, 5th Department of Internal medicine, Comenius University Bratislava, Bratislava, Slovakia

Background: Vitamin D deficiency is highly prevalent and shows strong seasonal variability. In hospitalized patients, low serum 25-hydroxyvitamin D (25(OH)D) concentrations may be linked to increased mortality. These relationships may be modified by season and by pandemic-related changes in supplementation during the COVID-19 period.

Objective: To quantify seasonality of serum 25(OH)D and evaluate the joint effect of vitamin D deficiency and cold months on in-hospital mortality in a large Central European inpatient cohort, including analyses across the COVID-19 period in Slovakia.

Methods: We conducted a retrospective cohort study of adult hospitalizations at a tertiary university hospital in Bratislava, Slovakia, between 2018 and 2023. Patients with serum 25(OH)D measured at admission were included (n = 6,914; women 50.3%). Vitamin D deficiency was defined as 25(OH)D <20 ng/mL. Seasonality was assessed by month/season and by warm versus cold months (warm: April–September; cold: October–March). To reflect the potential impact of COVID-19 on vitamin D status and seasonal patterns, analyses were stratified by calendar periods 2018-2019, 2020-2021 (COVID-19 period), and 2022-2023. Logistic regression models were used to identify independent predictors of in-hospital mortality and to test interaction between vitamin D deficiency and cold months.

Results: Mean serum 25(OH)D concentration at admission was 18.0 ± 11.2 ng/mL; vitamin D deficiency (<20 ng/mL) was present in 62% of admissions. 25(OH)D concentrations demonstrated significant seasonal variability with lower values in cold months. Seasonal patterns differed between 2018 and 2021, indicating attenuation of seasonal variability during the COVID-19 period. Overall in-hospital mortality was 16.8% and differed significantly by season ($P < .001$), with lower mortality in warm compared with cold months ($P < .001$). In multivariable models, admission 25(OH)D remained independently associated with mortality ($P = .02$), alongside age ≥65 years ($P < .001$) and malignancy ($P < .001$). In the combined season–deficiency model (reference: warm months without deficiency), mortality odds increased in warm months with deficiency (OR 1.40) and cold months without deficiency (OR 1.28), and were highest in cold months with deficiency (OR 2.38). A significant synergistic interaction between vitamin D deficiency and cold months was confirmed (OR ~1.33; 95% CI 1.12-1.58; $P < .001$).

Conclusions: In a large real-world inpatient cohort, vitamin D deficiency was frequent and strongly seasonal. The combination of vitamin D deficiency and cold months conferred the greatest mortality risk (OR 2.38), supporting season-aware risk stratification using admission 25(OH)D in hospitalized adults.

EP702 - ECE_1038 - Health inequalities in diabetes care over the last five decades (1975-2025): a global perspective

Pendar Farahani
NFMPC - Endocrinology Clinic, Milton, Canada

Background: Diabetes is growing epidemic, globally. Diabetes care is complex. Many factors can impact optimal diabetes care and access.

Objectives: 1—To explore determinant factors contributing to health inequalities in diabetes care, globally; 2—To explore the trends of changes in these factors in the last five decades.

Methods: systematic review of medical databases between 1975 and 2025.

Results: Sources of inequalities include geographical, social and personal factors. Geographical factors contributing to access to diabetes care have been studied by continents, countries, regions, and rurality. Social factors include household income, education level, food security, housing stability, and employment status, while personal factors include gender/sex, ethnicity/race, and culture. There are significant interactions between these risk factors in all levels (*P*-value .01-.0001).

Trends and Changes: conducted research studies between 2010 and 2025 demonstrated more than two-fold increase in publications compared to previous four decades (1975-2010) [*P*-value .0001]. Although the number of females, minorities and lower socioeconomic status participants in studies significantly and continuously increased in the last five decades [*P*-value .001, .001, .01], still significant inequality gaps exist in clinical studies related to diabetes care. Utilization of technologies such as

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

telemedicine and establishing local and integrated networks for diabetes care were increased significantly (*P*-value .0001). Trends of change in all continents are positive with different magnitude and velocity (*P*-value .0001). Although, technological and pharmacological advancements for diabetes care significantly improved over the last five decades, the rising prices of medication and equipment led to additional inequality in diabetes care.

Conclusions: Over the last five decades there have been tremendous efforts to address inequalities in diabetes care; there has been more awareness, more inclusion of minorities and women in studies, more publication, more evidence-based care, more patient-centered and tailored models of care. Although all trends are positive globally, the rising prices of medications and care impacted this trend negatively.

EP704 - ECE_1135 - Identification of risk factors for cardiovascular autonomic neuropathy in patients with type 2 diabetes mellitus and cardiovascular diseases based on insulin production

Olha Monashnenko[1] and Borys Mankovsky[2]
[1]*Kyiv, Ukraine;* [2]*D.F.Chebotarev State Institute of Gerontology NAMS of Ukraine, Kyiv, Ukraine*

Background and Aims: Cardiovascular autonomic neuropathy (CAN) is a serious complication of type 2 diabetes mellitus (T2DM) that significantly worsens patient prognosis. The aim of this study was to evaluate the relationship between clinical and laboratory parameters, particularly insulin secretion, and the development of CAN in patients with T2DM and concomitant cardiovascular diseases (CVD).

Materials and Methods: We included 82 patients diagnosed with T2DM and CVD. Based on the presence of cardiovascular autonomic neuropathy, patients were divided into two groups: a main group with existing CAN (n = 66) and a control group without CAN (n = 16). All participants underwent a detailed examination, including medical history, anthropometry, and laboratory tests. C-peptide levels were used as a key marker of endogenous insulin production. For statistical analysis, the Student's t-test and χ^2 test were used, and the significance level was set at $P < .05$.

Results: A comparative analysis showed that patients with CAN were significantly older (67.1 ± 8.4 vs 62.3 ± 9.1 years, $P < .05$) and had a longer duration of T2DM (12.8 ± 6.1 vs 8.5 ± 5.2 years, $P < .01$) compared to the control group. The CAN group also had a significantly lower glomerular filtration rate (72.5 ± 18.0 vs 84.2 ± 15.1, $P < .05$) and a markedly lower C-peptide level (2.1 ± 0.9 vs 2.9 ± 1.1 ng/mL, $P < .01$). A strong negative correlation was found between C-peptide levels and the duration of diabetes ($r = -0.65$, $P < .01$), indicating the depletion of insulin secretion over time.

Conclusions: The key risk factors for the development of CAN in patients with T2DM and CVD are older age, a longer duration of diabetes, reduced kidney function, and decreased endogenous insulin secretion. Impaired insulin production, confirmed by low C-peptide levels, is an independent and statistically significant risk factor for the development of CAN in this patient population. C-peptide assessment may serve as a useful tool for risk stratification and identifying patients who require more careful monitoring and preventive measures.

Abstract citation ID: lvag096.1108

EP710 - ECE_2689 - Budget impact analyses for the management of obesity: a literature review

Timothy Quek[1,2,3] and Leela Barham[3]
[1]*Tan Tock Seng Hospital, Singapore, Singapore;* [2]*Singapore, Singapore;* [3]*University of South Wales, Pontypridd, United Kingdom*

Background: Obesity is a common chronic disease with many major medical complications, resulting in a significant rising global economic burden. While lifestyle modifications, anti-obesity medications (AOMs), and bariatric surgery are three established modalities of treatment for obesity, the high cost of newer therapies such as GLP-1 agonists has intensified the need for budget impact analyses (BIAs) to aid in decision making on resource allocation. A literature review was performed to synthesize the findings of recent published BIAs.

Methods: A literature review was conducted following PRISMA 2020 guidance. PubMed and EMBASE databases were searched for English-language studies published between January 2015 and November 2025 reporting standalone BIAs or economic evaluations with a distinct BIA component. Data extraction was guided by the CHEERS 2022 framework, and results were synthesized narratively.

Results: Nine studies met the inclusion criteria: two on lifestyle interventions (both from the United States), three on AOMs (all from the United States), and four on bariatric surgery (two from the United States, one from Thailand, and one from Canada). All the included studies demonstrated a negative short-term budget impact, primarily driven by up-front treatment costs. Lifestyle programs typically showed lower program costs with healthcare utilization offsets from a reduction in obesity related complications and their treatment. For AOMs and bariatric surgery, cost savings were primarily observed in studies with longer time horizons exceeding five years. Two BIAs on anti-obesity medications and one BIA on bariatric surgery showed long-term savings driven by a reduction in metabolic complications and costs related to their treatment (eg, remission of Type 2 diabetes mellitus). Notably, four of the nine studies were industry-funded, all of which reported favourable budget impacts. Comparability and transferability of the study findings were limited by significant heterogeneity in study methodology and reporting.

Conclusions: Obesity treatments present a clear tension between shorter-term affordability and longer-term economic benefits. Although BIAs are often performed with shorter time horizons, such BIAs may fail to capture the full cost-offset potential of preventing chronic complications for chronic conditions like obesity. For sustainable implementation, policymakers could consider phased or targeted strategies focusing on high-risk populations, and/or the use of cheaper generic biosimilars as these become available. At the same time, it is important to remain mindful of the sensitivity of BIA estimates to underlying assumptions and industry influence.

This work was completed in partial fulfillment of an MSc in Applied Health Economics at the University of South Wales.

EP711 - ECE_3662 - Interactions between obstructive sleep apnea and endocrine and metabolic functions

Zachary Friedman and Hassan Heshmati
Endocrinology Metabolism Consulting, LLC, Hassan Heshmati and Valerie Shaw Endocrine Research, Anthem, AZ, United States

Introduction: Sleep is important for health. There are bidirectional interactions between sleep and the endocrine and metabolic systems. Obstructive sleep apnea (OSA) is a common sleep disorder that is caused by or does promote multiple endocrine and metabolic conditions. This review presents an update on the interactions between OSA and endocrine and metabolic functions.

Methods: A systematic search of literature was conducted for the period 2003 to 2025 using the search terms sleep, OSA, interactions, hormones, endocrine function, and metabolic function.

Results: Sleep is essential for health and well-being. There are complex interactions between normal sleep and multiple endocrine and metabolic functions. OSA, the most common sleep disorder, is characterized by disturbances in sleep patterns (arousals), snoring, and recurrent episodes of apnea or hypopnea, with a frequency of at least 5 episodes/hour. It is caused by partial or total obstruction of the pharynx. OSA affects approximately 1 billion people worldwide and is more prevalent in men than women for multiple reasons including differences in upper airway anatomy and sex hormones. Obesity is the leading cause of OSA. Indeed, more than 40% of patients with OSA have obesity. Type 2 diabetes is another risk factor to develop OSA. Gonadal hormones in women (eg, estrogen and progesterone) play an important role in the pathogenesis of OSA. They impact the upper airway patency, contractility of the genioglossus muscle, airway collapsibility, and fluid shifts. Estrogen and progesterone have a protective effect against OSA before menopause and their deficiency during menopause is responsible for an increased prevalence of OSA in postmenopausal women (prevalence may exceed 50%). Polycystic ovary syndrome (PCOS) is significantly associated with OSA in women. In return, OSA can promote or aggravate several endocrine and metabolic diseases such as hyperprolactinemia, hypercortisolism, hyperaldosteronism, type 2 diabetes, hypogonadism with infertility, and obesity. Regular exercise, continuous positive airway pressure (CPAP) therapy, and management of hormonal dysfunctions and obesity (diet, exercise, and behavioral change) have beneficial effects.

Conclusions: Obesity, type 2 diabetes, and gonadal deficiency (eg, menopause) are important risk factors for the development of OSA. People with OSA are also at increased risk of several endocrine and metabolic diseases including hyperprolactinemia, hypercortisolism, hyperaldosteronism, type 2 diabetes, hypogonadism, and obesity. Regular exercise, CPAP therapy, correction of hormonal abnormalities, and weight management (when indicated), are among the most recommended interventions.

EP712 - ECE_2513 - Hidden burden of iron deficiency without anemia in women with type 2 diabetes and heart failure with preserved ejection fraction

Lileia Petrovska[1,2], Iryna Kostitska[1], Taras Petrovskyy[1] and Roman Petrovskyy[1]
[1]*Ivano-Frankivsk National Medical University, Endocrinology, Ivano-Frankivsk, Ukraine;* [2]*Ivano-Frankivsk National Medical University, Endocrinology, Ivano-Frankivsk, Ukraine*

Background and Aims: Iron deficiency, particularly common in women, often remains underdiagnosed without anemia (IDWA) and can worsen quality of life and exacerbate cardiovascular and metabolic symptoms in those with type 2 diabetes (T2D) and heart failure with preserved ejection fraction (HfpEF). The aim of the study was to investigate the prevalence of IDWA and its relationship with clinical characteristics in women with T2D and HFpEF.

Materials and Methods: 30 women with T2D and HFpEF (mean age 59.1 ± 1.5 years; body mass index (BMI)- 34.2 ± 2.3 kg/m^2, waist circumference (WC) – 104.1 ± 2.1 cm, glycated hemoglobin (HbA_1C)- 7,.2 ± 0.2% and duration of T2D −7.4 ± 0.9 years) were comprehensively phenotyped including physical examination (blood pressure, heart rate, BMI, WC); laboratory tests: ferritin, transferrin saturation (TSAT), hemoglobin, and N-terminal pro–brain natriuretic peptide (NT-pro-BNP); instrumental evaluation: echocardiography to confirm LVEF >50%; functional assessment: NYHA class. All patients received standard therapy including SGLT2 inhibitors. IDWA was defined as ferritin <100 ng/mL or TSAT <20% with normal hemoglobin levels. Prevalence, functional status, and metabolic parameters were analyzed using descriptive statistics and compared between women with IDWA and women without confirmed iron deficiency.

Results: IDWA was present in 23 out of 30 women (76.7%), defined as ferritin <100 ng/mL or transferrin saturation (TSAT) <20% with normal hemoglobin levels. Women with IDWA had higher NYHA class (2.6 ± 0.5) compared to women without confirmed iron deficiency (1.9 ± 0.4), indicating worse functional capacity and more pronounced fatigue. Women with IDWA tended to have poorer glycemic control, with slightly higher HbA1c (7.3 ± 0.2%) versus women without confirmed iron deficiency (6.9 ± 0.1%). At the same time, BMI (34.5 ± 2.2 kg/m^2) and WC (104.7 ± 1.8 cm) were slightly higher in IDWA women compared to women without confirmed iron deficiency (BMI 33.4 ± 2.4 kg/m^2, WC 102.8 ± 1.9 cm), although these differences were not statistically significant. In summary, IDWA was common in women with T2D and HFpEF and was associated with worse functional status and trends toward adverse metabolic parameters.

Conclusions: IDWA is common in women with T2D and HFpEF, often underdiagnosed due to nonspecific symptoms, and is associated with worse functional status and metabolic trends, highlighting the clinical importance of routine iron assessment.

EP713 - ECE_1311 - Treatment of latent tuberculosis infection attenuating serum aryl hydrocarbon receptor in patients with type 2 diabetes

I-Te Lee
Taichung Veterans General Hospital, Division of Endocrinology and Metabolism, Department of Internal Medicine, Taichung, Taiwan

Backgrounds: Latent tuberculosis (TB) infection is a state of TB immunoreactive response without an active TB manifestation. The prevalence of latent TB infection is increased in the population with diabetes mellitus (DM). Latent TB infection has been reported to induce inflammatory reactions, including an elevated level of circulating aryl hydrocarbon receptor (AhR) in patients with type 2 DM. We hypothesized that tuberculosis preventive therapy (TPT) could reduce the circulating AhR.

Methods: In this prospective observational study, patients with type 2 DM and age $\geq$ 45 years received QuantiFERON-TB (QFT) test for screening latent TB infection. The patients with a positive result of the QFT test were enrolled for TPT. The enrolled patient received either 9 months of daily isoniazid (9H) or 3 months of weekly rifapentine plus isoniazid (3HP) according to their decision after evaluation by the pulmonologist and excluding active TB. Serum AhR concentrations were determined at baseline and after TPT.

Results: Among the 88 enrolled patients, serum AhR levels significantly decreased (median: −26.3 pg/mL; interquartile range [IQR]: −43.2, −6.0 pg/mL; $P < .001$). Based on the TPT regiments, 47 (53.4%) patients received the 3HP regimen and 41 (46.6%) received the 9H regimen, respectively. Subgroup analysis revealed that serum AhR levels significantly decreased in both groups of patients treated with 3HP (median: −28.3 pg/mL; IQR: −42.3, −5.9 pg/mL; $P < .001$) and patients treated with 9H (median: −23.9 pg/mL; IQR: −49.0, −6.9 pg/mL; $P < .001$). There was no significant difference in the magnitude of change in the AhR level ($P = .983$) between the 3HP and 9H groups. Linear regression analysis showed that the magnitude of change in AhR levels after TPT was not significantly associated with different TPT regimens ($P = .286$).

Conclusions: The serum AhR level significantly decreased after the TPT program in patients with type 2 DM and latent TB infection, and the magnitude of the decrease in the serum AhR level did not significantly differ between the 3HP regimen and the 9H regimen.

EP714 - ECE_2588 - Role of vitamin D-binding protein in the correction of vitamin D deficiency in patients with diabetic kidney disease

Viktoriia Yerokhovych[1], Yeva Ilkiv[1], Olena Karpenko[1], Maryna Bobryk[1], Veronika Zinych[1], Nazarii Kobyliak[1,2] and Iuliia Komisarenko[1]
[1]*Bogomolets National Medical University, Kyiv, Ukraine;* [2]*Kyiv, Ukraine*

Background: The increasing prevalence of kidney injury in patients with type 2 diabetes mellitus (T2D) is a significant clinical concern. Bone-mineral disorders are common in this population and require timely diagnosis and intervention. Vitamin D metabolism is regulated by various factors, including vitamin D-binding protein (VDBP), which has recently attracted attention due to its potential role in the pathogenesis of diabetic kidney disease (DKD).

Objective: To evaluate phosphorus-calcium metabolism in patients with DKD and investigate the association between serum VDBP levels and the effectiveness of vitamin D deficiency correction.

Methods: A total of 84 patients with T2D and chronic kidney disease (CKD) stages I–III were examined. Participants were divided into three groups based on estimated glomerular filtration rate (eGFR), and baseline calcium-phosphorus metabolism indicators were assessed. In the second phase, 32 patients received cholecalciferol supplementation and were followed for three months to evaluate changes in 25(OH)D levels.

Results: Median 25(OH)D levels indicated vitamin D deficiency across all groups. The third group had the lowest values - 13 (8.48-16.4) ng/mL - significantly lower than in the first and second groups ($P < .05$). Serum VDBP levels increased with declining eGFR: 93.6 (68.17-109.67) ng/mL in group I; 101.07 (75.34-132.84) ng/mL in group II; and 132.82 (97.3-168.8) ng/mL in group III. A statistically significant difference was observed between groups I and II ($P < .01$). Vitamin D correction was more effective in patients with lower baseline VDBP levels. Among those who failed to reach optimal 25(OH)D levels ($\geq$30 ng/mL), 31% had significantly higher serum VDBP concentrations.

Conclusions: VDBP is an important factor in vitamin D metabolism and should be considered when correcting bone-mineral imbalances in patients with DKD. The study showed that there is an increase in the level of VDBP with the progression of CKD against the background of T2D. Probably, elevated VDBP levels may impair treatment efficacy by reducing the bioavailability of free vitamin D, due to enhanced binding of its active form, $1,25(OH)_2D$.

EP722 - ECE_1774 - Nivolumab-induced pancreatitis and diabetes mellitus in a patient with metastatic melanoma

Ourania Psoma, Christos Zessides and Stelios Tigas
University of Ioannina, Department of Endocrinology, Ioannina, Greece

Introduction: The introduction of immune checkpoint inhibitors (ICIS) inaugurated a new era in the management of metastatic malignancies. However, their molecular action is inextricably linked to a plethora of immune-related adverse events (irAEs).We report a rare case of diabetes mellitus (DM) and chronic pancreatitis co-emerging in a patient on nivolumab (a PD-1 checkpoint inhibitor antibody) treatment for metastatic melanoma.

Case Description: A 27-year-old woman presented with right parotid enlargement and ipsilateral cervical lymphadenopathy. She reported that a blue nevus in the head area had been surgically excised 6 years prior to presentation. She underwent right parotidectomy and lymph node dissection; the histopathology report was consistent with metastatic melanoma stage IIIB (TxN2bM0). Systemic therapy with nivolumab (at a dose of 480

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

mg intravenously every 28 days) was initiated, and 2 months later she developed abdominal pain accompanied by elevated serum amylase levels. Magnetic resonance imaging revealed a suspicious lesion in the pancreatic tail, with increased metabolic activity on 18F-FDG PET-CT scan. Two months later she underwent endoscopic ultrasonography showing a diffusely edematous pancreas and mild parenchymal heterogeneity. Fine-needle biopsy was consistent with pancreatitis. Lymphocytic infiltration was noted with no evidence of malignancy or IgG4-related disease. Six months following nivolumab onset, the patient developed xerostomia and osmotic symptoms. Laboratory investigations demonstrated a fasting plasma glucose of 239 mg/dL, reduced C-peptide levels (0.16 ng/mL) and HbA1c 5.3%. The serum titers of islet-associated antibodies were negative. The patient was initially managed with multiple daily insulin injections and was subsequently started on continuous subcutaneous insulin infusion.

Discussion: ICI-induced DM is a rare irAE (incidence of less than 1%). Its pathophysiology, appears to be multifaced and remains incompletely elucidated. Type 1 diabetes related autoantibodies are commonly, though not always present. Although pancreatitis and DM have each been individually described in patients receiving ICIs, their coexistence has only sparsely been reported in the literature. Notably, a subset of affected patients exhibits radiological or biochemical features consistent with pancreatitis either preceding or coinciding with the diagnosis of DM, suggesting immune-mediated destruction of both the exocrine and endocrine pancreatic compartments.

We describe the case of a patient treated with nivolumab who presumably developed autoimmune pancreatitis followed by fulminant DM. Given the expanding use of ICIs, prompt recognition through careful monitoring of plasma glucose levels—prior to therapy initiation, throughout each treatment cycle, and following treatment discontinuation—is crucial.

EP724 - ECE_2170 - Clinical characteristics and outcomes in patients with T2DM admitted to an interventional stent placement procedure

Oyshabonu Sobirjonova[1], Mohammed Abdul Haseeb[2], Askar Sabirov[3] and Zulaykho Shamansurova[1]
[1]Tashkent, Uzbekistan; [2]Kimyo International University in Tashkent (KIUT), Tashkent, Uzbekistan; [3]AKFA Medline University Hospital, Tashkent, Uzbekistan

Background: Diabetes mellitus (DM) is a major risk factor for cardiovascular disease and is commonly associated with obesity, impaired cardiac function, and coronary artery disease. Nowadays, acute myocardial infarction is easily prevented and treated by interventional cardiac surgery, such as a stent. The aim of our study was a comparative analysis of clinical characteristics and outcomes in patients with and without DM admitted to a stent placement procedure.

Methods: A retrospective observational study was conducted at Akfa Medline University Hospital in Tashkent, Uzbekistan, by gathering data from medical records in a total of 12,026 patients treated in 2024 and 2025. Patients were divided into two groups: with and without DM. Demographic data, body mass index (BMI), echocardiographic ejection fraction (EF), coronary angiography reports, and mortality rate were analyzed. EF and angiography analyses were performed in patients with available data. Results were presented as absolute numbers and percentages.

Results: Of the total cohort, 196 patients (1.6%) had diabetes mellitus, and 11,830 patients (98.4%) did not have DM. The mean BMI in the overall 2025 cohort was 27.5 kg/m^2. Patients with diabetes had a higher mean BMI compared with non-diabetic patients (31.1 vs 26.8 kg/m^2). Echocardiographic data showed the mean EF was consistently lower (37% vs 42%) in patients with diabetes compared with non-diabetic patients. Coronary angiography, available in a limited subgroup, demonstrated more impaired coronary circulation among diabetic patients. Overall mortality was comparable across the cohort.

Conclusions: In this large hospital-based cohort, patients with diabetes mellitus had higher BMI and reduced cardiac function compared with non-diabetic patients. And suggested to underscore the cardiovascular vulnerability associated with DM and highlight the importance of comprehensive cardiovascular assessment in this population.

EP725 - ECE_1845 - Exploring the metabolic risks of weight loss therapy in Type 1 Diabetes: A case of DKA following Retatrutide injections

Hasan Jamjoom
LONDON, United Kingdom

Introduction: Retatrutide is a novel experimental weight loss agent which, in comparison to more commonly known weight modulators, is a triple agonist of the GIP, GLP-1, and glucagon receptors, and is currently undergoing phase 3 clinical trials to establish long term safety and efficacy. Its use remains predominantly research based and it is not licensed for clinical use within the United Kingdom or elsewhere. Although it has shown some promising results in relation to obesity and type 2 diabetes, its safety profile in patients with type 1 diabetes is yet to be established.

Case Report: A 20-year-old, 60-kg female patient with a background history of type 1 diabetes, on basal-bolus insulin (Levemir and Fiasp), presented to the emergency department following a period of intractable vomiting and reduced oral intake. On questioning, the patient reported being dissatisfied with her current weight and therefore had started a new weight loss injection which later transpired to be Retatrutide. She purchased it off a friend who had bought it from the United States. She reported only having had x3 doses, with the last dose being the day prior to admission. On presentation to the emergency department, she was mildly tachycardic but otherwise haemodynamically stable with no oxygen requirement. She appeared unwell with persistent nausea and retching. Her biochemistry showed her to be in severe diabetic ketoacidosis with blood sugars of 20mmol/l, ketones of 6.4mmol/l, pH of 6.8, and a Bicarbonate level of 4 mmol/l. She was commenced on a fixed rate insulin infusion at 0.1 units/kg/hour, in addition to fluid resuscitation and administering her basal insulin. She made steady progress as her labs improved, allowing her to be switched to variable rate insulin initially and then back to her usual subcutaneous insulin. She was

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

discharged from hospital with the recommendation of definitively discontinuing Retatrutide.

Discussion: While traditional GLP-1 receptor agonists have shown some efficacy in type 1 diabetes, particularly in cases of co-existent metabolic syndrome, this case illustrates the need for more comprehensive data when it comes to the safety of Retatrutide, especially in patients with type 1 diabetes. It also emphasises the importance of patient education and promoting vigilance when it comes to weight loss medication, particularly for those who purchase them from the black market or from non-reputable sources, which clearly poses a higher risk of potential drug contamination and hence adverse outcomes.

EP726 - ECE_3628 - Anaphylaxis after initiation of insulin glargine/lixisenatide in a patient with long-term tolerance to insulin glargine: a case report

Gökhan Rıza Baykal[1], Aslı Altınbezer[1], Şadan Soyyiğit[2], Oya Topaloglu[3], Reyhan Ersoy[3] and Bekir Cakir[3]
[1]*Ankara Bilkent City Hospital, Department of Endocrinology and Metabolism, Ankara, Türkiye;* [2]*Ankara Yıldırım Beyazıt University Faculty of Medicine, Ankara Bilkent City Hospital, Department of Pulmonary Diseases, Immunology and Allergy, Ankara, Türkiye;* [3]*Ankara Yıldırım Beyazıt University Faculty of Medicine, Ankara Bilkent City Hospital, Department of Endocrinology and Metabolism, Endocrinology and Metabolism, Ankara, Türkiye*

Background: Fixed-ratio combinations of basal insulin and GLP-1 receptor agonists, such as insulin glargine/lixisenatide, are increasingly used in type 2 diabetes mellitus (T2DM). Although hypersensitivity reactions have been reported, anaphylaxis remains rare. We describe an immediate-type systemic reaction fulfilling clinical criteria for anaphylaxis shortly after initiation of insulin glargine/lixisenatide in a patient who had tolerated insulin glargine for years.

Case: A 42-year-old woman with a long-standing history of T2DM and hypothyroidism had been treated for several years with a basal–bolus regimen consisting of daytime insulin aspart and evening insulin glargine, without any previous local or systemic allergic reactions. Her regimen was simplified by switching to once-daily insulin glargine 100 U/mL plus lixisenatide. On the third day of therapy, shortly after the evening injection, she developed generalised erythema and pruritic urticaria, lip and tongue swelling, dyspnea, palpitations and presyncope. She was admitted to the emergency department with a diagnosis of anaphylaxis and treated with intramuscular adrenaline, intravenous antihistamines, corticosteroids, and fluids. She required three days of intensive care unit monitoring followed by four days in a medical ward, with full clinical recovery. Thereafter, she was evaluated in an allergy and clinical immunology clinic. Based on the temporal relationship, clinical severity and her documented long-term tolerance to insulin glargine, the reaction was classified as an immediate-type, drug-induced anaphylaxis most likely related to lixisenatide. Permanent avoidance of lixisenatide-containing medications was recommended. Her previous regimen with insulin aspart and insulin glargine was restarted and has been continued without recurrence of allergic symptoms during follow-up.

Conclusions: This case illustrates that life-threatening anaphylaxis may occur early after starting insulin glargine/lixisenatide in a patient who has previously tolerated insulin glargine alone. Clinicians should be aware that the GLP-1 receptor agonist component of fixed-ratio combinations can unmask severe hypersensitivity reactions. Immediate discontinuation of insulin glargine/lixisenatide, referral for specialist allergy assessment and resumption of a previously tolerated insulin regimen represent a pragmatic management strategy, and reporting such events is essential to better characterise the safety profile of lixisenatide-containing therapies.

EP729 - ECE_2411 - Effect of short term subcutaneous liraglutide treatment on respiratory function in individuals with clinical obesity and obstructive sleep apnea

Maria Christou[1], Charikleia Tselepi[2], Panagiota Christou[1], Nikolaos Kavrakis[1], Paschalis Karagkiozakis[1], Eleni Christou[1], Katerina Papathanassiou[1], Athanasios Siolos[1], Christos Zessides[1], Christos Kyriakopoulos[2], Konstantinos Kostikas[2], Athanasios Konstantinidis[2] and Stelios Tigas[1]
[1]*University of Ioannina, Department of Endocrinology, Ioannina, Greece;* [2]*University of Ioannina, Department of Respiratory Medicine, Ioannina, Greece*

Introduction: Tirzepatide has demonstrated benefit in reducing the apnea-hypopnea index (AHI) in individuals with obstructive sleep apnea (OSA), while liraglutide and phentermine/topiramate have shown potential benefit. This study aimed to assess the effect of liraglutide on anthropometric characteristics and respiratory function in individuals with clinical obesity and OSA followed-up at a Greek tertiary center.

Methods: Individuals with class III obesity [body mass index (BMI) ≥40 kg/m^2] and OSA, already receiving continuous or bi-level positive airway pressure (CPAP or BiPAP) therapy, participated in the study and were treated with liraglutide 3 mg sc once daily. Anthropometric, spirometric and device-derived sleep apnea parameters were recorded at baseline and at 4 months. Results are presented as number (percentage), mean (standard deviation) or median (range).

Results: Forty-one individuals were recruited, of whom 29 completed the 4-month follow-up (mean age 58 ± 10 years, 48% males). Prediabetes, type 2 diabetes, dyslipidemia, hypertension, coronary heart disease and heart failure were present in 66%, 24%, 69%, 62%, 14% and 21%, respectively. Twenty-two (76%) received CPAP and 7 (24%) BiPAP therapy. Most individuals had severe OSA (87%) with a sleep study-derived AHI of 72 ± 29. Body weight decreased with liraglutide from 136.4 ± 26.8 to 126.4 ± 26.5 kg ($P < .01$) and BMI from 45.6 (40.1-66.3) to 43.0 (34.6-62.3) kg/m^2 ($P < .01$). Absolute and relative weight change were −9.9 (−28.2 + 0.6) kg and −7.4% ± 4.8, respectively with 76%, 24%, and 7% of individuals achieving ≥5%, ≥10%, and ≥15% weight loss, respectively. Waist circumference in men and women, neck circumference in men, waist-to-hip ratio in men and waist-to-height ratio were also significantly improved at 4 months. HbA1c decreased significantly [6.2% (5.1-9.1) to 5.7% (4.7-8.0), $P < 0.01$]. Spirometric indices did not show

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

statistically significant changes. Mean and 95th percentile positive airway pressure improved significantly (9.7 ± 2.5 to 8.5 ± 2.3 cmH2O, $P < .01$ and 11.3 ± 2.2 to 10.7 ± 2.2 cmH_2O, $P < .01$, respectively). Device use during sleep was also significantly decreased (402 ± 136 to 357 ± 90 minutes, $P = .04$). Adverse events were reported in 45% of individuals, mostly gastrointestinal (86%).

Conclusions: Among individuals with clinical obesity and OSA, liraglutide treatment was associated with clinically significant weight loss, along with reductions in positive airway pressure requirements and sleep device usage time.

Abstract citation ID: lvag096.1118

EP730 - ECE_2742 - Relationship between inflammation and micronutrients status in a cohort of obese Romanian paediatric patients

Ioana-Maria Crasan[1], Corina Delia[1,2], Anisoara Cimpean[1], Bogdan Pascu[2] and Elena Ionica[1]
[1]*University of Bucharest, Departament of Biochemestry and Molecular Biology, Bucharest, Romania;* [2]*National Institute for Mother and Child Health "Alessandrescu-Rusescu", Laboratory of Biochemistry, Bucharest, Romania*

Paediatric obesity is increasingly recognized as a state of low-grade, chronic inflammation that may coexist with micronutrient disturbances, yet integrated data in Romanian children and adolescents remain scarce.

This study aimed to (i) evaluate the relationship between inflammatory biomarkers and micronutrient status, focusing on vitamin D [25(OH)D] and iron, and (ii) assess whether BMI-for-age percentiles are useful for obesity classification in patients <18 years, complemented by Tanita bioimpedance measurements of body composition. We conducted a cross-sectional analysis of 60 paediatric patients (0.9-17 years; 31 females/29 males), stratified into two age groups (0-12 years, n = 31; 13-18 years, n = 29). We measured 25-hydroxyvitamin D, total calcium, phosphorus, serum iron and ferritin, inflammatory markers (high-sensitivity C-reactive protein, CRP; interleukin-6, IL-6), lipid profile (total cholesterol, LDL-C, HDL-C, triglycerides, VLDL-C) and glucose-insulin indices (fasting glucose, insulin, HOMA-IR). Weight status was classified using BMI-for-age percentiles (underweight, normal weight, overweight, obesity); in a subset (n = 21), Tanita bioimpedance provided fat percentage (FATP), fat mass (FATM), fat-free mass, total body water (TBW/WATERM), water percentage (WATERP) and predicted muscle mass (PMM). Vitamin D insufficiency/deficiency was frequent, with most participants presenting 25(OH)D below commonly used adequacy thresholds and adolescents showing lower values than younger children. BMI showed an inverse association with 25(OH)D, supporting an adiposity-linked reduction in vitamin D status. Inflammatory biomarkers were consistent with predominantly low-grade inflammation, with CRP distributions shifted upward in adolescents and the widest variability observed in obesity; IL-6 also displayed marked heterogeneity, including high outliers in participants with obesity. Metabolic markers suggested a more adverse cardiometabolic profile in higher adiposity categories, characterized by higher insulin and HOMA-IR and a lipid pattern compatible with obesity-associated dyslipidemia (higher TG/VLDL and less favourable HDL-C). In the Tanita subset, adiposity quantified by bioimpedance (FATM/FATP) correlated strongly with triglyceride-rich lipoproteins, while WATERP correlated inversely with TG/VLDL, indicating that body composition metrics may capture clinically relevant metabolic variation beyond BMI percentiles alone. Iron and ferritin suggested that reduced iron stores may coexist with obesity, while associations with CRP/IL-6 were not robust, implying that nutritional factors and growth-related demands may contribute in addition to inflammation.

Overall, BMI-for-age percentiles are useful for paediatric obesity screening in this Romanian cohort, and integrating Tanita body composition with biochemical profiling may improve phenotyping and support more targeted cardiometabolic and micronutrient risk stratification, particularly in adolescents.

EP731 - ECE_2992 - Clinic and metabolic profile in bariatric surgery candidates

Beatriz Gonçalves, Marta Lopes, Mariana Severino, Jose Rocha, Carolina Peixe, João Vieira, José Camolas, Raquel Lalanda, Filipa Nogueira, Olavo Gomes, André Paulino and Ana Paula Barbosa
Faculty of Medicine Lisboa, Endocrinology Department, Hospital Santa Maria, Lisboa, Endocrinology Department, Hospital Santa Maria, Lisboa, Lisboa, Portugal

Introduction: Obesity is a multifactorial chronic and systemic disease, characterized by multiple biochemical and hormonal changes which impact negatively both morbidity and mortality of obese individuals. In a hospital setting, it becomes crucial to characterize their clinical, metabolic and inflammatory profile in order to optimize risk stratification, plan appropriate therapeutic interventions, and reduce the burden of disease on the healthcare system.

Aims: This study aimed to evaluate the clinic and metabolic profile of the obesity surgery candidates.

Methods: The study included individuals with BMI ≥ 35 kg/m^2 candidates to obesity surgery, followed in both Endocrinology and Surgery Departments. Sociodemographic and anthropometric data were collected and laboratory tests were analyzed, including hemoglobin, ferritin, folic acid, vitamin B12, calcium, 25-OH-vitamin D, fasting blood glucose, HbA1c, total cholesterol, LDL, HDL, triglycerides, TSH, fT4, cortisol, AST, ALT, uric acid, urea, and creatinine. The statiscal analysis was done with software SPSS®, version 29.

Results: 29 individuals, 16(55.2%) females, mean age 51±9 years, mean weight 114.8 ± 17.4 Kg, mean height 1.68 ± 0.10 m and mean BMI 41.1 ± 1.4 Kg/m^2. Family history of obesity was present in 34.5%. There was a high prevalence of hypertension (82.8%) and dyslipidemia (82.8%) while type 2 diabetes was present in 34.5%. Hypovitaminosis D in 92.6%, mean elevated ferritin (162.1 ± 138.3 ng/ml), mean HbA1c 6.6 ± 1.2%, and reduced HDL (46 ± 9 mg/dl) were found. Men showed a higher prevalence of type 2 diabetes and sleep apnea, while women presented more primary hypothyroidism and anxiety-depressive symptoms. Furthermore, the comparison between the different BMI classes showed a trend towards higher values of glycemia, HbA1c and triglycerides in individuals with higher BMI, reflecting

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

a worsening of the metabolic profile with the degree of obesity.

Discussion and Conclusions: The results of this study reinforce the multifactorial and complex nature of obesity, highlighting that this condition goes far beyond simple excess weight, involving multiple domains such as metabolic, inflammatory, hormonal, and psychological changes. These findings underscore the importance of implementing individualized clinical strategies that integrate not only weight control but also an approach directed at the metabolic and inflammatory profile of each patient, as well as the identification and management of frequently associated psychological comorbidities.

EP732 - ECE_3081 - Insulin secretion assessment during oral glucose tolerance test

Tzvetelina Totomirova[1], Mila Arnaudova[2] and Nikolay Kostadinov[3]
[1]*Military Medical Academy, Clinic of Endocrinology and metabolic diseases, Sofia, Bulgaria;* [2]*MBAL Vita, Sofia, Bulgaria;* [3]*Burgaski Universitet Pfor. D-R Asen Zlatarov, Burgas, Bulgaria*

Background: Oral glucose tolerance test (OGTT) defines carbohydrate metabolism disorders. Glucose measurement should be performed on 0 minute and minute 120. There are different modifications of OGTT with measurement of glucose and insulin level on additional minutes and thus more detailed information is available.

The **aim** of our study is to evaluate the value of measurement of insulin secretion during oral glucose tolerance test

Materials and Methods: Our survey includes 107 patients (55 women, 52 men, mean age 44.01 ± 12.87 years). Mean weight was 99.07 ± 18.73 kg and mean BMI was 34.86 ± 6.0 kg/sq.m. All patients underwent OGGT. Measurement of insulin and glucose was performed on minute 0, 60, 120 and 180. HOMA-IR was calculated for assessment of hyperinsulinaemia. Correlation between glucose and insulin level on different minutes was assessed.

Results: On 60th minute there was significant moderate positive correlation between 60th minute glucose (7.81 ± 1.89 mmol/l) and 180th minute insulin (58.05 ± 32.01 mU/l) level ($r = -0.502$, $P < .001$). Difference between glucose level on minute 60 and minute 0 correlates negatively with minute 180 insulin level ($r = 0.402$), presenting the delay in first insulin response. No difference was found depending on age, gender and weight of patients.

Conclusion: Measurement of insulin level during OGTT presents additional information about insulin secretion curve and could be used for assessment of pathologically elevated insulin level as result of glucose stimulation and reveals early insulin secretion disorder.

Objective: Diabetic ketoalkalosis (DKALK) is a rare but potentially life-threatening condition characterized by metabolic alkalosis accompanied by persistent ketosis, which may develop during or after treatment of diabetic ketoacidosis (DKA). It may be associated with severe electrolyte disturbances and cardiac rhythm abnormalities. We report a pediatric case of DKALK complicated by significant QT prolongation following DKA treatment.

Case: A 12-year-old girl with newly diagnosed type 1 diabetes mellitus was referred to our center after receiving treatment for severe DKA at another hospital (glucose: 355 mg/dL, pH: 6.9, HCO_3: 6.5 mEq/L), including intravenous fluids, bicarbonate, and insulin infusion. On admission, she was conscious, hemodynamically stable, and showed no signs of dehydration.

Laboratory evaluation revealed partial resolution of metabolic acidosis with persistent ketonemia. Standard DKA management without bicarbonate therapy was continued in the pediatric intensive care unit. At 36. hour of treatment, the patient developed DKALK characterized by metabolic alkalosis, hypokalemia, hypomagnesemia, hypocalcemia, and ongoing ketosis. Concurrent electrocardiography demonstrated marked QTc prolongation (500-510 ms). Electrolyte replacement therapy and temporary discontinuation of insulin until correction of hypokalemia resulted in normalization of metabolic parameters and QTc interval. No ventricular arrhythmias occurred during follow-up.

Conclusions: DKALK developing after DKA treatment may be accompanied by persistent ketosis, significant electrolyte abnormalities, and marked QT prolongation, creating a substrate for potentially life-threatening ventricular arrhythmias. Therefore, careful and continuous monitoring of acid-base status, electrolyte balance, and cardiac rhythm is essential in patients with DKA, not only during acute management but also after transition to subcutaneous insulin therapy.

EP735 - ECE_2086 - Effect of obesity in progression of diabetic kidney disease in Korean patients with type 2 diabetes

Dong Hyeok Cho, Jin Ook Chung and Dong Jin Chung
Chonnam National University Hospital, Gwangju, South Korea

Background: The impact of obesity on progression of diabetic kidney disease is debated. We evaluated whether baseline obesity predicts renal deterioration in Korean patients with type 2 diabetes (T2D) and established CKD.

Methods: In this longitudinal cohort, 319 Korean T2D patients with CKD stage ≥2 (mean age 61.0 ± 11.4 years) were followed for 2.9 ± 1.1 years. Renal function was assessed by serum

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

creatinine, eGFR (Cockcroft-Gault), and urinary albumin-to-creatinine ratio (ACR). BMI categories (WHO Asia-Pacific): normal <23 kg/m^2, overweight 23-24.9 kg/m^2, obese ≥25 kg/m^2. Primary outcome was renal function decline, defined as sustained ≥30% eGFR reduction or progression to a higher albuminuria category. Multivariate logistic regression adjusted for age, sex, diabetes duration, HbA1c, total cholesterol, triglycerides, and hypertension.

Results: At baseline, mean diabetes duration was 12.6 ± 9.8 years, HbA1c 8.1%, and mean eGFR 52.2 mL/min/1.73 m^2. 41.5% (n = 132) of patients were obese. Obese patients had higher HbA1c (mean 8.5% vs 7.9%, $P = .01$), higher ALT (mean 36 vs 28 U/L, $P < .01$), and adverse lipid profiles. Baseline eGFR and median ACR did not differ significantly across BMI groups. Over follow-up, mean annual eGFR decline was greater in the obese group (−3.8 vs −2.4 mL/min/1.73 m^2/year; between-group difference −1.4; $P = .01$). Worsening albuminuria occurred in 28.0% of obese versus 17.2% of normal-BMI patients ($P = .02$). The composite renal decline endpoint occurred in 62 patients (19.4%): 38 (28.8%) obese and 24 (11.4%) non-obese (log-rank $P < .001$). In multivariate analysis, baseline obesity was independently associated with increased odds of renal function decline (adjusted OR 1.31; 95% CI 1.05-1.63; $P = .02$). Results were robust after additional adjustment for baseline ACR and use of renin-angiotensin blockers.

Conclusions: In this cohort of Korean T2D patients with CKD stage ≥2, baseline obesity was independently associated with faster eGFR decline and higher risk of clinically meaningful renal deterioration. These findings support incorporating weight-management strategies to potentially slow progression of diabetic kidney disease in this population.

EP739 - ECE_3957 - A novel secreted protein, JUV-161, reverses structural and functional muscle decline in Sarcopenia

Ashil Koranne, Hee Ju Kim, Ritwik Datta, Vengadeshprabhu Karuppagounder, Han Song, Zhihua Li, Thach Mai, Banmeet Anand, Colin Hislop, Priya Handa, Hanadie Yousef and Jeremy O'connell
Juvena Therapeutics.Inc, Redwood city, United States

Age-related sarcopenia is characterized by progressive skeletal muscle wasting, reduced fiber size, and loss of strength, leading to functional decline and increased frailty risk. Current therapeutic options are limited, highlighting the need for interventions that both preserve muscle mass and restore muscle function. At Juvena Therapeutics, we have developed a biologics-based drug discovery platform focused on identifying stem-cell secreted proteins capable of restoring tissue health in aged individuals. JUV-161 is a novel secreted protein engineered to promote muscle regeneration, repair, and functional recovery.

To evaluate the efficacy of JUV161 in sarcopenia, we treated aged C57BL/6 male mice (23-25 months old) with daily subcutaneous injections of JUV-161 (12 mg/kg) or vehicle control for three weeks followed by the assessment of body composition, muscle function and tissue histopathology.

JUV-161 treatment significantly improved body composition, as indicated by percent increase in lean mass from the baseline compared with vehicle-treated controls (+1.12% vs −3.23% in vehicle). Histological analysis revealed that JUV-161 reversed muscle aging in terms of fiber type composition, with increased frequency of fast-twitch fibers ($P < .01$) and a corresponding reduction in slow-twitch fibers ($P < 0.01$) compared to the vehicle-treated controls. These structural and compositional changes are closely aligned with the observed improvements in strength and functional performance. JUV161 treatment significantly improved specific forelimb grip strength (25.51 mN/g vs 23.20 in vehicle, $P < .05$) and all-limb grip strength (46.73 mN/g vs 41.21 mN/g in vehicle, $P < .01$), demonstrating meaningful gains in muscle function.

Collectively, these findings show that we successfully alleviated age-related muscle wasting, restored fiber size, and enhanced functional performance with JUV-161 in a model of sarcopenia. By simultaneously improving structural, compositional, and functional aspects of skeletal muscle, JUV-161 represents a promising therapeutic candidate for counteracting sarcopenia, mitigating muscle loss, and restoring strength in older adults. These data support further translational development of JUV-161 for clinical applications aimed at improving mobility, reducing frailty risk, and enhancing quality of life in aging populations.

EP741 - ECE_1533 - Physician workplace health behaviors and BMI: evidence from the healthy lifestyle and personal control questionnaire and organizational implications

Dana kagansky[1], Racheli Magnezi[2], Matan Elkan[1] and Orna Tal[1]
[1]*Shamir Medical Center (Assaf Harofeh), Endocrine Institute, Affiliated to the Gray Faculty of Medical & Health Sciences, Tel Aviv University, Beer Yaakov, Israel;* [2]*Bar-Ilan University, Department of Management, Ramat Gan, Israel*

Background: Physician well-being is central to organizational performance and patient care, yet workplace demands may erode healthy behaviors.

Objective: To examine associations between self-reported health behaviors and BMI among physicians and outline implications for workplace wellness.

Methods: Cross-sectional online survey of physicians using the 26-item Healthy Lifestyle and Personal Control Questionnaire (HLPCQ). Participants were categorized into normal weight (BMI < 25) and overweight (BMI ≥ 25) groups based on their BMI. Group differences were assessed, and multivariable logistic regression was performed.

Results: Of 200 respondents, 144 complete cases were analyzed; 54.2% had a BMI < 25. Higher BMI was associated with lower adherence to health-promoting behaviors, notably Dietary Harm Avoidance ($P < .001$), Daily Routine ($P = .05$), and Organized Physical Exercise ($P = .03$). Regression analysis identified Dietary Harm Avoidance and Organized Physical Exercise as protective factors against overweight ($P < .01$). Physicians in surgical specialties reported lower health behavior scores than non-surgical peers, particularly in Daily Routines ($P < .001$) and in total lifestyle scores ($P = .01$).

Conclusions: Workplace constraints on routines and activity are associated with BMI. These findings suggest that organizational approaches addressing harm-avoidant dietary environments

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

and protected time for structured exercise may be relevant to clinician health and role modeling.

EP742 - ECE_2750 - Lifestyle behaviors and BMI among medical students: a cross-sectional study using the HLPCQ Lifestyle behaviors and BMI among medical students: a cross-sectional study using the HLPCQ

Dana kagansky[1,2], Michal Bitan[3], Ofir Vinograd[1], Noa Levi[4], Hitam Hagog Natour[5] and Orna Tal[1]

[1]Shamir Medical Center (Assaf Harofeh), Endocrine Institute, Affiliated to the Gray Faculty of Medical & Health Sciences, Tel Aviv University, Beer Yaakov, Israel; [2]Shamir medical center, Endocrine Institute, Affiliated to the Gray Faculty of Medical & Health Sciences, Tel Aviv University, Beer Yaakov, Israel; [3]The College of Management Academic Studies, School of Computer Science, Rishon LeZion, Israel; [4]Tel Aviv University, Grey Faculty of Medical & Health sciences, Tel aviv, Israel; [5]Meir Medical Center, Institute of Endocrinology, Diabetes and Metabolism, Kfar Saba, Israel

Introduction: Health-promoting lifestyle behaviors are associated with BMI and metabolic health. Among healthcare professionals, these behaviors may also influence future patient counseling practices. However, data on lifestyle patterns and BMI among medical students remain limited.

Methods: A cross-sectional online survey was conducted among medical students using the 26-item Healthy Lifestyle and Personal Control Questionnaire (HLPCQ). BMI was self-reported, and participants were categorized as normal weight (BMI < 25), overweight (BMI 25-30), or obese (BMI ≥ 30). Group differences in the total HLPCQ score were assessed, and univariable and multivariable regression analyses were used to examine associations of the total and domain-specific HLPCQ scores with BMI.

Results: The questionnaire was distributed to 2,000 medical students, of whom 516 completed the full questionnaire. Among respondents, 370 were normal weight, 113 overweight, and 33 obese. The mean age was 29 years $\pm$ 4, and 68% were female. Total HLPCQ scores differed significantly across BMI categories ($P = .019$). Among the five questionnaire subdomains, daily routine and organized physical exercise scores were significantly associated with BMI ($P = .004$ and $P = .012$, respectively). In adjusted analyses, male sex, lower BMI, and younger age were independently associated with higher HLPCQ scores.

Conclusions: In this cohort of medical students, the total HLPCQ score was significantly associated with BMI. These findings underscore the relevance of overall lifestyle patterns during medical training, a formative period that may influence future physician health and lifestyle-related counseling practices.

EP745 - ECE_1013 - Extra-articular steroid injection induced diabetic ketoacidosis following lumbar medial branch block and radiofrequency ablation: A case report

Yotsapon Thewjitcharoen, Soontaree Nakasatien and Thep Himathongkam

THEPTARIN Diabetes, Thyroid and Endocrine Center, Vimut-Theptarin Hospital, Bangkok, Thailand

Background: Radiofrequency ablation (RFA) is an innovative procedure for managing chronic lower back pain caused by lumbar medial branch nerve irritation. Recently, clinicians prefer to inject corticosteroids into the axial space to enhance pain control and potentially limiting the size of thermal lesion. The addition of corticosteroids to RFA could lead to systemic effects as other routes of administration. However, the risks of the addition of corticosteroids must be weighed against the potential benefit. Here, we report a rare case of diabetic ketoacidosis following RFA treatment in an elderly patient with type 1 diabetes (T1D).

Clinical case: A 77-year-old man with long-standing T1D (diagnosed at age of 30) a history of alcoholism and lumbar spondylosis was brought to the emergency room with an altered state of consciousness and severe hyperglycemia as detected by continuous glucose monitoring (CGM). He denied fever, abdominal pain, or missed insulin doses. His medications included insulin degludec 10 units per day and insulin lispro 4-6 units per day. Glycemic control had been satisfactory with glycated hemoglobin (A1C) at 6.1% and time-in-range at 71% in the previous month. Upon admission, laboratory data showed random plasma glucose 452 mg/dL, A1C 7.1%, wide anion gap at 18 mEq/L, and estimated glomerular filtration rate at 64 mL/min/1.73 m^2. Further inquiry uncovered that the patient had undergone RFA treatment with Dexamethasone 8 mg injection into extra-articular lumbar facet joints 6 days earlier. The patient noticed worsening glucose level from CGM sensor but he did not increase the insulin dose due to poor appetite. The patient was diagnosed with DKA and was hospitalized in the intensive care unit. With treatments including hydration, insulin, and potassium replacement, DKA was resolved within 8 hours and renal function subsequently normalized. Additional investigations revealed no adrenal insufficiency. Insulin was increased for 2 weeks before returning to the normal dose. At the last follow-up of 6 months after DKA, his glycemic control was satisfactory at A1C $< 7.0\%$ and the patient was advised to follow “sick day rules" for diabetes self-management.

Conclusions: The possibility of adverse systemic effects of corticosteroid following extra-articular injection during RFA procedure to treat back pain should be considered among insulin-dependent patients. Spine surgeons and pain management specialists should be vigilant and consult the patient’s endocrinologist or primary physicians before performing the RFA procedure with steroid injection. Preemptive adjustments to insulin and education on sig day protocols are essential to prevent such adverse events.

EP746 - ECE_2412 - Misdiagnosis of type 1 diabetes as gestational diabetes mellitus in pregnancy: a case report highlighting the importance of clinical vigilance

Zaiem Zarkasi[1,2], Aakansha Sinha[1] and Aye Aye Thant[1]

[1]Manchester, United Kingdom; [2]Wythenshawe Hospital, Diabetes and Endocrinology, Wythenshawe, United Kingdom

Background: Hyperglycaemia diagnosed during pregnancy is most commonly attributed to gestational diabetes mellitus (GDM), though a minority of cases represent previously unrecognized type 1 diabetes mellitus (T1DM). Distinguishing between

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

these conditions is critical for appropriate management and postpartum care. We present a case of a 20-year-old primigravida initially diagnosed with GDM whose clinical features prompted re-evaluation and subsequent diagnosis of T1DM.

Case Presentation: A 20-year-old primigravida presented to antenatal clinic at 34 + 3 weeks gestation with a prior diagnosis of GDM made at 24 weeks based on impaired fasting glucose of 5.9 mmol/L. Her HbA1c at booking was 31 mmol/mol. Despite dietary modifications and subsequent treatment with metformin modified release and insulin, her glycaemic control remained challenging. Clinical features atypical for GDM included relatively low body mass index (BMI) prior to and during pregnancy, family history of type 1 diabetes, and progressive insulin requirements. At 34+3 weeks, these features prompted testing for diabetes-related autoantibodies including glutamic acid decarboxylase (GAD), islet cell antibody (IA-2), and zinc transporter 8 (ZnT8) antibodies, along with C-peptide measurement. Results revealed negative anti-GAD and IA-2 antibodies but positive ZnT8 antibody with low C-peptide, confirming T1DM. She was transitioned to basal-bolus insulin regimen with continuous glucose monitoring. Shortly thereafter, she experienced recurrent hypoglycaemia with rapid reduction in insulin requirements, likely representing the honeymoon phase of T1DM combined with physiological decline in insulin resistance in late third trimester. Additional testing excluded adrenal insufficiency and thyroid dysfunction. Foetal growth remained appropriate (44th centile at 36+2 weeks) with normal liquor volume and Doppler studies. She underwent induction of labour at 38 weeks followed by caesarean section, delivering a healthy male infant. Postpartum, insulin doses were immediately reduced to approximately 50% of the late pregnancy requirement in line with guidance, reflecting the abrupt fall in placental insulin resistance. She was followed up in the young adult diabetes clinic, with structured education and ongoing dose titration to accommodate resumption of normal eating and reduce hypoglycaemia risk.

Conclusions: This case underscores the importance of maintaining clinical vigilance and challenging initial diagnoses when clinical features are inconsistent with typical GDM presentation. Key distinguishing features of T1DM in pregnancy include normal pre-pregnancy BMI, family history of autoimmune diabetes, and higher insulin requirements. Timely recognition through appropriate autoantibody testing enabled correct diagnosis and management, ensuring insulin continuation postpartum rather than cessation as would occur with GDM, thereby preventing potential diabetic ketoacidosis and optimizing long-term patient care.

EP748 - ECE_2242 - Tailored prednisolone for Doege–Potter syndrome in a nonagenarian: a pattern-based approach

Hyewon Mun[1], Jang Won Son[2], Seongsu Lee[1], Sungrae Kim[1] and Soon-Jib Yoo[1]
[1]*The Catholic University of Korea Bucheon St Mary's Hospital, Bucheon-si, South Korea;* [2]*Bucheon-si, South Korea*

Background: Doege–Potter syndrome (DPS) is a rare paraneoplastic form of non-islet cell tumour hypoglycaemia (NICTH) mediated by autonomous secretion of "big" insulin-like growth factor-2 (IGF-2) from solitary fibrous tumours (SFTs). Although curative resection is definitive, it is often precluded by tumour extent or patient frailty in the extreme elderly. In such cases, glucocorticoids are commonly used; however, standard high-dose regimens are frequently poorly tolerated and optimal dosing remains unclear. We report a nonagenarian with DPS successfully managed using a tailored, relatively low-dose glucocorticoid strategy guided by glycaemic patterns and continuous glucose monitoring (CGM).

Case Description: A 90-year-old man was admitted for recurrent episodes of severe hypoglycaemia accompanied by impaired consciousness, fulfilling Whipple's triad. He had a history of type 2 diabetes but was not receiving any glucose-lowering medications. During a symptomatic episode (plasma glucose 48 mg/dL), insulin (<1.23 μIU/mL) and C-peptide (0.24 ng/mL) were suppressed, consistent with insulin-independent hypoglycaemia. Adrenal insufficiency was excluded by an adequate cortisol response to rapid ACTH stimulation. He had a biopsy-proven pulmonary SFT (12 × 18 cm) managed conservatively according to patient preference. Given the clinical context, NICTH was suspected, and a markedly elevated IGF-2/IGF-1 ratio (>29.67) strongly supported the diagnosis of DPS.

Management and Outcome: As surgical resection was not a viable option due to advanced age and comorbidities including cardiovascular disease, a medical strategy was initiated to mitigate IGF-2–mediated hypoglycaemia. To ensure sustained 24-hour glycaemic support, treatment was transitioned from intravenous hydrocortisone to oral prednisolone. Recognizing an initial nocturnal-dominant hypoglycaemia pattern, a twice-daily regimen was initiated with a higher evening dose, then titrated to a stable split-dose of 5 mg every 12 hours (10 mg/day). With structured education and consistent glucocorticoid coverage, the patient no longer required reactive, erratic carbohydrate intake. Following discharge, CGM-guided management confirmed the complete absence of hypoglycaemic episodes and improved glycaemic stability, with the coefficient of variation decreasing from 26.1% to 22.2%. Euglycaemia was maintained on this relatively low total dose without steroid-induced adverse effects.

Conclusions: In a nonagenarian with DPS who was not a surgical candidate, CGM-informed titration of a relatively low-dose, pattern-tailored split prednisolone regimen effectively prevented severe hypoglycaemia. This case suggests that aligning glucocorticoid timing with individual hypoglycaemia patterns may achieve a favourable therapeutic balance between efficacy and tolerability in frail elderly patients with NICTH.

EP749 - ECE_1417 - Beyond glycemia: a global snapshot of multisystem comorbidities in children and adolescents with type 1 diabetes (2005-2025)

Ashraf Soliman[1], Nada Alaaraj[1], Fawziya Alyafei[1], Noor Hamed[1], Shayma Ahmed[1] and Nada Soliman[2]
[1]*Hamad Medical Center, Pediatric Endocrinology, DOHA, Qatar;* [2]*Alexandria Health Directorate, MOH, Public Health, Alexandria, Egypt*

Background: Type 1 diabetes (T1D) in children and adolescents is increasingly recognized as a multisystem disorder, with a

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

substantial burden of autoimmune, cardiometabolic, microvascular, and psychosocial comorbidities. While individual complications are well described, integrated registry-based summaries using harmonized definitions remain limited.

Objective: To summarize the point-prevalence of major comorbidities in children and adolescents with T1D over the past two decades using large international registries and validated population-based studies.

Methods: A structured synthesis of PubMed-indexed literature (≈2005-2025) was conducted, prioritizing international registries (SWEET, SEARCH for Diabetes in Youth, DPV, T1D Exchange, NPDA/ADDN) and systematic reviews. Harmonized thresholds were applied where possible: overweight/obesity (BMI ≥85th percentile, WHO/CDC), LDL-hypercholesterolemia (LDL-C ≥100 mg/dL), hypertension (blood pressure ≥95th percentile), and screen-detected microvascular or psychological outcomes. Estimates are reported as point-prevalence.

Results: Celiac disease is the most frequent autoimmune comorbidity, with a global prevalence of approximately 3-5%, ranging from ~2% in parts of Asia and the Middle East to ~7-8% in Australia and Europe. Thyroid autoimmunity is also common but variably reported. Approximately 30% of youth with T1D are overweight or obese. LDL-hypercholesterolemia affects 9-20%, and hypertension is present in 6-10%. Overall, 30-40% exhibit at least one major cardiovascular risk factor, with a smaller subset showing clustering of two or more factors. Microalbuminuria is detected in approximately 5-12%, increasing with age, diabetes duration, and glycemic exposure. Retinopathy remains uncommon in early childhood but increases in adolescents with longer disease duration. Peripheral or autonomic neuropathy is identified in roughly 7-12% by objective testing. Psychological morbidity is substantial, with 25-35% screening positive for depressive or anxiety symptoms. At diagnosis, diabetic ketoacidosis occurs in approximately 25-35%, with wide inter-country variability.

Conclusions: Children and adolescents with T1D carry a significant, multidimensional comorbidity burden. Consistent findings across international registries highlight the need for integrated screening and early preventive strategies extending beyond glycemic control.

EP752 - ECE_2698 - Impact of basal insulin on glycaemic variability in pregnancy with focus on hypoglycaemia

Soumyabrata Roy Chaudhuri[1,2], Anirban Majumder[3], Poulomi Mukherjee[4] and Debmalya Sanyal[3]
[1]Woodlands Hospital, Kolkata, India; [2]KPC Medical College & Hospital, Endocrinology, Kolkata, India; [3]Kolkata, India; [4]Medical College Kolkata Masjid, Community Medicine, Kolkata, India

Background: Glycaemic variability is increasingly recognized as an important determinant of adverse pregnancy outcomes in women with gestational diabetes mellitus (GDM). Continuous glucose monitoring (CGM) allows detailed assessment of glucose patterns. Although GDM is primarily characterized by postprandial hyperglycaemia, many patients require basal insulin. NPH, detemir, and degludec are approved for use in pregnancy. While degludec has shown non-inferiority to detemir, there are no direct comparisons between NPH and degludec in pregnancy.

Objective: To compare glycaemic control using Time in Range (TIR), Time Below Range (TBR), and Time Above Range (TAR) in women with GDM treated with NPH versus degludec as basal insulin between 28 and 32 weeks of gestation, and to compare insulin dose requirements and nocturnal glycaemic patterns.

Methods: This was a prospective, investigator-initiated observational pilot study including 30 women with GDM. Participants received either NPH or degludec and underwent CGM using the Freestyle Libre Pro system for 14 days. All patients were prescribed a standardized diet of 30 kcal/kg/day and maintained diet diaries. CGM data, including 5-minute interval readings from midnight to 6 a.m., were analyzed. Patients unable to complete monitoring, those hospitalized during the study period, or those receiving antenatal steroids were excluded.

Results: The two groups were comparable at baseline, except that the NPH group required significantly higher total and bolus insulin doses at initiation of CGM. Patients treated with degludec had significantly higher TIR and lower TBR. By day 14, bolus insulin requirements were significantly lower in the degludec group, while basal and total daily insulin doses were similar between groups. Nocturnal hypoglycaemic events were significantly fewer in the degludec group, with more stable overnight glucose levels.

Conclusions: Insulin degludec as basal insulin during pregnancy is associated with better glycaemic stability and fewer hypoglycaemic events compared to NPH, suggesting that it may be a superior basal insulin option for managing GDM.

EP754 - ECE_2485 - Risk of cardiovascular disease and death by LDL cholesterol level in elderly patients with diabetes

Sung Hoon Yu[1], Sang Mo Hong[1], Jung Hwan Park[1], Kye-Yeung Park[1] and Han Kyungdo[2]
[1]Hanyang University College of Medicine, Department of Internal Medicine, Seoul, South Korea; [2]Department of Statistics and Actuarial Science, Soongsil University, Seoul, South Korea

Background and Aims: Low-density lipoprotein cholesterol (LDL-C) is a well-established causal risk factor for cardiovascular disease (CVD). However, there is controversy regarding the relationship between LDL cholesterol and mortality in elderly diabetic patients. We evaluated the associations between LDL-C and cardiovascular disease or mortality in national cohort study.

Methods: We performed a retrospective observational cohort study of 249,903 older (≥65 years old) diabetes patients without CVD from 2009 to 2017 using the NHID. We divided the subjects by LDL-C category. Primary composite outcomes were stroke, myocardial infarction, and all-cause death. All outcomes were analyzed by Cox proportional hazards regression analysis while controlling for baseline covariates.

Results: During a median follow-up of 7.26 years, the incident rate of composite primary outcomes was 30.95 per 1,000 person-years. In Cox proportional hazard modeling, the risk of the primary outcome associated with a linear association with CVD. In multivariable Cox proportional hazard models with the LDL-C reference group (<85 mg/dL), the risk of primary composite outcomes was increased 1.067 times (95%CI: 1.035-1.100), 1.149 times (95%CI: 1.115-1.183) and 1.222 (95%CI: 1.185-1.261) with

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

increasing LDL-C of respectively, ≥85 & <108 / ≥109 & <134, ≥134 (mg/dL) and had a linear association with LDL-C. And, these finding was consistent regardless of age, sex, smoking, chronic kidney disease, regular exercise, diabetic medications, insulin and statin. But mortality rate had inverse correlations.

Conclusions: In older patients with diabetes, increased LDL-C levels were associated with higher CVD risk, not with mortality rate.

EP756 - ECE_3152 - Does type 2 diabetes mellitus increase the risk of major adverse cardiovascular or cerebrovascular events in long-term follow-up in patients who undergo carotid artery stenting?

Piotr Seweryniak[1], Jacek Staszewski[2], Bernadetta Kałuża[3], Jan Domański[3], Robert Gil[4], Paweł Krzesiński[1] and Edward Franek[3,5]

[1]Military Institute of Medicine, National Research Institute, Department of Cardiology, Warsaw, Poland; [2]Military Institute of Medicine, National Research Institute, Department of Neurology, Warsaw, Poland; [3]National Medical Institute of the Ministry of the Interior and Administration, Department of Internal Medicine, Endocrinology and Diabetology, Warsaw, Poland; [4]National Medical Institute of the Ministry of the Interior and Administration, Department of Cardiology, Warsaw, Poland; [5]Mossakowski Medical Research Centre Polish Academy of Sciences, Department of Human Epigenetics, Warsaw, Poland

Background: Percutaneous transluminal angioplasty with carotid artery stenting (CAS) is a revascularization method used in patients with significant carotid artery stenosis. This method is preferred in patients over 70 years old with a symptomatic stenosis of ≥50%-99% and in those with contraindications for surgery. Type 2 diabetes mellitus (T2DM), which is a risk factor of atherosclerosis and a predictor of subsequent adverse cardiovascular events, may also worsen the prognosis of CAS patients. There are no data on long-term, 5-year risk of major adverse cardiac and cerebrovascular events (MACCEs), including transient ischemic attack, major stroke, myocardial infarction, or death, after a CAS procedure.

Purpose: The purpose of the study was to answer the question if T2DM is a prognostic factor of MACCEs in patients who undergo CAS due to symptomatic carotid artery stenosis.

Methods: A total of 99 patients were included in this study; all patients underwent CAS due to symptomatic stenosis. Quantitative carotid angiography (QCA) was used to assess stenoses treated with angioplasty. To evaluate the impact of T2DM and other clinical variables on developing a MACCE over a 5-year follow-up was used Cox proportional hazards model.

Results: Patients without T2DM (n = 71, 71.72%) did not differ from those with T2DM (n = 28, 28.28%) in terms of stenosis diameter (2.13 ± 1.05 vs 1.96 ± 1.01 [mm], $P = .52$), stenosis area (4.44 ± 4.36 vs 3.82 ± 3.41 [mm^2], $P = .55$), stenosis length (17.12 ± 7.84 vs 14.12 ± 5.66 [mm], $P = .08$), percent diameter stenosis (65.65 ± 12.75 vs 66.51 ± 13.99, $P = .55$), percent area stenosis (86.74 ± 8.42 vs 86.89 ± 10.53, $P = .61$) or stenotic flow reserve (2.43 ± 1.29 vs 2.19 ± 1.37, $P = .29$), laminar flow resistance (3.39 ± 12.69 vs 2.83 ± 6.31, $P = .47$), turbulent flow resistance (4.29 ± 18.13 vs 3.43 ± 8.26, $P = .37$). Cox proportional hazards model revealed that only age increases the risk of MACCEs (HR 1.07 95% CI 1.003-1.14, $P = .003$), with no such effect exhibited by other assessed variables, namely, T2DM (1.26, 0.38-4.14, $P = .7$), hypertension (1.49, 0.49-4.61, $P = .48$), smoking (0.43, 0.14-1.33, $P = .14$), dyslipidemia (1.36, 0.47-3.90, $P = .57$), male sex (0.16, 0.02-1.23, $P = .07$), percent diameter stenosis (1.07, 0.89-1.28, $P = .49$), and percent area stenosis (0.92, 0.71-1.19, $P = .53$).

Conclusion(s): Comorbid T2DM in the evaluated group showed no significant effect on long-term prognosis of developing MACCEs in patients who underwent CAS. Therefore, comorbid T2DM is not a contraindication to this procedure.

EP757 - ECE_3751 - Baseline phenotypic and biochemical characteristics of lipodystrophy patients at the time of diagnosis- data from a Romanian cohort

Adelina Badici[1], Iuliana Gherlan[1,2,3], Simona Galoiu[1,2], Lidia Radomir[2], Elena Braha[2], Ramona Dobre[1,2], Iulia Florentina Burcea[1,2], Iulia Grigore[2] and Catalina Poiana[1,2]

[1]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania; [2]"C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania; [3]C.I. Parhon National Institute of Endocrinology, București, Romania

Background: Lipodystrophy syndromes are rare adipose tissue disorders, underdiagnosed despite genetic advances.

Objective: To describe the clinical, genetic and metabolic characteristics of a lipodistrophy cohort diagnosed in a Romanian tertiary endocrinology centre.

Methods: Nineteen suspected cases were identified through database search; eight were excluded due to unmet clinical and biochemical diagnostic criteria. Genetic testing was available in 4/11 reported patients. The clinical and metabolic profile, hepatic steatosis and renal involvement were analysed in 11 patients.

Results: 10/11 patients had familial partial lipodystrophy syndromes (FPLD): 6 cases - FPLD type 2, 2 FPLD type 4, 1 FPLD type 3, 1 FPLD type 6; 1 patient (POLD1/MDPL) had progeroid generalised lipodystrophy. The heterozygous LMNA c.1444C>T (p.Arg482Trp) pathogenic variant was identified in the proband of a five-member FPLD2 family and in one unrelated patient; affected relatives were diagnosed clinically. In the FPLD4 family (father–daughter), only the proband underwent genetic testing and carried the heterozygous PLIN1 c.1210-1del splice-site variant, likely pathogenic, while the father fulfilled clinical criteria. The FPLD3-compatible case harboured a heterozygous PPARG c.220 +3A>G splice-region variant classified as VUS, but fulfilled the clinical and metabolic criteria. The patient MDPL carried a heterozygous POLD1 c.1812_1814del (p.Ser605del) pathogenic variant.

Nine patients were female, 2 male. Mean age at diagnosis was 27.6 years (range 4.92-46), including 3 pediatric cases.

FPLD2 showed marked limb lipoatrophy with fat accumulation in the trunk, face and neck, muscular hypertrophy and prominent veins; acanthosis, café-au-lait lesions and hyperandrogenism occurred, with one presenting a single central maxillary incisor

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

despite normal cerebral imaging. FPLD4 displayed similar lower-limb-predominant fat loss, the FPLD3-compatible case milder limb involvement with facial hirsutism, while FPLD6 presented lower-limb fat deficiency with acanthosis and café-au-lait spots. The MDPL case showed severe progeroid features with generalised lipoatrophy, deafness, hyperpigmentation, telangiectasias, and testicular insufficiency.

Comorbidities included neuropathy, thyroid disease, PCOS, hypertension, retinopathy, and craniofacial dysmorphism.

At diagnosis, 7/11 patients recieved antidiabetic treatment (2 insulin, 5 oral). Mean glucose was 124 mg/dL (range 76-297), mean HbA1c 6.87% (4.8-11.4). In non-insulin-treated patients, mean insulinemia was 75.12 µIU/mL (5.86-339.1), and mean HOMA-IR was 12.97 (1.21-75.4). 5/11 patients were receiving lipid-lowering therapy. Mean triglycerides were 183.7 mg/dL (86-406), total cholesterol 200 (135-247), HDL 42.58 (26.8-86), LDL 130.2(61–203) and VLDL 34.8 (20.8-52.8). Hepatic steatosis was present in 9 patients; 5 had proteinuria.

Conclusions: This cohort demonstrates severe metabolic burden and phenotypic heterogeneity, emphasising the need for early diagnosis and comprehensive screening.

EP758 - ECE_1236 - The prevalence of vitamin B12-deficiency in people living with type-1 diabetes and its associated factors: a dual-center cross-sectional study in Malaysia

Abdullah Shamshir Abd Mokti[1], Nurhanis Syazni Roslan[2], Carolina Shalini Singayar[3], Alia Nasriana Nasuruddin[1] and Raja Nurazni Raja Azwan[4]

[1]Hospital Tengku Ampuan Afzan, Kuantan, Malaysia; [2]University of Science, Malaysia, Kubang Kerian, Malaysia; [3]Hospital Selayang, Selayang, Malaysia; [4]Institut Endokrin, Hospital Putrajaya, Putrajaya, Malaysia

Background: Previous cross-sectional studies have reported association of vitamin B12-deficiency in patients with Type 1 Diabetes Mellitus(T1DM). A study in South India where vegetarianism is commonly practiced found that among 90 patients with T1DM, 45.5% had vitamin B12 deficiency.Currently there is paucity of data for B12-deficiency among T1DM patients in diverse-ethnic Malaysia.

Objectives: To determine the prevalence of vitamin B12 deficiency in patients with T1DM and its associated factors.

Method: This was a cross-sectional study which involved 104 patients at two endocrinology centers. Vitamin B12 level and anthropometric data were measured after an interview session on demographics, dietary and lifestyle, medical history and medications.

Results: 104 T1DM patients were screened and one excluded due to incomplete data. 15 out of 103 patients (14.5%) had vitamin B12-deficiency. The mean age was 29.50 years-old while BMI was 22.32 kg/m^2. Study population was female (64.1%), Malay (70.9%), non-smoker (88.3%) and non-alcoholic (96.1%). The mean duration of diagnosis was 10.59 years, with HbA1c of 10.3%, fasting blood glucose of 10.05 mmol/l. There was no significant difference between the variables except for body mass index (BMI). Patients with B12-deficiency were found to have a lower BMI (18.64 kg/m^2) as compared to patients with normal vitamin B12 (22.95 kg/m^2). In univariate analysis, we found that only BMI significantly predicted B12-deficiency with crude odds ratio: 0.493. Multivariable logistic regression analysis also found that BMI predicted B12-deficiency with adjusted OR: 0.485. With every one-unit increase in BMI, Type 1 diabetes patients were 51.5% less likely to have low vitamin B12 level

Conclusions: Results of our study shows that the prevalence of B12 deficiency among T1DM is 14.5% and with significant association with low BMI. These findings merits screening for B12-deficiency among T1DM patients with low BMI and further research is needed to explore the reasons.

EP759 - ECE_1882 - Thyroid hormone sensitivity index in patients with type 2 diabetes mellitus and depression

Ahmed Abdelhameed Osman[1], Eman Zaky Ahmed Abdelaziz Azzam[1], Ahmed Awad Gowaid[2] and Elshimaa Ganeb[1]

[1]Endocrinology unit , Department of internal medicine, Alexandria Faculty of Medicine, Alexandria, Egypt; [2]Faculty of Medicine, Alexandria University, Department of Neurology and Psychiatry, Alexandria, Egypt

Introduction: Diabetes mellitus (DM) is a chronic debilitating disease that affects a huge number of people, disturbing their quality of life. It is a widespread disease. Depression in patients with diabetes is often unrecognized and untreated leading to poor adherence to diabetes self-care plans and resulting in potentially negative health consequences including a higher risk for diabetic complications, functional impairment, and increased healthcare expenditure. Several thyroid abnormalities have been associated with mood disorders particularly depression. However, the vast majority of patients with depression do not have biochemical evidence of thyroid dysfunction. When thyroid abnormalities exist, they consist mainly of elevated T4 levels, low T3, elevated rT3, blunted TSH response to TRH, positive antithyroid antibodies, and elevated cerebrospinal fluid (CSF) TRH concentrations. A state of brain hypothyroidism in the setting of systemic euthyroidism (10) has been suggested. This could result from a defect in the thyroid hormone-receptor, (11) or in the thyroid hormone transport and uptake into the brain and neuronal cells.

Aim: The aim of the study was to measure thyroid hormone sensitivity indices in euthyroid diabetic individuals and to correlate the sensitivity index with the presence and the degree of depression.

Methods: This study was carried out on 70 euthyroid, diabetic patients visiting endocrinology or psychiatry outpatient clinic in Alexandria main university hospital as well as matching control.

Results: The results of the present study showed that according to DSM-5 criteria, more than half of the participants were not depressed (57.1%), while 42.9% were diagnosed with depression. Based on the Hamilton Depression Rating Scale, the majority of depressed patients had mild depression (56.7%), followed by moderate depression (33.3%), whereas severe depression was observed in a smaller proportion of cases (10.0%). No significant difference between depressed and non depressed patients regarding , thyroid hormone levels and thyroid indices, on the

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

other hand it was found also there was no significant association between degree of depression, thyroid indices and throid hormone levels in patients with depression. The results of this study showed that there was no significant difference between depressed and non depressed patients regarding glycemic levels, on the other hand it was found also there was no significant association between degree of depression and HbA1C, FBG and PPBG.

Conclusions: No significant association between incidence of depression and its degree with both thyroid function test and glycemic parameters though larger studies are required to confirm the results.

EP762 - ECE_3163 - Variant of uncertain significance in IRS 2 gene in patient with diabetes mellitus—case report

Milica Jakovljevic, Sandra Stankovic, Vesna Cvetkovic, Milica Ignjatović and Tatjana Stankovic
University Clinical Centre Nis, Pediatric Clinic, Endocrinology, Nis, Serbia

Introduction: A variant of uncertain significance (VUS) is a genetic variant identified during genetic testing but whose significance to clinical presentation is not known. Insulin receptor substrate 2 (IRS2) is important for pancreatic beta-cell survival and function, reduction of peripheral insulin sensitivity and insulin signaling.

Case Report: A17 year old female patient was referred to endocrinologist because of high fasting blood glucose levels measuring up to 19 mmol/L. Her symptoms were present for two weeks and included fatigue, mouth dryness and polyuria. Prenatal and early childhood medical history were unremarkable. Her father was diagnosed with type 2 diabetes mellitus (T2DM) at the age of 40 years. Initial laboratory findings were: HbA1c 12.5%, C peptides 1.6 ng/ml. She was started with insulin therapy with oral antidiabetics (Metformin). After 3 months, HbA1c was 6.4%. She was positive for GAD (Glutamic Acid Decarboxylase) autoantibodies 26.3 U/ml, while ICA (Islet Cell Antibodies), IA-2 (Insulinoma-Associated Antigen 2) and ZnT8 (Zinc Transporter 8) autoantibodies were negative. After one year, HbA1c was 7.5% and C peptides levels were 2.6 ng/ml. Autoantibodies were negative. Since it is possible to find positive autoantibodies in 1% of MODY patients, MODY was suspected and clinical genome sequencing was requested. The result was undetermined, since one heterozygous VUS with a 67.5% probability of pathogenicity leading to diabetes mellitus was detected in the IRS2 gene. The genetic heterozygous missense variant c.4012G>A, p.(Glu1338Lys) in the IRS2 gene replaces the amino acid glutamic acid with the amino acid lysine at position 1338 of the polypeptide chain. According to the American College of Medical Genetics and Genomics classification criteria, the detected variant in the IRS2 gene is classified as VUS – class 3. This variant was not found in either the gnomAD genomes or the gnomAD exomes (PM2_Supporting) and is predicted to result in alternative splicing and loss of function in IRS2. This disease is inherited in an autosomal dominant manner and can lead to T2DM. A father and younger sister are also tested and pending results. After three years since first being diagnosed the patient is on insulin therapy with C peptide 1.6ng/ml and HbA1c 6.3%.

Conclusions: A variant of uncertain significance (VUS) can possibly lead to disease development and remains important both for carrier monitoring and for further genetic counseling. A VUS found in IRS 2 gene can lead to development of diabetes mellitus.

EP768 - ECE_3429 - Use of tirzepatide: metabolic, functional and psychological outcomes

Khash Nikookam, Conor Bentley, Gavita Kaur, Usman Shah, Raj Tanday and Anna Hawkins
Barking, Havering and Redbridge University Hospitals NHS Trust, King George Hospital, Department of Endocrinology, London, United Kingdom

Tirzepatide is an effective treatment for weight management; however, data describing its impact beyond weight loss, on physical function, psychological wellbeing and cardiometabolic risk, remain limited. This service evaluation examined outcomes associated with tirzepatide delivered within a multidisciplinary weight management service.

A single-arm pre–post service evaluation was conducted in adults (≥18 years) receiving tirzepatide for at least three months within a multidisciplinary weight management service. Anthropometric measures, blood pressure, physical function (30-second sit-to-stand test and maximal bilateral handgrip strength), psychological wellbeing (PHQ-9 and GAD-7), dietary quality (PRIME Diet Quality Score), and cardiometabolic and nutritional biomarkers were assessed at baseline and follow-up. Data are reported as mean ± standard deviation. Paired analyses were performed with pairwise exclusion of missing data, using paired t-tests or Wilcoxon signed-rank tests as appropriate. Statistical significance was set at $p<0.05$ (two-tailed). Blood biomarker outcomes were analysed descriptively due to limited statistical power.

Eleven participants were included in the final analyses. Body mass index (BMI) decreased significantly following tirzepatide use, from 41.5 ± 5.9 kg/m^2 at baseline to 37.2 ± 4.8 kg/m^2 at follow-up ($P < .01$), accompanied by improvements in central adiposity, including a significant reduction in waist-to-height ratio and neck circumference (mean reduction 3.0 ± 1.5 cm, $P = .003$). Systolic blood pressure decreased from 137 ± 11 mmHg at baseline to 126 ± 12 mmHg at follow-up (mean change −10.9 mmHg, $P = .027$). No significant changes were observed in diastolic blood pressure or waist-to-hip ratio. Physical function improved significantly. Maximal handgrip strength increased from 32.1 ± 7.4 kg at baseline to 41.2 ± 10.8 kg at follow-up ($P < .01$). Lower-limb function also improved, with participants completing more repetitions on the 30-second sit-to-stand test (16.2 ± 4.3 vs 17.8 ± 3.9 repetitions; mean increase 1.6 repetitions, $P < .01$). Psychological wellbeing improved over the evaluation period. Mean GAD-7 scores decreased from 10.5 ± 6.4 to 3.8 ± 3.9 ($P < .01$), with parallel reductions observed in PHQ-9 scores. Dietary quality improved significantly, with PRIME Diet Quality Scores increasing from 20.4 ± 4.3 to 26.0 ± 3.1 ($P < .01$). Changes in cardiometabolic and nutritional biomarkers, including HbA1c, lipid profile, ferritin, folate and vitamin D, were directionally favourable but underpowered for formal statistical inference.**Conclusions:** within a multidisciplinary weight management service, tirzepatide use was associated with significant

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

improvements in BMI, physical function, and psychological well-being. These findings reinforce the value of an MDT approach integrating pharmacological and lifestyle interventions to improve care and outcomes.

EP771 - ECE_1494 - When imaging misleads: diagnostic approach of hypoglycemia in non-diabetic adults

Adina-Ioana Onofrei[1], Dana Tilici[1,2], Daniela Greere[1,3], Ruxandra Costinescu[1], Ana-Maria Arnautu[1], Mirona Dinca[1,2], Beatrice Grecu[1], Claudia Nacea[1] and Diana Paun[1,2,3]
[1]Emergency University Hospital of Bucharest, Endocrinology, Bucharest, Romania; [2]Doctoral School of Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [3]Bucharest, Romania

Introduction: Nowadays, the diagnostic protocol for seemingly healthy non-diabetic adults presenting with hypoglycemic disorders mainly relies on the biochemical and imaging diagnosis of an insulinoma. Based on cases evaluated in our clinic, we propose a more biochemically oriented diagnostic approach with greater consideration for insulin autoimmune syndrome. After confirming endogenous hyperinsulinemic hypoglycemia and excluding medication-related and factitious hypoglycemia, the main etiologies include insulinoma, insulinomatosis, microinsulinomas, proinsulinoma, noninsulinoma pancreatogenous hypoglycemia and insulin autoimmune hypoglycemia.

Case Descriptions: Between July 2024 and October 2025, six patients were evaluated in our clinic for symptomatic hypoglycemia. One patient had a confirmed insulinoma, and one had suspected insulinoma with discordant imaging findings and is scheduled for GLP-1R PET/CT. Two patients were diagnosed with Hirata's disease and had conflicting imaging results, and in two cases endocrinologic causes of hypoglycemia were excluded.

Notably, the first patient with Hirata's disease experienced hypoglycemic episodes occurring randomly during both daytime and nighttime; ^{99}?Tc-tektrotyd SPECT-CT findings were suggestive of insulinoma, while MRI revealed an atypical pancreatic lesion that could not definitively exclude this diagnosis. In the second patient with Hirata's disease, symptoms occurred in both fasting and postprandial states; MRI findings suggested insulinoma, whereas endoscopic ultrasound showed no pancreatic lesions, and exploratory laparotomy failed to identify a pancreatic tumor.

The patient awaiting GLP-1R PET/CT previously underwent pancreatic MRI, which demonstrated two lesions suggestive of benign vascular lesions, along with additional pancreatic microlesions with calcified/fibrous components. However, both subsequent and prior MRIs were normal. ^{99}?Tc-tektrotyd SPECT/CT showed findings suggestive of insulinoma, and endoscopic ultrasound identified a hypoechoic lesion. Despite this, abdominal CT findings were normal, and exploratory laparotomy failed to retrieve any pancreatic tumor. The patient has a history of positive autoantibodies (rheumatoid factor, anti-SS-A, anti-Ro-52), with negative insulin and insulin-receptor antibodies. Her symptoms became severe during pregnancy but had been present for more than one year prior.

Conclusions: Although insulinoma remains the most likely diagnosis once endogenous hyperinsulinemic hypoglycemia is proven, imaging studies are often inconsistent, may yield false-positive results in real-world clinical settings and some have limited availability. As a result, attention should be directed toward excluding Hirata's disease and type B insulin resistance, despite their rarity.

We propose the following laboratory measurements at the end of the selected provocative test: insulin, polyethylene glycol precipitation, proinsulin, C-peptide, β-hydroxybutyrate, anti-insulin antibodies, anti-insulin receptor antibodies, IGF-2 and IGF-1. In addition, basal measurements of cortisol, ACTH and TSH are recommended.

EP774 - ECE_2965 - When lipids turn lethal: acute pancreatitis from severe hypertriglyceridemia in diabetic pregnancy

Shebina Liz Mathews, Ann Francis, Kabeer Katariya and Cornelius Fernandez James
Pilgrim Hospital , Boston (United Lincolnshire Hospitals NHS Trust), Diabetes and Endocrinology, Boston, United Kingdom

Introduction: Hypertriglyceridemia-induced acute pancreatitis (HTG-AP) in pregnancy is rare and carries a significant morbidity/mortality risk to mother and fetus. This case highlights the importance of prompt diagnosis and a multidisciplinary approach.

Case Presentation: We present a 32-year-old lady (G7/P6+1) with history of gestational diabetes mellitus (GDM) in three previous pregnancies. Follow up HbA1c levels were not done after GDM pregnancies. She was non-compliant with the antenatal plans, with repeated non-attendance in the clinics. She engaged with the endocrine team only once during the current pregnancy. She stated she had been testing regularly and had glucose readings in target (pre-breakfast <5.3 and one-hour post-meal <7.8) while on diet control.

Within 4 weeks, at 35+5 weeks, she presented with abdominal/back pain with nausea. The initial blood sample could not be processed (lipemic serum). However, with point-of-care results (CBG 17.8, Ketone 2.1, pH 7.4, bicarbonate 24.5), VRIII was initiated, which helped clear the lipemia. Later blood tests revealed: eGFR >90 mL/min, amylase 259 U/L, CRP 278 mg/L, Total cholesterol 18.3 mmol/L, Triglyceride 39.5 mmol/L, HDL-cholesterol 0.5 mmol/L, Non-HDL-cholesterol 17.9 mmol/LHbA1c 88 mmol/mol, TSH 2.4 mU/L, FT4 11.6 pmol/L.

Ultrasound Abdomen: normal. Our diagnosis was: Suboptimal glycaemic control secondary to non-compliance and likely missed T2DM, severe hypertriglyceridemia and HTG-AP. Plan was to continue VRIII until triglycerides normalized, HDU bed, surgical review, emergency LSCS and CT-abdomen. CT showed focal pancreatic necrosis. She was discharged on insulin for diabetes and hypertriglyceridemia. Though lipid and diabetes clinic appointments were given, the patient repeatedly missed them.

Discussion: Hyperestrogenism and insulin resistance result in a 2-3-fold rise in triglycerides by the third trimester (gestational hypertriglyceridemia). This will be amplified in those with GDM or T2DM in pregnancy. HTG-AP usually occurs when triglycerides exceed 10 mmol/L, around six times the ULN. Diagnostic delay may occur because of assay interference from lipemic serum and the difficulty in doing a CT abdomen. Therefore, early lipid testing is essential whenever clinical suspicion persists despite lack of or

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

modest amylase/lipase results. Insulin promotes lipoprotein lipase synthesis and decreases triglyceride hydrolysis.

Conclusions: HTG-AP is a rare complication of late pregnancy, especially in those with uncontrolled diabetes mellitus. Early lipid testing is vital when suspicion persists, as pancreatic enzymes may rise only modestly in lipemic samples. Multidisciplinary management and postpartum follow-up play an integral role in optimizing maternal and neonatal outcomes in these cases.

EP777 - ECE_2524 - Trends in overweight and obesity among children and adolescents in Uzbekistan

Marlen Ibragimov[1,2], Zulaykho Shamansurova[1] and Zulaykho Shamansurova[1]
[1]*Central Asian University, AKFA Medline University Hospital, Tashkent, Uzbekistan;* [2]*Central Asian University in Tashkent - CAU, Medical School, Medical School, Toshkent*

Background: Overweight and obesity among children and adolescents are a growing global concern. The 5-19 age group is especially important, as habits formed during these years can impact health into adulthood. Comparing national trends to global patterns helps identify vulnerable groups and contributing factors.

Aim: To assess trends in overweight (including obesity) among 5-19-year-olds in Uzbekistan between 2010 and 2022, compare with worldwide estimates, and discuss in relation to food environment changes.

Methods: An observational analysis used publicly available data on overweight (including obesity) among children and adolescents aged 5-19 years from the NCD Risk Factor Collaboration, which was chosen for its comprehensive, standardized methodology. Prevalence was calculated as the mean of three age groups (5-9, 10-14, and 15-19 years), stratified by sex. Dietary energy supply data came from FAOSTAT Food Balance Sheets, a widely used resource for international food and nutrition statistics. The analysis focused on 2010 as the baseline and 2018-2022 as the recent interval.

Results: In Uzbekistan, the prevalence of overweight (including obesity) among children and adolescents aged 5-19 years increased from approximately 15% in 2010 to 17% in 2018 and further to 19% in 2022. Worldwide estimates were consistently higher, increasing from approximately 23% to 26% over the study period.

Across all age groups, overweight prevalence was higher among boys than girls in both Uzbekistan and globally. In 2022, boys aged 5-9 years had the highest prevalence, reaching about 25% in Uzbekistan and 30% worldwide, about 1.3-1.4 times higher than girls of the same age. The lowest prevalence was among girls aged 15-19 years: 13% in Uzbekistan and 25% worldwide.

During the same period, dietary energy supply in Uzbekistan rose from 2938.5 kcal/capita/day in 2010 to 3277.0 kcal/capita/day in 2022, about 11.5% higher than in 2010 and 1.1 times the global average in 2022 (2983.5 kcal/capita/day). The increase in overweight prevalence, particularly among children aged 5-9 years, coincided with the greater availability of energy-dense foods and the expansion of international fast-food outlets in Uzbekistan since around 2018.

Conclusions: From 2010 to 2022, overweight prevalence among 5-19-year-olds in Uzbekistan increased, mostly among boys aged 5-9 years. This trend occurred alongside greater availability of energy-dense foods and the expansion of fast-food franchises since 2018. While causality is uncertain, the findings highlight the need for early prevention strategies targeting childhood nutrition and weight gain.

EP779 - ECE_1940 - Compromised bioavailability of calcium and vitamin D following Roux-en-Y gastric bypass

Snezana Polovina[1], Mirjana Sumarac-Dumanovic[1,2], Dusan Micic[3], Danka Jeremic[4], Dusan Zivanovic[4], Nevena Radić[4], Djurdjina Lovovic[4], Danilo Lazarevski[1] and Pavle Gregoric[3]
[1]*University Clinical Center of Serbia, Belgrade, Clinic for Endocrinology, Diabetes and Diseases of Metabolism, Belgrade, Serbia;* [2]*Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Center of Serbia, Belgrade, Serbia;* [3]*University Clinical Center of Serbia, Belgrade, Emergency Center, Clinic for Emergency Surgery, Belgrade, Serbia;* [4]*University Clinical Center of Serbia, Belgrade, Clinic for Endocrinology, Diabetes and Diseases of Metabolism, Belgrade, Serbia*

Introduction: Patients with obesity undergoing Roux-en-Y gastric bypass (RYGB) are at risk for impaired calcium and vitamin D absorption. Reduced gastric acidity and the bypass of the primary sites of mineral absorption can trigger secondary hyperparathyroidism, characterized by elevated parathyroid hormone (PTH) secretion.

Methods: We evaluated serum calcium, 25-hydroxyvitamin D [25(OH)D], and PTH levels in 100 patients (33 males, 67 females; mean age 50.8 ± 11.6 years) at baseline, two years, and five years post-RYGB. Following European guidelines for bariatric surgery, patients received 1250 mg of calcium carbonate and 400 IU of vitamin D daily for the first two months. From the third month onward, supplementation was adjusted to 600 mg of calcium citrate and 2000 IU of vitamin D.

Results: Mean BMI decreased significantly from 43 ± 8.2 kg/m^2 at baseline to 29.2 ± 4.4 kg/m^2 at two years, followed by a slight increase to 31.9 ± 5.6 kg/m^2 at five years ($P < .001$). Serum calcium remained stable across all time points ($P = .83$ and .86). Baseline vitamin D levels were insufficient (52.79 ± 24.60 ng/mL) and showed a downward trend over time (46.5 ± 14.82 ng/mL at two years; 43.7 ± 22.5 ng/mL at five years; $P = .43$ and .08, respectively). Notably, mean PTH rose significantly from a baseline of 56.28 ± 25.42 pg/mL to 71.06 ± 35.4 pg/mL at two years ($P < .05$) and remained elevated at 73.05 ± 28.9 pg/mL at five years ($P < .05$).

Conclusions: These findings underscore the necessity of optimizing vitamin D status prior to surgery. Furthermore, the significant rise in PTH despite supplementation suggests that patient compliance or the adequacy of standard mineral regimens may decline after the first two postoperative years, necessitating long-term biochemical monitoring.

EP783 - ECE_1325 - Glycemic control in pediatric type 1 diabetes mellitus: a meta-analysis comparing insulin glargine with neutral protamine hagedorn (NPH) insulin regimens

Ignace Claire Gamallo[1], Caridad Santos[2] and Marichu Mabulac[1]
[1]Philippine Childrens Medical Center, Pediatric Endocrinology, Quezon City, Philippines; [2]Philippine Childrens Medical Center, Section of Pediatric Endocrinology, Quezon City, Philippines

Objectives: This study aimed to compare glycemic control and complications of multiple daily insulin injection (MDII) regimen using insulin glargine with NPH as basal insulin among children with T1DM.

Materials and Methods: This is a meta-analysis of RCTs comparing glycemic control and complications of MDII regimen using insulin glargine with NPH as basal insulin among children with T1DM. A systematic search using electronic databases (MEDLib via PubMed, Google Scholar, Cochrane Library and Clinical Trials Registry) was performed using the following keywords, such as "type 1 diabetes", "insulin glargine", "intensive insulin regimen", "children", "HBA1C", "effectiveness" "RCT" "DKA". Health Research and Development Information Network (HERDIN) for applicable local articles was also done. Odds ratio was computed and Forest plot was generated to interpret the outcomes of interest.

Results: A total of 509 children aged 1 to 18 years from 5 RCTs were included in this meta-analysis. Participants had a disease duration ranging from 5 months to 1 year at the time of diagnosis. Average reduction in HbA1c is significantly better in the insulin glargine, with a mean difference of −0.30 (95% CI = −0.34 to −0.26, $P <$ .00001) compared to the NPH group with low heterogeneity ($I^2 =$ 45%) . Furthermore, this study revealed lower hypoglycemia events (OR = 0.98, 95%CI =0.62 to 1.58, $P =$.95), and nocturnal hypoglycemia (OR =0.61, 95%CI =0.37 to 1, $P =$.05) in glargine. DKA was the most common TEAE reported in both groups and one study reported that hospitalization due to DKA was significantly more frequent in the NPH group. Microvascular complications were not assessed in any of the 5 studies.

Conclusions: Results of this meta-analysis showed that insulin glargine is superior to the NPH insulin in achieving glycemic control in T1DM children on MDII. Likewise, fewer hypoglycemia events and hospitalization due to DKA were reported with glargine versus NPH. With better achievement of glycemic targets, superiority in preventing complications is implied favoring the glargine group.

Keywords insulin glargine, neutral protamine hagedorn (NPH), glycemic control

EP784 - ECE_1864 - Demographic characteristics and glycemic profile of patients with type 1 diabetes using ypsomed HCL system at the university hospital of the Canary Islands

Selena Rodriguez Fernandez, Kevin David Díaz Gorrín, Javier Panizo Fra, Paula Pérez, Óliver Quintero Rodríguez, Ana Paola Leon Ocando, MacArena Sánchez-Gallego Alonso, Itziar Aznar Ondoño and Juan Ignacio Márquez De La Rosa
Hospital Universitario de Canarias, Endocrinology and Nutrition, San Cristóbal de La Laguna, Spain

Introduction: According to the American Diabetes Association, automated insulin delivery systems are the preferred method to improve glycemic outcomes and reduce hypoglycemia in Type 1 Diabetes Mellitus (T1DM). Currently, it is suggested that these devices should be offered at diagnosis or shortly after disease onset. In recent years, devices such as the Ypsomed AHCL system have shown increased use in clinical settings due to their integration with continuous glucose monitoring systems (CGMS) and technological improvements.

Objective: To study the demographic characteristics and glycemic profile of patients using the Ypsomed AHCL system at the University Hospital of the Canary Islands.

Materials and Methods: An observational, retrospective study including all patients using the Ypsomed AHCL system at the University Hospital of the Canary Islands in 2025.

Results: A sample of 20 patients was analyzed, 55% female (median age 47 years). The median duration of T1DM was 20 years.

Among patients using the Ypsomed AHCL system, 70% used the FSL3 sensor and 30% used Dexcom G6. Forty percent had prior insulin pump therapy (37.5% Tandem, 12.5% Medtronic, 37.5% Insight, and 12.5% Accu-Chek). Regarding initiation date, most patients started AHCL therapy in 2025.

Before AHCL initiation, patients had a median HbA1c of 6.80% and a mean of 7.05%. After AHCL implementation, median HbA1c decreased to 6.18% and mean to 6.29% (reduction of 0.59%, statistically significant). The GMI was 6.68%.

Glycemic Metrics:

Parameter	Pre-AHCL	Post-AHCL
TIR (median)	70%	78%
TAR (median)	25%	20%
TUR (median)	2%	2%
TIR (mean)	60%	78%
TAR (mean)	30%	20%
TUR (mean)	3%	2%

Statistical analysis (Wilcoxon):

- TIR: +12.65%*
- TAR: −9.8%*
- TUR: −1%

*Statistically significant results.

Only one patient experienced diabetic ketoacidosis after initiation of the Ypsomed AHCL system, and no patients reported severe hypoglycemia. Metadiabetic complications were present in 42.85% of patients (7 with retinopathy, 5 with nephropathy, 1 with neuropathy, 1 with stroke, and 1 with peripheral arterial disease). Regarding lipid control, mean LDL cholesterol was 89.45 mg/dL, and 60% of patients were above their LDL target.

Conclusions: The use of the Ypsomed AHCL system was associated with improved glycemic control (HbA1c reduction and increased TIR) without a significant increase in acute complications. These findings support the utility of this system as an effective tool in the management of T1DM. However, due

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

to the small sample size, larger studies are required to assess long-term outcomes and compare its role against other available technologies.

EP785 - ECE_2584 - Transformative impact of continuous glucose monitoring on glycemic control through lifestyle modification in a patient with non-insulin treated type 2 diabetes

Shafik Mansour[1,2] and Khaled Baagar[1]
[1]Doha, Qatar; [2]Hamad Medical Corporation, Qatar Metabolic Institute, Doha, Qatar

Current clinical practice guidelines have endorsed Continuous glucose monitoring (CGM) primarily for individuals using multiple daily insulin injections or insulin pumps.However, emerging data suggest that CGM may also benefit patients with type 2 diabetes (T2DM) who are not treated with insulin.

A 56-year-old male with a 17-year history of T2DM was referred from the primary care center to the diabetes clinic for suboptimal glycemic control with an HbA1c of 7.6%. His medical history was significant for obesity (weight 122 Kg, BMI 45.65 kg/m^2), ex-smoker, peripheral neuropathy, and peripheral arterial disease (PAD) with bilateral lower-limb intermittent claudication, limiting his walking distance to approximately 300 meters. His medications included a combination of sitagliptin 50 mg/Metformin XR 1000 mg twice daily, aspirin, and high-intensity statin (atorvastatin 80 mg). He was not performing self-monitoring of blood glucose, primarily due to inconvenience and the finger-prick discomfort.

The patient was motivated, and while he is waiting to get his appointment with us in the diabetes clinic, he initiated FreeStyle Libre CGM by himself without making any changes in his pharmacological therapy. Within the first month of the CGM use, he began to make notable lifestyle changes. He voluntarily reduced his intake of bread and rice, incorporated more vegetables, switched to small and frequent meals, and eliminated sugary foods. He could see in real-time the impact of different foods on his glucose levels, and he changed food choices guided by the CGM. Also, he began walking as tolerated, as his mobility was affected by his PAD.

His HbA1c improved significantly from 7.6% to 5.9%. Data from the 14-day CGM ambulatory glucose profile revealed an average glucose of 128 mg/dL, a glucose management indicator of 6.4%, time-in-range (TIR) of 93%, and time below range (TBR) of 1%. Glucose variability was 23.1%.

The patient described CGM as “transformative,” noting that seeing real-time changes in glucose helped him understand the immediate impact of different food choices and exercise. This feedback loop motivated sustained changes in behavior and eliminated the need for medication intensification to achieve glycemic control.**Conclusions:** Rapid and sustained improvement in glycemic metrics, achieved solely through behavioral changes prompted by CGM feedback, reinforces its role as more than a monitoring tool. The high TIR and low variability achieved in a short duration suggest that early CGM adoption in motivated patients may minimize the need for pharmacological intensification.

EP787 - ECE_3110 - Aflibercept as an effective alternative in anti-VEGF–resistant diabetic macular edema

Rekik Mona[1], Yoldez Ben Jemaa[1], Imene Kaibi[1], Kmar Maaloul[1], Nabila Rekik Majdoub[2] and Trigui Amira[1]
[1]Habib Bourguiba Hospital, Sfax, Tunisia; [2]Hôpital Universitaire Hédi Chaker, Sfax, Tunisia

Introduction: Diabetic macular edema (DME) remains a leading cause of visual impairment in patients with long-standing diabetes mellitus, and resistance to anti–vascular endothelial growth factor (anti-VEGF) therapy represents a significant therapeutic challenge.

Case Report: We report the case of a 63-year-old patient with a 33-year history of insulin-dependent diabetes mellitus. The patient was pseudophakic in both eyes and presented with bilateral diabetic macular edema. Despite intensive treatment with intravitreal bevacizumab, totaling 14 injections, the response was inadequate, with persistently reduced visual acuity measuring 2/10 in the right eye and 1/10 in the left eye.

Given the refractory nature of the macular edema, a therapeutic switch to intravitreal aflibercept was undertaken. The patient demonstrated a rapid and marked anatomical and functional response from after 5 aflibercept injections in each eye. Best-corrected visual acuity improved dramatically to 7/10 in both eyes and a significant reduction of macular edema on optical coherence tomography was achieved. This visual gain was accompanied by sustained anatomical stabilization, with no recurrence of macular edema observed during a follow-up period of one year.

Conclusions: This case illustrates the potential superiority of aflibercept in selected cases of bevacizumab-resistant diabetic macular edema, likely related to its broader spectrum of action and higher binding affinity for VEGF. Switching anti-VEGF agents should be considered in patients with suboptimal response to initial therapy, as it may lead to significant visual recovery and long-term disease control.

Objectives: To evaluate the efficacy and safety of Synthetic Semaglutide Injection manufactured by Sun Pharma (Test arm) with Ozempic® Injection (Reference arm) in Indian patients with type 2 diabetes mellitus (T2DM) with mild renal impairment (eGFR 60 to <90 mL/min/1.73 m^2).

Materials and Methods: This was a phase III, multicentre, randomized, open-label, active controlled study. Total 314 adults (18-65 years) with T2DM (HbA1c: 7.0-10.5%) on diet/exercise uncontrolled with stable metformin dose (≥1500 mg or maximum tolerated dose) for ≥12 weeks were enrolled. Eligible patients were randomized in a 1:1 ratio and received Test product (manufactured by Sun Pharma) or Reference product, subcutaneous injections in a weekly dose of 0.25 mg to 2 mg for 24 weeks. [CTRI Registration number: CTRI/2025/02/080592].

Results: This subgroup analysis included total 109 patients (Test arm [n=55] and Reference arm[n=54]) with mild renal impairment (eGFR 60 to <90 mL/min/1.73 m^2). HbA1c reduction (± SD) from baseline to Week 24 was comparable to comparator in this subgroup: $-1.95 \pm 0.72\%$ vs $-1.77 \pm 0.88\%$ ($P = .3920$). Significant reduction from baseline HbA1c was observed in both test arm and reference arm at Week 24. Significant reductions in post-prandial and fasting blood glucose levels at Week 24 were seen in both the study arms and the changes were comparable in this subgroup. Proportion of patients achieving HbA1c <7.0% from baseline to Week 24 were comparable between the Test arm and reference arm 42 (76.4%) vs 42 (77.8%) ($P = .7191$). One patient experienced hypoglycaemia. None of the patients required rescue medication. The incidence of treatment-emergent adverse events (TEAEs) was similar in both arms (Test arm = 66.2% and Reference arm = 69.5%). Most common TEAEs were gastrointestinal events (Diarrhoea, Nausea, Vomiting). Study medications were well tolerated.

Conclusions: Semaglutide injection (Test Product) demonstrated comparable glycaemic control to Reference product in T2DM patients uncontrolled on metformin monotherapy with mild renal impairment.

EP793 - ECE_2553 - Association of statin therapy with cognitive function and muscle mass in postmenopausal women

Sara Anić[1,2], Anja Akmadžić[1,3], Dunja Šojat[4,5], Ivan Lekić[6,7,8], Dunja Degmečić[9,10] and Tatjana Bačun[11,12,13]

[1]Faculty of Medicine Osijek, Osijek, Croatia; [2]Health Center of Osijek-Baranja County, Osijek, Croatia; [3]Clinical Hospital Center Osijek, Osijek, Croatia; [4]Faculty of Medicine Osijek, Department of Family medicine, Osijek, Croatia; [5]Health Center of Osijek-Baranja County, Family medicine, Osijek, Croatia; [6]Faculty of Medicine Osijek, Department of Internal medicine, Osijek, Croatia; [7]Health Center Zagreb Centar, Department of Internal medicine, Zagreb, Croatia; [8]Zagreb, Croatia; [9]Faculty of Medicine Osijek, Department of Psychiatry, Osijek, Croatia; [10]Clinical Hospital Center Osijek, Department of Psychiatry, Osijek, Croatia; [11]Faculty of Medicine Osijek, Department of Internal Medicine, Osijek, Croatia; [12]Faculty of Dental Medicine and Health, Department of Clinical medicine, Osijek, Croatia; [13]Clinical Hospital Center Osijek, Internal medicine clinic, Department of Endocrinology, Osijek, Croatia

Objective: The aim of this study was to investigate the effects of statin therapy on cognitive function and muscle mass percentage in postmenopausal women, as well as to examine associations based on age, duration of menopause, statin dose and lipid levels.

Study Design: This was a prospective study.

Participants and Methods: The study included 71 postmenopausal women aged 45 to 70, patients in primary care clinics of the Osijek-Baranja County Health Center. Anamnestic data were collected, and blood samples were analyzed for lipid profile values. Cognitive function was assessed using the MMSE test, while body composition was measured by bioimpedance. Statin dose was determined according to cardiovascular risk.

Results: The study was conducted on 71 participants with a median age of 60 years (range 50-70). High cardiovascular risk was noted in 33 (46.5%) participants, and moderate risk in 15 (21.1%). A greater number of participants treated with atorvastatin achieved target LDL cholesterol values compared to those treated with rosuvastatin (Fisher's exact test, $P = 0.03$). No significant change was observed in the percentage of muscle mass between initial and final measurements (Wilcoxon test, $P = .46$). A statistically significant improvement in cognitive function according to the MMSE test was recorded at the final control (Wilcoxon test, $P < .001$). Age was negatively correlated with muscle mass percentage (Spearman's Rho = −0.264, $P < .05$). Duration of menopause, statin dose, and total cholesterol showed no significant association with cognitive tests or muscle mass percentage ($P > .05$).

Conclusions: Statin therapy is associated with improvements in cognitive function in postmenopausal women, with no significant impact on muscle mass percentage. There are significant differences in achieving target LDL cholesterol values between statins, with atorvastatin being more effective.

Keywords atorvastatin, cognitive function, lipid profile, muscle mass, postmenopause, rosuvastatin, statins

Objective: The aim of this study was to investigate the effect of statin therapy on inflammation and body composition in postmenopausal women, as well as to examine associations based on age, lipid levels, and statin type.

Study Design: This was a prospective study.

Participants and Methods: The study included female participants aged 45 to 70 who were patients in primary care clinics of the Osijek-Baranja County Health Center. Relevant anamnestic data were collected, and blood samples were analyzed for inflammatory markers and lipid profiles. Body composition was assessed using bioelectrical impedance analysis, while the statin dose was determined based on cardiovascular risk using the SCORE table.

Results: The study included 67 women, divided into two groups based on the type of statin used. Among those who achieved target lipid levels, 20 women (57%) received atorvastatin. A statistically significant difference between the final and initial measurements was observed in body weight ($P = .001$, Wilcoxon test), body fat percentage ($P = .008$), BMI ($P = .02$), and hip circumference ($P = .001$). Positive correlations were found between triglycerides and WHR (Rho = 0.508), age and visceral fat (Rho = .334), while a negative correlation was found between total cholesterol and NLR (Rho = −0.360).

Conclusions: Although a statistically significant difference was found regarding the effect of statins on body composition, the changes were minimal and not clinically relevant. No effect was demonstrated on RDW or NLR. However, certain associations between the examined parameters were observed.

Keywords body composition, hydroxymethylglutaryl-CoA reductase inhibitors, inflammation, lipids, postmenopause

EP796 - ECE_3585 - LMNA-related familial partial lipodystrophy type 2 complicated by severe dilated cardiomyopathy: a fatal case report and experience with metreleptin therapy

Alina Alzhaxina, Assel Issabayeva, Kristina Baikadamova, Marzhan Rakhimzhanova and Aigul Durmanova
University Medical Center, Astana, Kazakhstan

Introduction: Familial partial lipodystrophy type 2 (FPLD2) is a rare autosomal dominant disorder caused by pathogenic *LMNA* variants. It is characterized by selective loss of subcutaneous fat, insulin resistance, dyslipidemia and hepatic steatosis. Cardiac involvement, including conduction defects and dilated cardiomyopathy (DCM), can be life-threatening.

Clinical Case: A 19-year-old girl presented with progressive cardiac dysfunction and a known diagnosis of *LMNA*-related FPLD2, confirmed at age 17 by a heterozygous pathogenic *LMNA* c.1488 +1G>A variant (HGMD CS094346; PMIDs 20848652, 34240052). She had acanthosis nigricans, hirsutism, muscular extremities, and loss of subcutaneous fat from the face, abdomen, and limbs (BMI 14.06 kg/m^2). At 16 years, she underwent ovarian cystectomy, and then she suffered an ischemic stroke affecting the left anterior and middle cerebral arteries. At 17 years, she developed hypertension and arrhythmias with alternating tachycardia and bradycardia. Echocardiography showed a dilated left ventricle, LVEF 14.3%, and mild pulmonary hypertension. NT-proBNP 276 pg/mL (N<125) indicated early cardiac damage, and an ICD was implanted.

Metreleptin (0.4 mL s.c. daily) was started at the age of 18 years. Labs before therapy: fasting glucose 80.2 mg/dL (74-106), insulin 218 µIU/mL, HbA1c 6.2%, C-peptide 3.54 ng/mL (1.1-4.4); TG 1.56 mmol/L (0.44-1.4), LDL 0.67 mmol/L (0.91-1.91), low HDL; ALT 114.9 U/L, AST 93.9 U/L (N<35), indicating hepatic steatosis. Imaging revealed moderate hepatomegaly with diffuse hepatic steatosis and parenchymal changes in the pancreas and kidneys. After one year of therapy, metabolic parameters normalized: fasting glucose 98.1 mg/dL, HbA1c 5.7%, ALT 32.5 U/L, AST 39 U/L, TG 61.2 mg/dL, LDL 62.1 mg/dL. However, NT-proBNP increased to 4363 pg/mL (N<125), consistent with worsening heart failure. Despite therapy, she died approximately one year after treatment initiation due to complicated pneumonia and terminal cardiac failure.

Discussion: This case demonstrates a clear dissociation in LMNA-related FPLD2. Metreleptin reversed hepatic steatosis and normalized metabolic markers but failed to stop cardiomyopathy progression. This confirms that cardiac decline is driven by primary structural defects in the nuclear envelope rather than metabolic toxicity. The early stroke and multi-organ involvement underscore that LMNA-mutations are aggressive, systemic laminopathies. Ultimately, metabolic improvement provides a false sense of security; heart failure in these patients progresses independently of glycemic or lipid control, necessitating early and rigorous cardiac intervention.

Conclusions: Metreleptin improved hepatic and metabolic markers but failed to halt cardiac deterioration in *LMNA*-related FPLD2. Early recognition of cardiac manifestations and multidisciplinary follow-up are crucial to improving outcomes.

EP798 - ECE_3902 - Severe nephrotoxicity after short-term multiple dietary supplements use in a type 2 old diabetic female - a case report

Daniel-Tudor Cosma[1,2]
[1]*Horezu City Hospital, Diabetes, Nutrition and Metabolic diseases Outpatient Clinic, Horezu, Romania;* [2]*Gerontohealthcare Clinic,*

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Diabetes, Nutrition and Metabolic diseases Outpatient Clinic, Ramnicu-Valcea, Romania

Dietary supplements are widely used for their perceived health benefits with minimal regulation. However, they have been associated with various toxicities including kidney disease.

A 76-year-old female with type 2 diabetes mellitus (DM) controlled through diet and complicated by peripheral neuropathy, under treatment with benfotiamine + B6 + B12, presented in the emergency department of a county hospital with generalized myalgia, oligoanuria and high blood pressure (BP $\leq$ 230 mmHg) after using 5 different dietary supplements by the same company for 3 weeks. Lab exams revealed creatinine = 11 mg/dl, hyperkalemia, metabolic acidosis, GPT = 600 U/L and CK = 25000 U/L, for which hemodialysis on a central venous catheter in right femoral vein was initiated. After 20 days the patient developed thrombosis on right common femoral vein for which intravenous anticoagulation was started. 2 months after initial presentation, she was referred to a University Nephrology Department for hemodialysis cessation after partial recovery of renal function. Besides twice positive ANA screen ratio, mild anemia, creatinine = 1.99 mg/dl, leukocyturia, asymptomatic bacteriuria and albumin/creatinine ratio of 30mg/g, all the other investigations were within normal limits. The patient was reevaluated in the University Nephrology Department after one month and then every 6 months, the last creatinine being 0.95mg/dl with an estimated glomerular filtration rate of 58 ml/min/1.73 m^2.

While dietary supplements are advertised and consumed with the promise of significant health benefits without side effects, evidence suggests minimal benefits and potential harm to human health. This case illustrates the severe renal injury requiring hemodialysis, long hospitalizations and intensive follow-ups after a short period of using multiple dietary supplements. Despite significant improvement in renal function, the patient remained with stage G3aA1 chronic kidney disease.

EP803 - ECE_2536 - Microalbuminuria as a marker of endothelial dysfunction in patients with Type 2 diabetes

Gabrijela Malesevic[1,2], Snjezana Popovic Pejicic[3] and Valentina Soldat Stankovic[1]

[1]Faculty of Medicine, University of Banja Luka, Republic of Srpska, Banja Luka, Bosnia and Herzegovina; [2]University Clinical Center of the Republic of Srpska, Banja Luka, Bosnia and Herzegovina; [3]Academy of Sciences and Arts of the Republic of Srpska, Banja Luka, Bosnia and Herzegovina

Introduction: Type 2 diabetes (T2D) is associated with an increased risk of cardiovascular diseases (CVD), with endothelial dysfunction representing an early event in the development of atherosclerosis. Microalbuminuria (MAU), defined as the presence of small amounts of protein in the urine (30-300 mg/24 h), is increasingly recognized as a potential marker of systemic vascular damage and early endothelial dysfunction in patients with T2D.

Objective: The aim of this study was to investigate the role of MAU as a marker of endothelial dysfunction in patients with T2D and its significance in the early identification of patients at increased cardiovascular risk.

Methods: The study included 60 patients with T2D without symptoms or signs of cardiovascular disease (CVD). Based on 24-hour urinary albumin levels measured by immunoturbidimetry, patients were divided into two groups: with and without microalbuminuria. All participants underwent exercise stress testing.

Results: In the group of patients with confirmed CVD, 90% had MAU, while in the group without CVD, microalbuminuria was present in only 18% of participants ($P < .01$). Combinations of MAU with HbA1c values and duration of diabetes, analyzed through three binary logistic regression models, were significant predictors of CVD confirmed by exercise testing, with an increase in these parameters associated with a higher probability of a positive stress test ($P < .01$).

Conclusions: MAU in patients with T2D can serve as a valuable biomarker of endothelial dysfunction and a predictor of cardiovascular risk. Its timely detection allows for early intervention and planning of preventive strategies to reduce cardiovascular complications.

EP805 - ECE_1039 - Gut microbiome imbalance in obesity and type 2 diabetes

Hassan Heshmati[1] and Gloria Lin[2]

[1]Endocrinology Metabolism Consulting, LLC, Hassan Heshmati and Valerie Shaw Endocrine Research, Anthem, AZ, United States; [2]CG Discovery, Inc., San Diego, CA, United States

Introduction: Gut microbiome is a complex community of microorganisms living in the digestive tract (mainly in the colon). It contains up to 100 trillion microbes, mainly bacteria (several thousand species), but also fungi, protozoa, archaea, and viruses. The taxonomic ranking of gut microbiome includes species, genera, families, orders, classes, and phyla. The predominant phyla (90%) are Firmicutes and Bacteroidetes. Gut microbiome influences human physiology and susceptibility to diseases. There are important interactions between gut microbiome and metabolic and endocrine parameters. This review presents an update on gut microbiome imbalance (dysbiosis) in obesity and type 2 diabetes.

Methods: A systematic search of literature was conducted for the period 2018 to 2025 using the search terms gut microbiome, dysbiosis, obesity, type 2 diabetes, and management.

Results: Over the entire lifespan, multiple factors impact gut microbiome composition. These factors include diet, age, pregnancy, diseases, and medications. Dysbiosis is observed in several disorders including obesity and type 2 diabetes. In obesity, dysbiosis is represented by a decrease in gene richness, a higher abundance of Firmicutes phylum, a lower abundance of Bacteroidetes phylum, an increase in Firmicutes to Bacteroidetes phyla ratio, and a lower abundance of Verrucomicrobia phylum (with lower presence of *Akkermansia* genus). Obesity is a major contributor to the development of type 2 diabetes. Approximately 80% of people with type 2 diabetes have obesity and their gut microbiome profile is relatively similar to people with obesity. Gut microbiome can be modulated to change the host metabolism and manage obesity and type 2 diabetes. Potential corrective interventions include diet

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

(eg, hypocaloric, low-fat, high-protein, and high-fiber diets), prebiotics (eg, oligofructose-enriched inulin), probiotics (eg, fermented milk containing *Lactobacillus gasseri* species), synbiotics (combination of prebiotics and probiotics), paraprobiotics (inactivated probiotics), postbiotics (beneficial metabolites of microorganisms), gut microbiota transplantation (addition of healthy stool), and bariatric surgery (eg, Roux-en-Y gastric bypass). The targeted gut microbiome should have high gene richness, low abundance of Firmicutes phylum, high abundance of Bacteroidetes phylum, low Firmicutes to Bacteroidetes phyla ratio (<1.0), and high abundance of Verrucomicrobia phylum (with high presence of *Akkermansia* genus).

Conclusions: Dysbiosis is associated with obesity and type 2 diabetes. Relevant gut microbiome changes include decreased gene richness, increased Firmicutes to Bacteroidetes phyla ratio, and low presence of *Akkermansia* genus. The correction of dysbiosis with different tools (eg, diet, prebiotics, probiotics, and gut microbiota transplantation) can help to manage obesity and type 2 diabetes.

EP811 - ECE_2213 - From pathways to precision: integrating clinical and genetic data for early Risk Stratification in Type 2 Diabetes

Siobhan O' Sullivan[1], Cynthia Al Hageh[2] and Pierre Zalloua[2]
[1]*College of Medicine and Health Sciences, Abu Dhabi, United Arab Emirates;* [2]*Public Health & Epidemiology, Khalifa University, Abu Dhabi, United Arab Emirates*

Type 2 diabetes (T2D) is a multifactorial endocrine disorder driven by insulin resistance, β-cell dysfunction, mitochondrial stress, and chronic low-grade inflammation. This heterogeneity underlies substantial variability in disease onset, progression, and therapeutic response, complicating early prediction, patient stratification, and treatment optimisation. Early genetic association studies identified variants in genes central to insulin action and β-cell function, including *IRS1*, *TCF7L2*, and *CDKAL1*, and linked genetic susceptibility to clinical traits such as dyslipidaemia, hypertension, and age. While informative, these single-layer analyses offered limited insight into the dynamic, tissue-specific processes that drive disease progression.

A systems biology framework addresses these limitations by integrating molecular and clinical information to characterise the endocrine networks underlying T2D. Longitudinal and single-cell studies reveal progressive impairment of functional β-cell subpopulations, tissue-specific stress responses, and disrupted inter-organ communication between pancreas, liver, adipose tissue, skeletal muscle, and gut. These coordinated disturbances evolve over time, reflecting the transition from compensated insulin resistance to β-cell failure and highlighting the temporal nature of endocrine dysfunction in T2D.

Pathway-level molecular signatures highlight endocrine-relevant disruptions in insulin signalling, nutrient sensing, mitochondrial function, and stress-response pathways that are not captured by conventional clinical measures alone. These insights support stratification of individuals into biologically distinct T2D endophenotypes with differing glycaemic trajectories, cardiometabolic risk profiles, and responses to therapy, moving beyond glucose-centric classification toward a pathophysiology-informed understanding of disease heterogeneity.

In our recent work, we analysed population-based data to examine the contribution of genetic susceptibility, alongside established clinical risk factors, improving early identification of individuals at risk of T2D. Integrative models incorporating clinical features and T2D-associated genetic variants enabled more refined stratification of endocrine risk, particularly in younger individuals, for whom early intervention may yield the greatest long-term benefit. These endocrine risk patterns were consistent across independent population-based cohorts, supporting their generalisability.

By embedding endocrine-relevant signatures within network-based models derived from population and molecular data, this systems-level approach provides a foundation for patient-specific simulations of disease trajectories and treatment response. Such models offer a conceptual basis for the future development of digital representations of endocrine disease progression, enabling exploration of how variation in insulin sensitivity, β-cell reserve, or inflammatory burden may shape disease evolution over time. Rather than replacing clinical judgement, these frameworks aim to support physiology-informed risk stratification and clinical decision-making.

EP814 - ECE_3766 - Semaglutide therapy in a woman with polycystic ovary syndrome and type 1 diabetes: a clinical case

Andriana Vereshchynska and Alina Urbanovych
State non-profit enterprise " Danylo Halytsky Lviv National Medical University", Lviv, Ukraine

Background: The prevalence of polycystic ovary syndrome (PCOS) among women with type 1 diabetes mellitus (T1DM) ranges from 24% to 40% regardless of body mass index, while obesity increases this risk nearly fourfold. The coexistence of T1DM, obesity and PCOS represents a complex clinical phenotype associated with a high metabolic and reproductive risk.

The pathophysiology of PCOS in T1DM is thought to be related to long-term exposure to high doses of exogenous insulin leading to systemic hyperinsulinaemia, as well as to chronic hyperglycaemia-induced impairment of peripheral insulin sensitivity. These mechanisms contribute to hyperandrogenism, disordered folliculogenesis and chronic anovulation.

In this context, glucagon-like peptide-1 receptor agonists (GLP-1), particularly semaglutide, represent a promising therapeutic strategy due to their effects on body weight reduction, insulin sensitivity improvement and potential reproductive benefits. However, clinical data in women with combined PCOS and T1DM remain scarce.

Aim: To evaluate the metabolic and reproductive effects of semaglutide in a woman with PCOS and type 1 diabetes.

Case Presentation: A 30-year-old woman with T1DM for 14 years, treated with basal–bolus insulin therapy, presented with obesity, oligomenorrhoea and hirsutism. Body mass index was 34.1 kg/m^2. Menstrual cycles occurred up to three times per year. Ultrasound examination revealed polycystic ovarian morphology.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Hormonal assessment showed elevated AMH (9.4 ng/mL), total testosterone (2.14 ng/mL) and LH/FSH ratio (3.2). Metabolic evaluation demonstrated poor glycaemic control (HbA1c 10.7%, TIR 22%), hypertriglyceridaemia (2.01 mmol/L) and elevated LDL-cholesterol (3.39 mmol/L).

After insulin therapy optimisation, GLP-1 RA treatment was initiated with liraglutide titrated to 3.0 mg daily for 12 weeks, followed by a switch to semaglutide with gradual titration to 1.0 mg once weekly for 18 weeks.

Results: After 30 weeks of treatment: body weight decreased by 15 kg (13% from baseline); total daily insulin requirement decreased by 21%; glycaemic control improved (HbA1c 7.1%, TIR 76%); triglyceridaemia (1.44 mmol/L) and LDL-cholesterol (2.13 mmol/L)$ menstrual frequency increased to one cycle every 45 days; clinical signs of hyperandrogenism diminished; AMH decreased to 6.01 ng/mL; both GLP-1 receptor agonists were well tolerated, with only mild and transient gastrointestinal adverse events.

Discussion and Conclusions: This clinical case demonstrates that semaglutide therapy in a woman with PCOS and type 1 diabetes was associated with significant improvements in metabolic control, body weight, insulin requirements and reproductive parameters. These findings support the potential role of GLP-1 receptor agonists as a pathogenetically oriented and personalised therapeutic option in this complex patient population.

Abstract citation ID: lvag096.1155

EP815 - ECE_1444 - The deceptive calm of normoglycaemia: fatal euglycaemic diabetic ketoacidosis in a case of septic cholangitis

Thaalitha Naidu Suranthiran Naidu[1], Anis Syakirah Azizol Rahman[1] and Wan Daizyreena Wan Jaafar[1,2]
[1]*Medical Department, Hospital Kemaman, Terengganu, Malaysia;* [2]*Radiology Department, Hospital Kemaman, Terengganu, Malaysia*

Euglycaemic diabetic ketoacidosis (EDKA) defined by profound ketoacidosis in the absence of marked hyperglycaemia, is an uncommon but potentially fatal metabolic emergency. It poses a diagnostic challenge and is often precipitated by infection, medications, or pregnancy.

We encountered a 67-year-old Malay woman with longstanding type 2 diabetes mellitus complicated by prior Ray's amputation of the right third to fifth toes, hypertension, bronchial asthma, and dyslipidaemia, who presented to our district hospital with a two-day history of diffuse abdominal pain and anorexia following ingestion of restaurant food. Her symptoms were accompanied by recurrent emesis and watery diarrhoea, resulting in omission of medications, including metformin, DPP-4 inhibitor, subcutaneous insulin, aspirin, statin, and antihypertensives. On admission, she appeared lethargic and septic, with hypotension (100/50 mmHg), tachycardia (97 bpm), and normothermia (36.8 °C). Capillary glucose was 4.4 mmol/L. Examination demonstrated preserved peripheral perfusion, reduced bibasal air entry, and absence of abdominal guarding or peripheral oedema.

Laboratory evaluation revealed severe high–anion-gap metabolic acidosis (pH 7.09, bicarbonate 9.8 mmol/L) with elevated serum ketones (5 mmol/L) and lactate (8.4 mmol/L). Additional abnormalities included hypalbuminaemia (32 g/L), acute kidney injury (creatinine 641 µmol/L, urea 17.2 mmol/L), anaemia (Hb 8.3 g/dL), leukocytosis (12×10^9/L), markedly elevated serum amylase (1701 U/L), with preserved hepatic function. C-reactive protein rose from 14.27 mg/L to 112.01 mg/L within 48 hours; HbA1c was 8.6%. Chest radiography showed cardiomegaly with blunted costophrenic angles, and computed tomography illustrated dilated extrahepatic biliary ducts consistent with acute cholangitis, concurrent pulmonary infiltrates but intact pancreatic parenchyma.

She was electively intubated for impending haemodynamic collapse and severe metabolic derangement. Management encompassed aggressive intravenous fluid resuscitation, vasopressor support, continuous insulin infusion with electrolyte correction, broad-spectrum antibiotics (ceftriaxone and metronidazole), and sustained low-efficiency dialysis for anuric renal failure. Blood cultures isolated *Cronobacter* species susceptible to ampicillin–sulbactam and gentamicin, prompting targeted antimicrobial therapy. Her ICU course was complicated by myocardial injury, evidenced by anterolateral ST-segment depressions and markedly elevated troponin (9.8 ng/mL). Despite transient stabilisation and extubation, she deteriorated with refractory septic shock culminating in pulseless electrical activity. Resuscitative efforts were unsuccessful, and endotracheal cultures subsequently isolated multidrug-resistant Acinetobacter baumannii.

This case underscores the imperative for heightened clinical vigilance for EDKA in diabetic patients presenting with severe infection and metabolic acidosis, even with normoglycaemia. Prompt recognition and aggressive management are critical, yet outcomes remain poor in fulminant sepsis complicated by multidrug-resistant pathogens.

EP816 - ECE_2033 - The clinical value of routine C-peptide measurement in diabetes diagnosis and management: a two-case series

Teona Kandinashvili[1,2]
[1]*National Center of Surgery, New Life Clinic, Tbilisi, Georgia;* [2]*New Life Clinic, Ambulatory, Tbilisi, Georgia*

Case 1**Background:** Accurate classification of diabetes type at diagnosis is crucial for appropriate management. Clinical presentation alone may be misleading, particularly in young patients with weight loss and ketosis. C-peptide measurement can provide valuable information regarding endogenous insulin secretion and guide therapeutic decisions.

Case Presentation: A 33-year-old man with no prior chronic illnesses presented with unintentional weight loss of 10 kg over two weeks, polydipsia, and polyuria. His body mass index was 19.5 kg/m^2. Laboratory evaluation revealed fasting plasma glucose of 309 mg/dL, HbA1c of 11.6%, and urinary ketones of 5 mmol/L. Given the clinical picture suggestive of type 1 diabetes, further evaluation was performed to determine diabetes type.

Results: Fasting C-peptide level was 2.49 ng/mL (reference range 0.73-4.37), indicating preserved endogenous insulin secretion. Based on this finding, insulin therapy was deferred, and treatment

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

with oral hypoglycemic agents (DPP-4 inhibitor combined with metformin), along with dietary modification and increased physical activity, was initiated.

Outcome: At a 2-week follow-up visit, the patient demonstrated significant improvement in glycemic control, with fasting glucose ranging from 90-125 mg/dL and 2-hour postprandial glucose between 145-185 mg/dL. Weight loss had stabilized, and the patient reported complete resolution of symptoms.

Conclusions: This case highlights the importance of C-peptide measurement in the initial evaluation of patients with newly diagnosed diabetes. Routine assessment of C-peptide may prevent misclassification of diabetes type and allow for individualized, effective treatment strategies.

Case 2

Case Presentation: A 49-year-old woman with a 20-year history of type 1 diabetes, hypertension, and obesity (BMI 39 kg/m^2) presented with nausea, vomiting, headache, dry mouth, and polyuria. Despite adherence to insulin therapy and diet, her glycemia fluctuated between 200-500 mg/dL, with progressive weight gain and uncontrolled blood pressure. Laboratory evaluation revealed metabolic acidosis, glucosuria, and ketonuria. Fasting C-peptide was 1.79 ng/mL (normal range 1.1-4.4), indicating preserved endogenous insulin secretion.

Management and Outcomes: The patient received intravenous fluid therapy and insulin adjustment, achieving stabilization of metabolic parameters. Subsequent outpatient management included a switch to oral therapy with metformin, DPP-4, and SGLT-2 inhibitors. Within 2 weeks, glycemic control improved (fasting glucose <130 mg/dL, postprandial <180 mg/dL), blood pressure normalized, and weight decreased by 10 kg.

Conclusions: This case illustrates that routine C-peptide measurement in long-standing type 1 diabetes can inform therapeutic decisions and support transition to combination oral therapy in patients with residual insulin secretion.

EP819 - ECE_1783 - The role of digital literacy in the prevention and management of adolescent obesity: a nursing perspective

Despoina Rizikou, Afroditi Tsalkitzi, Anastasia Ntikoudi and Eugenia Vlachou
Nursing, University of West Attica, Athens, Greece

Introduction: Adolescent obesity, recognized as a chronic disease, affected over 340 million individuals aged 5-19 globally in 2022 and is linked to persistent obesity in adulthood and early onset of type 2 diabetes. Meanwhile, over 90% of adolescents regularly use digital platforms for health information. In this evolving digital environment, nurses play a central role in supporting adolescents through digital tools and behavior change strategies. However, the effectiveness of such interventions is influenced by the level of digital literacy—the ability to access, evaluate, understand, and apply digital health information effectively, ethically, and safely, making it essential for equitable and effective nursing care.

Purpose: This study aims to explore the impact of digital literacy on the prevention and management of adolescent obesity and to emphasize the evolving role of nurses in assessing and strengthening digital competencies in young populations.

Method: A scoping review of 15 studies was conducted using PubMed, Cochrane Library and Scopus. Keywords such as digital "literacy", "adolescent obesity", "nursing interventions", "health technology" were used to identify studies published between 2019 and 2025.

Results: Recent evidence indicates that adolescents with limited digital literacy are more vulnerable to misinformation and disengagement from digital health tools and poor self-management, particularly in low and middle-income countries, where digital inequalities are more pronounced. Although the American Diabetes Association Standards of Care (2026) recommend the use of digital technologies in pediatric populations, they lack structured guidance on digital literacy. Nurses are well positioned to bridge this gap, provided they are digitally competent themselves, through validated tools such as the eHealth Literacy Scale (eHEALS) and the Digital Health Literacy Instrument (DHLI), which support assessment and education. Studies also highlight that parental digital literacy influences adolescents' ability to safely engage with online health content. Family-based digital literacy education improves outcomes in obesity prevention, particularly when guided by trained nurses. Ethical aspects such as privacy, consent, and online safety must also be considered.

Conclusions: Digital literacy is essential for effective digital health interventions in adolescent obesity care. The contribution of nurses is vital, as they play a key role in guiding, educating, and supporting adolescents and their families within the digital health landscape. Building on this role, nurses should integrate digital literacy assessment and education into everyday clinical and community practice. Future nursing frameworks should ensure that digital tools are accessible, understandable, and meaningful, with emphasis on training, valid assessment, and health equity.

EP821 - ECE_2156 - Citrate–fluoride tubes preserve glucose concentrations under routine conditions and improve diagnostic accuracy in two-step gestational diabetes screening and diagnosis

Bernardino González de la Presa[1], Alex Barragán[2], Sandra Oms[3], Eva Fernandez[3], Susana Santamaria[1], Akemys Watts[1], Emilio Ortega[4], Irene Vinagre[4], Federico Migliorelli[5] and Gregori Casals[6]
[1]Maternity Core Laboratory, Biomedical Diagnostic Center, Hospital Clínic of Barcelona, Barcelona, Spain; [2]Department of Biochemistry and Molecular Genetics, Hospital Clínic of Barcelona, FRCB-IDIBAPS, Barcelona, Spain; [3]Phlebotomy Center, Biomedical Diagnostic Center, Hospital Clinic of Barcelona, Barcelona, Spain; [4]Endocrinology and Nutrition Department, Hospital Clinic Barcelona, Barcelona, Spain; [5]Department of Maternal-Fetal Medicine, Hospital Clinic of Barcelona, Barcelona, Spain; [6]Department of Biochemistry and Molecular Genetics, CDB, Hospital Clínic de Barcelona, FCRB-IDIBAPS, Barcelona, Spain

Introduction: The diagnostic protocol for gestational diabetes mellitus (GDM) used in our laboratory is based on the two-step approach (O'Sullivan screening test and diagnostic oral glucose

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

tolerance test [OGTT]). For glucose measurement, the use of plasma obtained in the reference fluoride–EDTA tubes kept in ice–water slurry is recommended, as this procedure stabilizes glucose concentrations after sample collection and prevents glycolysis during the preanalytical phase. However, due to the complexity of handling this tube in routine, serum is commonly used instead. More recently, collection tubes containing fast-acting glycolysis inhibitors, such as citrate buffer, have become available as an alternative to the reference fluoride-EDTA tubes and are easier to implement in routine practice. Nevertheless, the use of these tubes is not yet widespread in routine, which may significantly influence the interpretation of test results.

Materials and Methods: The aim of this prospective study was to compare glucose measurements and their subsequent clinical impact across three sample types: serum (routine clinical practice), citrate-fluoride (S-Monovetter, GlucoEXACT), and fluoride–EDTA tubes processed in ice–water slurry (reference procedure). The study included 124 women undergoing the O'Sullivan screening test and 80 women undergoing a diagnostic OGTT. Diagnostic criteria followed American College of Obstreticians and Gynecologists (ACOG) recommendations. Glucose concentrations were measured using the Gluc Dimension method (Siemens).

Results: In both groups (O'Sullivan and OGTT), serum samples systematically showed lower glucose concentrations than samples collected in either glycolysis-inhibiting tubes (serum 129 ± 33 mg/dL, citrate-fluoride 134 ± 34 mg/dL, fluoride-EDTA: 136 ± 34 mg/dL; $P < .001$). Accordingly, for the O'Sullivan test, the proportion of positive results was significantly lower in serum samples (33.3%) compared with fluoride–EDTA (41.5%) and citrate-fluoride tubes (40.7%). A similar pattern was observed for the OGTT, with a prevalence of positive results of 24.7% in serum, compared with 45.5% in fluoride–EDTA and 42.1% in citrate-fluoride samples. In both the O'Sullivan test and the OGTT, differences in the proportion of positive results were significant between serum and fluoride–EDTA ($P < .01$), but not between citrate–fluoride and fluoride–EDTA. No false-negative results were observed with serum or citrate–fluoride samples.

Discussion: Citrate-fluoride tubes handled under the same simple preanalytical conditions as routine serum samples (room temperature, without immediate cooling or centrifugation) preserve glucose concentrations comparable to those obtained using rigorously processed reference fluoride–EDTA tubes and substantially reduce the risk of glucose underestimation associated with serum samples, thereby minimizing diagnostic misclassification in two-step GDM screening and diagnosis.

EP822 - ECE_1168 - Continuous Glucose Monitoring (CGM) technologies and Reactive Hypoglycemia (RH) management: a review of emerging clinical evidence

Pendar Farahani
NFMPC—Endocrinology Clinic, Milton, Canada

Background: Continuous Glucose Monitoring (CGM) has become a cornerstone of diabetes management, supported by robust randomized clinical trials (RCTs) and incorporated into standard care guidelines. Recently, CGM has been explored off-label for the management of Reactive Hypoglycemia (RH), a condition characterized by postprandial hypoglycemia in individuals without diabetes.

Objective: To evaluate the current clinical evidence from RCTs and observational studies regarding the use of CGM in RH management across diverse etiologies.

Methods: A systematic literature search was conducted using PubMed and Google Scholar, employing combinations of MeSH terms related to CGM, RH, postprandial hypoglycemia, and rare endocrine disorders. Studies were categorized based on RH etiology.

Results: Over 95% of published studies focused on patients with obesity or those who had undergone bariatric surgery, with or without diabetes. A limited number of cohort studies, case series, and case reports addressed CGM use in RH among patients without obesity or diabetes. These included individuals with chronic kidney disease, inborn errors of metabolism, autoimmune syndromes, cystic fibrosis, and paraneoplastic syndromes. Despite anecdotal benefits, the evidence base remains fragmented and largely observational.

Conclusions: There is insufficient high-quality clinical evidence to support CGM as a validated tool for RH management. CGM technologies are not currently approved by regulatory bodies such as the FDA or Health Canada for this indication, nor are they reimbursed by insurance programs. Future research should prioritize well-designed RCTs and longitudinal studies, particularly in rare endocrine conditions, to establish CGM's role in RH care—potentially as an "orphan indication" for "orphan diseases."

Abstract citation ID: lvag096.1160

EP823 - ECE_1873 - Current literature on the use of Probiotic and prebiotic with Glucagon like peptide- 1 receptor agonist therapy in patients with Type 2 diabetes

Thaw Htet[1,2] and Veronica Preda[3,4]
[1]*Endocrine department, Macquarie University Hospital, Sydney, Australia;* [2]*Macquarie University, Sydney, Australia;* [3]*Faculty of Medicine Health and Health Sciences, Macquarie University, Sydney, Australia;* [4]*Endocrine Department, Macquarie Hospital, Sydney, Australia*

Glucagon like peptide receptor-1 agonists(GLP-1 RAs) are commonly used in type 2 diabetes mellitus(T2DM). Gut microbiomes play an important role in human physiology and dysbiosis is associated with multiple diseases. Certain changes in the composition of gut microbiomes such *as Lactobacillus* and *Bacteroidetes* have been observed in T2DM. Gut microbiome can influence GLP-1 production via their metabolites such as short chain fatty acids(SCFA). Prebiotics and probiotics have positive influence on the gut microbiome. Prebiotics such as oligofructose and flavonoids were shown to have positive effect on GLP-1 production and glycaemic control. Probiotics such as *Lactobacillus* and *bifidobacterium* was shown to improve insulin and GLP-1 secretion. Hence, we have conducted a literature review to explore the use of probiotics and prebiotics in patients with T2DM on GLP-1 RAs.

The search strategy was based on PICOS Framework and searches were done via SCOPUS, EMBASE, Cochrane, EBSCOhost Medline and CINAHL databases from inception to

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

December 2025. Most studies exploring the use of probiotics and prebiotics in T2DM excluded GLP-1 RAs and insulin use. Only 4 studies included GLP-1 RA use. Probiotic supplementation(*bifidobacterium longum)* with dulaglutide for 12 weeks led to improvement in HbA1c, fasting plasma glucose level (FPG), inflammatory markers, blood pressure and lipid profile. Probiotic agent(*lactobacillus acidophilus, lactobacillus plantarum, bifibacterium lactis and saccharomyces boulardii*) with diabetes therapies including GLP-1 RA for 6 months showed improvement in HbA1c, FPG and total cholesterol levels compared with placebo group. However, Probiotic therapy(*lactobacillus speicies*) together with diabetes medications including GLP-1 RAs for 12 weeks showed no significant improvement in glycemic control, BMI, inflammatory markers and lipid levels. Synbiotic therapy consisting of probiotic(*lactobacillus caesi* and *bifidobacterium breve)* and prebiotic(galacto-oligosaccharide) for 24 weeks showed no significant improvement in inflammatory markers.

Our review identified that the use of probiotic and prebiotic with GLP-1 RAs has not been adequately studied despite the emerging role of gut microbiomes and GLP-1 RAs. Current evidence showed inconsistent benefits. Recent evidence showed the response to GLP-1 RAs can vary based on the diversities of the gut microbiome, and the use of probiotics and prebiotics may reduce gastrointestinal side effects of GLP-1RAs. Evolving evidence showed probiotics can be bioengineered and used as a part of targeted therapies in certain malignancies and gastrointestinal disorders .With the future direction of applying personalised and precision medicine in T2DM, further dedicated studies of the use of probiotic and prebiotics with GLP-1 RAs are needed.

Abstract citation ID: lvag096.1161

EP824 - ECE_1397 - Phased management of type 2 diabetes, obesity, and stress urinary incontinence using GLP-1 receptor agonist therapy and artificial urinary sphincter: a case report

Ivana Mickovski[1,2], Daniela Buklioska Ilievska[1,3] and Radmila Milosheska[3]
[1]*Faculty of Medical Sciences, Goce Delcev University, Stip, North Macedonia;* [2]*PZU Vasileva Kardio, Skopje, North Macedonia;* [3]*General City Hospital 8th September, Skopje, North Macedonia*

Background: Type 2 diabetes mellitus (T2DM) and obesity are frequently associated with stress urinary incontinence through metabolic, neuropathic, and mechanical mechanisms. Optimizing glycemic control and reducing body weight may improve urinary symptoms; however, severe cases often require surgical intervention.

Case Description: We report the case of a 43-year-old woman with a 10-year history of poorly controlled T2DM and obesity (BMI 39.2 kg/m^2), presenting with severe stress urinary incontinence requiring continuous diaper use. Baseline laboratory evaluation showed HbA1c 9.9%, fasting plasma glucose 200 mg/dL, dyslipidemia, and microalbuminuria. Conservative urological measures had failed.

Management: A phased treatment strategy was adopted, prioritizing metabolic optimization. The patient was treated with semaglutide 1 mg weekly, basal–bolus insulin therapy, metformin, and structured lifestyle modification. After six months, HbA1c improved to 6.7% and BMI decreased to 30.8 kg/m^2 (14% weight reduction). Despite metabolic improvement, urinary incontinence persisted. The patient subsequently underwent artificial urinary sphincter implantation.

Results: Postoperative recovery was uneventful. At three months follow-up, the patient reported complete continence with discontinuation of diaper use and significant improvement in quality of life. Glycemic control and weight reduction were maintained.

Conclusions: This case demonstrates that a stepwise approach—addressing glycemic dysregulation and obesity before surgical correction—can optimize outcomes in patients with T2DM-associated stress urinary incontinence. Combining GLP-1 receptor agonist therapy with timely surgical intervention offers effective metabolic control and durable functional recovery.

Keywords type 2 diabetes mellitus, obesity, stress urinary incontinence, GLP 1receptor agonist, metabolic control, weight loss, artificial urinary sphincter

Abstract citation ID: lvag096.1162

EP826 - ECE_3138 - Clinical management and follow-up after emergency attendance for acute glucose-related events in adults with type 1 diabetes

Víctor Siles-Guerrero, Aida Elhadri-Egea, Rosa Natalia García Pérez and Araceli Munoz-Garach
Hospital Universitario Virgen De Las Nieves, Granada, Spain

Introduction: Emergency attendance for acute glucose-related events in type 1 diabetes mellitus (T1DM) identifies a subgroup of patients with increased clinical complexity and potential gaps in ongoing diabetes management. These episodes often reflect underlying vulnerabilities that are not fully captured during routine outpatient follow-up and may be associated with recurrent emergency service utilisation. Understanding the clinical profile and outcomes of these patients using real-world data may help optimise post-event care pathways.

Objective: To describe clinical management characteristics and short- to mid-term outcomes following emergency attendance for acute glucose-related events in adults with T1DM.

Methods: A retrospective, observational, descriptive study was conducted including 66 adults with T1DM attended by prehospital emergency services between 2018 and 2022 due to acute glucose-related events. Data collected included demographic characteristics, prior diabetes-related emergency events, symptom awareness status, nocturnal occurrence of the index event, and need for subsequent emergency re-attendance during follow-up. Results are presented using descriptive statistics.

Results: The median age of the cohort was 42.5 years, with a predominance of male patients (65.2%). More than half of the cohort (54.5%) had a documented history of previous emergency attendance for similar acute glucose-related events prior to the index episode. Impaired symptom awareness was present in 43.9% of patients, suggesting reduced ability to recognise early warning symptoms. Nocturnal occurrence of the index event was reported in 53.0%, highlighting the relevance of events occurring during periods of reduced monitoring and delayed intervention. During follow-up, 22.7% of patients required at least one new emergency intervention for a recurrent acute glucose-related event. The clustering of prior emergency attendance, impaired

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

awareness, and nocturnal occurrence suggests persistence of vulnerability beyond the index emergency episode.

Conclusions: Among 66 adults with T1DM requiring emergency care for acute glucose-related events, a substantial proportion demonstrated recurrent emergency utilisation and clinical features suggestive of ongoing vulnerability. Emergency attendance may therefore represent a critical opportunity to identify high-risk individuals and to trigger structured reassessment and targeted follow-up within diabetes care pathways, with the aim of reducing recurrent emergency events and improving long-term management.

EP830 - ECE_3318 - Association between body composition parameters and ultrasonographic abdominal fat measurements and the development of gestational diabetes mellitus

Ana Segarra Balao, María de Damas Medina and Carmen María López Pérez
Endocrinology and Nutrition, Complejo Hospitalario de Jaén, Jaén, Spain

Objectives: To investigate the relationship between body composition parameters—including anthropometric measurements, muscle ultrasound, and bioelectrical impedance analysis—and the risk of developing gestational diabetes mellitus (GDM). A secondary objective was to determine the prevalence of metabolic syndrome in the studied cohort.

Materials and Methods: This is a prospective cohort study. All pregnant women with at least one risk factor for GDM who underwent an O'Sullivan test during the first trimester of pregnancy were included. Risk factors included maternal age >35 years, body mass index (BMI) >30 kg/m^2, previous GDM or adverse obstetric outcomes, first-degree family history of diabetes mellitus, or belonging to an ethnic group with a high prevalence of diabetes.

Demographic and clinical data, along with ultrasound and bioelectrical impedance parameters, were collected to assess body composition. Statistical analysis was performed using SPSS version 25®.

Results: A total of 30 women were included. Mean age was 33.4 ± 5.4 years, mean weight 74.1 ± 16.1 kg, and mean BMI 25.0 ± 5.6 kg/m^2. Mean waist circumference was 90.7 ± 11.9 cm. Two participants had a previous history of GDM, and none had a prior diagnosis of prediabetes. A family history of diabetes was present in 70% of cases. Two women were active smokers, while ten were former smokers who had quit during pregnancy. Polycystic ovary syndrome and hypertension were present in 10% of participants each; none had dyslipidemia or metabolic-associated fatty liver disease.

The mean O'Sullivan test value was 125.2 ± 30.5 mg/dL, with 10 participants showing positive results (>140 mg/dL). Mean handgrip strength was 25.7 ± 5.0 kg.

Muscle ultrasound showed a mean cross-sectional area of 4.58 ± 1.78 cm^2 and subcutaneous fat thickness of 1.77 ± 0.44 cm. Abdominal ultrasound revealed a mean total abdominal fat thickness of 1.96 ± 0.67 cm, with superficial and preperitoneal fat measuring 1.05 ± 0.47 cm and 0.99 ± 0.80 cm, respectively.

Bioelectrical impedance analysis demonstrated a mean fat-free mass of 45.8 ± 6.1 kg, fat mass of 26.4 ± 10.2 kg, skeletal muscle mass index of 8.05 ± 1.17 kg/m^2, hydration percentage of 73.3 ± 1.6%, and phase angle of 5.5 ± 0.6°.

Conclusions: These preliminary results from an ongoing study provide a descriptive analysis of anthropometric and body composition parameters in first-trimester pregnant women, most of whom presented no associated comorbidities.

EP832 - ECE_3865 - MASLD in diabetes mellitus: non-invasive assessment and sex-related differences

Liana Jashi[1], Tamar Shervashidze[2], Tamar Peshkova[3], Meri Beridze[3], Ketevan Dundua[4], Eter Margalitadze[3] and Maia Kobuladze[1]
[1]*Solomedi, Endocrinology, Avicenna—Batumi Medical University, Batumi, Georgia;* [2]*Avicenna—Batumi Medical University, T'bilisi, Georgia;* [3]*Batumi Shota Rustaveli State University, Batumi, Georgia;* [4]*David Agmashenebeli University of Georgia, T'bilisi, Georgia*

Background: Metabolically–dysfunction–associated steatosis liver disease (MASLD) is one of the most common metabolic comorbidities in patients with diabetes mellitus and is associated with progressive liver injury and increased cardiovascular risk. Its prevalence among patients with diabetes has reached alarming levels worldwide.

Objective: To assess the prevalence of MASLD, fibrosis risk, and sex-related differences in patients with diabetes mellitus using non-invasive diagnostic tools.

Methods: This study included 60 patients with diabetes mellitus aged 45-60 years, of whom 37 were women (61.7%), and 23 were men (38.3%). Body mass index (BMI) ranged from 26 to 36 kg/m^2. All patients were treated with metformin. Liver steatosis was assessed by abdominal ultrasound. Fibrosis risk was estimated using the FIB-4 index based on age, alanine aminotransferase (ALT), and platelet count. Data were analyzed according to sex.

Results: Hepatic steatosis was detected by ultrasound in 68.3% of patients, including mild steatosis in 41.5% and moderate steatosis in 26.8%. According to the FIB-4 index, 71.7% of patients were classified as having low fibrosis risk, 23.3% as intermediate risk, and 5.0% as high risk.

The prevalence of MASLD was 64.9% in women and 73.9% in men. Intermediate-to-high fibrosis risk was more frequent in men compared with women (34.8% vs 24.3%).

Conclusions: MASLD is highly prevalent among patients with diabetes mellitus. Non-invasive screening tools such as ultrasound and the FIB-4 index are effective for early identification of liver involvement and fibrosis risk. Consideration of sex-related differences may improve risk stratification and individualized management strategies.

EP834 - ECE_2519 - Fat loss vs muscle loss: bioimpedance trajectories in women and men during dietary weight management

Roxana Pui[1], Stefania-Alexandra Bunceanu[1] and Stoian Dana[2]
[1]*Department of Doctoral Studies, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania;* [2]*Discipline of Endocrinology,*

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Second Department of Internal Medicine, Universitatea de Medicină și Farmacie Victor Babeș, University of Medicine and Pharmacy "Victor Babes", Timișoara, Romania

Introduction: In clinical practice, dietary weight-loss outcomes are often assessed by changes in body weight and BMI, although clinically meaningful improvement depends on preferential fat loss with preservation of lean mass. Responses in routine care are heterogeneous, with marked early changes, plateaus, and occasional rebound. Objective body composition assessment may better characterize these patterns and support individualized dietary optimization and outcome evaluation. This study aimed to describe trajectories of weight and body composition during a structured hypocaloric program, focusing on sex-specific patterns and potential lean mass vulnerability, in patients managed with nutritional intervention only.

Methods: We conducted a retrospective observational study of adults with BMI $\geq$25 kg/m^2 managed between 2010 and 2020 in a specialized endocrinology and nutrition center in Timișoara, Romania. Patients received individualized hypocaloric nutritional plan with a staged energy deficit of ~1000 kcal/day below estimated energy requirements for 4-6 weeks, followed by ~750-500 kcal/day below requirements, with monthly follow-up for up to 6 months. Body composition was assessed serially using bioimpedance (Tanita BC-418), including body weight, BMI, trunk fat (%), total body fat (%), and total muscle mass (% and kg). Monthly trajectories were summarized separately for women and men.

Results: Weight and BMI decreased predominantly during early follow-up and then tended to stabilize. Trunk fat percentage showed an overall downward trend, while muscle mass fluctuated during caloric restriction, underscoring the value of monitoring beyond weight alone. Sex-stratified trajectories suggested different dynamics: men tended to show larger absolute reductions in weight and adiposity, whereas women showed patterns consistent with greater relative vulnerability to lean mass loss. In participants with paired baseline–final bioimpedance assessments, total body fat percentage decreased significantly in both sexes across all age decades ($P < .001$), indicating consistent adiposity improvement among those completing follow-up. The relationship between fat mass loss and muscle mass loss showed a variable positive trend, highlighting inter-individual heterogeneity and supporting a personalized approach.

Conclusions: Serial bioimpedance monitoring captured heterogeneous and sex-specific body composition trajectories during hypocaloric intervention. While adiposity improved significantly in participants who completed follow-up, signals of lean mass vulnerability—particularly in women—support sex-aware strategies emphasizing adequate protein intake, resistance training, and close body composition monitoring to minimize unintended muscle loss during dietary weight management.

EP835 - ECE_3442 - Allergy to dexamethasone: a rare pitfall in endocrine practice

Rihab Khochtali, Imen Halloul, Taieb Ach, Wiem Saafi, Hamza Elfekih, Ghada Saad and Yosra Hasni
Department of Endocrinology, Farhat Hached Hospital, Sousse, Tunisia

Background: Dexamethasone is widely used in endocrinology, particularly for diagnostic suppression tests. Hypersensitivity reactions to corticosteroids are rare, with a reported frequency ranging from 0.2% to 5%. This condition may represent both a diagnostic and therapeutic challenge.

Case Presentation: We report the case of a 55-year-old woman admitted to our department for evaluation of resistant hypertension evolving for six years, complicated with a left ventricular hypertrophy. Her medical history included type 2 diabetes treated with dual therapy, obesity (BMI: 39 kg/m^2), and documented allergies to penicillin and paracetamol.

Secondary causes of hypertension were investigated. Renal artery CT angiography excluded a renovascular cause. During the low-dose dexamethasone suppression test, the patient developed a mild acute urticarial reaction a few minutes after dexamethasone administration. The reaction persisted throughout the test, and resolved spontaneously afterward. Subsequent skin prick testing confirmed an allergy to both dexamethasone and betamethasone. As the dexamethasone suppression test was uninterpretable in this context, Cushing's syndrome was excluded using alternative screening methods: Late-night cortisol and 24-hour urinary free cortisol levels were normal.

Further evaluation of contributing factors to resistant hypertension revealed severe obstructive sleep apnea syndrome (OSAS), confirmed by polysomnography. The patient was managed with lifestyle and dietary measures, GLP-1 receptor agonist therapy (semaglutide), and continuous positive airway pressure for OSAS. After six months of follow-up, she achieved a 7% weight loss, with good blood pressure control under dual therapy and improved glycemic control on GLP-1 therapy.

Conclusions: Corticosteroid allergy is a rare but clinically significant condition that can complicate endocrine diagnostic procedures. Alternative diagnostic strategies should be considered when evaluating hypercortisolism in patients with confirmed corticosteroid hypersensitivity. Late-night salivary cortisol or repeated urinary free cortisol may represent safe alternatives for Cushing's syndrome screening in these patients.

EP838 - ECE_2208 - Cardiovascular risk factors in patients with newly diagnosed type 2 diabetes

Alla Shepelkevich[1], Diana Baalbaki[1], Alena Yurenia[2] and Yuliya Dydyshka[1]
[1]*Endocrinology, Belarusian State Medical University, Minsk, Belarus;* [2]*Minsk City Clinic Endocrinology Center, Minsk, Belarus*

Background: Type 2 diabetes (T2D) is associated with an increased risk of cardiovascular disease (CVD) and CV mortality. Additionally, multiple modifiable risk factors (obesity, dyslipidemia, hypertension) can further increase the risk of a poor outcome. Hence early identification of CVD risk factors in patients with T2D is crucial for proactive management and primary prevention.

Objectives: Assessment of cardiovascular risk factors and stratification of CVD risk in patients with newly diagnosed T2D.

Methods: A retrospective study was conducted among newly diagnosed T2D patients attending the outpatient clinic. Anthropometric measurements (BMI, WHR), biochemical

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

parameters (lipid panel, HbA1c) and past medical history were analyzed. Control group included patients matched by gender and age, without diabetes. The stratification of CVD risk was performed using SCORE2-Diabetes and SCORE2 in patients with T2D and controls respectively.

Results: 100 patients with T2D were enrolled (50F, 50M), median age 52 years [IQR 47-55]. Glycemic control was optimal with median HbA1c—7.1% [6.7-7.5]. Obesity was observed in 45% of T2D patients and 32% were overweight with BMI 30.6 [25.6-36.4] and WHR 0.95 [0.82-1.09]. Dyslipidemia was found in 61% of T2D patients with LDL—3.6 [2.97-4.1] mmol/L and triglycerides—1.76 [1.3-2.12] mmol/L that were significantly higher vs controls with LDL—2.7 [2.39-3.37] mmol/L and triglycerides—1.19 [0.93-1.49] mmol/L ($P < .5$). In addition to a higher level of HDL—1.3 [1.09-1.63] mmol/L was observed in controls vs T2D patients HDL—1.12 [0.96-1.32] mmol/L ($P < .5$). Co-occurring hypertension was present in 78% of T2D patients with systolic BP 141 [134-146] mmHg. Upon CVD risk evaluation in T2D patients—83% were at high/very high risk (41% and 42% respectively) and only 17% had moderate risk, whereas in the control group—35% had moderate risk and 65% of patients had low risk. Furthermore, none of the high and very high-risk patients had target LDL and only 23.5% of moderate risk patients were within their target LDL level.

Conclusions: Our findings show the prevalence of high/very high CVD risk (83%) and illustrate a constellation of modifiable CVD risk factors in patients with newly diagnosed T2D, which subjects them to an increased risk of major cardiovascular events. This emphasizes the significance of timely metabolic management alongside proper glucose control.

EP841 - ECE_3287 - Mortality predictors in digestive neoplasms via morphofunctional assessment

Ana Rocío Martínez Hartmann, Carlos López-Pereira, María González-Pacheco, Maria del Mar Roca-Rodriguez and Almudena Lara Barea

Endocrinology and Nutrition Department, Endocrinology and Nutrition, Puerta del Mar Hospital, Puerta del Mar Hospital, Cadiz, Spain

Introduction: Nutritional and functional status conditions the prognosis in patients with digestive cancer. Bioimpedance, muscle ultrasound, and functional tests allow for the identification of values associated with higher mortality, facilitating risk stratification and early intervention.

Objectives:

1. To determine the cut-off points for morphofunctional parameters (bioimpedance, muscle ultrasound, dynamometry, and Up and Go test) associated with mortality, differentiated by sex, in patients with digestive tumors.
2. To identify possible morphofunctional parameters that could serve as independent predictors of survival in this population.

Materials and Methods: A retrospective observational study was conducted on a series of patients with digestive cancer (biliary tract, pancreas, esophagus, stomach, colon, or rectum), evaluated using morphofunctional assessment techniques at our center (HUPM). Descriptive analyses, sex-stratified ROC curves, and survival analyses were performed.

Results: The cohort consisted of 131 patients, obtaining a median Phase Angle (PhA) of 4.6°, Body Cell Mass (BCM) of 21.4 kg, dynamometry of 20 kg, Timed Up and Go (TUG) of 6.5 seconds, and rectus femoris muscle area of 2.88 cm^2. Overall mortality was 37%.

The cut-off points associated with mortality were as follows:

Parameter	Men	Women	*P*-value
PhA	<4.6	<4.1	<.001
BCM	<23.1 kg	<19.3 kg	<.001
Rectus Femoris Area	<2.63 cm^2	<2.18 cm^2	<.001
Dynamometry	<32.5 kg	<14.3 kg	<.001
TUG	>5.6 seconds	>6 seconds	<.001

PhA was identified as an independent predictor of mortality in the Cox regression analysis (HR = 0.59; 95% CI 0.36-0.97; $P = .038$). Patients with PhA <3.8° presented a significantly lower median survival (19.5 vs 38.5 months) and reduced survival at 12 and 24 months (50.8% and 33.9% vs 79.2% and 60.7%).

Conclusions: Morphofunctional parameters allow for the identification of sex-differential cut-off points associated with mortality in digestive cancer. A PhA <3.8° is consolidated as an independent predictor of lower survival, along with dynamometry and TUG. These findings support the integration of bioimpedance, ultrasound, and functional tests into clinical practice to optimize individualized nutritional and functional intervention.

EP845 - ECE_2576 - Cardiovascular risk stratification and determination of lipoprotein a in patients with type 1 diabetes mellitus

Víctor Simón-Frapolli[1,2,3], Ángel López Montalbán[1], Ainoa Mallorquín Castillo[1], Teresa Campos Varela[1], Irene García Gómez[1] and Francisco José Tinahones Madueño[1,2,3]

[1]*Endocrinology and Nutrition, Hospital Universitario Virgen De La Victoria, Málaga, Spain;* [2]*Ibima Plataforma Bionand, Málaga, Spain;* [3]*Facultad de Medicina-UMA, Málaga, Spain*

Introduction: Elevated lipoprotein A, or Lp(a), is an independent risk factor for the development of atherosclerotic cardiovascular disease (CVD). Given its stability over time, the Spanish Society of Arteriosclerosis (SEA) suggests universal determination of Lp(a) coinciding with the first biochemical determination that includes the lipid profile, as it behaves as a modifier of cardiovascular risk (CVR) in the most widely used CVR stratifications to date. However, there is currently no consensus, as the European Atherosclerosis Society (EAS) recommends its measurement only in individuals with certain characteristics. In addition, in patients with type 1 diabetes mellitus (T1DM), the current criteria for CVR stratification are not specific, as they are usually extrapolated from studies conducted in patients with type 2 DM.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Objective: To assess CVR in patients with T1DM following the 2024 SEA Standards, as well as to study the frequency of Lp(a) determination in our clinical practice in these patients.

Materials and Methods: Descriptive observational study including 100 patients with T1DM reviewed in outpatient clinics at the Virgen de la Victoria Hospital between June 2023 and December 2024. Demographic, clinical and analytical variables were collected, and CVR stratification was performed. In addition, the analytical history of all patients was retrospectively explored to determine how many had had their Lp(a) level assessed at some point.

Results: The mean age of our sample was 43.91 ± 13.1 years and 61% of patients were women. 24% of patients were T1DM for <10 years, 25% for 10 to 20 years, and 51% for >20 years. 78% of patients were on multiple daily insulin (MDI) therapy and 22% on continuous insulin infusion systems (CIS), while 6% had >3 CVR factors and 32% had at least one CVR factor. 32% had target organ damage at the time of evaluation. 53% had a very high CVR, 25% had a high CVR and 22% had a moderate CVR. None of the patients had a low CVR, since the presence of DM by definition implies a moderate CVR. We note that the Lp(a) levels were determined in only one patient (1%) during follow-up.

Conclusions: The low determination of Lp(a) in T1DM patients may be due to the absence of an approved targeted treatment to date to reduce its levels. However, its measurement could be useful to reclassify CVR in primary prevention from moderate to high in approximately a quarter of patients (22%), and thus consider intensifying control targets for other CVR factors.

EP849 - ECE_2019 - An unusual cause of postprandial hypoglycemia: impaired gastric emptying

Pavel Cee[1], Jan Cap[1], Jiří Cyrany[2], Veronika Špačková[1] and Filip Gabalec[1]

[1]*The 4th Department of Internal Medicine, University Hospital Hradec Králové, Hradec Králové, Czech Republic;* [2]*The 2nd Department of Internal Medicine, University Hospital Hradec Králové, Hradec Králové, Czech Republic*

Introduction: Hypoglycaemia in patients not treated with insulin represents a diagnostic challenge. The most common causes include endogenous hyperinsulinism or insufficient counter-regulatory hormonal response. Disorders of gastrointestinal motility are less frequently considered. We present a case of recurrent hypoglycaemia associated with impaired gastric emptying.

Case Report: We present a 77-year-old woman with no history of major internal diseases, long-term follow-up for arterial hypertension, dyslipidaemia, and diet-controlled type 2 diabetes mellitus. Her history also included laparoscopic repair of a large hiatal hernia (upside down stomach) half a year before. She was admitted to our department for evaluation of recurrent symptomatic hypoglycaemia, which appeared approximately three weeks prior to hospitalization. Episodes typically occurred in the evening, about 3-4 hours after meals, with a frequency of once every two days, and were accompanied by sweating, tremor, and marked fatigue. The patient obtained a glucose sensor, with the lowest recorded value being 2.8 mmol/L.

A 72-hour fasting test was performed and was negative, excluding organic hyperinsulinism. Comprehensive laboratory tests, including hormonal profile and Synacthen test, revealed no pituitary dysfunction or other endocrine abnormalities. Further evaluation confirmed significant impairment of gastric emptying, which had been present for about a year and was originally detected as an incidental finding during gastroscopy and verified by 99mTc gastric emptying scintigraphy (Tougass protocol) with less than 50% evacuation of stomach after 4 hours. A prolonged oral glucose tolerance test (oGTT) demonstrated an initial increase in glycemia followed by a late decline into hypoglycaemic values. After excluding hyperinsulinism, treatment with a somatostatin analogue (lanreotide) was initiated to modulate postprandial insulin secretion. Following therapy, the frequency of hypoglycaemic episodes decreased markedly and now occurs approximately once every two weeks.

Conclusions: Rapid gastric emptying is a known cause of postprandial hypoglycaemia (dumping syndrome). Hypoglycaemia that occurs in patients with delayed gastric emptying is unusual. The pathophysiological mechanism may involve dysregulation of the enteroendocrine axis. Delayed delivery to the small intestine leads to disproportionate release of incretin hormones (particularly GLP-1 and GIP), stimulating insulin secretion and inhibiting glucagon. The result is an excessive insulin response and subsequent hypoglycaemia. Clinical improvement after lanreotide therapy supports this hypothesis, as somatostatin analogues suppress insulin and incretin secretion, thus reducing postprandial insulin hypersecretion. This case emphasises the need to consider gastrointestinal motility in the differential diagnosis of hypoglycaemia, even in patients without rapid gastric emptying.

EP850 - ECE_3354 - Evaluation of dyspnea, quality of life and lung function in Greek patients with COPD and Type 2 diabetes mellitus treated with roflumilast: a subgroup analysis of the ARGO study

Georgios Hillas[1], Christoforos Efthymiou[2], Dimitrios Zarifis[3], Maria Bertoli[4], Polyanthi Papanastasiou[4], Vasiliki Paraskeva[4], Alexandros Gkinis[4] and Paschalis Steiropoulos[5]

[1]*2nd Respiratory Medicine Department, "ATTIKON" University General Hospital, National and Kapodistrian University of Athens, Medical School, Athens, Greece;* [2]*Respiratory Medicine Department, "Papageorgiou" General Hospital of Thessaloniki, Thessaloniki, Greece;* [3]*Private Pulmonary Site, Patras, Greece;* [4]*Medical Department, ELPEN Pharmaceutical Co. Inc., Athens, Greece;* [5]*Respiratory Medicine Department, University General Hospital, Democritus University of Thrace, Medical School, Alexandroupolis, Greece*

Background: Type 2 diabetes mellitus (T2DM) is a common comorbidity in patients with chronic obstructive pulmonary disease (COPD) and is associated with increased morbidity, mortality, and disease complexity. Emerging evidence suggests that T2DM may adversely affect pulmonary mechanics, further impairing lung function. This subgroup analysis of the ARGO study evaluated the effects of roflumilast on dyspnea, health-related quality of life (HRQoL) and lung function in patients with severe COPD and concomitant T2DM in a real-world setting.

Methods: ARGO was a multicenter, non-interventional, observational study conducted in Greece (NCT05426915) that enrolled 750 patients with severe COPD. Of these, 140 patients with

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

concomitant T2DM and a mean (±SD) age of 72.7 ± 7.3 years, were included in this subgroup analysis. Patients were assessed at baseline (V_0) and after 3 (V_1), 6 (V_2) and 12 (V_3) months of treatment with roflumilast. Dyspnea was assessed using the modified Medical Research Council (mMRC) scale, HRQoL using the validated Greek version of the Clinical COPD Questionnaire (CCQ) and lung function by Forced Expiratory Volume in 1 second (FEV_1) % predicted.

Results: Among patients with T2DM, roflumilast treatment was associated with a progressive reduction in dyspnea severity, demonstrated by a shift from higher (mMRC grades 4-3) to lower (mMRC grades 2-1) over time. HRQoL, as assessed by the CCQ, improved significantly at 3, 6, and 12 months compared with baseline ($P < .001$, paired t-test), exceeding the minimal clinically important difference (MCID > 0.4). Mean CCQ scores (±SD) decreased from 3.50 ± 1.07 at baseline to 2.26 ± 0.98 at 12 months. Lung function also showed clinically meaningful improvement (MCID $FEV_1 \geq 0.1$L) at 6 and 12 months, with FEV_1% predicted increasing from 47.76 ± 13.95 at baseline to 54.51 ± 16.30 at 12 months. Similar improvements in HRQoL and lung function were observed in the overall ARGO study population, indicating consistency of treatment effects irrespective of T2DM status.

Conclusions: In this real-world subgroup analysis, treatment with roflumilast was associated with reduced dyspnea severity and clinically significant improvements in HRQoL and lung function in patients with severe COPD and concomitant T2DM. These findings are consistent with those observed in the overall ARGO study population.

EP851 - ECE_3849 - Nutritional ultrasound in the study of sarcopenia in diabetes mellitus

Maria Jiménez Aceituno, Ana de Gracia Valero, Carlos Castro Mesa and Ana Segarra Balao
Endocrinology and Nutrition, Complejo Hospitalario de Jaén, Jaén, Spain

Introduction: Diabetes is consistently associated with an increased risk of muscle mass loss and functional impairment, promoting the development of sarcopenia. In this clinical framework, nutritional ultrasound has emerged as a pivotal tool for the objective quantification of muscle architecture and adiposity.

Objectives: To evaluate muscle mass and abdominal fat distribution via nutritional ultrasound in diabetic patients, analyzing its correlation with glycemic control and comparative variances across diabetes subtypes.

Material and Methods: A prospective observational study was conducted including patients with Type 1 (T1DM), Type 2 (T2DM), LADA, and pancreatogenic diabetes. Rectus femoris ultrasound was utilized to measure cross-sectional area (CSA), circumference, and muscle axes. Additionally, abdominal ultrasound assessed preperitoneal and visceral fat layers.

Results: The study included 75 patients with a mean age of 52.84 ± 14.91 years. The sample consisted of 56.8% men and 43.2% women, with a mean 11.56 ± 3.22%. The average BMI was 27.54 ± 4.16 kg/m^2. Diagnostic distribution was: 65.3% Type 1, 17.3% LADA, 12% Type 2, and 5.3% pancreatogenic diabetes.

	DM Type 1	DM Type 2	DM LADA	DM Pancreatogenic	*P*-value
X-axis (cm)	3.76 ± 0.99	3.01 ± 0.77	3.36 ± 0.52	3.40 ± 0.73	187
Y-axis (cm)	1.57 ± 0.35	2.93 ± 5.12	1.56 ± 0.36	1.53 ± 0.47	186
Area (cm^2)	5.10 ± 2.38	3.20 ± 1.56	4.16 ± 1.33	5.16 ± 2.77	97
Preperitoneal Fat (cm)	0.59 ± 0.34	0.45 ± 0.17	0.49 ± 0.29	0.55 ± 0.23	727

A trend toward a smaller rectus femoris area was observed in patients with type 2 diabetes, with no significant differences in other ultrasound parameters across subtypes. The lack of statistical significance may be attributed to the limited sample size, particularly within certain subgroups.

Conclusions: Preliminary results suggest differences in muscle and adipose composition depending on the diabetes mellitus subtype. Expanding this cohort will be necessary to confirm these findings.

Abstract citation ID: lvag096.1173

EP852 - ECE_3334 - Pregnant women with type 1 Diabetes Mellitus on Hybrid closed-loop systems

Dimitra Pappa, Eleftheria Barmpa, Anastasia-Konstantina Sakali and Alexandra Bargiota
Department of Endocrinology and Metabolic Diseases, University Hospital of Larissa, Larissa, Greece

Background and Aims: Women with type1 Diabetes Mellitus (DM1) is important to maintain good glycemic control during pregnancy, avoiding perinatal and maternal complications. Hybrid closed-loop systems (HCLS) are widely used in diabetes management but data are restricted on using during pregnancy. Here we present two such cases of our center.

Methods: Two women with DM1 attending our outpatient clinic for 5 years, managing their diabetes with HCLS (MiniMed780), were studied during their pregnancy. CGSmetrics; time in range (TIR;63-140 mg/dl), above range (TAR;>140 mg/dl), below range (TBR;63-54 mg/dl, TBR54;<54 mg/dl) and coefficient variation (CV) were recorded on the 14th, 34th and 38th gestational week (GW), as well as gestational age at delivery (GAd), childbirth type and offspring birthweight (ofBW).

Results: WomanA; 23 years old, having diabetes for 3 years, on HCLS for 6 months, had her first pregnancy unplanned, and presented on the 14thGW with TIR = 90%, TAR = 10%, TBR = 0%, CV = 24,4%. She chose to remain on HCLS and on 34thGW had TIR = 95%, TAR = 5%, TBR = 0%, CV = 18,8%, on 38thGW TIR = 93%, TAR = 7%, TBR = 0%, CV = 21,9%.

WomanB; 29 years old, having diabetes for 17 years, on HCLS for 2 years, had an unplanned second pregnancy and presented

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

on the 14thGW with TIR = 51%, TAR = 41%, TBR = 3%, CV = 34,1%. She continued on HCLS and on 34thGW had: TIR = 71%, TAR = 28%, TBR = 1%, CV = 26,1%, on 38thGW TIR = 79%, TAR = 19%, TBR = 2%, CV = 32,2%.

Both women had caesarean section on 39th GAd, delivered healthy female babies 3600gr and 3830gr ofBW respectively, and had no maternal or perinatal complications.

Conclusions: HCLS seem to improve CGSmetrics in women with DM1 during pregnancy, improving their glycemic control, minimizing their stress for hypoglycemia.

EP853 - ECE_2527 - The contradictory side of bariatric surgery: late dumping syndrome manifesting as hypoglycemia unawareness and bone fractures

Dominyka Suminskaite[1] and Diana Simoniene[2,3]
[1]Faculty of Medicine, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Institute of Endocrinology, Lithuanian University of Health Sciences, Kaunas, Lithuania; [3]Endocrinology, University of Lithuanian Health Sciences, Kaunas, Lithuania

Introduction: Late dumping syndrome is a recognized long-term complication of Roux-en-Y gastric bypass, characterized by postprandial hyperinsulinemic hypoglycemia due to rapid nutrient delivery to the small intestine and exaggerated incretin-mediated insulin secretion. Clinical manifestations range from adrenergic symptoms to neuroglycopenia, including syncope and impaired hypoglycemia awareness, affecting quality of life. Bariatric surgery is associated with increased bone turnover, reduced bone mass, and an elevated fracture risk.

Case Presentation: A 37-year-old woman with a history of morbid obesity underwent laparoscopic Roux-en-Y gastric bypass. Her preoperative body mass index (BMI) was 37.6 kg/m^2 (106 kg, height 168 cm), which decreased to 25.2 kg/m^2 (71 kg) postoperatively.

Approximately five years after surgery, she developed recurrent postprandial episodes of weakness, tremor, hunger, and progressive neuroglycopenic symptoms, including evening syncope, often triggered by meals or mild physical activity. Capillary glucose monitoring documented hypoglycemia as low as 2.4 mmol/L, while continuous glucose monitoring revealed nadirs of 1.9 mmol/L during symptomatic episodes. Fasting plasma glucose remained normal (5.2 mmol/L).

A mixed-meal tolerance test demonstrated postprandial hypoglycemia with elevated insulin and C-peptide levels, confirming hyperinsulinemic hypoglycemia and supporting the diagnosis of late dumping syndrome. Initial management consisted of dietary modification. Due to persistent symptoms, pharmacological therapy with diazoxide provided only transient improvement. Ongoing severe hypoglycemia and the development of hypoglycemia unawareness (sensory threshold 1.9 mmol/L) prompted escalation to acarbose.

Four years postoperatively, the patient sustained a non-traumatic cervical fracture, followed by a lumbar vertebral fracture associated with elevated CTX levels. Endocrine causes, including Cushing's syndrome and parathyroid dysfunction, were excluded. To address skeletal fragility, calcium citrate and high-dose vitamin D supplementation were initiated, followed by off-label intravenous zoledronate therapy.

Conclusions: Bariatric surgery remains an effective strategy for reducing obesity-related morbidity; however, clinicians must remain vigilant for paradoxical long-term complications, including dumping syndrome–related hypoglycemia and skeletal fragility. This case underscores the challenges of managing complex post-bariatric hypoglycemia and highlights the importance of multidisciplinary follow-up to prevent neuroglycopenic complications and monitor skeletal outcomes.

EP854 - ECE_3854 - Off-label use of semaglutide (Ozempic®) for weight reduction: a real-world case series of 20 patients

Entela Puca[1,2,3], Sonila Bitri[4], Nereida Xhabija[5], Dea Puca[6] and Edmond Puca[7]
[1]Endokrinology, Western Balkans University, American Hospital, Tiranë, Albania; [2]Endocrinology, Research, Western Balkans University, Tirana, Albania; [3]Endocrinology, Western Balkans University, Tirana, Albania; [4]Western Balkans University, Tiranë, Albania; [5]Cardiology, Western Balkans University, American Hospital, Tiranë, Albania; [6]Lady of Good Counsel University, Tirana, Albania; [7]Infectious Disease, University Center Mother Teresa, Tirana, Albania

Background: Obesity is a chronic metabolic condition closely linked to insulin resistance and increased cardiometabolic risk. While semaglutide 2.4 mg is specifically approved for obesity treatment, lower doses of semaglutide (Ozempic®) are frequently used off-label for weight reduction in everyday clinical practice. However, real-world data describing outcomes with these lower doses remain scarce.

Objective: To evaluate weight loss outcomes and tolerability of off-label semaglutide (Ozempic®) in adults with overweight or obesity in a routine outpatient setting.

Methods: This real-world case series included 20 adult patients (17 women and 3 men) with overweight or obesity, with a mean age of 42 years and a mean baseline BMI of 33 kg/m^2. All patients were managed in an outpatient endocrinology clinic. Semaglutide (Ozempic®) was initiated at 0.25 mg once weekly and gradually titrated according to clinical response and tolerability; all patients reached a maximum dose of 1.0 mg weekly. The mean follow-up period was 6 months. Changes in body

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

weight and BMI were assessed using routine clinical data. Adverse events and treatment discontinuations were systematically recorded. Off-label prescribing was based on clinical judgment and informed patient consent.

Results: After 6 months of treatment, patients experienced a mean weight reduction of 9.8% from baseline, accompanied by a consistent decrease in BMI across the cohort. Gastrointestinal adverse events—primarily nausea and reduced appetite—were reported by 8 patients (40%) and were mostly mild to moderate in severity. Treatment was discontinued in 2 patients due to intolerance. No serious adverse events were observed.

Conclusions: In this real-world case series, off-label use of semaglutide (Ozempic®) at doses up to 1.0 mg weekly was associated with clinically meaningful weight loss over 6 months and an acceptable tolerability profile. These findings suggest that lower-dose semaglutide may be an effective option for weight reduction in routine clinical practice, while underscoring the need for larger prospective studies to better define long-term safety and efficacy.

Keywords Semaglutide, Ozempic®, off-label use, obesity, weight loss, real-world evidence, case series

EP855 - ECE_2646 - Type 4 renal tubular acidosis misdiagnosed as diabetic ketoacidosis in a patient with Type 2 diabetes mellitus

Kiran Hullur, Naina Skariah and Bilal Jajah
Darlington Memorial Hospital, Darlington, United Kingdom

Background: Type 4 renal tubular acidosis (RTA) is a rare cause of hyperkalemic metabolic acidosis that can mimic diabetic ketoacidosis (DKA), especially in patients with diabetes and advanced age. Recognition is critical to avoid inappropriate management.

Case Details: A 69-year-old woman with a background of hypertension, obstructive sleep apnea, ischemic heart disease, heart failure, and poorly controlled type 2 diabetes mellitus was admitted with a left axillary abscess requiring incision and drainage. Blood tests on admission revealed raised inflammatory markers, moderate hyponatremia, mild hyperkalemia, metabolic acidosis, hyperglycaemia, and raised ketone levels. Blood cultures grew an ESBL-producing organism, and she was treated with meropenem. Her regular medications including dapagliflozin, metformin, amlodipine, losartan, and spironolactone, were withheld in view of sepsis and electrolyte abnormalities. She was managed as diabetic ketoacidosis (DKA) according to hospital protocol. However, despite six days of treatment, she remained acidotic with worsening hyponatremia and hyperkalemia.

She was subsequently referred to the endocrinology team. Adrenal insufficiency was excluded. It was noted that her anion gap remained normal throughout admission, suggesting that the metabolic acidosis was not primarily driven by DKA, raising suspicion of type 4 renal tubular acidosis (hyporeninemic hypoaldosteronism). Enoxaparin, used for venous thromboembolism prophylaxis, was identified as a likely contributing factor in addition to the longstanding diabetes.

Enoxaparin was discontinued and replaced with fondaparinux, and fludrocortisone therapy was initiated. Biochemical improvement was observed within 24 hours, with normalization of electrolytes and resolution of metabolic acidosis within six days. Fludrocortisone was subsequently discontinued.

Discussion: This case highlights type 4 RTA secondary to enoxaparin masquerading as DKA. Treatment including hypotonic fluids worsened electrolyte disturbances that only normalized after discontinuation of enoxaparin and temporary fludrocortisone therapy.

Low-molecular-weight heparin is commonly used for DVT prophylaxis in hospitalized patients. Heparin has a direct toxic effect on the adrenal zona glomerulosa cells and should be considered as a cause of Type 4 RTA in patients presenting with hyperkalemia, hyponatremia, and metabolic acidosis. Switching to fondaparinux, a synthetic selective factor Xa inhibitor, may be a safer alternative in such scenarios.

Current JBDS and NICE DKA diagnostic criteria do not include anion gap, which may contribute to misdiagnosis in atypical cases, while the American Diabetes Association guidelines recommend it in unclear or atypical presentations.

Assessment of the anion gap is crucial in atypical presentations of suspected DKA and should be emphasized in future national DKA guidelines.

EP856 - ECE_2195 - When obesity is a symptom: hypothalamic hamartoma and panhypopituitarism—CASE REPORT

Teresa Alegria Neto[1], Mariana Agapito Fonseca[1], Miguel Duarte[1], Catarina Isabel Lopes[1], Mariana de Griné Severino[1], Marta Vaz Lopes[1], Sónia Do Vale[1,2], Rita Santos[1,2] and Ema Lacerda[1,2]
[1]Endocrinology, Diabetes and Metabolism, ULS Santa Maria, Lisbon, Portugal; [2]Lisbon, Portugal

Panhypopituitarism is a rare condition characterized by global pituitary hormone deficiency, which can present with non-specific symptoms such as weight gain, fatigue or infertility. Hypothalamic hamartomas are uncommon benign malformations that may impair hypothalamic–pituitary function, although a causal relationship is not always demonstrable.

We report the case of a 28-year-old male referred to an Obesity Outpatient Clinic for grade III obesity (BMI 48.2 kg/m^2). The patient was previously of normal weight until the age of 12, when progressive weight gain began during treatment with daily subcutaneous injections for a “growth problem” of unknown specification. He had no dysmorphic features or family history of obesity. Laboratory evaluation revealed secondary hypothyroidism [TSH 1.85 μU/mL (0.30-4.20), FT4 0.72 ng/dL (0.85-1.70)], secondary hypogonadism [FSH 2.0 U/L (1.5-12.9), LH 2.71 U/L (1.3-9.8), testosterone 48.9 ng/dL(240-830)], and low IGF-1 [41.7 ng/mL(135-271)], consistent with panhypopituitarism. Adrenal insufficiency was excluded. MRI of the sellar region showed a 7 mm hypothalamic hamartoma. Previous records confirmed childhood treatment for growth hormone deficiency and secondary hypothyroidism, with an MRI from childhood already documenting the hamartoma, stable since 2005. Multidisciplinary discussion with neurosurgery concluded that the lesion was stable and required no surgical or imaging follow-up. A direct cause-effect could not be established between the presence of the hamartoma and the panhypopituitarism.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Current therapy included levothyroxine and intramuscular testosterone, and after 6 months of levothyroxine and 2 months of testosterone, the patient reported significant clinical improvement, with more energy levels and less depressed mood, with a weight loss of 4 kg.

This case highlights the importance of thorough hormonal assessment in patients with severe obesity. The coexistence of long-standing panhypopituitarism raises diagnostic challenges regarding etiology and emphasizes the need for multidisciplinary management.

EP860 - ECE_1154 - Enhancing transition from paediatric to adult endocrine care: a prospective study of patient experience and intervention feasibility

Vera Haidar[1] and Nilanjana Ray[2]
[1]Imperial College London, London, United Kingdom; [2]London, United Kingdom

Objectives: Transition from paediatric to adult endocrine services is a critical period during which young people with chronic conditions are vulnerable to loss to follow-up, suboptimal disease management, and long-term health consequences. Despite national recognition of the importance of high-quality transition pathways, data evaluating the existing transition experience remains limited. This study aims to assess the current transition process and analyse the feasibility of a newly developed structured transition checklist to support pathway optimisation.

Methods: A prospective evaluation was conducted using a standardised questionnaire administered to young people who had transitioned to adult services within the preceding two years. Outcomes included understanding of the transition pathway, preparedness for self-management, perceived support from paediatric and adult teams, and recommendations for improvement. Findings from this initial cycle informed development of a structured transition checklist and accompanying patient information leaflet, guided by validated transition frameworks, Ready Steady Go and the Transition Readiness Assessment Questionnaire (TRAQ).

Results: A total of eight patients completed the survey. Most participants (87.5%) transitioned at age 17, with the remaining 12.5% transitioning at age 16. Nearly two thirds of respondents (62.5%) felt that they had been transitioned too early. Understanding of the transition process was limited, with 75% rating their understanding as 3/5. Preparedness for self-management was also suboptimal, with 37.5% rating this as 2/5 and 37.5% as 3/5.Perceived support declined between paediatric and adult services (mean scores 3.75/5 and 2.9/5, respectively). Notably, no participants received supportive transition materials (including, prompt sheets, checklists, or written transition plans), despite 87.5% indicating that such resources would have been beneficial. Overall satisfaction with the transition process was moderate (mean 3.4/5).

Conclusions: Significant gaps persist in transition preparedness, perceived support, and availability of patient-centred resources within endocrine transition pathways. Young people demonstrated strong receptiveness to structured written interventions. The newly developed transition checklist and patient information leaflet appear feasible for wider implementation, with ongoing work evaluating their longer-term impact on patient experience and engagement.

EP866 - ECE_2713 - Continuous glucose monitoring in prediabetes and newly diagnosed type 2 diabetes: a pilot case series

Ilona Rudnieva[1], Nazarii Kobyliak[1,2], Viktoriia Yerokhovych[1], Oksana Klymenko[3], Yeva Ilkiv[1] and Galyna Mykhalchyshyn[1]
[1]Bogomolets National Medical University, Kyiv, Ukraine; [2]Medical Laboratory CSD, Kyiv, Ukraine; [3]Department of Hypoxia, Bogomoletz Institute of Physiology, Kyiv, Ukraine

Introduction: Type 2 diabetes mellitus (T2DM) and prediabetes are major global health challenges due to high prevalence, asymptomatic early stages, and risk of cardiovascular and microvascular complications. By 2050, the number of people with diabetes is projected to reach 852.5 million, with 90%-95% of cases being T2DM. Early detection and glycemic control are crucial, but conventional self-monitoring provides limited insight into daily glucose fluctuations, particularly postprandial. Continuous glucose monitoring (CGM) enables detailed assessment of glycemic variability and may support personalized early management.

Aim: To evaluate the clinical and metabolic utility of CGM in patients with prediabetes and newly diagnosed T2DM.

Materials and Methods: This pilot observational case series included two patients: a 26-year-old woman with prediabetes, obesity class I, and subclinical hypothyroidism, and a 61-year-old man with newly diagnosed T2DM, obesity class I, and hypertension. Both underwent CGM for one month. CGM data were analyzed alongside anthropometrics, body composition, lipid profile, markers of carbohydrate metabolism (fasting plasma glucose, HbA1c, fructosamine, C-peptide, HOMA-2), and health-related quality of life (SF-36). Patients received standard pharmacological therapy and lifestyle guidance tailored using CGM findings.

Results: In the prediabetes patient, baseline HbA1c was 5.7% with normal fasting glucose (4.9 mmol/L). CGM revealed postprandial hyperglycemic excursions not detected by routine labs. After one month, body weight decreased from 88.5 to 85.8 kg, body fat from 46.7% to 43.7%, and visceral fat from 12 to 11. Fructosamine decreased from 225.6 to 218.7 μmol/L, HDL cholesterol increased from 0.95 to 1.1 mmol/L, and quality-of-life scores improved, particularly physical functioning (80→90) and vitality (60→80). In the T2DM patient, baseline HbA1c was 6.73% and fasting glucose 7.27 mmol/L. After one month, fasting glucose decreased to 6.77 mmol/L. Weight remained stable (89.5 kg), but waist circumference decreased from 103 to 100.5 cm, body fat from 33.5% to 31.5%, visceral fat from 20 to 17, and lean mass increased from 59.5 to 61.3 kg. Triglycerides decreased from 1.5 to 1.1 mmol/L, HDL cholesterol increased from 1.1 to 1.3 mmol/L, and emotional well-being improved from 64 to 84.

Conclusions: CGM provides clinically relevant insights into glycemic variability in prediabetes and newly diagnosed T2DM, including postprandial excursions undetected by conventional

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

labs. Even over a short period, CGM-guided management improved glycemic control, body composition, lipid profile, and quality of life. Follow-up assessments at 3 and 12 months will evaluate the durability of metabolic effects, patient motivation, and long-term prevention of disease progression.

EP868 - ECE_3991 - Obesity and muscle health in atrial fibrillation: 6-month lifestyle intervention in the ongoing FATBEAT study

Krzysztof Glaser[1,2,3], Mikiko Watanabe[4] and Marek Ruchala[1]
[1]Poznan, Poland; [2]Department of Experimental Medicine, Section of Medical Pathophysiology, Food Science and Endocrinology, Sapienza University of Rome, Roma, Italy; [3]Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences, Poznań, Poland; [4]Department of Experimental Medicine, Section of Medical Pathophysiology, Food Science and Endocrinology, Sapienza University of Rome, Rome, Italy

Atrial fibrillation (AF), the most common sustained arrhythmia, substantially increases stroke, heart failure, and mortality risk. Obesity aggravates AF through systemic inflammation, epicardial and visceral fat accumulation, oxidative stress, and atrial remodeling. Higher BMI and central adiposity consistently associate with increased AF incidence and persistence, and reduced muscle mass and function (sarcopenia) may be an independent risk factor. On the other hand, higher adherence to the mediterranean diet seems protective. Whether muscle mass sparing weight loss achieved through higher adherence to a mediterranean pattern may lead to improved AF outcomes is underinvestigated.

A 70-year-old woman with paroxysmal AF was enrolled in FATBEAT. The patient reported 1-2 monthly AF episodes for the past 6 years; she presented with overweight and central obesity (weight 73.5 kg, height 161.5 cm, BMI 28.2 kg/m^2, waist 90.5 cm, hips 107 cm). Blood pressure 129/85 mmHg, HR 66 bmp.

Right-hand grip strength was 27.5, 24.9, 23.9 kg; sit-to-stand test 18 reps/30s, suggesting preserved muscle mass. However, the SARC-F score 2/10 indicated sarcopenia risk screening (2 points indicate low risk).

The 14-item PREDIMED questionnaire (Prevención con Dieta Mediterránea), a validated Mediterranean diet adherence tool, scored 3/14 at baseline, reflecting poor intake of vegetables, fruits, legumes, nuts, fish, and olive oil. The patient was provided with structured lifestyle counseling targeting PREDIMED improvement without pharmacotherapy, according to the study protocol she was enrolled in.

After 6 months, the patient reported 7% weight loss, with waist and hip circumference reduction (87.5 cm, and 105 cm, respectively). Blood pressure (129/86 to 125/75 mmHg), and heart rate (66 to 62 bpm) improved. Interestingly, grip strength rose markedly (right: 34, 32, 32 kg; left: 20, 29.5, 30 kg), and SARC-F dropped to 1/10, suggesting improved muscle function despite the weight loss. AF episodes totaled 1-2 over 6 months; PREDIMED improved to 8/14.

This case suggests that a structured lifestyle intervention aligning to the mediterranean diet principles may achieve muscle-preserving weight loss, strength gains, and, above all, reduced AF burden in patients with central obesity and AF.

Abstract citation ID: lvag096.1181

EP869 - ECE_2483 - Morphofunctional assessment and in-hospital complications in post-critically ill patients after covid-19 pneumonia as a function of the metabolic disease "continuum"

Víctor Simón-Frapolli[1,2,3], Isabel Mª Vegas-Aguilar[2,4], Isabel Cornejo-Pareja[2,4], Francisco José Tinahones Madueño[2,3,4] and Jose Manuel Garcia-Almeida[2,4]
[1]Hospital Universitario Virgen De La Victoria, Málaga, Spain; [2]Ibima Plataforma Bionand, Málaga, Spain; [3]Facultad de Medicina-UMA, Málaga, Spain; [4]Endocrinology and Nutrition, Hospital Universitario Virgen De La Victoria, Málaga, Spain

Introduction: Patients with elevated cardiovascular risk are a subgroup of patients at increased risk of developing severe COVID-19 disease, a condition associated with a significant in-hospital morbidity and mortality rate. Abdominal obesity (waist circumference ≥102 cm for men or ≥88 cm for women), diabetes mellitus (DM), arterial hypertension (AHT) (figures ≥135/85 mmHg or on treatment), an HDL <40 mg/dl (men) or <50 mg/dl (women) or under treatment, and hypertriglyceridemia (≥150 mg/dl or under treatment) are cardiovascular risk factors (CVRF) that correlate positively with the risk of cardiovascular disease at the population level, and that together (≥3 of them) make up the so-called metabolic syndrome. Likewise, metabolic disease is expressed morphologically as an alteration in muscle mass as well as in the proportion and distribution of body fat mass (adiposity) with a relative increase in visceral fat.

Objective: To determine whether there are differences in body composition as well as in complications during ICU stay and sequalae after admission in post-critical patients with metabolic syndrome with respect to patients without any CVRF and patients with one or more CVRF (DM, hypertension, dyslipidemia and abdominal obesity) without being part of this syndrome.

Method: Prospective observational study including 75 patients who were admitted to the ICU for severe COVID-19 pneumonia. Demographic, clinical and analytical data, medical history, and a complete morphofunctional assessment by bioimpedanciometry with phase angle, nutritional ultrasound, dynamometry and functional tests were performed 14-21 days after hospital discharge. Differences in body composition and complications during hospitalization were analyzed using ANOVA, according to the presence of metabolic syndrome, isolated CVRF or absence of CVRF.

Results: Patients with metabolic syndrome show statistically significant differences compared to patients with isolated CVRF in weight (91.1 ± 18.1 kg vs 105.3 ± 27.4 kg, respectively), BMI (29.4 ± 5.7 vs 32.9 ± 6.7 kg/m^2), as well as in FM% (30.8 ± 7.1% vs 34.7 ± 8.1%). In addition, they present statistically significant differences in ASMMI (7.4 ± 1.5 kg vs 8.4 ± 1.6 kg) and RF-Y axis (1.13 ± 0.3 cm vs 1.41 ± 0.5 cm). No statistically significant differences were observed in functional tests, analytical variables, in-hospital complications, or sequelae after admission.

Conclusions: The presence of metabolic syndrome, with respect to isolated CVRF, shows statistically significant differences in parameters related to low muscle mass (lower ASMMI and RF-Y axis), but in our sample there were no differences in parameters

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

related to visceral adiposity, analytical variables, functional tests, in-hospital complications or sequelae after admission.

EP876 - ECE_3911 - Lipodystrophy a rare case of diabetes mellitus-clinical consideration in pediatric patient

Mihaela Kebakoska[1], Cvetanka Volkanovska Ilijevska[2], Irfan Ahmet[2], Marija Zivkovic[3], Aksinja Gabreska Kebakoska[4] and Valentina Velkoska Nakova[5]

[1]General Hospital Prilep- North Macedonia, Prilep, North Macedonia; [2]Diabetes and Metabolic Disorders, Faculty of Medicine, University Clinic for Endocrinology, Ss. Cyril and Methodius University, Skopje, North Macedonia; [3]Prilep, North Macedonia; [4]Center for Public Health, Prilep, North Macedonia; [5]Faculty of Medical Sciences, Goce Delcev University, Internal medicine, Stip, North Macedonia

Abstract: Familial partial lipodystrophy of the Dunnigan type 2 (FPLD2) is a rare autosomal dominant disorder characterized by progressive loss of subcutaneous adipose tissue in the trunk and extremities and an abnormal accumulation of adipose tissue in the face, neck and intrabdominal organs. Metabolic disorders such as insulin resistance, diabetes mellitus, hypertriglyceridemia, MAFLD, and PCOS, invariably accompany FPLD2.

Case Presentation: A 16-year-old female patient, diagnosed with type 2 DM at age 8, was referred to our clinic for endocrine care. The patient appeared athletic, with prominent muscles and veins and no subcutaneous adipose tissue in the trunk and extremities. The Cushingoid appearance was caused by abnormal facial and neck adipose tissue accumulation. Acanthosis nigricans around the neck and generalized hirsutism were present. The gynecologic history was unremarkable. Laboratory results showed hypertriglyceridemia, hyperinsulinemia, and hyperandrogenemia. An ultrasound revealed hepatic steatosis and the fibroscan estimated liver stiffness was 4 kPa. Additionally, we assessed the patient's mother. She suffered a myocardial infarction at 46 and had similar muscle phenotype and subcutaneous fat deficit. We diagnosed her with DM type 2 and dyslipidemia. Genetic validation of FPLD 2 was indicated and results are pending.

Conclusions: Our case report seeks to heighten clinician awareness of FLPD2 in pediatric and adolescent patients. Lipodystrophy typically occurs throughout puberty. A comprehensive clinical evaluation of abnormalities in fat tissue distribution is a prerequisite for clinical suspicion. Recognition of FLPD2 enable patients, and afflicted family members to be adequately screened for cardiometabolic abnormalities, thus enabling timely and targeted interventions.

Keywords familial partial lipodystrophy

EP878 - ECE_2743 - Unusual DKA presentation secondary to Budesonide used for IgA nephropathy treatment

Ammar Ahmad and Taimoor Shafiq

Medicine and Specialties, Worcestershire Acute Hospitals NHS Trust, Worcestershire, United Kingdom

Introduction: Budesonide has become one of the most important and effective medication in management of IgA Nephropathy. With improving research and clinical trials, drugs like Budesonide have helped to make breakthrough in reducing the progression of IgA Nephropathy to ESRD and a better control of the disease. At the same time, with wider use of these Budesonide, we have come across unexpected new complications.

This case report highlights newer and unexpected complication in a patient under treatment for IgA Nephropathy with target release Budesonide

Method: I am presenting this case report about patient who presented to A&E with DKA while being on treatment with Budesonide for IgA Nephropathy.

I have used data from the clinic letters and investigations carried out for the patient during his clinic appointments and hospital admission due to DKA. I have used the data from clinics correspondence and correlated it with the investigations and events at the hospital.

Discussion: I am presenting the case of a gentleman in his 40s who was referred to OP Renal clinic for unexplained haematoproteinuria. On subsequent clinic follow ups and investigations, it was established that the patient had IgA nephropathy for which he was started on treatment with ACE inhibitors, SGLT-2 inhibitors and later, he was started on the Budesonide.

While being on treatment with Budesonide for his IgA nephropathy, he presented to A&E with DKA.

He was started on treatment for his hyperglycaemia and followed up by Endocrinology team in the clinic.

On following up the patient in the clinic, it was established that the DKA presentation was secondary to Budesonide use. After stopping Budesonide, his glycaemic control improved and subsequently, his HbA1c and glycaemic control came back to normal range.

Results: This report highlights that we are seeing advancements in clinical care and better outcomes due to the newer medications' availability. At the same time, introduction of these newer drugs like Budesonide may lead to unexpected complications.

As far as I am aware, this is first case report showing DKA secondary to Budesonide use. This case report will help to highlight and adopt better follow up strategies for patients being treated with target release Budesonide.

EP879 - ECE_2957 - Correlation between vitamin D deficiency and hyperandrogenism in individuals with insulin resistance

Solomiia Plakhetko[1,2] and Alina Urbanovych[1]

[1]State Non-profit Enterprise "Danylo Halytsky Lviv National Medical University", Lviv, Ukraine; [2]State Non-profit Enterprise "Danylo Halytsky Lviv National Medical University", Lviv, Ukraine

Background and Aims: Vitamin D (VD) deficiency is a prognostic marker influencing the risk of insulin resistance (IR). IR plays a pivotal role in the pathogenesis of obesity, type 2 diabetes mellitus, and polycystic ovary syndrome (PCOS). Currently, the impact of VD on the course of IR is being extensively studied, highlighting its influence on total testosterone and glycated hemoglobin (HbA1c) levels.

Objective: To evaluate the correlation between VD insufficiency/deficiency and hyperandrogenism in patients with IR based on

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

body mass index (BMI) and waist circumference (WC), and to determine their association with HbA1c levels.

Materials and Methods: Our study involved 41 women aged 22 to 45 years, including 24 individuals with alimentary-constitutional obesity (BMI 35,3 ± 5,2 kg/m^2) and 17 overweight individuals (BMI 27,1 ± 2,3 kg/m^2). Laboratory parameters included HOMA-IR index, 25-hydroxyvitamin D (25(OH)D), HbA1c, and total testosterone. Anthropometric data included weight, height, and waist circumference (WC).

Results: VD deficiency was more pronounced in patients with obesity. Levels of 25(OH)D, HOMA index, HbA1c, and total testosterone achieved statistical significance in obese patients (19,8 ± 10,8 ng/mL; 7,9 ± 3,0; 5,8 ± 2,1% %; 2,3 ± 1,1 ng/mL, respectively) compared to overweight individuals (19,8 ± 10,8 ng/mL; 7,9 ± 3,0; 5,8 ± 2,1%; 2,3 ± 1,1 ng/mL, respectively). Additionally, WC was significantly higher in obese patients (102,1 ± 19 cm) compared to the overweight group (84,5 ± 16,5 cm) ($P < .05$).

Lower serum 25(OH)D levels correlated with higher BMI (r = −0,32, $P < 0,05$), whereas HOMA index positively correlated with BMI (r = −0,16, $P < 0,05$). Furthermore, decreased serum 25(OH)D levels correlated with increased HbA1c (r = −0,15, $P < 0,05$). Increased WC was associated with lower 25(OH)D (r = −0,12, $P < 0,05$), higher HOMA-IR (r = 0,39, $P < 0,05$) and elevated total testosterone (r = 0,3, $P < 0,05$).

Conclusions:

1. Patients with obesity exhibit lower VD levels; the deficiency worsens with increasing severity of obesity and HOMA-IR scores.
2. In individuals with obesity and VD deficiency, a significant increase in total testosterone levels is observed.

Abstract citation ID: lvag096.1185

EP881 - ECE_3032 - Severe glycaemic fluctuations post-high-dose glucocorticoid exposure in an adolescent female: pitfalls in diagnosis leading to the diagnosis of Wilson disease

Mariam Kobuladze[1], Shota Janjgava[1,2] and Elene Giorgadze[1]
[1]*National Institue of Endocrinology, Tbilisi, Georgia;* [2]*Ivane Javakhishvili Tbilisi State University, Tbilisi, Georgia*

Severe glycaemic fluctuations following high-dose glucocorticoid exposure in an adolescent female: diagnostic pitfalls culminating in the diagnosis of Wilson disease.

Background: Severe glycaemic variability in adolescents is most commonly attributed to diabetes mellitus, endocrine hypersecretion syndromes, or factitious disorders. Exposure to high-dose glucocorticoids may further confound diagnostic evaluation by inducing cushingoid features and accentuating metabolic disturbances. Diagnosis of other metabolic etiologies is essential when glycaemic patterns and conventional diagnostic indices do not correlate.

Case presentation: An 18-year-old female was referred for endocrinological evaluation because of rapid weight gain (12 kg), violaceous striae, facial edema, weakness, headaches, and intense carbohydrate craving following treatment with high-dose systemic glucocorticoids for acute unilateral sensorineural hearing loss. The treatment consisted of high-dose intravenous prednisolone followed by oral tapering, after which cushingoid features developed rapidly.

From early adolescence, the patient had experienced recurrent nocturnal tremor associated with documented hypoglycaemia (plasma glucose 42 mg/dL), as well as marked glycaemic variability with intermittent extreme hyperglycaemia reportedly exceeding 600 mg/dL. Glycaemic indices were markedly discordant: HbA1c values repeatedly ranged between 4.0% and 5.1%, whereas continuous glucose monitoring–derived estimates reached 7.2%. Autoimmune diabetes screening, including antibodies against GAD, IA-2, pancreatic islet cells, and ZnT8, was negative.

Early metabolic assessment demonstrated low fasting insulin (1.27 μIU/mL) and C-peptide (0.5 ng/mL), which later normalized, indicating fluctuating endogenous insulin secretion. Oral glucose tolerance testing showed normal fasting glucose, a modest post-load increase, followed by late hypoglycaemia. Biochemical evaluation revealed mildly elevated plasma noradrenaline, with normal adrenaline and glucagon concentrations. Cross-sectional imaging demonstrated structurally normal adrenal glands, preserved circadian cortisol secretion, and no pituitary or abdominal pathology.

Extended metabolic screening revealed profoundly reduced serum ceruloplasmin and markedly increased 24-hour urinary copper excretion, exceeding diagnostic thresholds for Wilson disease.

Conclusion: High-dose glucocorticoid exposure can induce cushingoid features and exacerbate extreme glycaemic variability, while mild catecholamine elevation may misdirect diagnostic evaluation toward adrenal pathology. The diagnosis of Wilson disease in this patient underscores the importance of considering disorders of copper metabolism in adolescents presenting with unexplained fluctuating glycaemia, discordant HbA1c values, and negative pancreatic autoimmunity. Wilson disease–associated bile acid dysregulation and reduced farnesoid X receptor activity may alter glucocorticoid receptor signaling and cortisol metabolism. Together with reduced cortisol clearance and increased peripheral 11β-HSD1 activity, this might predispose to tissue-specific glucocorticoid excess in the absence of overt hypercortisolism. This case highlights the need for a broad, structured diagnostic approach in complex endocrine presentations.

EP884 - ECE_3140 - Patterns of emergency service utilisation in adults with type 1 diabetes attended for acute metabolic disturbances

Víctor Siles-Guerrero, Rosa Natalia García Pérez, Aida Elhadri-Egea and Martín López de la Torre-Casares
Hospital Universitario Virgen De Las Nieves, Granada, Spain

Introduction: Emergency service utilisation related to acute metabolic disturbances remains frequent in adults with type 1 diabetes mellitus (T1DM) and represents a relevant component of diabetes-related healthcare burden. These emergency episodes often reflect underlying clinical vulnerability, impaired symptom recognition, and challenges in day-to-day diabetes self-management. However, real-world descriptive data

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

characterising patterns of emergency utilisation and short-term outcomes in this population remain limited.

Objective: To describe patterns of emergency service utilisation and short-term outcomes in adults with T1DM attended for acute metabolic disturbances.

Methods: An observational, retrospective, descriptive study was conducted including 66 adults with T1DM attended by emergency medical services between 2018 and 2022 due to acute metabolic disturbances. Variables analysed included history of previous emergency attendance for similar events, nocturnal occurrence of the index episode, symptom awareness status, and need for emergency re-attendance during follow-up. Data were analysed using descriptive statistics and are presented without inferential comparisons.

Results: A previous history of emergency attendance for acute metabolic disturbances was present in 54.5% of patients, indicating that more than half of the cohort had experienced recurrent emergency utilisation prior to the index episode. Impaired symptom awareness affected 43.9%, suggesting reduced capacity to recognise early warning signs of acute metabolic imbalance. Nocturnal occurrence was reported in 53.0% of events, highlighting the frequency of episodes arising during periods of reduced monitoring and delayed response. Following the index emergency attendance, 22.7% of patients required at least one further emergency intervention during follow-up. Collectively, these findings illustrate a recurrent pattern of emergency service utilisation within a substantial subset of patients with T1DM.

Conclusions: Among 66 adults with T1DM, emergency service utilisation for acute metabolic disturbances frequently followed a recurrent pattern and was commonly associated with impaired symptom awareness and nocturnal occurrence. These descriptive real-world data suggest that emergency attendance may serve as an important marker of ongoing vulnerability. Systematic analysis of emergency utilisation patterns may help identify patients who could benefit from proactive follow-up, structured reassessment, and targeted preventive strategies aimed at reducing recurrent emergency interventions.

EP889 - ECE_1624 - "Educating Families, Empowering patients: the diabetes nurse's role in self-management—a narrative review"

Afroditi Tsalkitzi[1], Despoina Rizikou[1], Anastasia Ntikoudi[1] and Eugenia Vlachou[1,2]
[1]Athens, Greece; [2]Nursing, University of West Attica, Athens, Greece

Background: Diabetes self-management constitutes a complex and demanding process that extends beyond the individual patient and is substantially influenced by the family context. Growing evidence indicates that family support plays a pivotal role in treatment adherence, psychological well-being, and long-term glycaemic outcomes. The diabetes specialist nurse is uniquely positioned to provide structured education and to actively engage family members in facilitating effective diabetes self-management.

Aim: This narrative review aims to examine the contribution of family involvement in diabetes self-management and to emphasise the role of the diabetes specialist nurse in educating and empowering family members to support patients in everyday diabetes care.

Methods: A literature search was conducted across major databases (including PubMed, Google Scholar and Scopus) to identify relevant studies published between 2017 and 2025. Search terms included *"diabetes"*, *"self-management"*, *"family support"*, *"diabetes nurse"* and *"nurse-led education"*. A total of 16 publications met the inclusion criteria and were included in the narrative synthesis.

Results: The reviewed literature consistently indicates that family involvement is associated with improved self-care behaviours, enhanced self-efficacy, better emotional well-being and improved glycaemic outcomes. Family-based diabetes self-management education programmes demonstrate positive effects on adherence to dietary recommendations, glucose monitoring, physical activity and medication regimens. Studies in paediatric populations highlight the mediating role of self-efficacy in the relationship between family support and emotional well-being, while evidence from adult and older populations confirms the value of structured family participation in self-management education. Despite these benefits, family involvement remains insufficiently and inconsistently integrated into routine diabetes care. The diabetes specialist nurse plays a pivotal role in assessing family needs, delivering individualised education, facilitating effective communication and supporting families in adopting supportive rather than controlling behaviours.

Conclusions: The diabetes specialist nurse plays a central role in translating evidence into clinical practice by educating and empowering family members to support diabetes self-management. Integrating structured family education into diabetes care pathways has the potential to improve clinical and psychosocial outcomes. However, further research is required to develop standardised, nurse-led family education models and to evaluate their long-term effectiveness.

EP890 - ECE_3267 - Educational level and risk of severe hypoglycaemia in patients with diabetes: a clinical observational study

Aida Elhadri-Egea, Víctor Siles-Guerrero, Rosa Natalia García Pérez and Araceli Munoz-Garach
Hospital Universitario Virgen de las Nieves, Granada, Spain

Background: Effective diabetes self-management is influenced by multiple sociodemographic factors, including educational level. Limited health literacy may impair self-care skills and increase the risk of adverse metabolic outcomes, such as severe hypoglycaemia.

Objective: To evaluate the association between patients' educational level and the frequency of severe hypoglycaemic episodes.

Methods: Data from 66 patients with diabetes were analysed, including educational level and history of severe hypoglycaemia. Patients were stratified according to educational attainment, and comparisons between groups were performed using appropriate statistical tests to assess differences in the occurrence of severe hypoglycaemic events.

Results: Patients with lower educational levels showed a higher frequency of severe hypoglycaemic episodes compared with those with higher educational attainment ($P = .07$). Although this association did not reach conventional statistical

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

significance, a clear trend was observed, suggesting a potential influence of educational level on diabetes self-management and hypoglycaemia risk.

Conclusions: Lower educational level may be associated with an increased risk of severe hypoglycaemia in patients with diabetes. These findings highlight the need for tailored diabetes education programmes adapted to patients' health literacy levels to improve metabolic control and reduce the risk of hypoglycaemia.

Abstract citation ID: lvag096.1189

EP1673 - ECE_1097 - The association between type 2 diabetes and the risk of developing bronchial asthma using the Korean national health insurance service data and upper respiratory disease claims database

Heung Yong Jin[1], Jong Seung Kim[1], Jae Seok Jeong[1], Tae Sun Park[2], Jungmin Kim[3] and Jin Woo Jung[4]
[1]Endocrinology and Metabolism, Jeonbuk National University, Medical School, Jeonbuk National University Hospital, JeonJu, South Korea; [2]Endocrinology and Metabolism, Jeon Ju Hospital, Jeon Ju, South Korea; [3]St.Carollo Hospital, Suncheon, South Korea; [4]Endocrinology and Metabolism, Wonkwang University, School of Medicine, Iksan, South Korea

Background/Aim: Although it has been suggested that diverse chronic diseases besiedes well known micro-/macrovascular complications, including chronic obstructive pulmonary disease (COPD) and bronchial asthma, may be more prevalent among people with type 2 diabetes mellitus (T2DM), the precise causal relationship remains unclear between these chronic diseases and T2DM. Therefore, we investigated the incidence of bronchial asthma or asthma exacerbation in individuals with T2DM compared with those without diabetes using data from the National Health Insurance Service (NHIS) and asthma cohort.

Methods: We conducted a retrospective cohort study using two nationwide databases: (1) a 3.5 million-patient upper respiratory disease claims database (2008-2022) and (2) a 1 million-person cohort from the NHIS (2015-2021). People with T2DM were identified and matched 1:1 to non-diabetic controls using full propensity score matching.

Results: After matching, the cohort included 142 662 T2DM and 142 662 non-diabetic controls (non-DM). During follow-up, people with T2DM exhibited significantly increased risk for bronchial asthma and asthma exacerbation events compared with non-DM (Bronchial asthma-HR 1.08 (95% CI 1.04-1.13), asthma exacerbation-HR 1.97 (95% CI 1.48-2.61) in T2DM vs non-DM). The risk of bronchial asthma and exacerbation tended to increase in people with T2DM irrespective of diabetic peripheral neuropathy (DPN) as follows (bronchial asthma: HR 1.1 (95% CI 0.99-1.22) vs HR 1.12 (95% CI 1.08-1.17) in DM with DPN and DM without DPN vs non- DM in each; asthma exacerbation: HR 2.08 (95% CI 1.1-3.93) and HR 2.06 (95% CI 1.54-2.75) in DM with DPN and DM without DPN vs non- DM in each). However, the risk of both bronchial asthma and exacerbation showed a significant decreasing trend in diabetic patients treated with GLP-1 receptor agonists (GLP 1RA) or with sodium-glucose cotransporter-2 inhibitors (SGLT2Is) as follows (Bronchial asthma HR 0.7 (95% CI 0.6-0.82) in DM treated with SGLT-2Is and HR 0.42 (95% CI 0.1-1.67) in DM treated with GLP-1 RA vs non-DM in each).

Conclusions: Our study showed that the incidence of bronchial asthma tended to be higher and the occurrence of asthma exacerbations was even more common in people with T2DM irrespective of complications such as DPN. Therefore, in addition to the well-known complications of T2DM, further research is warranted to elucidate the potential associations between T2DM and various other chronic diseases that may develop in diabetic patients.

Abstract citation ID: lvag096.1190

EP1678 - ECE_1322 - Maternal exposure and re-exposure at adulthood to a high-fat diet induce long-term alterations to the pancreatic beta-cell morphometry and secretory function in male offspring

Daniele Sales, Adriana Zanella, Carolina Carvalho and Carla Collares-Buzato
Department of Biosciences, Federal University of São Paulo (UNIFESP), Santos, Brazil

Maternal nutrition can influence the metabolism and health of offspring through a process known as metabolic programming, which can lead to lifelong endocrine and metabolic disorders. The cellular and tissue mechanisms involved in metabolic programming are not fully understood, with limited studies addressing the endocrine pancreas. This study investigated the morphometric and functional alterations in pancreatic beta-cells in male offspring from dams fed a high-fat diet (HFD) during pregnancy and lactation, as well as after 30-day re-exposure to this diet in adulthood. C57BL/6 adult mice were mated, and from the first day of pregnancy, dams received either a standard diet (SD) (4.5% fat) or HFD (35% fat). After weaning (day 21), male offspring were maintained on SD until 90 days old and, then, subdivided by diet until euthanasia at 120 days: CON/CON (continuous SD), CON/HF (SD until 90 d, HFD for the last 30 d), HF/CON (HFD during gestation/lactation, SD until euthanasia) and HF/HF (HFD during gestation/lactation and last 30 d). Male offspring aged 12 and 21 days from the HF/CON group exhibited a significant postprandial hyperglycemia, with 21-day-old mice also showing increased body weight compared to the CON/CON group. In contrast, 120-day-old offspring from the HF/CON group displayed decreased body weight and postprandial glycemia, without significant differences in visceral fat, insulinemia, or responses to glucose and insulin tolerance tests compared to the CON/CON group. Meanwhile, the HF/CON adult offspring exhibited marked changes in islet structure, some already detected as early as 12 days of age, including reduced islet area and number per pancreas section, decreased total beta-cell area, smaller beta-cell size, and a lower beta-to-non-beta cell ratio. These islet morphometric alterations in HF/CON mice were accompanied by impairment of the beta-cell cytoskeletal F-actin organization and diminished glucose-stimulated insulin secretion (GSIS) in vitro. Adult HFD exposure induced overweight, increased adiposity, hyperglycemia, hyperinsulinemia, glucose intolerance, insulin resistance, and compensatory beta-cell area expansion, which were similar between the CON/HF and HF/HF groups. HF/HF offspring, however, displayed a more pronounced decrease in GSIS compared to CON/HF and HF/CON groups, suggesting an interaction between

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

early metabolic programming and adult diet. In conclusion, HFD consumption by mothers during pregnancy and lactation induces long-term changes in islet structure and beta-cell secretory capacity in offspring, which may influence their response to further metabolic challenges.

Background: Variability in statin response and tolerability represents a major challenge in cardiovascular prevention among postmenopausal women. Genetic variation in hepatic statin transport and metabolic factors may contribute to differences in treatment outcomes. This study explored the clinical relevance of the SLCO1B1 c.521T > C variant and baseline vitamin D status in relation to LDL-cholesterol (LDL-C) target attainment and statin-related adverse effects during atorvastatin or rosuvastatin therapy.

Methods: A cohort of 145 postmenopausal women initiating statin therapy was prospectively followed for up to 16 weeks with monthly dose titration to achieve guideline-recommended LDL-C targets. Lipid parameters, liver transaminases, and creatine kinase were monitored throughout follow-up, and treatment-related adverse effects were systematically recorded. SLCO1B1 c.521T > C genotyping and baseline vitamin D assessment were performed, and their associations with treatment response and tolerability were analyzed.

Results: Overall LDL-C target attainment was significantly higher in women treated with rosuvastatin compared with atorvastatin ($P = .02$), accompanied by greater reductions in LDL-C and other atherogenic lipids. SLCO1B1 genotype did not influence lipid-lowering efficacy or dose requirements. In contrast, carriers of the T/C genotype experienced a higher incidence of statin-related adverse effects, particularly during atorvastatin therapy ($P = .008$). Baseline vitamin D status was not independently associated with LDL-C target attainment or adverse effects, although women with severe deficiency tended to show attenuated LDL-C reduction.

Conclusions: In postmenopausal women, SLCO1B1 c.521T > C polymorphism appears to be more relevant for statin tolerability than for lipid-lowering efficacy. Rosuvastatin demonstrated superior overall lipid control and a more favorable safety profile compared with atorvastatin. These findings highlight the potential clinical relevance of pharmacogenetic information for statin selection, particularly in relation to treatment tolerability.

EP891 - ECE_2921 - Immune checkpoint inhibitor–induced type 1 diabetes mellitus in a patient with breast cancer

Katerina Stefanaki[1,2], Olympia Michalopoulou[3], Vasiliki Marinou[2], Vasiliki Kotsini[3], Sofia Pegka[4], Melpomeni` Moustaki[1,2] and Stavroula A. Paschou[1,2]

[1]Department of Clinical Therapeutics, Endocrine Unit and Diabetes Center, School of Medicine, National and Kapodistrian University of Athens, Alexandra Hospital, Athens, Greece; [2]Department of Clinical Therapeutics, Alexandra Hospital, Medical School of the National and Kapodistrian University of Athens, Athens, Greece; [3]Third Internal Medicine Clinic, Metropolitan General Hospital, Athens, Greece; [4]Endocrinology Department, Amalia Fleming General Hospital, Athens, Greece

Background: Immune checkpoint inhibitors (ICIs) have become an integral part of modern oncological treatment. Despite their clinical efficacy, ICIs are associated with immune-related adverse events, including endocrine complications. New-onset type 1 diabetes mellitus (T1DM) is a rare but severe complication, often characterized by abrupt onset and presentation with diabetic ketoacidosis (DKA). Given the increasing use of ICIs across multiple cancer types, recognition of this complication is of growing clinical relevance for endocrinologists and oncologists alike.

Case Report: We report the case of a 52-year-old woman with no previous history of glucose intolerance who was diagnosed with poorly differentiated breast carcinoma. The patient received neoadjuvant chemotherapy followed by immunotherapy with the anti–PD-1 agent pembrolizumab. Two months after initiation of immunotherapy, she presented to the emergency department with polyuria, polydipsia, and general weakness. Clinical examination was remarkable for rapid heart rate, signs of extracellular volume depletion (dry skin and mucosa) and breath smell of acetone. Initial laboratory work-up revealed severe hyperglycemia (plasma glucose 671 mg/dL), high anion gap metabolic acidosis (arterial pH 7.25, bicarbonate 11.6 mmol/L), and marked ketonuria (+++), confirming the diagnosis of DKA. Of note, glycated hemoglobin was only mildly elevated (HbA1c 6.3%), indicating recent onset of hyperglycemia. C-peptide levels were markedly reduced (0.13 ng/mL), consistent with absolute insulin deficiency, while anti–glutamic acid decarboxylase (anti-GAD) antibodies were positive (80.5 IU/mL), indicating an autoimmune pathophysiological mechanism. Therefore, immune-mediated T1DM related to pembrolizumab was diagnosed. The patient was treated with intravenous fluids, continuous insulin infusion,

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

and potassium replacement, followed by transition to a basal–bolus insulin regimen.

Conclusions: Immune checkpoint inhibitor–induced T1DM is a rare but serious endocrine adverse event, most commonly associated with PD-1 inhibitors. It is characterized by rapid β-cell destruction and frequently presents with DKA. Glucose monitoring and vigilance are essential for early diagnosis and prompt management of patients receiving immunotherapy.

EP892 - ECE_1971 - Occult parathyroid carcinoma presenting as thyroid cystic lesion with cutaneous tract seeding after robotic surgery

Chun-Jen Hsiao and Wei-Yih Chiu
National Taiwan University Hospital, Taipei City, Taiwan

Introduction: Parathyroid carcinoma is a rare endocrine malignancy that may closely mimic benign thyroid disease or thyroid carcinoma, particularly when classic biochemical features of primary hyperparathyroidism are absent. Misclassification at presentation may lead to an inappropriate surgical approach. While minimally invasive and robotic techniques are increasingly used for thyroid disease, their implications in undiagnosed parathyroid carcinoma remain uncertain.

Case Presentation: A 59-year-old woman presented to a local hospital with a progressively enlarging left neck mass and throat discomfort. Neck computerized tomography (CT) scans demonstrated a large cystic lesion in the left thyroid lobe extending into the anterior mediastinum with tracheal deviation, initially suspected to be a thyroid neoplasm. She subsequently underwent robotic bilateral axillo-breast approach thyroidectomy. Histopathologic examination unexpectedly revealed parathyroid carcinoma. Three to four months following surgery, she developed locoregional recurrences in the supraclavicular and contralateral cervical regions, which were treated with repeated excisions. Nine months after surgery, she was referred to our hospital with progressive hypercalcemia and elevated parathyroid hormone levels. Imaging identified recurrent disease in the anterior mediastinum and cutaneous/subcutaneous metastases involving the right breast and chest walls. The anatomic distribution of these metastatic lesions corresponded to the prior robotic surgical access pathway, suggesting cutaneous tract seeding. Despite aggressive surgical debulking, the patient developed recurrent hyperparathyroidism with refractory hypercalcemia, requiring repeated hospitalizations and intensive medical therapy. Tissue genomic analysis identified PTEN loss and a TP53 mutation, neither of which are targetable with available therapies. Ultimately, distant metastases to bone and liver were detected, rendering further curative surgery unfeasible. Given the extent of disease progression and the lack of effective therapeutic options, management focused on controlling hypercalcemia and exploring chemotherapy or immunotherapy as potential treatment approaches.

Conclusions: This case demonstrates how parathyroid carcinoma can mimic a thyroid cystic lesion and remain unrecognized until after robotic surgery performed for presumed thyroid disease. Cutaneous tract seeding emerged as an early recurrence pattern, underscoring the importance of preoperative suspicion and careful selection of the initial surgical approach.

Abstract citation ID: lvag096.1194

EP893 - ECE_2333 - When prostate meets thyroid: incidental follicular thyroid carcinoma detected by PSMA PET/CT—a case report

Ionela-Madalina Gherghe[1], Cristina Capatina[1,2], Medeea Georgescu[1] and Catalina Poiana[1,2]
[1]*'C.I. Parhon' Institute of Endocrinology, Bucharest, Romania;* [2]*Bucharest, Romania*

Background: Prostate-specific membrane antigen (PSMA) PET/CT has become an essential tool in the staging of prostate cancer due to its high sensitivity and specificity. While PSMA expression is often associated with prostate malignancies, increasing evidence has documented its presence in other tumor types, including thyroid carcinomas. The synchronous occurrence of prostate and thyroid cancers remains extremely rare, with only a few cases reported to date, and the putative molecular/pathophysiological links between these malignancies remain largely unexplored.

Case Presentation: We report the case of a 65-year-old man recently diagnosed with poorly differentiated acinar prostate adenocarcinoma (G3, Gleason grade 9), referred for thyroid evaluation following PSMA-PET/CT performed for disease staging. PSMA-PET/CT revealed expected tracer uptake in the prostate and focal uptake in the thyroid. Thyroid ultrasonography demonstrated a $2.2 \times 2.5 \times 3.28$ cm nodule in the inferior pole of the left lobe with iso- and hypoechoic components, classified as TI-RADS 4. Fine needle aspiration biopsy (FNAB) cytology was highly suggestive of poorly differentiated carcinoma (Bethesda VI).

The patient underwent total thyroidectomy and histopathological examination confirmed an encapsulated follicular thyroid carcinoma with angioinvasion and minimal capsular invasion. The initial treatment for prostate cancer included radiotherapy combined with androgen deprivation therapy using Goserelin. Postthyroidectomy, he remains under careful multidisciplinary follow-up, including both urological and endocrinological surveillance, and is scheduled for adjuvant radioiodine therapy.

Conclusions: This case highlights the potential benefit of PSMA-PET/CT not only for prostate cancer staging but also for the incidental detection of other clinically significant pathologies, such as thyroid carcinoma. Clinicians ought to be watchful when interpreting incidental PSMA uptake outside the prostate, further studies being required to evaluate the clinical significance and feasibility of targeted thyroid screening in patients with prostate cancer.

EP894 - ECE_3699 - Highly-differentiated follicular carcinoma of ovarian origin: a case report of a rare disease

Renato Diana[1], Claudio Cusini[2] and Livio Luzi[1,2]
[1]*Department of Biomedical Sciences for Health, University of Milan, Milan, Italy;* [2]*Department of Endocrinology, Nutrition and Metabolic Diseases, IRCCS Multi Medica, Sesto San Giovanni, MI, Italy*

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Introduction: Highly-differentiated follicular carcinoma of ovarian origin (HDFCO) is an extremely rare neoplasm consisting of a struma ovarii with extra-ovarian extension.

Clinical case: A 50-year-old woman presents to the gynecology clinic complaining of abdominal pain. On abdominal examination, a mass was palpable in the left iliac fossa. An abdominal CT scan showed an ovarian mass measuring 10 cm. A left hysteroannessiectomy and multiple peritoneal biopsies were performed. Histological examination revealed a mature teratoma with features of struma ovarii, showing an immunophenotype positive for thyroglobulin, TTF-1, synaptophysin and alpha-actin; periuterine fibroadipose tissue showed microlocalizations of well-differentiated thyroid-type follicular structures, consistent with the diagnosis of HDFCO. Thyroid function tests were within normal limits. Thyroid ultrasound revealed three subcentimetric nodules without suspicious features. Thyroglobulin levels in the following months remained within the normal range (3.1 ng/mL), consistent with the presence of a normal volume thyroid. Whole-body Iodine-131 scintigraphy showed physiological uptake in the thyroid bed and multiple focal areas of uptake in the abdominopelvic region. Whole-body 18F-FDG PET/CT scan showed no areas of increased glucose metabolism. Adjuvant radiometabolic treatment with I-131 was indicated following total thyroidectomy. Blood tests performed prior to thyroidectomy confirmed normal thyroid function and slightly increased thyroglobulin levels (9.9 ng/ml) however still consistent with the presence of a normal volume gland. Levothyroxine replacement therapy was introduced after thyroidectomy. Histological examination of the thyroid revealed features of nodular follicular disease. The patient underwent radioiodine therapy (5550 MBq of I-131 administered after levothyroxine withdrawal). At that time, TSH was 51.8 mU/L, thyroglobulin 10.6 ng/mL, and anti-thyroglobulin antibodies 13 U/mL (normal values <115 mU/L). The post-therapy whole-body scan showed increased radioiodine uptake in the thyroid bed consistent with thyroid remnant tissue, and multiple focal areas of radioactive iodine uptake throughout almost all abdominal quadrants, findings compatible with peritoneal disease localization. Six months after radioiodine therapy, the patient, while on levothyroxine replacement therapy at 112 mcg daily, showed suppressed TSH (0.02 mU/L) and undetectable thyroglobulin, indicating a successful response to radioiodine treatment. Given the undetectable thyroglobulin levels, no further whole-body scintigraphy was performed. The patient underwent a contrast-enhanced abdominal CT scan, which showed no pathological findings in the abdominopelvic region. Thyroglobulin levels remained undetectable. Three years after left adnexectomy and one year after radioiodine therapy the patient is disease-free and continues the periodic follow-up. Given the rarity of the disease, there is no shared consensus regarding the optimal therapeutic strategy nor follow-up approach.

EP895 - ECE_1555 - Incomplete radiofrequency ablation promotes tumor growth and angiogenesis in thyroid cancer

Chi-Yu Kuo[1], Shih-Ping Cheng[1], Yi-Chiung Hsu[2], Ying-Syuan Li[1] and Shao-Chiang Chang[1]
[1]MacKay Memorial Hospital, Taipei, Taiwan; [2]National Central University, Taoyuan, Taiwan

Background: Radiofrequency ablation (RFA) has emerged as a treatment option for low-risk papillary thyroid cancer, but concerns remain regarding incomplete ablation and its uncertain oncologic consequences. This study investigated the biological effects of sublethal heat exposure on thyroid cancer cells following incomplete RFA.

Methods: NOD/SCID mice with xenograft tumors underwent RFA or sham ablation. Tumor growth was monitored, and histological analyses, including the Ki-67 labeling index and microvessel density, were performed. Additionally, papillary thyroid cancer cell lines were subjected to transient heat treatment. Colony formation, thyrosphere formation, wound healing, invasion assays, and VEGF secretion were assessed.

Results: Following incomplete RFA, xenograft tumors exhibited accelerated growth with scattered viable PAX8-positive cells in necrotic areas. The RFA group demonstrated significantly higher Ki-67 labeling indices and microvessel density compared to the controls. In vitro, transient heat treatment significantly increased colony formation, thyrosphere size, cell migration, and invasion across all cell lines. Heat-treated cells exhibited upregulated expression of cyclin D1, CDK1, ZEB1, N-cadherin, and heat shock proteins. VEGF secretion and HIF-1α expression were elevated, promoting endothelial tube formation. Low-dose ganetespib, an HSP90 inhibitor, effectively mitigated these pro-tumorigenic effects.

Conclusions: Incomplete RFA induces heat stress responses that promote proliferation, migration, invasion, and angiogenesis in thyroid cancer cells. These findings highlight the importance of achieving complete tumor ablation during RFA procedures. Long-term clinical studies are warranted to establish the oncologic safety of RFA for thyroid cancer treatment.

EP896 - ECE_2307 - An isolated ovarian tumor tentacles reaches the heart and brain

Tomer Saad, Akirov Amit, Hiba Masri and Ilan Shimon
Kiryat Ono, Israel

Case Report: A 55-year-old woman without any known cardiac history was hospitalized duo to ongoing exercise intolerance. We performed a TEE following a TTE demonstrating massive tricuspid regurgitation and moderate pulmonic, aortic and mitral regurgitation with a patent foramen ovale. Considering the findings and the clinical presentation, we completed a urine collection test showing an elevated 5-hydroxyindoleacetic acid (5-HIAA) level of 95 mg/24 hours. A Gallium-68 PET/CT revealed an isolated pathologic uptake in the left pelvic originating from the ovary. The patient started Somatuline injections and after further imaging and a multidisciplinary discussion, she was scheduled for laparoscopic bilateral salpingo-oophorectomy. During the operation, despite commencing an Octreotide infusion 48 hours prior to the procedure, she underwent a carcinoid crisis. In addition, a brain CT scan showed multiple cardio-embolic ischemic strokes. The patient 5-HIAA and nt-pro-BNP levels are improving and she is recuperating prior to her valve replacement surgery.

Introduction: While Carcinoid Syndrome usually arises from intestinal neuroendocrine tumors, ovarian NETs represent a

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

distinctive group with unique implications on clinical presentation and cardiac involvement. Carcinoid Heart Disease (CHD) occurs in approximately 20%-50% of patients with Carcinoid Syndrome and has a significant impact on prognosis and survival. Ovarian NETs, bypass the portal system and hepatic metabolism, and are associated with CHD even in the absence of liver metastases.

The disease primarily effects right-sided cardiac valves, resulting in regurgitation, stenosis, and eventually right heart failure. Left-sided involvement is less common but may occur in the presence of a patent foramen ovale or extremely high hormone levels. Somatostatin analogues have a key role in the treatment, aiming to control symptoms, reduce serotonin secretion, and prevent cardiac disease progression. In patients with severe symptoms, valves replacement surgery is essential and has demonstrated symptomatic improvement and increased survival.

Conclusions: This case emphasizes how an isolated ovarian carcinoid without any dissemination can lead to severe CHD with right and left side involvement and multiple cardioembolic strokes in the presence of a patent foramen ovale. The decision regarding the optimal timing and order of the tumor removal and valve's replacement is a complex dilemma that should be tailored individually for each patient.

EP897 - ECE_1384 - The relevance between mortality in prostate cancer patients receiving androgen deprivation therapy and 5α-reductase inhibitors

Yu-Tang Chen[1], Dai-Wei Liu[2] and Ren-Jun Hsu[3]
[1]*Buddhist Tzu Chi Medical Foundation, Hualien Tzu Chi Hospital, Hualien City, Taiwan;* [2]*Department of Radiation Oncology, Hualien Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Hualien City, Taiwan;* [3]*Hualien City, Taiwan*

Background: Benign prostatic hyperplasia is often treated with 5α-reductase inhibitors (5-ARI), which might affect androgen activity.

Objective: To investigate the association between 5-ARI use and androgen deprivation therapy (ADT) in patients with prostate cancer.

Materials and Methods: This retrospective cohort study linked National Health Insurance (NHI) data with data from the Taiwan Cancer Registry (TCR) and Taiwan Death Registry (TDR) between 1997 and 2016. Prostate cancer patients who received ADT were classified into 5-ARI users and non-users. Inverse probability of treatment weighting (IPTW) was adopted for the primary analysis. The outcomes were overall mortality and prostate cancer-specific mortality. IPTW was used for the sensitivity analysis.

Results: A total of 55 744 patients with prostate cancer were enrolled in this study. Among 44 566 who received ADT, 3332 used 5-ARI, and 35 489 did not, with a mean follow-up of 5.5 years. Compared with non-5-ARI users, 5-ARI users showed no increased risk of all-cause mortality (hazard ratio [HR]: 0.96; 95% confidence interval [CI]: 0.89-1.04) and prostate cancer-specific mortality (HR: 0.96; 95%: CI 0.87-1.06) in the matched analysis. Dutasteride users showed a decreased prostate cancer-specific mortality risk when combined with gonadotropin-releasing hormone (GnRH) agonists and oral antiandrogens (HR: 0.85; 95% CI: 0.73-0.99) in the subgroup analysis.

Conclusions: 5-ARIs were not associated with an increased risk of mortality in prostate cancer patients receiving ADT. This finding provides clinical evidence for the potential safety of 5-ARI use in ADT patients.

EP899 - ECE_1632 - Hypoglycemia of tumoral origin: diagnostic challenge of the role of IGF-2

Susana Mallea-Gil, Leyla Vivana Flores Rios, Yamila Sanchez, Bibiana Coca, Cindhy Castro and Carolina Ballarino
Endocrinology, Hospital Militar Central, Buenos Aires, Argentina

Hypoglycemia is a potentially life-threatening condition in which identifying the underlying etiology is essential for therapeutic management. On rare occasions, it may present as a paraneoplastic syndrome associated with the secretion of aberrant forms of insulin-like growth factor 2 (IGF-2) by extra-pancreatic tumors, which exerts insulin-mimetic effects. An elevated IGF-2/IGF-1 ratio constitutes a key biochemical finding.**Clinical Case:** A 49-year-old man with six-month history of lung carcinoma undergoing treatment with pembrolizumab, pemetrexed, and carboplatin presented to Emergency Room with profuse diaphoresis, fever and altered mental status. On admission, severe hypoglycemia was documented: 28 mg/dL, corrected with 25% dextrose. Physical examination: blood pressure 90/60 mmHg, heart rate 97 bpm, temperature 38 °C, oxygen saturation of 96%, bilateral rhonchi and distension with non-tender hepatomegaly. The patient reported unquantified weight loss and night sweats over recent weeks. Laboratory findings: hematocrit 35%, hemoglobin 11 g/dL, leukocytes 15 600/mm^3, neutrophils 75%, sodium 130 mEq/L and potassium 4.3 mEq/L. During dextrose infusion, glucose reached 99 mg/dL. C-peptide levels were normal.

Chest CT revealed bibasilar pneumonia, prompting initiation of ampicillin–sulbactam. Abdominal MRI showed multiple hepatic lesions suggestive of metastases and a 10 × 14 mm nodular lesion in the left adrenal gland compatible with a lipid-rich adenoma.

Due to suspicion of adrenal insufficiency, intravenous hydrocortisone was initiated with clinical improvement, tapering was continued to 30 mg/day; however, the patient again developed symptomatic hypoglycemia, including one episode of 47 mg/dL with insulin levels of 0.75 µUI/mL (2.6-24.9), ruling out endogenous and exogenous hyperinsulinism.

Pituitary profile: cortisol 19.4 µg/dL, IGF-1 <15 ng/mL (90-130 ng/mL), total testosterone 0.22 ng/mL (2.41-8.27 ng/mL), FSH 2.1 mIU/L (1.4-18 mIU/L), LH 1.7 mIU/L (1.5-9.3 mIU/L), and normal thyroid function tests.

In the context of persistent hypoglycemia with suppressed insulin levels, markedly low IGF-1, and positive response to glucocorticoids, aberrant IGF-2 secretion from a non-islet cell tumor was considered the most likely etiology. Fractionated meals and methylprednisolone 20 mg every 12 hours were prescribed, achieving glycemic stability and allowing hospital discharge. The patient died six months after discharge.

Conclusions: IGF-2–mediated paraneoplastic hypoglycemia is a rare, underdiagnosed entity with poor prognosis in Argentina,

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

largely due to the unavailability of IGF-2 measurement. Ruling out common etiologies of hypoglycemia, suspecting a paraneoplastic syndrome, integrating the biochemical findings, and observing the favorable response to glucocorticoids were key to establishing a presumptive diagnosis, which proved essential for appropriate management.

Abstract citation ID: lvag096.1200

EP900 - ECE_3120 - Clinical characteristics of medullary thyroid carcinoma according to RET mutation status

Dusan Ilic, Sanja Ognjanovic, Bojana Popovic, Valentina Elezovic Kovacevic, Milica Opalic Palibrk, Lena Radic, Katarina Krstic, Natalija Dragicevic and Djuro MacUt
Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Centre of Serbia, Department for Endocrine Tumors and Hereditary Cancer Syndromes, Belgrade, Serbia

Background: Medullary thyroid carcinoma (MTC) is a rare neuroendocrine malignancy arising from parafollicular C cells of the thyroid gland. Activating mutations of the RET proto-oncogene play a central role in the pathogenesis of hereditary MTC and MEN2 syndromes and are also detected in a subset of apparently sporadic cases. Although RET mutations are known to influence the clinical and biochemical features of medullary thyroid carcinoma, their impact on disease presentation, tumor burden, and biochemical phenotype at diagnosis varies across reported cohorts and clinical series.

Objective: To compare demographic, clinical, pathological, biochemical, and MEN2-associated characteristics of RET-positive and RET-negative patients with medullary thyroid carcinoma.

Methods: We retrospectively analyzed 433 patients with histologically confirmed MTC who underwent genetic testing for RET mutations. The mean age at diagnosis was 49.3 ± 16.3 years. Age at diagnosis, nodal (N0 vs N+) and distant metastatic status (M0 vs M1), preoperative serum calcitonin levels, and MEN2-associated manifestations, including pheochromocytoma and primary hyperparathyroidism (PHPT), were compared between RET-positive and RET-negative patients. Analyses of nodal and distant metastases were restricted to cases with available staging data.

Results: RET-positive patients were diagnosed at a significantly younger age compared to RET-negative patients ($P < .001$). Among patients with available nodal status ($n = 248$), RET-positive patients had a significantly lower prevalence of nodal metastases at diagnosis compared to RET-negative patients (29.4% vs 44.2%, $P = .024$). Among patients with available distant metastatic status ($n = 187$), the prevalence of distant metastases did not differ significantly according to RET mutation status (8.1% vs 14.2%, $P = .21$). Preoperative serum calcitonin levels tended to be lower in RET-positive patients, although this difference did not reach statistical significance ($P = .074$).

MEN2-associated manifestations were strongly associated with RET positivity. Pheochromocytoma was observed exclusively in RET-positive patients (53.3% vs 0%, $P < .001$), while primary hyperparathyroidism was more frequent in the RET-positive group (16.3% vs 7.7%).

Conclusions: RET-positive medullary thyroid carcinoma represents a distinct clinical phenotype characterized by earlier age at diagnosis, a significantly lower prevalence of nodal metastases, and frequent MEN2-associated manifestations, without an increased burden of distant metastatic disease at presentation. These findings likely reflect earlier detection of disease in genetically predisposed individuals and further support the importance of routine RET genetic testing in all patients with medullary thyroid carcinoma.

EP901 - ECE_2369 - Insulin signaling activity in women with breast and endometrial cancer in the setting of type 2 diabetes: the role of obesity and insulin resistance

Tamara Vatseba[1], Liubov Sokolova[2] and Volodymyr Pushkarev[2]
[1]*Endocrinology Department, Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine;* [2]*V.P. Komisarenko Institute of Endocrinology and Metabolism of the National Academy of Medical Sciences of Ukraine, Kyiv, Ukraine*

Introducion: Recent studies indicate an increased risk of breast cancer (BC) and endometrial cancer (EC) in women with type 2 diabetes mellitus (T2DM). The mechanisms underlying the association between cancer and diabetes include the effects of obesity, hyperinsulinemia, cytokine imbalance, dysbiosis, hyperglycemia, and oxidative stress. These factors exert their effects through intracellular signaling pathways, particularly the insulin signaling PI3K/Akt/mTOR. PRAS40 is a component of this pathway and a physiological inhibitor of mTORC1; its phosphorylation promotes mTOR activation. **The aim** of this study was to assess PI3K/Akt/mTOR pathway activity by measuring phosphorylated PRAS40 (pT246) in women with breast and endometrial cancer diagnosed in the setting of T2DM, and to analyze its association with obesity and insulin resistance.

Methods: Phospho-PRAS40 content in peripheral blood mononuclear cells were measured by enzyme-linked immunosorbent assay (ELISA) using kit KHO0421 (Invitrogen, USA) on a Bio-Tek Instruments microplate reader at 450 nm. Serum insulin and IGF-1 levels were determined using a Stat Fax 303+ automated analyzer with Insulin ELISA EIA-2935 and IGF-1 600 ELISA EIA-4140 kits (DRG, Germany). Insulin resistance was assessed using HOMA-IR. Differences were assessed using Student's t-test. Correlations were analyzed using Pearson's correlation coefficient (r).

Results: Women with T2DM and cancers of both localizations exhibited obesity, insulin resistance, and significantly elevated IGF-1 levels compared with the control group ($P < .05$). Compared with controls, phospho-PRAS40 content were significantly lower in women with T2DM and BC ($t = 9.67$; $P < .001$) and in those with T2DM and EC ($t = 8.26$; $P < .001$). In women with BC, phospho-PRAS40 positively correlated with BMI ($r = 0.738$; $P < .05$) and HOMA-IR ($r = 0.696$; $P < .05$). In women with EC, phospho-PRAS40 positively correlated with insulin ($r = 0.789$; $P < .05$).

Conclusions: Reduced PRAS40 phosphorylation in women with breast and endometrial cancer and T2DM may reflect suppression of PI3K/Akt/mTOR pathway activity, potentially due to

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

competition between signaling pathways and insulin signaling inhibitors. The positive correlation of BMI, HOMA index, insulin, and phospho-PRAS40 supports the role of obesity in PI3K/Akt/mTOR activation involved in oncogenesis.

EP903 - ECE_2515 - Peptide receptor radionuclide therapy (PRRT): response assessment and novel approaches

Calin Cristiana[1,2], Iulia Florentina Burcea[1,2], Ramona Dobre[1,2], Teodor Constantin[2] and Catalina Poiana[1,2]

[1]*Endocrinology Department, Carol Davila University of Medicine and Pharmacy, INE C.I. Parhon, București, Romania;* [2]*Endocrinology, Endocrinology I, Institutul National de Endocrinologie C. I. Parhon București, București, Romania*

Introduction: Peptide Receptor Radionuclide Therapy (PRRT) is an advanced systemic treatment with targeted action used for neuroendocrine tumors (NETs), a rare and diverse group of malignancies that arise from neuroendocrine cells. Many of these tumors overexpress somatostatin receptors, allowing PRRT to selectively deliver radiation to tumor cells while minimizing damage to healthy tissues.

Methods: We conducted a retrospective study on 93 patients diagnosed with NETs, of whom 54 (58%) had metastatic disease. Additionally, 15 patients (16.1%) underwent PRRT, including 11 gastroenteropancreatic NETs, 2 lung NETs, and 2 extra-adrenal paragangliomas.

Results: All patients who underwent PRRT had metastatic disease, with liver metastases being the most common (11 patients). They received an average of 3.8 PRRT cycles (±1.46).

Among them, 14 out of 15 patients (93.3%) received PRRT with beta emitters ([177]Lu), while 1 patient (6.7%) underwent treatment with both beta ([177]Lu) and alpha emitters ([225]Ac). Moreover, 12 out of 15 patients (80%) received PRRT with somatostatin receptor agonists, while 3 (20%) underwent combination therapy with both a somatostatin agonist (DOTATOC) and an antagonist (DOTA-JR11 or DOTA-LM3). Regarding treatment response, 8 out of 15 patients (53.3%) had stable disease, 4 (26.7%) achieved a partial response, 2 (13.3%) experienced progressive disease, and 1 patient (6.7%) had a complete response, according to RECIST criteria. The progression-free survival (PFS) was 23.25 months (±27.2 months). Among these patients, 5 died (33.3%), with a median overall survival (OS) of 17.8 months (±10.9).

Conclusions: In conclusion, the efficacy of PRRT in treating patients with metastatic NETs, according to this study, was notable, with 53.3% of patients experiencing stable disease and 26.7% achieving a partial response. Furthermore, combination therapies, including the use of somatostatin receptor agonists and antagonists, as well as the administration of alpha emitters in one case, suggest additional potential in improving therapeutic responses and overcoming tumor resistance.

EP905 - ECE_3681 - The picture of adrenocortical carcinoma recurrence upon mitotane in adjuvant setting in a cohort from Central Europe Center

Agnieszka Kotecka-Blicharz[1], Kornelia Hasse-Lazar[1], Jordi Gras-Ozimek[1], Alexander Cortez[2], Tomasz Gawlik[1], Aleksandra Sygula[3], Magdalena Wyciślik[1], Łukasz Kluczyński[1], Barbara Jarząb[1] and Daria Handkiewicz-Junak[1]

[1]*Department of Nuclear Medicine and Endocrine Oncology, Maria Sklodowska-Curie National Research Institute of Oncology, Gliwice, Poland;* [2]*Department of Biostatistics and Bioinformatics, Maria Sklodowska-Curie National Research Institute of Oncology, Gliwice, Poland;* [3]*Gliwice, Poland*

As adrenocortical carcinomais the malignancy known for its preponderance to relapse, adjuvate therapy is a crucial issue in patient management.The clinical justification for the use of adjuvant therapy is to reduce the risk of local and distant recurrenceand/or improve survival. Mitotane is the mainstay of adjuvant treatmentin adrenocortical carcinoma.

The main objective of the study was to assess the characteristics oradrenocortical recurrence upon adjuvant mitotane treatment depending on known risk factors.

We retrospectively reviewed medical recordsfrom the Department of Nuclear Medicine and Endocrine Oncology, Maria Sklodowska-Curie National Research Institute of Oncology, Gliwice Branch, atertiary center in Poland. We identified 88 patients treated with mitotane in the adjuvant setting between 2002 and 2024. The exclusion criteria wereENSAT stage IV andR2 resection. The date of recurrence was defined as the date ofradiological evidence of a new neoplastic lesion.Recurrence-free survivalwas calculated from thetime of initial surgeryto the first radiological evidence of recurrence. The risk of recurrence was assessed according to ENSAT stage, Ki67, and hormonal activity.

Among the 88 patients, 22 (25%) patients were in the ENSAT IIIstage. Ki67 above 10% was confirmed in 39 patients (44%). In 17 patients (19%), resection was evaluated as R1.Recurrence was confirmed in 50% of patients receiving adjuvant mitotane treatment. However, in the subgroup of patients with Ki 67 between 10 and 20% recurrence rate was 66,7% and in Ki67 >20% reached70%. Regardingthe ENSAT stage,the relapse occurred in11,1% patients withENSAT I stage, 52,4% with the ENSAT II, and 45,4% in the ENSAT III stage.The median time to recurrence was 28 months (range 1-258).66% of recurrences occurred within 24 months. The median follow-up timewas 42 months (range 2-288). In both univariate and multivariate analyses, Ki67 andENSAT stage were factors significantly influencing the risk of recurrence. A significant effect of tumor hormonal activity on the risk of recurrence was confirmed only in univariate analysis.

Reported data show a stillhigh recurrence rate in adrenocortical carcinomapatients with with Ki 67 >10% despite mitotaneadjuvant treatment.The results raisethe need for more individualized and maybe more aggressive adjuvant treatmentin adrenocortical carcinoma patients with high Ki67.

EP906 - ECE_2666 - Surgical management of ectopic Cushing syndrome from a pulmonary carcinoid supported by intraoperative ACTH monitoring

Agata Pokrzywa[1], Janusz Pachucki[2], Jan Domański[2,3], Zuzanna Roszkowska[4], Lukasz Koperski[5], Dariusz Wąsowski[6], Malgorzata Bobrowicz[2] and Urszula Ambroziak[2]

[1]Department of Internal Medicine and Endocrinology, University Clinical Center of the Medical University of Warsaw, Warsaw, Poland; [2]Department of Internal Medicine and Endocrinology, Medical University of Warsaw, Warsaw, Poland; [3]Doctoral School of the Medical University of Warsaw, Medical University of Warsaw, Warsaw, Poland; [4]Student Scientific Club "Endocrinus" Affiliated to the Department of Internal Medicine and Endocrinology, Medical University of Warsaw, Warsaw, Poland; [5]Department of Pathology, Medical University of Warsaw, Warsaw, Poland; [6]Department of Thoracic Surgery, National Medical Institute of the Ministry of the Interior and Administration, Warsaw, Poland

Introduction: The crucial element in the management of Cushing's syndrome (CS) is the establishment of the source of hormonal excess, thus enabling proper treatment. In cases of ectopic CS, however, this task is challenging as illustrated by the present case.

Case Presentation: A 36-year-old man was referred to the Endocrinology Department for the evaluation of hypercortisolemia. On admission he reported 15-kg weigh gain and muscle mass loss, and presented with overt cushingoid features (facial rounding and plethora and violaceous striae on the abdomen and upper limbs) and hypertension (180/110 mmHg). Biochemical testing confirmed hypercortisolemia with elevated urinary free cortisol (UFC): 3623 ug/24 h, elevated night salivary cortisol: 2.84 ug/dL, morning serum ACTH 115.5 pg/mL and borderline hypokaliemia 3.51 mmol/L. The dynamic testing including high-dose dexamethasone suppression test (HDDST), overnight single-dose metyrapone test and desmopressin stimulation test were performed. In the HDDST there was partial suppression of serum cortisol (to 18.6 ug/dL) and supression of UFC to 130 ug/24 h, in the metyrapone test 80% decrease in serum cortisol and 33% rise in serum ACTH, and in the desmopressin test 13% rise in serum cortisol and 44% rise in serum ACTH. Taking into consideration the results of dynamic tests, the Cushing's disease (CD) was suspected, however no focal abnormality was detected on contrast-enhanced pituitary MRI. Chest CT revealed an irregular 8×6 mm contrast-enhancing nodule in segment 3 of the left lung. The decision was made to apply visible tumor resection strategy, assuming that the lung lesion is the source of the hormonal excess. Intraoperative ACTH level monitoring was performed to support the diagnosis. The patient underwent thoracoscopic wedge resection of a suspicious lesion. A marked ACTH surge instead of decline was observed after excision, and intraoperative pathology revealed a neuroendocrine tumor near the resection margin. The procedure was therefore extended to an upper lobectomy, after which ACTH levels showed a rapid and sustained decline. After surgery, the patient experienced weight loss and normalization of arterial blood pressure with biochemical normalization consistent with remission.

Conclusions: This case highlights the diagnostic challenges associated with ectopic CS, particularly in situations in which endocrine test results mimic those of CD and imaging studies are non-definitive. Intraoperative ACTH measurement may serve as an excellent tool to navigate the location of a tumor and confirm the total resection.

Abstract citation ID: lvag096.1205

EP907 - ECE_1299 - Predominantly noradrenaline-producing adrenal phaeochromocytoma in a 24-year old presenting with neurological and cardiovascular symptoms

Nicholas Lo and Zhi Wen Loh

Department of Endocrinology, Tan Tock Seng Hospital, Singapore, Singapore

A young man presented to the Emergency Department with a thunderclap headache, described as the worst headache of his life. He did not have any significant past medical history but had a strong family history of young hypertension, with his brother and father having been first diagnosed with hypertension at a young age. Physical examination was unremarkable but vitals monitoring showed paroxysms of hypertension with systolic blood pressure >200 mmHg.

Secondary hypertension work up showed a right suprarenal mass first noted on an ultrasound renal artery doppler scan. CT adrenals showed 2 nodules of the right adrenal, one 4.3 cm and the other 2.5 cm in diameter. The left adrenal was normal. Hormonal evaluation with 2 samples of 24-hour urine catecholamines and metanephrines showed raised noradrenaline and normetanephrines more than 10 times the upper limit of normal. Urine adrenaline levels were normal and urine metanephrine levels were mildly elevated only in the first sample. A Gallium 68-DOTATATE scan was performed to evaluate for metastases and other sources of noradrenaline secretion, which showed tracer avid right adrenal nodules suspicious for phaeochromocytoma and no evidence of distant metastases. The diagnosis of a solitary right adrenal pheochromocytoma was made.

The patient was treated with pre-operative alpha blockade with phenoxybenzamine, and atenolol was added later on due to reflex tachycardia the patient experienced. The right adrenal gland was resected with an open right adrenalectomy and repeat 24-hour urine catecholamines and metanephrines showed normalization post-operatively.

Noradrenaline-producing adrenal phaeochromocytomas such as in this case are an unusual presentation as phaeochromocytomas originating from the adrenal medulla usually primarily secrete metanephrines. This is due to the presence of the enzyme phenyl ethanolamine N-methyltransferase (PNMT) exclusively located in the adrenal glands, regulated by cortisol, which converts noradrenaline to adrenaline. Moreover the clinical presentation of this patient was atypical showing paroxysms of hypertension. Noradrenaline-producing phaeochromocytomas typically show sustained hypertension, while adrenaline-producing tumours typically show paroxysms of hypertension.[1]

EP908 - ECE_2080 - Aggressive multisystem MEN2A due to a RET p.Cys634Trp mutation: recurrent pheochromocytoma, metastatic medullary thyroid carcinoma, and primary hyperparathyroidism

Ana Khvedelidze[1], Mariam Bardadze[2], Lika Tetradze[2], Nino Gvajaia[2], Nikoloz Tepnadze[2] and Tamaz Mgaloblishvili[1]

[1]*American MD (USMD) Program, Tbilisi State Medical University, Tbilisi, Georgia;* [2]*Endocrinology, Tbilisi State Medical University, Tbilisi, Georgia*

Background: Multiple Endocrine Neoplasia type 2A (MEN2A) caused by pathogenic RET mutations is associated with medullary thyroid carcinoma (MTC), pheochromocytoma, and primary hyperparathyroidism. Mutations affecting RET codon 634 are linked to a particularly aggressive phenotype with early onset, metastatic disease, and recurrence. We report a genetically confirmed MEN2A case illustrating the multisystem, recurrent nature of codon 634-associated disease.

Case Presentation: A 55-year-old woman presented with episodic hypertensive crises. Imaging revealed bilateral adrenal masses consistent with pheochromocytoma, supported by markedly elevated plasma metanephrines. Right adrenalectomy confirmed pheochromocytoma with moderate proliferative features; left adrenal disease was managed conservatively. Subsequent longitudinal follow-up demonstrated persistent adrenal lesions and a stable pulmonary nodule.

Biochemical evaluation later revealed hypercalcemia with inappropriately elevated parathyroid hormone levels, hypercalciuria, and nephrolithiasis, consistent with primary hyperparathyroidism. Genetic testing identified a heterozygous RET c.1900C>G (p.Cys634Trp) mutation, confirming MEN2A.

Total thyroidectomy with lymph node dissection demonstrated medullary thyroid carcinoma with lymph node metastases and lymphovascular invasion, alongside incidental papillary thyroid microcarcinomas. Postoperatively, calcitonin and carcinoembryonic antigen levels remained persistently elevated. Functional imaging showed uptake consistent with recurrent pheochromocytoma and probable parathyroid adenomas.

Discussion: This case highlights the aggressive and persistent clinical course associated with RET codon 634 mutations, characterized by bilateral and recurrent pheochromocytoma, metastatic MTC, and biochemical primary hyperparathyroidism. Persistent postoperative calcitonin elevation and recurrent functional imaging findings emphasize the need for vigilant long-term surveillance. Incidental papillary thyroid microcarcinomas may coexist with MEN2A-associated MTC and should not distract from the dominant disease biology.

Conclusions: MEN2A associated with RET p.Cys634Trp mutations can manifest as an aggressive, multisystem, and recurrent endocrine neoplasia syndrome. Lifelong biochemical monitoring, periodic functional imaging, and early genetic screening of relatives are essential to optimize outcomes in affected patients.

EP909 - ECE_2236 - RNA-exosome dysregulation: core and PAXT complexes as novel mediators of MASLD-HCC oncogenesis

María Isabel Pozo-Relaño[1,2,3,4], Víctor J. Fernández-Ramírez[1,2,3,4], Samanta Lozano de la Haba[1,2,3,4], Manuel Rodriguez-Peralvarez[1,5,6], Raul M. Luque[1,2,3,4], Juan Luis López-Cánovas[1,2,3,4] and Manuel D. Gahete[1,2,3,4]

[1]*Maimonides Biomedical Research Institute of Cordoba (IMIBIC), Cordoba, Spain;* [2]*Cordoba, Spain;* [3]*Department of Cell Biology, Physiology and Immunology, University of Cordoba, Cordoba, Spain;* [4]*Reina Sofia University Hospital Cordoba, Spain;* [5]*CIBER Obesity and Nutrition (CIBERobn), Madrid, Spain;* [6]*Department of Hepatology and Liver Transplantation, Reina Sofia University Hospital, Cordoba, Spain*

Metabolic-associated steatotic liver disease (MASLD) has emerged as the primary chronic liver dysfunction worldwide, frequently culminating in the development of hepatocellular carcinoma (HCC). Emerging evidence underscores the critical importance of RNA metabolism and surveillance in liver pathophysiology, where the RNA-Exosome complex plays a decisive role. Nevertheless, the precise molecular mechanisms and the specific contributions of this machinery during the pathological transition from metabolic steatosis to malignancy remain to be fully elucidated.

Our objective was to characterize the dysregulation of various RNA-Exosome complexes across the MASLD-HCC spectrum and to explore their subsequent clinical and functional implications. To this end, we evaluated the expression profile of the RNA-Exosome machinery across 18 independent cohorts (2 retrospective and 16 *in silico*) of MASLD, Metabolic Dysfunction-Associated Steatohepatitis (MASH), MASH-related HCC, HCC and control (normal or adjacent tissue) samples. To identify the most relevant alterations, we employed VIP-score (Variable Importance in Projection) ranking, selecting those complexes that exhibited the most significant dysregulation within tumor samples (Top-10 VIP-score). Clinical associations and Gene Set Enrichment Analysis (GSEA) were complemented by extensive *in vitro* and *in vivo* functional assays through the targeted molecular modulation of representative complex components.

Our results demonstrate a profound and progressive dysregulation of the RNA-Exosome machinery, with a generalized overexpression from early MASLD to HCC. Specifically, the Core and PAXT complexes emerged as the most altered machineries across all cohorts. High expression of these complexes, represented by key components such as EXOSC4 (Core) and ZFC3H1 (PAXT), significantly correlated with poor overall survival, increased invasiveness, and the enrichment of oncogenic pathways like MYC targets and mTOR signaling. In vitro silencing of these specific components significantly reduced tumor aggressiveness parameters (cell proliferation, migration, colony formation, and sphere-forming capacity), whereas their overexpression promoted a more malignant phenotype. Crucially, in vivo studies confirmed the pro-tumorigenic potential of the machinery, where silencing Core components inhibited tumor growth, while its induction significantly increased tumor volume and progression.

In conclusion, our findings demonstrate that the RNA-Exosome machinery, driven by its Core and PAXT complexes, is a critical

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

regulator of the MASLD-HCC axis. This study highlights the entire RNA-Exosome machinery as a promising source of prognostic biomarkers and a novel therapeutic vulnerability in the context of metabolic dysregulations and, specifically, MASLD-HCC.

EP910 - ECE_2626 - Predictors of malignancy in pheochromocytoma and paraganglioma

Mirjana Đukić[1], Ivana Kraljevic[2,3], Mirsala Solak[2], Annemarie Balaško[2], Anja Barac Nekic[2], Tanja Skoric Polovina[2], Karin Zibar Tomsic[2], Hrvoje Popovac[2], Tina Dusek[2,3] and Darko Kastelan[2,3]

[1]Department of Endocrinology, General Hospital „Dr. Ivo Pedišić", Sisak, Croatia; [2]Department of Endocrinology, University Hospital Centre Zagreb, Zagreb, Croatia; [3]School of Medicine, University of Zagreb, Zagreb, Croatia

Background: Pheochromocytomas and paragangliomas (PPGL) are rare neuroendocrine tumours lacking definitive histopathological criteria for malignancy. About 15-20% of PPGLs show malignant potential, necessitating long-term follow-up. This study aimed to identify clinical and biochemical predictors of malignant PPGL.

Methods: A total of 94 patients with PPGL were included. Malignancy was defined by the presence of metastatic disease at initial diagnosis or during follow-up. Tumour size, age at diagnosis, and urinary metanephrines were compared between patients with benign and malignant disease. Time-to-event outcomes were analysed using Kaplan–Meier estimates.

Results: Malignant PPGL was identified in 14/94 (14.9%) patients, with a median follow-up of 77.5 months (IQR 25.5-129.5). Malignant tumours were significantly larger compared to benign (median 77.5 mm vs 50 mm, $P < .001$), and tumour size demonstrated good discriminatory performance for malignancy (ROC AUC 0.810). A tumour size ≥68 mm predicted malignancy with 71% sensitivity and 84% specificity. Patients with malignant PPGL also had higher urinary normetanephrine levels (median 84.28 µmol/dU vs 12.1 µmol/dU; ROC AUC 0.875), with a cut-off of 34.1 µmol/dU corresponding to 82% sensitivity and 83% specificity. No significant difference in age at diagnosis was observed between benign and malignant PPGL.

Conclusions: Large tumour size and markedly increased urinary normetanephrines may serve as predictive markers of malignant PPGL, warranting closer follow-up.

EP911 - ECE_2884 - Anti-secretory and anti-proliferative actions of next-generation dual subtype 2 and 5 somatostatin receptor ligands in neuroendocrine tumor models

Margarita Bistika[1], Francesco Fedeli[1], Francesco Ascione[1], Alessandro Marangelo[2], Fabio Guzzi[1], Joerg Schrader[3], Alan Harris[4] and Natalia Pellegata[1]

[1]1Department of Biology and Biotechnology "L. Spallanzani", University of Pavia, Pavia, Italy; [2]Helmholtz Munich, Neuherberg, Germany; [3]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [4]Grossman School of Medicine, New York, United States

Introduction: First-generation somatostatin receptor ligands (SRLs) mainly target SSTR2, whereas neuroendocrine tumors (NETs) often express multiple SSTR subtypes, frequently SSTR5. Dual SSTR2/SSTR5 targeting may enhance anti-hormonal and antiproliferative effects. We evaluated five novel dual SSTR2/SSTR5 agonists (SMTR-001 to SMTR-005) in preclinical NET models to assess their anti-secretory and anti-proliferative effects in representative preclinical NET models.

Methods: The human insulinoma-derived NT-3 cell line and the murine AtT-20 corticotroph cell line, both expressing SSTR2 and SSTR5, were treated with 1-50 nM of the novel SRLs or reference agents (octreotide, pasireotide). Insulin and ACTH secretion were quantified by ELISA and cell viability was measured after 72 h (AtT-20) or 5 days (NT-3). A putative lead compound, SMTR-002, was further tested in 3D spheroid cultures of NT-3 cells. Intracellular cAMP modulation was evaluated after forskolin stimulation in AtT-20 cells.

Results: In NT-3 cells, all dual SRLs inhibited insulin secretion (−65% to −95%), with SMTR-002, SMTR-004, and SMTR-005 showing significantly greater inhibition than octreotide at 10 nM. Each compound also reduced cell proliferation (−30% to −44%). In 3D cultures of NT-3 cells, SMTR-002 reduced insulin secretion to a degree comparable to octreotide but, unlike octreotide, significantly decreased cell proliferation. In AtT-20 cells, four novel SRLs significantly reduced ACTH secretion (-11% to -69%), with SMTR-001 and SMTR-004 showing efficacy comparable to pasireotide. SMTR-002 and SMTR-003 demonstrated the greatest antiproliferative effects (−53% and −48% at 10 nM). In AtT-20 cells, SMTR-002 also suppressed forskolin-induced cAMP accumulation more strongly than reference SRLs.

Conclusions: Dual SSTR2/SSTR5 agonists exhibit antisecretory and antiproliferative activity in NET models that was similar or even superior to reference SRLs. These findings support their further development as next-generation SRLs for SSTR2/5-expressing tumors.

EP912 - ECE_3058 - Multianalyte or multiple monoanalytes? A comparison of serum visfatin and chromogranin A as diagnostic biomarkers in neuroendocrine tumors

Paweł Komarnicki, Jan Musiałkiewicz, Adam Maclejewski, Michalina Czupińska, Elżbieta Wrotkowska, Paweł Gut and Marek Ruchala

Department of Endocrinology, Metabolism and Internal Diseases, Poznan University of Medical Sciences, Poznan, Poland

Background: Chromogranin A (CgA) remains the most widely used Neuroendocrine Tumor (NET) biomarker, despite its suboptimal sensitivity and specificity. Initial reports about serum visfatin, an adipocytokine involved in inflammation and metabolic regulation, demonstrate moderate diagnostic performance in NETs versus healthy controls. However, its performance has not been directly compared with established NET biomarkers.

Aims: To compare the diagnostic performance of serum visfatin and chromogranin A in pancreatic and small intestinal

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

neuroendocrine tumors, and to evaluate whether their combined assessment improves diagnostic discrimination.

Methods: Serum visfatin and CgA levels were analyzed in 77 patients with NETs (33 pancreatic NETs, 44 small intestinal NETs) and 29 healthy controls. Group comparisons were performed using Mann–Whitney U tests. Diagnostic performance was evaluated using receiver operating characteristic (ROC) curve analysis. Paired ROC curves were compared using DeLong's test, and classification performance between biomarkers was assessed using McNemar's test.

Results: Median visfatin and CgA concentrations were significantly higher in all NET patients compared with controls ($P = .007$ and $P = .018$, respectively) as well as in pancreatic NETs ($P = .019$ for visfatin; $P = .018$ for CgA). In small intestine NETs, only visfatin showed a significant increase ($P = .007$), while CgA did not ($P = .062$). Visfatin and CgA demonstrated comparable diagnostic performance for NETs versus controls (AUC 0.68 [95% CI 0.57-0.78] vs 0.65 [0.55-0.75]), with no significant difference in DeLong's test ($P = .72$). Similarly, no differences in ROC performance were observed between biomarkers in panNETs ($P = .96$) or siNETs ($P = .57$). A combined visfatin–CgA model improved discrimination compared with standalone biomarkers (AUC 0.75), although with borderline statistical significance ($P = .08$).

Conclusions: Serum visfatin demonstrates diagnostic performance directly comparable to chromogranin A in NETs and provides more performanceacross tumor subtypes. The improved performance of combined biomarkers suggests a complementary rather than competing role, supporting further evaluation of visfatin as NET biomarker.

EP916 - ECE_1781 - Large symptomatic simple hepatic cysts as the presenting feature of primary neuroendocrine tumor: a diagnostic pitfall

Hitam Hagog Natour[1], Nadim Abu Rashed[2], Pnina Rotman-Pikielny[1,3], Feda Fanadka[2] and Michal Kasher Meron[1,3]

[1]Meir Medical Center, Institute of Endocrinology, Diabetes and Metabolism, Kfar Saba, Israel; [2]Department of Radiology, Meir Medical Center, Kfar Saba, Israel; [3]Gray Faculty of Medical and Health and Sciences, Tel Aviv, Israel

Primary hepatic neuroendocrine tumors (pHNET) represent an exceedingly rare neuroendocrine neoplasm that may present with nonspecific symptoms or be incidentally discovered as a large hepatic mass during imaging for unrelated reasons. We report the case of a 46-year-old woman who presented to the emergency department with persistent abdominal pain and unintentional weight loss. Cross-sectional imaging demonstrated two large cystic lesions (largest measuring 14 cm) involving both hepatic lobes, without apparent solid components, mural nodularity, or radiologic features suggestive of malignancy. Given the benign radiologic appearance, conservative management with clinical surveillance was recommended. However, the patient was lost to follow-up and re-presented one year later with worsening abdominal pain and mild elevation of liver enzymes. Repeat imaging demonstrated slight interval increase in the size of the cystic lesions, prompting surgical unroofing for symptomatic relief.

Histopathological examination and immunohistochemical analysis revealed a Grade 2 neuroendocrine tumor, Ki67 of 3%. Ga-68 DOTATATE PET/CT staging demonstrated widespread metastatic disease involving multiple lymph nodes and osseous sites, without identification of an extrahepatic somatostatin receptor-expressing lesion. She was treated with somatostatin analog therapy, showing stable disease on 6-month follow-up imaging. The patient remained clinically asymptomatic for carcinoid syndrome throughout the disease course.

This case highlights a diagnostic pitfall: pHNET may present as predominantly cystic lesions that mimic benign entities on conventional imaging, potentially delaying diagnosis. Maintaining a low threshold of suspicion for malignancy in large or symptomatic hepatic cysts is essential for timely diagnosis and appropriate management.

EP917 - ECE_2843 - Primary thyroid lymphomas—from suspicion to confirmation

Andreea-Cristina Stanciu, Ionela Baciu, Dan Alexandru Niculescu, Dumitru Alina Maria, Daniela Balosache, Anda Dumitraşcu, Dana Cristina Terzea and Catalina Poiana

Bucuresti, Romania

Introduction: Primary thyroid lymphoma (PTL) is a rare malignancy of the thyroid gland, accounting for less than 5% of all thyroid cancers. Due to its rapid growth and compressive symptoms PTL often mimics aggressive thyroid carcinomas, particularly anaplastic thyroid carcinoma, making early diagnosis challenging but crucial, given its significantly better prognosis when treated appropriately.

Objectives: To highlight the diagnostic challenges, clinical presentation, and therapeutic outcomes of primary thyroid lymphoma through a case series, emphasizing the importance of appropriate biopsy techniques and multidisciplinary management.

Methods: We present a case series of three elderly patients (two males aged 78 and 85 years, and one female aged 75 years) admitted into our clinic in the last 3 years for rapidly enlarging cervical thyroid masses associated with compressive symptoms such as dysphagia, dysphonia, and dyspnea. All patients had biochemical and imaging features suggestive of autoimmune thyroid disease. Diagnostic workup included thyroid function tests, autoantibody assessment, neck ultrasound, computed tomography or magnetic resonance imaging, fine-needle aspiration biopsy (FNAB), core needle biopsy, histopathology and immunohistochemistry. Treatment regimens and outcomes were documented.

Results: Clinical presentation with rapid onset of compressive symptoms was highly suggestive of anaplastic thyroid carcinoma and FNAB was non-diagnostic or misleading in all cases, showing either low cellularity or raising suspicion for undifferentiated carcinoma. Definitive diagnosis was established only after core needle biopsy or surgical lymph node excision with

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

immunohistochemically confirmation of the diagnosis. Corticosteroid administration led to rapid symptomatic improvement regarding the compressive symptoms. All patients were referred to hematology and treated with chemotherapy regimens (CHOP or R-CHOP) with favourable clinical and imagistic responses, despite advanced local disease at diagnosis. At the time of this analysis all patients were alive, one of them being in complete remission.

Conclusions: Primary thyroid lymphoma should be suspected in patients presenting with rapidly enlarging thyroid masses especially on a background of autoimmune thyroiditis. FNAB alone is often not sufficient for diagnosis, and core needle biopsy with immunohistochemistry represents the gold standard. Early recognition is essential, as PTL responds well to chemotherapy, even in advanced stages, and unnecessary extensive surgery can be avoided. Multidisciplinary collaboration is key to optimizing outcomes in this rare but treatable condition.

EP918 - ECE_2056 - Correlation of loss of ATRX expression with scintigraphic imaging studies in pancreatic neuroendocrine neoplasms

Marina Tsoli[1], Maria Panagaki[1], Christina Papadima[1], Georgios Kyriakopoulos[2,3] and Gregory Kaltsas[1]
[1]*Endocrine Unit, 1st Department of Propaedeutic Internal Medicine, Laiko Hospital, National and Kapodistrian University of Athens, Athens, Greece;* [2]*Department of Histopathology, Evagelismos General Hospital, Athens, Greece;* [3]*Athens, Greece*

Background: Somatic inactivating mutations of ATRX (α thalassemia/mental retardation syndrome X-linked) in pancreatic neoplasms (panNENs) are associated with aggressive phenotype and are considered an independent prognostic factor of poor overall survival.

Aims: The aim of this study was to evaluate the correlation of ATRX loss, as assessed by immunohistochemistry, with scintigraphic imaging data in patients with panNENs.

Materials and Methods: We collected retrospectively the data of patients with panNENs in whom immunohistochemistry for ATRX loss was performed and we evaluated the relationship of genetic alterations with nuclear imaging studies.

Results: We analyzed the data of 81 patients (31 female) with mean age (±SD) at diagnosis 56.6 ± 11.8 years. 17 patients had grade 1 panNEN, 55 grade 2 and 9 well-differentiated grade 3 panNEN. 38 (46.9%) patients suffered from stage IV disease. 26 (32.1%) patients presented loss of ATRX. 76 patients (34.2% with loss of ATRX) had positive somatostatin receptor scintigraphy. No significant difference was observed, regarding the SRS positivity, in patients with loss or retain of ATRX ($P = .112$). 47 patients (8 with loss of ATRX) underwent an FDG-PET/CT. Significantly higher percentage of patients with grade 3 pNEN had positive FDG-PET/CT compared to patients with grade 1 or 2 pNEN ($P = .01$). No significant difference was observed, regarding the FDG-PET/CT positivity, in patients with loss or retain of ATRX ($P = .337$). No significant correlation was observed between the loss of ATRX and FDG-PET/CT positivity (r-0.14, $P = .347$).

Conclusions: The loss of ATRX does not seem to affect the results of scintigraphic imaging studies in patients with panNENs.

EP919 - ECE_3814 - Therapeutic challenges in medullary thyroid carcinoma with paraneoplastic Cushing syndrome

Stanescu Laura-Semonia[1,2], Andrei Muresan[2], Teodor Constantin[2], Dumitru Ioachim[2] and Corin Badiu[1,2]
[1]*Endocrinology, Endocrinology IV, "C Davila" University of Medicine and Pharmacy, Bucharest, Romania;* [2]*Research Department, Endocrinology IV, C.I. Parhon National Institute of Endocrinology, București, Romania*

Introduction: Medullary thyroid carcinoma is a rare neuroendocrine malignancy, and in fewer cases associates paraneoplastic Cushing's syndrome (PCS) through ectopic secretion of ACTH. Severe hypercortisolism drives rapid clinical deterioration, substantial morbidity, and often reflects aggressive tumor biology. We describe four cases that illustrate the heterogeneous presentation, complex biochemical evolution, and demanding multimodal management.

Case 1: A 70-year-old woman was referred with metastatic MTC diagnosed after biopsy of a left axillary lymph node. She presented with dyspnea, proximal muscle weakness, and marked hypokalemia, with calcitonin 174 000 pg/mL, CEA > 1000 ng/mL, ACTH 156 pg/mL, cortisol 58 µg/dL. Imaging revealed extensive cervical, mediastinal, hepatic, and pulmonary metastases, hyperplastic adrenal glands, and a normal pituitary. Germline RET testing was negative. After thyroid surgery, tumor immunostaining confirmed ectopic ACTH production, then vandetanib was initiated to 300 mg/day, resulting in biochemical improvement (calcitonin 82 000 pg/mL, ACTH 28 pg/mL, cortisol 13 µg/dL).

Case 2: A 53-year-old man presented with a rapidly enlarging cervical mass, hypertension, hyperglycemia and cushingoid habitus. Initial biochemical evaluation demonstrated MTC with PCS: calcitonin 1950 pg/mL, CEA 97.9 ng/mL, ACTH 115 pg/mL, elevated urinary free cortisol (>1590 µg/24 h). Imaging revealed an invasive right-sided thyroid mass, normal adrenals and pituitary. He underwent total thyroidectomy with extensive neck dissection; Immunohistochemical examination confirmed ectopic ACTH and somatic RET M918T mutation identified. Vandetanib was initiated for persistent MTC and PCS, with improvement of biochemical markers (calcitonin 58.3 pg/mL, CEA 13.7 ng/mL, ACTH 15.07 pg/mL, cortisol 10.46 µg/dL).

Case 3: A 20-year-old man initially underwent left adrenalectomy for presumed adrenal Cushing syndrome, but ACTH-dependent hypercortisolism soon recurred with a new pituitary micronodule, leading to pituitary radiotherapy and later right adrenalectomy. Six months later, a thyroid and mediastinal mass were detected, and biopsy confirmed MTC, presumed to be the ectopic ACTH source. He underwent cytoreductive thyroidectomy with mediastinal mass resection, with preoperative calcitonin >900 pg/mL and ACTH 88 pg/mL.

Case 4: A 53-year-old woman presented with metastatic MTC and PCS, calcitonin >2000 pg/mL, ACTH 153.8 pg/mL, morning cortisol 49.81 µg/dL, and marked hypokalemia. CT imaging revealed an invasive right-lobe thyroid mass with cervical lymph-node, hepatic, and bone metastases, hyperplastic adrenal glands, and a normal pituitary. Medical stabilization was unsuccessful, necessitating bilateral adrenalectomy as rescue therapy.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Conclusions: MTC-associated PCS remains a rare, life-threatening presentation marked by severe biochemical instability and complex management. Early recognition and rapid cortisol control are essential, but outcomes improve significantly when targeted systemic therapies are available.

EP920 - ECE_3044 - Improving thyroid nodule malignancy prediction on ultrasound through contrastive learning and curriculum-based fine-tuning

Ana-Silvia Corlan[1,2,3], Costi Flavia[4] and Darian Onchis[2]
[1]*Internal Medicine, Endocrinology, University of Medicine and Pharmacy Timisoara, Timisoara, Romania;* [2]*Faculty of Sciencies, PhD student, Computer Science, West University of Timisoara, Timisoara, Romania;* [3]*Artificial Intelligence, Endocrinology, West University of Timișoara, University of Medicine and Pharmacy Timisoara, Timișoara, Romania;* [4]*Faculty of Sciencies, Computer Science, West University of Timisoara, Timisoara, Romania*

Background: Ultrasound is the first-line imaging modality for thyroid nodules, yet malignancy risk stratification remains challenging due to inter-observer variability and the limited availability of biopsy-proven annotated datasets. We aimed to evaluate whether contrastive self-supervised learning, combined with confidence-based curriculum fine-tuning, can improve data-efficient thyroid nodule classification on ultrasound.

Methods: We implemented a contrastive learning framework using a SimCLR-style architecture with a ResNet encoder to learn ultrasound-specific feature representations without labels. Self-supervised pretraining was performed using ultrasound-appropriate augmentations (ROI-based cropping, horizontal flipping, noise injection, and intensity scaling). The pretrained encoder was subsequently fine-tuned for malignancy classification on the publicly available TN5000 dataset (5000 thyroid nodules with cytological or histopathological confirmation).

To further improve training stability and generalization, we incorporated **confidence-based curriculum learning**, whereby training samples were progressively introduced from high-confidence ("easy") to low-confidence ("hard") cases based on model-predicted malignancy probabilities. Model performance was evaluated on a held-out test set and compared with a baseline convolutional neural network trained from scratch.

Results: Contrastive self-supervised pretraining substantially improved feature quality, yielding clearer separation between benign and malignant nodules in the learned embedding space. On the TN5000 test set, the SimCLR-initialized model with staged fine-tuning achieved a higher discriminative performance than the baseline CNN (AUROC 0.905 vs 0.880).

Incorporation of confidence-based curriculum learning further stabilized optimization and improved the sensitivity–specificity trade-off. At a fixed decision threshold of 0.5, the contrastive model demonstrated fewer false-positive classifications among benign nodules while maintaining high sensitivity for malignancy detection. Overall, the combined approach resulted in a more favorable clinical error profile compared with conventional supervised training.

Conclusions: Contrastive self-supervised learning enables robust feature extraction from unlabeled thyroid ultrasound data and significantly enhances malignancy risk stratification when combined with large annotated datasets such as TN5000. The addition of confidence-based curriculum learning further improves training efficiency and generalization in this noisy imaging domain. This data-efficient strategy may complement existing structured reporting systems and support more consistent AI-assisted decision-making in thyroid imaging.

Limitations: The study is limited by reliance on a single public dataset for labeled fine-tuning and the absence of prospective multi-center validation.

EP922 - ECE_1974 - Efficacy and tolerability of fezolinetant administration after current diagnosis of prostate cancer in an elderly man with acquired childhood-age hypergonadotropic hypogonadism

Massimo Giusti[1,2,3,4] and Giulia Graziani[5]
[1]*Endocrine Unit, Centro Clinico Diagnostico Priamar, Savona, Italy;* [2]*Department of Internal Medicine, University of Genoa, Genoa, Italy;* [3]*Centro Clinico Diagnostico Priamar, Endocrine Unit, Savona, Italy;* [4]*Centro Clinico Diagnostico Priamar, Savona, Italy;* [5]*Endocrine-Metabolic Unit, ASL2 Savonese, Savona, Italy*

Background: Vasomotor symptoms (VMS) are the most frequently described effects of androgen withdrawal in men. Testosterone (T) is the standard treatment for VMS, but suspected or diagnosed prostatic cancer often limit its use.

Case Presentation: An 88-year-old man came to our attention for uncomfortable VMS, mainly nocturnal sweating. VMS were long-standing and had been alleviated by oral/transdermal T. The man had undergone surgery for cryptorchidism at the age of 6 years; at 18 years of age he was deemed fit for military service, and at 25 years of age was married. Male infertility was subsequently documented. After 2013, he was unavailable for endocrinological examination, and T was discontinued.

Objective and Clinical Data: Normal male behaviour, glabrous facies and few pubic hairs. Empty scrotal sac and no evidence of testes on imaging. Low serum T (0.25 ng/mL), high FSH (31 mIU/mL) and normal-for-age PSA (3.86 ng/mL) were found.

Intervention: In November 2023, the patient started monthly (250 mg i.m.) T administration, which relieved VMS. After 3 months, plasma T was 2.0 ng/mL, but PSA had risen to 17.5 ng/mL. T was stopped. Multi-parametric MRI, followed by prostate fusion needle biopsy (July 2024) were diagnostic for prostate cancer (Gleason score 3+4). Leuprolide acetate and bicalutamide were started.On anti-androgenic drugs, plasma T was < 0.1 ng/mL, PSA 0.8 ng/mL, LH <1 mIU/mL, and FSH 22 mIU/mL. In July 2025, the patient provided written consent to start fezolinetant (45 mg/day orally), an NK3R-antagonist. He was asked to register relevant VMS daily, have liver function and hormones checked, and fill in the self-rating Kellner Symptoms Questionnaire (KSQ).

Results: On fezolinetant, liver function remained normal and FSH decreased to 3 mIU/mL, while PSA (<0.1 ng/mL), plasma T (<0.1 ng/mL) and LH (<1 mIU/mL) remained unchanged.The median number of major VMS decreased from 9/week to 0/week. During brief discontinuation of the drug, due to its temporary unavailability, VMS did not exceed 3/week.All KSQ scales (anxiety,

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

depression, somatization, hostility) improved. The greatest improvement was in somatization, with a 78% reduction. No structural progression of prostate cancer was observed.

Comment: Fezolinetant was well tolerated and efficacious in this man, now 91 years old. VMS, particularly nocturnal sweating disappeared and quality of life improved markedly. Interestingly, fezolinetant seems to increase the suppression of the hypothalamus-pituitary-gonadal axis (FSH) due to anti-androgen treatment. Long-term follow-up will be necessary in order to ascertain the impact of fezolinetant on prostate cancer progression.

EP924 - ECE_3201 - Thyroid metastasis from renal cell carcinoma: an uncommon clinical presentation

Carlos Lopez Sarmiento, Maria Elena Jerez Arzola, Pablo Delgado Moya, Jonay Rodríguez Morales, Virginia Collantes Alcalá, Diego García Gonzalez, Bárbara Alonso Moreno, Covandonga Rodríguez Mangas and Said Mohamed Said
Hospital Universitario Doctor José Molina Orosa, Arrecife, Spain

Introduction: Clear cell renal cell carcinoma (ccRCC) most frequently metastasizes to the lungs, bones, and liver, with thyroid involvement being rare.

Case Description: A 64-year-old woman with a history of arterial hypertension, migraine with aura, allergic asthma, scoliosis, and spondyloarthrosis, as well as a left hemithyroidectomy in 2000 for a benign nodule and Hashimoto's thyroiditis. She had multiple drug allergies and a history of severe intolerance to octreotide. In December 2015, she was diagnosed with G2 ccRCC, stage pT2aNx, and underwent right radical nephrectomy with laterocaval lymphadenectomy.

In March 2019, she developed oligometastatic gastric recurrence, treated with subtotal gastrectomy with Roux-en-Y reconstruction, D1 lymphadenectomy, and cholecystectomy. Subsequently, she developed severe dumping syndrome and malabsorption, resulting in severe caloric-protein malnutrition requiring multiple admissions to Endocrinology, prolonged parenteral nutrition support, and close follow-up due to sarcopenia risk. After a slow initial course, her nutritional status progressively improved, allowing discontinuation of home parenteral nutrition in 2020.

During oncological follow-up, imaging studies between 2019 and 2021 showed no evidence of active disease. However, in April 2024, the patient noticed the sudden appearance of a painful, rapidly enlarging right cervical mass, associated with compressive symptoms (dyspnea, orthopnea, and dysphagia). Cervical ultrasound revealed a nodular right thyroid with a predominantly cystic dominant lesion (TIRADS 2) and two solid nodules (TIRADS 4). Fine-needle aspiration (FNA) of the solid nodules was benign, but core needle biopsy of the cystic lesion confirmed thyroid metastasis from clear cell renal carcinoma, with immunohistochemistry positive for vimentin, CD10, and cyclin D1, and negative for thyroglobulin.

The case was evaluated by a multidisciplinary head and neck tumor board, and palliative decompressive surgery was recommended due to compressive symptoms. In November 2024, a right hemithyroidectomy was performed, confirming histopathologically a 2×1.5 cm thyroid metastasis from ccRCC with free surgical margins. Concomitant pulmonary micrometastases were also identified and confirmed by biopsy.

Given stage IV disease and an intermediate IMDC score, first-line systemic therapy with sunitinib was initiated, with dose adjustments for hematologic and gastrointestinal toxicity. At subsequent follow-up, the patient shows partial response with clinical stability, continuing joint monitoring by Oncology and Endocrinology.

Conclusions: Thyroid metastases from ccRCC typically appear years after the initial diagnosis and can mimic benign thyroid disease. This case highlights the rare thyroid localization of renal cell carcinoma metastasis and the associated nutritional management challenges.

EP925 - ECE_2224 - When obesity masks hypoglycaemia: insulinoma presenting with rapid weight gain

Arfa Ahmed Assad, Shahroz Azhar, Huriya Siddique, Muhammad Murtaza Shafqat, Hira Irfan and Ayesha Amin
Endocrinology, Internal Medicine & Endocrinology, Pakistan Kidney And Liver Institute & RC, Lahore, Pakistan

Background: Insulinomas are rare pancreatic neuroendocrine tumors, occurring in 1-4 per million individuals and accounting for 1-2% of pancreatic neoplasms. Diagnosis is often delayed due to their variable and nonspecific presentations. Patients may present with hypoglycemia or neuroglycopenic symptoms, which are frequently misattributed to neuropsychiatric, cardiac, or neurological disorders, prolonging the time to diagnosis. We report a case in which rapid, unexplained weight gain was the predominant presenting feature, ultimately leading to the diagnosis of a pancreatic insulinoma.

Case Presentation: A 35-year-old male presented to an obesity clinic with a 40 kg weight gain over two months, resulting in a body mass index of 43.8 kg/m^2. He had no known comorbidities, and initial evaluation including thyroid function tests, cortisol, and routine metabolic panels was unremarkable. On further history, he reported intermittent dizziness, tremors, palpitations, and two episodes of transient loss of consciousness. Laboratory evaluation during symptomatic episodes revealed hypoglycemia with a plasma glucose of 42 mg/dL. Further testing showed a low HbA1c of 3.5%, with inappropriately elevated insulin (163 pmol/L) and C-peptide (10.6 ng/mL), confirming endogenous hyperinsulinemic hypoglycaemia. Sulfonylurea screening was negative and a supervised 72-hour fasting test reproduced hypoglycemia with adrenergic and neuroglycopenic symptoms, fulfilling Whipple's triad. Contrast-enhanced MRI revealed a 2.8 cm well-circumscribed lesion in the pancreatic tail, hypointense on T1 and hyperintense on T2 sequences, with homogeneous arterial enhancement, initially raising suspicion for a solid pseudopapillary neoplasm. Endoscopic ultrasound localized a hypervascular mass consistent with insulinoma. Evaluation for multiple endocrine neoplasia type 1 was negative, with normal serum calcium, parathyroid hormone, prolactin, and pituitary hormone levels.The patient underwent laparoscopic enucleation, and histopathology confirmed a well-differentiated

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

benign pancreatic neuroendocrine tumor with strong immunopositivity for insulin, chromogranin A, and synaptophysin. Postoperatively, hypoglycemia resolved completely, body weight decreased from 113 kg to 84 kg over four months, and HbA1c normalized to 5.4%, with transient mild hyperglycemia resolving conservatively. He continues routine follow-up with fasting glucose monitoring and imaging surveillance.

Conclusions: This case highlights the importance of comprehensive diagnostic evaluation in patients presenting with rapid weight gain, including the consideration of neuroendocrine tumors when clinical history or associated symptoms suggest hypoglycemia. Meticulous history-taking and attention to subtle neuroglycopenic or adrenergic features can prevent delayed diagnosis and avoid potentially life-threatening complications.

EP927 - ECE_1191 - The spectrum of endocrine paraneoplastic syndromes in neuroendocrine neoplasms: real-world data from a tertiary referral center

Christina Papadima[1,2], Maria Evangelia Koloutsou[1,2], Marina Tsoli[1,2], Maria Panagaki[1,2], Georgios Kyriakopoulos[3,4], Aggeliki Karapanagioti[1,2], Anna Angelousi[1,2] and Gregory Kaltsas[1,2]

[1]European Reference Network on Rare Endocrine Conditions (ENDO-ERN), Laikon General Hospital, National and Kapodistrian University of Athens, Athens, Greece; [2]First Department of Propaedeutic and Internal Medicine, Athens, Greece; [3]Evangelismos Hospital, Athens, Greece; [4]Department of Pathology, Athens, Greece

Introduction: Endocrine paraneoplastic syndromes (EPNS) are rare but clinically relevant manifestations of neuroendocrine neoplasms (NENs), resulting from ectopic hormone secretion, complicating diagnosis, delaying tumor identification, and adversely affecting patient management and morbidity. Although EPNS have been reported in up to 8-15% of patients with NENs, real-world data regarding the prevalence of clinically overt EPNS, timing of presentation, and impact on management across several NEN subtypes remain limited.

Methods: Retrospective analysis of 1218 patients with histologically confirmed NENstreated at our center. The cohort comprised 767 pancreatic NENs, 214 thoracic NENs (lung and thymus), 153 NENs of unknown primary origin (UOP), and 84 pheochromocytomas/paragangliomas. Demographic characteristics, histologic features, type and timing of EPNS onset, therapeutic strategies, and follow-up outcomes were systematically collected and analyzed.

Results: EPNs were identified in 21/1218 patients (1.7%), all with well-differentiated NENs (mean age 65 years; 16 males). Ectopic adrenocorticotropin (ACTH) secretion was observed in 15 (71%), parathyroid-hormone-related-peptide (PTHrP) secretion in 4 (19%), and calcitonin secretion in 2 patients (9%) respectively.

The most frequent primary tumor site was pancreatic NEN in 10 patients (48%, 1.3% of pancreatic NENs), followed by thoracic primaries in 9 patients (42%, 4.2% of thoracic NENs) (6 lung and 3 thymus). One patient had a pheochromocytoma, while another had a tumor of UOP. EPNS-related clinical features preceded tumor diagnosis and prompted further diagnostic evaluation in 9 patients (42.9%), were synchronous to diagnosis in 5 patients (23.8%) and developed meta-chronously in 7 patients (33.3%).

First-line surgical treatment was performed in 11 patients (52%). Patients with unresectable or metastatic disease (15 patients, 71%) required multimodal non-surgical management, including molecularly targeted therapies, systemic chemotherapy, peptide receptor radionuclide therapy, and radiotherapy. Despite optimized medical treatment, 5 patients (24%) ultimately underwent bilateral adrenalectomy for refractory Cushing's syndrome. During follow-up, 2 patients (10%) remained disease-free after first-line surgery, while 9 patients (43%) died, reflecting the high morbidity associated with EPNS.

Conclusions: EPNs are associated with high clinical complexity and heterogeneous outcomes. ACTH secretion and pancreatic neuroendocrine tumors predominated in this cohort. Compared with the existing literature, the lower prevalence observed likely reflects the inclusion of clinically overt endocrine paraneoplastic syndromes only, excluding subclinical hormone secretion and isolated immunohistochemical hormone expression.Early recognition, prompt hormonal control, and multidisciplinary management are essential to optimize patient outcomes. Real-world data from specialized centers provide valuable insights into these rare conditions.

EP928 - ECE_2155 - Outcomes and prognostic factors in ectopic cushing syndrome: the experience of two tertiary referral centers

Gustaw Laskowski[1], Zuzanna Roszkowska[2], Lukasz Dzialach[1], Malgorzata Bobrowicz[2], Urszula Ambroziak[2] and Przemysław Witek[1]

[1]Department of Internal Medicine, Endocrinology, and Diabetes, Warszawski Uniwersytet Medyczny, Warszawa, Poland; [2]Department of Internal Medicine and Endocrinology, Warszawski Uniwersytet Medyczny, Warszawa, Poland

Ectopic Cushing syndrome (ECS) is an uncommon cause of ACTH-dependent Cushing syndrome associated with high morbidity and mortality. Systemic inflammation-based scores (SIBS) are accessible prognostic tools in oncology, but their value in ECS remains uncertain.

We performed a retrospective observational study of patients with ECS managed at two tertiary endocrinology referral centers in Warsaw, Poland, between February 2004 and October 2025. Demographic, tumor-related, clinical, and biochemical variables at diagnosis were extracted from a dedicated database. SIBS (neutrophil-to-lymphocyte ratio [NLR], platelet-to-lymphocyte ratio [PLR], lymphocyte-to-monocyte ratio [LMR], and systemic immune-inflammation index [SII]) were calculated from baseline laboratory parameters. To minimize confounding by acute inflammation, patients with C-reactive protein (CRP) >5 mg/L were excluded from SIBS analyses. The final cohort included 30 patients.

Primary tumor sites were the lung (60%), pancreas (10%), thymus (3%), bladder (3%), adrenal gland (3%), and occult origin (20%). Metastatic disease was present in 65% of patients. Survival was markedly heterogeneous, with a median survival of 50.61 days. Tumor resection was performed in 45% and was associated with improved survival compared with non-surgical management (log-rank test, $P = .0119$; HR = 0.225, $P = .0230$). Higher ACTH, morning cortisol, and late-night cortisol

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

concentrations were associated with increased mortality risk (HR = 1.002, $P = .0014$; HR = 1.023, $P = .0003$; HR = 1.027, $P = .0037$). Interestingly, patients who developed metastatic disease demonstrated significantly higher ACTH levels compared to those without metastases ($P = .0015$). After excluding CRP-elevated cases, NLR correlated with ACTH (r = 0.575; $P = .0157$) and morning cortisol (r = 0.658; $P = .0041$), while PLR correlated inversely with ACTH (r = −0.607; $P = .0098$). Notably, none of the evaluated SIBS predicted survival, although the strongest non-significant trend was observed for NLR ($P = .0994$).

ECS is characterized by frequent metastatic disease, severe hypercortisolism, and poor early survival. Surgical resection, when feasible, is associated with significantly better outcomes. Baseline ACTH concentration and the severity of hypercortisolism may have prognostic relevance for overall survival. Hormonal state correlates with inflammatory indices, but SIBS did not independently predict survival in this cohort. However, larger datasets are required to clarify their prognostic significance.

EP932 - ECE_3520 - Initial clinical presentation differs substantially between ectopic Cushing's syndrome and Cushing's disease and could be the reason for the diagnostic delay. ERCUSYN Krakow database

Aleksandra Gamrat-Żmuda[1,2], Mari Minasyan[1], Alicja Hubalewska-Dydejczyk[1] and Aleksandra Gilis-Januszewska[1]
[1]*Department of Endocrinology, Jagiellonian University Medical College, Krakow, Poland;* [2]*Doctoral School of Medical and Health Sciences, Jagiellonian University Medical College, Krakow, Poland*

Background: Cushing's syndrome (CS) is often diagnosed with delay due to nonspecific initial symptoms. Clinical presentation differs across CS etiologies with ectopic Cushing's syndrome (ECS) showing often the most nonspecific initial presentation.

Objectives: To identify differences in initial clinical presentation between patients with ECS and Cushing's disease (CD) to facilitate earlier recognition and appropriate diagnostic pathways.

Methods: A retrospective analysis was performed using data from the Kraków ERCUSYN registry and included 34 patients with ECS and an equal number of age- and sex-matched patients with CD (hospitalized 2000-2025). Initial symptoms were identified based on medical records and retrospective patient history obtained at the time of diagnosis. Patients with small cell lung cancer were excluded due to severe general condition, rapidly progressive disease course, and the inability to obtain a reliable retrospective clinical history.

Results: The sources of ECS were predominantly neuroendocrine tumors (23), most commonly pulmonary carcinoids (7) and gastroenteropancreatic neuroendocrine tumors(9), with less frequent involvement of other malignant (6) and benign (2) neoplasms; in 3 cases, the source of ACTH secretion remained unidentified. Time to diagnosis from first symptoms was significantly shorter in the ECS than in the CD (2 vs 12 months, $P < .001$). In 21 (62%), ECS was diagnosed at a metastatic stage, including distant organ metastases in 19. The most frequent initial symptoms among patients with ECS were hypokalemia (52.9%), muscle weakness (38.2%), and edema (35.3%). Hypokalemia as an initial symptom was markedly more frequent in ECS patients than in those with CD (52.9%vs 5.9%,$P < .001$). However, on laboratory evaluation at diagnosis, hypokalemia was observed in 94.1% of patients with ECS and with 44.1% of patients with CD ($P < .001$). Weight loss occurred more often in ECS, whereas weight gain was significantly more common in CD (14.7% vs 59.0%,$P = .003$). Striae were observed exclusively in CD (17.6% vs 0%, $P = .03$). Muscle weakness was common in both groups, with similar prevalence. Edema and diabetes mellitus tended to be more frequent in ECS, although these differences did not reach statistical significance. Other features such as plethora, hypertension, headache, and visual disturbances were more often reported in CD but were not discriminatory at presentation.

Conclusions: ECS and CD differ substantially in their initial clinical presentation. ECS is characterized by more nonspecific and predominantly catabolic first manifestations, with hypokalemia as the most frequent initial symptom. However, hypokalemia as an initial symptom is less frequent than that observed during laboratory evaluation at the diagnosis, suggesting that early hypokalemia is underrecognized.

Abstract

(A 59-year-old man without relevant past medical history presented with a history of chronic diarrhoea for 6 years. He experienced intermittent episodes of profuse watery diarrhoea and weight loss without associated flushing or abdominal pain. He was extensively evaluated in the past, where infective and inflammatory causes were excluded. Laboratory analysis, including a colonoscopy, did not help in establishing a diagnosis

His condition was progressively worsening over time, resulting in a hospital admission with profuse diarrhoea complicated by acute kidney injury.

Cross-sectional imaging revealed a 10 × 7.5 cm mass on the tail of the pancreas. His calcitonin level was markedly elevated at a value of 2480 ng/L (<11.8), while his carcinoembryonic antigen level and thyroid imaging were within normal limits.

He underwent an endoscopic ultrasound and biopsy of the pancreatic lesion. The histology confirmed a well-differentiated (G2) pancreatic neuroendocrine tumour (Ki-67-10%).

A 68-Gallium-DOTATATE PET CT scan demonstrated the pancreatic lesion to be SSTR-avid with no SSTR-avid lesions elsewhere.

Following discussion at the neuroendocrine tumour multidisciplinary team meeting, he was started on somatostatin analogue therapy and underwent a curative resection (distal subtotal pancreatectomy and spleenectomy).

Post surgery, his calcitonin level normalised and his symptoms completely resolved with no residual disease in his post-surgical scans. Currently, he is on routine surveillance.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Calcitonin-secreting pancreatic neuroendocrine tumours are very rare and often overlooked in the evaluation of chronic diarrhoea. In the presence of suggestive symptoms and negative preliminary investigations, consideration of functional pancreatic NET syndromes in chronic diarrhoea evaluation would be indicated, as timely interventions may improvesurvivaland morbidity.)

EP934 - ECE_3189 - Integrated transcriptomics and beta-cell modelling of pancreatic cancer–associated new-onset diabetes

Klaus Brusgaard[1,2], Erol Eyüpoğlu[3], Havva Eyüpoğlu[4], Mustafa Akkiprik[4], Nedime Serakinci[3,5] and Can Erzik[3]

[1]Department of Regional Health Research, University of Southern Denmark, Odense, Denmark; [2]Departement of Regional Health Research, Universitet of Southern Denmark, Odense, Denmark; [3]Department of Medical Biology and Genetics, Marmara Universitesi, İstanbul, Türkiye; [4]Department of Medical Biology and Genetics, Marmara Universitesi, İstanbul, Türkiye; [5]Faculty of Art and Sciences, Moleculear Biology and Genetics, Cyprus International Unniversity, Lefkosa, Türkiye

Introduction: New-onset diabetes (NOD) can precede pancreatic ductal adenocarcinoma (PDAC) and may reflect a paraneoplastic effect on pancreatic islets. The signalling mechanisms driving beta-cell dysfunction in PDAC-associated NOD remain poorly defined.

Purpose: We test whether PDAC-derived factors induce a Notch-biased program in beta-cells, leading to dysfunction and reduced viability, and whether pharmacological Notch inhibition can partially reverse these effects.

Material and Methods: Public transcriptomic datasets from PDAC cohorts with NOD and long-term diabetes were analysed for pathway enrichment and candidate signatures. For experimental validation, conditioned medium (CM) from KPCY pancreatic cancer cells was applied to MIN6 beta-cells under chronic exposure, with or without the gamma-secretase/Notch inhibitor DAPT. Readouts included bulk RNA-seq to quantify Notch target gene expression (HES1, HEY1/HEY2) and broader beta-cell response programs; beta-cell viability (CellTiter-Glo); apoptosis (Caspase-Glo 3/7); and Western blot for HES1 as a marker of Notch activation.

Results: Notch-related pathway enrichment was observed in PDAC-associated NOD across patient comparisons. In MIN6 cells, chronic exposure to KPCY-conditioned medium reduced beta-cell viability compared to controls. This reduction was partially reversed by DAPT.

Conclusion/Perspective: These findings support a model in which PDAC-to-beta–cell communication activates Notch-associated programs that may contribute to PDAC-associated NOD. Ongoing RNA-seq and Western blot analyses will further characterize Notch target activation and broader beta-cell stress and dedifferentiation responses. RNAseq data will be presented. These results will help guide future biomarker development and identify potential intervention targets.

EP935 - ECE_3721 - A Case of Parathyroid Carcinoma Presenting with Mild Hypercalcemia

Selin Celik[1], Ozge Sahin Kimyon[1], Necmettin Ozkanbas[2], Bahar Atasoy[3], Sema Ciftci[4] and Hamide Piskinpasa[1]

[1]Department of Endocrinology and Metabolism, University of Health Sciences, Bakirkoy Dr. Sadi Konuk Research and Training Hospital, İstanbul, Türkiye; [2]Pathology, Sağlık Bilimleri Üniversitesi Bakırköy Doktor Sadi Konuk Eğitim Ve Araştırma Hastan, Bakırköy, Türkiye; [3]Radiology, Sağlık Bilimleri Üniversitesi Bakırköy Doktor Sadi Konuk Eğitim Ve Araştırma Hastan, Bakırköy, Türkiye; [4]Endocrinology and Metabolism, Sağlık Bilimleri Üniversitesi Bakırköy Doktor Sadi Konuk Eğitim Ve Araştırma Hastan, Bakırköy, Türkiye

Introduction: Parathyroid carcinoma is a rare endocrine malignancy, accounting for less than 1% of primary hyperparathyroidism cases. Despite typically being associated with markedly elevated serum calcium and parathyroid hormone levels, definitive diagnosis is usually made postoperatively by histopathology. We report a rare case of parathyroid carcinoma presenting with only mild hypercalcemia.

Case: A 44-year-old male with no history of chronic disease or medication use was referred to our clinic after incidental detection of hypercalcemia. Laboratory evaluation showed a euthyroid state with a serum calcium level of 12.2 mg/dL, albumin of 4.4 g/L, and PTH of 178 pg/mL. Physical examination was unremarkable and the patient had a history of surgery for nephrolithiasis. There was no history of fractures or family history of hyperparathyroidism. Ultrasonography demonstrated a TIRADS3 nodule measuring 43 × 36 × 28 mm occupying the entire right thyroid lobe, as well as a lesion measuring 19 × 26 × 26 mm inferior to the left thyroid lobe, consistent with a parathyroid adenoma. No pathological lymph nodes were observed. Tc-99msestamibi scintigraphy showed focal uptake in the inferior aspect of the left thyroid lobe, compatible with a parathyroid adenoma. Bone densitometry was normal. Fine-needle aspiration biopsy of the thyroid nodule was reported as benign.The patient was diagnosed with PHPT accompanied by a benign solitary thyroid nodule, and right lobectomy with left inferior parathyroidectomy was planned. Two months after the initial diagnosis, preoperative tests revealed a serum calcium level of 12.5 mg/dL and a markedly elevated PTH level of 643 pg/mL. Intraoperatively, the parathyroid gland was firm, gray and fixed to the surrounding muscles. Frozen section demonstrated invasion into adjacent muscle tissue, raising suspicion for parathyroid carcinoma. Therefore, left central lymph node dissection, left thyroid lobectomy, and wide excision of the parathyroid lesion including strap muscles were performed. Histopathology showed benign thyroid tissue, while the parathyroid specimen exhibited features suggestive of carcinoma, including cytological atypia, fibrous bands, and skeletal muscle invasion. No lymphovascular or perineural invasion was detected, surgical margins were negative, and the Ki-67 proliferation index was <5%. The patient was normocalcemic at one month postoperatively, and genetic mutation analysis was planned.

Discussion: Differentiating parathyroid carcinoma from adenoma based on clinical and biochemical findings is challenging, and diagnosis is usually made postoperatively. Although severe hypercalcemia (>14 mg/dL), markedly elevated PTH (>500 pg/

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

mL), large tumor size (>3 cm), and invasive imaging features may suggest carcinoma, they are not diagnostic. Our case demonstrates that parathyroid carcinoma can occur despite mild hypercalcemia and small tumor size.

EP936 - ECE_1975 - G-protein coupled estrogen receptor (GPER) modulates melanin prodution

Giada Mercanile[1,2], Carmela Perri[1,3], Clara Lazzaretti[1], Samantha Sperduti[1,4], Manuela Simoni[1,4,5], Cristina Magnoni[2] and Livio Casarini[1,4]

[1]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; [2]Unit of Dermatology, Department of Medical and Surgical Sciences, University of Modena and Reggio Emilia, Modena, Italy; [3]International PhD School in Clinical and Experimental Medicine (CEM), University of Modena and Reggio Emilia, Modena, Italy; [4]Center for Genomic Research, University of Modena and Reggio Emilia, Modena, Italy; [5]Department of Medical Specialties, Azienda Ospedaliero-Universitaria di Modena, Modena, Italy

Melanin is produced by melanocytes to protect skin from UV radiation-mediated DNA damage. Melanogenesis is induced by α-melanocyte-stimulating hormone (α-MSH), which binds to melanocortin-1 receptor (MC1R) and requires the allosteric modulation by melanocortin receptor accessory protein (MRAP) to activate the cyclic adenosine monophosphate (cAMP) pathway. However, melanin excess occurs in pregnancy, during use of hormonal contraceptive pills, melanoma and melasma, suggesting that other hormones could be involved in melanogenesis. Our preliminary data demonstrated that skin hyperpigmentation may be due to overexpression of G protein-coupled estrogen receptor (GPER), another GPCR detected in skin cells and displaying MRAP-like allosteric behaviour.

We aim to assess whether GPER may act as an allosteric partner for MC1R, leading to α-MSH-mediated melanin hyperproduction.

Experiments were performed using skin tumour Sk-Mel-2 and Sk-Mel-28 cell lines, and human primary melanocytes over/under-expressing GPER. Cells were treated 48 h with 100 nM α-MSH, in the presence or in the absence of increasing doses (0-50 nM range) of estradiol and progesterone. *MC1R*, *MRAP* and *GPER* gene expression levels were evaluated by droplet-digital PCR, while the GPER-MC1R interaction by proximity ligation assay (PLA). Intracellular cAMP levels and melanin production were measured by bioluminescence resonance energy transfer (BRET) and spectrophotometric analysis. 5 independent experimental replicates were performed and statistically analysed by Kruskall-Wallis test and Dunn's post-test ($P < 0.05$).

In transfected MC1R-expressing Sk-MEL-2 and -28 cell lines, α-MSH increases cAMP levels compared to untreated cells ($P < .05$), regardless of GPER and MRAP co-expression. Control experiments demonstrated that sex steroids failed to induce cAMP increase ($P \geq .05$). Under GPER/MC1R and MRAP/MC1R co-expression, α-MSH leads to higher cAMP level increase than MC1R-expressing cells ($P < .05$). In primary melanocytes, nM progesterone concentrations induced GPER expression and melanin production in a steroid dose-dependent manner. Under progesterone exposure, melanocyte treatment with 100 nM α-MSH enhances the melanogenesis compared to progesterone-untreated cells ($P < .05$), while no effects were found under cell exposure to estradiol ($P \geq .05$).

Cell exposure to progesterone increases GPER expression, which replaces MRAP-specific allosteric functions and triggers marked response to α-MSH, as a mechanism leading to hyperpigmentation in melasma and skin cancer.

EP937 - ECE_2462 - Cost effectiveness and efficacy of cinacalcet in patients with hypercalcaemia

Furhana Hussein, Bhavini Bhatt, Hafsah Hussain, Mariana Dram, Godwin Simon, Belayet Hossain and Gideon Mlawa

Barking Havering andRedbridge Hospitals NHS Trust, London, United Kingdom

Introduction: Cinacalcet is a highly effective agent for controlling hypercalcaemia in patients with parathyroid carcinoma, secondary hyperparathyroidism on dialysis or primary hyperparathyroidism (PHPT) who cannot undergo parathyroidectomy surgery due to comorbidities and risk of anaesthesia.

Symptoms of hypercalcaemia include lethargy, confusion, constipations, renal stones, depression, osteoporosis leading increased risk of fractures. These complications can lead to hospital admissions.

Cinacalcet works as a calcimimetic by increasing the sensitivity of the calcium-sensing receptor on parathyroid gland cells to extracellular calcium leading to inhibition of parathyroid hormone (PTH) secretion, thus lowering serum calcium levels.

Aim: Looking at management of hypercalcaemia with cinacalcet and the cost effectiveness and efficacy on the NHS.

Methods: Retrospective single-centre study looking at patients started on cinacalcet for hypercalcaemia and their response to treatment and comparing cost effectiveness in the NHS.

19 patients were identified at Queen's Hospital, London, UK (BHRUT–Barking, Havering and Redbridge University Hospitals NHS Trust) in 2025.

Results: 19 patients were identified as being started on cinacalcet for hypercalcaemia.

63% were female

Majority of the patients were in the age group 71-80 years old (37%) then followed by over 80 years of age at 26%

100% had serum calcium levels reduced after starting cinacalcet.

In total there were 18 hospital admission for these 19 patients. Research has showed that the average cost of admission in the NHS cost approximately £500. Therefore, this is equivalent to approximately £9000. However, the longer the hospital stay the more it would cost. The average cost of cinacalcet 30 mg, 28 tablets pack on the NHS is £5.08.

5 patients eventually underwent parathyroidectomy surgery

Conclusions: Hypercalcaemia can be treated with cinacalcet to maintain serum calcium levels and avoid complications and admissions to hospital. The implications of not diagnosing and treating hypercalcaemia in timely manner with cinacalcet can result in more complications in patients that may lead to multiple hospital admissions costing the NHS more money. 1 year supply

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

of 30 mg cinacalcet once daily can cost approximately £60.96 under the NHS compared to an average hospital admission costing £500. Our study showed that using cinacalcet to manage hypercalcaemia is cost effective and has good efficacy for treating hypercalcaemia the NHS by reducing complications, need for surgery and avoiding multiple hospital admissions.

EP938 - ECE_2657 - Beyond the classic triad: an unusual presentation of MEN2A with salivary gland carcinoma and papillary thyroid cancer

Elaine Saugar, Deciara Jacome Torres M. Mesquita, Pascual De Santis and Angel Alejandro
Miami, United States

Introduction: Multiple endocrine neoplasia type 2 (MEN2) is an autosomal dominant syndrome caused by germline gain-of-function mutations in the RET proto-oncogene on chromosome 10q11.21, affecting neural crest-derived tissues including the thyroid, adrenal, and parathyroid glands. It is classified as MEN2A or MEN2B, with MEN2A accounting for 70-80% of cases. Presentation typically occurs before age 35. Medullary thyroid carcinoma develops in nearly 98% of patients and is often the initial manifestation. Pheochromocytomas occur in about 50% of cases and are frequently bilateral, while primary hyperparathyroidism affects about 25% of patients, usually later in life. We report a unique case of MEN2A with atypical late presentation and rare associated malignancies.

Case Presentation: A 60-year-old Hispanic male presented with abdominal pain and sepsis secondary to acute cholecystitis, complicated by NSTEMI and newly diagnosed non-ischemic cardiomyopathy. The patient was undergoing outpatient evaluation for MEN2A due to known RET mutations in his three children. CT imaging revealed bilateral adrenal nodules suspicious for pheochromocytomas in the setting of elevated plasma free metanephrine (520 pg/mL). Following alpha and beta blockade, he underwent right total and left partial adrenalectomy with cholecystectomy. Pathology confirmed bilateral low-grade pheochromocytomas, and postoperative adrenal function remained intact. Subsequent thyroid ultrasound demonstrated bilateral highly suspicious nodules in the setting of elevated plasma calcitonin (4,451 pg/mL). Total thyroidectomy revealed medullary thyroid carcinoma (T2N1a) and incidental papillary thyroid carcinoma, follicular variant (pT1aN0a). He never developed hyperparathyroidism. Five years later, routine surveillance imaging identified a left parotid mass. Biopsy confirmed salivary duct carcinoma. He received neoadjuvant trastuzumab/pertuzumab followed by parotidectomy, neck dissection, and reconstruction. Tumor sequencing identified pathogenic PIK3CA and RET mutations on exons 10 (p.Q546R) and 11 (p.C634S), respectively, without RET fusion. He is currently receiving adjuvant radiation therapy.

Discussion: This case demonstrates an expanded MEN2A phenotype with delayed presentation, pheochromocytoma as the initial manifestation, coexisting papillary thyroid carcinoma, and subsequent salivary gland carcinoma. Although RET fusions are implicated in subsets of papillary thyroid and salivary gland tumors, these represent somatic events distinct from germline RET mutations in MEN2A. Several case reports have documented the unusual association between MEN2A and papillary thyroid carcinoma; however, there appear to be no prior reports linking MEN2A with salivary gland carcinoma. This case highlights the importance of recognizing atypical and late-onset manifestations of MEN2A and underscores the role of genetic and molecular evaluation in guiding lifelong surveillance and individualized management.

EP939 - ECE_2703 - When you hear hoofbeats think horses but remember zebras: a case of life-threatening VIPoma

Maja Wróblewska[1], Agata Belińska[1,2], Maria Kałas[3,4], Jacek Szypenbejl[3,4], Anna Lewczuk-Myślicka[1,2], Mariusz Siemiński[3,4] and Renata Świątkowska-Stodulska[1,2]
[1]*Department of Endocrinology and Internal Medicine, University Clinical Centre, Gdańsk, Poland;* [2]*Department of Endocrinology and Internal Medicine, Faculty of Medicine, Medical University of Gdańsk, Gdańsk, Poland;* [3]*Department of Emergency Medicine, University Clinical Centre, Gdańsk, Poland;* [4]*Department of Emergency Medicine, Faculty of Medicine, Medical University of Gdańsk, Gdańsk, Poland*

Introduction: Vasoactive intestinal peptide-secreting tumor (VIPoma) is a rare neuroendocrine neoplasm (NEN), with an annual incidence of 1 per million. It is usually located in the pancreatic tail. VIPoma syndrome, caused by excessive unrestricted VIP secretion, presents as severe fasting-persistent watery diarrhea, hypokalemia, and achlorhydria, known as “WDHA syndrome” or Verner-Morrison syndrome. Management of VIPoma includes symptom-oriented pharmacotherapy, conservative treatment options such as somatostatin analogs (SSAs), and surgery.

Case Report: A 69-year-old woman was admitted to the emergency department (ED) in hypovolemic shock due to massive watery diarrhea up to 10 liters per day. The physical examination revealed generalized flushing and marked dehydration, with an initial blood pressure of 80/38 mmHg and a heart rate of 122 beats per minute. Venous blood gas showed metabolic acidosis with pH of 7.12 and hypokalemia of 2.8 mmol/L. The gastroenteritis PCR panel was negative. After initial treatment (intravenous fluids, hydrocortisone, vasopressors) and stabilization of vital parameters in the ED, the patient was transferred to the Department of Endocrinology for suspected rare WDHA syndrome. Continuous infusion of octreotide resulted in resolution of diarrhea; the patient also started lanreotide. Blood tests confirmed elevated VIP—180 pmol/L ($N < 24$ pmol/L), calcitonin—941 pg/mL ($N < 11.5$), and chromogranin A 253.8 ng/mL ($N < 102$). Approximately 2 months earlier, the patient was hospitalized due to similar symptoms associated with hyperglycemia and hypercalcemia. A CT scan of the abdomen showed a solitary, irregular, polycystic mass measuring $70 \times 38 \times 65$ mm located in the pancreatic area. Tumor biopsy in an outpatient setting revealed low-grade NEN, but no further procedures followed.

PET/CT with 68Ga-DOTATATE confirmed three pancreatic lesions with high expression of the somatostatin receptor, the largest measuring 48×32 mm with SUVmax 26.5. After a multidisciplinary team meeting, the patient was qualified for surgery. Subtotal pancreatectomy and splenectomy with partial gastrectomy and partial colectomy was performed, the surgery was uneventful. The resected NEN was G2 with Ki67 4%. Since

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

the procedure, the patient has been asymptomatic with good biochemical control.

Discussion: Although VIPoma is a rare disease, the characteristic clinical course can facilitate an initial diagnosis. Fasting-persistent watery diarrhea with severe electrolyte disturbances should prompt the idea of rare neuroendocrine causes, the so-called "zebras". Elevated calcitonin, a biomarker more easily accesible than VIP, may contribute to secretory diarrhea. Early recognition and initiation of appropriate therapy can save lives and, in the long term, can preserve the quality of life of patients.

EP940 - ECE_3332 - Managing a rare case of recurrent ACTH secreting tumour and the role of MDT

Furhana Hussein, Amanda Mlawa, Olga Dolacinska, Assem Madeniyetova, Lina Eltayieb, Fatumo Issa, Amy Kelt, Aneliya Sirkova, Mariana Dram and Gideon Mlawa
Barking Havering and Redbridge Hospitals NHS Trust, London, United Kingdom

Introduction: Atypical carcinoid tumours are rare which account for about 15% of all carcinoid tumours. Some of those tumours secrete adrenocorticotrophic hormone (ACTH) causing Cushing`s syndrome.

Case: A 39-year-old woman was referred with few months history of weight gain, irregular menstrual periods, muscle aches, difficult going up the stairs, headaches and blurred vision. In 2000, she was diagnosed with ectopic thoracic carcinoid leading to Cushing`s syndrome. This was surgically treated. She had remained symptom free until early 2016. On presentation to another hospital her 9 am cortisol was raised at 770 nmol/L, 24 hour urinary free cortisol was 1992 nmol/24 hr, and cortisol was not suppressed with both low and high dose dexamethasone suppression test. Her ACTH was high at 118 ng/L. The CXR showed raised left hemidiaphragm.CT chest showed $2.5 \times 3 \times 1.9$ cm mass on left side of superior mediastinum adjacent to arch of the aorta.

She was started on metyrapone 250 mg three times a day. Resection of the tumour was carried out.During the surgical procedure the tumour was found to be involving the pulmonary vessels, phrenic nerve, and left upper lobe. Histology showed tumour composed of sheet of cells, with small amounts of indistinct cytoplasm, oval nuclei and stippled chromatin and necrosis and presence of mitoses of approximately one mitotic figure per 5 high power fields in keeping with recurrent atypical carcinoid tumour.

Disussion: Atypical adrenocorticotrophic hormone (ACTH) secreting tumours are uncommon, and together with typical carcinoid tumours constitutes less than 5% of all lung tumours.

These can be more aggressive tumours with worse prognosis compared to typical pulmonary carcinoid tumour which are well differentiated and are associated with good prognosis

Atypical carcinoid tumours can be differentiated from other neuroendocrine tumours based on histological criteria such as increased mitotic activities, amount and pattern of necrosis, cell size, amount of cytoplasma,nuclear chromatin

Conclusions: Atypical carcinoid with regional lymph node metastasis are likely to be recurrent and respond poorly to standard chemotherapy.

This case demonstrates that the tumour can be very slow growing in nature. Patients with atypical adrenocorticotrophic hormone (ACTH) secreting carcinoid tumours should be followed up and screened for Cushingfor many years in the MDT setting.

EP941 - ECE_3958 - Recurrent or metastatic paraganglioma in patients with succinate dehydrogenase D mutations: a case series

Sereen Fatima, Safwaan Adam and Jan Hoong Ho
The Christie NHS Foundation Trust, Endocrine Department, Manchester, United Kingdom

Background: Germline mutations in the succinate dehydrogenase complex (SDH) gene group (particularly SHDB and SDHD) predispose individuals to hereditary paraganglioma-pheochromocytoma (PGL/PCC) syndromes, with variable penetrance. SDHD/SDHB mutations account for between 70-80% of PGL/PCC syndromes attributed to pathogenic variants in a gene. SDHB mutations are associated with extra-adrenal paragangliomas with an increased risk of metastatic disease and are generally associated with higher morbidity and mortality. In comparison, pathogenic SDHD variants are associated with multifocal head and neck paragangliomas (HNPGL) with a much lower metastatic risk of <5%.

Cases: Herein, we present a case series of 3 patients referred to our unit with paragangliomas, all of whom had either metastatic or recurrent disease. All 3 were found to have mutations of the SDHD gene on genetic testing.

	Patient 1	Patient 2	Patient 3
Age	52	27	33
Gender	Male	Female	Male
Type of tumour	Carotid body paraganglioma	3 separate head and neck paragangliomas	Left and right carotid body tumours
Age at presentation (of first tumour)	32	16	18
Family history	Unknown	Head and neck paragangliomas in father,	Unknown

(*continued*)

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Continued

	Patient 1	Patient 2	Patient 3
		uncle, paternal aunt and paternal cousin	
Functional?	Yes	Yes	No
3-methoxytyramine level (0.0-180.0 pmol/L)	552.3 (high)	908.0 (high)	<75.0 (normal)
Metanephrine level (0.0-510.0 pmol/L)	188.1 (normal)	213.9 (normal)	121.8 (normal)
Normetanephrine level (0.0-1180.0 pmol/L)	373.8 (normal)	894.0 (normal)	374.0 (normal)
Treatment for first tumour	Resection	External beam radiotherapy due to presence of metastatic disease at presentation and location of primary tumour. Patient having discussion about systemic treatments	Excision
Recurrence	2 years after resection	-	-
Metastases	-	Multiple lung nodules	Right spheno-orbital paraganglioma and metastatic lesions to the right orbit, pancreas, right retropharyngeal region, tentorium cerebri and multiple lesions to the lungs and skeleton
Treatment of recurrent / metastatic disease	Resection of recurrent PGL	Palliative radiotherapy	PRRT
Progress	Clinical stability	Currently undergoing treatment	Good response to PRRT, stable disease with reduced functional burden

Discussion: This case series demonstrates patients with germline SDHD mutations who presented with metastatic or recurrent disease. This highlights the need to consider metastatic potential in patients with these mutations. This series emphasizes the need for regular follow-up and on-going surveillance in patients with PGL/PCC syndromes caused by mutations in the SDHD gene, and to maintain an index of suspicion for metastatic or recurrent disease in these patients also.

EP942 - ECE_1937 - Giant pelvic paraganglioma: diagnostic and therapeutic challenges

Vasiliki Venetsanaki[1,2,3], Efthimia Karra[2,3] and Eleni Armeni[2,3]
[1]*Department of Endocrinology, Diabetes and Metabolism, University Hospital of Heraklion, Heraklion, Greece;* [2]*Department of Endocrinology, Royal Free London NHS Foundation Trust, London, United Kingdom;* [3]*Neuroendocrine Tumor Unit, ENETS Centre of Excellence, Royal Free London NHS Foundation Trust, London, United Kingdom*

Introduction: Paragangliomas are rare, extra-adrenal neuroendocrine tumors arising from sympathetic or parasympathetic paraganglia. They may be hormonally active, secreting catecholamines, or remain clinically silent. Paragangliomas may occur sporadically or in association with inherited genetic syndromes and their biological behavior ranges from benign to metastatic. Pelvic paragangliomas are exceedingly rare and pose a diagnostic and surgical challenge.

Case: A 51-year-old male patient with a 15-year history of hypertension was being evaluated for secondary hypertension. Cross-sectional imaging revealed a solid, enhancing retroperitoneal mass measuring $9 \times 7.5 \times 6$ cm with central necrosis and small areas of calcification within it. The differential diagnosis at that time included a retroperitoneal sarcoma or an exophytic small bowel gastrointestinal stromal tumour.

The patient underwent a biopsy of the retroperitoneal mass without complications. Histopathological findings were consistent with a paraganglioma. Subsequent biochemical evaluation demonstrated elevated normetanephrine and 3-methoxytyramine, supporting the diagnosis. Functional imaging with

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

^{68}Ga-DOTATATE and ^{18}F-FDG PET showed intense tracer uptake confined to the right pelvic mass.

Eight months after the initial diagnosis, the patient underwent surgery. Intraoperatively, a large, lobulated and vascular paraganglioma that was adherent to the bifurcation of the right common iliac vein was identified. During dissection, iatrogenic injury to the right common iliac vein and the origin of right internal iliac vein occurred, resulting in an estimated blood loss exceeding 4.5 liters. Postoperatively, the patient required intensive care management for hypovolemic shock. His recovery was further complicated by sepsis, postoperative ileus requiring re-operation, hypertensive crises and pulmonary oedema. Twenty-nine days after surgery the patient was discharged. Definitive histology confirmed a paraganglioma and genetic testing revealed that the patient was heterozygous for a likely pathogenic SDHB missense variant.

Following the complicated surgical history, the patient was referred for ^{177}Lu-DOTATATE (PRRT) therapy to manage the residual disease in the pelvis which had increased in size. The patient was treated with four cycles of PRRT with slight reduction in tumour size but refused further surgical intervention. Fourteen months later, the patient had progressive disease and chemotherapy with capecitabine and temozolamide was initiated.

Conclusions: A giant paraganglioma in the pelvis is a complicated and rare tumor. Biochemical testing and functional imaging can provide conclusive diagnostic evidence. Surgical management remains the first line of treatment but PRRT and systemic therapy have proven effective in the management of paragangliomas when surgery is not an option.

EP943 - ECE_3402 - Vitamin D status and metabolic parameters in patients with concomitant parathyroid adenoma and breast cancer: a retrospective case–control pilot study

Müge Yılmaz[1], Serhat Özçelik[1], Busra Kanbur[1], Senem Boz Aksoy[1], Ece Seçgin Demir[1], Meryem Özoğlu[1], Naile Gokkaya[1], Ziya Mithat Bıyıklı[1], Hatice Odabaş[2], Nedim Turan[2], Aylin Ege Gül[3] and Kadriye Aydin[1]

[1]Department of Endocrinology and Metabolism, Kartal Dr.Lütfi Kırdar City Hospital, İstanbul, Türkiye; [2]Department of Medical Oncology, Kartal.Dr.Lütfi Kırdar City Hospital, İstanbul, Türkiye; [3]Department of Pathology, Kartal.Dr.Lütfi Kırdar City Hospital, İstanbul, Türkiye

Background: Primary hyperparathyroidism (pHPT) has been linked to an increased risk of malignancies, including breast cancer. However, data on metabolic and vitamin D characteristics in patients with concomitant parathyroid adenoma and breast cancer, as well as their relationship with tumor biology, remain limited.

Methods: This retrospective single-center study included female patients with newly diagnosed parathyroid adenoma, with or without concomitant breast cancer. Patients with multiple endocrine neoplasia, multigland parathyroid disease, or chronic kidney and liver diseases were excluded. Metabolic parameters and 25-hydroxyvitamin D levels—were recorded. Group comparisons were performed using non-parametric tests, with age-adjusted analyses using linear regression models.

In patients with concomitant breast cancer, tumor pathological features (ER, PR, HER2, and Ki-67) and radiotherapy status were recorded, and associations between Ki-67 and biochemical and metabolic parameters were assessed using Spearman's rank correlation analysis.

Results: A total of 16 patients with concomitant breast cancer and parathyroid adenoma and 36 patients with parathyroid adenoma only were included. Among breast cancer patients, 75.0% had invasive ductal carcinoma; all were estrogen receptor–positive, 75.0% were progesterone receptor–positive, and 25.0% were HER2-positive. Radiotherapy was administered to 68.75% of patients.

Patients with breast cancer had significantly lower 25-hydroxyvitamin D levels and higher BMI compared with controls ($P < .05$). Parathyroid hormone levels were positively correlated with BMI ($\rho = 0.653$, $P = .011$). No significant correlations were observed between the Ki-67 proliferation index and preoperative PTH, calcium, or 25-hydroxyvitamin D levels, although a weak positive trend with vitamin D was noted. Notably, Ki-67 showed a strong inverse correlation with fasting glucose levels ($\rho = -0.717$, $P = .002$).

In the parathyroid adenoma–only group, metabolic parameters demonstrated expected correlations, without significant associations between parathyroid-related biochemical markers and metabolic indices.

Conclusions: The coexistence of severe vitamin D deficiency in patients with both parathyroid adenoma and breast cancer may therefore suggest a bidirectional interaction affecting both parathyroid disease and breast tumorigenesis. In the breast cancer group, no significant correlations were observed between the Ki-67 proliferation index and preoperative PTH, calcium, or 25-hydroxyvitamin D levels, although a weak positive trend with vitamin D was noted. Considering that all patients with breast cancer in the study had estrogen receptor–positive tumors, it may be hypothesized that vitamin D deficiency and parathyroid pathologies interact predominantly with estrogen-dependent signaling pathways rather than directly influencing tumor proliferative processes.

EP944 - ECE_3405 - Retroperitoneal leiomyosarcoma mimicking an adrenal mass: diagnostic pitfalls in the adrenal area

Leandro Augusto Silva[1], Ana Paula Moreira[2], Arnaldo Figueiredo[2], João Martins Gama[2], Carla Baptista[2] and Leonor Gomes[2]

[1]Endocrinology Department, Portuguese Institute of Oncology of Coimbra, Coimbra, Portugal; [2]Local Health Unit of Coimbra, Coimbra, Portugal

Introduction: Adrenal masses are common neoplasms; while often benign, some may be malignant. Leiomyosarcomas are a rare subtype of soft tissue malignancy, may remain asymptomatic for prolonged periods and can be incidentally diagnosed or present with nonspecific symptoms such as abdominal or flank pain or weight loss. Importantly, retroperitoneal sarcomas are often not considered in the differential diagnosis of adrenal tumours, and some lesions may have an extra-adrenal origin, given

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

the complex anatomy surrounding the adrenal gland, contributing to diagnostic challenges.

Clinical Case: A 80-year-old female patient was referred to Endocrinology for functional assessment of a left adrenal mass, detected on abdominal CT for vomiting, alternating constipation/diarrhea, left flank discomfort, and 15 kg weight loss in one month. CT showed an indeterminate oval lesion with heterogeneous enhancement near the left renal hilum, 29 × 21mm; MRI revealed a retroperitoneal tumour possibly pedunculated from the left adrenal gland. No symptoms of hormonal hypersecretion were reported. On physical examination, no pain or palpable masses/organomegaly, without endocrine stigmata. Functional work-up was negative. In 18F-FDG-PET/CT, a 32 mm mass without clear plane from the left adrenal gland, with increased uptake (SUVmax = 5.6) and, right upper pulmonary lobe (RUL) ground-glass nodule, 15mm, with uptake (SUVmax = 1.5), both suspicious for malignancy. Follow-up CT, with the known irregular left-sided mass enlarging to 37 × 25mm, with uncertain origin (possibly adrenal), raising suspicion of adrenocortical carcinoma. Pulmonary review with stable lung lesion on high resolution CT, proposed for imaging surveillance. After Nuclear Medicine discussion, 18F-FDOPA-PET/CT was performed, identifying the 44 × 30mm mass with mildly increased uptake (SUVmax = 3) and 16mm RUL nodule with uptake (SUVmax = 1.4), with differential diagnostic considerations including retroperitoneal ganglioneuroma/paraganglioma and pulmonary neuroendocrine tumour. After discussion with Urology, left adrenal lesion excision was planned. Intraoperatively, large adrenal/renal hilum mass without cleavage planes and suspected pancreatic invasion; incisional biopsy was performed. Histopathology revealed a grade 1 leiomyosarcoma, without MDM2 amplification. Due to clinical deterioration, referred to palliative care for best supportive care.

Conclusions: We report the case of a presumed adrenal lesion subsequently diagnosed as leiomyosarcoma. Retroperitoneal leiomyosarcoma should be included in the differential diagnosis of adrenal/suprarenal masses. Tumour origin may be uncertain (adrenal vs invasive), as in our case. Because adrenal lacks smooth muscle cells, it is thought to most likely arise from the smooth muscle components of adrenal blood vessels. Importantly, has no specific clinical presentation or radiologic features and lacks reliable tumour markers, making early preoperative diagnosis challenging.

Abstract citation ID: lvag096.1234

EP945 - ECE_1538 - Niclosamide ethanolamine is a novel therapeutic agent for human pancreatic cancer

Ying-Ray Lee[1], Tzu-En Chiu[2] and Wan-Chi Tsai[3]
[1]*Department of Microbiology and Immunology, Kaohsiung Medical University, Kaohsiung City, Taiwan;* [2]*Kaohsiung City, Taiwan;* [3]*Department of Medical Laboratory Science and Biotechnology, Kaohsiung Medical University, Kaohsiung City, Taiwan*

Pancreatic ductal adenocarcinoma (PDAC) is an aggressive and highly lethal malignancy, with a five-year survival rate of approximately 12%. For patients who are not eligible for surgical resection, current therapeutic modalities, including chemotherapy, radiotherapy, targeted therapy, and immunotherapy have shown limited efficacy in improving survival outcomes, underscoring an urgent unmet need for novel therapeutic strategies.

Niclosamide ethanolamine (NEN), a derivative of the antiparasitic agent niclosamide, has been reported to exhibit anticancer activity in various malignancies by inhibiting tumor cell proliferation and metastasis, inducing apoptosis, and enhancing chemosensitivity. However, the therapeutic potential and molecular mechanisms of NEN in PDAC remain largely unexplored. In this study, we aimed to investigate the antitumor effects of NEN in PDAC and elucidate its underlying mechanisms.

Our results demonstrated that NEN treatment significantly suppressed PDAC cell proliferation, as evidenced by reduced cell viability and colony formation. Cell cycle analysis further revealed that NEN induced G0/G1 phase cell cycle arrest. Additionally, trypan blue exclusion assays, flow cytometric analysis, and Western blotting consistently confirmed that NEN treatment promoted apoptosis in PDAC cells. Mechanistic studies indicated that both extrinsic and intrinsic apoptotic pathways were activated upon NEN exposure. Moreover, Western blot analyses revealed that NEN treatment activated the AKT, ERK, and p38 signaling pathways. Pharmacological inhibition of these pathways significantly attenuated NEN-induced apoptosis, suggesting that NEN-mediated apoptotic effects are dependent on AKT, ERK, and p38 signaling.

In conclusion, this study provides the first evidence that NEN exerts potent antitumor activity against PDAC by inhibiting cell proliferation, inducing cell cycle arrest, and promoting caspase-dependent apoptosis through the AKT, ERK, and p38 signaling pathways. These findings highlight NEN as a promising therapeutic candidate for PDAC and warrant further preclinical and clinical investigation.

EP946 - ECE_1529 - Microenvironment-dependent activation of FAK promotes growth of gastrointestinal neuroendocrine tumors

Alice Castenetto, Francesco Gambera, Anna Chinnì, Clarissa Gissi, Francesca D'este and Teresa Gagliano
Udine, Italy

Neuroendocrine tumors (NETs) are a rare and heterogeneous group of neoplasms arising from neuroendocrine cells distributed throughout the epithelium. The majority of NETs develop in the gastrointestinal tract (GI-NETs) and are characterized by indolent growth combined with a marked resistance to therapy and a relatively low mutational burden. Because GI-NETs are frequently not driven by classical oncogenic mutations, increasing attention has focused on alternative mechanisms of tumor progression, including epigenetic regulation and signals derived from the tumor microenvironment. Among stromal components, fibroblasts represent a major cellular population with the potential to modulate tumor behavior, yet their contribution to GI-NET biology remains poorly defined. The aim of this study was to investigate the influence of fibroblasts on GI-NET cell proliferation and phenotypic plasticity.

Primary human fibroblasts and GI-NET cell lines (GOT1 and COLO320DM) were used as experimental models. Tumor cells were cultured either in direct contact with fibroblasts or exposed to fibroblast-conditioned media to distinguish contact-dependent from soluble factor–mediated effects. Cell proliferation was evaluated using standard viability-based assays, while

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

phenotypic changes were assessed by immunofluorescence analysis of epithelial markers. Expression levels of focal adhesion kinase (FAK) were measured by QPCR, and the subcellular localization of phosphorylated FAK (p-FAK) was analyzed by confocal microscopy.

We found that direct co-culture with fibroblasts significantly enhances GI-NET cell proliferation, whereas conditioned media exerted minimal or no effects, indicating that physical interaction between fibroblasts and tumor cells is required to promote growth. Moreover, fibroblast co-culture disrupted the membrane localization of E-cadherin in GI-NET cells, suggesting a shift toward a mesenchymal-like phenotype. Importantly, fibroblasts induced a significant upregulation of FAK mRNA expression in tumor cells. For the first time, we also observed a marked nuclear translocation of phosphorylated FAK in GI-NET cells upon direct contact with fibroblasts, revealing a previously unrecognized mechanism of microenvironment-driven FAK signaling in this tumor type.

In conclusion, our data demonstrate that fibroblasts play a pivotal role in modulating GI-NET proliferation and phenotypic plasticity through contact-dependent mechanisms and identify nuclear p-FAK as a novel feature of tumor–stroma crosstalk in GI-NETs. These findings provide new insight into the contribution of the tumor microenvironment to GI-NET pathogenesis and support further investigation into FAK-dependent pathways as potential therapeutic targets.

EP947 - ECE_1770 - Severe hypergastrinemia with mild clinical expression: the modulating role of autoimmune atrophic gastritis in metastatic gastrinoma

Raquel Calheiros[1,2], Sara Santos[1,2], Pedro Souteiro[1,2], Ana P. Santos[1,2] and Joana Oliveira[1,2]
[1]*Portuguese Oncology Institute of Porto (IPO Porto), Porto, Portugal;* [2]*Porto Comprehensive Cancer Center (P.CCC), Department of Endocrinology, Porto, Portugal*

Background: Gastrinomas are rare functioning neuroendocrine tumors characterized by inappropriate gastrin secretion leading to gastric acid hypersecretion and Zollinger–Ellison syndrome. Diagnosis usually requires the demonstration of hypergastrinemia in the setting of low gastric pH. In clinical practice, however, gastric pH assessment may be unavailable, and coexisting gastric disorders may confound symptomatic and biochemical interpretation,, and delay the diagnosis.

Case Presentation: We report the case of a 78-year-old woman with a well-differentiated pancreatic neuroendocrine tumorand extensive hepatic and lymph node metastases. The tumor was identified during evaluation of abdominal and pelvic discomfort. Cross-sectional imaging revealed a 61mm exophytic mass in the pancreatic body with diffuse liver metastases.Liver biopsy histopathology confirmed a metastatic pancreatic neuroendocrine tumor, with a Ki-67 proliferation index <3% and strong expression of neuroendocrine markers. Functional imaging with 68Ga-DOTATOC PET demonstrated very intense somatostatin receptor expression throughout the entire tumor burden.

Biochemical evaluation revealed extreme fasting hypergastrinemia (99007 pg/mL). Clinically, the patient reported chronic abdominal pain and recurrent diarrhea but lacked other hallmark features of Zollinger–Ellison syndrome, such as peptic ulcer disease, severe gastroesophageal reflux, or significant weight loss. Gastric pH measurement was not available, limiting physiological confirmation of acid hypersecretion. Upper gastrointestinal endoscopy revealed body-predominant atrophic gastritis with focal intestinal metaplasia, active Helicobacter pylori infection and no ulcerations. In this context, autoimmune atrophic gastritis was suspected, which would explain the mild clinical expression of such high gastrin levels. Further tests showed positive anti-parietal cell antibodies and vitamine B12 deficiency, supporting this diagnosis. Germline genetic testing for MEN1 and CDKN1B revealed no pathogenic variants. LAR octreotide was initiated leading to diarrhea improvement, a dramatic fall in the gastrin levels (460 pg/mL in the last evaluation) and structural stable disease during the last three years.

Conclusions: This case represents a pathophysiological challenge. On one hand, an autoimmune atrophic gastritis could explain the clinical picture and be seen here as protective factor by reducing parietal cell mass and attenuating acid secretion, thereby limiting ulcerative complications despite extreme gastrin. On the other hand, atrophic gastritis itself can cause secondary hypergatrinemia, which may be a confounding effect.Awareness of such interplay is essential to avoid misinterpretation of isolated hypergastrinemia and to ensure timely diagnosis.

Abstract citation ID: lvag096.1237

EP949 - ECE_3090 - A single centre review of succinate dehydrogenase subunit pathogenic variant carriers.

Stephanie Miles, Christine May and Bahram Jafar-Mohammadi
OCDEM, Churchill Hospital, Oxford, United Kingdom

Objective: Carriers of germline pathogenic variants in succinate dehydrogenase subunits A to D (SDHx) are predisposed to phaeochromocytoma and paraganglioma (PPGL) requiring long-term surveillance. We audited disease-affected and asymptomatic SDHx pathogenic variant carriers against international consensus guidelines and analysed the presentation and management of PPGLs.

Methods: A retrospective analysis of electronic medical records of SDHx pathogenic variant carriers was performed by identifying cases through coding. Records between January 2019 and December 2024 were audited against annual review of symptoms, metadrenalines measurement, and MRI head to pelvis 3 yearly.

Results: 40 index cases and 34 non-index cases were identified. The median age of genetic diagnosis and first tumour was 42 and 41 years respectively.

Cohort characteristics:

Pathogenic variant	Asymptomatic	Disease-affected
SDHA	1	6
SDHB	16	23
SDHC	2	2
SDHD	1	23

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Number of tumours by site in cohort:

	SDHA	SDHB	SDHC	SDHD
Head and neck	1	20	0	46
Mediastinal	0	3	1	4
Pheochromocytoma	1	1	0	3
Abdominal	1	6	0	2
GIST	3	0	1	0
RCC	0	2	0	0
Other	3	1	0	1
Total number of tumours	9	33	2	56
Metastatic sites	4	0	0	2

During the audit period 37 tumours were detected in 25 carriers (34%). MRI screening detected 74% of tumours, and 20% were detected on screening CT; 6% of tumours were detected after symptoms prompted investigation. PPGLs were functional in 10 patients (36%); two head and neck tumours were functional (7%).

Primary treatment of tumours was excision (48%), observation (26%), radiotherapy (19%), and stereotactic ablative radiotherapy (3%). One carrier had radiotherapy after excision.

One patient died during the audit period with a SDHA pathogenic variant; metastatic phaeochromocytoma was listed on the death certificate as a contributing factor but not the cause of death.

Compliance against audit standards demonstrated 78% of carriers were reviewed in clinic yearly. A review of symptoms was documented in 75% and 75% had metadrenalines yearly; 61% had 3 yearly imaging including the whole neck to pelvis.

Conclusions: our cohort adds to the available data in this rare disease and demonstrates the significant burden of SDHx pathogenic variant associated disease. Case identification may have been limited by reliance on coding to identify cases. Audit demonstrates the challenges of managing the volume of appointments and investigations for both the NHS and patients, who may need to travel significant distances to tertiary centres.

EP950 - ECE_3248 - Tracing an SDHD-Related Paraganglioma Cluster Across Generations

Simina Plesca[1], Diana Martiniuc[2], Ingrid-Ioana Stafie[2,3] and Cristina Preda[2,3]

[1]"St Spiridon" Clinical Emergency County Hospital Endocrinology, Iasi, Romania; [2]Iasi, Romania; [3]"Gr. T. Popa" University of Medicine and Pharmacy, Iasi, Romania

Introduction: Paragangliomas are rare neuroendocrine tumours arising from sympathetic or parasympathetic paraganglia and are frequently associated with germline variants in succinate dehydrogenase (SDH) genes. SDHD variants are typically associated with head and neck disease, show variable penetrance, and demonstrate a parent-of-origin effect related to genomic imprinting, with clinical manifestations occurring mainly after paternal transmission.

Case Presentation: We report a 41-year-old woman who was referred for endocrine reassessment after undergoing excision of a right carotid body paraganglioma . Her symptoms began at the age of 28, during her first pregnancy, with persistent right-sided hemicrania, together with gestational hypertension, sinus tachycardia and atrial extrasystoles. Repeated urinary fractionated metanephrines remained within the normal range. Cervico-thoraco-abdominal CT showed bilateral carotid body paragangliomas (40 mm on the right and 13 mm on the left), and the right-sided tumour was completely resected. Histopathology confirmed a moderately differentiated parasympathetic paraganglioma (GAPP score 5-6) with vascular invasion and positive margins. Following surgery, headache and blood pressure improved, although the recovery was complicated by transient hypoglossal nerve palsy.Somatostatin receptor scintigraphy (99mTc-Tektrotyd) showed intense tracer uptake in the left carotid lesion, with no other abnormal findings. Further endocrine evaluation excluded syndromic associations, including MEN2 and the 3P association. Germline testing with a hereditary paraganglioma–phaeochromocytoma panel identified a heterozygous likely pathogenic SDHD c.52+2T>C variant, together with a CHEK2 c.470T>C (p.Ile157Thr) moderate cancer-risk variant. In keeping with the genetic findings, several relatives were also affected. These included the patient's father, who had bilateral carotid paragangliomas and colorectal cancer at 41 years of age; a paternal uncle who declined surgery; a paternal aunt treated with radiotherapy; and a cousin who died during reoperation, with her sister more recently diagnosed with paraganglioma.. The patient has three asymptomatic children who are currently undergoing clinical and genetic surveillance.

Conclusions: This case illustrates the value of careful family assessment in recognising hereditary paraganglioma syndromes and directing appropriate genetic testing. Identification of a pathogenic SDHD variant supports lifelong surveillance and cascade testing in at-risk relatives, with the aim of reducing morbidity and improving preventive care.

Keywords paraganglioma, SDHD, familial clustering, genomic imprinting, genetic screening

EP951 - ECE_3328 - Targeting the inflammasome machinery: a multi-omic approach to identify new diagnostic markers and therapeutic strategies in brain tumors

Natalio Leiva-Hidalgo[1,2,3], Ignacio Gil-Duque[1,2,3], Miguel E. G-Garcia[1,2,3], María Ortega-Bellido[1,2,3], Miguel Ángel Núñez-Santos[1,2,3], Manuel D. Gahete[1,2,4], Antonio C. Fuentes-Fayos[1,2,3] and Raul M. Luque[1,2,4]

[1]Maimónides Biomedical Research Institute of Córdoba (IMIIBIC)/ Reina Sofía University Hospital, Córdoba, Spain; [2]Department of Cell Biology, Physiology, and Immunology, University of Córdoba, Córdoba, Spain; [3]Reina Sofía University Hospital, Córdoba, Spain; [4]Biomedical Research Networking Center for Physiopathology of Obesity and Nutrition (CIBERobn), Madrid, Spain

Glioblastoma (GBM) remains the most prevalent and lethal primary brain endocrine-related cancer in adults. Despite current gold standard therapies, late-stage diagnosis and inherent therapeutic resistance result in a bad prognosis, with median survival

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

rates limited to 10-12 months. Consequently, there is an urgent clinical need to identify novel diagnostic/prognostic biomarkers and therapeutic targets to improve patient management and quality of life. GBM is characterized by profound cellular heterogeneity and a complex tumor microenvironment (TME), wherein the immune system plays a key role in modulating tumor-associated inflammation. An essential component of this inflammatory response is the inflammasome machinery, a multiprotein complex activated by cellular stress and damage, being closely linked to immune evasion, cell death, and TME remodeling. In this study, we characterized the expression pattern of inflammasome components using a high-throughput qPCR array based on microfluidic technology. We analyzed a well-characterized cohort of GBM patients ($n = 63$) compared to non-tumor brain (NTB; $n = 19$) samples. Our results revealed a profound and widespread dysregulation of the inflammasome machinery in GBM tissue. These findings were subsequently validated in multiple independent external cohorts using RNA-seq, microarray and proteomic data, confirming the robustness of the observed expression patterns. To further address the complexity of this tumor, we characterized specific cell populations using an external single-cell sequencing dataset. Remarkably, the expression of key inflammasome components (highlighting MYD88) correlated significantly with aggressive clinical parameters and poor prognosis, including reduced survival rates, higher recurrence, EGFR amplification, and MGMT promoter methylation status. In silico pathway analysis further demonstrated that MYD88 expression is associated with critical pathways in GBM pathophysiology, such as epithelial-to-mesenchymal transition (EMT), hypoxia, angiogenesis, and NF-κB signaling. To evaluate the functional relevance of these findings, we performed in vitro modulation of MYD88 through transient silencing (siRNA) and pharmacological inhibition. Notably, we also addressed the challenge of chemoresistance by evaluating these modulations in a temozolomide (TMZ)-resistant GBM cell model developed within our laboratory. These interventions significantly reduced key oncogenic parameters, including cell proliferation, migration rate, and colonies and tumorspheres formation. In conclusion, this study demonstrates that the inflammasome machinery is a critical driver of GBM progression. Our data highlights MYD88 as a potential master regulator of tumor aggressiveness, positioning it as a novel diagnostic/prognostic biomarker and a promising therapeutic target to improve outcomes for patients suffering from this devastating disease.

EP952 - ECE_3631 - From primary hyperparathyroidism to multifocal pNETs: neoplastic spectrum of MEN1 in early adulthood

Kalliopi Pantelia, Vasiliki Antonopoulou, Aggeliki Kyriakou, Marinella Tzanela and Theodora Stratigou
Department of Endocrinology "D. Ikkos"- Diabetes Center-EndoERN-Evangelismos General Hospital, Athens, Greece

Background: Multiple Endocrine Neoplasia type 1 (MEN1) is characterized by multifocal and recurrent endocrine neoplasms, most commonly involving the parathyroid glands and the gastroenteropancreatic neuroendocrine system.

Case Presentation: A 20-year-old male was diagnosed with primary hyperparathyroidism following detection of hypercalcemia during evaluation of a presyncopal episode. Physical examination was unremarkable. Biochemical evaluation revealed elevated serum calcium (12.4 mg/dL), parathyroid hormone (185.8 pg/mL) and urinary calcium excretion. Imaging demonstrated a large left inferior parathyroid lesion. The patient underwent subtotal parathyroidectomy, with pathology revealing three parathyroid adenomas and loss of nuclear menin expression.

Given the early onset and multiglandular disease, molecular analysis was performed and identified a heterozygous pathogenic MEN1 mutation (c.1378C>T, p.Arg460Ter), confirming the diagnosis of MEN1. Further evaluation revealed unremarkable pituitary imaging, but multifocal pancreatic lesions on MRI, subsequently confirmed by 68Ga-DOTATOC with high somatostatin receptor expression (SUVmax 68). Biochemical evaluation of neuroendocrine activity revealed mildly elevated chromogranin A (5.9 nmol/L, reference <3) and significantly increased plasma glucagon levels (418 pg/ml, reference <250) at initial assessment. Surgical management consisted of subtotal pancreatectomy. Histopathological examination demonstrated multiple well-differentiated neuroendocrine neoplasms: a pancreatic head pNET G2 measuring 3.0 cm, a pancreatic body glucagon-positive pNET G1 measuring 2.5 cm, an additional pNET G1 measuring 0.8 cm, four pNETs (0.5-3 mm), and a duodenal NET G2 measuring 0.6 cm. No lymph node metastases were identified (pancreas pT2(m)N0, duodenum pT1N0). Serial measurements demonstrated normalization of neuroendocrine markers.

Six months later, endoscopic ultrasound and MRI revealed new small lesions (5-9 mm), in the pancreatic remnant one confirmed (EUS-FNB) as a G1 glucagon (+) pNET. 68Ga-DOTATOC showed only mild uptake in lymph nodes, attributed to inflammation. Subsequent MRI revealed additionally an irregular mass measuring 3.5×2.7 cm in the lesser sac. Neuroendocrine tumor markers remained within normal limits. Following multidisciplinary re-evaluation, the irregular lesion was attributed to a post-procedural hematoma. The patient was therefore placed under close surveillance.

Conclusions: This case illustrates the aggressive neoplastic burden and early multifocality of MEN1-associated gastroenteropancreatic neuroendocrine tumors. Pancreatic neuroendocrine tumors in MEN1 are traditionally diagnosed after the 2nddecade of life. The diagnosis of multiple pNETs at 20 years of age in this patient is early but within the expected MEN1 spectrum. Detailed tumor characterization is critical for surgical decision-making and long-term surveillance in young MEN1 patients.

EP953 - ECE_3666 - To highlight the importance of surveillance for ovarian cancer in women with MEN2A with RET positive mutations and to consider prophylactic oophorectomies

Veronica Chirila and Bushra Ahmad
Diabetes and Endocrinology, Bristol Royal Infirmary, Bristol, United Kingdom

Case History: We present a fit and well 50-year-old patient who was very concerned about the genetic predisposition for ovarian cancer following the early death of her mother of ovarian cancer at the age of 61 (diagnosed at 51).

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

The genetic screening demonstrated RET mutation (Val804leu). Our lady was reviewed in the endocrinology clinic, underwent surveillance and medullary thyroid cancer was detected and had thyroidectomy in February 25. Histology results showed medullary thyroid cancer T1N1M0.

There is no metastatic disease found on the staging CT scans.

After discussion, our patient has decided to go for a prophylactic oophorectomy after menopause in view of her risk of ovarian cancer.

Investigations: Radiology: US thyroid (December 24): an ill-defined lesion with micro and macro calcifications.

CT neck/chest/abdomen/pelvis (December 24):No lymphadenopathy or metastatic disease was found.

US neck (March 25): no concerning lymphadenopathy

MRI pelvis (April25): no adnexal masses seen

Biochemistry: Bloods (December 24): calcitonin 165 (<4.8), CEA 11.1 (<5.2).

Post thyroidectomy bloods (Apr 25): calcitonin<3

Conclusion and Discussions: Recent genomic analyses have identified recurrent somatic RET missense mutations in 2% of epithelial ovarian cancer (EOC) cases. Some of the RET mutations have oncogenic properties. Therefore, RET can act as an oncogenic driver in a subset of EOC and RET inhibitors such as Vandetanib have shown activity against EOC cells harbouring RET mutations in clinical trials.[1] Current guidelines recommend prophylactic oophorectomy to women with known BRCA1 or BRCA2 mutations or other mutations predisposing to ovarian cancer such as BR1P1, RAD51C and RAD51D.[2] However, prophylactic oophorectomy is also considered for women with strong family history of ovarian cancer, even in the absence of a confirmed pathogenic mutation, due to the possibility of undiscovered or untested genetic risk.[3] Therefore, this abstract highlights the importance of inclusion criteria for female patients with MEN2A with confirmed genetic RET mutation in the panel list for prophylactic oophorectomy.

The discovery of RET pathogenic variant in the EOC patients suggests a previously underestimated role for RET in EOC tumorigenesis. Also highlights the potential use of RET in targeted therapy to treat EOC patients.[1]

EP954 - ECE_2126 - CYP26B1 and RARB genetic variants in radioiodine-refractory papillary thyroid carcinoma

Rafał Fyda[1], Bartosz Partyński[2], Anna Nogieć[3], Alicja Hubalewska-Dydejczyk[4,5] and Malgorzata Trofimiuk-Muldner[4]

[1]*Students' Scientific Group, Chair and Department of Endocrinology, Jagiellonian University Medical College, Kraków, Poland*

[2]*Department of Endocrinology, Endocrine Oncology, Nuclear Medicine and Internal Diseases, University Hospital in Kraków, Kraków, Poland;* [3]*Haematological Diagnostics and Genetics Unit, University Hospital in Krakow, Kraków, Poland;* [4]*Department of Endocrinology, Chair and Department of Endocrinology, Jagiellonian University Medical College, Kraków, Poland;* [5]*Dep of Endocrinology, Jagiellonian University Medical College, Krakow, Poland*

Background: Radioiodine-refractory papillary thyroid carcinoma represents a major therapeutic challenge, as it is associated with limited treatment options and poorer clinical outcomes. Retinoids, including 13-cis retinoic acid, have been investigated as agents capable of restoring iodine uptake by modulating thyroid-specific gene expression. However, clinical responses have been inconsistent and limited to a small subset of patients. There is also scant data linking serum vitamin A concentrations with the clinical course of thyroid cancer. It might suggest that biological factors influencing retinoids metabolism and signaling may play a role.

Objective: The aim of this study was to determine whether patients with non-radioiodine-avid PTC differ from the general population with respect to genetic variants in *CYP26B1*, a key enzyme involved in retinoic acid catabolism, and *RARB*, encoding retinoic acid receptor beta.

Materials and Methods: Nineteen patients with histologically confirmed PTC and documented loss of radioiodine uptake were included. The cohort consisted of 10 men (52.6%) and 9 women (47.4%), with a mean age at diagnosis of 51.2 ± 19.0 years. According to AJCC 8th edition staging, tumors were classified as T1 in 31.6%, T2 in 21.1%, T3 in 26.3%, and T4 in 21.1% of patients; nodal metastases (N1) were present in 78.9%, and distant metastases (M1) in 36.8%. Multifocal disease was observed in 78.9% of cases. Patients received multiple courses of RAI therapy, with a mean cumulative administered activity of 9358 ± 3757 MBq; 68.4% received two RAI treatments, while the remainder received three or more. Genomic DNA extracted from peripheral blood was analyzed using Sanger sequencing of selected regions of *CYP26B1* and *RARB*. Identified variants were compared with reference allele frequencies from population databases.

Results: Sequencing identified only previously reported variants within the analyzed regions of *CYP26B1* and *RARB*. No statistically significant differences in allele or genotype frequencies were observed between patients with non–radioiodine-avid PTC and the general population. No rare or potentially pathogenic variants specific to the study cohort were identified.

Conclusions: In this cohort, no relevant genetic alterations were identified in *CYP26B1* or *RARB*. Therefore, those components of retinoic acid pathway are not likely to contribute to reported in the literature difference in the PTC behavior in relation to serum vitamin A concentrations.

EP955 - ECE_2594 - Extensive Tumor Spectrum in MEN1: From Silent Adrenal Adenoma to Aggressive Adrenocortical Carcinoma with Cushing's Syndrome

Violetta Rosiek, Ksenia Janas and Beata Kos-Kudła

Endocrinology, Department of Endocrinology and Neuroendocrine Tumors, Department of Pathophysiology and Endocrinology, Medical University Of Silesia, Katowice, Poland

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Introduction: Multiple endocrine neoplasia type 1 (MEN1) is typically characterized by the triad of parathyroid, pancreatic, and pituitary tumors. However, the syndrome can manifest with an unusually broad spectrum of non-classical and aggressive malignancies. Adrenocortical carcinoma (ACC) is an exceedingly rare manifestation of MEN1, with fewer than 20 cases described in the literature.

Case Presentation: We report a 43-year-old woman with genetically confirmed MEN1 and a remarkably complex phenotype. Her clinical history included a typical pulmonary carcinoid (resected, Ki-67 5%), primary hyperparathyroidism, a pituitary prolactinoma, and multifocal G1 neuroendocrine tumors (NETs) of the pancreasand duodenum. She also underwent surgery for an incidental clear cell papillary renal cell carcinoma.

The hallmark of this case was the rapid evolution of a left adrenal lesion. Initially identified as a hormonally silent 19 mm adenoma, the lesion demonstrated dramatic growth during surveillance, reaching 110 × 72 mm within 18 months. This rapid enlargement was accompanied by a functional transformation, leading to biochemical hypercortisolism and the development of overt clinical Cushing's syndrome. Histopathology confirmed high-grade ACC. Despite the stability of other MEN1-related lesions under somatostatin analog therapy, the aggressive progression of the ACC, with liver and suspected peritoneal metastases, required the initiation of systemic EDP-M chemotherapy (etoposide, doxorubicin, cisplatin, and mitotane).

Conclusions: This case illustrates the extreme clinical heterogeneity of MEN1 and highlights the potential for rapid transformation of a dormant, non-functional adrenal lesion into an aggressive, hormone-secreting malignancy. It underscores the critical need for vigilant, lifelong multidisciplinary surveillance, as functional and morphological changes in adrenal lesions can signal a shift toward highly aggressive disease.

EP956 - ECE_1059 - Atypical Carney Complex (CNC) presenting with acromegaly, pheochromocytoma, and cardiac myxoma: a rare multisystem presentation

Kiana Ghannadi[1], Chan Ju Baek[2], Fatemeh Ghannadi[2], Ashkan Parsa[3] and Iman Hemmati[4]
[1]*Faculy of Science, The University of British Columbia, Vancouver, Canada;* [2]*Department of Family Medicine, University of British Columbia, Seawall Medical Centre, Vancouver, Canada;* [3]*Division of Cardiology, University of British Columbia, Vancouver, Canada;* [4]*Division of Rheumatology, University of British Columbia, Vancouver, Canada*

Introduction: Carney Complex (CNC) is a rare autosomal-dominant neoplasia syndrome most often caused by PRKAR1A mutations, leading to dysregulated cAMP-protein kinase A signalling. Typical features include cardiac and extracardiac myxomas, pigmented skin lesions, and endocrine overactivity. Early recognition is essential to prevent complications and enable genetic screening. We report a case of CNC initially managed as presumed vasculitis, presenting with recurrent embolic events and multiple endocrine and non-endocrine tumours, including pheochromocytoma.

Case Report: A woman in her early 30s presented with six months of progressive myalgia and irregular plantar vascular lesions. Elevated C-reactive protein (15 mg/L) prompted suspicion for vasculitis, and she was prescribed prednisone. She subsequently developed palmar purpura, subungual tenderness, intermittent visual disturbances, and recurrent upper-extremity numbness. Echocardiography identified a 4.1-cm left atrial myxoma attached to the interatrial septum with mild inflow stenosis; the mass was resected without complication.

Post-resection evaluation identified an ocular blue nevus. Imaging revealed a 6-cm right adrenal pheochromocytoma, thyroid colloid cysts, and psammomatous melanotic schwannomas. Pituitary MRI demonstrated a macroadenoma, and endocrine testing showed elevated IGF-1 (702 µg/L) and chromogranin A. Endoscopic transsphenoidal resection confirmed a mixed somatotroph-lactotroph adenoma. Persistent acromegaly was treated with lanreotide, cabergoline, and pegvisomant, achieving IGF-1 normalisation (149 µg/L). She remains on long-term pegvisomant therapy with imaging surveillance. Adrenalectomy after alpha-blockade was uneventful. Follow-up MRI showed stable schwannomas without pheochromocytoma recurrence. Echocardiography demonstrated preserved ejection fraction (62%) with abnormal global longitudinal strain (–14%) and no myxoma recurrence. PRKAR1A testing is ongoing.

Discussion: This case illustrates the diagnostic challenge posed by multisystem CNC, particularly when early findings mimic rheumatologic disease. The patient's vasculitis-like lesions were secondary to embolisation from an atrial myxoma, which, along with a GH-secreting pituitary adenoma and psammomatous melanotic schwannomas, fulfils diagnostic criteria for CNC. Although pheochromocytoma is uncommon in classic CNC, it has been reported in expanded phenotypes and may overlap with the Carney-Stratakis spectrum. Its presence in this case broadens the recognised tumour spectrum of CNC and emphasizes the need for comprehensive endocrine and genetic evaluation. Early echocardiographic evaluation should be considered in patients with unexplained vasculitic-appearing lesions and systemic symptoms to exclude embolic cardiac sources.

Conclusions: CNC should be considered in patients presenting with multiple endocrine and non-endocrine tumours or atypical cutaneous findings. This case underscores the expanding phenotypic spectrum of CNC, particularly the coexistence of pheochromocytoma and acromegaly, and reinforces the importance of comprehensive endocrine evaluation and lifelong multidisciplinary surveillance.

Multiple endocrine neoplasia type 1 (MEN1) is a genetic syndrome characterized by the development of multiple

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

neuroendocrine tumors involving the parathyroid glands, gastroenteropancreatic tract, pituitary gland, and less frequently the adrenal cortex, thymus, and bronchi; it may also be associated with other non-endocrine tumors.

LCNEC of the lung is a rare and aggressive cancer. The average 5-year survival rate is 35%, but it can vary significantly depending on the stage at diagnosis, with much lower survival rates in advanced metastatic disease.

We report the case of a 49-year-old female patient carrying the MEN1 mutation c.1937insC in exon 10. She presented with primary hyperparathyroidism and multiple pancreatic neuroendocrine tumors treated with somatostatin analogues since 2023.

In August 2024, a chest CT scan revealed an increase in size of a known pulmonary micronodule, described as a solid nodule with spiculated margins, highly suspicious for malignancy. The patient therefore underwent FDG-PET, which showed intense uptake in the pulmonary lesion, and Gallium-PET, which demonstrated the presence of somatostatin receptor–expressing lesions in the pancreatic, pulmonary, and right pulmonary hilar/perihilar regions.

Bronchoscopy and fine-needle aspiration of the hilar lymph node were performed, with cytopathological diagnosis of a well-differentiated, low-grade neuroendocrine neoplasm (Ki-67 = 3%). The patient underwent right lobectomy with lymphadenectomy in April 2025.

Histological examination revealed a combined carcinoma with a LCNEC component (90%, Ki-67 60%) and adenocarcinoma with solid and acinar growth patterns (5% and 5%, respectively, TTF-1 positive). In addition, metastases from LCNEC were present in multiple interlobar, peribronchial, subcarinal, and paratracheal lymph nodes (pT3, pN2).

Restaging was performed using FDG-PET, brain MRI, and chest–abdomen CT. These investigations showed significant disease progression, with the appearance of multiple new pulmonary nodules, mediastinal and laterocervical lymphadenopathies, and lesions consistent with metastases involving the liver, adrenal glands, pelvis, intestine, skeleton, and brain.

Molecular analysis performed on tumor tissue identified an ALK gene rearrangement, thus Lorvatinib 100 mg/d was started in June 2025.

At follow-up, in October 2025, the multiple brain nodular lesions appeared markedly reduced in volume or even no longer individually recognizable; secondary pulmonary nodules and hilar-mediastinal lymphadenopathy were no longer detectable; the hepatic metastasis was unchanged; the solid nodule located in the left hypochondrium and the right adrenal mass showed a reduction in size; and sclerosis of bone lesions was observed at sites of previous metastases. The drug was well tolerated, with only mild side effects, opening the possibility of an improved long-term prognosis.

EP959 - ECE_1040 - Role of visfatin in cancers

Haitham Abu-Lebdeh[1,2,3] and Hassan Heshmati[4]
[1]*Division of Endocrinology, Diabetes, Metabolism and Nutrition, Mayo Clinic, Rochester, MN, United States;* [2]*Endocrinology, Mayo clinic, Rochester, United States;* [3]*Mayo Clinic, Rochester, United States;* [4]*Endocrinology Metabolism Consulting, LLC, Hassan Heshmati and Valerie Shaw Endocrine Research, Anthem, AZ, United States*

Introduction: Visfatin, a hormone first described in 2005, is an adipocytokine synthesized predominantly by the visceral adipose tissue but also by several other organs (eg, liver, muscle, heart, lung, kidney, and placenta). The gene of visfatin is located on chromosome 7q22.3. Visfatin consists of 491 amino acids. Visfatin plays an important role in inflammation and has been implicated in the proliferation of several cancers. This review presents an update on the role of visfatin in cancers.

Methods: A systematic search of literature was conducted for the period 2013 to 2025 using the search terms visfatin, cancer, proliferation, metastasis, chemotherapy, and prognosis.

Results: Visfatin has pro-oncogenic activity in several cancers. It promotes tumor proliferation through the activation of key oncogenic pathways (eg, enhancement of intracellular nicotinamide adenine dinucleotide synthesis needed for deoxyribonucleic acid repair) leading to increased angiogenesis, epithelial mesenchymal transition, and immune suppression. There is an increase in serum visfatin levels in different cancers. Studies in breast cancer, esophageal cancer, and gastric cancer have reported that visfatin is associated not only with inflammation, angiogenesis and tumor proliferation, but also with metastasis and resistance to chemotherapy. High serum visfatin levels are associated with poor prognosis of cancers. Serum visfatin level can be used as a biomarker in different cancers (eg, gastrointestinal and pancreatic cancers). Inhibitors of visfatin activity (eg, FK866, CHS828, and KPT-9274) represent promising therapeutic tools for cancers but the demonstration of their benefit and safety requires further clinical studies.

Conclusions: Visfatin is a hormone synthesized predominantly by the visceral adipose tissue. It is involved in multiple pathological conditions including inflammation and the proliferation of several cancers such as breast cancer and upper gastrointestinal cancers (eg, esophageal and gastric cancers). Elevated serum visfatin levels are associated with metastasis, drug resistance, and correlate with poor cancer prognosis. Serum visfatin level can be used as a prognostic biomarker in cancers. The potential benefit of inhibiting visfatin activity in the treatment of cancers requires further investigations.

EP960 - ECE_3671 - Beyond JAK2: Endocrine and Paraneoplastic Causes of Secondary Polycythemia

Paola Girardi[1], Francesco Ramundo[2], Valerio De Stefano[2] and Alfredo Pontecorvi[1]
[1]*UOC Medicina Interna, Endocrinologia e Diabetologia, Fondazione Policlinico A. Gemelli, IRCCS, Rome, Italy;* [2]*UOC Ematologia, Fondazione Policlinico A. Gemelli, IRCCS, Rome, Italy*

Background: Endocrine Secondary Polycythemia (ESP) is an entity in which hormonal dysregulation enhances erythropoietic drive, resulting in increased hemoglobin and hematocrit levels (>16.5 g/dL and >49% in men; >16 g/dL and >48% in women). ESP should be clearly differentiated from Polycythemia Vera, a clonal myeloproliferative neoplasm associated with constitutive activation of the JAK–STAT signaling pathway, most commonly due to the JAK2 V617F mutation.

Although a comprehensive systematic review is currently lacking, an expanding body of literature documents the occurrence of ESP across a broad spectrum of endocrine and metabolic disorders.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Methods: We performed a narrative review aimed at delineating the principal endocrine-related causes of secondary polycythemia, conditions that are frequently overlooked or erroneously classified as idiopathic. A systematic search of the PubMed database was conducted, including human studies published between 1963 and 2025.

Search terms included:

- "endocrine related polycythemia"
- "secondary polycythemia in endocrinopathies"
- "SGLT2 inhibitor–induced polycythemia"
- "tyrosine kinase inhibitor–induced polycythemia"
- "paraneoplastic syndrome–induced polycythemia"
- "endocrine cancer–induced polycythemia"
- "polycythemia and uterine fibromyoma"

Of the 263 records identified, 73 articles met the inclusion criteria and were selected for qualitative analysis.

Results: Available evidence indicates that ESP, although uncommon, predominantly arises from three major pathogenetic settings.

Endocrine Disorders: include endogenous hyperandrogenism associated with adrenocortical, testicular, or ovarian tumors; erythropoietin-secreting pheochromocytomas; hypercortisolism; acromegaly; hyperthyroidism; and hyperparathyroidism.

Drug-Related Causes: encompass androgen replacement therapy for hypogonadism, anabolic steroid misuse, sodium–glucose cotransporter 2 inhibitors, and antiangiogenic tyrosine kinase inhibitors.

Paraneoplastic Syndromes: represent an additional etiological group and include paragangliomas and somatostatinomas (Pacak–Zhuang syndrome), gastrointestinal neuroendocrine tumors, LH-secreting pituitary gonadotropinomas, POEMS syndrome, renal cell carcinoma, supratentorial meningiomas, hemangioblastomas, and erythropoietin-producing uterine fibroids.

Conclusions: ESP represents a rare but clinically relevant cause of secondary polycythemia. Increased awareness and a structured diagnostic approach are essential to identify underlying endocrine or paraneoplastic etiologies. Early recognition may improve clinical management and enable the implementation of targeted therapeutic strategies, particularly in JAK2-negative polycythemias that are frequently—and incorrectly—classified as idiopathic.

EP961 - ECE_2291 - Contrasting Genetic and Sporadic Malignant Adrenal Paraganglioma: A Case Series

Raluca Pirvu[1], Ramona Dobre[1,2], Iulia Florentina Burcea[1,2], Oana Pietrareanu[1] and Catalina Poiana[1,2]

[1]*National Institute of Endocrinology C.I. Parhon, Bucharest, Romania;* [2]*Carol Davila University of Medicine and Pharmacy, Bucharest, Romania*

Adrenal paragangliomas are rare neuroendocrine tumors arising from adrenal chromaffin cells, characterized by catecholamine hypersecretion and significant cardiovascular morbidity. Although most adrenal paragangliomas are benign, a minority exhibit malignant behavior, defined by local invasion or distant metastases, as reliable histopathological criteria predicting malignancy are lacking. Malignant adrenal paraganglioma therefore remains a diagnostic and therapeutic challenge. Up to 40% of adrenal paragangliomas are associated with hereditary syndromes. Genetic background influences clinical presentation, biochemical phenotype, surveillance strategies and prognosis, however malignant disease may also occur in apparently sporadic cases.

We present a series of three malignant adrenal paragangliomas illustrating genetic and sporadic forms across different ages. The first case involves an 18-year-old male initially diagnosed at age 15 with arterial hypertension and a left adrenal mass, which was surgically resected and confirmed as adrenal paraganglioma. Two years later, a contralateral adrenal tumor with malignant features (PASS 4, ki-67 >3%) developed and right adrenalectomy was performed. Tumor recurrence was subsequently confirmed by functional imaging, which demonstrated metabolically active bilateral adrenal lesions with minimal somatostatin receptor expression and early biochemical relapse. Genetic testing revealed a pathogenic VHL mutation.

Case 2 is a 38-year-old female presenting with a large left adrenal mass (10 cm) revealed by Menard's triad of headaches, palpitations and sweating. Biochemical markers were markedly elevated. Histopathological examination after adrenalectomy confirmed malignant adrenal paraganglioma (PASS 8). Postoperative biochemical remission was achieved, although mediastinal lymphadenopathy was detected on follow-up imaging.Given a significant family history of malignancy, genetic testing was performed and pathogenic mutations were excluded.

Case 3 involved a 57-year-old male with a right adrenal mass and markedly elevated plasma and urinary metanephrines. Following adrenalectomy, histopathology demonstrated adrenal paraganglioma with high malignant potential (PASS 8, Ki-67 18%). Sustained biochemical remission was observed and follow-up imaging showed no evidence of recurrence.

Malignant adrenal paragangliomas are rare tumors with highly variable clinical presentations, occurring in both hereditary and sporadic contexts. Genetic status informs tumor distribution, surveillance strategies and risk assessment however phenotypically aggressive disease may develop regardless of genotype. While histopathological scoring systems provide important information on malignant potential, they cannot reliably predict the clinical evolution of the disease. These cases emphasize the importance of early recognition, individualized surgical and medical management, and lifelong biochemical and imaging follow-up to detect recurrence or metastasis promptly, ensuring optimal long-term outcomes.
