AW6 - Basic science—molecular memory—how the liver remembers fasting

Ido Goldstein
The Hebrew University, Jerusalem, Israel

Mammals withstand frequent and prolonged fasting periods due to hepatic production of ketone bodies. Because the hepatic fasting response is tightly regulated transcriptionally, we asked whether transcription factor and enhancer activity impose a transcriptional program during repeated fasting and whether this generates effects distinct from a single fasting bout.

We found that mice undergoing alternate-day fasting respond profoundly differently to a following fasting bout compared to mice first experiencing fasting. Hundreds of genes enabling ketogenesis were "sensitized", meaning that while their level was reduced back to basal levels upon refeeding, their induction became stronger in the next fasting bout. The activity of thousands of enhancers was also sensitized. Enhancer sensitization was governed by the transcription factor PPARα: sensitized enhancers harbored increased binding of PPARα and gene sensitization was abolished in hepatocyte-specific PPARα-deficient mice. As a result of sensitization, repeated fasting led to augmented ketogenesis compared to a single fasting bout; an effect which was absent in hepatocyte-specific PPARα-deficient mice.

In summary, we found a transcriptional memory mechanism where past fasting events are "remembered" in hepatocytes, sensitizing their enhancers to the next fasting bout and increase ketogenesis via amplified gene induction. Our findings reveal a new adaptation mechanism to repeated environmental signals: transcription factor-mediated sensitization of enhancers resulting in an amplified transcriptional response.

PL2 - Hormones for life: the enigma of LH and HCG

Manuela Simoni
Department of Biomedical, Metabolic and Neural Sciences; Unit of Endocrinology—OCSAE, University of Modena and Reggio Emilia, Modena, Italy

The reason why two hormones acting on the same receptor, ie LH and hCG acting on LHCGR, are necessary for reproduction remain enigmatic. The beta subunit gene of hCG (CGB) evolved from the *LHB* gene from a frame shift mutation and successive, multiple gene duplications, so that one *LHB* and six *CGB* genes exist in the species *Homo*. Such a complication is justified by a progressive specialization of hCG function, which should be differentiated from that of LH. Yet the two hormones have been traditionally thought to be equivalent and our textbook knowledge about "LH action" derives form experiments in rodents (which do not have hCG) using hCG instead of LH. *In vitro* experiments demonstrate that the two hormones have different activity on signal transduction, being hCG mainly steroidogenic (via cAMP) and LH acting as a growth and anti-apoptotic factor (via ERK and AKT signaling). The LHCGR discriminates between the two ligands through exon 10, encoding the hinge region. *In vivo*, deletion of exon 10 results in lack of LH action with hypergonadotropic hypogonadism in the presence of normal androgenization, suggesting that hCG can act on the deleted receptor while LH cannot.

The main actions of hCG are: 1) maintenance of pregnancy via stimulation of progesterone by the corpus luteum; 2) embryo implantation; 3) development of the fetal testis; 4) development of the fetal thyroid (through TSH receptor); 5) virilization of the external genitalia via the backdoor steroidogenic pathway. Therefore, hCG is essential for male fetal development and androgenization. The main action of LH is evident in females: LH is essential for follicular maturation, ovulation and luteinization of granulosa cells.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

In theca cells LH stimulates progesterone and androgen production via expression of StAR and steroidogenic enzymes. In the male, the action of LH is less clear. Preliminary results suggest that, in men with hypogonadotropic hypogonadism, LH alone is unable to stimulate testosterone production, which probably requires FSH action as well.

In conclusion, hCG is essential for primate pregnancy but has developed a number of other functions, while the function of LH is only partly understood. The enigma continues …

PL3 - Human exposure to microplastics and implications for health

Majorie van Duursen
Vrije Universiteit Amsterdam, Amsterdam, The Netherlands

The increasing production and use of plastics poses a serious threat to human endocrine health. Chemicals can leach from plastics that are know to interact with our endocrine system and have been associated with endocrine-related diseases and disorders, including subfertility and changes in age of pubertal onset. More recently, scientific and societal attention has been been directed towards micro- and nanoplastics (MNPs); small plastic particles resulting of plastic degradation. While MNPs are found everywhere in the environment, and increasing number of studies report on the occurrence in humans as well, the health impact they may have on humans remains unclear. Studies addressing human health impact generally suffer from poor exposure assessment and limited number of participants. This talk will address the current state of science, including the scientific challenges we are facing in the complex field of plastics research.

Abstract citation ID: lvag096.004

PL4 - Cellular diversity of the hypothalamus

Tibor Harkany
Medical University of Vienna

The hypothalamus is the central site where neurendocrine modules cocluster in the brain. During evolution, cellular diversification rather than progeny expansion had taken place to increase the specificity, precision, and adaptive potential of neuroendocrine output pathways. This is why the hypothalamus became a brain region with a unique constellation of cell types, including exceptional numbers of phase- and state transitions to allow for maximal flexibility. Here, I will discuss developmental principles that underpin the organization of neuroendocrine command centers for brain-body communication, and integrate them with extrahypothalamic neurocircuits that offer upstream control. Thereafter, I will showcase novel understanding on neuron-glia communication and circuit-specific interactions to control bodily metabolism. A central role for neuropeptides, which are commonly co-released with fast neurotransmitters, will be made in defining cell states, labile neurocircuit output, and disease vulnerabilities. These topics will be presented and discussed by combining single-cell techniques with optical and chemical manipulations to experimentally modulate, disrupt or even attempt to repair neuroendocrine cell contingents of the hypothalamus.

Abstract citation ID: lvag096.005

PL5 - Shining light in the darkness of pheochromocytoma

Karel Pacak
AKESO, Prague, Czech Republic

Pheochromocytomas and paragangliomas (PPGLs) remain among the most genetically complex and clinically unpredictable endocrine tumors, associated with substantial morbidity and metastatic potential. Yet what was once a field defined by uncertainty is rapidly becoming a model of precision oncology. Over the past decade, comprehensive genomic discovery has unveiled more than 25 susceptibility genes and seven biologically distinct molecular clusters, redefining PPGL as a family of molecularly stratified diseases. Genotype now informs biochemical phenotype, metastatic risk, imaging strategy, and therapeutic vulnerability. Contemporary international guidelines embed this taxonomy into daily practice, ensuring that precision is no longer theoretical, but operational. Newly established international consensuses and evidence-based guidelines now formally incorporate this molecular taxonomy into screening protocols for *SDHx* mutation carriers, imaging selection algorithms, metastatic management strategies, and lifelong surveillance frameworks, ensuring that precision is no longer theoretical, but operational. Functional imaging has evolved from a “one tracer fits all” philosophy to cluster-specific precision selection. The emerging “precision imaging card” concept links molecular background with radiopharmaceutical choice, enabling biologically informed detection and treatment planning. Theranostics, integrating ^{68}Ga-DOTATATE imaging with ^{177}Lu-DOTATATE or ^{225}Ac-DOTATATE therapy, demonstrates that diagnosis and treatment are no longer separate acts, but a continuous, biologically guided strategy. Prospective clinical data confirm durable disease control, while HIF-2α inhibition and anti-angiogenic tyrosine kinase inhibitors expand systemic options for advanced disease. Beyond tumor cells, the microenvironment, angiogenesis, immune architecture, macrophage predominance, emerges as both signal and therapeutic target. Multi-omic integration and international data sharing are reshaping how we define aggressiveness, recurrence, and therapeutic response. Artificial intelligence now stands at the horizon. Predictive models integrating molecular, biochemical, imaging, and clinical variables are beginning to identify metastatic potential at diagnosis and anticipate therapeutic efficacy. Generative AI may soon assist in designing personalized therapeutic strategies for resistant disease. Together, these advances shine unprecedented light into the biological darkness of PPGL with molecular clarity and predictive precision, transforming a once enigmatic endocrine tumor into a model of globally collaborative, data-driven precision medicine.

PL6 - Thyroid hormone action in bone

Graham Richard Williams
Department of Medicine, Imperial College London, Molecular Endocrinology Laboratory, Room 10N5, Commonwealth Building, London, United Kingdom

Introduction: Thyroid hormone (T3) has critical roles during skeletal development, growth, and adult bone maintenance.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Hypothyroidism delays bone development and linear growth, whereas thyrotoxicosis accelerates skeletal maturation and is an important risk factor for osteoporosis in adulthood. Even sub-clinical hyperthyroidism is associated with fracture, and treatment with thyroxine at doses that suppress TSH increases bone turnover and decreases bone mineral density. Skeletal phenotypes resulting from abnormal T3 action in genetically modified mice faithfully reproduce genetic disorders in humans and reveal complex physiological relationships between centrally regulated thyroid status and peripheral T3 actions.

Methods: We generated mutant mice with cell-specific thyroid hormone deficiency in each of the major skeletal cell lineages. Skeletal tissues were analysed at birth, weaning, during rapid growth and in adulthood by whole mount staining of the skeleton, X-ray microradiography, back-scattered electron scanning-electron microscopy, histology and histomorphometry. We established primary cultures of cartilage-forming chondrocytes, bone-forming osteoblasts and co-cultures of osteoblasts and bone-resorbing osteoclasts from T3 receptor (TR) deficient mice for analysis of T3-target gene expression by RNAseq.

Results: T3 actions during skeletal development were mediated by TRα in chondrocytes via target genes involved in gene transcription, membrane transport and signalling, hypertrophic chondrocyte differentiation, bone morphology, extracellular matrix organisation, and cellular and extracellular matrix interactions. T3 actions in adults were mediated by TRα in osteoblasts via target genes involved in bone formation, osteoclastic bone resorption, glycolysis and oxidative phosphorylation, and endocrine, paracrine and cytokine signalling. T3 actions in osteocytes modulated skeletal responses to oestrogen deficiency. By contrast, osteoclasts responded indirectly via TRα-mediated T3-actions in osteoblasts.

Conclusions: The skeleton is exquisitely sensitive to thyroid hormones throughout life and T3 actions are mediated by TRα in chondrocytes and cells of the osteoblast lineage.

Abstract citation ID: lvag096.007

PL7 - The bone rebound phenomenon: understanding bone loss mechanisms after Denosumab withdrawal

Bente Langdahl
Endocrinology and Internal Medicine, Aarhus University Hospital, Aarhus, Denmark

Denosumab (DMAB) is a human monoclonal antibody that binds to the receptor activator of nuclear factor κB ligand (RANKL) and inhibits the binding of RANKL to RANK, an interaction responsible for osteoclast formation, function, and survival. Treatment with DMAB reduces bone resorption, leading to rapid and significant increases in BMD and decreases the risk of both vertebral and non-vertebral fractures.

If DMAB is discontinued, bone turnover not only returns to pre-treatment levels but increases above, a phenomenon known as bone turnover overshoot. This overshoot lasts for 6-12 months before slowly normalizing toward pre-treatment level and is associated with loss of the BMD gained during DMAB therapy as well as an increased risk of multiple vertebral fractures.

The bone turnover overshoot after DMAB discontinuation distinguish DMAB from bisphosphonates, which have residual skeletal binding that provides partial, long-lasting antiresorptive effects even after treatment is stopped. Some aspects of the physiology underlying the overshoot activation of bone resorption upon discontinuation of DMAB are known, but much remains unknown. RANKL accumulates in the bone microenvironment during treatment with DMAB and the OPG response when RANKL is no longer bound to DMAB appears insufficient to counter the rapidly increasing unbound RANKL. Studies in mice have also shown an accumulation of resting pre-osteoclast-type cells, called osteomorphs that can rapidly become active osteoclasts. The mechanostat may also play a role, as bone mass tends to adjust towards an individual's genetically determined pre-treatment level in the absence of drug interference. Clinical observations support some of these mechanisms; several studies have suggested that BMD gain during DMAB and/or the DMAB treatment duration correlates with subsequent BMD loss after discontinuation.

Bisphosphonates offer the best, although incomplete, protection against the overshoot of bone turnover, whereas SERMs, anabolic therapy, and DMAB tapering do not reliably prevent the bone turnover overshoot or fractures. Clinicians should therefore support persistence with DMAB, avoid unplanned discontinuation, and ensure that any planned discontinuation is followed by a timely initiation of a potent bisphosphonate, with consideration of repeated dosing in patients with prolonged DMAB exposure.

DMAB is an effective antiresorptive treatment for osteoporosis, superior to bisphosphonates in improving BMD, but its discontinuation carries clinically significant risks of bone loss and vertebral fractures. Consequently, discontinuing DMAB requires long-term treatment planning, and the timely initiation of appropriate sequential therapy is essential to optimize patient outcomes.

PL8 - GLP-1 and beyond: next-gen therapies for obesity and metabolic disease

Lotte Bjerre Knudsen
Novo Nordisk, Ringstedt, Denmark

Glucagon-Like Peptide-1 receptor agonists (GLP-1RAs), such as liraglutide and semaglutide, are long-acting pharmacological agents approved for diabetes and obesity management, with additional benefits on cardiovascular, renal, and hepatic systems, and emerging potential in brain-related disorders with significant unmet needs. These fatty acid-acylated molecules bind non-covalently to serum albumin, enhancing pharmacokinetic stability, and signal through a specific GLP-1 receptor expressed on select cell types across various organs. GLP-1RAs mimic the multifaceted physiological roles of GLP-1, a key regulator of post-prandial responses, including glucose homeostasis, appetite regulation, and other biological processes. Peripherally administered GLP-1RAs access specific brain regions via circumventricular organs expressing GLP-1

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

receptors, as shown in rodent whole-brain imaging. The weight loss mechanism is primarily driven by brain GLP-1R activation, reducing energy intake through neuromodulation and potentially altering reward signaling to influence food choice. GLP-1RAs also reduce systemic inflammation by approximately 50%, as measured by C-reactive protein, which, alongside reductions in blood pressure, triglycerides, blood glucose, and body weight, is hypothesized to decrease atherosclerotic burden. Furthermore, the application of omics in clinical trials has elucidated diverse mechanisms underlying GLP-1RA efficacy across diseases, highlighting their broad therapeutic potential and informing drug repurposing approaches. Beyond GLP-1, additional mechanisms come from amylin, GIP and glucagon agonism.

S1.1 - Genetics of low/intermediate risk thyroid cancer

Abstract Unavailable

Abstract citation ID: lvag096.009

S1.2 - Treatment of low/intermediate risk thyroid cancer

Emese Mezosi
Ist Department of Internal Medicine, Clinical Center, University Medical School of Pecs, Pécs, Hungary

Differentiated thyroid cancer generally has an excellent prognosis, and treatment strategies increasingly emphasize risk-adapted and individualized management. The 2025 guidelines of the American Thyroid Association recommend a stratified approach based on estimated risk of structural recurrence, categorizing patients into low, low–intermediate, intermediate–high, and high-risk groups. In patients with low or intermediate risk, the primary goal of therapy is to achieve disease control while minimizing treatment-related morbidity through a de-escalated management strategy.

Surgery remains the cornerstone of initial treatment. For selected patients with small, intrathyroidal tumors, thyroid lobectomy may be sufficient, while total thyroidectomy is generally reserved for larger tumors, multifocal disease, or cases with nodal involvement. The updated guidelines place greater emphasis on conservative surgical approaches and, in carefully selected patients with very low-risk tumors, even active surveillance may be considered.

Postoperative radioactive iodine (RAI) therapy is no longer routinely recommended for low-risk patients. Instead, RAI is selectively applied based on clinicopathologic features and recurrence risk. In intermediate-risk disease, RAI may be considered on an individualized basis, particularly in the presence of lymph-node metastases, microscopic extrathyroidal extension, or vascular invasion. Recommended administered activities typically range from 30-100 mCi.

Long-term management includes risk-adapted surveillance with neck ultrasonography, serum thyroglobulin or anti-thyroglobulin antibody monitoring, and dynamic risk stratification to guide the intensity of follow-up. A more conservative approach to thyroid-stimulating hormone (TSH) suppression is also recommended to reduce adverse effects. Overall, the current recommendations highlight personalized care, selective use of adjuvant therapies, and de-escalation of treatment intensity.

Abstract citation ID: lvag096.010

S1.3 - Targeted therapy in radioiodine refractory thyroid cancer

Laura Fugazzola
Università di Milano, Milan, Italy

Radioiodine-refractory thyroid cancer (RAIR-TC) represents a challenging subset of differentiated thyroid cancers characterized by loss of iodine avidity and poor or absent response to conventional radioactive iodine therapy. Over the past decade, advances in molecular biology have significantly improved the understanding of the genetic alterations driving these tumors, leading to the development of targeted therapeutic strategies. Key oncogenic pathways implicated in RAIR-TC include mutations in BRAF, RAS, RET/PTC rearrangements, and alterations in the MAPK and PI3K-AKT signaling pathways.

Targeted therapies, particularly tyrosine kinase inhibitors (TKIs), have emerged as the cornerstone of treatment for patients with progressive RAIR-TC. Agents such as lenvatinib and sorafenib have demonstrated improved progression-free survival by inhibiting multiple kinases involved in tumor proliferation and angiogenesis, including VEGFR, FGFR, and RET. More recently, selective inhibitors targeting specific genetic alterations, such as BRAF and RET inhibitors, have shown promising efficacy with improved safety profiles compared to multikinase inhibitors.

Despite these advances, challenges remain, including the development of resistance, treatment-related toxicities, and variability in patient response. Ongoing research is focused on combination therapies, redifferentiation strategies to restore radioiodine uptake, and the identification of predictive biomarkers to guide personalized treatment.

In conclusion, targeted therapy has transformed the management of RAIR-TC, offering meaningful clinical benefit. Continued investigation into tumor biology and therapeutic optimization is essential to further improve outcomes in this aggressive disease subset.

S2.1 - Tanycytes at the crosstalk between reproduction and metabolism

Daniela Fernandois
INSERM U1172, Lille, France

Tanycytes are specialized ependymoglial cells that line the walls and floor of the third ventricle, serving as gatekeepers for peripheral blood-borne signals entering hypothalamic circuits that regulate **reproduction** and energy homeostasis. These cells extend processes toward the median eminence and arcuate nucleus, facilitating the transport of metabolic hormones and designed drugs—including leptin and GLP-1 analogs—into the mediobasal hypothalamus. Estrogens, acting via estradiol receptor alpha (ERα), play a crucial role in regulating the hypothalamic–pituitary–gonadal axis and energy balance. However, the mechanisms by which they influence tanycyte function are only beginning to be understood.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Using transgenic mice with tanycyte–selective ERα deletion, ovariectomized models, primary tanycyte cultures, and human post-mortem tissue, we show that estradiol–ERα signaling in tanycytes is crucial for both reproductive and metabolic functions. Female mice with tanycyte–selective ERα deletion become acyclic, display elevated estradiol and LH levels, and require more attempts to achieve successful pregnancy, pointing to impaired fertility. At the cellular and circuit level, tanycytes contact and communicate with NPY neurons, suggesting that tanycytic estrogen/ERα sensing participates in GnRH–NPY communication to fine–tune LH release according to peripheral metabolic cues.

In parallel, estradiol signaling through tanycytic ERα increases leptin uptake and release, and facilitates the entry of leptin and semaglutide into the mediobasal hypothalamus—effects that are especially pronounced in females. Loss of ERα in tanycytes leads to notable structural and morphological alterations, indicating disrupted transport and barrier functions. Furthermore, analysis of human tissue demonstrates that ERα expression in tanycytes during menopause is both sexually dimorphic and sensitive to menopausal status. Together, these results establish tanycytic ERα signaling as a critical integrator of gonadal and metabolic cues within hypothalamic networks, offering a mechanistic explanation for sex- and age-dependent changes in fertility and energy homeostasis, and highlighting tanycytes as promising therapeutic targets for modulating the gonadal–metabolic axis.

S2.2 - Metabolic impact of PFAS and environmental factors on breast milk and microbiota of mother-infant dyads

Matej Orešič[1,2]
[1]University of Turku, Turku, Finland; [2]Örebro University, Örebto, Sweden

Early-life exposure to environmental chemicals, particularly per- and polyfluoroalkyl substances (PFAS) and related persistent organic pollutants (POPs), is increasingly recognized as a key determinant of metabolic health. In this talk, I will present findings from longitudinal mother–infant cohort studies integrating metabolomics, lipidomics, and microbiome profiling to elucidate how these exposures shape early-life biology.

Our work demonstrates that prenatal and early postnatal exposure to PFAS and POP mixtures is associated with profound alterations in lipid metabolism, including ceramides, phospholipids, and acylcarnitines, as well as disruptions in bile acid and amino acid pathways. These metabolic changes are closely linked to shifts in gut microbiota composition and microbial-derived metabolites, highlighting a coordinated perturbation of host–microbiome interactions. Notably, breast milk emerges as a central interface in this process, acting both as a route of exposure and as a modulator of infant metabolic and microbial development.

We further show that different classes of environmental pollutants exert partially distinct yet overlapping effects: PCBs exhibit strong and consistent associations with lipid and microbiome alterations, while PFAS display broader but more heterogeneous metabolic signatures. Across studies, bile acid metabolism and gut–liver axis signaling emerge as key pathways linking environmental exposures to systemic metabolic outcomes.

These findings challenge traditional toxicological paradigms by demonstrating that environmentally relevant exposures reprogram metabolic networks early in life through microbiome-mediated mechanisms. A systems-level, multi-omics perspective is therefore essential to understand how the exposome shapes developmental trajectories and long-term disease risk.

S2.3 - Anti-Mullerian hormone (AMH) role in programming PCOS

Paolo Giacobini[1,2]
[1]INSERM U1172, Univ. Lille, Inserm, CHU Lille, U1172 -LilNCog(JPARC) –Lille Neurosciences & Cognition, Lille, France; [2]Lille Neuroscience and Cognition, Lille, France

Polycystic ovary syndrome (PCOS) is the most prevalent reproductive and metabolic disorder, affecting up to 13% of women worldwide. Although initially characterized as a reproductive condition and the leading cause of anovulatory infertility, PCOS is now recognized as a systemic disorder associated with long-term comorbidities, including obesity, type 2 diabetes, cardiovascular disease, and an increased risk of neuropsychiatric disorders. Despite its substantial impact on women's health, there is currently no cure for PCOS, underscoring the urgent need for improved therapeutic strategies.

Hyperandrogenism and elevated circulating anti-Müllerian hormone (AMH) levels are hallmark features of PCOS. Recent studies using animal models demonstrate that prenatal and/or postnatal exposure to excess AMH predisposes female offspring to develop reproductive and metabolic abnormalities that closely resemble the human condition. These studies highlight an unexpected role for AMH in the development of PCOS, beyond its classically described ovarian function.

By leveraging a PCOS-like mouse model with pharmacological preclinical interventions and clinical investigations, we have identified key neuronal populations involved in PCOS pathophysiology. These findings reveal a central neuroendocrine contribution to disease etiology and highlight novel therapeutic avenues for the treatment of PCOS.

S2.4 - GLP1 induced weight loss and pregnancy

Ursula Winterfeld
Swiss Teratogen Information Service and Clinical Pharmacology Service, Centre Hospitalier Universitaire Vaudois (CHUV) and University of Lausanne, Lausanne, Switzerland

The increasing use of glucagon-like peptide-1 receptor agonists (GLP-1 RAs) in women of reproductive age raises important clinical questions at the interface between metabolism, fertility, and pregnancy safety. Emerging evidence suggests potential benefits on ovulation and fertility in women with obesity and polycystic ovary syndrome. Consequently, their use in the preconception period is expanding.

However, GLP-1 RAs are not recommended during pregnancy due to the absence of randomized controlled trials in pregnant populations and findings of reproductive toxicity in animal studies. Current recommendations advise discontinuation prior to conception, particularly for long-acting agents. Despite this, real-

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

world data indicate increasing exposure during early pregnancy, often in the context of unplanned pregnancies.

This situation requires distinguishing between two different clinical questions: the potential teratogenic risk associated with early pregnancy exposure, and the metabolic consequences of treatment discontinuation before conception. Addressing these questions demands different types of evidence and has distinct implications for clinical counseling.

This presentation will review the available data on preconception benefits of GLP-1 RAs, summarize current knowledge on pregnancy outcomes following inadvertent exposure, including recent findings from the European Network of Teratology Information Services (ENTIS), and discuss emerging evidence on metabolic changes after discontinuation. Finally, implications for counseling women treated with GLP-1 receptor agonists who are planning pregnancy or present with early exposure will be discussed.

Abstract citation ID: lvag096.015

S3.2 - RNA processing: another regulatory layer of islet cell function

Lori Sussel
Barbara Davis Center for Diabetes, University of Colorado, Aurora, United States

Emerging data from both mouse models and human islets indicate that islet cells dynamically regulate RNA metabolism in response to environmental cues. Because β cells must rapidly adapt to fluctuations in nutrient availability, RNA processing offers a fast yet durable layer of regulatory control, but this level of regulation remains relatively understudied. In addition, cell type–specific aberrant splicing and the resulting protein isoforms contribute to β cell dysfunction in both T1D and T2D. Our work has identified RNA-binding proteins (RBPs) and altered splicing programs that influence islet cell identity and β cell function. We and others have also shown that N6-methyladenosine (m6A)—the most abundant and best-characterized RNA modification in mammals—differs in abundance between diabetic and non-diabetic donor islets, and emerging evidence suggests that this modification impacts both alternative splicing and cell differentiation. To define these mechanisms, we are using mouse models with disruptions in m6A regulatory pathways combined with single-cell long-read sequencing to determine how RNA modifications control islet cell–specific splicing and functional outcomes.

Abstract citation ID: lvag096.016

S3.3 - Latest advances in amylin therapeutics for obesity treatment

Thomas Lutz
University of Zurich, Institute of Veterinary Physiology, Zurich, Switzerland

The pancreatic hormone amylin has originally been discovered in and isolated from pancreatic islet amyloid deposits. In few species only, including primates and felines, the amylin molecule has the propensity to aggregate into oligomers and eventually mature amyloid fibrils. However, monomeric hormonal amylin produces a large variety of beneficial metabolic effects that make the non-fibrillar forms of amylin a fascinating candidate for the treatment of metabolic diseases. Amylin is co-synthesized and co-secreted with insulin, and it is an important control of eating, mainly by its physiological effect on meal-ending satiation. Chronically, amylin and its receptor analogues also lead to substantial weight loss. Here, I will review the current knowledge on the central nervous system pathways mediating amylin's metabolic effects and how this may translate in effective pharmacotherapy. Amylin receptor pharmacology is complex because of the existence of several distinct amylin receptor subtypes, and we only start to understand the specific actions mediated by these subtypes. The latter aspect is also relevant to understand potential differences in tolerability among different amylin receptor agonists which are in different phases of clinical developments.

S4.1 - Emerging genetic factors in young-onset and familial pituitary tumors

Adrian Daly
Department of Endocrinology, Centre Hospitalier Universitaire de Liège, University of Liège, Liège, Belgium

Clinically evident pituitary adenomas affect 1:1000 individuals and most cases remain genetically unexplained. Pituitary adenomas have a very limited repertoire of known germline genetic causes and most affect neuroendocrine pathways. Among these, the most prevalent are rare loss of function (LOF) variants in AIP that cause young onset and familial isolated pituitary adenomas (FIPA), primarily acro-gigantism and prolactinomas. Duplications disrupting a conserved topologically associating domain (TAD) at GPR101 cause sporadic and familial X-linked acrogigantism (X-LAG). Pituitary adenomas also form part of genetic syndromes including multiple endocrine neoplasia (MEN) 1, MEN4, MEN5, and Carney complex. Recent genetic research has highlighted the major contribution of germline deleterious variants to tumorigenesis across many tissue types. In particular, young age at diagnosis and a positive family history of tumors are two key indicators of the presence of underlying germline deleterious genetic variants in cancer-related molecular pathways. These approaches are beginning to be applied to anterior pituitary tumors in both selected/focused screening populations and in unselected patient groups. Recent work using NGS panels has linked deleterious variants in DNA mismatch repair (MMR) genes to the development of pituitary adenomas in rare instances. Using whole exome sequencing and clinical databases, groups have identified pathogenic variants in genes like PMS2, MSH2, and MLH1 in various populations. While some of these variants occurred in individuals with Lynch syndrome (and undergoing screening), others occur in patients with sporadic pituitary tumors without a known family history of Lynch syndrome. While established risk genes like AIP and MEN1 remain significant players in pituitary tumorigenesis, the broader landscape of DNA

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

repair genes may play a larger role than previously appreciated. In this presentation, we will trace existing knowledge on pituitary tumorigenesis and cancer risk genes and will highlight new research from our international research collaboration examining the potential contribution of novel pituitary risk genes in the etiology of aggressive young-onset pituitary tumors and FIPA. These emerging findings may have relevance for genetic counseling and could expand targeted management strategies in patients with pituitary tumors.

S4.2 - Age-related changes in pituitary function

Abstract Unavailable

Abstract citation ID: lvag096.018

S4.3 - Approach to older patients with a pituitary adenoma: challenges and future directions

Niki Karavitaki
Centre for Endocrinology, Diabetes and Metabolism, Birmingham Health Partners, Birmingham, United Kingdom

Non-functioning pituitary adenomas account for the majority of pituitary tumours detected in the elderly population. They usually present with pressure effects to surrounding structures (mainly visual deterioration or manifestations of hypopituitarism) or they can be detected incidentally. Other types of pituitary adenomas are less common and can relate with increased morbidity and mortality.

The presence of various comorbidities in the older patients affecting their frailty and fitness for surgery pose challenges for the surgical resection of pituitary adenomas in this age group. Nonetheless, a number of contemporary studies have suggested that complication rates after transsphenoidal surgery do not differ from those encountered in younger patients. Furthermore, satisfactory endocrine remission rates have been reported for functioning tumours. In non-functioning pituitary adenomas, the decisions for surgical intervention and its specific aims should rely on multidisciplinary team discussion with the contribution of anaesthesiology and geriatric medicine and after balancing the pros and cons of active management versus observation alone. Further strategies for use of adjuvant radiotherapy post-operatively should also be individualised taking into account the risk of tumour regrowth and its clinical sequelae over time.

Studies that will allow the development of reliable risk stratification and will guide the evidence-based selection of optimal management pathways in older patients with pituitary adenomas are needed.

Abstract citation ID: lvag096.019

S5.1 - Heat stress effects on ovarian function and fertility

Aileen Keating
Iowa State University, Ames, United States

Female infertility is a consequence of heat stress and has been recognized in production animals for decades and more recently in women. Systemically, heat stress compromises intestinal barrier integrity and elevates circulating insulin, both physiological perturbations that can independently compromise female fertility. In production animals, heat stress is phenotypically characterized by anovulation, reduced conception rates, and low pregnancy maintenance. In women, heat stress is linked with preterm birth, birth defects, fetal growth restriction and death and altered ovarian function. Ovarian endocrine disruption and molecular sequelae due to heat stress have been partially identified. Using pig and mouse models, the impacts of heat on ovarian follicle number, ovarian steroid hormone concentrations and the ovarian proteome have been characterized. Reduced female fertility is detrimental not only to quality of life in humans, but also to animal welfare, agricultural economics/sustainability and human food security. Thus, identifying mechanisms that compromise female fertility is needed for developing mitigation strategies.

Abstract citation ID: lvag096.020

S5.2 - Human in utero exposures to air pollution

Paul Fowler
University of Aberdeen

WHO estimates that over 99% of all humans are exposed to excess air pollution. At the same time air pollution is ubiquitous globally, transported around the world in the atmosphere. Air pollution includes gases like ozone, CO, O_3, nitrogen dioxides chemicals like lead, sulphur, particulate matter (PM), including PM_{10} and $PM_{2.5}$ μm micro and nanoparticles. These particles consist of metals, black carbon and plastics. Overall air pollution is a complex mixture: acids, inorganic compounds, organic chemicals, soot, metals, soil/dust particles, and biological materials. Components of air pollution also including endocrine disrupting chemicals and man-made chemicals, such as “forever chemicals”, PFAS. Exposure to air pollution in utero is a cause of multiple developmental deficits and post-natal health deficits and affects millions of pregnancies globally. The presentation will introduce air pollution, examples of adverse consequences and summary of major issues of concern. In addition, issues, such as the movement of pollutants between air and water and other matrices will be discussed.

Abstract citation ID: lvag096.021

S5.3 - Thyroid hormone system–disrupting effects on neurosensory system development—lessons learned from the zebrafish model

Lisa Baumann
Vrije Universiteit Amsterdam

Early vertebrate development is partly regulated by thyroid hormones (THs) and can therefore be disrupted by environmental pollutants that interfere with the TH system (thyroid hormone system–disrupting chemicals, THSDCs). Because THs play a key role in neurosensory development, these systems represent sensitive endpoints for detecting endocrine disruption in humans and environmental non-target species, such as fish. Using the popular (eco)toxicology model zebrafish (Danio rerio), we examined the impact of model THSDCs on several neurosensory structures and assessed whether early-life effects are reversible. THSDC exposure induced pronounced alterations in eye development, including changes in size, pigmentation, and retinal cell

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

structure. Specificity of effects was confirmed by molecular analyses (TH levels and transcriptomics) and behaviour assays. Notably, these effects showed partial reversibility after a short recovery period. Based on this work, zebrafish eye development assessment is currently undergoing OECD validation as a standardized thyroid-related endpoint in fish. In addition to extensive results on THSD-induced effects on eye development, preliminary data indicating that early TH system disruption also affects the brain and olfactory epithelium development in zebrafish embryos will be presented. Using transgenic zebrafish lines and confocal microscopy, we observed developmental changes in total brain volume and in olfactory epithelium area, suggesting broader neurosensory sensitivity to TH perturbation. Together, these data demonstrate that multiple components of the zebrafish neurosensory system respond to THSDCs during early development, with potential for recovery effects. Because the endocrine system is highly conserved across vertebrates, these findings from zebrafish may also provide insights relevant to human thyroid-dependent neurosensory development and potential vulnerabilities to TH system disruption.

Abstract citation ID: lvag096.022

S6.1 - New models on pheochromocytoma: organoids

Patricia Dahia
Division of Hematology and Medical Oncology, University of Texas Health Science Center at San Antonio, San Antonio, Texas, United States

Pheochromocytomas and paragangliomas (PPGLs) are rare chromaffin cell-derived neuroendocrine tumors derived from sympathetic (catecholamine-producing) or parasympathetic (nonsecretory) lineage, frequently driven by dysregulation of hypoxia-inducible factor (HIF) signaling, particularly HIF-2α. Although often benign, PPGLs can metastasize unpredictably, with limited therapeutic options once disseminated. Progress has been hindered by the lack of robust preclinical models, especially those that capture their molecular complexity and microenvironmental influences. To address this gap, we established patient-derived tumor organoids (PDOs) from 35 PPGLs, comprising a broad spectrum of clinical and molecular phenotypes. The organoids retained key immunohistochemical, genomic, transcriptomic, and catecholamine-secretory features of their parental tumors. PPGL organoids cultured under hypoxic conditions generally exhibited enhanced viability, supporting hypoxia as a driver of cell survival. Hypoxia activated HIF-1α and expanded *ASCL1*-positive cell populations, suggesting a shift toward a more immature chromaffin state. In contrast, long-term normoxic cultures activated hypoxia inducible factor 2α (HIF-2α) and acquired a hybrid sympathoblast–mesenchymal identity in subpopulations with upregulation of extracellular matrix and cell cycle markers, independent of genotype. These PDO features resemble high-risk neuroblastoma subtypes and establish a molecular parallel suggestive of shared lineage plasticity and pathogenic programs, which are also detectable in primary PPGLs. Drug screening across a library of up to 51 drugs and combinations revealed both shared and unique vulnerabilities, with response rates to belzutifan resembling clinical observations. The CDK4/6 inhibitor abemaciclib, previously unexplored in PPGLs, elicited the strongest activity. Abemaciclib-responsive PDOs and their matched tumors, including a metastatic sample, exhibited epithelial mesenchyme transition enrichment, nominating potential biomarkers for patient stratification. Our results establish PDOs as a novel platform for modeling neuroendocrine tumor biology, reveal microenvironment-driven plasticity in PPGLs with potential translational relevance, and identify actionable vulnerabilities in a disease with few effective systemic therapies.

S6.2 - Use of artificial intelligence in management of pheochromocytoma

Abstract Unavailable

Abstract citation ID: lvag096.023

S6.3 - Cardiovascular complication of pheochromocytoma and paraganglioma

Ondrej Petrák
General University Hospital in Prague, III. internal clinic—clinic of endocrinology and metabolism, Praha, Czech Republic

Background: Adrenaline-producing tumors are mostly characterized by a sudden release of catecholamines with episodic symptoms. Noradrenergic ones are usually less symptomatic and characterized by a continuous overproduction of catecholamines that are released into the bloodstream. Their effects on the cardiovascular system can thus be different. The aim of this study was to determine the prevalence of cardiovascular complications by catecholamine phenotype.

Methods: We retrospectively analyzed data on the prevalence of cardiovascular events in 341 consecutive patients with pheochromocytoma and paraganglioma treated from 1995 to 2023. Biochemical catecholamine phenotype was determined based on plasma or urinary catecholamines and metanephrines.

Results: According to the phenotype, 153 patients had noradrenergic pheochromocytoma and paraganglioma and 188 had adrenergic pheochromocytoma and paraganglioma. In the whole sample, the incidence of serious cardiovascular complications was 28% (95 patients), with no difference between the phenotypes or sexes. The noradrenergic phenotype had significantly more atherosclerotic complications (composite end point of type 1 myocardial infarction and symptomatic peripheral artery disease; odds ratio, 3.58 [95% CI, 1.59-8.83]; $P = .003$), while the adrenergic phenotype more often had type 2 myocardial infarction and takotsubo-like cardiomyopathy (OR, 0.24 [95% CI, 0.09-0.57]; $P = .002$). These changes remained even after adjustment for conventional risk factors of atherosclerosis.

Conclusions: We found a 28% incidence of cardiovascular complications in a consecutive group of patients with pheochromocytoma and paraganglioma. Patients presenting with a noradrenergic phenotype have a higher incidence of atherosclerotic complications, while the adrenergic phenotype is associated with a higher incidence of acute myocardial damage due to takotsubo-like cardiomyopathy.

S7.1 - Focus on Osteogenesis imperfecta viewpoint

Neil Gittoes

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

University of Birmingham, Institute of Metabolism and Systems Research, Birmingham, United Kingdom

Osteogenesis imperfecta (OI) is a heterogeneous group of rare, heritable disorders of connective tissue characterised primarily by increased bone fragility and reduced bone mass. Most forms arise from pathogenic variants affecting type I collagen synthesis, structure, or processing, leading to impaired bone matrix quality and abnormal skeletal biomechanics. Clinical severity ranges from mild with few fractures to perinatal lethality. In most forms of OI, fracture risk is highest during the period of linear growth, and during adolescence, fracture risk reduces rapidly. Bisphosphonates remain the mainstay of medical therapy, and in children, the evidence base is stronger for fracture prevention and attendant improvements in bone density. Recent data in adults questions the role of bisphosphonates and teriparatide in conferring a meaningful benefit in fracture prevention. Newer anabolic and targeted molecular approaches—such as sclerostin inhibition and TGF–β pathway modulation—show emerging promise. Optimal care is multidisciplinary, incorporating endocrinology, orthopaedics, physiotherapy, and genetics to improve function, mobility, and quality of life.

From a generalist perspective, recognising a rare syndrome of fracture susceptibility can be challenging when a child or young adult presents with a fracture, which is a common occurrence, usually linked to an active lifestyle. Often, the number of fractures and mechanism of injury can highlight suspicion of such susceptibility. This talk will review features of OI that should be considered when faced with a young adult with fractures.

S7.2 - Focus on hypophosphatasia viewpoint

Abstract Unavailable

Abstract citation ID: lvag096.025

S7.3 - Focus on X-linked hypophosphatemia

Catherine Chaussain
Université Paris Cité, Paris, France

Bones and teeth are the most important mineralized tissues in the body. They share several mechanisms related to their development and mineralization, including the signaling pathways that regulate the differentiation of their cell types.[1,2] Therefore, dental complications are a common morbidity in patients with endocrine disorders. Depending on the disorder, either the tooth structure, its morphology, or the number of teeth may be affected. Rare bone disorders related to the mineral homeostasis or affecting genes encoding a component of the extracellular matrix can dramatically affect tooth mineralization. As a consequence, patients may endure early tooth loss, or high susceptibility to caries, periodontitis or pulp infections.[1,2,3] The aim of this presentation will be to present the dental aspects of rare endocrine diseases and the impact of their complications on the patient's quality of life. In addition, we will show how a thorough dental examination can support the diagnosis of a rare endocrine disorder, and how ultrastructural examination of the tooth can provide new insights into the pathophysiological mechanisms associated with the disorder. In addition, we will discuss how the ultrastructural examination of the tooth can reveal how a systemic treatment improves the mineralization process. Overall, this presentation will urge the need to include a dentist as part of the multidisciplinary team caring for the patient.

S8.1 - Strategies for clinical screening of MEN1 mutation carriers

Gerlof D. Valk
University Medical Center Utrecht, Utrecht, The Netherlands

Multiple Endocrine Neoplasia type 1 (MEN1) is a rare autosomal dominant hereditary syndrome caused by inactivation mutations in the *MEN1* gene. MEN1 patients are predisposed to tumors of endocrine and non-endocrine organs. The clinical management of mutation carriers is challenging because of the variable penetrance and the unpredictable course of the disease. Due to limited available evidence, the 2012 Clinical Practice Guidelines for MEN1 were predominantly based on expert opinion, leaving room for interpretation and variation in practices. However, the more protocolized screening increased the evidence on the natural course of the syndrome. The updated (2025) MEN1 clinical practice recommendations offer more evidence based refinements in the management of patients based on three systematic reviews and a Delphi consensus procedure.

Clinically diagnosed patients have a different clinical course compared to mutation carriers with now addressed consequences for clinical management. As for primary hyperparathyroidism, subtotal parathyroidectomy is now the initial procedure of choice. Guidance is given on the timing of initial parathyroidectomy as well as on the controversial topic of unilateral clearance in young patients. Neuroendocrine tumors (NETs) generally have an indolent course but still lead to a 10-15 years shorter life expectance because aggressive cases do occur. The main challenge is to balance between a less intensive surveillance and timely treatment. Pituitary adenomas are most often prolactinomas

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

and nonfunctioning microadenomas with an excellent prognosis and good response to therapy. Clinically relevant manifestations are already seen at the pediatric age and recommendations are now given on mutation screening in children of a MEN1 parent and subsequent initiation of screening for manifestations. In conclusion, more guidance is given for care tailored to the needs of the individual patient and improving outcomes on an individual basis. Studies are now needed to define predictors of tumor behavior and effects of more individualized interventions.

S8.2 - GER surgical strategies for patients with MEN1 (parathyroid, pancreas)

Detlef Bartsch
Dept. Visceral-, Thoracic- and Vascular Surgery, University Hospital Marburg, Marburg, Germany

Surgical management plays a central role in the treatment of MEN1-associated disease, but remains challenging due to the multifocal and recurrent nature of these tumors. This presentation focuses on contemporary surgical strategies for MEN1 associated primary hyperparathyroidism (pHPT) and pancreatic neuroendocrine tumors (pNETs). PHPT occurs in more than 90% of patients. Because multiglandular disease is the rule, the standard surgical approaches include subtotal parathyroidectomy or total parathyroidectomy with autotransplantation, however, nowadays focussed, limited resection is also considered. Key considerations include timing of surgery, prevention of persistent or recurrent disease, and management of reoperative neck surgery. pNET represent a major determinant of MEN1-related morbidity and mortality. Surgical decision-making is complex due to the frequent multiplicity of lesions and the variable biological behavior of functional and non-functional tumors. Current strategies balance the risks of duodenopancreatic surgery with the oncologic benefits of tumor removal. Indications for resection, operative techniques such as enucleation versus formal pancreatic resection, local ablative treatments and surveillance strategies will be discussed.

S9.2 - Expanding horizons of kisspeptin: from sexual behaviour to skeletal health

Alexander Comninos
Imperial College London, Imperial College Healthcare NHS Trust, London, United Kingdom

Kisspeptin is best known as the master regulator of the reproductive hormone axis, yet growing evidence suggests its influence extends well beyond reproductive hormone control. In this lecture, I will discuss how kisspeptin signalling represents an important integrative pathway linking reproductive biology with behaviour and skeletal health.

Drawing on translational work spanning experimental models and human studies, I will present evidence demonstrating that kisspeptin influences aspects of sexual and emotional behaviour, providing insight into how reproductive neuroendocrine signals may shape human behavioural responses. Our findings highlight a broader role for kisspeptin in modulating human behaviour, with potential therapeutic implications for disorders of mood, emotion and sexual desire.

I will then discuss recent work exploring the role of kisspeptin in bone biology. Reproductive status is closely linked to skeletal health, and research from our group and others suggests that kisspeptin may positively influence bone metabolism. Understanding these pathways could open avenues for novel therapeutic approaches in metabolic bone disease.

Together, these findings illustrate the expanding physiological and pharmacological horizons of kisspeptin, positioning it as a key modulator of reproductive, behavioural and skeletal biology.

S9.3 - Non-canonical effects of non-reproductive factors on reproduction

Eva González Suárez
Spanish National Cancer Research Centre (CNIO), Tumor Biology and Immunology program, Madrid, Spain

The hypothalamic-pituitary-gonadal axis (HPG) controls pubertal development, sexual maturation, and fertility. We identified a role of hypothalamic microglia in controlling the HPG axis through Rank signaling. Whole-body and microglia Rank depletion led to hypogonadotropic hypogonadism (HH) resulting from an alteration in gonadotropin-releasing hormone (GnRH) neuron function. In addition, we identified rare gene variants of RANK in patients with HH. Transcriptional profiling upon Rank loss revealed defective microglia activation and morphological alterations in the median eminence, decreasing the contacts and engulfment of GnRH terminal projections and impairing GnRH neuronal responses to kisspeptin. Overall, our data uncover the microglia as regulator of GnRH neuronal function through Rank signaling, with potential implications for reproductive maturation and fertility

Dra. Eva Gonzalez is PhD in Molecular Biology, is a Senior scientist and group leader of the Transformation and Metastasis laboratory, at the Spanish National Cancer Research Center (CNIO) in Madrid, Spain.

S10.3 - Early life exposure to EDC and cognitive function in humans and animals

Sakina Mhaouty-Kodja
Development Adaptation & Aging, Sorbonne University—Institut de Biologie Paris Seine, Paris, France

Human populations are exposed to chemical substances released in the environment through agricultural and industrial activities. Among these chemicals, endocrine disrupting compounds (EDC) have the ability to interfere with the endocrine system leading to adverse effects. Epidemiological studies suggested associations between EDC exposure and reduced markers of the cognitive function. Exposure of rodents to EDC exhibiting either thyroid or sex steroid disrupting activities was shown to interfere with cognitive processes. In particular, exposure to environmentally relevant doses of phthalates, used as plasticizers and identified as anti-androgens, impacted learning and memory, reduced dendritic spine density, increased neuroinflammation and blood brain permeability, and altered the kynurenine pathway of tryptophan metabolism in the hippocampus.

However, as human populations are exposed to mixtures of chemicals, it is important to get insights into their effects and mechanisms following developmental exposure. This was performed in mice through exposure of dams to an EDC mixture identified in human breast milk. The obtained data show that male and female offspring born from exposed dams exhibited altered temporal order memory, novel object recognition and anxiety state level. The underlying cellular and molecular mechanisms are under investigation.

An overview of all these human and experimental data will be given, with a special focus on how they can be integrated to assess the risk or hazard for human cognitive health to EDC exposure.

S12.3 - Management of CAH across the life span

Henrik Falhammar
Department of Endocrinology, Metabolism and Diabetes, Karolinska University Hospital, Stockholm, Sweden

Management of congenital adrenal hyperplasia (CAH) requires a lifelong, multidisciplinary approach that adapts to the evolving physiological and psychosocial needs of each patient. 21-hydroxylase deficiency accounts for 95%-99% of all CAH. Classic CAH due to 21-hydroxylase deficiency typically presents in infancy, necessitating early diagnosis through newborn screening and prompt initiation of glucocorticoid and mineralocorticoid therapy to prevent adrenal crises. During childhood, management centers on optimizing growth and development while avoiding both undertreatment—associated with hyperandrogenism—and overtreatment, which risks iatrogenic Cushingoid features and impaired growth potential. Regular monitoring of hormones, growth velocity, and bone age is essential, alongside careful titration of therapy.

The transition to adolescence introduces new challenges, including puberty induction or modulation, fertility considerations, metabolic risk, and gender identity or body image concerns. A structured transition program supports the shift toward autonomous disease management and ensures continuity of care. In adulthood, treatment goals broaden to include preservation of fertility, cardiometabolic health, bone density, and psychological well-being. Women may face issues related to menstrual function, polycystic ovarian morphology, or sexual health, whereas men may develop testicular adrenal rest tumors requiring surveillance.

Adrenal crisis is most common during childhood but can occur at any age and is the most common cause of death in CAH and is therefore of utmost importance to prevent.

Throughout life, emerging therapies—including modified-release hydrocortisone, CRF1 antagonists, and gene-based approaches—offer potential to reduce androgen excess and glucocorticoid exposure. Comprehensive care should integrate endocrinologists, surgeons, psychologists, reproductive specialists, and genetic counsellors. Effective lifelong management of CAH requires individualized therapy, anticipatory guidance through key developmental stages, and ongoing evaluation of both clinical outcomes and quality of life.

S13.1 - CCN3, a maternal brain hormone stimulating bone building

Thomas Ambrosi
UC Davis, University of California Davis, Sacramento, United States

During lactation, the high calcium demand for milk production leads to substantial bone loss, compounded by a sharp drop in estrogen. We discovered that cellular communication network factor 3 (CCN3), a brain-derived hormone secreted by a subset of neurons in the arcuate nucleus, compensates for this deficit by acting as a potent osteoanabolic factor. CCN3 increases skeletal stem cell activity, enhances bone

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

remodeling, and accelerates fracture repair in mice of both sexes in experimentally-induced and age-related osteoporosis. Physiologically, CCN3 expression rises during lactation, and its reduction causes maternal bone loss and impaired offspring survival under low-calcium conditions. Results of non-human primate serum sample analysis bolster translational implications of these findings. In sum, we identify CCN3 as a maternal brain hormone essential for skeletal adaptation and a promising therapeutic target to build bone.

S13.3 - Fibroblast growth factor 23 (FGF23) and bone mineralization

Marie-Helene Lafage-Proust
Université Jean Monnet—INSERM UMR 1059 Sainbiose, Saint Priest En Jarez, France

Bone mineralization is a tightly regulated process involving two complementary phases: primary mineralization, corresponding to the rapid deposition of hydroxyapatite crystals within the osteoid matrix, and secondary mineralization, a slower process leading to progressive crystal maturation and increased mineral density. These processes critically depend on systemic and local regulation of calcium–phosphate homeostasis.

Phosphate plays a central role in skeletal mineralization, as a substrate for hydroxyapatite formation. Its systemic balance is maintained through coordinated actions of the kidney, intestine, and bone, under hormonal control including FGF23, Vitamin D and PTH.

Fibroblast growth factor 23 (FGF23), a bone-derived hormone mainly produced by osteocytes, is a key regulator of phosphate metabolism. FGF23 increases renal phosphate excretion and suppresses 1,25-dihydroxyvitamin D synthesis, thereby decreasing intestinal phosphate absorption. Through these actions, FGF23 indirectly modulates bone mineralization by controlling phosphate availability.

In turn, FGF23 is regulated by dietary phosphate load, Vitamin D and PTH. In addition, recent data unraveled the effects of inflammation and iron metabolism on FGF23 control.

Beyond its systemic indirect effects, accumulating evidence suggests that FGF23 may exert direct actions on osteoblasts activity and matrix mineralization independently of its renal effects.

This presentation will briefly report current knowledge on bone mineralization, phosphate metabolism, and FGF23 biology, highlighting both established pathways and emerging concepts regarding direct skeletal effects of FGF23 and new regulation pathways.

S14.1 - Tissue specific thyroid hormone signalling

Balázs Gereben
HUN-REN Institute of Experimental Medicine, Budapest, Hungary

The human thyroid gland primarily synthesizes thyroxine (T4), a metabolically stable prohormone requiring mostly extrathyroidal peripheral deiodination to T3 for cellular activity. The hypothalamic-pituitary-thyroid (HPT) axis maintains a relatively stable circulating thyroid hormone (TH) level. However, TH signaling within the brain exhibits rapid, cell-type specific modulation, demonstrating a capacity for local regulation largely independent of circulating TH concentrations. T3 production in the brain is largely dependent on the type 2 deiodinase (D2), a selenoenzyme predominantly expressed in glial cells—specifically astrocytes in extrahypothalamic regions and tanycytes within the hypothalamus. Globally, hypothyroidism affects hundreds of millions of individuals, and current standard-of-care treatment predominantly utilizes L-T4 monotherapy. Although this approach effectively normalizes thyroid-stimulating hormone (TSH) levels, a significant proportion (~10%-20%) of patients experience persistent residual symptoms, notably cognitive dysfunction often described as “brain fog”, suggesting tissue hypothyroidism and substantially impacting quality of life. Utilizing our Thyroid Hormone Action Indicator (THAI) mouse model, we have recently elucidated a molecular mechanism underlying the incomplete restoration of T3-dependent brain functions despite normalized TSH following L-T4 treatment. This mechanism involves glial subtype-specific differential regulation of D2 ubiquitination. Specifically, while tanycytic D2 in the mediobasal hypothalamus with direct impact on HPT function remains resistant to T4-mediated, ubiquitination-dependent inhibition and maintains sufficient T3 production for TSH normalization, D2 activity in extrahypothalamic astrocytes throughout the brain parenchyma is impaired by excess T4. This highlights the potential need for individualized assessment of tissue-level TH action in select patient populations. Our newly developed, minimally invasive methodology for evaluating human tissue TH action will be also discussed, that incorporates novel biomarkers and a Machine Learning-based predictive system.

S14.2 - Towards precision endocrinology: personalizing TSH reference ranges using genetic profiles

Aleksander Kus

Thyroid-stimulating hormone (TSH) is the cornerstone of thyroid function assessment, yet its interpretation relies on broad population-based reference ranges that may not reflect individual physiology. Increasing evidence indicates that TSH levels are strongly influenced by genetic factors, resulting in substantial inter-individual variability but relatively stable intra-individual setpoints. This suggests that integrating genetic information can refine TSH interpretation and advance a precision medicine approach in thyroidology.

A recent population-based study demonstrated that a polygenic score (PGS), constructed from common genetic variants associated with TSH regulation, explained a meaningful proportion of variability in TSH concentrations, exceeding the proportion explained by FT4 and other clinical determinants. Individuals stratified by genetic risk presented distinct TSH distributions, supporting the concept of genetically determined setpoints within the hypothalamic–pituitary–thyroid axis. Applying genetically informed reference ranges resulted in substantial (~25%-30%) reclassification of individuals previously labelled with subclinical thyroid dysfunction, which could alter treatment decisions in these patients.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Complementary research also highlights the strong genetic architecture of autoimmune thyroid disease (AITD). A PGS based on multiple genetic variants associated with thyroid autoimmunity was able to identify individuals at an increased risk of developing AITD in the general population. Moreover, among the individuals diagnosed with subclinical hypothyroidism, individuals with higher PGS score presented a higher risk of progression to overt thyroid dysfunction. This showed that PRS can potentially improve the diagnostic accuracy in thyroid hormone deficiency as well as help to predict the clinical course of subclinical disease.

Together, these findings underscore the potential of genetics to improve future clinical decision-making and set the research directions for personalized, genetically informed management of thyroid dysfunction.

S15.1 - Adipocytes in a dish: the benefits and blind spots of in vitro fat modeling

Johan Fernø
Haukeland University Hospital

Cell culture models are central to studying adipocyte biology, and primary human adipose tissue progenitor cells (ASPCs) are widely used because they better reflect in vivo biology and capture inter-individual variation compared to immortalized cell lines. However, these models have limitations, including restricted expansion capacity, artifacts introduced during tissue processing, and uncertainty about how well different 2D and 3D adipocyte models represent mature adipocytes and intact adipose tissue. Here, we present data on how in vitro culture conditions influence the identity and function of primary human ASPCs. Using single-cell flow cytometry and bulk RNA sequencing, we show that ASPCs undergo substantial shifts in cell-surface marker expression and transcriptional programs during culture. These molecular changes are accompanied by altered responsiveness to adipogenic stimuli, reflected in cellular lipid accumulation. We further compare adipocyte differentiation in primary 2D and 3D culture models and assess their similarity to mature adipocytes from the same donors. Finally, we analyze mature adipocytes isolated from subcutaneous and visceral depots across numerous donors to determine how depot-specific functional characteristics are preserved ex vivo. Our findings reveal how standard culture conditions reshape ASPC biology and highlight some important limitations of commonly used in vitro adipocyte models. We also provide insight into how 2D and 3D adipocyte models recapitulate distinct aspects of mature adipocyte biology and demonstrate that mature adipocytes retain depot-specific signatures even under ex vivo conditions.

S16.1 - Genetic causes of pituitary tumours

Sunita De Sousa
Royal Adelaide Hospital, Adelaide, Australia

Familial pituitary tumours are thought to account for 5% of all pituitary adenomas, relating to germline variants in *AIP, MEN1, CDKN1B, PRKAR1A, SDHA, SDHB, SDHC*, *SDHD* and *MAX*. In addition, germline or mosaic *GPR101*-containing X chromosome microduplications produce the X-linked acrogigantism (X-LAG) phenotype, and postzygotic gain-of-function variants in *GNAS* produce McCune-Albright syndrome.

Amongst sporadic pituitary adenomas, somatic variants are detected in *GNAS* and *USP8* in approximately 50% of somatotrophinomas and corticotrophinomas, respectively. Widespread somatic copy number variation is also frequently found on tumour testing of functioning pituitary adenomas and aggressive non-functioning pituitary adenomas. Recently, somatic variants in *TP53*, *ATRX* and *SF3B1* in pituitary adenomas have been proposed as harbingers of aggressive tumour behaviour. Outside of the pituitary literature, somatic variants in the mismatch repair (MMR) genes and *BRAF* have been demonstrated to predict tumour responses to immune checkpoint inhibitor therapy and BRAF inhibitor therapy, respectively.

Our increasing scientific understanding of the genetic causes of pituitary tumours has been paralleled by improved clinical access to genetic technologies, meaning that clinicians are now able to consider genetic testing in their patients with pituitary tumours. Germline testing may guide pituitary tumour management, gene-specific tumour surveillance, cascade testing and reproductive planning, whilst somatic testing offers—at least theoretically—the possibility of targeted tumour therapy.

This talk will provide an updated overview of the germline and somatic genetic changes found in pituitary adenomas and translation of these developments into a clinical approach to genetic testing in patients with pituitary adenomas.

Abstract citation ID: lvag096.038

S16.2 - Stem cells in development of pituitary tumours

Karine Rizzoti
The William Harvey Research Institute, London, United Kingdom

Postnatal pituitary stem cells give rise to most adult gonadotrophs.

Gonadotrophs are pituitary endocrine cells essential for reproduction, producing luteinizing hormone (LH) and follicle-stimulating hormone (FSH) that act on the gonads to drive germ cell maturation and steroidogenesis, under the control of hypothalamic GnRH and gonadal feedback. They first appear in the embryonic pituitary and expand after birth; although they can show heterogeneous responses to GnRH, they appear so far as transcriptionally relatively homogeneous.

We have recently shown that adult murine gonadotrophs have an unsuspected dual origin: most adult gonadotrophs are in fact generated postnatally, originating from pituitary stem cells from early postnatal life up to puberty, while embryonic gonadotrophs are maintained in a distinct domain in the

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

gland. Postnatal gonadotroph differentiation occurs independently of GnRH signalling and gonadal hormones. The existence of gonadotrophs with distinct developmental origins has implications for how reproductive function is established and regulated in health and disease.

- Gonadotrophs first appear in the embryonic pituitary and expand postnatally.
- Postnatal expansion result from differentiation of pituitary stem cells.
- Pituitary gonadotrophs have a dual origin, most being generated postnatally, with a small proportion of embryonic gonadotrophs persisting.
- Postnatal expansion occurs independently of GnRH.
- We are investigating the implications of these distinct developmental origins for reproductive function in health and disease.

Abstract citation ID: lvag096.039

S16.3 - Management of pituitary microadenomas: a practical approach

Tina Dusek
Zagreb University School of Medicine

Pituitary microadenomas, defined as pituitary adenomas smaller than 10 mm in diameter, are increasingly detected due to widespread use of high-resolution imaging. While many are incidental findings, a significant proportion are hormonally active and clinically relevant. A practical, patient-centred approach is essential to ensure appropriate evaluation, avoid overdiagnosis, and guide optimal management.

This lecture will provide a structured framework for the assessment and management of pituitary microadenomas. Key steps include careful clinical evaluation, targeted biochemical testing to identify hormone hypersecretion (particularly prolactin, growth hormone, and ACTH excess), and appropriate use of magnetic resonance imaging. Special emphasis will be placed on distinguishing true pathological lesions from incidentalomas and avoiding unnecessary interventions.

Management strategies vary depending on tumour functionality. Prolactinomas are primarily treated with dopamine agonists, whereas other functioning adenomas may require surgical intervention. In contrast, non-functioning microadenomas are often managed conservatively with periodic monitoring. The role of follow-up imaging and hormonal reassessment will be discussed, along with current guideline recommendations.

Through clinical cases and evidence-based recommendations, this session aims to equip clinicians with practical tools for decision-making in everyday practice, balancing early detection with avoidance of overtreatment.

JS1.1 - Bilateral nodular adrenocortical diseases, from micronodular in children to macronodular in adults

Abstract Unavailable

Abstract citation ID: lvag096.040

JS1.2 - Biological differences between pediatric and adult adrenal tumours

Enzo Lalli
Inserm, Valbonne, France

Adrenal tumours in children and adults arise from the same organ but exhibit important differences in biology, clinical behaviour and therapeutic responses. Paediatric adrenocortical tumours (ACTs) are rare, often hormonally active and frequently associated with germline mutations, particularly in *TP53*, reflecting strong genetic predisposition. In contrast, adult adrenocortical carcinomas (ACCs) are typically sporadic, genetically heterogeneous and characterized by chromosomal instability and recurrent somatic alterations in *TP53*, *CTNNB1* and *ZNRF3*. Developmental context further distinguishes these tumours: the paediatric adrenal cortex retains foetal features that influence cell differentiation, tumour phenotype and hormone secretion, whereas adult tumours arise from a differentiated adrenal environment.

These differences manifest clinically: children commonly present with androgen excess, rapid tumour growth and localized disease, whereas adult tumours more often exhibit cortisol excess and are diagnosed at the stage of advanced disease. Histopathological criteria established for adult tumours, such as the Weiss score, often overestimate malignancy in paediatric cases, necessitating paediatric-specific indices like the Wieneke scoring system. Epigenetic and transcriptomic analyses reinforce this divergence, showing foetal-like gene expression in paediatric tumours and more dedifferentiated, proliferation-associated signatures in adult tumours.

Understanding these age-specific biological and molecular distinctions is crucial for accurate diagnosis, prognostication and treatment planning. Paediatric adrenocortical tumours may respond differently to chemotherapy and mitotane compared with adults, highlighting the risk of inappropriate extrapolation of adult treatment protocols.

My presentation will integrate data on epidemiology, developmental biology, molecular genetics and clinical outcomes to provide a comprehensive overview of the differences between paediatric and adult adrenal tumours. Emphasis will be placed on the implications for tailored diagnostic criteria, therapeutic strategies and the need for international collaborative research to optimize patient outcomes across age groups.

Abstract citation ID: lvag096.041

JS1.3 - Clinical management of children with adrenal cortical cancer

Verena Wiegering
Universitätsmedizin Frankfurt, Frankfurt, Germany

Pediatric adrenocortical carcinoma (ACC) is a rare and aggressive malignancy arising from the adrenal cortex, with an estimated incidence of 0.2-0.3 cases per million children per year. Despite its rarity, ACC represents one of the most clinically significant endocrine tumors in childhood due to its potential for rapid progression and frequent hormone secretion. In pediatric patients, ACC often presents with signs of hormonal excess, most commonly virilization caused by androgen overproduction, but may also include features of Cushing syndrome or mixed endocrine

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

syndromes. Early recognition of endocrine symptoms can facilitate earlier diagnosis, which is a key determinant of outcome.

The cornerstone of curative treatment for pediatric ACC is complete surgical resection of the primary tumor. Achieving an R0 resection remains the most important prognostic factor for long-term survival. Surgical management should ideally be performed in specialized centers with experience in pediatric oncologic and endocrine surgery to minimize tumor rupture and ensure appropriate staging. Adjuvant therapy may be considered depending on tumor stage, resection status, and risk stratification. The adrenolytic agent mitotane has been used in selected cases, often in combination with cytotoxic chemotherapy regimens such as etoposide, doxorubicin, and cisplatin for advanced or metastatic disease.

Pediatric ACC is frequently associated with genetic predisposition syndromes, particularly germline TP53 mutations as seen in Li–Fraumeni syndrome. Therefore, genetic counseling and testing are recommended for affected patients and their families. Multidisciplinary management involving pediatric oncology, endocrinology, surgery, genetics, and supportive care is essential to optimize outcomes. To continuously improve understanding, treatment, and prognosis, international networks and expert tumor boards such as ENSAT-PACT are essential.

Prognosis depends largely on stage at diagnosis, completeness of tumor resection, and biological tumor behavior. While localized disease treated with complete resection can have favorable outcomes, advanced or metastatic ACC remains challenging to treat. Continued international collaboration and clinical research are critical to improving risk stratification, treatment strategies, and survival in this rare pediatric malignancy.

JS4.1 - Diabetes subclassification using ANDIS: from five clusters to clinical impact

Emma Ahlqvist
Clinical Sciences Malmö, Lund University, Malmö, Sweden

Adult-onset diabetes is characterized by considerable heterogeneity in metabolic presentation, disease progression, and risk of complications. Traditional diagnostic categories, which largely distinguish only between autoimmune and non-autoimmune forms, provide limited resolution for understanding this variation. The ANDIS cohort was created to systematically enroll all newly diagnosed cases of diabetes in a defined region and to collect standardized clinical, biochemical, and longitudinal

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

data. Using these data, we applied unsupervised clustering methods to examine whether patterns in routinely measured clinical variables could reveal more granular subgroups within non-autoimmune diabetes.

This analysis identified five reproducible clusters (SAID, SIDD, SIRD, MOD, and MARD) each characterized by distinct profiles in glycemia, insulin secretion, insulin resistance, body composition, age at onset, and markers of autoimmunity. Follow-up studies within ANDIS and replications in several independent cohorts have demonstrated that these subgroups show meaningful differences in glycemic progression, therapy needs, and rates of complications such as kidney disease. These findings suggest that subclassification may help explain why individuals with seemingly similar initial diagnoses experience markedly different trajectories over time.

In this presentation, I will summarize the development of the five-cluster model, the evidence supporting its reproducibility, and key results from longitudinal analyses within the ANDIS cohort. I will focus on what the clusters reveal about underlying disease mechanisms and how these data-driven subgroups compare with existing clinical markers used in diabetes assessment. The aim is not to propose immediate changes to routine clinical care, but to present how systematic population-based data collection and unbiased analytical approaches can improve our understanding of diabetes heterogeneity and provide a framework for generating more targeted hypotheses in diabetes research.

Abstract citation ID: lvag096.046

JS4.2 - Omics approaches to Asian Diabetes: genetic and molecular insights

Soo Heon Kwak
Internal Medicine, Seoul National University Hospital, Seoul, South Korea

The clinical landscape of type 2 diabetes (T2D) is undergoing a paradigm shift from a glucose-centric approach to a more nuanced, stratification-based strategy. This evolution is particularly crucial for East Asian (EA) populations, whose metabolic phenotypes—characterized by early beta-cell failure and distinct fat distribution—often deviate from Western models. In this symposium, we present a comprehensive framework that bridges multidimensional omics data to clinical phenotypes, aiming to decode the biological heterogeneity of T2D through computational methods and large-scale Korean biobank data.

Central to our approach is a deep learning-based integration of genomics, proteomics, and metabolomics. By mapping these high-dimensional data into a clinically relevant latent space, we identified four robust T2D subtypes that significantly outperform traditional single-omics models in terms of classification accuracy (ARI 0.78). Our analysis reveals that the molecular drivers of these subtypes are fundamentally different; for instance, the Mild Age-Related Diabetes (MARD) subtype is predominantly characterized by proteomic signatures, whereas the Severe Insulin-Resistant Diabetes (SIRD) subtype is more closely linked to metabolic dysregulation. Crucially, these molecular clusters are directly tied to clinical outcomes, with SIRD showing a heightened prevalence of chronic kidney disease and the Severe Insulin-Deficient (SIDD) subtype correlating strongly with diabetic retinopathy.

To further ground these findings in population-specific biology, we established a “Multi-Omics Atlas” of 5438 Korean individuals. This resource allowed us to identify over 1000 proteometabolic signatures and, more importantly, 138 EA-specific genetic signals that are absent in European cohorts like the UK Biobank. A standout discovery is the causal link between the ALDH2 protein and the metabolite 2-hydroxyisovalerate, a branched-chain amino acid metabolite uniquely associated with insulin resistance in East Asians. Through Mendelian randomization and colocalization, we demonstrate how these population-specific genetic architectures dictate systemic metabolic responses, providing a molecular explanation for the EA-specific T2D phenotype.

Taken together, this integrated research highlights that the future of diabetes management lies in understanding the interplay between genetic predisposition and molecular manifestations. By leveraging deep learning for precise subtyping and identifying EA-specific molecular markers, we provide a robust foundation for population-specific precision medicine. These insights not only enhance our understanding of diabetes heterogeneity but also pave the way for identifying novel, targeted therapeutic interventions tailored to the East Asian population.

Abstract citation ID: lvag096.047

JS4.3 - Data-driven subclassification of type 2 diabetes in Korea: from clinical phenotyping to precision intervention

Sang Youl Rhee
Endocrinology and Metabolism, Digital Health, Kyung Hee University College of Medicine, Seoul, South Korea

Background: Type 2 diabetes mellitus (T2DM) is a pathophysiologically heterogeneous disease. Its clinical phenotype in East Asians differs substantially from Western populations, with impaired insulin secretion—rather than insulin resistance—playing a predominant role. Subclassification frameworks derived from European cohorts may therefore not adequately capture Korea-specific phenotypes, necessitating data-driven approaches tailored to this population.

Methods: Using exploratory factor analysis applied to a multicenter retrospective cohort of 6603 middle-aged Korean T2DM patients from three tertiary hospitals (2008-2020), we identified distinct metabolic patterns and examined their associations with diabetes-related complications using Cox proportional hazard models, adjusted for age, sex, medications, and comorbidities.

Results: Three clinically distinct metabolic patterns were identified: the Obesity and Hypertension pattern (OH-P), the Liver Function-related HyperGlycemia pattern (LFHG-P), and the Decreased Kidney Function pattern (DKF-P). Each pattern conferred a unique complication risk profile. The OH-P was associated with increased peripheral vascular disease risk (HR 1.26; 95% CI 1.02-1.57), while the LFHG-P — characterized by hyperglycemia, dyslipidemia, and elevated liver enzymes—was associated with higher risks of myocardial infarction (HR 1.79; 95% CI 1.13-2.82) and atrial fibrillation (HR 1.54; 95% CI 1.07-2.23). The LFHG phenotype appears Korea-specific, potentially reflecting genetically reduced insulin secretory capacity compounded by high-carbohydrate dietary patterns.

Conclusions: These findings demonstrate that ethnicity-aware, multivariate clinical phenotyping can meaningfully resolve metabolic heterogeneity in Korean T2DM and identify pattern-specific complication risks. Advancing from retrospective EMR-based

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

approaches toward prospective, multimodal data collection—integrating genetics, imaging, and lifestyle variables—represents the next critical step. To this end, we are initiating a Korea National Institute of Health-funded multi-center prospective study, with the presenter as principal investigator, to develop precision complication prediction models tailored to the Korean population.

JS5.3 - Transversal working group on genomic testing

Thomas Eggermann
Center for Human Genetic and Clinical Genomics, Medical Faculty, RWTH University Aachen, Aachen, Germany

To faciliate focused activities for topical issues in genomic testing, ENDO-ERN has established a transversal working group (WG) in 2024. The major purposes of the WG group are to improve guidelines, identify gaps and updates in the field of genetic testing of endocrine disorders; to smooth and make genetic testing guidelines applicable, which consider daily routine and the best standard for genetic testing ensuring cooperation with other societies and avoiding double work; to suggest a standardised genetic testing regime whenever possible to guarantee a standarised testing procedure all over Europe; to orchestrate and to channel the activities of Endo-ERN in the field of genetics, to avoid fragmentation and unhelpful developments in genetic testing. In addition to a general overview on the WG, the presentation will focus on the joint activities to achieve a joint agreement on genetic testing and reporting from the clinical point of view, and the cooperation of ENDO-ERN with the European Society of Human Genetics.

JS5.5 - The peadiatric thyroid cancer registry

Hanneke van Santen
Department of Pediatric Endocrinology, Wilhelmina Children's Hospital, UMCU, Princess Maxima Center for Pediatric Oncology, Utrecht, The Netherlands

Although differentiated thyroid carcinoma (DTC) is the most frequent endocrine pediatric cancer, it is rare in childhood and adolescence. While tumor persistence and recurrence are not uncommon, mortality remains extremely low. Complications of treatment are however reported in up to 48% of the survivors. Due to the rarity of the disease, current treatment guidelines are predominantly based on the results of small observational retrospective studies and extrapolations from results in adult patients. In order to develop more personalized treatment and follow-up strategies (aiming to reduce complication rates), there is an unmet need for uniform international prospective data collection and clinical trials.

The European pediatric thyroid carcinoma registry aims to collect clinical data for all patients ≤18 years of age with a confirmed diagnosis of DTC who have been diagnosed, assessed, or treated at a participating site. This registry is a component of the wider European Registries for Rare Endocrine Conditions project which has close links to Endo-ERN, the European Reference Network for Rare Endocrine Conditions. A multidisciplinary expert working group was formed to develop a minimal dataset comprising information regarding demographic data, diagnosis, treatment, and outcome. We constructed an umbrella-type registry, with a detailed basic dataset. In the future, this may provide the opportunity for research teams to integrate clinical research questions.

JS6.1 - Gestational diabetes: a critical window for cardiovascular prevention

Laura Lopez
Sanatorio Santa Rosa, Santa Rosa, Argentina

Background: Gestational Diabetes Mellitus (GDM) is now recognized as a profound "metabolic stress test" that unmasks a woman's underlying cardiovascular (CV) and metabolic vulnerability. This talk explores GDM not as a transient condition, but as a chronic phenotype identifying women at high risk for future disease.

Methods: We synthesized evidence from systematic reviews involving over five million women and recent clinical trials, including the "Steady Sugar" study, to evaluate the magnitude of cardiovascular risk (CVR) and the impact of Continuous Glucose Monitoring (CGM) on clinical outcomes.

Findings: Women with a history of GDM have a twofold higher risk of future major CV events, which manifests within the first decade postpartum. Crucially, progression to type 2 diabetes (T2DM) explains only 23.3% of this risk, suggesting that GDM is an independent marker of early vascular dysfunction. In this context, technology has proven to be a vital ally; real-time CGM identifies nocturnal and postprandial excursions missed by traditional monitoring. The "Steady Sugar" trial demonstrated that CGM use significantly improves outcomes, reducing unscheduled cesarean sections (20.0% vs 44.4%) and neonatal intensive care admissions compared to standard care.

Conclusions: GDM represents a unique clinical opportunity to identify and intervene in a high-risk vascular phenotype before overt disease occurs. A comprehensive management strategy must transition from reactive glucose monitoring to a continuum of care that integrates advanced technologies during pregnancy and rigorous postpartum surveillance. By combining 6-week reclassification, lifelong annual monitoring, and primordial prevention through breastfeeding, clinicians can effectively shift the trajectory of cardiovascular health for this population.

JS6.2 - Cardiovaascular health in menopause: key aspects and management

Abstract Unavailable

Abstract citation ID: lvag096.051

JS6.3 - The cardiometabolic–hepatic axis in menopause

Poli Mara Spritzer
Universidade Federal do Rio Grande do Sul, Hospital de Clinicas de Porto Alegre, Porto Alegre, Brazil

The perimenopause is associated with an increase in cardiometabolic risk driven in part by estrogen deficiency. In this setting, the cardiometabolic–hepatic axis describes the interconnected metabolic disturbances linking cardiovascular risk factors, metabolic syndrome, and metabolic dysfunction–associated steatotic liver disease (MASLD).

Declining estrogen levels contribute to adverse changes in lipid metabolism, body composition, and vascular function. Around the time of the final menstrual period, total cholesterol, LDL-C, and apolipoprotein B increase, while visceral fat accumulation promotes central obesity, insulin resistance, and metabolic syndrome. Concurrently, the prevalence and severity of MASLD rise, with postmenopausal women exhibiting a higher risk of advanced fibrosis and loss of the relative protection observed during premenopausal years.

Management should prioritize lifestyle intervention, with 7%-10% weight loss associated with improvements in hepatic steatosis, inflammation, and fibrosis. Healthy dietary patterns, regular physical activity, and comprehensive control of cardiometabolic risk factors are essential. Incretin-based therapies offer promising multisystem benefits by targeting both hepatic and cardiometabolic pathways. For patients with noncirrhotic MASH and stage F2-F3 fibrosis, a liver-directed pharmacologic option has also recently become available in some countries. In selected perimenopausal and early postmenopausal women with vasomotor symptoms and MASLD, transdermal estrogen-based hormone therapy may offer additional metabolic and hepatoprotective effects, although this approach requires further validation in prospective trials.

In conclusion, perimenopause represents a critical window for cardiovascular and hepatic risk assessment. Effective management should integrate lifestyle modification, cardiometabolic optimization, and individualized pharmacologic strategies based on fibrosis stage and comorbidity profile.

EYS1.1 - Using genomics to characterize features of aggressiveness in PitNETs”

Nesrine Benanteur
Institut Cochin, Equipe Bertherat, Paris, France

Aggressive evolution of pituitary neuroendocrine tumors (PitNETs) is rare, and metastatic spread is even more uncommon. As a result, defining aggressiveness and malignancy in PitNETs remains difficult, making these outcomes challenging to predict and understand. The aim of our work was to establish a molecular definition of aggressiveness in PitNETs using integrated genomic approaches.

PitNET samples from 206 patients were analyzed. Associations between nine clinicopathological features of aggressiveness and tumor omics profiles were investigated. The omics data included transcriptome, DNA methylation, chromosomal alterations, and gene mutations. In addition, clonal tumor evolution was monitored longitudinally in seven patients.

Among the nine clinicopathological features of aggressiveness evaluated, only rapid progression, progression after radiotherapy, Ki67/MIB1 proliferation index ≥10%, temozolomide treatment, metastases, and specific death were associated with distinct omics signatures. In contrast, tumour maximal diameter ≥40 mm, cavernous invasion, and sphenoid invasion did not show associations with specific molecular profiles.

Although the omics signatures linked to these features of aggressiveness partially overlapped, they remained distinct between corticotroph and mammo-somato-thyrotroph tumor lineages. Within each lineage, a shared molecular signature of aggressiveness was identified, characterized by a proliferative transcriptome signature combined with DNA hypermethylation. Alterations in several genes were associated with aggressive features, including mutations in known cancer-related genes such as *TP53* and *CDKN2A*, as well as alterations in *LRP1B*, identified here as a novel PitNET-associated gene. In contrast, alterations in *USP8* and *GNAS* were not associated with aggressive features.

Integrating gene alterations with methylome and transcriptome signatures allowed the identification of a subset of molecularly aggressive PitNETs. Notably, these molecular signatures remained globally stable throughout disease progression, despite increasing aggressiveness and potential clonal divergence.

Overall, this integrated multi-omics analysis provides a histomolecular definition of aggressiveness in PitNETs. Prospective cohort studies will be required to validate these molecular signatures and determine their prognostic value.

EW1.1 - Thyroid diseases: exploring sex differences in prevalence, treatment pattern and outcomes

Helena Filipsson Nyström
Department of Endocrinology, Institution of Medicin, Göteborg, Sweden

This 20-minute presentation will explore gender-specific patterns in the prevalence, diagnosis, and outcomes of thyroid diseases.

Hypo- and hyperthyroidism shows a clear female predominance, both in hypothyroidism, Graves' disease and toxic multinodular goitre, although the underlying mechanisms differ. Graves' disease occurs throughout adult life, with incidence peaks following pregnancy and during menopause, whereas toxic nodular goitre and hypothyroidism increase with age.

Thyroid dysfunction is common during pregnancy, underscoring the importance of appropriate, pregnancy-specific reference ranges for thyroid hormones to ensure accurate diagnosis and optimal treatment. The presentation will also address the effects of mild iodine deficiency during pregnancy. In addition, the impact of thyroid disorders on mental health, brain function, and cognitive performance in adults will be discussed.

Abstract citation ID: lvag096.055

EW1.2 - Obesity and type 2 diabetes: sex differences in risk factors, treatment responses, and long-term complications

Alexandra Kautzky-Willer
Department of Medicine III, Medical University of Vienna, Vienna, Austria

Obesity and type 2 diabetes are chronic diseases which are dramatically increasing worldwide leading to lower health- and lifespan of the patients and high costs and an enormous burden on the public health care system. Both biological and psychosocial factors, environment and lifestyle are involved in the pathogenesis of these metabolic disorders and thus important sex- and gender-based differences are evidenced. These differences have also important implications for lifestyle intervention (nutrition and exercise) and drug therapy. At the global level, prevalence of obesity is higher in women than men, including higher rates of preclinical obesity, especially at young age. Type 2 diabetes mellitus is usually diagnosed at a younger age and lower body fat mass in men compared to women. Women with newly diagnosed type 2 diabetes commonly have a more unfavourable risk factor profile including higher prevalence of hypertension. Psychosocial stress might play a prominent role in diabetes risk in women who also show higher levels of diabetes distress and higher prevalence of depression which further exacerbates their cardiometabolic risk. There are differences between men and women regarding comorbidities, the manifestation of complications and the initiation of and adherence to therapy. Women with diabetes show greater relative risk of CVD and mortality than men. Thus, more research on sex and gender differences, including the pathophysiologcal mechanisms, is necessary to increase the evidence in the future.

NSA2 - Modeling GnRH neurons development

Taneli Ravio
Department of Physiology, University of Helsinki, Helsinki, Finland

Modeling human GnRH neuron development using hPSCs—from protocol development to disease modeling

Understanding human GnRH neuron biology has long been limited by the inaccessibility of primary human tissue and the unique developmental origin of these neurons. Human pluripotent stem cells (hPSCs) provide a powerful platform to overcome these limitations, enabling the reconstruction of developmental trajectories, identification of key signaling mechanisms, and modeling of human reproductive disorders in a patient-specific context.

In this presentation, I will discuss how the field has evolved from initial protocol development toward mechanistic insight and disease modeling, and finally toward reconstructing increasingly complex elements of the human reproductive axis.

Pioneering the field: from concept to reproducible protocol

Our early work in the field was driven by a fundamental question: is it possible to generate GnRH neurons from hPSCs at all? Initial differentiation attempts in my laboratory were based on a strategy to mimic olfactory placode differentiation, but this resulted in limited efficiency and unclear cellular identity. A major breakthrough was achieved with the development of a protocol combining dual SMAD inhibition, FGF8b treatment, and NOTCH inhibition. This approach enabled robust and reproducible generation of GnRH neurons and formed the basis of the key publication in Stem Cell Reports (Lund et al, 2016; PMID: 27426041). Thus, the field transitioned from proof-of-concept to a reproducible and disseminated

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

methodology that enabled broader exploration of human GnRH neuron biology.

From developmental biology to mechanism

Once a reliable and reproducible protocol was established, our focus shifted toward understanding the mechanisms that drive GnRH neuron specification. We demonstrated that GnRH neuron differentiation is sensitive to FGF8b dose, suggesting that their specification is not a binary process but is quantitatively regulated (Yellapragada et al. 2022; PMID: 35833364). In parallel, inhibition of FGFR1 signaling was shown to impair GnRH neuron formation, highlighting the importance of the FGF8–FGFR1 axis. These findings suggest that FGF signaling acts at the level of neural progenitor cells, influencing cell fate decisions and regional identity. Decoding the transcriptional landscape at the single cell level, we were subsequently able to demonstrate developmental trajectories of hPSC-derived GnRH neurons (Wang et al 2022; PMID: 36153707). Also, WNT inhibition during dual SMAD inhibition phase was shown to contribute to GnRH ontogeny. This raises the possibility that multiple developmental routes may exist and/or that GnRH neuron specification is more plastic than previously assumed, but still the FGFR1-FGF8 signaling appears to be the key. Emerging data, including our ongoing work on *DLX5* may further expand our understanding in this context, although these findings are still under investigation.

Disease modeling: translating developmental insight

One of the most important advances enabled by these models is the ability to study human disease mechanisms directly in GnRH neurons. In the context of precocious puberty, we have investigated the role of *MKRN3* and *DLK1* in GnRH neuron ontogeny from hPSCs (Yellapragada et al. 2019 PMID: 30800097; Eskici et al. 2025; PMID: 4092404). Similarly, we have modelled gonadotropin deficiency induced by mutations in genes such as *POGZ* (Eskici et al. 2023; PMID: 37619992, and *MADD* (Pulli et al. 2024; PMID: 38775154) by employing our hPSC-derived model. Overall, these studies demonstrate that hPSC-derived GnRH neurons provide a powerful system to functionally validate genetic findings and link them to specific developmental mechanisms.

Past, present, and future

The trajectory of the field can be viewed along three axes. In the past, the key question was whether GnRH neurons could be generated from human stem cells. In the present, the focus is on understanding the signaling pathways and developmental mechanisms that govern their specification, as well as applying these insights to disease modeling. Looking to the future, the field is moving toward increasing biological complexity. This includes the development of three-dimensional models, incorporation of migration and network formation, and expansion to additional cell types. A particularly exciting direction is the generation of kisspeptin neurons from hPSCs, which act upstream of GnRH neurons and are critical regulators of reproductive function. Combining GnRH and kisspeptin neurons in integrated systems may ultimately allow reconstruction of key elements of the human reproductive axis in vitro.

Take-home message

The field has evolved from protocol development to mechanistic understanding and disease modeling, and is now moving toward system-level reconstruction of human reproductive neuroendocrinology. Human pluripotent stem cell models are no longer only a tool to generate GnRH neurons—they are becoming a platform to understand, and ultimately rebuild, the human reproductive axis.

D1.1 - Surgery in mild autonomous cortisol secretion—against

Ioannis Ilias
Department of Endocrinology, Hippokration General Hospital, Athens, Greece

Background: Mild autonomous cortisol secretion (MACS) is commonly observed in adrenal incidentaloma patients and it leads to an increased prevalence of arterial hypertension, diabetes mellitus, and other cardiometabolic comorbidities. The indication of adrenalectomy in these patients is not well defined.

Objective: To critically review the data supporting both the surgical and conservative management of MACS, specifically vis-à-vis clinically relevant outcomes, patient safety, and guidelines.

Methods: Analysis of the literature along with the 2023 ESE-ENSAT guidelines.

Results: Adrenalectomy could be beneficial for surrogate endpoints including hypertension and glycemic control. However, the original literature, which is mainly retrospective and heterogeneous, does not provide conclusive information. More importantly, improvement in hard endpoints, has never been proven. Surgically treated patients show a high incidence of postoperative adrenal insufficiency, which may be prolonged. MACS typically has an indolent natural history, with a low annual probability of progressing to overt Cushing's syndrome. The majority of publications regarding surgery for MACS appear to be neutral or positive about the matter, however, negative views have increased after 2019.

Conclusions: In the absence of convincing evidence for improved survival or cardiovascular outcomes, and given the significant risk of harm, adrenalectomy should not be the default treatment for MACS. Conservative management with aggressive treatment of comorbidities and selective use of medical therapy should be considered to be the ethical and evidence-based default, reserving surgery for highly selected patients with clearly progressive or refractory disease.

MTE5 - Medullary thyroid cancer: from genetics to clinic

Antonio Matrone[1,2]

[1]*Department of Clinical and Experimental Medicine, Unit of Endocrinology, University Hospital of Pisa, Pisa, Italy;* [2]*Unit of Endocrinology, Department of Clinical and Experimental Medicine, University Hospital Of Pisa, Pisa, Italy*

The current presentation consistently highlights that molecular profiling is central to modern management of medullary thyroid carcinoma (MTC). RET mutations drive nearly all hereditary cases and the majority of sporadic and advanced MTC, making germline testing mandatory in all patients and somatic testing essential in advanced disease for prognostic stratification and therapeutic decisions. Hereditary cases, particularly if MTC is driven by molecular alteration of the RET gene linked to the phenotype of type 2 Multiple Endocrine Neoplasia (MEN 2), need careful and specific management. It should be considered that the gene carriers, those still not affected by MTC but who carry the RET mutation, need to be followed up in a specific manner. From a clinical perspective, biochemical markers, calcitonin, and CEA, are key tools across the disease continuum. Calcitonin is crucial for early diagnosis and screening in selected thyroid nodules, while postoperative levels and doubling times are strong prognostic indicators and guide follow-up intensity. Imaging is used in a stepwise approach, escalating from ultrasound and CT scan, mainly total body with i.v. contrast medium, to functional imaging (ie, 18F-DOPA PET) in cases of biochemical or structural persistence.

Management differs by risk:

- **Low-risk or cases that are cured after surgery** can often be managed with active surveillance and tailored follow-up based on biomarker trends.
- **Advanced MTC cases** require a more careful follow-up to identify those in which active therapy is needed. The progressive MTC cases, mainly according to progressions defined by a specific imaging, require systemic therapy, initiated based on tumor burden, progression rate, and symptoms rather than biochemical elevation alone.

Therapeutically, multikinase inhibitors (vandetanib, cabozantinib) improve progression-free survival but are limited by toxicity and resistance. In contrast, highly selective RET inhibitors (selpercatinib) represent a major advance, offering higher response rates, better tolerability, and activity even after prior treatments—though restricted to RET-mutant disease and still challenged by resistance mechanisms. Overall, integrating molecular data, biomarkers, and imaging enables a personalized, risk-adapted approach that improves outcomes across both early and advanced MTC.

MTEBS4 - Seeing is believing: imaging live cell behaviour in the pituitary gland

Patrice Mollard
University of Montpellier, Institute of Functional Genomics, CNRS UMR5203, INSERM U1191, Montpellier, France

Advanced *in vivo* imaging technologies have revolutionized our understanding of pituitary gland function by revealing the critical importance of three-dimensional cellular organization in hormone secretion in mouse models. Using innovative approaches such as two-photon microscopy, intra-vital microscopes fitted with long-distance objectives and GRIN lens-equipped miniscopes in awake mice, researchers have demonstrated that pituitary endocrine cells are organized in intermingled 3D multicellular networks rather than functioning as isolated units. These networks generate coordinated calcium signals that translate hypothalamic signals into precisely-timed hormone pulses released into the bloodstream. The integration of high-resolution *in vivo* imaging with spatial transcriptomics and single-cell multi-omics now helps identify key ion channels, signaling molecules, and plasticity mechanisms governing these cellular networks. These findings challenge classical views of pituitary function and reveal that spatial cellular organization is fundamental to endocrine homeostasis. Furthermore, this integrated approach offers unprecedented opportunities to understand pituitary disorders at the cellular and molecular level, potentially leading to improved diagnostic tools and therapeutic strategies. While direct high-resolution imaging of the human pituitary remains technically challenging due to its anatomical location, insights from genetically-modified mouse models provide translatable knowledge that bridges fundamental research and clinical applications in endocrinology.

PCC1.2 - Symposium 1: growth hormone deficiency—GHD in Cushing's disease: diagnosis and management

Kevin CJ Yuen
Barrow Pituitary Center, Barrow Neurological Institute and St. Joseph's Hospital and Medical Center, University of Arizona College of Medicine, Phoenix, AZ, United States

Growth hormone deficiency (GHD) occurs in Cushing disease (CD) patients mainly because of treatment-related effects (eg, pituitary surgery and radiation therapy), but tumor mass effect may also contribute to the development of GHD in the minority of CD patients due to corticotroph macroadenomas. However, several comorbidities associated with active CD may persist after remission of hypercortisolism. Growth hormone deficiency shares many clinical features seen in CD patients, and its presence after disease remission worsens the systemic complications caused by previous hypercortisolism. In patients with active hypercortisolism, GH secretion is suppressed, but may recover after disease remission is achieved. Hence, GH testing should only be performed at least 1-2 years after remission for the correct diagnosis. Treatment for GHD (either daily or long-acting GH formulations) in CD adult patients has been associated with improvements in body composition, muscle strength, exercise capacity, quality of life, cardiovascular health, bone mineral density and reversal of metabolic dysfunction-associated steatotic liver disease, whereas for GHD in CD pediatric patients, improvement in adult height is one of the major goals of GH replacement. While generally safe, GH replacement requires careful monitoring to ensure effectiveness and tolerance (particularly hyperglycemia) in treated patients.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Oulu University Hospital, Research Unit of Clinical Medicine, Oulu, Finland; [3]Department of Women's and Children's Health, Department of Gynecology and Reproductive Medicine, Karolinska Institutet and Karolinska University Hospital, Solna, Sweden

Polycystic ovary syndrome (PCOS) affects 11%-13% of reproductive-aged women and is characterized by hyperandrogenism, polycystic ovarian morphology, and menstrual irregularities. It is a major cause of anovulatory infertility and affected women have an increased risk of implantation failure and miscarriage, likely due to endometrial dysfunction. Recently, we published the first PCOS Endometrial Cell Atlas (PECA 1.0), which revealed cell-type-specific disease signatures in proliferative-phase endometrium. Here, we comprehensively characterize how different cell types and their transcriptomic signatures evolve across the menstrual cycle in PCOS by establishing PECA 2.0. pEndometrial biopsies were obtained, after informed consent, from women with and without PCOS who had similar age and BMI ($P > .05$ two-tailed Welch's t-test). Combined with the PECA 1.0 study (12 PCOS, 5 controls), our current single-nuclei (sn) RNA-seq dataset of 62 samples covers proliferative (7 PCOS, 7 controls), early secretory (6 PCOS, 3 controls), mid-secretory (7 PCOS, 5 controls), and late secretory phases (4 PCOS, 3 controls), as well as the anovulatory state (3 PCOS). Libraries were prepared from snap-frozen biopsies using Chromium GEM-X technology v 4.0 (10X Genomics). After data quality control, the final PECA 2.0 dataset included 998 832 high-quality nuclei: 625 593 from PCOS and 373 239 from control endometrium. We identified four main clusters: epithelial ($n = 478$ 789), stromal ($n = 453$ 832), immune ($n = 55$ 708), and endothelial cells ($n = 10$ 503). Reintegration revealed 11 epithelial, 7 stromal, 5 endothelial, and 16 immune cell subpopulations. The proliferative phase PCOS endometrium has a decreased proportion of proliferative stromal cells (56.26%) compared to controls (92.96%; Mann-Whitney U, adj. $P = .124$; Levene's test, adj. $P = .018$). Moreover, disrupted decidualization was demonstrated by a decreased proportion of decidualized stromal cells in PCOS late secretory phase samples (45.77%) compared to controls (59.98%; Mann-Whitney U, adj. $P = .124$; Levene's test, adj. $P = .011$). Levene's test results indicate significantly greater variability in these cell proportions in PCOS samples. The PCOS Endometrial Cell Atlas across the menstrual cycle, PECA 2.0, maps cellular heterogeneity and reveals transcriptomic signatures of endometrial dysfunction in PCOS at high resolution. This resource provides a foundation for developing precise diagnostic tools, targeted therapies, and preventive strategies to improve endometrial health.

PCC2.3 - In vitro endometrium of insulin resistant women with polycystic ovary syndrome

Anja Dekanski[1], Gustaw Eriksson[1], Tanja Turunen[1], Timotej Strmen[2], Tina Gorsek Sparovec[1], Angelica Lindén Hirschberg[3], Elin Chorell[2], Nayere Taebnia[1] and Elisabet Stener-Victorin[1]

[1]Department of Physiology and Pharmacology, Karolinska Institutet, Stockholm, Sweden; [2]Department of Public Health and Clinical Medicine, Umeå University, Umeå, Sweden; [3]Department of Women's and Children's Health, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden

Introduction: Endometrial dysfunction in polycystic ovary syndrome (PCOS) can lead to reduced fertility, miscarriage, and higher endometrial cancer risk. Additionally, our recent PCOS endometrial single-cell atlas shows cell type specific transcriptomic disease signatures. *In vitro* endometrial systems mirroring the PCOS tissue of origin is crucial for future mechanistic insight and novel target testing. We hypothesized that PCOS-associated endometrial disease features can be preserved in primary human endometrial epithelial organoids (EEOs) and single-layer stromal cells, under optimized conditions.

Methods: We established and characterized EEOs ($n = 4$ PCOS; $n = 4$ controls) and stromal cells ($n = 6$ PCOS; $n = 6$ controls) from proliferative phase endometrial biopsies of women with and without PCOS. Women with PCOS were hyperandrogenic and insulin resistant. Both cell systems were differentiated with 10 nM estradiol and 1 uM progesterone. EEOs and stromal cells were collected for bulk RNA sequencing and stained for typical differentiation markers. In stromal cells, we also performed lipidomics using liquid chromatography coupled to quadrupole time-of-flight mass spectrometry, and cellular bioenergetics using Seahorse XFe96. Additionally, we used a PCOS-like anovulatory hormonal environment and a healthy hormonal environment with estrogen, progesterone and androgen levels fluctuating. We tried EEO stimulation in these hormonal environments in both a static and microfluidic setting.

Results: In the initial EEO set-up very few transcriptomic differences were captured between PCOS and Control origin cells. In stromal cells, progesterone receptor staining was reduced, and maximal respiration trended lower in PCOS. Differentially expressed genes (DEGs) in stromal cells included upregulation of fibro activation protein (*FAP*) gene and downregulation of *CARD16*. Lipidomics analysis showed PCOS stromal cells uniquely accumulated insulin-resistance-associated ceramides during differentiation. At day 14, PCOS stromal cells had significantly elevated C20-ceramide and reduced cardiolipins. Fluctuating hormonal environment and the microfluidics setting were able to recapitulate more of the transcriptomic differences between PCOS and Control in EEOs.

Conclusions: Preliminary data shows that in the static hormonal environment *in vitro*, that does not closely recapitulate neither the normal menstrual cycle nor the PCOS irregular menstrual cycle, the EEOs lose most of their PCOS phenotype *in vitro*, while stromal cells retain more of it. Mimicking the PCOS-like and healthy-like hormonal environment and using microfluidics exacerbated transcriptomic differences in EEOs. Stromal cells from women with PCOS had DEGs related to proliferation and inflammation, and lipid dysregulation associated with metabolic dysfunction. In the next steps we are establishing co-culture systems to combine EEOs and stroma, but also adipose and endometrial cells.

PCC2.10 - Session 1 -targeting the androgen receptor to treat cardiometabolic complications in PCOS

Damian Romero
Pharmacology and Toxicology, University of Mississippi Medical Center, Jackson, United States

Polycystic Ovary Syndrome (PCOS) is the most common endocrine disorder in reproductive-age women and is strongly associated with hyperandrogenemia and cardiometabolic dysfunction. Hyperandrogenic phenotypes are particularly prone to obesity, insulin resistance, dyslipidemia, and adipose tissue dysfunction. Although androgen receptor (AR) signaling is central to the pathophysiology of these abnormalities, traditional antiandrogens are limited by safety concerns, including hepatotoxicity. Thus, innovative strategies to modulate AR activity with improved specificity and safety are urgently needed.

We investigated the therapeutic potential of selective AR degradation using the PROTAC ARV-110 in a well-established hyperandrogenemic mouse model of PCOS. Peripubertal dihydrotestosterone (DHT) exposure induced increased body weight, adiposity, glucose intolerance, hypercholesterolemia, and hyperleptinemia. ARV-110 dose-dependently reduced AR protein levels across metabolic tissues and attenuated DHT-mediated increases in body weight and fat mass, without affecting lean mass. Treatment improved glucose homeostasis, reduced circulating leptin, and favorably modified the adiponectin to leptin ratio, a marker of adipose tissue dysfunction.

Unbiased proteomic analyses were performed in both liver and kidney to define tissue-specific molecular responses. In the liver, ARV-110 was the primary driver of proteomic remodeling, broadly altering metabolic, translational, and proteostatic pathways, with high-dose treatment producing pathway disruptions consistent with hepatotoxicity. In the kidney, DHT was the dominant driver of molecular change, markedly altering gene expression programs related to translation, ribosomal activity, and protein quality control. ARV-110 produced a dose-dependent modulation of these DHT-induced signatures in hyperandrogenemic mice, partially reversing multiple translational and proteostatic pathways, particularly at the higher dose, although renal profiles were not fully restored to control patterns.

These findings establish targeted AR degradation as a mechanistically novel and potentially transformative therapeutic strategy for hyperandrogenemia-driven cardiometabolic disease in PCOS, offering a precision approach that moves beyond receptor blockade toward selective modulation of androgen signaling.

PCC4.3 - Practical session—thyroid ultrasound—practical demonstration, ultrasound-guided fine needle aspiration technique—practical demonstration, radiofrequency ablation for Thyroid nodules—practical demonstration

Filip Gabalec, David Fibigr, Tereza Grimmichova, Jan Jiskra, Jan Kratky and Darina Reva
4th Department of Internal Medicine—Hematology, University Hospital Hradec Králové, University Hospital Hradec Kralove and Charles University, Faculty of Medicine in Hradec Kralove, Hradec Králové, Czech Republic

This workshop will present the basic principles and technical aspects of radiofrequency ablation (RFA) used in the treatment of thyroid nodules. The procedure and the moving-shot technique will be demonstrated under ultrasound guidance. Participants will have the opportunity to practice the technique in a safe educational environment using simulation models prepared from gelatin as well as biological tissue models such as chicken breast and liver. These models allow realistic training of needle placement, electrode manipulation, and basic ablation techniques without risk to patients. The workshop aims to provide physicians with practical experience and a better understanding of the RFA procedure.

PCC4.4 - Radiofrequency ablation for thyroid nodules

Darina Reva
Otorhinolaryngology and Head and Neck Surgery, Regional Hospital Pardubice and Faculty of Health Studies, University of Pardubice, Pardubice, Czech Republic

Introduction: Radiofrequency ablation (RFA) is a minimally invasive treatment method that has become an established alternative to surgery for selected benign thyroid nodules. The procedure is performed under ultrasound guidance and allows targeted thermal destruction of nodular tissue while preserving the surrounding thyroid parenchyma and thyroid function. RFA has been increasingly adopted in clinical practice due to its favorable safety profile and good clinical outcomes.

Methods: This presentation will provide an overview of the technical principles of ultrasound-guided RFA for thyroid nodules. The procedure, including patient preparation, equipment, and the moving-shot technique, will be described. Particular attention will be given to ultrasound guidance during the procedure, protection of surrounding structures, and strategies to minimize complications. Expected clinical outcomes such as nodule volume reduction and improvement of compressive or cosmetic symptoms will also be discussed.

Conclusions: Radiofrequency ablation represents a safe and effective minimally invasive treatment option for thyroid nodules. Understanding the technical aspects of the procedure and appropriate ultrasound guidance is essential for achieving optimal outcomes and minimizing complications in clinical practice.

PCC4.6 - Ultrasound features associated with Thyroid Cancer

Tereza Grimmichova
Department of Internal Medicine, University Hospital Královské Vinohrady and Third Faculty of Medicine, Prague, Czech Republic

Thyroid nodules are frequently found in the thyroid gland; between 19% and 67% of individuals are found to have nodules on high-resolution ultrasound, with 5%-10% being malignant. The most common thyroid cancer is papillary cancer (PTC); in particular, papillary microcarcinoma is frequently found incidentally. Despite the striking increase in incidence over the last decades, the mortality rate for thyroid cancer has remained low. However, there are rising trends in incidence-based mortality for thyroid cancer, particularly in cases of advanced-stage papillary thyroid cancer.

It is crucial to correctly stratify the malignancy risk of nodules to balance overdiagnosis against the risk of overlooking clinically significant tumors. Sonography is the most sensitive method for thyroid nodule examination. Risk stratification systems known as TIRADS (Thyroid Imaging Reporting and Data System) were developed using specific ultrasound features to estimate the likelihood of malignancy and provide guidance on whether fine-needle aspiration (FNA) biopsy is warranted. TIRADS must use a combination of sonographic features to properly establish the risk of thyroid nodules.

Implementing TIRADS should lead to standardized reporting, improved communication, unified recommendations, and a reduction in unnecessary FNAs. While there are currently many overlapping risk stratification systems, the International TIRADS (I-TIRADS) lexicon has been developed as a first step toward a unified, universally accepted system. It defines specific thyroid nodule features—illustrated with sonograms—such as composition, echogenicity, margins, direction of growth (shape), echogenic foci (including microcalcifications), and lymph node status. Typical sonographic features of a thyroid nodule with a

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

higher risk of malignancy include a solid composition, a markedly hypoechoic appearance, irregular margins, a taller-than-wide shape, microcalcifications, and signs of extrathyroidal extension. Interobserver agreement for individual sonographic features is usually fair to good, with substantial agreement regarding the indication for fine-needle aspiration biopsy. In summary, TIRADS provides a user-friendly and clinically necessary framework for assessing thyroid nodules.

PCC5.11 - The EAA guidelines on Klinefelter syndrome

Jolanta Slowikowska-Hilczer
Medical University of Łódź

Among patients with Klinefelter syndrome (KS) clinical features are highly variable; however, the most common characteristics include severely impaired spermatogenesis and Leydig cell dysfunction, resulting in azoospermia and hypergonadotropic hypogonadism. In addition, a broad spectrum of neurocognitive and psychosocial manifestations has been described, along with an increased prevalence of cardiovascular, metabolic, and bone-related disorders, which may contribute to the elevated morbidity and mortality observed in KS. Moreover, compared with the general male population, patients with KS appear to have a higher prevalence of coagulation and autoimmune disorders. Both genetic and epigenetic mechanisms related to the supernumerary X chromosome, as well as testosterone deficiency, contribute to this pathological profile.

The majority of patients with KS are diagnosed in adulthood, although symptoms may already become apparent during infancy, childhood, or adolescence. An expert panel of academicians appointed by the EAA developed the first consensus guidelines for the management of KS. These guidelines provide recommendations and practical suggestions for the care of patients with KS across different developmental stages, from childhood and adolescence to adulthood. The recommendations are based on recent research findings, as well as expert evaluation and validation.

Rare bone and mineral disorders often masquerade as common clinical problems, leading to delays in accurate diagnosis and optimal management. This symposium, part of the ESE Rare-CaPaB Educational Programme, brings together expert clinicians to illustrate how typical presentations—such as fragility fractures in young adults and seizures with hypocalcemia—can conceal underlying rare etiologies. Through two case-based discussions, the session highlights multidisciplinary perspectives across osteogenesis imperfecta, hypophosphatasia, X-linked hypophosphatemia, non-surgical hypoparathyroidism, and pseudohypoparathyroidism. By integrating focused viewpoints from endocrinology, metabolic bone disease, and related specialties, the program aims to improve recognition, diagnostic pathways, and tailored treatment strategies for these rare conditions.

PCC6.6 - Session 2. Fracture risk in Parathyroid disorders prevention and treatment of fractures in hypo—and hyperparathyroidism

Stefan Pilz
Medical University of Graz

The basic concept of fracture prevention is based on assessment of fracture risk with tools such as FRAX and evaluating whether it exceeds intervention thresholds for anti-osteoporosis drugs. Historically, fracture risk thresholds were set to match the risk level of persons with previous fragility fractures, and this aligned well with cost-effectiveness calculations. Due to price reductions for bisphosphonates over time, these medications may nowadays be cost-effective in patients well below current intervention thresholds, thereby contributing to debates on thresholds for anti-osteoporosis drugs.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Fracture prevention in patients with primary hyperparathyroidism (PHPT) can be done by parathyroidectomy, anti-osteoporosis drugs or a combination of them. Anti-fracture efficacy of parathyroidectomy in PHPT patients has not been documented in the few randomized controlled trials (RCT), but these investigations were limited by eg, low participant numbers and several sorts of potential bias such as group differences in anti-osteoporosis drugs. Large observational studies have documented significantly lower fracture incidence in PHPT patients undergoing parathyroidectomy as compared to those managed conservatively. Importantly, this fracture risk reduction was similar in patients with and without osteoporosis and in those with and without a guideline indication for parathyroidectomy. The current PHPT guidelines from the Fifth International Workshop recommend parathyroidectomy in PHPT patients with a T-score of ≤ -2.5 at the hip, spine or 1/3 radius and/or a prevalent vertebral fracture or incident low-trauma fracture during follow-up. For diagnostic purposes, bone mineral density (BMD) measurements and vertebral fracture screening are recommended in PHPT. Evaluations of FRAX in PHPT patients were released after publication of the 2022 PHPT guidelines and showed that FRAX provides reasonable fracture prediction though moderately underestimates fracture probabilities in PHPT. Whether and how to use FRAX in PHPT patients for decisions on parathyroidectomy remains unclear and the task for future guideline revisions. PHPT patients with low BMD who do not undergo parathyroidectomy can be treated with anti-osteoporosis drugs such as eg, bisphosphonates or denosumab. Evidence suggests that i.v. bisphosphonate treatment with zoledronate one to three months after parathyroidectomy results in a higher BMD as compared to parathyroidectomy alone, but several questions remain on the efficacy and optimal timing of a combination therapy with parathyroidectomy and anti-osteoporosis drug treatment. Clinicians should be aware that cinacalcet can effectively lower calcium in PHPT patients but does not increase BMD, though it may well be combined with anti-osteoporosis drugs if needed.

Patients with chronic hypoparathyroidism (HypoPT) do not have a significantly increased risk of major osteoporotic fractures in large registry studies. The Revised European Society of Endocrinology Clinical Practice Guideline for the treatment of HypoPT suggests assessing fracture risk as recommended for the general population. Pharmacological anti-osteoporosis treatment in HypoPT should also be performed by adhering to general population guidelines, but considering the potential risk of hypocalcemia with antiresorptive treatments in these patients.

PCC6.7 - Session 3. Primary hyperparathyroidism—defining optimal management—current and future medical options

Abstract Unavailable

Abstract citation ID: lvag096.072

PCC6.8 - Session 3. Primary hyperparathyroidism—defining optimal management—debate—parathyroidectomy should be performed in cases of mild PHPT—for the motion

Jens Bollerslev

Department of Endocrinology, Morbid Obesity and Preventive Medicine, Oslo University Hospital, Oslo, Norway

Primary hyperparathyroidism (PHPT) is a prevalent disease especially in peri- and postmenopausal women,[1,2] where most patients are asymptomatic and diagnosed based on biochemical work-up for various, non-calcium related reasons. Nevertheless, these patients do present subtle metabolic abnormalities that might be related to the increased PTH rather than the slightly elevated calcium level.[3-5]

A series of international workshops during the last three and a half decades have discussed the management of asymptomatic PHPT, with only modest changes in indications for parathyroidectomy (PTX), the only curative treatment.[6,7] In asymptomatic PHPT patients with organ manifestations there is an indication for PTX, but these manifestations are purely defined,[5] and thereby a matter of discussion.[8]

Based on clinical markers on morbidity, recent data indicate that it seems safe to observe truly asymptomatic PHPT patients without organ manifestations for at least a decade. These data include kidney function, all fractures and overall mortality.[9-11] However, whereas bone turnover normalizes in PHPT by PTX with a subsequent normalization of BMD, long-term observation without intervention is followed by a state of high bone turn-over and a continuous loss of bone mass, including in the axial skeleton.[10] These data are of concern for bone health during long-term observation without intervention in asymptomatic PHPT.

Most patients do have PHPT due to a single, benign parathyroid adenoma accessible for cure by PTX.[3] PTX of a single adenoma has a very high cure rate (>98%) in specialized centers, with a low recurrence rate (about 1% in a ten-year perspective).[12]

As the population grow older with a healthier and more active elderly population, a more pro-surgery approach for asymptomatic PHPT should be considered and discussed,[1-15] including cost-effective/benefit analyses.[8]

N1.2 - Immunotherapy induced endocrinopathies

Helen Turner
Oxford Centre for Diabetes, Endocrinology and Metabolism, Oxford University Hospitals NHS Trust, Oxford, United Kingdom

Immune checkpoint inhibitors are a new group of monoclonal antibodies against checkpoints in normal T Lymphocyte activation enabling immune system activation in order to target cancer cells. They have transformed the management of an increasing spectrum of malignancies. However immune related adverse effects are common, and endocrine dysfunction is frequently observed.

Guidelines exist to help guide clinical care, and the monitoring and management of the endocrinopathy seen with checkpoint inhibitors involves a partnership with Oncology. In the 15 years since first used, there has been an increase in patients needing specialist investigation, management, follow-up and advice/support in Endocrine Departments.

Patients may have pre-existing endocrine problems, or receive glucocorticoid treatment for other immune related inflammatory adverse effects and need steroid safety advice, or may have an incidentally detected abnormality detected in an endocrine organ.

The endocrine specialist nurse is integral to all these aspects and collaboration with oncology is essential for optimal patient outcomes.

How Do I... Sessions

Abstract citation ID: lvag096.074

H1.1 - How do I manage thyroid emergencies (thyrotoxic crisis and myxedema coma)

Corin Badiu

Thyroid emergencies—thyrotoxic crisis (thyroid storm) and myxedema coma—are life-threatening conditions requiring immediate admission to an Intensive Care Unit (ICU). Both conditions are often triggered by precipitating events such as infection, surgery, or trauma which should be promptly treated in a multi-disciplinary approach.

1. Management of Thyrotoxic Crisis (Thyroid Storm)

Management follows a multimodality approach to block the production, release, and peripheral effects of thyroid hormones. Clinical diagnosis is often supported by the Burch-Wartofsky Point Scale (BWPS), where a score above 45 is highly suggestive of storm. When treating thyroid storm, we should consider the five "Bs":

1. Beta-blocker
2. Block synthesis (ie, antithyroid drugs);
3. Block release (ie, iodine);
4. Block T4 into T3 conversion (ie, high-dose propylthiouracil [PTU], propranolol, corticosteroid);
5. Block enterohepatic circulation (ie, cholestyramine)

Several drugs are critical in intervention:

Beta-Blockers: Administer immediately to control heart rate and reduce adrenergic symptoms. Propranolol: Used to manage symptoms. It is preferred because it also helps block the peripheral conversion of T4 to T3. Esmolol: IV infusion may be used for rapid titration in the ICU. Take care to avoid vascular collapse.

Block Synthesis (*Thionamides*): Administer agents such as Propylthiouracil (PTU) or Methimazole to stop new hormone production. PTU is often preferred initially because it also inhibits the peripheral conversion of T4 to T3. Administer thionamides every 4-6 hours, due to rapid metabolism of these drugs during thyroid storm, orally, rectally or via a nasogastric (NG) tube in the unresponsive patient with a loading PTU dose of 600 mg followed by doses of 200-250 mg every 6 h.

Block Release (*Inorganic Iodine*): Administer Lugol's solution or SSKI to block hormone release. Critical: Wait at least one hour after the first thionamide dose to prevent providing "fuel" for further hormone synthesis.

Block T4 into T3 conversion—*Glucocorticoids*: Use Hydrocortisone to inhibit T4 to T3 conversion and treat potential relative adrenal insufficiency.

Block enterohepatic circulation (cholestyramine) 4 g orally two to four times each day.

Supportive Care: All actions are performed in ICU setting, ensuring adequate rehydration, repletion of electrolytes, treatment of comorbid disease such as infection until stabilization. Use cooling blankets and acetaminophen for fever. Avoid salicylates (Aspirin), as they can displace thyroid hormones from binding proteins and worsen the crisis. Plasmapheresis is a second-line "rescue" therapy used for patients with thyroid storm who are refractory to standard medical management or have contraindications to first-line. Refractory cases are defined as failure to improve within 24-48 hours of starting standard multidrug therapy.

2. Management of Myxedema Coma

Myxedema coma represents the most severe and life-threatening manifestation of hypothyroidism, characterized by multiorgan dysfunction. It is a medical emergency that requires immediate admission to an ICU. Clinical diagnosis is suspected on Popevenciuc score evaluating multiorgan dysfunction across six clinical and metabolic domains: thermoregulatory, central nervous system, cardiovascular, gastrointestinal, metabolic disturbances and precipitating event. A score above 60 is suggestive of myxedema coma.

Treatment must begin as soon as the diagnosis is suspected, often before laboratory confirmation, due to high mortality rates (30%-60%).

1. Glucocorticoids: Administer Hydrocortisone IV (100 mg iv) every 8 hours to address potential adrenal insufficiency before thyroid hormone replacement to avoid triggering an adrenal crisis. Thyroid hormones increase the metabolism of cortisol. If the patient has underlying adrenal insufficiency (common in autoimmune or pituitary causes), starting thyroid treatment alone can trigger a fatal adrenal crisis.

2. Thyroid Hormone Replacement: T4 (Levothyroxine): Administer via IV loading dose, often 200-400 µg, followed by a daily maintenance dose. Since the gut is often edematous and absorption is poor, medications must be given IV. T3 (Liothyronine) may be added for more rapid action, administered via IV initially, then at intervals, taking care about cardiovascular action. Monitor for arrhythmias or myocardial ischemia, especially in elderly patients or those with known heart disease.

3. Supportive care and monitoring in ICU setting: frequent checking of mental status, body temperature, cardiovascular status, and electrolytes are mandatory. The following topics should be considered:

Airway: Anticipate the need for mechanical ventilation for respiratory failure or airway compromise.

Rewarming: Use passive measures like warming blankets; avoid aggressive active rewarming to prevent vasodilation and cardiovascular collapse.

Fluids: Treat hyponatremia with water restriction; use hypertonic saline only if levels are extremely low or seizures occur.

In conclusion, thyroid emergencies, despite rare, requires a multidisciplinary approach, involving prompt admission into ICU and treatment of precipitating factors. Limited access to specific drugs (PTU, Colestiramine, IV thyroxine or T3) in some countries might pose problems in the prompt management of these disorders.

H1.2 - How do I manage differential diagnosis of hypoglycemia

Emanuel Christ
Novo Nordisk Pharma Switzerland, Basel, Switzerland

Plasma glucose concentrations depend on glucose appearance rate, ie, a combination of exogenous carbohydrate intake in the postabsorptive and gluconeogenesis and glycogenolysis in the fasting state and glucose disappearance rate ie, uptake of glucose in the target tissues. The main organs for gluconeogenesis and glycogen storage are the liver and the kidney. The main regulatory hormones to keep the glucose concentration within normal range are insulin and its counterregulatory hormones such as glucagon, epinephrine, cortisol and growth hormone.

If hypoglycemia is documented the management of differential diagnosis follows the pathophysiology. In an ill or medicated patient, hypoglycemia is only one of the symptoms in a clinical context and the etiology of hypoglycemia is straightforward, ie, known diabetes on insulin or insulin secretagogues, critical illness including severe kidney or liver failure or counterregulatory hormone deficiencies. The very rare etiology of hypoglycemia in the context of a non-islet cell tumor (often neoplasia of mesenchymal origin with a high tumor burden and secretion of IGF-2) is also part of the differential diagnosis.

More challenging is the seemingly well individual with an autonomous insulin secretion, also called endogenous hyperinsulinemic hypoglycemia (EHH). Clinically these patients present with the classical Whipple's triad and a panoply of mainly neurological symptoms while the symptoms of the sympathetic nervous system are often less pronounced due to hypoglycemia unawareness. Weight gain, however, is often recorded. Hypoglycemia may occur postprandially (after postgastric bypass hypoglycemia or the insulin autoimmune hypoglycemia) or fasting (benign and malignant insulinoma, non-insulinoma-pancreatogenous-hypoglycemia, factitious).

The focus of this talk will include investigations of EHH (biochemical proof of EHH and localization of insulinoma using conventional and molecular imaging). New developments in this area are presented.

H1.3 - How do I manage mild autonomous cortisol secretion (MACS)

Alessandro Prete
Department of Metabolism and Systems Science, College of Medicine and Health, University of Birmingham, Birmingham, United Kingdom

Mild autonomous cortisol secretion (MACS) is no longer a niche endocrinology problem. As adrenal incidentalomas are detected with increasing frequency, clinicians are being asked ever more often to decide who should be tested, how far investigation should go, and which patients may benefit from intervention. Yet MACS rarely presents in black and white: it lies on a clinical spectrum, overlaps with common cardiometabolic disease, and raises difficult questions around surgery, conservative care, postoperative adrenal insufficiency, and long-term follow-up.

This talk will provide a practical approach to the management of MACS. It will cover who should and should not be investigated, how to interpret diagnostic tests, and how to assess cardiometabolic risk in a structured way. It will also address the decisions clinicians find hardest: when to recommend adrenalectomy, how to approach bilateral disease, how to manage postoperative glucocorticoid replacement and recovery of the hypothalamic-pituitary-adrenal axis, and when patients can be safely followed in primary care.

OC1.1 - ECE_3815 - Pregnancy outcomes by thyroid autoantibody status in euthyroid and subclinical hypothyroid women- insights from a nationwide cohort study

Uri Yoel[1,2], Merav Fraenkel[1,2] and Tamar Eshkoli[1,2]
[1]*Endocrinology, Soroka University Medical Center, Beer Sheva, Israel;* [2]*Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer Sheva, Israel*

Background: Although an increased risk of miscarriage has been well documented in women with subclinical hypothyroidism and thyroid autoantibodies, the independent effect of thyroid autoimmunity on other obstetric outcomes, particularly among euthyroid and subclinical hypothyroid women, remains unclear.

Objective: To evaluate pregnancy outcomes and complications, excluding miscarriage, according to thyroid autoantibody status among euthyroid and subclinical hypothyroid women.

Methods: All live-birth pregnancies (2013-2022) among Clalit Health Services-insured women were screened. Pregnancies in women aged ≥18 years with available thyrotropin (TSH) and thyroid autoantibody (anti–thyroid peroxidase and/or anti–thyroglobulin) measurements were included; women with a history of hypothyroidism or levothyroxine treatment were excluded. Pregnancies were stratified by thyroid function and autoantibody status into euthyroid (mean pregnancy TSH <4 mIU/L) or subclinical hypothyroid (TSH ≥4 mIU/L), with or without thyroid autoantibodies (one or both). To address confounding, antibody-positive and antibody-negative groups were balanced using inverse probability weighting (IPW) based on propensity scores estimated from maternal age, ethnicity, socioeconomic status, use of in vitro fertilization, history of recurrent pregnancy loss, and smoking. Analyses included univariate comparisons of obstetric outcomes and weighted quasi-Poisson regression to estimate adjusted incidence rate ratios for composite pregnancy complications.
Results: Of 338 352 screened live-birth pregnancies, 25 484 were included in the final analysis. In univariate analyses, most maternal and neonatal outcomes were clinically comparable across groups. Although statistically significant differences were observed for selected outcomes such as gestational diabetes, labor induction, assisted delivery, premature rupture of membranes, and certain placental or amniotic fluid abnormalities, these differences were inconsistent across comparisons and did not reflect clinically meaningful increases in severe outcomes. In weighted Poisson regression analyses, thyroid antibody positivity among euthyroid women was associated with a slightly lower rate of composite pregnancy complications compared with antibody-negative euthyroid women (IRR 0.92, 95% CI 0.89-0.96). No association between thyroid antibody status and composite complications was observed among women with subclinical

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

hypothyroidism (IRR 1.01, 95% CI 0.91-1.12). Importantly, no significant difference was identified between euthyroid antibody-negative women and subclinical hypothyroid antibody-positive women (IRR 0.96, 95% CI 0.91-1.01).

Conclusions: Thyroid antibody positivity was not associated with clinically meaningful increases in pregnancy complications among euthyroid or subclinical hypothyroid women. These findings suggest that, in the absence of overt hypothyroidism, thyroid autoimmunity alone may not warrant intensified obstetric monitoring.

OC1.2 - ECE_1905 - Efficacy of radioactive iodine of 15 mCi in treatment in pediatric patients with Graves' disease: a prospective multicenter study

Chenghang Liu and Bin Liu
Department of Nuclear Medicine, West China Hospital, Sichuan University, Chengdu, China

Objective: Currently, there is a lack of consensus on activity of radioactive iodine (RAI) to be administered for pediatric patients with Graves' disease. This prospective multicenter study aimed to investigate that the efficacy of 15 mCi RAI in treatment of pediatric patients with Graves' disease, and to determine risk factors influencing treatment failure.

Methods: From October 2021 to March 2025, pediatric patients (aged ≤21 years) with Graves' disease who had been prepared for RAI therapy were prospectively recruited at 4 tertiary hospitals in Southwest China. All enrolled patients were given 15 mCi RAI. Remission and failure rates were evaluated at 6 months post-RAI. Statistical analysis was performed using logistic regression.

Results: A total of 102 patients were enrolled in the study (mean [range] age, 18 [12-21] years; 83 females [81%]). The cure rate of 15 mCi RAI treatment was 79.4%, including 75 patients (73.5%) with hypothyroidism, 6 (5.9%) with euthyroidism. Multivariable logistic regression analysis demonstrated that disease duration, thyroid mass, and TRAb titers were significantly associated with the therapeutic efficacy. The disease duration of >8 months (OR = 11.30, 95% CI = 2.72-46.93), thyroid mass of >43.5 g (OR = 4.30, 95% CI = 1.17-15.72), and TRAb titers of >8.5-fold the upper normal limits (OR = 7.38, 95% CI = 1.73-31.50) were independent risk factors for therapeutic failure.

Conclusions: For the treatment of pediatric patients with Graves' disease, the use of a fixed-activity of 15 mCi RAI has a high success rate without additional measurements or calculations. The adoption of a standard dose of 15 mCi RAI may help implementing a streamlined and uniform RAI therapy process for pediatric patients with Graves' disease.

OC1.3 - ECE_3490 - Teprotumumab efficacy in long- and short-duration thyroid eye disease: post hoc analysis of four trials

Prem Subramanian[1], George Kahaly[2], Sara Wester[3], Zhenxun Wang[4], Tomoko Hayashida[4], Juan Ayala-Haedo[4] and Terry Smith[5]

[1]*Sue Anschutz-Rodgers University of Colorado Eye Center, Aurora, United States;* [2]*Department of Medicine I, Johannes Gutenberg University (JGU) Medical Center, Mainz, Germany;* [3]*Bascom Palmer Eye Institute, University of Miami, Miami, United States;* [4]*Amgen Inc., Thousand Oaks, United States;* [5]*Department of Ophthalmology and Visual Sciences, W. K. Kellogg Eye Center, and Department of Internal Medicine, University of Michigan Medical School, Ann Arbor, United States*

Teprotumumab, an insulin-like growth factor-1 receptor inhibitor, has demonstrated efficacy treating signs & symptoms of thyroid eye disease (TED) in patients with high or low clinical activity score (CAS) and short & long duration TED. We evaluate pooled efficacy data of teprotumumab in patients with TED <1-year & ≥1-year disease duration, independent of disease activity as measured by CAS.

Data from patients with moderate-severe TED were pooled from teprotumumab clinical trials. Patients were to receive 8 infusions of teprotumumab. Observed proptosis response (≥2 mm-improvement), CAS response (≥2-point improvement in patients w/baseline CAS ≥3), overall response (proptosis + CAS response in patients with baseline CAS ≥3), diplopia response (Gorman scale ≥1-point improvement in patients with baseline score >0), & TED-specific Graves' Ophthalmopathy Quality of Life (GO-QoL, 0-100 scale) score improvement are reported among teprotumumab-treated patients with TED diagnosis <1 or ≥1 year.

Teprotumumab-treated patients from clinical trials were pooled: Phase 2 (NCT01868997) & OPTIC (NCT03298867), OPTIC open-label extension (OPTIC-X[NCT03461211]), OPTIC-J (jRCT2031210453), OPTIC-J open-label extension, Phase 4 (NCT04583735), and Phase 4 open-label extension. For the <1-year TED duration group ($n = 144$), 43 Phase 2, 41 OPTIC, 16 OPTIC-X, 27 OPTIC-J, and 17 OPTIC-J open-label patients were included. For the ≥1-year group ($n = 81$), 42 Phase 4, 12 Phase 4 open-label, 21 OPTIC-X and 6 OPTIC-J open-label patients were included. TED duration was mean (SD) of 6.5 (2.9) months for the <1-year TED duration group($n = 144$) and 46.7 (29.5) months and for the ≥1-year group ($n = 81$); 88% (127/144) and 84% (68/81) completed treatment, respectively. At week 24, observed proptosis response was 82% (113/137) for shorter TED duration and 72% (54/75) for longer duration; change from baseline was mean (SD) −3.0 (1.7) mm ($n = 137$) and -2.6 (1.6) mm ($n = 75$), respectively. The observed overall response rate at week 24 was 80% (98/123) and 71% (12/17), observed diplopia response rate was 66% (69/104) and 57% (17/30), and complete resolution of diplopia was observed in 50% (52/104) and 47% (14/30), respectively. Additionally, clinically meaningful improvements in overall GO-QoL scores were observed in both groups as well as for the appearance and visual function subscales.

Although patients with earlier treatment had higher response rates overall, those treated with teprotumumab had clinically meaningful responses regardless of time since TED diagnosis or level of disease activity across all endpoints.

OC1.4 - ECE_1840 - IL-17$^+$ γδ T cells mediate thyroid hormone excess–induced metabolic dysfunction

Hyon-Seung Yi[1,2]

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

[1]Daejeon, South Korea; [2]Internal Medicine, Endocrinology and Metabolism, Chungnam National University, Daejeon, South Korea

Background and Research Aim: Thyrotoxicosis induces systemic catabolic effects such as muscle wasting and bone loss, traditionally attributed to direct actions of thyroid hormones (TH) on target tissues. However, the immune mechanisms linking TH excess to metabolic pathology remain unclear. This study aims to determine whether γδ T cells mediate TH-induced musculoskeletal dysfunction and to elucidate the underlying immunometabolic mechanisms.

Methods: To address this question, we employed a translational approach combining patient samples and experimental models. Immune and metabolic parameters were profiled in newly diagnosed Graves' disease patients before and after 12 weeks of methimazole treatment. In parallel, a murine model of TH excess was established via intraperitoneal T4 injection. γδ T cells were analyzed using flow cytometry, single-cell RNA sequencing (scRNA-seq), and paired γδ TCR sequencing. Functional validation was performed using TCRδ knockout (KO) mice, IL-17A neutralization, adoptive γδ T cell transfer, and in vivo stable isotope tracer infusion to quantify lipid turnover and oxidative metabolism.

Results: TH excess promoted the expansion of Vδ1 γδ T cells with heightened IL-17A expression in both humans and mice. In patients, normalization of thyroid function led to a reduction in IL-17A–producing γδ T cells, coinciding with improved muscle strength and bone density. scRNA-seq and TCR-seq revealed selective clonal enrichment of IL-17A–producing Vδ1 subsets under TH excess, supported by enhanced chromatin accessibility at IL-17A loci. In mice, TH-induced muscle weakness, fiber-type switching, and bone loss were all mitigated in TCRδ KO mice or with IL-17A antibody treatment. Metabolically, TH excess increased adipose lipolysis and suppressed muscle fatty acid oxidation, leading to accumulation of lipid intermediates—changes that were absent in TCRδ KO mice. TH also enhanced glycolysis and acetyl-CoA production in γδ T cells, promoting histone acetylation and IL-17A expression through epigenetic remodeling. Adoptive transfer of TH-activated γδ T cells partially recapitulated the muscle and bone phenotypes, while CD1d-deficient mice retained full γδ T cell responses, suggesting a CD1d-independent mechanism of activation.

Conclusions: Our findings establish Vδ1 γδ T cells as essential immunometabolic mediators of thyrotoxicosis. TH excess drives IL-17A expression through metabolic–epigenetic reprogramming, redefining thyrotoxicosis as an immune-driven endocrine disorder with implications for biomarker development and therapeutic targeting.

OC1.5 - ECE_3515 - Thyroid nodules in pediatric patients: which is the performance of the ultrasound risk stratification systems in identifying malignancy?

Carla Gambale[1], Giulia Lisi[1], Elisa Minaldi[1], Alessandro Prete[1], Eleonora Molinaro[1], Teresa Rago[1], Maria Scutari[1], Liborio Torregrossa[2], Rossella Elisei[1] and Antonio Matrone[1]

[1]Unit of Endocrinology, Department of Clinical and Experimental Medicine, University Hospital of Pisa, Pisa, Italy; [2]Molecular Pathology and Critical Area, Department of Surgical, Medical, University Hospital of Pisa, Pisa, Italy

Objectives: Thyroid nodules are quite rare in pediatric (≤18 years) patients; however, several studies reported a higher malignancy rate in this population. The aim of this study was to evaluate the ultrasound (US) characteristics of thyroid nodules in pediatric patients and to assess the performance of the main US risk stratification systems (RSS) in identifying malignant nodules. In addition, we investigated the correlation between US RSS categories and cytological findings.

Methods: We retrospectively analyzed US features and cytology results of a consecutive series of thyroid nodules diagnosed for the first time in pediatric patients at our department between 2016 and 2022. Nodules were classified according to EU-TIRADS, 2015 ATA, and AACE/ACE-AME systems, while cytology was reported according to the Italian Consensus classification.

Results: The study included 271 nodules from 221 patients. Most patients were females (74.2%), with a median age at cytological evaluation of 16 years (IQR 14-17). The median nodule size was 1.9 cm (IQR 1.4-2.9). Cytological diagnoses were TIR5 in 9.3%, TIR4 in 4.0%, TIR3b in 8.8%, TIR3a in 19.5%, TIR2 in 32.7%, TIR1C in 13.6%, and TIR1 in 12.1% of nodules. Ultrasound features were available for 216 nodules (79.7%). The thyroid was multinodular in 34.3% of cases. Most nodules were solid (74.1%), isoechoic (49.1%), wider than tall (80.6%), had well-defined margins (82.9%), and without calcifications (77.8%). Approximately one-third of nodules were classified as highly suspicious for malignancy according to all three RSS (EU-TIRADS 5: 35.2%; 2015 ATA high suspicion: 30.6%; AACE/ACE-AME high risk: 35.2%). However, in high-risk and low/intermediate-risk nodules, according to ultrasound features, only about 25% and 10% of cases were suspicious or malignant at citology (TIR4-TIR5), respectively.

Conclusions: Our findings indicate that the US risk stratification systems used at present are clinically poorly reliable in predicting malignancy in pediatric nodules and it would be desirable to have US dedicated risk stratification systems for children and adolescents.

Clinical and Surgical Sciences, Alma Mater Studiorum-University of Bologna, Bologna, Italy

Background: The BRAFV600E mutation is a pivotal oncogenic driver in Papillary Thyroid Carcinoma (PTC). While Variant Allele Frequency (VAF) is commonly used to quantify mutational burden, it is significantly influenced by the proportion of non-neoplastic cells within the sample, potentially underestimating the biological aggressiveness of the tumor.

Objectives: We evaluated whether the estimated percentage of mutated neoplastic cells (MNC)—calculated by correcting the VAF for sample tumor cellularity—provides superior predictive capacity compared to isolated VAF in defining the risk of recurrent or persistent disease (RPD).

Methods: We performed custom multigene NGS panel analysis on cytological or histological thyroid samples of 253 consecutive patients who underwent thyroid surgery for BRAFV600E PTC. We excluded patients with multiple coexisting mutations. For each sample, VAF was determined via sequencing, and the percentage of MNC was derived using a mathematical algorithm. Predictive performance for both variables was evaluated using ROC curves, Kaplan-Meier analysis, and a multivariate Cox model.

Results: The cohort ($n = 253$) showed a mean VAF of 21.4% and a median MNC percentage of 89.4% (IQR: 60.00-100.00%). Over a mean follow-up of 44.6 months, RPD occurred in 50 patients (19.8%). Association studies showed no significant differences in VAF between the RPD and disease-free groups ($P = .229$). Conversely, the percentage of MNC was significantly higher in RPD patients (median 100.0% vs 85.7%, $P = .013$). Univariate analysis revealed significant differences in the median MNC percentage according to tumor size <2 cm vs ≥2 cm (85.3% vs 97.5%, $P = .017$), minimal extrathyroidal extension (82.5% vs 92.9%, $P = .023$), and lymph node involvement <5 vs ≥5 (86.2% vs 98.0%, $P = .031$). ROC analysis confirmed VAF's ineffectiveness as a predictor of RPD (AUC 0.529; $P = .543$). In contrast, the MNC percentage demonstrated significant discriminative power (AUC 0.610; $P = .010$), allowing the identification of an optimal prognostic cut-off of 95.7%. Kaplan-Meier curves showed significantly worse progression-free survival for patients with MNC percentage ≥95.7% (Log Rank $P = .007$; median survival 86 months). Finally, multivariate Cox regression confirmed that a MNC percentage ≥95.7% is a strong independent predictor of recurrence (HR 3.88; 95% CI: 1.71-8.81; $P = .001$) together with male sex and higher stimulated thyroglobulin levels at radioiodine treatment.

Conclusions: Our findings suggest that the percentage of MNC is a more reliable prognostic biomarker than simple VAF. Achieving mutational quasi-homogeneity (≥95.7%) identifies a high-risk subgroup, emphasizing the importance of correcting molecular data for cellularity to achieve precise risk stratification.

OC2.1 - ECE_1752 - HMGA1 as a molecular link between insulin resistance and tau-driven neurodegeneration: evidence from human omics, genetics, and preclinical models

Maria Mirabelli[1], Francesco Saverio Brunetti[1], Eusebio Chiefari[1], Daniela Foti[2] and Antonio Brunetti[1]

[1]*Department of Health Sciences, Magna Græcia University, Catanzaro, Italy;* [2]*Department of Experimental and Clinical Medicine, Magna Græcia University, Catanzaro, Italy*

Introduction: Insulin resistance (IR) contributes to neurodegeneration, but the mechanisms linking impaired insulin signaling to tau pathology are unclear. High mobility group A1 (HMGA1), a key regulator of insulin receptor (INSR) transcription, may connect metabolic dysfunction and tauopathy. We examined whether reduced HMGA1 function increases susceptibility to IR and tau-driven neurodegeneration, and investigated the underlying mechanisms.

Methods: We used a translational, multi-system approach, including analyses of human post-mortem brain transcriptomics from Alzheimer's disease (AD)-relevant regions; *in silico* identification of HMGA1 binding motifs in the *MAPT* regulatory regions; cellular studies in retinoic acid (RA)-differentiated SH-SY5Y neurons; *MAPT* promoter luciferase assays following HMGA1 manipulation or pharmacological disruption; a case-control genetic study of the loss-of-function *HMGA1* variant rs146052672 with cognitive and cerebrospinal fluid (CSF) biomarker assessments; and in vivo validation in *Hmga1*-null mice.

Results: Bulk RNA-seq of hippocampal tissue from individuals with dementia revealed a robust inverse correlation between HMGA1 and MAPT expression, confirmed across tau-expressing neurons and glia by single-nucleus transcriptomics. MAPT levels remained largely stable across AD stages, suggesting early transcriptional setting rather than late induction. Computational analyses identified conserved HMGA1 binding motifs within repressive regions of the human and mouse *MAPT* promoter. In RA-differentiated SH-SY5Y cells, neuronal maturation was accompanied by reduced intracellular HMGA1, increased tau expression, decreased INSR levels, and heightened oxidative stress, alongside progressive increases in extracellular total tau and p-tau181. Promoter assays demonstrated that HMGA1 represses *MAPT* promoter activity in a dose-dependent manner, an effect lost with HMGA1 silencing or disruption of HMGA1-DNA binding. Clinically, the rs146052672 variant was more frequent in AD cases than controls (17.6% vs 5.0%; $P<.05$) and independently associated with tauopathy. Variant carriers exhibited a higher prevalence of diabetes, greater IR consistent with reduced INSR availability, worse cognitive performance (MMSE 14.7 ± 4.6 vs 19.7 ± 4.1; $P < .05$), and elevated CSF tau and p-tau181. These findings were mirrored in *Hmga1*-null mice, including hyperglycemia, increased brain tau and p-tau, reduced Insr expression, and AD-like neuropathological and behavioral features.

Conclusions: HMGA1 is a key transcriptional regulator linking IR to tau-driven neurodegeneration. By bridging IR and tau pathology, HMGA1 emerges as a promising biomarker and a potential therapeutic target in neurodegenerative disease.

OC2.2 - ECE_3929 - JUV-161 restores glucose homeostasis and skeletal muscle function in Type 2 diabetic mouse model

Vengadeshprabhu Karuppagounder, Ritwik Datta, Hee Ju Kim, Ashil Koranne, Annie Yang, Sharon Louie, Kimberly Crutcher, Ted Yu, Danielle Yi, Zhihua Li, Thach Mai,

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Banmeet Anand, Colin Hislop, Priya Handa, Hanadie Yousef and Jeremy O'connell
Juvena Therapeutics, Redwood city, United States

Background: Loss of skeletal muscle mass and strength is a frequent yet underappreciated complication of type 2 diabetes (T2D), contributing to impaired glucose disposal and progressive metabolic dysfunction. Most antidiabetic therapies primarily address glycemia without directly improving muscle health. JUV-161 is a novel biologic identified through a machine learning driven, multi-omics platform designed to discover regenerative factors from stem cell–derived secretomes. This study examined whether JUV-161 can simultaneously improve metabolic control and muscle function in a severe murine model of T2D, alone and in combination with semaglutide.

Methods: Nine-week-old male db/db mice were assigned to four treatment arms ($n = 12$-15/group): vehicle, JUV-161 (48 mg/kg), semaglutide (6 nmol/kg), or JUV-161 combined with semaglutide. All treatments were administered daily by subcutaneous injection for 21 days. Longitudinal assessments included body weight, body composition by EchoMRI, and fasting glucose. Insulin sensitivity and glucose handling were evaluated during the final treatment week, along with forelimb and all-limb grip strength and in vivo hindlimb muscle force. At study termination, hindlimb muscle weights and circulating metabolic biomarkers were analyzed.

Results: Treatment with JUV-161 led to a progressive reduction in fasting glucose that was further enhanced when combined with semaglutide. Measures of insulin sensitivity demonstrated superior glucose clearance in JUV-161 treated animals, with the largest improvement observed in the combination group. Consistent with these findings, long-term glycemic control, assessed by HbA1c, was improved relative to vehicle controls (8.3%), with reductions observed for JUV-161 (7.2%), semaglutide (7.4%), and the combination (6.3%). Beyond glycemic control, JUV-161 favorably modulated circulating markers associated with liver function and systemic metabolism, with broader effects observed following combination therapy. Markers of muscle injury and renal stress were reduced in JUV-161 treated mice, while improvements in lipid-associated markers were specific to combination treatment. Functionally, JUV-161 significantly increased grip strength and enhanced gastrocnemius contractile performance across stimulation frequencies. These functional gains were accompanied by preservation of lean mass and significant increases in tibialis anterior and gastrocnemius muscle weights.

Conclusions: JUV-161 confers dual metabolic and musculoskeletal benefits in a severe model of T2D, improving glycemic control while enhancing muscle mass and function. These findings highlight JUV-161 as a promising first-in-class biologic that addresses both metabolic dysfunction and diabetes-associated muscle decline, supporting its translational potential either alone or in combination with established antidiabetic therapies.

OC2.3 - ECE_1423 - Research on the role of PRMT6 in promoting proliferation of pancreatic β-Cells

Changliu Xu, Shuhui Liang, Fenghua Lai, Nan Chen, Haipeng Xiao, Yanbing Li and Xiaopei Cao
The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Objective: Protein arginine methyltransferase 6 (PRMT6) is mainly localized in the nucleus, where it regulates gene transcription and controls the cell cycle, growth, and proliferation. Previous studies have shown that PRMT6 expression is significantly higher in the pancreatic islets of leptin-deficient obese diabetic mice (ob/ob) compared to control mice. This study aims to investigate the impact of PRMT6 on the proliferation of pancreatic β-cells.

Methods: In vitro, PRMT6 overexpression and knockdown models were established in mouse β-cell lines (MIN6 and β-TC6). Palmitic acid treatment was used to simulate a lipotoxic environment. Cell cycle distribution was analyzed by flow cytometry, and cell growth and proliferation were assessed using CCK8 assays and EdU incorporation assays. In vivo, 20 male C57BL/6J mice were fed a high-fat diet for 24 weeks and injected with recombinant adeno-associated virus vectors carrying either PRMT6 (AAV-PRMT6) or a negative control. Weekly measurements of body weight and fasting blood glucose were taken, and glucose and insulin tolerance tests were performed after 6 weeks.

Results: PRMT6 overexpression promoted the transition of the MIN6/β-TC6 cell cycle from G0/G1 to G2/S and increased cell growth and proliferation, while PRMT6 knockdown had the opposite effects. Palmitic acid treatment reduced cell growth, and knockdown of PRMT6 worsened this reduction. Overexpression of PRMT6 partially alleviated the palmitic acid-induced decrease in proliferation. In vivo, AAV-PRMT6-treated mice showed no significant differences in body weight, fasting blood glucose, or insulin tolerance compared to control mice. However, the glucose insulin tolerance tests revealed a significantly lower area under the curve for glucose levels in the AAV-PRMT6 group.

Conclusions: PRMT6 promotes the proliferation of pancreatic β-cells and improves glucose tolerance in diabetic mice. This suggests that PRMT6 may play a potential role in the regulation of β-cell proliferation and glucose homeostasis, providing insights into potential therapeutic strategies for diabetes.

Abstract citation ID: lvag096.086

OC2.4 - ECE_1405 - SGLT-2 inhibitor-induced erythrocytosis increases risk of lower limb amputation in persons with type 2 diabetes—a nationwide cohort study

Aidar Gosmanov[1,2] and Darren Gemoets[1]
[1]*Stratton VA Medical Center, Albany, United States;* [2]*Department of Medicine, Division of Endocrinology, Albany Medical College, Albany, United States*

The evidence is controversial whether type 2 diabetes (T2D) therapy with SGLT-2i can increase risk of lower limb amputations (LLA). Recent large-scale studies have clearly demonstrated that SGLT-2i cause erythrocytosis which in turn can potentially increase blood viscosity. The aim of this investigation was to assess incidence of LLA in T2D patients treated with SGLT-2i in presence and absence of erythrocytosis. In this retrospective cohort study we studied US Veterans with T2D who had complete medical records data, baseline hematocrit (Hct) <52.0%

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

measured within 1 year before the start of study, adequate adherence with SGLT-2i, no testosterone prescription, and no history of erythrocytosis or prior LLA and received care between 3/2013-12/2023. Among 691104 patients (mostly males (94.5%) and Caucasians (Whites 70.2%/Blacks 19.4%) with mean age 65.7 yrs) we identified control (no record of SGLT-2i use) and new SGLT-2i users and followed hematocrit for 1 year to identify those who developed new erythrocytosis defined as hematocrit ≥52%. Primary endpoints were odds ratio (OR) of new diagnosis of LLA calculated by logistic regression model adjusted for case-mix. The SGLT-2i use for 1 year resulted in significant hemoglobin A1c reduction and hematocrit increase compared with the control group and was associated with about 6-fold ($P < .001$) increase in erythrocytosis risk after adjusting for baseline characteristics: 0.58% of control patients developed erythrocytosis compared with 3.66% in the SGLT-2i group. In the models adjusted for multiple baseline characteristics, new-onset erythrocytosis in control group was not while in the SGLT-2i group was associated with 2.16-fold ($P < .001$) higher odds of LLA. For the first time, we demonstrated that, in a large T2D cohort, a new diagnosis of erythrocytosis defined by hematocrit ≥52% was accompanied by increased incidence of LLA in SGLT-2i-treated patients but not in those who received other anti-hyperglycemic agents. While further studies needed to confirm these findings, we recommend closely monitoring hematocrit trends in people with T2D receiving SGLT-2i.

OC2.5 - ECE_1969 - Interleukin-6 signaling modulates glucagon-stimulated gluconeogenesis from amino acids in humans

Hanna Litscher[1], Lena-Marie Leikam[1], Peter Plomgaard[2], Gerrit van Hall[3] and Beckey Trinh[1]
[1]Basel, Switzerland; [2]Rigshospitalet, The Centre for Physical Activity Research, Copenhagen, Denmark; [3]Rigshospitalet, Clinical Metabolomics Core Facility, Copenhagen, Denmark

Background: Over the past 25 years, interleukin-6 (IL-6) has been recognized not only as a key regulator of immune function but also as a context-dependent mediator of energy allocation. We previously demonstrated that chronic blockade of IL-6 signaling increases circulating plasma amino acid concentrations in healthy humans. Glucagon is a major regulator of amino acid metabolism, and patients lacking glucagon secretion after total pancreatectomy similarly exhibit hyperaminoacidemia. We therefore hypothesized that IL-6 signaling facilitates glucagon-induced amino acid catabolism and gluconeogenesis.
Methods: In this randomized, double-blind, placebo-controlled trial, 26 healthy participants were randomized 1:1 to receive either the IL-6 receptor antagonist tocilizumab (8 mg/kg body weight) or normal saline (placebo). After three weeks, overnight-fasted participants underwent a pancreatic clamp using octreotide, insulin, and glucagon to sequentially mimic low- and high-glucagon states, while insulin was maintained at basal fasting levels. A subset of 15 participants received concomitant infusion of stable isotope tracers (L-[3-^{13}C]alanine and [6,6-$^{2}H_2$]glucose). Sequential blood samples were collected throughout the clamp. The primary endpoint was the difference between groups in the maximal glucagon-induced reduction in total plasma amino acids. Key secondary endpoints included rates of gluconeogenesis and the contribution of alanine to gluconeogenesis assessed by tracer kinetics.

Results: No significant treatment effect was observed for the maximal reduction in total plasma amino acids during high glucagon (placebo: 344.1 ± 142.1 μmol/L [14.5 ± 6.2%] vs tocilizumab: 433.8 ± 168.5 μmol/L [18.1 ± 8.0%]) or for total rates of gluconeogenesis across clamp phases (all $P \geq .724$). In contrast, for gluconeogenesis from alanine, a significant treatment × phase interaction was observed ($P = .021$), with rates being 1% lower at baseline and 20% lower during high-glucagon conditions in the tocilizumab group. Similarly, the proportional contribution of alanine to total gluconeogenesis showed a significant treatment × phase interaction ($P = .011$), with reductions of 6% at baseline and 24% during high glucagon compared with placebo. These findings indicate a phase-dependent modulation of alanine-derived gluconeogenesis following IL-6 receptor blockade.

Conclusions: IL-6 signaling appears to facilitate glucagon-stimulated gluconeogenesis from amino acids in humans, particularly under high-glucagon conditions. This identifies IL-6 as a modulator of glucagon–amino acid interplay in human metabolism.

OC2.6 - ECE_2853 - Uncovering hidden metabolic patterns in healthy post-menopausal women

Alicia Santamaría-Quiles, Jesús Roca-García, Angela Rubio Tenor and Ines Pineda-Torra
Seville, Spain

Cardiovascular diseases remain the leading cause of mortality for women worldwide. Menopause marks a critical endocrine transition; the cessation of ovarian function and a reversal of the estrogen-to-androgen ratio elicit a pro-inflammatory and atherogenic metabolic shift, driving a sharp increase in cardiovascular risk.

The aim of this study was to characterize the metabolic landscape associated with menopause. We investigated the disparities between pre- and post-menopausal women employing targeted Nuclear Magnetic Resonance (NMR)-based metabolomics. This approach was further coupled with machine learning algorithms to determine how inflammation modulates these lipid profiles in post-menopausal women, with the ultimate goal of defining subclinical patterns relevant for early preventive strategies.

We recruited a cohort of pre- ($n = 68$; age 18-45) and post-menopausal women ($n = 59$; age 55-68; time since menopause: 0-28 years). All participants were healthy with no history of cardiovascular disease. Women on hormone replacement therapy, with autoimmune disorders, or with a recent vaccination (<3 weeks) were excluded. Serum metabolomic analysis was performed targeting lipoproteins, glycoproteins, low-molecular-weight metabolites, and lipid profiles. Finally, machine learning models were trained to identify a metabolic signature predictive of an inflammatory-associated lipid profile in post-menopausal women.

Post-menopausal women exhibited metabolic dysregulation driven by elevated lipids, pro-atherogenic apolipoprotein B, and inflammatory glycoproteins. In contrast, amino acid and glucose profiles remained largely unaltered, confirming that menopause-related risk is primarily mediated by lipid-inflammatory pathways. Metabolic variance was strongly

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

influenced by GlycA, an NMR biomarker reflecting acute-phase protein glycosylation. Given that chronic low-grade inflammation is a key driver of atherosclerosis progression, and GlycA serves as a robust predictor of subclinical cardiovascular risk, we used this biomarker to stratify post-menopausal women into high and low inflammation subgroups. While clinical profiles between inflammatory groups were mostly comparable, the high-inflammation subgroup displayed significantly higher systolic blood pressure, linking subclinical inflammation to vascular strain. A logistic regression model yielded the best performance (AUC: 0.945) identifying alanine, triglycerides, linoleic acid, omega-3 fatty acids, DHA, and large VLDL particles as primary drivers. Subsequently, an AutoScore analysis defined a selective 3-metabolite diagnostic signature validated in an independent test set (AUC: 0.869).

Our findings reveal the inflammatory nature of the post-menopausal metabolic landscape. We demonstrate that even in healthy women, inflammation drives specific metabolic patterns associated with heightened cardiovascular risk. Upon external validation, the identified metabolic signature would represent a powerful tool for early risk stratification, facilitating precision medicine interventions at a preclinical stage.

Cushing's disease (CD) is caused by adrenocorticotropic hormone (ACTH)-secreting pituitary tumors. Despite various treatment options, patients still suffer from high recurrence rates, stressing the need to find better prognostic biomarkers and develop improved treatments. First, however, a comprehensive understanding of CD tumor biology is needed. Recurrent genetic alterations have been identified as potential drivers of tumorigenesis in CD. However, their impact at the molecular and clinical levels remains largely unknown. Therefore, we aimed to investigate the impact of genetic alterations at the genomic, chromosomal and transcriptomic levels in patient samples and on clinical outcomes.

Copy number variation (CNV) profiles of 129 CD tumors were assessed using whole exome sequencing (WES) or shallow whole genome sequencing (sWGS) and verified using FISH analysis. Mutations were determined using WES/WGS and Sanger sequencing. Transcriptomic changes were investigated using single-nucleus RNA sequencing (snRNA-seq.).

We identified high chromosomal losses and gains in 47/129 tumors, while the rest were CNV-low tumors. We found that CNV patterns were not random, as losses and gains were largely mutually exclusive across tumors, leading to further subgrouping into CNV-loss and CNV-gain tumors.

When examining variants, *USP8* mutations were enriched in CNV-low tumors, whereas *TP53* mutations were exclusively found in CNV-loss tumors which also showed higher tumor mutational burden and microsatellite instability.

CNV-loss tumors were enriched for pathogenic mutations in chromosome organization pathways with high cellular frequencies, suggesting a potential explanation for CNVs. We studied tumors from preceding and following surgery of the primary tumors and recurrences from five patients and revealed identical CNV profiles even after up to 994 days, underlining the high genomic stability despite massive genetic alterations.

Clinically, CNV-loss or CNV-gain tumors exhibited an approximately 30-fold increased risk of recurrence, highlighting CNVs as a potential prognostic biomarker.

At the transcriptomic level, snRNA-seq. analyses of nine CD tumors showed similarities between CNV-low (both *USP8* mutated and wild-type) and a CNV-gain tumor; however, there were strong differences compared to CNV-loss tumors. We could further show that chromosomal loss directly affected loss of corresponding transcripts, which may be exploited for clinical intervention.

Taken together, our study brings important new insights into tumor biology of CD by discovering CNV-defined tumor subgroups with strong differences in genetic characteristics, transcriptomic landscapes and clinical outcomes. CNV analysis of CD tumors and the high genomic stability may enable future prediction of recurrences and provide potential for novel and better patient-specific treatment options.

OC3.2 - ECE_2189 - Disrupted peripheral circadian clock gene expression in patients with Cushing's syndrome

Tim Terlutter[1], Elisabeth Nowak[1,2], Hanna F. Nowotny[1], Annie Sriramachandran[1], Pia Kruse[1], Marceli Chojnacki[1], Pia Wagner[1], Sarah Ilmberger[1], Elina Kotzeva[1], Stephanie Zopp[1], Martin Reincke[1] and Nicole Reisch[1]
[1]Munich, Germany; [2]Department of Medicine IV, LMU University Hospital, LMU Munich, Munich, Germany

Background: Endogenous Cushing's syndrome (CS) is characterised by a loss of physiological circadian cortisol rhythmicity, which contributes to typical comorbidities such as sleep disturbances, depression, and cardiometabolic complications. We aimed to investigate the effects of prolonged cortisol excess on peripheral circadian clock gene expression during active disease and in remission.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Methods: This prospective single-centre study included 54 patients with active CS (21 adrenal, 29 pituitary, 4 ectopic) and 54 sex-, age- and BMI-matched healthy controls. Seventeen patients (10 adrenal, 7 pituitary) were additionally assessed longitudinally during remission with persistent adrenal insufficiency and physiological hydrocortisone replacement therapy. Morning blood samples (8-12 AM) were collected and peripheral mononuclear blood cells were isolated within six hours using density gradient centrifugation. The mRNA expression of 11 core circadian clock genes (*CLOCK*, *ARNTL*, *CRY1*, *CRY2*, *PER1*, *PER2*, *PER3*, *NR1D1*, *TIMELESS*, *WEE1*, *CREB1*) was quantified by real-time qPCR.

Results: Patients with active CS showed significantly reduced mRNA expression of *CLOCK* ($P = .033$), *NR1D1* ($P = .0057$), *TIMELESS* ($P = .0039$), *PER2* ($P = .0004$), *PER3, CREB1* (both $P = .0002$), *ARNTL*, *CRY1*, and *CRY2* (all $P < .0001$). *PER1* and *WEE1* expression did not differ significantly between groups. No significant differences were observed between ACTH-dependent and -independent CS. After a median remission duration of 5.0 months (IQR 3.5-7.0), expression levels of *CLOCK*, *PER2*, *PER3*, *ARNTL*, *CRY1*, *CRY2*, and *CREB1* had normalised. In contrast, *NR1D1* was upregulated compared with both healthy controls ($P = .0003$) and patients with active CS ($P = .0011$). TIMELESS expression remained slightly, though not statistically significantly, lower relative to controls ($P = .069$). *WEE1* expression was reduced compared with patients with active CS ($P < .0001$).

Conclusions: Cortisol excess in CS is associated with broad alterations in peripheral circadian clock gene expression. Most changes are reversible after remission. However, persistent dysregulation of *NR1D1* indicates lasting circadian alterations and merits further investigation of downstream pathways and clinical associations.

OC3.3 - ECE_1982 - No circadian rhythmicity of neurophysin I, a surrogate marker for oxytocin

Cihan Atila[1,2], Rakithan Murugesu[1,2], Shalini Mekkattu[1,2], Deborah Rudin[2,3,4], Dino Lüthi[2,3,4], Matthias Liechti[2,3,4] and Mirjam Christ-Crain[1,2]

[1]Department of Endocrinology, Diabetology and Metabolism, University Hospital Basel, Basel, Switzerland; [2]Department of Clinical Research, University of Basel, University Hospital Basel, Basel, Switzerland; [3]Division of Clinical Pharmacology and Toxicology, University Hospital Basel, Basel, Switzerland; [4]Department of Biomedicine, University of Basel, University Hospital Basel, Basel, Switzerland

Purpose: Oxytocin (OXT) plays key roles in social behaviour, stress regulation, and reproductive physiology. OXT deficiency has been described in pituitary disorders and is associated with increased anxiety and impaired prosocial behaviour. Despite growing clinical interest, the circadian regulation of OXT remains poorly defined, largely due to methodological limitations in measuring endogenous OXT. Neurophysin I (NP-I), a stable carrier protein co-released with OXT, represents a reliable surrogate marker. Characterizing the circadian profile of NP-I may therefore provide important insights into oxytocinergic function with implications for diagnostics and future replacement strategies.

Methods: This study is a secondary analysis of a prospective, observational trial conducted in healthy adults under highly standardized conditions. Thirteen participants underwent hourly blood sampling over 24 hours following overnight fasting, controlled fluid intake, standardized meals, and regulated light exposure and physical activity. All assessments were performed on the clinical research ward to minimize external influences on hormone secretion.

Results: Thirteen healthy participants (median age 23 years [IQR, 19-24]; 46% female; BMI 22.8 ± 1.6 kg/m^2) underwent 24-hour hormone profiling. NP-I concentrations ranged from 50 to 8607 pg/mL. The overall median NP-I concentration was 822 pg/mL [339-1392], with a mean of 1609 pg/mL (2084). Individual median 24-hour NP-I concentrations ranged from 143 pg/mL [114-186] to 7103 pg/mL [6380-7714]. Across participants, NP-I levels peaked at approximately 05:30 and reached a nadir at approximately 16:30. The estimated oscillation amplitude was small (35 pg/mL) and not statistically significant (95% CI-110 to 181; $P > .05$), indicating the absence of a robust population-level circadian rhythm. Female participants exhibited higher NP-I concentrations than males (median 1372 pg/mL [468-5344] vs 687 pg/mL [297-932]), with markedly elevated levels—approximately four- to five-fold higher—in two women using hormonal contraception.

Conclusions: Under resting, unstimulated conditions, circulating NP-I levels in healthy adults do not display significant circadian rhythmicity, suggesting stable basal oxytocinergic output. Exploratory findings indicate potential sex-related differences that warrant further investigation.

States; [18]Hospital of Clinics of the Federal University of Minas Gerais, Belo Horizonte, Brazil; [19]University of Milano, Milano, Italy; [20]University of Leicester, Leicester, United Kingdom; [21]University of Frankfurt, Frankfurt am Main, Germany; [22]University of Basel, Basel, Switzerland

Background: Prolactinomas are commonly treated with dopamine agonists (DA), which normalise prolactin levels in most patients. However, patient-reported long-term tolerability remains poorly characterised. Adverse effects—particularly impulse control disorders (ICDs)—may be underrecognized due to the lack of disease-specific screening tools and the limited feasibility of existing instruments developed for other conditions. This study assesses patient-reported treatment experiences and side effects across treatment modalities and introduces and evaluates a novel, brief ICD screening tool tailored to patients with prolactinoma.

Methods: International, cross-sectional survey study between 01/06/2025-02/01/2026, coordinated by the University Hospital Basel, Switzerland. Adults (≥18 years) with prolactinoma were recruited by their local physicians. The survey assessed symptoms at diagnosis, treatment history, DA-associated adverse effects, and behavioural changes. Impulsivity and ICDs were assessed using the Barratt Impulsiveness Scale (BIS), the Questionnaire for Impulsive–Compulsive Disorders in Parkinson's Disease (QUIP), and the newly developed BASEL-ICD-S questionnaire. Patients were analysed according to current DA exposure. Receiver operating characteristic (ROC) analyses were used to derive cut-offs for detecting high impulsivity and pathological ICD sub-domains in randomly assigned development and validation cohorts.

Findings: 528 patients were included (median age 40 years [31-49], 73% female, median disease duration 5 years [2-11]). Common manifestations at diagnosis included menstrual irregularities in women (82%), reduced libido in men (80%), as well as tiredness (70%) and mood changes (64%) overall. Primary treatment was medical in 87% and surgical in 9%, while 4% were newly diagnosed and had no treatment started. Among DA-treated patients ($n = 406$), the most frequent side effects were fatigue (51%), dizziness (43%), headache (38%), and gastrointestinal complaints (36%). BIS, QUIP, and BASEL-ICD-S total scores were higher in DA-treated than not DA-treated patients ($n = 406$) (all $P < .001$). High impulsivity (BIS score >74) was more frequent in DA-treated patients (22% vs 7%). A BASEL-ICD-S total score of ≥25 identified high impulsivity with good discrimination in both development (AUC 0.88) and validation cohorts (AUC 0.89), and with high negative predictive value (96%). Pathological ICDs in DA-treated patients included gambling (7.4% vs 1.6%), compulsive buying (28.1% vs 13.9%), and hypersexual behaviour (17.7% vs 5.7%). BASEL-ICD-S subscores demonstrated good to excellent discrimination across ICD domains (AUC ranges 0.75-0.99), with stable performance in the validation cohort (AUC 0.76-0.91).

Conclusions: Prolactinomas were associated with a substantial symptom burden. DA therapy was frequently accompanied by adverse effects, increased impulsivity, and other ICDs. The BASEL-ICD-S demonstrated robust performance as a brief screening tool for behavioural side effects in patients with prolactinoma.

OC3.5 - ECE_1667 - TP53 R248Q promotes immune escape of pituitary neuroendocrine tumors through cooperative interactions between SPP1+ TAMs and EndMT-CAFs

Wan Su[1], Zhang Ye[2], Yong Yao[2] and Lin Lu[1]
[1]Endocrinology, Peking Union Medical College Hospital, Beijing, China; [2]Beijing, China

Aggressive pituitary tumors remain difficult to manage due to invasive growth, frequent recurrence, and resistance to therapy and effective molecularly targeted treatments are still lacking. Accumulating evidence from previous clinical and genomic cohorts has demonstrated a high prevalence of TP53 alterations in aggressive pituitary tumors, implicating TP53 dysregulation as a potential driver of malignant progression. However, despite its established association with tumor aggressiveness, the mechanistic role of TP53 mutations in pituitary tumor biology—particularly in shaping tumor–stroma–immune interactions—remains poorly understood.

To address this gap, we integrated single-cell transcriptomics from 34 pituitary tumors with in vitro functional assays, including co-culture systems, collagen matrix contraction assays, flow cytometry, cytokine profiling, and a tri-culture Transwell model incorporating Trp53-mutant mouse pituitary tumor cell lines and patient-derived TP53-mutant tumor organoids.

Single-cell transcriptomic analysis of pituitary tumors revealed marked activation of the TP53 signaling pathway in aggressive case, together with occurrence of the hotspot mutation TP53(Arg248Gln). Detailed characterization of cancer-associated fibroblasts (CAFs) heterogeneity demonstrated a selective expansion of EndMT-CAFs in TP53-mutant tumors. Pseudotime modeling reconstructed fibroblast differentiation trajectories and identified a fibrosis-associated ECM program linked to EndMT (Endothelial-to-Mesenchymal Transition). Functionally, co-culture experiments demonstrated that TP53-mutant tumor cells induced EndMT-CAFs differentiation and promoted a pro-invasive CAF phenotype. In parallel, immune profiling revealed an enrichment of SPP1$^+$ tumor-associated macrophages (TAMs), reduced T-cell infiltration, and enhanced cytokine- and ECM-mediated communication networks in TP53-mutant tumors. Flow cytometric and cytokine analyses further showed that TP53 (Arg248Gln) tumor cells preferentially drove macrophage polarization toward an SPP1$^+$ TAM state through tumor-derived cytokine signals.

To interrogate coordinated stromal–immune interactions, a tri-culture Transwell system was established to model an immune-exclusion niche in vitro. Within this system, EndMT-CAFs and SPP1$^+$ TAMs cooperatively amplified ECM remodeling, forming a structured stromal barrier that enhanced tumor cell proliferation and invasion while restricting CD8$^+$ T-cell infiltration and effector function.

Collectively, these findings demonstrate that TP53(Arg248Gln) promotes pituitary tumor invasion by orchestrating EndMT-CAFs and SPP1$^+$ TAMs recruitment, thereby driving ECM remodeling and establishment of an immune-exclusion niche that supports tumor progression and immune escape. This work provides a mechanistic framework and potential therapeutic entry points for targeting aggressive pituitary tumors.

OC3.6 - ECE_3431 - PitNET-associated SOX2+ pituitary stem cells: a transcriptomic landscape of 1534 patients

Bence Kövér[1], Ian Kruk[2], James Kaufman-Cook[1], Yasmine Kemkem[1], Miriam Vazquez Segoviano[1], Olivia Sherwin[1], Hui-Chun Lu[1] and Cynthia Andoniadou[1]

[1]*Centre for Craniofacial and Regenerative Biology, King's College London Guy's Campus, London, United Kingdom;* [2]*McGill University, Montreal, Canada*

The anterior pituitary gland contains SOX2+ pituitary stem cells (PSCs) that persist into adulthood. The role of PSCs remains obscure with regards to the initiation and maintenance of pituitary neuroendocrine tumours (PitNETs). To quantify the abundance and gene expression profile of tumour-associated PSCs, we carefully curated and uniformly reprocessed all publicly available human pituitary (healthy or PitNET) transcriptomic datasets (1441 bulk and 93 single-cell).

Analysis of bulk and single-cell samples in a shared embedding identified 5 broad PitNET subtypes, and a clear separation by transcription factor lineage (POU1F1+, NR5A1+, TBX19+). The majority of PitNETs with the clinical annotation "Null-cell" were clustered with NR5A1+ samples (85% (28/33)).

Cell type annotation of 93 single-cell samples (~420 000 cells) revealed the presence of PSCs in healthy pituitaries, and residual PSCs associated with PitNETs. Tumour-associated PSCs expressed known PSC markers, such as *SOX2*, *SOX9*, as well as newly identified markers in mice, such as *RUNX1*, *NFIB* or *SLIT2* (total of 3896 genes upregulated vs tumour cells). In addition, differential expression analysis revealed 1349 upregulated and 2298 downregulated genes in tumour-associated PSCs compared to healthy PSCs.

Across single-cell datasets, tumour-associated PSCs were present in 47% (37/78) of samples (POU1F1+ 47% (15/32); NR5A1+ 44% (8/18); TBX19+ 60% (9/15); Null-cell 33% (1/3)), at a median frequency of 1.8% of cells, as compared to 6.4% of cells in healthy tissue. To enable reproducible detection of cell types (including PSCs) in PitNET single-cell data, we release a machine learning-based annotation tool implemented in the *epitome_tools* Python package.

To further characterise stem cell abundance, we applied cell-specific marker signatures to deconvolute the cell type composition of 1441 high-quality bulk transcriptomic samples (1102 PitNETs, 339 Healthy). This analysis also identified a PSC compartment in 93% of healthy samples (316/339) and in at least 29% of PitNETs (POU1F1+ 36% (130/358); NR5A1+ 17% (39/225); TBX19+ 15% (26/167); Null-cell 15% (5/33)). In PitNETs, this analysis identified a median PSC abundance of 1.2%, compared to 3.3% in healthy tissue.

In summary, we find that SOX2+ PSCs are widely detectable across PitNET samples, regardless of tumour lineage or assay technology. In addition, tumour-associated PSCs exhibit an altered transcriptome compared to healthy PSCs, which might affect tumourigenesis. Importantly, none of the single-cell or bulk samples were fully composed of PSCs, suggesting that PitNETs always exhibit some level of differentiation. Follow-up work will examine the predictive power of PSC abundance on tumour invasion and recurrence.

OC4.1 - ECE_2808 - Chronic subcutaneous kisspeptin-10 sustains gonadotrophin secretion for 12 days without tachyphylaxis in healthy men

Jovanna Tsoutsouki[1,2], Arthur Yeung[1], Maria Phylactou[1,2], Kanyada Koysombat[1], Sandhi Nyunt[1], Megan Young[1], Aaran Patel[1], Elisabeth Daniels[1], Aureliane Pierret[1], Edouard G. Mills[1,2,3], Alexander Comninos[1,2,3], Ali Abbara[1,2] and Waljit Dhillo[1,2]

[1]*Department of Metabolism, Digestion and Reproduction, Imperial College London, London, United Kingdom;* [2]*Department of Endocrinology, Imperial College Healthcare NHS Trust, London, United Kingdom;* [3]*Endocrine Bone Unit, Imperial College Healthcare NHS Trust, London, United Kingdom*

Introduction: Kisspeptin is a key hypothalamic regulator of gonadotropin-releasing hormone and gonadotrophin (LH/FSH) secretion and has major therapeutic potential for hypogonadotrophic hypogonadism. While acute kisspeptin administration robustly stimulates gonadotrophin release in humans, concerns regarding receptor tachyphylaxis have limited its chronic clinical use. We evaluated, for the first time in humans, whether chronic subcutaneous administration of kisspeptin-10 can sustain gonadotrophin secretion without desensitisation.

Methods: In a randomised, single-blind, crossover, placebo-controlled study, healthy eugonadal men (18-40 years) received chronic subcutaneous kisspeptin-10 infusion via two paradigms: (1) continuous infusion (180 nmol/hr for 5 days, $n = 4$), with LH/FSH sampling every 15 minutes on days 1 and 5; and (2) intermittent infusion (150 nmol/hr for 8 hours daily with 16 hours rest for 12 days, $n = 7$), with 15-minute sampling on days 1, 8, and 12. Sampling sessions lasted up to 8.5 hours. In a subset ($n = 4$), an intravenous kisspeptin-10 bolus (1 nmol/kg) was administered immediately after cessation of the day-12 infusion to assess receptor responsiveness. Separate saline visits ($n = 12$) served as controls.

Results: Continuous 5-day kisspeptin-10 infusion induced robust gonadotrophin responses on both days. Mean gonadotrophin increases from baseline were significantly greater than saline (LH: -0.16 ± 0.19; FSH: -0.19 ± 0.08 IU/L) on day 1 (LH 4.11 ± 0.68 IU/L, $P < .0001$; FSH 0.84 ± 0.27 $P = .0003$) and day 5 (LH 1.65 ± 0.32, $P = .0039$; FSH 0.34 ± 0.21, $P = .049$), indicating partial but not complete attenuation by day 5.

Intermittent 12-day kisspeptin-10 administration sustained gonadotrophin secretion with mean LH increases from baseline significantly exceeding saline (-0.16 ± 0.19 IU/L) on day 1 (1.68 ± 0.25 IU/L; $P < .0001$), day 8 (1.04 ± 0.22 IU/L; $P = .006$), and day 12 (1.14 ± 0.33 IU/L; $P = .003$), with no significant decline across days. FSH showed similar patterns (mean increase in FSH from baseline in IU/L: saline -0.19 ± 0.07, vs day 1, $P < 0.0001$; vs day 8, $P = .030$; vs day 12, $P = .003$). Critically, an intravenous kisspeptin-10 bolus after 12 days elicited preserved gonadotrophin increases compared with saline (LH: 3.25 vs 2.76 IU/L; FSH: 0.61 vs 0.07 IU/L), confirming absence of receptor desensitisation.

Conclusions: This study provides the first evidence that chronic subcutaneous kisspeptin-10 administration can sustain gonadotrophin secretion in humans for up to 12 days without inducing tachyphylaxis. An intermittent infusion strategy preserves

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

kisspeptin receptor sensitivity while effectively activating the hypothalamic-pituitary-gonadal axis. These findings establish a clinically feasible protocol with strong translational potential for treating conditions characterised by hypothalamic kisspeptin deficiency, including functional hypothalamic amenorrhea and obesity-related hypogonadism.

OC4.2 - ECE_3288 - Dynamic endocrine responses to kisspeptin to decode hypothalamic-pituitary dysfunction in women with obesity

Sandhi Nyunt[1,2], Kanyada Koysombat[1,2], Megan Young[1], Agathoklis Efthymiadis[1,2], Patrick McGown[1,2], Aaran Patel[1,2], Bijal Patel[1,2], Arthur Yeung[1,2], Jovanna Tsoutsouki[1,2], Aureliane Pierret[1,2], Elisabeth Daniels[1,2], Maria Phylactou[1,2], Edouard G. Mills[1,2], Chioma Izzi-Engbeaya[1,2], Tricia Tan[1,2], Alexander Comninos[1,2], Ali Abbara[1,2] and Waljit Dhillo[1,2]

[1]Department of Metabolism, Digestion and Reproduction, Imperial College London, London, United Kingdom; [2]Department of Endocrinology, Imperial College Healthcare NHS Trust, London, United Kingdom

Background: Obesity frequently co-exists with and exacerbates polycystic ovary syndrome (PCOS). PCOS is characterised by increased hypothalamic GnRH neuronal activity, whereas animal models of obesity suggest that it reduces hypothalamic function. Kisspeptin stimulates hypothalamic GnRH neurons enabling direct assessment of hypothalamic dysfunction, whereas GnRH testing assesses pituitary responsiveness. Limited data exist evaluating hypothalamic and pituitary function in women with obesity, both with and without PCOS.

Methods: Women underwent an 8-hour assessment of LH pulsatility during the early follicular phase (days 1-5 of menstrual cycle), alongside dynamic endocrine testing with intravenous GnRH (100 µg) and kisspeptin-54 (9.6 nmol/kg) on separate occasions. Participants included lean eugonadal women (BMI 18.5-24.9 kg/m^2; LeEug; $n = 31$), obese eugonadal women (BMI ≥30 kg/m^2; ObEug; $n = 7$), lean women with PCOS (LePCOS; $n = 26$), and women with obesity and PCOS (ObPCOS; $n = 23$). Hormones were measured every 10-15 minutes. Baseline hormone concentrations were compared using Kruskal Wallis test with post hoc Dunn's test and hormone rises over time were analysed using two-way ANOVA.

Results: Median (IQR) of serum LH (IU/L) was lower with obesity in both eugonadal women and those with PCOS: ObEug (2.2, IQR 1.9-2.9), LeEug (3.5, 2.6-4.6), LePCOS (5.3, 3.3-7.4), ObPCOS (4.0, 2.6-5.5) ($P = .01$ for LePCOS vs obPCOS). Baseline FSH did not differ significantly between groups: ObEug (median 5.7, IQR 4.7-7.2), LeEug (5.6, 4.6-6.9), LePCOS (4.7, 4.2-6.1), ObPCOS (5.0, 4.7-5.7).

The LH rise from baseline following kisspeptin-54 was reduced in ObEug compared with LeEug women ($P = .043$). Likewise, the FSH rise from baseline following kisspeptin-54 in eugonadal women was reduced with obesity compared with lean women ($P = .0003$). However, obesity was associated with an increased FSH response to Kisspeptin-54 in women with PCOS ($P = .013$).

The LH ($P = .0008$) and FSH ($P < .0001$) responses to GnRH were reduced with obesity in eugonadal women. In women with PCOS, the FSH response was also reduced ($P = .02$), although the LH response was not significantly altered ($P = .3$).

Conclusions: Obesity is associated with reduced gonadotrophin concentrations, due to multiple mechanisms including increased renal clearance. Dynamic testing revealed that obesity attenuates pituitary responsiveness to GnRH. In contrast, we show for the first time that hypothalamic responses to kisspeptin were divergent, being increased in PCOS but reduced in eugonadal women. These data highlight fundamental differences between the neuroendocrine disturbances in women with PCOS and those due to obesity alone.

OC4.3 - ECE_1644 - Increased prospective cardiovascular disease risk in 127,517 Nordic women with polycystic ovary syndrome. a national cohort study

Dorte Glintborg[1], Meri-Maija Ollila[2], Noona Koskenkari[2], Jens-Jakob Møller[3], Daniella Calla[4], Frida Gyllenberg[4], Katrine Rubin[3], Paula Pesonen[2], Marianne Skovsager Andersen[1], Inger Sundström-Poromaa[4] and Terhi Piltonen[2]

[1]Department of Endocrinology, Odense, Denmark; [2]Oulu University Hospital, Oulu, Finland; [3]OPEN, Odense, Denmark; [4]Uppsala University, Uppsala, Sweden

Background: Cardiovascular disease (CVD) risk factors are prevalent in women with PCOS, but prospective data regarding CVD in population-based cohorts are limited.

Aim: To investigate prospective risk of CVD in Nordic women with PCOS.

Design: National register-based study in women with PCOS and age-matched controls originating from Denmark (PCOS Denmark, N = 27 298, controls, N = 135 019), Finland (PCOS Finland, N = 20 765, controls, N = 59 122), and Sweden (PCOS Sweden, N = 79 454, controls, N = 393 669). The main study outcome was CVD. CVD was defined according to ICD-10 diagnostic codes for major adverse cardiac events, pulmonary embolism and/or deep venous thrombosis. Cox regression analyses estimated HR with 95% CI and adjusted analyses included BMI and education.

Results: The median age at cohort entry was 28 years (Denmark) and 29 years (Finland and Sweden) and the median follow-up time was 8.0 to 10.0 years. The unadjusted hazard ratio (HR, 95% CI) for CVD in women with PCOS was 1.30 (1.20; 1.41) in Denmark, 1.45 (1.31; 1.60) in Finland, and 1.52 (1.44; 1.60) in Sweden. Models remained significant after adjusting for obesity and level of education. In a combined meta-analysis including all countries (PCOS, N = 127 517, controls, N = 587 810, the adjusted HR for CVD in women with PCOS was 1.32 (1.25; 1.39). In women with BMI <25 kg/m^2 and no type 2 diabetes, the adjusted HR for CVD risk was 1.40 (1.26; 1.55).

Conclusions: The risk of CVD was increased in women with PCOS across the three Nordic countries, also among women with BMI <25 kg/m^2.

OC4.4 - ECE_2998 - Unraveling the role of hyperandrogenism in the development of metabolic dysfunction-associated steatotic liver disease (MASLD) in polycystic ovary syndrome

Andrea Rodriguez-Martin[1,2], Victor Serrano-Lopez[1,2], Esperanza Uceda-Rodriguez[1,2], Carmen Torres-Granados[1,2], Valentina Dorta-Bouza[3], Francisco Ruiz-Pino[1,2,4], Azahara Espejo-Cordero[1,2], Ana Belen Rodriguez[1,2,4], Rubén Nogueiras[3], Manuel Tena-Sempere[1,2,4] and Miguel Angel Sanchez-Garrido Nogueras[1,2,4]

[1]University of Cordoba, Cordoba, Spain; [2]Maimónides Biomedical Research Institute of Córdoba, Cordoba, Spain; [3]Deparment of Physiology (CIMUS), University of Santiago de Compostela, Santiago de Compostela, Spain; [4]CIBER Fisiopatología de la Obesidad y Nutrición (CIBEROBN), Cordoba, Spain

Polycystic ovary syndrome (PCOS) is the most prevalent endocrine disorder among premenopausal women, characterized by hyperandrogenism and reproductive dysfunction. PCOS is often linked also to metabolic abnormalities, and women with PCOS have four-fold increased risk of developing metabolic dysfunction-associated steatotic liver disease (MASLD).

MASLD is a prevalent liver condition, affecting 35%-70% of women with PCOS. MASLD encompasses a spectrum of hepatic manifestations that begin with liver fat accumulation, which may progress to non-alcoholic steatohepatitis (NASH), a more severe stage of the disease that can lead to cirrhosis, liver failure and hepatocellular carcinoma.

Cumulative evidence suggests that the higher incidence of MASLD in PCOS women may be linked to the metabolic derangements associated with this endocrinopathy, including obesity and insulin resistance. Chronic hyperandrogenism might contribute also to the development of MASLD in women with PCOS. However, the mechanisms underlying MASLD in PCOS and the pathophysiological role of androgen excess in this condition remain unknown.

Here, we investigated the role of hyperandrogenism in MASLD pathogenesis using a well-validated murine model of PCOS, based on postweaning androgenization (PWA) of female mice, and a liver-specific androgen receptor knockout (LARKO) model. In PWA mice, we characterized the effects of chronic androgen excess, alone or in combination with an obesogenic diet, on metabolic and hepatic profiles at 15, 18 and 23 weeks of androgen exposure. By week 15, androgen excess significantly increased body weight, impaired insulin sensitivity and serum parameters, and promoted hepatic steatosis and collagen deposition. Interestingly, combination of hyperandrogenism and high-fat diet (HFD) consumption markedly worsened metabolic and hepatic outcomes. Longitudinal monitoring revealed a time-dependent aggravation of both metabolic and histological derangements at the 18 and 23-week timepoints.

Notably, LARKO mice exposed to chronic hyperandrogenism (LARKO PWA) exhibited partial protection against hepatic injury. While their metabolic profiles were similar to those of the hyperandrogenized controls (PWA), LARKO PWA mice showed a significant reduction in liver fat, collagen accumulation and hepatic inflammation, as well as a marked decrease in circulating transaminases and lipid levels. Notably, this protective effect was even more pronounced when mice were fed a HFD.

Our findings demonstrate that chronic hyperandrogenism is a major factor for MASLD progression in PCOS, especially when concurrent with obesity, via hepatic androgen receptor activation. Liver AR signaling may be considered a primary driver of (and eventual therapeutic target for) hepatic pathology in PCOS, independent of systemic metabolic dysfunction.

OC4.5 - ECE_2984 - Early pregnancy maternal progesterone supplementation alters fetal frontal cortex gene expression in male fetuses

Katarzyna Siemienowicz[1], Anna Sherriffs[1], Mick Rae[1] and Colin Duncan[2]

[1]School of Applied Sciences, Edinburgh Napier University, Edinburgh, United Kingdom; [2]Centre for Reproductive Health, The University of Edinburgh, Edinburgh, United Kingdom

Prenatal fetal exposure to steroids is a “Goldilocks phenomenon”, where too much or too little hormone is detrimental. Progesterone is critical to support and maintain pregnancy. Maternal progesterone supplementation is commonly used during assisted reproduction and as a treatment for increased risk of miscarriage, up to 16 weeks’ gestation. Progesterone and its metabolites are neuroactive steroids necessary for brain development. Effects of increased prenatal exposure to progesterone on fetal brain development are poorly understood. We previously reported that maternal progesterone administration increased male, but not female, fetal progesterone concentrations and disturbed normal hypothalamic-pituitary function in d75 sheep male fetuses (equivalent to 15 weeks of human gestation). We hypothesised that maternal progesterone supplementation in early pregnancy would alter gene expression in the fetal male frontal cortex.

Pregnant ewes received either 200 mg of intramuscular progesterone (P) or vehicle (C) twice weekly from day 20 until sacrifice at day 75 of gestation. These doses and timings were clinically realistic. Fetal frontal cortex was collected from males ($C = 10$; $P = 7$), RNA extracted, and gene expression measured by RNA sequencing (RNAseq) and qPCR. Data was further contextualised using Ingenuity Pathway Analysis (IPA).

There was no difference in the expression of genes encoding steroid receptors (AR, ESR1, ESR2 and PGR) and steroid metabolising enzymes (CYP17, HSD17B, CYP19 and AKR1C2), except for increased expression of SRD5A1 ($P < .05$), an enzyme that metabolises progesterone to 5α-dihydroprogesterone and testosterone to dihydrotestosterone, in the fetal male frontal cortex from progesterone-treated pregnancies. RNAseq revealed that there were 437 nominally differentially expressed genes (DEGs) in response to progesterone supplementation. IPA analysis indicated dysregulations of numerous pathways ($P < .05$, absolute Z score>2), including increased iron uptake and transport, cyclophilin signalling pathway, and decreased CREB and reelin signalling in neurons, calcium signalling, FAK signalling and G-protein coupled signalling, all with potential impact on brain development.

Progesterone is known to cross the placental barrier, entering the fetal circulation, reaching the developing brain and regulating key events in neural development. Progesterone may also be metabolised to different steroid classes locally within the

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

developing brain. There is evidence in humans for increased fetal steroidogenic activity in autism, with oestradiol, oestrone and progesterone showing the largest effects on autism likelihood. Identified pathways and individual DEGs have links to neurological disorders and cognitive impairment. Whilst we cannot predict long-term consequences of these temporal gene expression shifts during fetal life, we demonstrated perturbed gene expression during development that warrants further investigation.

OC4.6 - ECE_3281 - Clinical determinants and evolution of bone health in an adult population with Turner syndrome: insights from a monocentric study

Laura Rotolo[1,2], Matteo Malagrinò[1,2], Carolina Cecchetti[2,3], Paola Dionese[1,2], Elisabetta Belardinelli[1,2], Beatrice Solmi[1,2], Guido Zavatta[1,2], Uberto Pagotto[1,2] and Alessandra Gambineri[1,2]

[1]Division of Endocrinology and Diabetes Prevention and Care, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy; [2]Bologna, Italy; [3]Endocrinology Unit, Ospedale Morgagni-Pierantoni, Forlì, Italy

Background: Early-onset low bone mineral density(BMD) is a hallmark of Turner syndrome(TS); however, its pathogenesis and specific risk factors remain poorly understood.

Aim: To investigate low BMD and fragility fractures (FF) prevalence and determinants, and longitudinal BMD trend in a large population of adult TS patients attending a tertiary hospital with a structured transition program.

Methods: Cross-sectional and longitudinal analyses were conducted on 174 TS patients (median age: 37.5 yrs; range: 15.3-70.7 yrs) at the time of their most recent dual-energy X-ray absorptiometry (DXA). We evaluated anthropometrics, bone metabolism markers, karyotype, typical comorbidities, details about prior/current estrogen replacement treatment (ERT) and rhGH treatment (rhGHT). Metabolic bone disease (MBD) was defined as low BMD/osteoporosis (Z-score≤−2 if spontaneous menstruation/current ERT, T-score≤−2.5 if post-menopausal/stopped ERT), and/or FF occurrence.

Results: Most patients displayed 45,X0 karyotype and primary amenorrhea ($n=71$;41.0% and $n=136$;79.1%, respectively). ERT was started at a median age of 16.0 yrs (IQR: 14.0-18.0), lasting 19.0yrs (IQR: 12.0-26.0). rhGHT was administered in 119 patients (69.6%).

MBD was identified in 74 (42.5%) patients, 12 of them experiencing FF, and 10 currently receiving antifracturative treatment. Multiple regression analysis identified later age at spontaneous/induced menarche (OR = +1.19, $P=.042$), higher levels of bone alkaline phosphatase (BAP; OR = +1.07, $P=.013$) and larger aortic size index (OR = +4.44, $P=.034$) as independent predictors of MBD prevalence.

Clinical FF occurred mostly at vertebral and wrist sites, with an early onset (mean age 36.2 ± 15.5 yrs). Notably, five patients with normal BMD experienced FF; nonetheless, DXA diagnosis of low BMD/osteoporosis remained a reliable predictor of FF (OR = +7.2; $P=.004$). Multiple regression analysis showed that later age at menarche (OR = +1.37; $P=.071$) and nephropathy (OR = +8.28; $P=.021$) were independently associated with the presence of FF. Age, karyotype, rhGHT, prior/current ERT analysed as daily dose, type of estrogen, route of administration and duration, were not related to MBD or FF occurrence.

Linear mixed models ($n=147$) showed substantial overall stability of lumbar BMD over time (0.003 g/cm^2/y; $P=.002$). However, patients with primary amenorrhea and later age at menarche maintained lower values over time (−0.052 g/cm^2/y; $P=.001$, −0.008 g/cm^2/y; $P=.001$, respectively). Finally, a negative relationship was found between bone turnover markers and lumbar BMD trends (BAP: −0.002 g/cm^2/y; $P=.019$, cross-laps: −0.072 g/cm^2/y; $P=.002$). Karyotype, rhGHT and ERT showed no significant impact on lumbar BMD over time.

Conclusions: MBD in TS patient has a multifactorial pathogenesis. As modifiable factor, early ERT initiation is probably paramount to obtain and maintain adequate BMD for TS patients, and prevent the occurrence of FF. Continuous, lifelong monitoring of bone health is essential for all TS patients.

OC5.1 - ECE_2788 - Sex differences in clinical presentation, management and outcome in hospitalized patients with hyponatremia

Angelique Savelberg[1], Laura Potasso[2,3], Romy van der Groef[1,4], Sebastian Neggers[1], Mirjam Christ-Crain[2,3], Ewout Hoorn[5] and Julie Celine Refardt[1,2,3]

[1]Department of Internal Medicine, Division of Endocrinology, Erasmus Medical Center, University Medical Center Rotterdam, Rotterdam, The Netherlands; [2]Department of Endocrinology, Diabetology and Metabolism, University Hospital Basel, Basel, Switzerland; [3]Department of Clinical Research, University of Basel, Basel, Switzerland; [4]Erasmus Medical Center, Rotterdam, The Netherlands; [5]Division of Nephrology and Transplantation, Erasmus Medical Center, University Medical Center Rotterdam, Internal Medicine, Rotterdam, The Netherlands

Introduction: Hyponatremia is the most common electrolyte disorder in hospitalized patients. Observational studies show a higher prevalence of hyponatremia in hospitalized female patients, but other sex-related differences in hyponatremia among hospitalized patients remain largely unknown.

Aim: To explore the impact of sex on the clinical presentation, management and outcomes of hyponatremia in hospitalized patients.

Methods: Predefined secondary analysis of a large European multi-center trial that randomized hospitalized patients with hyponatremia (plasma sodium <130 mmol/L) to targeted correction or standard of care, aiming to evaluate the effects on mortality and rehospitalization. Sodium trajectories were modelled using multivariable linear mixed models adjusted for age, sex and etiology with patient-specific random effects. The effect of sex on mortality and rehospitalization was analyzed with a multivariate cox proportional hazard model adjusting for age, hyponatremia etiology, treatment received, baseline plasma sodium, and Charlson Comorbidity Index. The difference in the likelihood of receiving treatment was assessed using the chi-square test. Subgroup analyses were performed for both the standard of care group and the targeted therapy group.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Results: 2173 patients (52.2% female, median age 73 years, median baseline plasma sodium of 127 mmol/L) were analyzed. Female patients more frequently had diuretic-induced hyponatremia (RR 1.51, 95%CI 1.13-2.03), and less often hypervolemic hyponatremia (RR 0.77, 95%CI 0.63-0.93). Female patients more often reported symptoms at baseline (RR 1.10, 95% CI 1.06-1.13) and were more likely to receive treatment when randomized to the standard of care group (RR 1.16, 95%CI 1.06-1.27). Additionally, female patients had a slightly lower plasma sodium over the entire trajectory of hospitalization (−0.4 mmol/L, $P = .003$). Female sex was independently associated with a lower 30-day mortality (HR 0.59, 95%CI 0.43-0.81) and 30-day rehospitalization (HR 0.76, 95%CI 0.60-0.68) rate. These sex differences persisted when adjusting for hyponatremia etiology.

Conclusions: While having lower plasma sodium levels and more frequently reporting symptoms, hospitalized female patients with hyponatremia had a lower hazard for 30-day mortality and rehospitalization. This raises the question of whether sex-specific mechanisms underlie differences in hyponatremia symptomatology and outcomes.

Abstract citation ID: lvag096.102

OC5.2 - ECE_1983 - Diagnosing vasopressin deficiency using mannitol-stimulated copeptin

Sven Lustenberger[1], Friederike Riehle[1], Talitha Hildebrandt[1], Cemile Bathelt[1], Joseph Verbalis[2], Cihan Atila[1] and Mirjam Christ-Crain[3]

[1]Department of Endocrinology, Diabetology and Metabolism, University Hospital Basel, Basel, Switzerland; [2]Georgetown-Howard Universities Center for Clinical and Translational Science, Georgetown University, Washington, United States; [3]Basel, Switzerland

Background: The differential diagnosis between arginine vasopressin (AVP) deficiency (formerly known as central diabetes insipidus) and primary polydipsia remains challenging. To date, the method with the highest diagnostic accuracy is osmotically-stimulated copeptin—a surrogate marker of AVP—measured during hypertonic saline infusion. However, this method is often limited to experienced hospitals, requires close monitoring, and is contraindicated in some patients. An alternative simpler osmotic stimulation test would be highly desirable. Intravenous mannitol has been shown to increase plasma osmolality and stimulate AVP release. In this study, we investigated the effects of mannitol infusion on copeptin and its potential as a diagnostic tool in diagnosing AVP-deficiency.

Methods: In part 1 we conducted a randomized double-blind placebo-controlled cross-over trial to investigate the effect of mannitol infusion on copeptin in 22 healthy adults. Participants presented for two visits, each receiving either mannitol infusion (1 g/kg in 30 minutes, maximum 80 g) or placebo (normal saline) in random order. Serum copeptin was measured at baseline and at 30, 45, 60, 90, and 150 minutes. In part 2 we included 10 patients with AVP-deficiency and 10 patients with primary polydipsia. Participants presented for one visit, receiving open label mannitol infusion (1.5 g/kg in 30 minutes, maximum 120 g), and blood samples were taken at baseline, 30 and 90 minutes. The primary endpoint was copeptin levels after infusion of mannitol versus placebo (part 1) and in patients with AVP-deficiency versus patients with primary polydipsia (part 2).

Results: In healthy adults, median [IQR] baseline copeptin was 4.5 pmol/L [<2.7, 7.0] before mannitol infusion and 4.4 pmol/L [3.1, 6.7] before placebo infusion. Mannitol infusion was associated with a significant treatment effect, increasing copeptin at 30 minutes by +9.3 pmol/L compared to placebo (95% CI: +7.8, +10.8; $P < .001$).

In patients, baseline copeptin was <2.7 pmol/L [<2.7, <2.7] in primary polydipsia and <2.7 pmol/L [<2.7, <2.7] in AVP deficiency. After 30 minutes, the treatment effect on copeptin was +9.0 pmol/L in primary polydipsia (95% CI: +5.6, +12.3; $P < .001$) compared to AVP-deficiency. The best cutoff for differentiating AVP-deficiency from primary polydipsia was at 5.5 pmol/L with 100% sensitivity and 100% specificity.

Conclusions: Mannitol infusion represents a promising new approach for differentiating AVP deficiency from primary polydipsia. Its short test duration, straightforward dosing, minimal monitoring requirements and no relevant side effects make it accessible, cost-effective and safe, with the potential to become the new diagnostic standard of care.

Abstract citation ID: lvag096.103

OC5.3 - ECE_3463 - Foxl2 in establishing the gonadotrope lineage via a Fshb distal super-enhancer

Philippa Melamed[1], Tal Refael[1], Gil Golan[1], Daniella Darsa[1], Lilach Pnueli[1] and Karine Rizzoti[2]

[1]Haifa, Israel; [2]The Francis Crick Institute, London, United Kingdom

Follicle-stimulating hormone (FSH) levels are regulated by activin whose actions at the *Fshb* proximal promoter have been well-characterized. However, distal regulatory elements that confer its cell-specific expression and hormonal responsiveness are less clear. Analysis of scATAC-seq data revealed an extensive region in a gene-desert ~59-123 kb upstream of the mouse *Fshb* gene that contains several sites of gonadotrope-specific open chromatin, suggesting regulatory functions. The two most proximal sites (−59 kb and −67 kb) were seen in chromatin conformation capture (3C) to form distinct interactions with *Fshb* and *Kcna4*, located 230 kb upstream of *Fshb*. The region is transcribed abundantly into chromatin-associated lncRNAs which, like *Fshb* and *Kcna4*, are also upregulated by activin. Chromatin immunoprecipitation (ChIP) revealed that the −67 kb locus is bound by the lineage-specific transcription factor (TF), Foxl2, as well as chromatin architectural proteins, Brd4 and Med1, while Ctcf was enriched further upstream, at −123 kb; the binding of all increased following activin exposure. Brd4 and Med1 characterize “super-enhancers” and the expression of both *Fshb* and *Kcna4* was strongly inhibited by the BET inhibitor JQ-1, indicating super-enhancer regulation of both genes. Moreover, targeting CRISPR interference to each of the two more proximal peaks confirmed their differential effects on *Fshb* and *Kcna4* expression. Taken together with the 3C data, these results demonstrate that the −67 kb locus mediates basal and activin-stimulated *Fshb* expression, while the site at −59 kb contributes to activin-stimulation of both genes.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Single-cell multiomics revealed that the −67 kb locus is partially accessible in pituitary stem cells and throughout gonadotrope differentiation, preceding opening of the *Fshb* promoter, although it is closed in other differentiated cell types. Given that Foxl2 was found to bind this element, we hypothesized that this TF might keep the chromatin open at the locus. We thus characterized its protein interactome and investigated effects of its knockout (KO) in a gonadotrope cell line. The Foxl2 KO resulted in significantly elevated histone H3 levels across the −67 kb site, indicating more compact chromatin. Its protein interactors included Supt16h, a component of the FACT histone chaperone complex, which we show also binds this locus, and whose association was significantly reduced after Foxl2 deletion. Our findings have thus uncovered novel mechanisms governing gonadotrope differentiation and function, highlighting a distal "super-enhancer" in the regulation of *Fshb* expression, coordination with *Kcna4*, and a role for Foxl2 at this distal site during early establishment of the gonadotrope lineage.

Abstract citation ID: lvag096.104

OC5.4 - ECE_3532 - Constitutive active expression of ZFP36L1 in anterior pituitary SOX2+ stem cells results in pituitary hypoplasia and a failure of terminal differentiation via a non-cell autonomous mechanism

Olivia Sherwin[1,2], Saba Manshaei[3], Thea Willis[1], Hiba Hamdi[3], Yasmine Kemkem[1], Miriam Vazquez Segoviano[1], Bence Kover[1], James Kaufman-Cook[1], Shermin Mak[3], Dominic Withers[4], Jesus Gil[4], Juan Pedro Martínez-Barbera[3] and Cynthia Andoniadou[1]

[1]King's College London Guy's Campus, London, United Kingdom; [2]Technische Universität Dresden Medizinische Fakultät, Dresden, Germany; [3]London, United Kingdom; [4]Imperial College London, London, United Kingdom

SOX2+ pituitary stem cells (PSCs) are a critical source of signalling cues during pituitary development, yet the molecular orchestrators of this paracrine environment remain poorly defined. In this study, we identify ZFP36L1 as a key regulator of secreted factor expression within the PSC niche and demonstrate that its precise control is essential for terminal differentiation during pituitary organogenesis.

Using a *Sox2-CreERT2* model to induce constitutive active ZFP36L1 (ZFP36L1-CA) in PSCs from E12.5, we observed severe pituitary hypoplasia and a profound lack of terminal differentiation across POU1F1+ and NR5A1+ hormone-producing lineages by E18.5. To determine the nature of this developmental arrest, we performed mosaic lineage tracing via tamoxifen titration. Notably, wild-type cells neighbouring ZFP36L1-CA cells also failed to undergo hormone commitment, establishing a non-cell autonomous defect and suggesting a disruption of the extrinsic signalling environment.

This requirement for regulated ZFP36L1 expression was further validated using a *Hesx1-Cre* model, where early developmental ZFP36L1-CA expression resulted in dwarfism, perinatal lethality, and failure of POU1F1+ and NR5A1+ endocrine cell commitment. Crucially, this differentiation defect was rescued when *Hesx1-Cre* mutant pituitaries were co-cultured with normal PSCs, providing functional confirmation that the phenotype is driven by the loss of essential stem-cell-derived paracrine signals.

Mechanistic interrogation through scRNA-seq and mRNA *in situ* hybridisation identified secreted factors regulated by ZFP36L1 that co-localise with PSCs *in vivo*. ELISAs confirmed that these factors are actively secreted by PSCs and are significantly downregulated upon ZFP36L1-CA expression.

Collectively, these findings establish that ZFP36L1 regulation in PSCs is indispensable for pituitary organogenesis. These experiments identify specific paracrine mediators required for terminal differentiation in the anterior pituitary, offering new molecular targets for efficient regenerative approaches.

Background: Soluble alpha Klotho (sαKL) is an anti-aging protein with multiple functions in ion-regulation, antioxidative stress and energy metabolism. We previously demonstrated markedly elevated sαKL concentrations in active acromegaly (approximately 4-8x upper limit of normality), suggesting a role of growth hormone (GH)/insulin-like growth factor I (IGF-I) excess in its regulation. However, it appears that most patients with acquired adult-onset GH deficiency (AoGHD) exhibit sαKL concentrations within the lower reference interval for normal subjects. This indicates that factors other than GH/IGF-I signaling may be involved in the regulation of sαKL. This may be insulin, as in vitro studies have suggested that insulin stimulates sαKL secretion.

AoGHD and childhood onset GH deficiency (CoGHD) are distinct entities with differences in etiology, quality of life, insulin sensitivity, and possibly in longevity.

Objective: The purpose of this work was to assess sαKL concentrations in AoGHD (associated to insulin resistance) and CoGHD, by studying the Itabaianinha cohort, a congenital isolated GH deficiency (IGHD), due to the homozygous GHRH-R mutation (c.57 + 1G→A). These subjects exhibit severe short stature associated with low serum concentrations of IGF-I and IGFBP-3, increased secretion of glucagon-like peptide-1, favorable miRNA and stanniocalcin-PAPPA-system profiles, increased insulin sensitivity, and normal longevity.

Methods: We measured concentrations of sαKL, IGF-I and IGFBP-3 in 78 AoGHD, 23 IGHD subjects and 11 proven normal homozygous. All measurements were performed at the LMU University. The results are presented in median (interquartile range).

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Results: In comparison to normal homozygous, IGF-I (µg/L) and IGFBP-3 (µg/L) (158.5 (128.2-189.7), 3433 (2817-3622), respectively) were reduced in both AoGHD (IGF-I: 38.5 (29.2-51.7), IGFBP-3: 1814 (1275-2722)) and IGHD (IGF-I: 11.5 810-21.9), IGFBP-3: 596 (479-707), respectively), more markedly in IGHD ($P < .001$ for all). sαKL concentrations (pg/mL) were similar in IGHD and normal homozygous (1052 (782-1349) and 993 (921-1301), respectively, $P > .05$). In contrast, sαKL was significantly lower in AoGHD 617 (468-793) pg/mL compared to IGHD ($P < .001$).

Conclusions: Patients with AoGHD exhibit sαKL concentrations within the lower normal reference interval, confirming the influence of the GH/IGF-I axis on sαKL regulation. However, individuals with IGHD have normal concentrations of sαKL, probably contributing to their normal longevity. Thus, increased insulin sensitivity, a hallmark of IGHD, may contribute to the maintenance of sαKL concentrations in this specific cohort.

OC5.6 - ECE_2863 - Defining the YAP/TEAD–SOX2–NFI network underlying pituitary stem cell maintenance and differentiation

Miriam Vazquez Segoviano[1], Bence Kover[1], Emily Lodge[2], James Kaufman-Cook[1], Yasmine Kemkem[1], Olivia Sherwin[1], Marika Charalambous[1,3], Stuart Sealfon[4], Frederique Ruf-Zamojski[5] and Cynthia Andoniadou[1,6]
[1]King's College London Guy's Campus, London, Northern Ireland; [2]University College London, London, United Kingdom; [3]The Francis Crick Institute, London, Northern Ireland; [4]Icahn School of Medicine at Mount Sinai, New York, United States; [5]Cedars-Sinai Medical Center, Los Angeles, United States; [6]Technische Universität Dresden Medizinische Fakultät, Dresden, Germany

Resident stem cells in the anterior pituitary contribute to all hormone-secreting cell types throughout life and are essential for maintaining proper gland function. While pituitary stem cells (PSCs) are highly active during early postnatal stages, they become largely quiescent in adulthood, underscoring the requirement for tightly controlled transcriptional programs to balance stem cell maintenance and lineage commitment. Disruption of this balance can lead to pituitary dysfunction and disease; however, the molecular mechanisms governing pituitary stem cell fate decisions remain poorly understood.

The transcriptional co-activator YAP, acting through TEAD transcription factors (TFs), has been established as a central regulator of PSC fate, promoting SOX2$^+$ stem cell self-renewal and proliferation while repressing differentiation. Using an inducible YAP overexpression model combined with single-nuclei multiomic analyses, we have previously identified members of the Nuclear Factor I (NFI) family as candidate core regulators of PSC function. However, how NFIs influence PSC behaviour and how they integrate within the YAP/TEAD and SOX2 regulatory framework remains unclear.

Here, we generated doxycycline-inducible SOX2 and NFI overexpression cell lines, alone and in combination, in pituitary-derived GH3 and LβT2 cells. Integration of RNA-seq and ATAC-seq analyses, complemented by immunofluorescence, revealed transcriptional and chromatin accessibility changes associated with pituitary lineage commitment. We show that SOX2 overexpression alone is sufficient to repress lineage-associated transcription factor programs at the transcript, chromatin and protein levels, whereas NFIs exert both shared and lineage-specific regulatory effects. Moreover, our data support a model in which YAP acts upstream to induce SOX2 expression, while NFIs function downstream of SOX2 to fine-tune lineage commitment.

Together, these findings identify the YAP/TEAD–SOX2–NFI axis as a core regulatory network controlling the balance between PSC maintenance and differentiation. This axis provides a framework to better understand PSC regulation, with potential implications for regenerative and therapeutic strategies in the pituitary.

OC6.1 - ECE_1021 - FOS and JUN regulate oxidative stress and steroidogenesis in human aldosterone-producing adenomas

Jia Wei[1], Eleonora Duregon[2], Mauro Papotti[2], Thomas Knoesel[3], Martin Bidlingmaier[1], Silviu Sbiera[4], Martin Reincke[1] and Tracy Williams[1]
[1]Medizinische Klinik und Poliklinik IV, Ludwig-Maximilians-Universität (LMU) München, Klinikum der Universität München, Munich, Germany; [2]Division of Pathology, Department of Oncology, University of Turin, Turin, Italy; [3]Institute of Pathology, Ludwig-Maximilians-Universität (LMU) München, Munich, Germany; [4]Department of Internal Medicine I, Division of Endocrinology and Diabetes, University Würzburg, University Hospital, Würzburg, Germany

Aldosterone-producing adenomas (APAs) are a major cause of primary aldosteronism (PA). While oxidative stress and steroidogenesis are intricately linked in adrenal disorders, their interplay and mechanistic basis in APA pathogenesis remain to be fully elucidated. Here, by integrating RNA sequencing of oxidative stress-exposed human adrenocortical cells with spatially-resolved transcriptomic profiling of human adrenal sections, we uncover a previously unrecognized role for the activator protein-1 (AP-1) transcription factors FOS and JUN as key mediators linking oxidative stress to steroidogenesis in PA. Their expression and activation are spatially restricted, coinciding with regions of elevated oxidative stress. Phosphorylated FOS and JUN were exclusively detected in the adrenal cortex adjacent to functional adenomas (APAs and cortisol-producing adenomas), with negligible levels in cortex adjacent to non-functional adenomas and in normal adrenal cortex. In vitro, oxidative stress induced the upregulation and activation of FOS and JUN. Conversely, co-overexpression of FOS and JUN suppressed key steroidogenic genes (*StAR*, *CYP11B1*, *CYP11B2*), reduced aldosterone and cortisol secretion, and increased reactive oxygen species accumulation. Together, this work demonstrates that FOS and JUN are central to coordinating the redox-steroidogenesis axis, linking molecular changes in the peritumoral cortex to tumor function and microenvironmental remodeling.

Background: Primary aldosteronism (PA) is a major cause of secondary arterial hypertension, characterized by autonomous aldosterone production. The mineralocorticoid receptor (MR) binds aldosterone and is expressed in the adrenal cortex specifically in the zona glomerulosa (ZG) and in aldosterone-producing adenomas. Given the role of MR in tissue remodeling and its expression in aldosterone-producing cells, we hypothesized that MR could be involved in the pathophysiology of PA through autocrine-paracrine mechanisms.

Objectives: To define the cell-autonomous roles of MR in aldosterone-producing cells using ZG-specific MR knockout mice combined with single-nucleus transcriptomics.

Methods: We generated Cyp11b2-Cre-driven MR knockout (MRKOAd) mice and performed morphological, hormonal and molecular phenotyping under standard and low-salt diets. Single-nucleus RNA sequencing (snRNAseq) across four conditions was analyzed to define population-specific MR functions and plasticity mechanisms.

Results: MR deletion reduced Cyp11b2 and aldosterone synthase (AS) expression in the adrenal cortex, with sex-specific effects on ZG architecture, but no change in basal aldosterone levels. This was associated with reduced proliferation and PKA activation, without modification of Wnt/β-catenin signaling. Under low salt diet, increased aldosterone production was accompanied by ZG expansion and increased AS expression in wild type mice, which was abolished in MRKOAd mice of both sexes. snRNAseq analysis revealed three mechanistically distinct plasticity programs following LSD: (1) ZG maintained identity through MR-dependent proliferation; (2) ZG_ZF transition zone showed robust plasticity driven by environmental signals (10% MR-dependent); and (3) zona fasciculata resolved into two subpopulations - ZF1 underwent authentic MR-dependent ZG transdifferentiation supported by constitutive metabolic priming, while ZF2 showed Cyp11b2 induction without acquiring ZG identity. MR-dependent genes, representing 28% of plasticity genes, accounted for 69% of functional ZG signature changes and converged on metabolic pathways (oxidative phosphorylation, ATP synthesis, steroid biosynthesis), establishing MR as an orchestrator of metabolic reprogramming.

Conclusions: MR plays distinct, cell-population-specific roles across the adrenal cortex. MR maintains ZG function in an autocrine-paracrine loop under basal conditions and regulates proliferative capacity, ZG architecture sex-specifically, and orchestrates metabolic transformation required for adrenal cortex plasticity following a salt challenge.

Introduction: Primary aldosteronism (PA) is a common cause of secondary hypertension. Adrenal vein sampling (AVS) remains the reference method for PA subtyping, but it is invasive and technically challenging, limiting patients access to curable adrenalectomy. We evaluated the accuracy of non-invasive ^{11}C-Metomidate (MTO) PET/CT compared with AVS for guiding treatment.

Methods: We conducted a prospective, within-patient, multicentre trial enrolling patients with confirmed PA. All participants underwent both AVS and MTO PET/CT. Subtyping results were reviewed in a multidisciplinary meeting to recommend medical or surgery therapy. Unilateral adrenalectomy was offered when lateralization was demonstrated by AVS (lateralization index ≥4 times using aldosterone-to-cortisol ratios of the dominant to non-dominant adrenal veins) and/or MTO PET/CT (SUVmax in adrenal adenoma >1.25 times of the SUVmax of contralateral adrenal). The primary endpoint was complete biochemical success more than six months post-surgery, assessed by PA surgical outcome (PASO) criteria. The study was powered to test for non-inferiority of MTO PET/CT versus AVS (margin

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

−17%; 90% power; α = .01). Secondary endpoints included prediction of classical unilateral PA using HISTALDO criteria with CYP11B2-immunohistochemistry staining, characterization of somatic driver mutations (Sanger and whole-exome sequencing), and evaluation of hybrid hormones (18-oxocortisol and 18-hydroxycortisol) as markers of *KCNJ5*-mutant unilateral PA. (ClinicalTrials.gov: NCT06100367)

Results: A total of 106 patients completed both subtyping tests (mean age 48.4 ± 10.1 years; 71% male), and 101 had at least 6 months post-treatment follow-up. Unilateral PA was identified by both tests in 30 patients, by PET/CT only in 17, and by AVS only in 18. Five patients with bilateral PA opted for surgery, and 1 with unilateral PA was lost to follow-up. Surgery was performed in 69 patients; 64 (92.8%) achieved complete biochemical success, 4 (5.8%) had absent biochemical success, and 1 pending final evaluation. CYP11B2-immunohistochemistry was available in 52 surgical specimens and showed classical unilateral PA in 46 (88.5%). MTO PET/CT and AVS correctly identified classical unilateral PA in 32 (69.6%) and 31 (67.4%) cases, respectively. Somatic mutation analysis ($n = 34$) detected PA driver mutations in 33 (97.1%): *KCNJ5* (52.9%), *CACNA1D* (14.3%), *ATP1A1* (6.1%), *ATP2B2* (2.0%) and *CTNNB1* (2.0%). Hybrid hormones levels were significantly higher in patients with *KCNJ5*-mutant versus patients with non-*KCNJ5*-mutant tumours and offers an opportunity to identify unilateral *KCNJ5*-mutant PA.

Conclusions: Subtyping using MTO PET/CT is non-inferior to AVS and identifies patients with surgically curable unilateral PA not identified with AVS. Molecular imaging with MTO PET/CT offers an alternative first-line subtyping approach when available.

Background: Distinguishing unilateral primary aldosteronism (UPA/APA) from bilateral adrenal hyperplasia (BAH) is essential for treatment selection, yet the gold standard, adrenal venous sampling (AVS) is invasive, technically demanding and its availability remains limited. We previously identified a 6-miRNA combination (miR-146a-5p, miR-24-3p, miR-130b-3p, miR-99b-5p, miR-151a-3p, miR-199a-3p) capable of distinguishing APA from BAH using a neural network and deep learning approach. External validation remains the critical bottleneck for clinical translation of such biomarker panels.

Aim: To validate our previous 6-miRNA combination on a larger, independent multi-center dataset.

Methods: Peripheral plasma samples from 205 patients with AVS-confirmed PA were collected from nine centers and combined with our original discovery cohort ($n = 108$), yielding a total of 313 samples. MiRNA expression was quantified utilizing RT-qPCR with cel-miR-39 as spike-in and let-7d-5p as endogenous controls. Initial cross-center analysis revealed significant batch effects possibly attributable to inter-plate, inter-time and/or inter-center variability. To address this, we implemented plate-wise Z-score normalization, calculating miRNA-specific Z-scores within each plate to harmonize measurements. We expanded our analytical framework to six machine learning algorithms: KERAS deep neural network, Random Forest, XGBoost, Support Vector Machine, Logistic Regression, and Naive Bayes. Core clinical parameters (age, sex, plasma aldosterone, renin, imaging findings) were integrated as additional features. Ensemble predictions were generated via soft and hard voting. Model performance was assessed using 5-fold cross-validation.

Results: Using models trained on the original ($n = 108$) dataset, the validation performance matched training performance, confirming generalizability. On the harmonized 313-sample dataset, Random Forest achieved the highest individual performance (AUC 0.828), with XGBoost (0.809) and Keras (0.805) performing comparably. Soft voting ensemble yielded an AUC 0.815, a balanced accuracy of 72.9%, and an overall F1-score of 0.725. For BAH identification, the positive predictive value reached 80.0% and specificity was 84.3%.

Conclusions: This multi-center study validates circulating miRNAs for non-invasive PA lateralization and establishes a harmonization framework enabling cross-population application. The 80% positive predictive value for BAH suggests clinical utility in identifying patients whose pharmacological treatment could begin much sooner, leaving further lateralization procedures for only UPA cases. Additional cohort expansion and prospective validation are warranted to confirm the clinical utility of the approach.

Background: Adrenocortical carcinoma (ACC) is a rare aggressive malignancy with a poor prognosis. Standard treatments, including mitotane, platinum-based chemotherapy, and immune checkpoint inhibitors (ICI), show limited efficacy, with response rates below 25%, although exceptional and durable responses are occasionally observed. This study aimed to identify transcriptomic signatures associated with treatment response in advanced ACC.

Methods: A total of 133 patients with metastatic ACC treated with mitotane monotherapy, platinum-based chemotherapy, or ICI were recruited from eight European centers. The primary endpoint was the best objective response according to RECIST radiological criteria. The cohort was intentionally enriched for complete or prolonged responses lasting more than 12 months.

Transcriptomes were generated from tumor RNA extracted from frozen or paraffin samples, using 3' RNA-sequencing (QuantSeq, Lexogen). Transcriptomic analyses included unsupervised clustering, differential gene expression analyses (DESeq2 and GSEA) comparing responders and non-responders, and estimation of immune and stromal cell populations (MCP-counter).

Results: Among the 84 patients with available clinical data (69% female, median age 49 y), mitotane was administered to 60 patients, with 11 responses (18%; 7 partial responses [PR] and 4 complete responses [CR]), 11 stable disease (SD, 18%) and 38 progressive disease (PD, 63%). Platinum-based chemotherapy was administered to 62 patients, with 20 responses (32%, 14 PR and 6 CR), 14 SD (23%) and 28 PD (45%). ICI were administered to 13 patients, with 4 responses (30%, all PR), 1 SD (8%) and 8 PD (62%).

Unsupervised clustering identified 4 main transcriptomic clusters. One cluster was enriched in ICI responders (3/4, 75% vs 1/9, 11% in other clusters; $P = .05$) and was characterized by enrichment in immune-related pathways (lymphocyte mediated immunity, immune response regulation, adaptative immune response) and by a higher proportion of T cells ($P = .0006$), and myeloid cells ($P < 10^{-5}$, $<10^{-6}$ and 0.0003 for monocytes/macrophages, dendritic cells and neutrophils respectively).

Differential expression analyses identified 104, 17, and 192 genes associated with response to mitotane, platinum-based chemotherapy, and ICI, respectively. Mitotane response was associated with higher expression of *PON3*, encoding a paraoxonase involved in redox signaling. Platinum response was associated with higher expression of *ACSM2A* and *ACSM2B*, encoding acyl-coA synthetase. In addition to immune pathway activation, response to ICI was associated with downregulation of Wnt signaling.

Conclusions: Transcriptomic profiling reveals distinct molecular signatures associated with treatment response in advanced ACC. These findings warrant validation in independent cohorts and may contribute to improved patient stratification in the future.

Background: Adrenocortical carcinoma (ACC) is a rare and aggressive malignancy with high rates of post-operative recurrence. Current surveillance relies on frequent imaging, which is costly, exposes patients to cumulative radiation, and may miss early relapse. Liquid biopsy approaches offer a non-invasive alternative, but their comparative and combined utility in ACC remains unclear.

Methods: In this prospective pilot study, we evaluated three liquid biopsy modalities for ACC monitoring: 1. circulating cell-free DNA (ccfDNA) targeted next-generation sequencing (NGS) for

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

somatic mutations in ACC-specific genes, 2. low-pass whole-genome sequencing (lpWGS) for copy number calling and circulating tumour DNA detection, and 3. urinary steroid metabolomics (USM) by gas chromatography/mass spectrometry (32 adrenocortical steroid metabolites). USM profiles were assessed by three clinicians and three mass-spectrometry experts. Ten patients with histologically confirmed ACC (9F/1M, median age 37.5 yrs, one atypical case) were followed longitudinally from diagnosis through post-operative surveillance, ie, 6-8 weeks (early post-OP), 3 and 6 months. Tumour tissue, baseline and serial plasma and 24-hour urine samples were analysed and compared with standard radiological assessments. The diagnostic performance of individual and integrated liquid biopsy approaches was assessed.

Results: Somatic single-nucleotide variants (SNVs) were identified in 70% of primary tumours and detected in baseline ccfDNA in 50% of patients, while lpWGS identified CNVs in 100% of tumour samples and a non-zero tumour fraction in 60% of baseline ccfDNA samples. During follow-up, four patients developed disease recurrence at standard imaging. ccfDNA sequencing detected recurrence in 2/4 patients, including one case identified exclusively by lpWGS. Post-operative USM profiles were available for 7 patients (urine samples being not available for the other 3 cases) and identified recurrence in both cases with radiology relapse – but with variable sensitivity depending on expert consensus criteria. An integrated approach combining ccfDNA targeted NGS, lpWGS, and USM achieved the highest diagnostic performance, with a sensitivity of 75% and specificity of 80% for recurrence detection.

Conclusions: Each liquid biopsy modality captures complementary biological features of ACC and presents specific strengths or weaknesses. An integrated, multimodal liquid biopsy strategy improves detection of disease recurrence compared with any single approach and represents a promising non-invasive adjunct to imaging for ACC surveillance. Larger prospective studies are warranted to validate these findings and refine clinical implementation.

OC7.1 - ECE_2484 - Pancreatic neuroendocrine neoplasms share germline DNA repair gene predisposition with breast, ovarian and colorectal cancer syndromes (BRCA2, CHEK2 and MMR)

Beata Jurecka-Lubieniecka[1], Malgorzata Ros-Mazurczyk[1], Aleksandra Sygula[1], Alexander Cortez[1], Marcela Krzempek[1], Anna Barbara Tuleja[2], Agnieszka Kotecka-Blicharz[1], Malgorzata Oczko-Wojciechowska[1] and Daria Handkiewicz-Junak[1]

Mutations in DNA repair genes are major drivers of both hereditary and sporadic malignancies, including breast, ovarian, prostate, colorectal adenocarcinoma, and pancreatic cancer. Familial tumors are typically associated with earlier onset and a more aggressive clinical phenotype. Advances in diagnostics and therapies targeting defective DNA repair pathways provide opportunities to improve outcomes and quality of life. Current recommendations from the National Comprehensive Cancer Network (NCCN) and the European Society for Medical Oncology (ESMO) support germline genetic testing patients with these malignancies.

In pancreatic neuroendocrine neoplasms (pNENs), germline alterations in DNA repair genes have recently emerged as significant contributors to tumorigenesis. Large-scale genomic studies conducted by the International Cancer Genome Consortium (ICGC) identified pathogenic germline variants in approximately 11% of 102 patients with pNENs, including alterations in BRCA1/2 and CHEK2—well-established predisposition genes for breast and ovarian cancers—as well as MUTYH, which is associated with colorectal cancer susceptibility. Comparable results have been reported in US cohorts, in which pathogenic germline variants were detected in 14% of pNEN cases. Notably, these variants were frequently identified in patients with apparently sporadic disease and without a family history suggestive of hereditary cancer syndromes.

In the present study, germline DNA from 57 Polish patients diagnosed with pNENs was analyzed using targeted next-generation sequencing of a panel of DNA repair genes. Germline variants were identified in 14 patients (24.6%), including individuals both with and without a positive family history of malignancy. Pathogenic variants in BRCA2 and CHEK2 were detected in two cases. In addition, variants of uncertain significance (VUS) were identified in mismatch repair (MMR) genes in seven patients, raising concern for a potential predisposition to colorectal cancer syndromes, similar to that observed in association with MUTYH alterations.

Our findings are consistent with previous genomic studies and indicate that the germline landscape of pNENs includes clinically meaningful alterations in DNA repair pathways, similar to those observed in other solid tumors. These results support routine germline testing in patients with clinically sporadic pNENs, along with testing of relatives when pathogenic variants are confirmed, as already reflected in NCCN recommendations for patients with pNENs. Such variants may serve as biomarkers with potential therapeutic implications, and affected patients require appropriate oncologic surveillance focused on hereditary cancer risks.

Integrating germline diagnostics with genetically informed therapies may represent an important step toward precision medicine in pNENs. However, larger multicenter studies are needed to validate these observations and optimize clinical implementation.

Background: Biopsy of phaeochromocytomas and paragangliomas (PPGLs) is discouraged due to the perceived risk of catecholamine-related complications. However, a recent systematic review showed that this recommendation is primarily supported by case reports.

Methods: This multicentre retrospective cohort study included patients with PPGLs who underwent percutaneous biopsy. The predefined primary outcome was biopsy-related mortality rate (95% confidence interval [CI]) for biopsies performed at participating centres, since fatal cases elsewhere would be unlikely to be referred. Secondary outcomes included the incidence (95% CI) of serious catecholamine-related and non-catecholamine-related complications among all included patients.

Findings: Across 19 centres, 222 patients underwent 234 biopsies. Among these, 67% (136/203) had elevated epinephrine/norepinephrine (or metabolites) and 12·7% (29/229) received alpha-adrenoceptor blockade before biopsy. One death, due to biopsy-related infection, was reported. The mortality rate was 0·9% (1/106, 0·02-5·1%) among patients whose biopsies were performed at participating centres. Serious catecholamine-related complications occurred after four biopsies (1·7% [4/233, 0·5-4·3%]) and included tachyarrhythmia, hypertensive crisis, and/or cardiogenic shock. No serious catecholamine-related complications occurred in patients without catecholamine excess ($n = 67$) or following biopsy of metastatic lesions ($n = 120$). Serious non-catecholamine-related complications occurred after ten biopsies (4·3% [10/233, 2·1-7·8%]), mainly bleeding and infection.

Interpretation: Percutaneous biopsy of PPGLs was associated with a 0·9% mortality-rate. Serious complications occurred in 6·0%, of which most were not catecholamine-related. These findings challenge current recommendations that biopsy should be avoided in suspected or confirmed PPGL, and support a personalised, risk-benefit-based approach to the procedure.

OC7.3 - ECE_1415 - Glucocorticoid inhibition enables mono- and bispecific CAR-T cells to overcome immunotherapeutic resistance in adrenocortical carcinoma

Marc Philipp Schauer[1,2], Weber Justus[2], Laura Sophie Landwehr[1], Andrea Stabile[2], Peter Spieler[2], Barbara Altieri[1], Silviu Sbiera[1], Hermann Einsele[2], Martin Fassnacht[1] and Hudecek Michael[2,3]

[1]Würzburg, Germany; [2]Department of Internal Medicine II, Chair for Cellular Immunotherapy, University Hospital Würzburg, Würzburg, Germany; [3]Branch Site Cellular Immunotherapy, Fraunhofer Institute for Cell Therapy and Immunology (IZI), Würzburg, Germany

Glucocorticoids (GC) are secreted by ~60% of adrenocortical carcinoma (ACC) lesions and negatively affect immune-recognition and -therapy. Despite our previous observation that ROR1 expression is tightly linked to and triggered by GC secretion in ACC, GC inhibition induced a significant reduction of ROR1 making combinatorial CAR-T cell therapies with clinically relevant GC inhibitors obsolete.

Hence in this study, we applied transcriptomic and proteomic target screens to identify new potential CAR targets to overcome this ACC-intrinsic antigen-modulating resistance mechanism. In our screens, we identified B7-H3 - an immunomodulatory CAR

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

target - to be significantly upregulated in a large ACC patient cohort ($n = 135$) while being strongly associated with worse clinical outcome and poor overall survival. We observed B7-H3 to be inversely regulated to ROR1. Molecular analyses revealed a strong increase of B7-H3 upon GC inhibition driven by improved intratumoral STING pathway signaling that is usually abrogated upon glucocorticoid receptor (GR) signaling and ROR1 upregulation. We show that GCs induce ROR1 driven cancer proliferation, while GC inhibition upregulates B7-H3 by disrupting GR/NF-κB complex tethering enabling nuclear translocation of Stat3 and NF-κB. Phosphoproteomic analyses confirmed a direct link to B7-H3 induction and target modulation through pStat3 and pNF-κB. To further utilize this GC-related antigen interplay and to overcome antigen-mediated resistance, we developed different mono- and dual targeting CAR-T cells that showed potent antitumor efficacy alone and in combination with GC inhibitors. However, single transcriptomic data indicated B7-H3 expression in some healthy tissues increasing the risk of on-target off-tumor toxicity. Hence, we exploited the role of co-opted intracellular proximal T cell signaling molecules that can be repurposed into T cell surface receptors to engineer a synthetic logic gate CAR-T cell platform. By switching target binding domains, we were able to generate an asymmetric Functionally Layered and Unequal eXpression (FLUX)-CAR system which enables gradient-level AND-gating through spatially defined adaptor placement. When testing FLUX-CAR-T cells alone and together with GC inhibitors, we could selectively eliminate high antigen expressing ACC while obviating CAR-T cell killing in low single antigen positive tissues and inducing complete and persistent ACC tumor eradication in preclinical models.

Taken together this study provides a new ACC-specific GC-related therapy resistance mechanism as well as a safe and broadly applicable new CAR-T cell platform to overcome antigen-dependent therapeutic failure in GC secreting ACC.

Background: Sex- and gender-based medicine is gaining relevance in oncology, highlighting how biological sex and gender-related factors may influence cancer outcomes. However, data on sex-related differences in prognosis, treatment efficacy, and tolerability in neuroendocrine tumours(NETs) remain limited.

Aim: To evaluate the impact of sex on clinical characteristics, treatment patterns, efficacy, and tolerability of somatostatin analogues (SSAs) and peptide-receptor-radionuclide-therapy (PRRT) in patients with gastroenteropancreatic neuroendocrine tumours (GEP-NETs).

Materials & Methods: This was a retrospective multicentre study including patients with GEP-NETs from 16 Italian centres participating in the NIKE project. Demographic data, disease characteristics, comorbidities, lifestyle factors, and treatment-related efficacy and safety outcomes for SSAs and PRRT were collected and analysed.

Results: A total of 500 patients were included (267 men, 233 women), with a median follow-up of 69 months. Mean age at diagnosis was significantly higher in men than in women (59.09 $\pm$ 13.8 vs 56.06 $\pm$ 14.4 years, $P = .018$). Men more frequently presented with advanced-stage disease ($P < .05$) and metastatic disease at diagnosis (67.4% vs 53.0%, $P < .001$).

Men also showed a higher prevalence of comorbidities (diabetes: 33.1% vs 19.0%, $P < .001$; hypertension: 49.6% vs 39.7%, $P = .026$) and unhealthy lifestyle factors, including alcohol consumption and smoking ($P < .001$).

PRRT was more frequently administered in men than in women (40.8% vs 28.9%, $P < .001$).

Although no sex differences were observed in the proportion of patients treated with SSAs, women showed a significantly longer duration of response to SSAs compared with men ($P = .003$). Progression-free survival (PFS) was longer in women treated with SSAs (median 108 vs 84 months in men) and with PRRT (60 vs 48 months), although the latter difference did not reach statistical significance ($P = .333$).

Regarding tolerability, no significant sex differences were observed in overall adverse events related to SSAs or PRRT. However, when stratifying patients by median year of diagnosis, women developed SSA-related adverse events earlier than men (mean time: 6.00 $\pm$ 7.21 vs 16.82 $\pm$ 25.49 months, $P = .030$), whereas men experienced a higher incidence of PRRT-related nephrotoxicity ($P = .034$).

Multivariable Cox regression analysis for PFS in SSA-treated patients showed that alcohol consumption was the only independent predictor of disease progression in the overall cohort ($P = .005$), regardless of sex. Sex-stratified analyses revealed distinct risk profiles: in women, advanced stage at diagnosis was the only significant predictor of progression (HR = 6.2, $P = .034$), while in men alcohol consumption was significantly associated with progression (HR = 2.09, $P = .01$), with metastatic disease at diagnosis showing a borderline association ($P = .051$).

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Conclusions: Sex influences the natural history of NETs, treatment allocation, and response to SSAs and PRRT. Although not an independent predictor of progression, sex modulates the effect of key prognostic factors, including alcohol consumption and disease stage. A gender-informed approach may support more personalised management of NET patients.

OC7.5 - ECE_3450 - Intraoperative hypotension versus hypertension in patients with pheochromocytoma and paraganglioma: a multicenter Chinese study of 998 cases

Minghao Li[1], Ndikuriyo Herve Pasteur[1], Junjie Chen[1], Yong Wang[2], Danlei Chen[3], Jingjing Jiang[4] and Longfei Liu[1]
[1]*Xiangya Hospital, Central South University, Changsha, China;* [2]*The Fifth Affiliated Hospital of Sun Yat-sen University, Zhuhai, Guangdong, China;* [3]*The First People's Hospital of Yunnan Province, Kunming, Yunnan, China;* [4]*Zhongshan Hospital, Fudan University, Shanghai, China*

Background: Pheochromocytomas and paragangliomas (PPGLs) are neuroendocrine tumors characterized by excessive catecholamine production, which predisposes patients to intraoperative hypertensive crises (IHC) and/or hypotension (IOH). This study aims to investigate the perioperative characteristics and identify risk factors associated with different hemodynamic profiles during PPGL surgery.

Methods: We conducted a retrospective analysis of patients with pathologically confirmed PPGL who underwent surgical resection between January 2010 and December 2024 across four tertiary medical centers in China. Data collected included demographic, clinical, tumor-related, genetic, and perioperative variables. IOH was defined as mean arterial pressure (MAP) <65 mmHg, and IHC as systolic blood pressure ≥180 mmHg. Patients were stratified into four hemodynamic groups: no IOH/IHC, IHC only, IOH only, and both IOH/IHC. Multivariable logistic regression was employed to identify independent predictors for each hemodynamic category.

Results: Among the 998 patients analyzed, 324 had no IOH/IHC, 306 had IHC only, 181 had IOH only, and 187 experienced both IOH and IHC. Postoperative intensive care unit (ICU) admission was highest in the combined IOH/IHC group (56.5%, 105/186), compared to the IOH-only (38.7%, 70/181), IHC-only (24.3%, 74/305), and no-instability groups (17.6%, 57/324). In multivariable analysis, older age (OR 4.931, 95% CI 1.523-15.965), presence of pre-surgical hypertension (OR 0.554, 95% CI 0.366-0.839), and preoperative α-blocker use (OR 2.006, 95% CI 1.225-3.487) were independent predictors of IOH only. Laparoscopic surgery (OR 1.483, 95% CI 1.001-2.197) and kinase-signaling pathway gene variants (OR 2.561, 95% CI 1.749-3.751) were predictors of IHC only. For combined IOH/IHC, independent predictors included older age (OR 5.319, 95% CI 2.077-13.623), tumor diameter ≤4.05 cm (OR 0.513, 95% CI 0.339-0.777), and kinase-signaling gene variants (OR 2.681, 95% CI 1.701-4.224).

Conclusions: Patients with PPGL exhibit distinct hemodynamic profiles during surgery, each associated with specific risk factors. Perioperative strategies—including surgical approach selection and α-blocker administration—should be tailored based on age, tumor size, pre-surgical hypertension, and genetic background to optimize intraoperative hemodynamic stability.

OC7.6 - ECE_2870 - SOX2-positive cells in pheochromocytoma and paraganglioma: implications for tumour initiation and maintenance

Yasmine Kemkem[1], Mark Quinn[2], Bence Kover[1], Alice Santambrogio[1,3], James Kaufman-Cook[1], Olivia Sherwin[1,3], Dimitria Brempou[2], Miriam Vazquez Segoviano[1], Paul Carroll[4], Louise Izatt[5], Paul Chapple[6], Stefan Bornstein[1,3], Nicole Bechmann[3], Charlotte Steenblock[3], Rebecca Oakey[2] and Cynthia Andoniadou[1,3]
[1]*Centre for Craniofacial and Regenerative Biology, King's College London, London, United Kingdom;* [2]*Department of Medical and Molecular Genetics, King's College London, London, United Kingdom;* [3]*Department of Internal Medicine III, University Hospital Carl Gustav Carus, Technische Universität, Dresden, Germany;* [4]*Guy's & St. Thomas' NHS Foundation Trust, London, United Kingdom;* [5]*Department of Clinical Genetics, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom;* [6]*Faculty of Medicine and Dentistry, William Harvey Research Institute, Queen Mary University of London, London, United Kingdom*

Pheochromocytomas (PCCs) and paragangliomas (PGLs) are rare neuroendocrine tumours which arise from neural crest–derived chromaffin cells of the adrenal medulla and extra-adrenal paraganglia, respectively. Metastatic disease occurs in up to 40% of PPGLs and is associated with a median overall survival of seven years. Despite advances in the molecular characterisation of PPGLs, progress in prognostic stratification and the development of targeted therapies remains limited, reflecting an incomplete understanding of the cellular mechanisms underlying tumour initiation and progression. In several malignancies, tumour growth and dissemination are sustained by cells with stem-like properties, due to their ability to self-renew and give rise to differentiated cells. We have recently shown that, in the human adrenal, a subset of sustentacular cells are postnatal adrenomedullary stem cells expressing the stem cell transcription factor SOX2, specified along the neural crest migratory trajectory. In this study, we investigated whether SOX2-positive cells in PCCs and PGLs display features consistent with a tumour-initiating cell population.

Using transcriptomic profiling of 10 published and 3 new tumour datasets and expression analyses of an additional cohort of 19 tumours, we demonstrate the presence of SOX2-expressing cells across a broad range of PPGLs independent of tumour location, aggressiveness, or underlying genetic mutation. Transcriptomic analyses reveal a highly proliferative cell population co-expressing SOX2 and chromaffin cell markers. To determine whether expression of SOX2 is sufficient to promote proliferation, we overexpressed *Sox2* in PC12 cells, a well-characterised rat pheochromocytoma cell line. Cell cycle analysis showed that *Sox2* expression does not confer a proliferative advantage, supporting its role in PPGL as a stem cell hallmark. However, PPGLs enriched in SOX2+ cells showed differential expression of several genes encoding pro-tumourigenic paracrine

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

factors. Ligand-receptor analysis further confirmed signalling from tumour chromaffin cells to other cell populations. In summary, *in silico* analyses support that tumours enriched in proliferative SOX2+ chromaffin tumour cells have distinct oncogenic gene expression and a secretory signature consistent with cancer promotion. This suggests both a direct contribution and an indirect paracrine role of SOX2+ tumour chromaffin cells in PPGL tumour maintenance.

Isolation of SOX2-positive PPGL cells under stem cell–promoting conditions, followed by xenotransplantation onto the chicken chorioallantoic membrane, demonstrated their capacity for expansion and metastatic behaviour *in ovo*, confirming their tumour-initiating potential.

This study redefines the cellular origins of PPGLs by identifying SOX2-positive tumour cells with tumour-initiating potential. These findings may inform improved PPGL tumour stratification and offer new avenues for therapy.

Abstract citation ID: lvag096.119

OC8.1 - ECE_3665 - CheckED—EU Real-World endocrine-disrupting chemicals (EDCs) profiling enables exposure-informed prevention counselling and tracks reductions in exposure proxy indices across everyday settings.

Aleksandra Rutkowska[1,2], Szymon Graczyk[1], Aleksandra Olsson[1] and Heidrun Fammler[3]
[1]*DetoxED LTC, Gdańsk, Poland;* [2]*Division of Community Nursing & Health Promotion, Medical University of Gdansk, Gdańsk, Poland;* [3]*Baltic Environmental Forum Germany, Hamburg, Germany*

Endocrine-disrupting chemicals (EDCs) are ubiquitous environmental exposures and preventable upstream drivers of endocrine and metabolic disorders, including obesity, insulin resistance, thyroid dysfunction and reproductive disease. Yet European endocrinology lacks scalable real-world systems to quantify EDC multi-class exposure burden, identify modifiable sources, and demonstrate achievable exposure reduction supporting prevention and clinical counselling. This gap is critical for women of reproductive age, as pregnancy is a sensitive window shaping maternal metabolic adaptation, placental signalling and foetal endocrine development (DOHaD).

To quantify EU-wide EDC multi-class exposure burden in real-world settings, and determine whether feasible micro-habit changes can measurably reduce exposure burden relevant to endocrine prevention.

Data were collected using the CheckED mobile application developed within LIFE ChemBee and Interreg NonHazCity 3. The app prospectively captured anonymised, free-of-charge structured data on demographics, anthropometry, housing indicators, plastic/food-contact behaviours, and exposure-relevant routines across 15 EU countries. Exposure to bisphenols, phthalates, alkylphenols and brominated flame retardants (BFRs) was estimated using algorithm-derived class-specific composite exposure proxy indices (continuous scores) based on exposure-source databases implemented in the application. The study included 7061 women (260 pregnant) and 2102 men; 9988 participants completed one assessment and 1370 repeated assessments enabling within-person longitudinal comparisons.

Over 99% of participants had non-zero exposure proxy indices for at least one EDC class. Men showed higher bisphenol, phthalate and alkylphenol proxy indices than women (all $P \leq .00001$). Pregnancy was not associated with lower exposure proxy indices compared with non-pregnant women ($P = .38$). Higher BMI showed small but consistent correlations with exposure proxy indices across classes (Spearman $\rho \approx 0.14$-0.17). Among repeated users, bisphenol proxy scores decreased following micro-habit changes in lifestyle ($P = .006$) and the home environment ($P = .001$). Phthalates and alkylphenols did not change significantly in lifestyle ($P = .11$; $P = .15$), but decreased significantly in the home environment ($P = .0006$; $P = .001$).

EU real-world exposure profiling reveals consistent sex-specific EDC multi-class exposure burdens and demonstrates that pregnancy is not associated with lower exposure proxy indices, highlighting an urgent prevention gap in reproductive endocrinology. BMI-associated higher exposure proxy burden supports the clinical relevance of EDC exposure in metabolic risk stratification. Importantly, feasible micro-habits produced measurable reductions in exposure proxy indices, indicating prevention is implementable beyond awareness campaigns. CheckED provides a scalable digital support tool for endocrinologists to deliver exposure-informed counselling. These findings position endocrine disruption as a preventable driver of chronic endocrine disease risk in Europe and support integrating source-targeted prevention into endocrine care and EU public health strategies.

Introduction: The LIFE-MILCH project (www.lifemilch.eu) investigates exposure to EDCs in mother-infant pairs. Analyzing EDCs in BM and in mothers' and infants' urine samples (IU), with occupational and lifestyle exposure data, the study explores associations of exposure with growth, adiposity, pubertal stages, anogenital distances and neurodevelopment. We present data on exposure to EDCs in BM and IU during the first year of life.

Methods: 689 mother-infant pairs were enrolled in Parma,Reggio Emilia and Cagliari, Italy. Healthy mothers with uncomplicated pregnancies were enrolled at 36-41weeks of gestational age. We present data on 336 BM and IU samples collected at 1(T1), 3(T2), and 6(T3) months after delivery. EDCs were measured by UPLC-MS/MS[4 different bisphenols,11 polycyclic aromatic hydrocarbons(PAHs),14 phthalates and metabolites(PHTHs),7parabens,3polar pesticides,2 pyrethroids].

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Results: Among bisphenols, BPA had the highest detection rate in BM (51.2% at T1 and 49.8% at T3), while it was in 32.9% of IU samples at birth and in 67.6% at T3. BPS was found in 10.7% of BM samples at T1 and in 18.3% at T3;in 22.4% IU samples at T0 and in 41.2% at T3. BPFDGE was almost undetectable in BM but was found in IU. PAHs, except indeno(1,2,3-cd)pyrene and dibenz(a,h)anthracene at T1, were scarcely detectable in BM but were stable in IU samples(up to 27.7%). Among parabens,MePB and EtPB were the most prevalent. In BM, MePB was in 51.2% at T1 and in 56.2% at T3;EtPB was in 42.3% at T1 and in 52.6% at T3. In IU, MePB was in 52.6% at T0 and in 82.4% at T3;EtPB was in 27.6% at T0 and 41.2% at T3. Glufosinate was in 27.4% of BM samples at T1 and in 31.9% at T3; in 44.7% IU samples at T0 and in 38.2% at T3. In all BM and urine samples, high levels of PHTHs were detected. DBP was in 90.2% of BM samples at T1 and in 86.5% at T3;in 30.3% IU samples at T0 and in 79.4% at T3. MBP,DEP,MEP,BBP,MnOP,MEOHP, were similarly detectable at different % over time in both BM and IU.DEHP,DnOP were subtly detectable.Overall,detectable EDCs were above the LOQ in approximately 50% of samples. EDCs in BM increased the probability of finding the same chemicals in IUs,but other sources contributed over time. Relationships with mothers' nutrition were investigated,yielding interesting findings.

Conclusions: Findings confirm BM as a vehicle of environmental contamination. As infancy represents a critical window of exposure, this calls for better biomonitoring, awareness, prevention campaigns and actions to reduce exposure.

OC8.3 - ECE_3540 - Mapping the European regulatory landscape of endocrine-disrupting plastic chemicals

Olwenn Martin[1,2]
[1]*Plastic Waste Innovation Hub, UCL Arts and Sciences, London, United Kingdom;* [2]*Plastic Waste Innovation Hub, UCL Arts and Sciences, University College London, London, United Kingdom*

Background: A wide variety of chemical additives,, some of which are known endocrine disrupters are intentionally added to plastics to enhance their performance or appearance. As most are not covalently bound to the polymeric matrix, they can readily migrate from materials or micro- and nanoplastic particles (MNPs) during and after the often very short useful life of the product. Due to the ubiquity and multitude of uses of plastic materials, releases of plastic additives to their surrounding environment across their lifecycle are regulated across regulatory silos in multiple pieces of legislation. Common plastic additives were mapped against regulatory requirements for various uses at different lifecycle stages.

Methods: Through a bottom-up approach, the 417 high production volume, common, additives listed under ECHA's plastic additive initiative (PlasI), their function and the type of polymers in which they are typically used were mapped against the regulations listed in the European Chemical Agency chemical legislation database (EUCLEF). The text of all legislations within EUCLEF was reviewed for articles relevant to chemicals generally, plastic additives and those addressing endocrine disrupting properties of substances specifically.

Results: Only 3 PlasI additives have been listed in the REACH candidate list of substances of very high concern (SVHC) due to their ED properties; the plasticisers dibutylphthalate (DBP) and diethylhexylphthalate (DEHP), and the flame retardant triphenyl phosphate (TPP), while 7 are currently being assessed for their ED properties. The protection of workers and the safety of products will only cover ED additives that are also carcinogens, mutagens or reproductive (CMR) toxicants or have been identified as SVHCs. DBP and DEHP are currently still authorised for use in food contact materials and for the supply of drinking water. For cosmetics, 10 SVHC PlasI additives (including TPP and decabromodiphenyl ether) are neither prohibited, restricted or listed as allowed colourants, preservatives or UV filters. In medical devices, endocrine disrupting substances are only allowed in invasive devices above 0.1% by weight if no suitable alternative is available.

Discussion: This exercise demonstrated that only a handful of plastic additives with potential ED properties are currently covered by EU regulation. In addition to exemptions and derogations, there are also uses for which known ED plastic additives are authorised. There are encouraging legislative developments, such as a new hazard class for ED properties or digital product passports, but without requirements to routinely test for ED properties using new approach methodologies, these may have only limited impact.

OC8.5 - ECE_3147 - Bone mineral density (BMD) evaluated using REMS is associated during the first year of life with early life exposure to endocrine-disrupting chemicals (EDCs)

Anna-Mariia Shulhai[1], Virginia Beretta[1], Letteria Anna Morabito[2], Francesca Nuti[3], Michele Casoria[3], Federica Grassi[1], Tommaso Aversa[2], Domenico Corica[2], Giorgia Pepe[2], Andrea Dall'asta[1], Anna Maria Papini[3], Serafina Perrone[1], Malgorzata Wasniewska[2] and Maria Street[1]
[1]*Medicine and Surgery, University of Parma, Pediatric Clinic, Parma, Italy;* [2]*University of Messina, Messina, Italy;* [3]*University of Florence, Florence, Italy*

Background: Human data on early exposure to EDCs and bone outcomes remain limited. This study-clinical trial*(NCT06750523)* evaluated bone status from intrauterine life and investigated factors affecting BMD in infants. We present data on early-life exposure to EDCs and BMD from birth to 12 months of age.

Materials and methods: This prospective, longitudinal cohort study analyzed urinary concentrations of EDCs in 88 full-term, healthy AGA infants at 1month of age. 52 compounds were analyzed, including bisphenols(BPA,BPS,BPF,BPFDGE), phthalates(DBP,BBP, DEHP,DEP,DMP,DnOP,MBP,MBzP,MEHP,MEHHP,MEOHP,MEP,MMP, MnOP), parabens(EtPB,MePB,PrPB,iBuPB,iPrPB) and per- and polyfluoroalkyl substances (PFAS:11Cl- PF3OUdS,4-2_FTS,8-2_FTS,6-2_FTS,9Cl-PF3ONS,ADONA,FBSA,FOSA,GenX_HFPO-DA,PFBA,PFBS, PFDA, PFDS, PFDoDA, PFHpS, PFHxS, PFNA, PFNS, PFOA, PFOS, PFPHpA,PFPHxA, PFPeA, PFPeS, PFTrDA,PFTreDA, PFUnDA) by UPLC-MS/MS. BMD was assessed usingRadiofrequency Echographic Multi Spectrometry(REMS), and BMD z-scores were defined at 48hours after birth(V0),at 1(V1),3(V3),6(V6) and 12 months of life(V12). Associations between urinary EDC concentrations and BMD z-scores across time points were evaluated by correlation and principal component(PCA) analyses.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Results: At V0 BMD z-score was 1.31 ± 0.87; −0.09 + 0.61 at V1; −0.06 ± 0.99 at V3; −0.03 ± 0.97 at V6, and -0.04 ± 1.01 at V12. At birth, BMD z-scores were different in males and females (*P*:.028),but this disappeared thereafter. In the infant's urine, BPA was detected in 62.5% of samples, BPS in 19.3%;EtPB in 1.1%, MePB in 21.6%,PrPB in 9.1%. Among PFAS,6-2_FTS was detected in 73.9% of samples, PFBA in 70.5%,PFDA in 3.4%,PGHxS in 29.5%,PFNA in 15.9%,PFOA in 69.3%,PFOS in 76.1%, PFPHpA in 78.4%, PFPHxA in 63.6%. DBP was detected in 2.3%, MBP in 100%, MBzP in 22.7%, MEHHP in 62.5%, MEHP in 1.1%, MEOHP in 42.0% and MEP in 98.9%. BPA and PFDA were associated with BMD z-score at V0(r: −0.31, *P*:.025 and r:0.99, *P*:.038, respectively). MePB was associated with BMD z-scores at V6 and V12(r:−0.52,*P*:.044 and r:−0.738,*P*:.009).PFHxS, PFNA and PFOS presented associations with BMD z-scores at V6(r: −0.49, *P*:.015; r:−0.615, *P*:.037; r:−0.287,*P*:.030). Phthalates showed the most consistent associations with BMD at both V6 and V12. DEP showed a linear association with BMD z-scores at 6(r:−0.557, *P*:.039) and 12(r:−0.703, *P*:.035) months. MBP,MBzP and MEOHP were associated with BMD z-scores at V12(r:−0.346, *P*:.015; r: −0.654,*P*:.040; r:−0.501, *P*:.021). Notably, PCA found a cluster (19%) of BPA and phthalates(MBzP, MBP, MEOHP) with BMD z-score at V12, suggesting that higher exposure is associated with lower BMD at 1 year of age. Additionally, PFHxS contributed to BMD z-scores at V1, V3 and V6 (13.4%).

Conclusions: Early-life exposure to EDCs may be associated with lower BMD during the first year of life. This emphasizes that infancy is a vulnerable window for environmental exposure and skeletal development, highlighting the need to reduce EDC exposure for better bone health.

OC8.6 - ECE_2842 - Association of gestational exposure to a mixture of endocrine disrupting chemicals with placental function

Rutuja Dhamale[1], Tim Korevaar[1], Hans Krabbe[2], Robin Peeters[1] and Arash Derakhshan[1]
[1]*Rotterdam, The Netherlands;* [2]*Department of Clinical Chemistry and Laboratory Medicine, Medisch Spectrum Twente, Enschede, The Netherlands*

Introduction: Endocrine disrupting chemicals (EDCs) interfere with the endocrine system and the function of affiliated organs. The placenta regulates the maternal-fetal interface and is a major endocrine organ producing human chorionic gonadotropin (hCG). However, the potential of EDCs to interfere with placental function remains unclear.

Aim: To study the association of gestational exposure to a mixture of 22 EDCs (phthalates, bisphenols, perchlorate, thiocyanate, nitrate and pesticides) with placental function.

Methods: We investigated the association of the mixture with gestational age adjusted serum hCG concentrations, placental function markers (placental growth factor [PlGF], soluble fms-like tyrosine kinase [sFlt-1]) during early and mid-pregnancy, and placental weight at birth using Bayesian Kernal Machine Regression in women with uncomplicated pregnancies participating in Generation R cohort.

Results: In 1496 included women, higher exposure to EDCs during early pregnancy was associated with a lower hCG and placental weight. We identified fetal-sex specific effects, with more pronounced associations in women carrying a female fetus. The common drivers of these associations were mono-methyl, mono-isobutyl, mono-butyl and mono-2-heptyl phthalates (mMP, mIBP mBP, mHpP with posterior inclusion probabilities >0.40). Higher concentrations of mBzP was associated with higher hCG in women carrying female fetus and lower hCG in women carrying male fetus. We did not identify any association of the EDC mixture with placental function markers.

Discussion: Higher exposure to EDCs was associated with lower hCG concentrations and lower placental weight in a fetal sex-specific manner. Our results highlight the need for further experimental studies to elucidate underlying sex-specific modes of action of EDCs and to investigate the risk of pregnancy complications as a result of placental disruption by EDCs.

OC9.1 - ECE_3866 - Unravelling the sexually dimorphic role of adrenocapsular progenitor cells during stress adaptation of the adult adrenal gland

Panagiota Siatra[1], Diana Leuker-Cozma[1], Timothé Benoit[2], Yasmine Neirijnck[2], Stefan Bornstein[1], Andreas Schedl[2] and Charlotte Steenblock[1]
[1]*Department of Internal Medicine III, University Hospital Carl Gustav Carus, Technische Universität Dresden, Dresden, Germany;* [2]*Université Côte d'Azur, Inserm, CNRS, Institut de Biologie Valrose, Nice, France*

Chronic stress is a pervasive concern in the modern society. The HPA axis dysregulation in chronic stress and psychiatric disorders is tightly linked with hypertrophy and hyperplasia of the adrenal gland. These stress-induced cellular adaptations may involve capsular progenitor behaviour. However, little is known about the contribution of resident progenitor cells to these stress-induced cellular changes. To address this, we used single-cell RNA-seq to investigate the regulation of adrenocapsular progenitors during restraint stress. We analyzed UMAP representations of the stressed and non-stressed mouse adrenal cortex, generated for the first time for both sexes, revealing sex-specific features. Within the adrenal capsule cluster, we observed a stress-induced shift in capsular progenitor populations in both sexes. More specifically, in the male adrenal capsule, the capsular markers *Nr2f2* and *Rspo3*, a signalling molecule involved in the control of cell renewal in the tissue, were enriched under stress. In contrast, the distribution of capsular markers remained unchanged in the female adrenal capsule between stressed and non-stressed condition. This sex-differential capsular response was further confirmed by qPCR analysis. To determine whether the observed shifts reflect altered recruitment or differentiation of capsular cells, we performed lineage tracing of *Gli1*$^{+}$ adrenocortical progenitors during restraint stress using a tamoxifen-inducible *Gli1:CreERT2/R26R:eYFP* mouse line and both sexes. In stressed males, migratory patches of *Gli1*$^{+}$ spindle-like cells appeared in the zona glomerulosa, resembling previously described adrenocortical neoplasms and expressing GATA4, a marker of the adrenogonadal primordium. In females, where *Gli1*$^{+}$ cells normally contribute to homeostatic tissue renewal, preliminary results suggest that the subcapsular patches of *Gli1*$^{+}$-derived cells are rather reduced under stress. Overall, this

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

may suggest that in female mice the process of capsular progenitor cell recruitment is reduced when the need for increased steroid production occurs. Collectively, these findings confirm a sexually dimorphic capsular response during restraint stress. Further analysis of differentially expressed genes in these capsular populations and shifts may reveal molecular candidates mediating remodeling and paracrine signaling between the capsule and adrenal cortex during stress. These factors could directly or indirectly modulate stress response and the steroid production, highlighting the capsule as an active regulator of adrenal stress physiology.

OC9.2 - ECE_1670 - Single-cell transcriptomic profiling reveals divergent endocrine, immune, and angiogenic programs between ACTH/CRH-secreting and non-secreting pheochromocytomas

Wan Su[1], Shiwei Chen[2], Jinghua Liu[1], Di Zhang[1], Zheng Zhang[2] and Lin Lu[1]
[1]*Endocrinology, Peking Union Medical College Hospital, Beijing, China;* [2]*Peking University First Hospital, Beijing, China*

Background: Ectopic ACTH and/or CRH-secreting pheochromocytomas are rare catecholamine-secreting tumors originating from adrenal medulla, which could also secrete ectopic adrenocorticotropic hormone (ACTH) and corticotrophin-releasing hormone (CRH), mimicking Cushing syndrome and complicating the diagnosis clinically. The extremely low incidence limits the comprehensive understanding and management for specific individuals accompanied with this kind of tumor. Furthermore, mechanisms of tumorigenesis and ectopic ACTH secretion in pheochromocytomas are unknown. Studying this rare type of tumor will help tailor therapies to the specifically molecular and metabolic characteristics of pheochromocytomas.

Methods and Materials: Fresh tumor and peritumoral specimens were collected from three ACTH + &CRH+ pheochromocytoma patients and three ACTH-&CRH- pheochromocytoma patients, and then were digested and sent to construct single-cell library as well as sequencing. Subsequent analysis and immunohistochemical staining were conducted to explore the difference of ACTH + &CRH+ pheochromocytomas from the ACTH-&CRH- ones and normal tissues.

Results: We constructed the linear trajectory of 2 types of pheochromocytomas. The cluster of intermediate cells that differentiated into mature ACTH + &CRH+ pheochromocytomas showing high expression of CEBPB, and the immunohistochemical staining revealed that CEBPB was higher in ACTH + &CRH+ ones. Besides, Higher expression of POMC and PNMT was observed in ACTH + &CRH+ pheochromocytomas compared with ACTH-&CRH- ones, being in accordance with the clinical information that three ACTH + &CRH+ pheochromocytoma patients had relatively higher catecholamine levels. T cells in ACTH + &CRH+ pheochromocytomas were activated by signals, like HLA-B, promoting their cytotoxic functions, while T cells in ACTH-&CRH- ones were subject to inhibitory signals, especially from M2 macrophages. What's more, a population of endothelial cells marked by SELE was identified in ACTH + &CRH+ pheochromocytomas, showing strong interaction with CD8+ T cells and facilitating lymphocyte infiltration, particularly the $GZMK^{+}IL7R^{+}$ T cells. While ACTH-&CRH- pheochromocytomas were enriched in glycolysis and HIF signaling pathways, and characterized by lacking T cell infiltration, with macrophages being the dominant immune cells.

Conclusions: CEBPB plays a significant role in the fate transition of pheochromocytomas and may drive ACTH secretion. In addition, ACTH + &CRH+ pheochromocytomas are considerated as relatively immunologically "hot" tumors but poor in angiogenesis. In contrast, ACTH-&CRH- pheochromocytomas lack immune infiltration while exhibiting extensive angiogenesis. Immunotherapies may be effective for the former, and the latter may benefit from anti-angiogenic therapies.

OC9.3 - ECE_2794 - Insulin and adiponectin regulate adrenal steroidogenesis in obesity by shaping cholesterol availability and lipid droplet dynamics

Diana Leuker-Cozma[1,2,3], Panagiota Siatra[1,2], Stefan Bornstein[1,2,3], Cynthia Andoniadou[1,2,3] and Charlotte Steenblock[1,2]
[1]*Department of Internal Medicine III, Molecular Endocrinology, Technische Universität Dresden Medizinische Fakultät, Dresden, Germany;* [2]*Department of Internal Medicine III, University Hospital Carl Gustav Carus Dresden, MK3-L03, Dresden, Germany;* [3]*King's College London Guy's Campus/Guy's Hospital, London, United Kingdom*

Metabolic diseases are highly prevalent worldwide and are frequently associated with increased glucocorticoid (GC) output as a result of hyperactivation of the hypothalamus-pituitary-adrenal gland axis. Current studies highlight that metabolic disturbances can directly influence adrenocortical function, but direct mechanistic explanations remain scarce. Here, we investigated these molecular mechanisms using complementary *in vivo* mouse models of diet-induced obesity and *in vitro* studies of adrenocortical cell responses to metabolic cues. Using a high-fat diet (HFD)-induced obesity model, we characterized the temporal onset of adrenal steroidogenesis over a 16-week period and correlated adrenal output with metabolic parameters. We observed a delayed onset of increased plasma corticosterone at 16 weeks of HFD, coinciding with transcriptional and morphological changes in the adrenal gland, and impaired glucose and insulin tolerance. Increased GC output was preceded by hyperleptinemia and hyperinsulinemia and coincided with decreased adiponectin expression in the perirenal adipose tissue, while circulating plasma ACTH levels remained unchanged. To dissect the direct effects of these metabolic cues, we treated primary spheroids derived from mouse adrenocortical cells with insulin, adiponectin and leptin. Insulin increased and adiponectin decreased spheroid diameter and steroidogenic gene expression, while leptin affected these to a lesser extent. Integration of bulk RNA sequencing data revealed insulin-responsive gene networks regulating cholesterol metabolism at multiple levels, influencing lipid droplet storage, lysosomal accumulation and inhibition of lipophagy. We confirmed the *in vivo* relevance of these mechanisms by demonstrating that altered lipid droplet distribution and altered lipophagy gene expression coincided with increased GC output at 16 weeks of HFD. Together, our data indicates that obesity-associated corticosterone elevation could be due to chronic effects from metabolic disturbances

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

rather than early HPA axis activation. Early hyperinsulinemia and adiponectin-mediated suppression of adrenal steroidogenesis promote lipid storage and prime the cells for increased cholesterol availability while limiting lipophagy. At later disease stages, sustained hyperinsulinemia, insulin resistance, lipotoxicity and reduced adiponectin could cause a switch in lipophagy, subsequently increasing glucocorticoid production. Overall, our findings identify insulin and adiponectin as key regulators of adrenal cholesterol metabolism, lipid storage and lipophagy, and suggest that their dysregulation drives maladaptive steroidogenesis in obesity, metabolic syndrome and adrenal-related diseases. These results further highlight local adipose tissue–adrenal gland crosstalk as a central mechanism in adrenal adaptation to metabolic stress.

OC9.4 - ECE_3373 - A multicentre real-world crossover study of once-daily prednisolone versus hydrocortisone in adrenal insufficiency

Katharine Lazarus[1,2], Zin Htut[1,2], Kavita Narula[1], Cara Go[1,2], Angelica Sharma[1,2], Sirazum Choudhury[1,2] and Karim Meeran[1,2]

[1]Imperial College Healthcare NHS Trust, London, United Kingdom; [2]Imperial College London, London, United Kingdom

Background: Adrenal insufficiency (AI) requires lifelong glucocorticoid (GC) replacement to maintain metabolic, cardiovascular, and immune homeostasis. Standard hydrocortisone therapy, usually given three times daily, has a short half-life and produces fluctuating, non-physiological cortisol exposure. This may contribute to persistent symptoms, reduced quality of life, and increased cardiometabolic risk. Once-daily low-dose prednisolone, with its longer biological half-life and greater GC receptor affinity, may provide more stable daytime GC exposure and a more physiological and convenient replacement option.

Methods: This prospective, multicentre, open-label crossover observational study included adults aged 18-85 years with primary or secondary AI receiving stable GC replacement for at least 4 months. Participants were assessed on their usual regimen and then switched to the alternative GC with at least 4 months' follow-up. Outcomes included cardiometabolic measures, routine biochemical markers, bone turnover markers, and quality of life assessed using a modified SF-36 questionnaire, analysed using within-participant comparisons.

Results: A total of 213 participants completed both study visits (mean age 56.3 years; 63% female; 27% primary AI). Among those treated with prednisolone, the median daily dose was 4 mg (IQR 3-4 mg). Switching from hydrocortisone to prednisolone ($n = 194$) was associated with significant improvements in cardiometabolic outcomes, including reductions in body weight (−2.01 kg; $P < .001$), body mass index (−0.51 kg/m^2; $P = .005$), systolic blood pressure (−5.32 mmHg; $P < .001$), diastolic blood pressure (−2.52 mmHg; $P = .002$), and HbA1c (−0.79 mmol/mol; $P = .001$). The total cholesterol–HDL ratio decreased by 0.18 ($P = .006$). No significant changes were observed in renal, electrolyte, inflammatory, or bone turnover markers. Patient-reported outcomes improved, with significant increases in SF-36 scores for general health (+4.5; $P = .031$), energy (+9.2; $P < .001$), and well-being (+4.6; $P = .017$), while nausea scores showed no significant change (+2.4; $P = .13$). In contrast, participants switching from prednisolone to hydrocortisone ($n = 19$) experienced weight gain (+2.15 kg; $P = .005$), increased triglycerides (+0.68 mmol/L; $P = .037$), and reduced HDL cholesterol (−0.19 mmol/L; $P = .003$), while other parameters remained unchanged.

Conclusions: Low-dose once-daily prednisolone was associated with more favourable cardiometabolic outcomes and improved patient-reported wellbeing compared with hydrocortisone, supporting its use as an effective and potentially preferable GC replacement option in adults with AI.

OC9.5 - ECE_2036 - Adults with classic congenital adrenal hyperplasia taking crinecerfont demonstrated sustained decreases in glucocorticoid doses: 2-year results from the CAHtalyst™ adult study

Irina Bancos[1], Oksana Hamidi[2], Florian Kiefer[3], Rosario Pivonello[4], Aled Rees[5], Mabel Yau[6], Jacques Young[7], Jean Chan[8], Andrea Hartzell[8], Sanjay Keswani[8], Vivian Lin[8], Eiry Roberts[8], Julia Sturgeon[8] and Richard Auchus[9]

[1]Mayo Clinic College of Medicine, Rochester, United States; [2]University of Texas Southwestern Medical Center, Dallas, United States; [3]Medical University of Vienna, Vienna, Austria; [4]Federico II University, Naples, Italy; [5]Cardiff University, Cardiff, United Kingdom; [6]Icahn School of Medicine at Mount Sinai, New York, United States; [7]Bicêtre Hospital, AP-HP, Université Paris-Saclay, Paris, France; [8]Neurocrine Biosciences, Inc., San Diego, United States; [9]University of Michigan Medical School, Ann Arbor, United States

Background: Crinecerfont is a novel corticotropin releasing factor type 1 receptor (CRF_1) antagonist that is FDA-approved as an adjunct to glucocorticoid (GC) replacement to control androgens in patients (≥4 years) with classic congenital adrenal hyperplasia (CAH). This study evaluated changes in GC doses in adults who received up to 2 years of crinecerfont in the phase 3 CAHtalyst™ Adult trial (NCT04490915).

Methods: Participants who completed the double-blind placebo-controlled and open-label periods (Month 12 [M12]) continued on crinecerfont in an open-label extension. Mean % change from baseline (BL) in GC dose (at M12, M18, M24) and % achieving ≤11 mg/m^2/d (at M24) were assessed while androstenedione (A4) was maintained/improved relative to BL with decrease in GC dose set to 0 if A4 was not ≤120% of BL or ≤upper limit of normal. These outcomes were also assessed based on observed GC dose (ie, without imputation based on A4) at M18 and M24, when GC doses could be adjusted without reference to BL A4.

Results: At BL, mean ± SD daily GC dose was 17.6 ± 4.9 mg/m^2/d [32.3 ± 9.3 mg/d] and mean A4 after the morning GC dose was 12.2 ± 14.3 nmol/L. Mean ± SEM % changes from BL in GC dose while maintaining/improving A4 relative to BL were: M12, -26 ± 1.6%; M18, −28 ± 1.7%; M24, −25 ± 1.8%. Moreover, 45% (67/149) of participants achieved a physiologic GC dose (≤11 mg/m^2/d) while maintaining/improving A4 at M24. Observed mean ± SEM % decreases from BL in GC dose (without imputation based on A4) were -38 ± 1.2% at M18 and −38 ± 1.2% at M24, with observed mean GC doses of 10.6 ± 0.2 mg/m^2/d [19.4 ± 0.5 mg/d] at M18 and 10.6 ± 0.2 mg/m^2/d [19.4 ± 0.5 mg/d] at M24. In addition, 71% (114/161) and 69% (103/149) of

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

participants achieved a physiologic GC dose at M18 and M24, respectively, without imputation based on A4. Despite decreased GC doses, mean changes from BL in A4 were −0.4 ± 1.1 nmol/L at M18 and +2.0 ± 1.0 nmol/L at M24. Crinecerfont was overall well-tolerated; no new safety signals were observed during long-term treatment.

Conclusions: Adults with CAH taking crinecerfont, a novel CRF_1 antagonist recently approved for androgen control in patients with both salt-wasting and simple virilizing forms of CAH, had substantial reductions in GC doses that were maintained for up to 2 years, with over two-thirds of participants achieving a GC dose in the physiologic range. Crinecerfont is a well-tolerated treatment option for patients with CAH to reduce chronic supraphysiologic GC exposure, which might improve long-term outcomes.

OC9.6 - ECE_2087 - Modified-release hydrocortisone rapidly normalizes reproductive hormone regulation in women with non-classic congenital adrenal hyperplasia

Matthias Auer, Lea Tschaidse, Orsela Dervishi, Kathrin Bayer, Ann-Christin Welp, Martin Bidlingmaier, Sonja Kunz, Hanna F. Nowotny and Nicole Reisch
Internal Medicine and Endocrinology, LMU Hospital Munich, Medical Clinic and Polyclinic IV, Munich, Germany

Introduction: Non-classic congenital adrenal hyperplasia (NCCAH) often necessitates glucocorticoid (GC) therapy to suppress adrenal androgen excess, which frequently underlies menstrual irregularities and subfertility. While conventional GCs are standard, their pharmacokinetic profiles often fail to mimic the physiological cortisol circadian rhythm, particularly the nocturnal surge required to suppress early-morning ACTH and subsequent androgen escape. Modified-release hydrocortisone (MR-HC; Efmody®) provides a superior pharmacokinetic profile, but its efficacy in NCCAH remains insufficiently characterized.

Methods: In this retrospective observational cohort study conducted between September 2021 and November 2025, 30 women with NCCAH were evaluated (median follow-up 22.5 months). At baseline, 15 patients presented with irregular menses or secondary amenorrhea, and 16 expressed a desire to conceive. Participants were either treatment-naive ($n = 10$) or transitioned from conventional GCs ($n = 20$). The primary endpoints were biochemical androgen control (salivary 17-OHP, serum testosterone), restoration of the regularity of the menstrual cycle, and time to conception.

Results: Fifteen women presented with irregular menses or secondary amenorrhea. Thirteen of fourteen evaluable women (92.6%) demonstrated restoration of ovulatory function, defined as return of a regular menstrual cycle or conception within six months. One woman with hypothalamic hypogonadism remained amenorrheic and initiated hormone replacement therapy. Cycle normalization occurred at a median MR-HC dose of 10 mg (IQR 10-15 mg); all but two women used a single bedtime dose. Among the 16 women seeking pregnancy, 10 conceived within 57.5 weeks (IQR 20.25-64) after treatment initiation. Transition to MR-HC, independent of prior glucocorticoid exposure, significantly reduced morning salivary 17-OHP and serum testosterone levels. Metabolic effects were minimal: body weight decreased slightly over time, and HbA1c showed a transient rise, primarily in treatment-naive women with normalization by the third visit. Blood pressure, fasting glucose, and lipid parameters remained largely unchanged.

Conclusions: Once-daily nightly MR-HC effectively suppresses the adrenocortical axis in women with NCCAH, facilitating rapid restoration of menstrual cyclicity and successful conception at lower total daily GC doses than conventional regimens. These findings suggest that MR-HC is a potent and metabolic-neutral therapeutic option for the reproductive management of NCCAH, potentially reducing the necessity for assisted reproductive techniques.

Autosomal dominant hypocalcemia type 1 (ADH1), due to gain-of-function variants in the calcium-sensing receptor gene (*CASR*), manifests as low parathyroid hormone (PTH), hypocalcemia, hypercalciuria, hyperphosphatemia and hypomagnesemia. Standard of care (SoC) treatment, calcium and active vitamin D, worsens hypercalciuria and can lead to renal morbidity. Encaleret, an investigational, oral, negative allosteric modulator of the CaSR, normalized mean albumin-corrected blood calcium (cCa) and 24-hour urine calcium excretion (UCa) in a Phase 2b study of ADH1.

CALIBRATE (NCT05680818) is a global, Phase 3, randomized, controlled, open-label trial of encaleret for ADH1. After screening, all participants entered Period 1 (P1), a 4-week (W) SoC maintenance period. Participants were then randomized 2:1 to encaleret or SoC in Period 2 (P2), a 20W dose titration period. SoC was stopped prior to encaleret initiation; encaleret dose was adjusted to achieve target cCa. Both treatment groups then entered Period 3 (P3), a 4W dose maintenance period, with the final visit at W24.

Sixty-seven participants (16-76 y) with ADH1 due to 46 distinct *CASR* variants were randomized; 66 completed P3W24. The composite primary endpoint assessed the proportion of those randomized to encaleret ($n = 45$) achieving target cCa (2.08-2.68 mmol/L) AND UCa (<7.0(M), <6.25(F) mmol/day) at P3W24 compared to themselves on SoC at P1W4. This endpoint was met in 75.6% of encaleret-treated participants at P3W24 compared to 4.4% at P1W4 ($P < .0001$). Encaleret increased mean cCa by P2Day3 and decreased mean UCa by P2W3, the first time after encaleret these analytes were measured, and were maintained through P3W24. Within the encaleret group, 91.1% had PTH ≥1.6 pmol/L (nl 1.6-6.9) at P3W24 compared with 6.7% at P1W4 ($P < .0001$); 91.1% achieved normal serum phosphate (0.81-1.55 mmol/L) at P3W24 compared with 55.6% at P1W4 ($P = .0002$). Additional analyses between groups assessed the proportion of those randomized to encaleret versus SoC who achieved these endpoints at P3W24. More participants randomized to encaleret (75.6%) had cCa and UCa within the target ranges compared to those randomized to SoC ($n = 21$) at P3W24 (19%; $P < .0001$). In the SoC group, 0% had PTH ≥1.6 pmol/L at P3W24 ($P < .0001$ compared to 91.1% on encaleret), and 52.4% had normal serum phosphate at P3W24 ($P = .0003$ compared to 91.1% on encaleret). Encaleret was well-tolerated with no discontinuations in the encaleret arm. Few serious adverse events (AE) were reported with frequency similar between treatment arms.

These results establish encaleret as a potential disease-specific therapy for ADH1 with clinically meaningful efficacy, safety, and tolerability.

Introduction: Hypoparathyroidism is a rare endocrine disease, in which insufficient parathyroid hormone (PTH) can lead to systemic complications. Historically, conventional therapy for hypoparathyroidism (active vitamin D and calcium) aims to correct hypocalcemia but does not address underlying insufficient PTH. Palopegteriparatide is a prodrug of PTH (1-34), administered once daily and designed to provide active PTH within the physiological range for 24 hours/day. It is approved in multiple countries for the treatment of hypoparathyroidism. This analysis evaluated the safety and efficacy of palopegteriparatide throughout the phase 2 PaTH Forward trial.

Methods: PaTH Forward included a 4-week, double-blind, randomized, placebo-controlled period and a 262-week open-label extension (OLE). OLE efficacy endpoints included independence from conventional therapy (≤600 mg/day of elemental calcium and no vitamin D) and maintenance of normocalcemia (2.07-2.64 mmol/L). Bone turnover markers C-terminal telopeptide of type 1 collagen (CTx) and procollagen type 1 N-terminal propeptide (P1NP), and bone mineral density (BMD) measured by dual x-ray absorptiometry were assessed regularly. Renal function was assessed using estimated glomerular filtration rate (eGFR). Hypoparathyroidism-related symptoms and impact were measured using the Hypoparathyroidism Patient Experience Scales. Safety assessments included serum chemistries, 24-hour urine calcium, and treatment-emergent adverse events (TEAEs).

Results: Fifty-six of 59 participants (95%) completed the trial. Of those, 95% (53/56) were independent from therapeutic doses of calcium, 96% (54/56) were independent from active vitamin D, and 88% (49/56) were normocalcemic. Mean (SD) albumin-adjusted serum calcium was 2.25 (0.17) mmol/L at Week 266. Mean CTx and P1NP increased from the low end of normal at baseline, peaked by Week 26, and declined thereafter, remaining stable above baseline through Week 266. Mean BMD Z-scores trended towards age- and sex-matched norms at multiple regions, remaining above zero through Week 266. Mean (SD) eGFR was 78.01 (22.16) mL/min/1.73 m^2 at Week 266, reflecting a mean (SD) increase of 9.38 (14.08) mL/min/1.73 m^2. Hypoparathyroidism-related symptoms and impacts on physical functioning and daily life improved by Week 4 with palopegteriparatide treatment and were maintained through Week 266. Mean (SD) 24-hour urine calcium levels normalized with palopegteriparatide treatment and remained below the upper limit of normal (≤6.2 mmol/day) through Week 266 (mean 3.61 [2.01] mmol/day). Most TEAEs were mild-to-moderate; no TEAEs led to trial or study drug discontinuation.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Conclusions: Palopegteriparatide demonstrated durable safety and efficacy in adults with hypoparathyroidism, enabling independence from conventional therapy and maintaining normocalcemia while providing sustained improvements in patient-reported outcomes for participants through Week 266.

OC10.3 - ECE_2879 - Dynamic postoperative PTH as a strong predictor of hypoparathyroidism after total thyroidectomy: a large cohort analysis

Miguel Paja[1,2,3], Leire Pérez de Azpeitia[2], Josune Rodríguez-Soto[3], Cristina Moreno[3], Eider Etxeberria[3], Javier Espiga Alzola[3], Ana Izuzquiza[3], Iñigo Hernando[2,3], María Ausín[3], Jon Portu[3], Jon Garai[3], Alejandra Santamaría[3], Amaya Exposito[2], Aitzol Lizarraga[2], Aitziber Ugalde[3], Amelia Oleaga[2] and Elena Cruz-Iglesias[3]
[1]*Endocrinology & Nutrition, Biobizkaia Health Research Institute, Bilbao, Spain;* [2]*EHU, Basque Country University, BIlbao, Spain;* [3]*Osakidetza, Basurto University Hospital, BIlbao, Spain*

Background: Postoperative hypoparathyroidism (poHypoPT) is a frequent complication of total thyroidectomy. Its early identification is clinically relevant, and postoperative PTH dynamics—particularly the 24-hour decline—have emerged as strong predictors. poHypoPT is best defined as an undetectable or inappropriately low postoperative PTH level in the presence of hypocalcaemia, with or without symptoms. This study evaluates its incidence and predictive factors in a large surgical cohort.

Methods: We retrospectively analysed patients who underwent total thyroidectomy, with or without central neck dissection (CND), between 2016 and 2022. poHypoPT was defined by at least one of the following: (a) corrected calcium (CorCa) <7.5 mg/dL; (b) CorCa <8.0 mg/dL with simultaneous PTH <15 pg/mL during postoperative admission; (c) hypocalcaemic symptoms resolving with oral or intravenous calcium during admission or after discharge; or (d) PTH <10 pg/mL at 24 hours. Variables included demographics, thyroid function, surgical characteristics, intraoperative parathyroid identification, and postoperative PTH dynamics (baseline, immediate, and 24-hour values).

Results: A total of 768 patients were included (79.7% women; median age 54 years). Hyperthyroidism (TSH <0.1) was present in 19.3%. CND was performed in 25%, and malignancy was suspected or confirmed preoperatively in 50%. poHypoPT occurred in 296 patients (38.5%). It was associated with younger age, lower BMI, female sex, surgery for suspected/confirmed malignancy, CND, greater immediate and 24-hour postoperative declines in PTH, total calcium and CorCa, and larger gland size by specimen weight. In multivariate analysis excluding calcium and PTH values (diagnostic criteria), age, sex, and postoperative PTH dynamics remained independent predictors. When PTH dynamics were excluded, CND was the strongest predictor (OR 3.58; IC_{95}: 2.49-5.18). PTH at 24 hours (PTH24H) showed the highest diagnostic accuracy (AUC 0.930). A PTH24h >17.5 pg/mL predicted a 93.3% probability of not developing poHypoPT, while a reduction <68.8% from baseline predicted its absence with 96.37% sensitivity and 80.9% specificity with a predictive negative value of 97.3%.

Conclusions: Using strict biochemical and clinical criteria, poHypoPT incidence reached 31.5%. Lower BMI and female sex were modest predictors. Postoperative PTH dynamics—particularly a 24-hour PTH >17.5 pg/mL or a decline <70% from baseline—demonstrated excellent negative predictive value and are reliable tools for early risk stratification after total thyroidectomy.

OC10.4 - ECE_2600 - Genetic testing of over 400 individuals with non-surgical hypoparathyroidism shows gain-of-function CASR variants as the most common genetic cause identified

Michael Mannstadt[1], Lyndsay Smith[2], Ananth Sridhar[2], Mary Scott Roberts[2], Scott Adler[2] and Arun Mathew[2]
[1]*Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, United States;* [2]*BridgeBio Pharma, San Francisco, United States*

Hypoparathyroidism is a rare endocrine disorder characterized by low serum calcium with undetectable or inappropriately low parathyroid hormone levels, leading to disrupted mineral homeostasis. Hypoparathyroidism is most often caused by inadvertent injury to or removal of the parathyroid glands during neck surgery. Increasingly, genetic causes are being recognized as diagnostic testing expands and awareness for non-surgical etiologies grows. Genetic forms of hypoparathyroidism may present as isolated disease or as part of a broader syndrome, and include disorders affecting parathyroid gland development, parathyroid hormone synthesis or secretion, and autoimmune-mediated injury to the parathyroid glands.

Individuals with a clinical diagnosis of non-surgical hypoparathyroidism, a positive family history, or suspicion of a genetic etiology are eligible to enroll in a no-charge sponsored genetic testing program in the United States and Canada. The next-generation sequencing panel leveraging a whole-exome backbone includes 26 genes associated with hypoparathyroidism: *ACADM*, *AIRE*, *ATP1A1*, *CASR*, *CHD7*, *CLDN16*, *CLDN19*, *CNNM2*, *DHCR7*, *EGF*, *FAM111A*, *FXYD2*, *GATA3*, *GCM2*, *GNA11*, *HADHA*, *HADHB*, *KCNA1*, *NEBL*, *PTH*, *SEMA3E*, *SLC12A3*, *SOX3*, *TBCE*, *TBX1,* and *TRPM6*.

A total of 446 participants (mean age 29 years, range 0-83 years) were tested during 2020-2025. 294 pathogenic or likely pathogenic variants or variants of uncertain significance were identified across 222 individuals (50%). Among these 222 individuals, *CASR* was the most frequently affected (40%), followed by *AIRE* (18%), *GATA3* (10%), *TBX1* (10%), *GNA11* (6%), *DHCR7* (4%), *GCM2* (4%), *SLC12A3* (4%), *CHD7* (3%), *ACADM* (3%), *HADHA* (3%), *FAM111A* (2%), *SEMA3E* (2%), *HADHB* (2%), *CNNM2* (1%), *EGF* (1%), *NEBL* (1%), *CLDN19* (1%), *PTH* (1%), *TRPM6* (1%), and *CLDN16*, *FXYD2*, *KCNA1, SOX3*, and *TBCE* (each under 1%). Notably, 60 individuals had more than one variant identified, reflecting either multiple variants within a single gene or variants identified in multiple genes.

In non-surgical hypoparathyroidism without another clear cause, genetic testing and family evaluation are recommended by the current practice guidelines. Identification of genetic etiology can clarify the underlying defect, guide therapy selection, and prompt targeted evaluation and counseling, consistent with recent adult clinical-practice guidance and best practice

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

recommendations. In this cohort, the most common genetic form of hypoparathyroidism was autosomal dominant hypocalcemia type 1, caused by gain-of-function *CASR* variants (20% of the total population; 88/446). Overall, genetic testing offers a practical, high-yield pathway to establish definitive diagnoses in non-surgical hypoparathyroidism and, consistent with consensus guidance, may thus enable informed counseling for patients and families, better targeted evaluation, and more precise management.

Abstract citation ID: lvag096.134

OC10.5 - ECE_2799 - Bone and blood transcriptome profiles in postmenopausal osteoporotic vertebral fracture patients

Lucie Šedová[1], Josef Včelák[2], Adam Král[2], Blanka Chylíková[1] and Ondřej Šeda[1]

[1]*First Faculty of Medicine, Charles University, Institute of Biology and Medical Genetics, Prague, Czech Republic;* [2]*Prague, Czech Republic*

Osteoporotic vertebral fractures (OVF) represent a major cause of morbidity, yet Bone Mineral Density (BMD) often fails to accurately predict fracture risk. A significant proportion of fractures occur in individuals with BMD scores above the osteoporotic threshold, as BMD measures bone quantity rather than quality (microarchitecture and turnover). Consequently, there is a critical need to identify specific molecular profiles and biomarkers that reflect bone quality to improve risk stratification for OVF.

Methods: This study aimed to elucidate the distinct genomic and transcriptomic profiles associated with OVF vs non-osteoporotic controls. Intraoperative vertebral bone tissue and peripheral blood were collected from postmenopausal women undergoing surgery for OVF ($n = 67$) and patients undergoing elective thoracolumbar surgery without osteoporosis (Control, $n = 48$). RNA was extracted from intraoperative vertebral bone tissue and peripheral blood. RNA sequencing libraries were prepared using the NEBNext Ultra II Directional RNA Library Prep Kit for Illumina and sequenced using Illumina NovaSeq6000 as 150-bp paired-end reads. We performed differential expression and gene ontology and pathway analyses to compare osteoporotic and non-osteoporotic samples.

Results: The control and OVF groups were age-matched (73.3 ± 5.4 vs 73.9 ± 7.4 years in OVF, $P = .6$), with similar profiles regarding prevalence of concomitant cancer, hyperuricemia, dyslipidemia, hypertension, inflammation, thyreopathies, smoking status or medication (except for osteoporosis-specific medication). Control group showed slightly higher body mass index (28.9 ± 4.3 vs OVF 26.5 ± 4.2, $P = .004$) and prevalence type 2 diabetes. Transcriptomic analysis of bone tissue revealed 285 differentially expressed genes (FDR <0.05; >2-fold change), with 256 downregulated and 29 upregulated in OVF. Gene ontology and pathway analysis identified enrichment in extracellular matrix organization, collagen fibril organization and PI3K-Akt signalling pathways (all Bonferroni-corrected $P < 10^{-4}$). Transcriptomic analysis of blood revealed only 23 significantly differentially expressed genes with 6 downregulated and 17 upregulated in OVF. Interestingly, the most significantly downregulated gene in OVF blood was lactoferrin with known roles in bone formation, conversely, among the most upregulated genes in OVF were Syndecan 1, long non-coding RNA LINC00958 or myomesin-2, all previously linked to bone homeostasis.

Conclusions: This study identifies a distinct transcriptomic signature distinguishing OVF patients from controls, characterized by disrupted collagen and matrix organization pathways. Furthermore, the data suggests potential non-invasive biomarkers for assessing bone quality and fracture risk beyond standard BMD measurements.

OC10.6 - ECE_1238 - Real-world safety of romosozumab in high cardiovascular risk patients

Joshua Stokar[1,2,3] and Auryan Szalat[1,2]

[1]*Hadassah Medical Center, Jerusalem, Israel;* [2]*Faculty of Medicine, The Hebrew University of Jerusalem, Jerusalem, Israel;* [3]*Hadassah Medical Center, Endocrinology, Internal Medicine, Jerusalem, Israel*

Introduction: Use of Romosozumab for treatment of osteoporosis is hindered by a black box regulatory warning regarding an increased risk for major adverse cardiovascular (MACE). We previously demonstrated that romosozumab was not associated with increased MACE in patients without recent cardiovascular (CV) events; however, data on its safety in individuals with recent CV events remain limited.

Objective: To compare 1-year cardiovascular risk following initiation of romosozumab versus parathyroid hormone (PTH) analogues in patients with documented recent acute CV events prior to therapy.

Methods: Using TriNetX, a global federated electronic health record network, we identified adults who initiated romosozumab or a PTH analogue (abaloparatide or teriparatide) after experiencing an acute myocardial infarction or cerebral infarction within the preceding year. Propensity-score matching (PSM) generated 702 patients per cohort, balanced across 54 demographic, clinical, medication, and laboratory variables. Outcomes were assessed from day 1 to day 365 post-index. The primary endpoint was incident 3-point MACE (3P-MACE): acute myocardial infarction, acute stroke, or death. Secondary endpoints included myocardial infarction, cerebrovascular events, acute heart failure, and all-cause mortality. Hazard ratios (HRs) were calculated using Cox proportional hazards models.

Results: During 1-year follow-up, romosozumab was not associated with excess cardiovascular risk compared with PTH analogues. Event counts and hazard ratios (HR [95% CI]) for romosozumab vs PTH analogues were: 3P-MACE: 293 vs 321; HR 0.94 (0.80-1.10); Myocardial infarction: 72 vs 84; HR 0.88 (0.65-1.21); Acute heart failure: 31 vs 38; HR 0.84 (0.52-1.35); CVA or TIA: 222 vs 238; HR 0.97 (0.81-1.16); Death: 30 vs 44; HR 0.72 (0.45-1.14).

Conclusions: Among patients with recent major cardiovascular events, romosozumab was not associated with an increased risk of cardiovascular events or mortality compared with PTH analogues. These real-world findings support the cardiovascular safety of romosozumab even in patients at very high baseline cardiovascular risk, challenging the conclusions derived from the ARCH trial.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Marta Bueno[6], Andres Cardona[1], Lourdes Gomez[1] and Albert Lecube[1]
[1]Hospital Universitari Vall d'Hebrón, Barcelona, Spain; [2]Vall d'Hebron University Hospital, Barcelona, Spain; [3]Hospital Universitario Araba, Vitoria-Gasteiz, Spain; [4]Parc Taulí, Sabadell, Spain; [5]Hospital de Bellvitge, L'Hospitalet de Llobregat, Spain; [6]Hospital Universitario Arnau de Vilanova, Lleida, Spain

Introduction: The modest durability of lifestyle-based weight management and, until recently, the limited access to safe and effective anti-obesity drugs have helped drive the growing uptake of bariatric surgery (BS). However, 25%-30% of individuals fail to attain clinically meaningful weight loss, and as many as 50% develop substantial weight regain beyond the second postoperative year. Obesity has a strong genetic component (heritability ~40%-75%), with more than 120 genes implicated. To support preoperative risk stratification, we developed the OBEGEN clinico-genetic score (range −4 to +4; cut-off 0.662), which combines 8 single-nucleotide polymorphisms with 3 clinical variables to classify BS candidates as "good" or "bad" weight-loss responders (J Pers Med. 2021;11:1040).

Methods: A total of 342 patients undergoing BS were analyzed and stratified according to the OBEGEN score. Outcomes included percentage total weight loss (%TWL), the proportion of patients achieving >20% TWL, and weight regain >30%. These outcomes were assessed at 6 months and annually from 1 to 5 years postoperatively. Continuous variables were compared using t-tests or ANOVA, and categorical variables using chi-square or Fisher's exact tests, as appropriate.

Results: Across follow-up, good responders consistently achieved greater %TWL than bad responders (1 year: 34.1% vs 29.6%, $P <$ .001; 5 years: 26.3% vs 22.9%, $P = .006$), with the greatest between-group difference observed at 3 years (30.5% vs 22.3%, $P < .001$). The proportion of patients achieving >20% TWL was significantly higher among good responders at 1 year (96.4% vs 86.9%, $P = .002$), 2 years (92.8% vs 78.3%, $P < .001$), and 4 years (78.7% vs 60.0%, $P = .001$). At 5 years, weight regain >30% was numerically more frequent among good responders, although this difference did not reach statistical significance (9.6% vs 4.1%, $P = .095$).

Conclusions: Clinical–genetic stratification using the OBEGEN score identifies distinct postoperative weight-loss trajectories following bariatric surgery. Differences between responder groups are most pronounced during the first three years and diminish by year five, coinciding with an apparent increase in weight regain among individuals initially classified as good responders. These findings highlight the potential value of incorporating genetic information into early postoperative risk stratification and follow-up planning, while underscoring the need for sustained long-term support in all patients undergoing BS.

Background: Congenital leptin deficiency (CLD) is a rare monogenic cause of severe early-onset obesity and hyperphagia, with limited long-term real-world evidence on metreleptin therapy. In this study, we aimed to evaluate the long-term clinical outcomes and safety of metreleptin therapy in a large, multicenter cohort of pediatric and adult patients.

Methods: We conducted a multicenter, observational cohort study including 17 patients with CLD (10 pediatric, 7 adult) across 8 centers. Clinical characteristics, genetic findings, longitudinal anthropometric measurements, metabolic parameters, and total daily metreleptin doses were systematically evaluated. Pediatric and adult cohorts were analyzed separately to account for age- and growth-related trajectories. Repeated-measures analyses were performed in subgroups with complete longitudinal data. One patient who developed loss of efficacy due to neutralizing antibodies was presented separately.

Results: Obesity onset clustered within the first year of life in 87.5% of patients, and hyperphagia was present in all patients at baseline. Pathogenic or likely pathogenic *LEP* gene variants were identified in most cases; three individuals with ongoing genetic analyses were included based on markedly low leptin levels and a robust clinical response to metreleptin. Across the entire cohort, metreleptin induced a marked, time-dependent reduction in BMI (median −25.7% at month 6; −40.7% at month 18). In pediatric patients, BMI and BMI SDS decreased substantially (mean BMI SDS 5.52 ± 1.47 at baseline to 2.66 ± 1.37 by month 24) and remained stable long term; all children showed a net BMI SDS reduction at last follow-up. Linear growth was preserved, with stable height SDS and no evidence of growth attenuation. In adults, BMI decreased from 55.7 kg/m^2 at baseline to 29.9 kg/m^2 by month 18, with subsequent inter-individual variability but overall preservation of therapeutic gains. Glycemic and lipid parameters remained largely within reference ranges, no severe adverse events occurred, and total metreleptin doses remained stable without systematic escalation. A boy with a large deletion in the *LEP* gene started metreleptin at 24 months and initially lost 10 kg. By month 6, he began regaining weight and developed injection-site reactions. He tested strongly positive for neutralizing antibodies and was later treated with an investigational agent.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Conclusions: This multicenter cohort is among the largest real-world series jointly evaluating pediatric and adult patients with congenital leptin deficiency. Metreleptin was effective and well-tolerated during long-term follow-up in routine clinical practice. Neutralizing antibody–associated loss of efficacy occurred in one patient; otherwise, responses were sustained without clinically relevant safety signals.

OC11.3 - ECE_1591 - Food-induced cortisol and short-term energy partitioning during overfeeding in healthy men: a randomized, placebo-controlled crossover study

Gabriele Cypaite[1], Jil Chevailler[1], Zanetti Lisa[1], Lorena Wyniger[1], Susanne Thierry[1], Michael Epstein[2] and Eleonora Seelig[1]
[1]*Division of Endocrinology, Diabetology and Metabolism, University Hospital Basel, Basel, Switzerland;* [2]*Statistical Consulting, Letchworth, United Kingdom*

Background: Food intake elicits a small but measurable increase in circulating cortisol levels. The physiological relevance of this response remains uncertain.

Methods: In this randomized, placebo-controlled, crossover study, 20 healthy lean men were enrolled at the University Hospital Basel, Switzerland. Participants received either a block-and-replace regimen mimicking physiological cortisol rhythm (metyrapone plus hydrocortisone) or placebo (1:1 randomization). Each participant completed two 3-day overfeeding periods (4000-5000 kcal/day), once under each treatment condition. The block-and-replace regimen suppressed the postprandial cortisol rise. The primary outcome was insulin sensitivity assessed using a mixed-meal tolerance test. Secondary outcomes included body weight as well as lean and fat mass measured by body impedance analysis. Outcomes were analyzed using mixed-effects models.

Results: All 20 participants completed the study per protocol. There was no evidence for a treatment effect on insulin sensitivity (Matsuda Index estimate: −121.175; standard error: 148.217; $P = .424$) or total body weight (estimate: −0.502 kg; SE 0.317; $P = .131$). However, the block-and-replace treatment significantly reduced fat mass (estimate: −1.532 kg; SE 0.435; $P = .002$) and increased lean mass (estimate: 1.968 kg; SE 0.489; $P = .001$) compared with placebo.

Conclusions: Although the intervention did not affect the primary metabolic endpoint, suppression of the food-induced cortisol response was consistently associated with a shift towards lower fat mass and higher lean mass during short-term overfeeding. These findings point to a previously unrecognised role of postprandial cortisol in energy partitioning in humans and suggest that modulation of this response may represent a biologically relevant target for future investigation.

OC11.5 - ECE_1834 - Progesterone attenuates the metabolic benefits of estradiol in late-onset hormone replacement in ovariectomized mice

Alessandra Gonçalves da Cruz, Anne Raissa Melo Santos, Felipe Nunes de Camargo, Bruna Maria Fantini Trinca, Jessica Denielle Matos Dos Santos, José Francisco Turino Silva, Jorge Felipe Argenta Model, Sandro Leão Matos and João Paulo Camporez
Departamento de Fisiologia, Faculdade de Medicina de Ribeirão Preto—Universidade de São Paulo, Ribeirão Preto, Brazil

Hormone replacement therapy is considered a valuable strategy with protective effects against insulin resistance and obesity. However, data are limited on the metabolic effects of late-initiated treatment with estradiol (E2) combined with progesterone (P4).

Our aim was to assess the effects of late-onset combined E2 and P4 treatment on insulin resistance and lipid profile in high-fat-fed ovariectomized female mice.

Eight-week-old female C57BL/6J mice underwent bilateral ovariectomy and were allocated to four groups: OVX, E2, P4, E2 + P4. Hormone therapy was evaluated 12 weeks after ovariectomy to model advanced menopause. E2 and/or P4 were delivered via subcutaneous pellets for 4 weeks. All animals received a high-fat diet 45%. Body composition, glucose tolerance test (GTT), HOMA-IR, fasting insulin, total cholesterol, liver histology (Oil Red O), and hepatic and muscle triglycerides (TAG) levels were measured. Protein levels of estrogen receptor alpha (ERα) and sterol regulatory element-binding protein-1c (SREBP1c), related to fatty acid and TAG synthesis, were also analyzed (CEUA 1031/2021R1).

Even after a prolonged period following ovariectomy, E2 treatment alone improved the analyzed parameters compared with OVX, reducing body weight gain and fat mass and increasing lean mass percentage. Area under the curve (AUC) during GTT, fasting insulin, HOMA-IR, TAG content in liver and muscle (confirmed by histology), and cholesterol levels were also reduced after late E2 treatment. However, when E2 was combined with P4, E2 + P4 did not show the same improvements observed with E2 alone. Final body weight in E2 + P4 did not differ from P4 and OVX but was higher than in E2. Fat mass percentage in E2 + P4 was lower than in P4 and OVX but higher than in E2, whereas lean mass percentage was higher than in P4 and OVX but lower than in E2. AUC did not differ among E2 + P4, P4, and OVX, but was higher in E2 + P4 than in E2. E2 + P4 also showed higher tissue TAG than E2. Plasma cholesterol didn't differ among E2 + P4, P4, and E2, although all were lower than OVX. Fasting insulin and HOMA-IR were higher in E2 + P4 than in E2. Regarding protein content, E2 + P4 and E2 showed higher ERα levels than OVX, while SREBP1c was lower in E2 + P4 than in E2.

The simultaneous combination of E2 and P4 attenuated or abolished several of the protective effects observed with E2 alone, suggesting a modulatory role of P4 on E2-mediated metabolic actions and lipogenic signaling. Further studies are needed to identify the exact pathways involved in this mechanism.

Introduction: Children born small for gestational age (SGA) constitute a heterogeneous population with diverse growth and metabolic trajectories. Low birth length and/or weight increases the risk of impaired growth and metabolic dysfunction, the latter mainly in those exhibiting rapid postnatal catch-up. Among relevant cytokines, fibroblast growth factor 21 (FGF21), its co-receptor β-Klotho, and adiponectin (Adn) have emerged as biomarkers of insulin sensitivity and glucose homeostasis. FGF21 also interacts with the GH/IGF-I axis, influencing linear growth and contributing to GH resistance. Characterizing the FGF21/β-Klotho system and Adn may help elucidate the mechanisms linking growth patterns to metabolic risk in SGA children.

Aims: To investigate associations between anthropometric measures, metabolic parameters, and the FGF21/β-Klotho–Adn axis in SGA children, with particular focus on glycaemic control and lipid metabolism.

Methods: This cross-sectional study included 60 SGA children (birth weight and/or length <−2.0 SDS, INeS charts) aged 4-16 years, thirteen of whom (21.7%) receiving recombinant GH (rGH) therapy for short stature. Anthropometric data, body composition (TANITA BC-420MA), and metabolic markers—including fasting glucose, insulin, HbA1c, IGF-I SDS, lipid profile, FGF21, β-Klotho, and Adn—were collected. HOMA-IR and QUICKI indices were calculated.

Results: The cohort (35F/25M; mean age 9.5 ± 2.9 years) included 23.3% children with height <−2.0 SDS. Median concentrations were: FGF21 139.6 pg/ml, β-Klotho 720.2 pg/ml, and Adn 4.3 ng/ml. HbA1c showed a significant positive association with height gain ($P = .018$; $P = .023$ adjusted for Mid-parental height). FGF21 and β-Klotho were strongly correlated ($P < .001$), whereas Adn showed no relationship with either marker. Both FGF21 and β-Klotho were inversely associated with triglycerides ($P = .043$ and $P = .026$), and β-Klotho and Adn correlated positively with HDL cholesterol ($P = .029$ and $P = .024$). None of the biomarkers were associated with glycaemic indices and IGF-I SDS levels. In children receiving rGH, lipid-related associations disappeared, and FGF21–β-Klotho and Adn instead correlated with HbA1c ($P = .043$, $P = .036$, $P = .041$, respectively).

Conclusions: Our findings support a link between postnatal height catch-up growth and metabolic risk, as shown by the association between height and HbA1c—a marker predictive of future diabetes even in healthy paediatric populations. Unexpectedly, the FGF21–β Klotho system showed an inverse relationship only with triglycerides; however, these lipid-related associations were no longer present in children undergoing rGH therapy. In treated patients, FGF21–β-Klotho and adiponectin, instead, correlated with glycaemic markers, suggesting that rGH may alter the metabolic context in which FGF21 operates, shifting its associations from lipid to glucose metabolism.

OC12.1 - LBA_ECE_1384 - Integrating lncrnas expression with machine learning for accurate preoperative diagnosis of thyroid cancer

Melissa Borsa[1], Corrado Possieri[2], Valeria Pecci[1], Pietro Locantore[1], Antonella Farsetti[3], Alfredo Pontecorvi[1] and Simona Nanni[1]

[1]*Catholic University of the Sacred Heart of Rome, Rome, Italy;* [2]*University Tor Vergata of Rome, Rome, Italy;* [3]*CNR Iasi, Rome, Italy*

Background and Aim: Thyroid nodules are increasingly detected in clinical practice, poising a major clinical challenge in distinguishing benign from malignant lesions and often leading to unnecessary surgery. Indeed, only 25%-30% of TIR3B and 50%-80% of TIR4 nodules are confirmed as malignant on final histology, resulting in surgical overtreatment.

Recent evidence highlights the role of long non-coding RNAs (lncRNAs) in thyroid cancer, but their clinical application remains in the research phase.

In this context, the aim of this project is to develop a machine learning-driven lncRNAs level-based strategy to improve diagnostic accuracy enabling more personalized treatment strategies.

Methods: Patients were enrolled at the Endocrinology and Diabetes Center of Fondazione Policlinico Gemelli (Rome, Italy) and undergoing to fine-needle aspiration (FNA) biopsies for suspicious nodules ($n = 356$). Expression of selected lncRNAs (MALAT1, HOTAIR and PVT1) was evaluated by Droplet Digital PCR (ddPCR) in FNAs. The lncRNAs expression levels and cytological and histopathological data, from 161 patients, have been used to developed a "Decision Tree" based predictive model. Among these patients, 125 are inliers (38 benign and 87 malignant lesions), contain TIR3A ($n = 28$), TIR3B ($n = 37$) and TIR4 ($n = 60$). To prevent overfitting, the model was restricted to a maximum of 5 decision variables per split and 12 number of leaf nodes.

Results (overall cohort): The predictive model demonstrated an accuracy of 93% in benign/malignant classification, and 80% in 10-fold cross-validation. In the overall cohort, the "decision tree" strategy achieved 91% sensitivity and 97% specificity, with a positive predictive value (PPV) of 98% and a negative predictive value (NPV) of 82%. In addition, in TIR3A lesions, we obtained a sensitivity of 73% and a specificity of 100% with a PPV of 100% and NPV of 77%. While, in TIR3B lesions, sensitivity and specificity were 93% and 100%, respectively with a PPV of 100% and an NPV of 97%. Of note, the expression levels of lncRNAs in both thyroid nodule and lymph node analysis showed significantly higher MALAT1 and PVT1 expression in malignant samples.

Conclusions: Overall, these finding suggest that an integrated analysis of lncRNAs in FNA biopsies may serve as a reliable diagnostic tool to reduce unnecessary surgery and supporting personalized patient management.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Background: Hemithyroidectomy (HT) is the most frequently performed thyroid operation. Although part of the thyroid gland is preserved, postoperative hypothyroidism (hypoT) develops in a considerable proportion of patients. Identifying patients at increased risk of hypoT following HT may improve risk stratification and support surgical decision-making and postoperative surveillance. However, population-based data on the incidence of hypoT after HT and the predictive value of postoperative thyroid function remain limited.

Objective: To estimate the risk of hypoT following HT in a Danish population and evaluate preoperative thyroid-stimulating hormone (TSH) as predictor of postoperative hypoT.

Methods: We conducted a nationwide, population-based cohort study including all adult Danish patients undergoing HT from 1998 to 2024. We excluded patients <18 years or with preoperative medical treatment for hypoT or hyperthyroidism (hyperT), and patients having additional thyroid surgery after HT. The primary outcome was postoperative hypoT defined as initiation of thyroid hormone replacement therapy (TRT) following HT. We generated a matched cohort (1:10) from the general population based on sex and year of birth. Matching criteria included being alive at the time of HT, no treatment for hypoT or hyperT before HT, and no previous thyroid surgery. We estimated the cumulative incidence (risk) of hypoT using the Aalen–Johansen estimator with death as a competing risk and compared the risk between HT patients and the matched reference cohort. Subgroup analyses were performed according to preoperative TSH categories for the patients where these data were available.

Results: We identified 41 056 thyroid operations in 38 257 patients, of whom 29 423 met the inclusion criteria and were compared with a matched reference cohort of 294 230 individuals. Due to data availability, preoperative TSH measurements were only available for the period 2008-2024, including 16 136 patients (54, 8%). The 5-year risk of hypoT following HT was 21.0%, compared with 1.2% in the matched reference cohort. The risk of hypoT increased with higher preoperative TSH levels. The 5-year risk was 9.2% among patients with preoperative TSH <1 mIU/L, 19.5% for TSH 1-2 mIU/L, 42.8% for TSH 2-3 mIU/L, and 73.2% for TSH >3 mIU/L.

Conclusions: One out of five patients developed hypoT within five years after a HT. Higher preoperative TSH levels were strongly associated with an increased risk of postoperative hypoT. Preoperative TSH may therefore be a useful predictor for risk stratification and patient counselling when informing about the risk of postoperative hypoT.

OC12.3 - LBA_ECE_1123 - Tocilizumab and Sirolimus show higher response rates than methylprednisolone as first-line treatment for moderate-to-severe active Graves' Orbitopathy: a proof-of-concept study

Silvia Corrias, Giulia Faa, Federica Diana, Filippo Lixi, Giuseppe Giannaccare, Erica Ragno, Gianluigi Canu, Francesca Pigliaru, Stefano Mariotti, Francesco Boi and Giulia Lanzolla
Cagliari, Italy

Objective: Tocilizumab and sirolimus have emerged as potential therapeutic alternatives for moderate-to-severe active Graves' Orbitopathy (GO). This study aimed to compare the clinical efficacy and safety of tocilizumab, sirolimus, and ivGCs in patients with moderate-to-severe active GO.

Materials and Methods: Fifty-two consecutive patients with moderate-to-severe active GO were retrospectively evaluated: 14 treated with sirolimus (2 mg on day 1, followed by 1 mg/day for 12 weeks), 14 with tocilizumab (8 mg/kg once monthly for 4 months), and 24 with methylprednisolone (500 mg/weekly for 6 weeks, followed by 250 mg/weekly for 6 weeks), as first line treatment. Sirolimus and tocilizumab were administered when methylprednisolone was contraindicated. Clinical assessments were performed at baseline and 12 weeks after treatment completion. Primary endpoint: overall GO outcome based on a composite evaluation. Secondary endpoints: proportion of responders and the change from baseline in 1) quality of life, evaluated by GO-QoL questionnaire; 2) proptosis; 3) Clinical Activity Score (CAS); 4) ocular motility; 5) eyelid aperture.

Results: The overall response rate was significantly higher with tocilizumab (85%, OR 14.6, 95% CI 2.49-72.3; $P = .002$) and sirolimus (71%, OR 6.07, 95%CI: 1.39-21.2; $P = .018$) compared with methylprednisolone (29%). CAS response was significantly greater with tocilizumab (92%, OR 13.0, 95%CI: 1.94-148; $P = .012$) and sirolimus (71%) (OR 6.0, 95% CI 1.09-30.1; $P = .039$) versus methylprednisolone (50%). Proptosis response was significantly higher with tocilizumab (85%, OR 30.0, 95%CI: 4.27-153; $P < .0001$) and sirolimus (50%) (OR 6.67, 95%CI: 1.33-24.3; $P = 0.014$) versus methylprednisolone (16.6%). QoL response was significantly higher with tocilizumab (92%) (OR 18.0, 95%CI: 2.95-89.6; $P = .0005$) and sirolimus(65%) (OR 5.4, 95%CI: 1.24-22.7; $P = .037$) versus methylprednisolone (25%). Consistently, mean reductions in CAS, proptosis and QoL were significantly greater in both sirolimus ($P = .01$, .02 and .003 respectively) and tocilizumab groups (all $P < .0001$) compared to with methylprednisolone. Eyelid aperture and diplopia response rates did not differ significantly across groups. However, ocular ductions showed greater improvement in tocilizumab ($P = .009$) and sirolimus ($P = .01$) groups compared with methylprednisolone. No significant differences in adverse effects were observed across groups. On multivariate logistic regression, treatment with tocilizumab (OR 28.5,95% CI 3.1-64.1) and sirolimus (OR 7.35, 95%CI 1.33-53.5) were associated with a greater probability of response compared to methylprednisolone, regardless of baseline CAS, TRAb levels and smoking habit.

Conclusions: As novel therapies targeting precise molecular pathways are emerging in the treatment landscape of GO, both tocilizumab and sirolimus demonstrated significantly superior response rate compared to methylprednisolone, with comparable safety profiles and sustainable costs. If confirmed in randomized trials, these findings support the use of IL-6 inhibition and mTOR pathway modulation as first-line therapeutic strategies in GO.

Background: Chronic hypoparathyroidism (cHypoPT) is a rare endocrine disease caused by parathyroid hormone (PTH) deficiency, resulting in hypocalcemia, hypercalciuria, and low bone turnover. Despite conventional therapy (oral active vitamin D and/or calcium) and PTH replacement therapies, there is a need for additional treatments that stabilize calcium and provide control of symptoms and urinary calcium (uCa) excretion with balanced effects on bone. Eneboparatide is a long-acting, novel PTH 1 receptor agonist in development to meet these goals in patients with cHypoPT.

Objectives: To assess the efficacy and safety of daily subcutaneous (SC) eneboparatide for 24 weeks versus placebo in patients with cHypoPT, followed by a 28-week open-label extension (OLE).

Methods: Design: Phase 3, multicenter, randomized, double-blind, parallel, placebo-controlled, 24-week treatment, followed by an OLE (NCT05778071).

Participants: 200 adults (77% women; 154/200) aged 18-80 with cHypoPT were randomized 2:1 to eneboparatide or placebo. All patients who completed the 24-week period enrolled in the OLE ($n = 187/200$).

Intervention: After optimization to ensure albumin-adjusted serum calcium (ADsCa) was within 7.8-9 mg/dL (1.95-2.25 mmol/L), participants received a daily SC injection of eneboparatide or placebo. Conventional therapy was progressively reduced, and uptitration of eneboparatide was permitted according to a predefined protocol. Uptitration was not permitted in the last 4 weeks but was allowed again in the OLE.

Outcomes: The primary efficacy endpoint was the proportion of participants achieving independence from active vitamin D and therapeutic doses of oral calcium (ie, >600 mg/day) and normal ADsCa (8.3-10.6 mg/dL [2.07-2.64 mmol/L]). Key secondary endpoints included normalization of uCa excretion in participants with hypercalciuria at baseline and improvement in symptoms and physical functioning as assessed by disease-specific patient-reported outcomes (PROs). Safety parameters were evaluated, and bone safety measures included serum bone turnover biomarkers and bone mineral density (BMD).

Results: All primary and key secondary endpoints met statistical significance at week 24. A higher proportion of patients receiving eneboparatide achieved the primary endpoint versus placebo (31% [41/132] vs 6% [4/68] [$P < .0001$]). 57% (43/76) of hypercalciuric eneboparatide patients normalized uCa excretion versus 20% (9/45) of placebo patients ($P = .0001$). Through week 52, ADsCa was stable with conventional therapy and eneboparatide titration, and uCa excretion and PRO benefits persisted. Mild-to-moderate hypocalcemia was the most frequently reported adverse event. Changes in bone turnover biomarkers and BMD were consistent with balanced bone turnover.

Conclusions: Eneboparatide provides prolonged, positive results and clinical benefits for patients with cHypoPT with acceptable safety.

Background: Tumour-associated macrophages (TAM) are key regulators of the tumour microenvironment. Single-nucleus RNA data indicate that macrophage infiltration decreases from normal adrenal glands (NAG) to adrenocortical adenomas

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

(ACA) and carcinomas (ACC). However, a comprehensive characterisation of TAM polarisation across adrenocortical tissues is still lacking.

Aim: To characterise TAM infiltration and polarisation in ACA and ACC compared with NAG, and to investigate associations with clinicopathological characteristics.

Methods: Immunohistochemistry for CD16 (immune-infiltration marker), CD68 (M1/M2-marker), and M2-like markers (CD163, CD206, CD204) was performed in a cohort of 250 adrenocortical tumours (102 ACA and 148 ACC, including 130 primary and 18 recurrent/metastatic cases) and 16 NAG. Immunostaining was quantified using QuPath (v0.5.1) and expressed as percentage of positive pixels. Associations with circulating white blood cell parameters and clinicopathological characteristics, including hormonal secretion and clinical outcomes, were analysed.

Results: In NAG, median CD68 expression (2.4%) was lower than other markers (CD16 = 10.3%, CD163 = 5.8%, CD206 = 7.4%, CD204 = 8.2%; $P < .001$). In ACA and ACC, CD68 (1.6% and 1.81%) and CD206 (1.6% and 0.33%) were lower than CD16 (6.2% and 5.24%), CD163 (6.6% and 2.97%), and CD204 (7.9% and 4.96%) (all $P < .001$). While CD68 expression remained stable across all tissues, CD206 was reduced in ACA compared with NAG. In ACC, all M2-like markers were significantly decreased compared with both NAG and ACA ($P < .001$), and CD16 was lower than in NAG ($P = .036$), indicating a global loss of macrophage infiltration in ACC. No differences were observed between primary and recurrent/metastatic ACC.

In endocrine inactive ACA (EIA), but not in cortisol-producing ACA (CPA), CD68, CD16 and CD204 inversely correlated with circulating lymphocyte-to-monocyte ratio (LMR) (all $P < .05$). In ACC, this pattern was reversed, with CD68 inversely correlating with LMR only in cortisol-secreting tumours ($P = .020$). Cortisol excess was associated with reduced macrophage infiltration (lower CD68 and CD16 in CPA vs EIA and inverse correlation between cortisol and CD16 in ACC) and with distinct polarisation profiles: $CD163^+/CD206^-$ in ACA and $CD163^+/CD206^-/CD204^-$ in ACC (all $P < .05$). These associations were observed in women but not in men, suggesting sex-specific immune modulation.

Advanced ENSAT tumour stage, Ki67>10%, Weiss score ≥ 7 were associated with a $CD204^+/CD163^-/CD206^-$ macrophage profile ($P < .05$). No marker correlated with overall or progression-free survival.

Conclusions: TAM exhibit distinct and dynamic polarisation patterns across adrenocortical tissues. Cortisol excess and sex shape TAM phenotypes, while aggressive ACC is characterised by a specific TAM profile. These findings highlight the complexity and heterogeneity of the immune microenvironment in adrenocortical tumours.

RC1.1 - ECE_3438 - Thyroid disease during pregnancy: pre-existing disease or pregnancy-specific abnormality?

Leonie Warringa, Joris Osinga, Arash Derakhshan, Vincent Jaddoe, Sjoerd Van Den Berg, Robin Peeters and Tim Korevaar
Academic Center for Thyroid Diseases, Erasmus MC, Internal Medicine, Rotterdam, The Netherlands

Background: Both overt and subclinical thyroid disease are associated with adverse pregnancy outcomes such as miscarriage, preterm birth and pre-eclampsia. It remains unclear if thyroid function test abnormalities that are first diagnosed during pregnancy, result from the changes in gestational thyroid physiology or if they were already present prior to pregnancy and only diagnosed for the first time during pregnancy. However, preconception thyroid function data of women with gestational thyroid disease is scarce.

Methods: This study included 2718 women of the Generation R Next study, a population-based prospective cohort from pregnancy planning through postpartum in Rotterdam. The prevalence of abnormalities in thyroid function tests during both the preconception and gestational periods was assessed using various reference ranges, and individual trajectories were illustrated with Sankey diagrams. For those women with thyroid function test abnormalities in pregnancy, the mean thyroid hormones concentrations of preconception were determined.

Results: A subgroup of 503 women had thyroid function measurement during preconception and subsequent pregnancy. The median interval between the thyroid function measurements was 4.2 months (95% range 0.9-13.0). The overall prevalence of thyroid function test abnormalities was largely consistent during preconception and pregnancy. However, when assay cutoffs are applied during pregnancy, prevalence of eg subclinical hyperthyroidism changed from 1.4% to 8%. Women with (subclinical) hypothyroidism or hypothyroxinemia during pregnancy had a higher preconception TSH than euthyroid pregnant women (3.08 mU/L, 3.83 mU/L and 2.25 mU/L vs 1.65 mU/L) and women with hyperthyroidism during pregnancy had a significant lower preconception TSH (0.53 mU/L vs 1.65 mU/L). Women with hypothyroxinemia during pregnancy had a lower preconception FT4 than euthyroid pregnant women (15.6 pmol/L vs 17.9 pmol/L).

Conclusions: This is the first study to show that thyroid function test abnormalities identified during pregnancy are predominantly likely to present pre-existing thyroid disease rather than a failure to adapt to gestational thyroid physiological changes.

RC1.2 - ECE_3230 - Ocular surface dysfunction in Graves' orbitopathy (GO): quantitative conjunctival hyperemia as a novel tool to identify active GO

Federica Diana, Alessandro Colleo, Laura Pinna, Filippo Lixi, Francesco Nannipieri, Francesca Saba, Sara Bernardi, Silvia Corrias, Giuseppe Giannaccare, Stefano Mariotti, Francesco Boi and Giulia Lanzolla
Quartu Sant'Elena, Italy

Introduction: Dry eye disease (DED) is a frequent but underrecognized feature of Graves' orbitopathy (GO), and the relationship between ocular surface alterations, GO activity and severity remains insufficiently characterized. The aims of this cross-sectional observational study were 1) to compare the prevalence of DED in GD without GO, mild GO, moderate-to-severe active GO, and healthy controls; 2) to evaluate the relationship between a)non-invasive break-up time (NIBUT), b)tear meniscus height (TMH), c)meiboscore, and d)quantitatively assessed conjunctival hyperemia and the clinical activity score (CAS).

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Materials and Methods: A total of 138 consecutive patients with GD (F:101, M:37), including 109 with GO and 29 without GO, along with 67 age- and sex-matched healthy controls, were enrolled. DED was defined by the presence of symptoms (Ocular Surface Disease Index [OSDI] ≥33) and abnormalities in NIBUT and/or TMH, measured by Oculus Keratograph 5M.

Results: DED was diagnosed in 78/138 (56.5%) of GD patients with a significantly higher frequency compared with healthy controls (OR 6.2; 95% CI 3.01-13.27; $P < .0001$). Within the GD cohort, DED was more frequent in patients with GO compared with those without GO (OR 2.91; 95% CI 1.16-7.12; $P = .01$), with a significant difference between moderate-to-severe active GO and mild GO (OR 4.06; 95% CI 1.38-10.48; $P = .007$).

NIBUT was significantly reduced in patients with moderate-to-severe active GO compared with healthy controls ($P < .0001$), GD without GO ($P = .01$), and mild GO ($P = .013$). TMH was reduced in moderate-to-severe active GO compared with GD without GO ($P = .01$), mild GO ($P = .002$), and healthy controls ($P = .0005$). Meiboscore values were higher in GD patients without GO ($P = .01$), mild GO ($P < .0001$), and moderate-to-severe active GO ($P < .0001$) compared with healthy controls.

Quantitatively measured conjunctival hyperemia was significantly increased in moderate-to-severe active GO compared with mild GO ($P = .04$), GD without GO ($P = .003$), and healthy controls ($P < .0001$). Notably, conjunctival hyperemia showed a significant correlation with CAS ($P < .0001$, $r = 0.60$, 95% CI 0.45-0.71), which was confirmed in multivariate analysis ($P = .002$). Higher conjunctival hyperemia values were independently associated with active GO ($\chi^2 = 28.01$, $P < .0001$), with good discriminative ability (AUC = 0.76).

Conclusions: DED is highly prevalent in GD, particularly in patients with moderate-to-severe active GO. Among ocular surface parameters, quantitative conjunctival hyperemia is uniquely and independently associated with GO activity and may represent a useful tool to identify patients with active GO.

Abstract citation ID: lvag096.148

RC1.3 - ECE_1308 - Serum exosomes from patients with Graves' orbitopathy promote proliferation of orbital fibroblasts

Chia-Hung Lin[1] and Cheng-Yu Tsai[2]
[1]National Taiwan University Hospital, Zhongzheng District, Taiwan; [2]Taipei, Taiwan

Introduction: Graves' orbitopathy (GO) is characterized by orbital soft tissue expansion due to inflammation and adipogenesis. While the pathogenesis involves the activation of orbital fibroblasts (OFs), the specific intercellular signaling mechanisms remain incompletely understood. Exosomes are extracellular vesicles that facilitate cell-to-cell communication by transferring bioactive cargo, including proteins and nucleic acids, effectively protecting them from degradation in the systemic circulation. Previous research indicates that the protein and microRNA profiles within serum exosomes differ significantly among patients with GO, Graves' disease (GD), and healthy controls. However, the functional impact of these circulating extracellular vesicles on orbital tissue remains unclear. This study aimed to compare the effects of serum exosomes derived from patients with GO, GD without GO, and non-GD controls on the proliferation of OFs.

Methods: Serum exosomes were isolated from patients with GO, GD without GO, and non-GD controls. The exosomes were characterized by nanoparticle tracking analysis (NTA) and Western blotting for exosomal markers. Primary orbital fibroblast cell lines were established from orbital fat tissue obtained during surgery from both GO and non-GO subjects. OFs were co-cultured with serum exosomes (5 μg/well) from the distinct study groups. Cell proliferation was assessed using CCK8 and Crystal Violet assays up to 120 hours.

Results: A total of 12 participants (4 GO, 4 GD without GO, and 4 non-GD controls) were enrolled in this study for serum sample, while OFs were isolated from orbital fat obtained from 3 GO and 3 non-GO subjects. NTA and Western blot analysis confirmed the successful isolation of exosomes, showing typical size ranges and expression of exosomal markers. In cell proliferation experiments, both CCK-8 and Crystal Violet assays consistently demonstrated that treatment with serum exosomes from GO patients significantly promoted the proliferation of OFs compared to those treated with serum exosomes from GD without GO or non-GD controls (all $P < .05$). Notably, this pro-proliferative effect was universally observed regardless of whether the OFs derived from GO patients or non-GO subjects.

Conclusions: Our findings demonstrate that circulating serum exosomes in patients with Graves' orbitopathy possess the capacity to stimulate the proliferation of OFs, suggesting that serum exosomes may serve as an important mediator in the pathogenesis of GO. Ongoing studies are now focusing on the impact of these exosomes on myofibroblast differentiation, adipogenesis, and hyaluronan production, as well as identifying the specific protein or miRNA candidates within the exosomal cargo responsible for this effect.

RC1.4 - ECE_2209 - Gut microbiota in patients with Hashimoto's thyroiditis isolated or framed in polyautoimmunity

Marco Centanni, Ilaria Stramazzo, Anna Carretti and Camilla Virili
Endocrine Unit SM Goretti Hospital, Medical-Surgical Sciences and Biotechnologies, Sapienza University of Rome, Latina, Italy

Background: The colonization of germ-free murine models with different bacterial species enlightened the role of gut microbiota in shaping immune response. A role for gut microbiota has been hypothesized in both the pathogenesis and clinical presentation of different autoimmune disorders, including thyroid autoimmunity. No data are available about gut microbiota composition in patients with Hashimoto's thyroiditis (HT) associated to further non-endocrine autoimmune disease and this was the aim of the this study.

Patients and Methods: We examined the fecal microbial composition of 58 euthyroid adult patients (50F/8M) with HT subdivided into three groups: A) 24 with isolated HT (iHT); B) 22 with HT and gastric atrophy (HT+GCA) and C) 12 with HT and vitiligo (HT+VIT). None of the enrolled patients followed unbalanced diets, had further disorders, or used interfering drugs or

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

supplements. Nineteen matched healthy subjects (HD) were used as an internal control group. Microbiota composition was determined via 16s rDNA sequencing of the hyper-variable region V3-4 on Illumina MiSeq; α- and β-diversity indices and all statistical analysis were computed in Qiime2.

Results: All autoimmune patients showed a significant increase in the relative abundance of Firmicutes spp. and Actinobacteria spp. ($P < .00001$) and a reduced relative abundance of Proteobacteria spp. and Bacteroidetes spp. compared to HD ($P < .001$). Firmicutes/Bacteroidetes ratio was significantly higher in groups iHT, HT+GCA and HT+VIT than in HD ($P < .0001$); to note, this ratio was higher in HT+VIT group than in iHT patients ($P = .046$). α-diversity analysis revealed that both the richness and phylogenetic diversity of microbial communities were higher in every study group than in HD ($P < .001$ and $P < .0001$, respectively). Upon β-diversity analysis, the phylogenetic distance was highly clusterized in all patient groups compared to HD in both the Unweighted ($P = .001$) and the Weighted ($P = .001$) UniFrac analyses. The LEfSe analysis, revealed that Lachnospiraceae, Peptostreptococcaceae and Bifidobacteriaceae, encompassing the bacterial species *Fusicatenibacter saccharivorans*, *Anaerostipes hadrus* and *Blautia massiliensis*, were significantly associated to patients with HT+VIT (group C). In contrast, patients with HT+CAG (group B) were strongly associated to Lachnospiraceae and Streptococcaceae, with the prevalence of *Streptococcus salivarius*, whereas patients with HT were mostly associated to *Blautia faecis*, in accordance to ANCOM results.

Conclusions: These results described the variations in relative taxa abundances as well as phylogenetic distances between the gut microbial communities in autoimmune patients and those in healthy controls. Specific signatures at family and species level characterized the different autoimmune disorders associated to HT.

Abstract citation ID: lvag096.150

RC1.5 - ECE_1492 - Patterns of amiodarone-related thyroid dysfunction and associated comorbidities: a nationwide study

Adnan Zaina[1] and Sameer Kassem[2]
[1]*The Azrieli Faculty of Medicine, Clalit Medical Health Care Services, Endocrinology, Bar-Ilan University, Safed, Israel;* [2]*Carmel Medical Center, Internal Medicine, Technion Israel Institute of Technology, Haifa, Israel*

Introduction: Amiodarone is the most commonly used antiarrhythmic medication in the Western world, with a multifaceted mechanism of action. It is highly effective in treating and preventing both atrial and ventricular tachyarrhythmias. Despite its efficacy, amiodarone use is associated with significant side effects, including thyroid dysfunction, pulmonary fibrosis, hepatic impairment, and cardiac rhythm disturbances.

Objective: This study evaluated amiodarone-induced thyroid dysfunction (AITD) in previously euthyroid individuals and assessed associated cardiovascular risks.

Methods: A retrospective cohort of patients prescribed amiodarone from 2010 to 2022 was studied. Patients with a history of thyroid disease were excluded. Eligible participants with normal TSH levels were included. Patients were followed for up to 5 years and categorized into four groups based on TSH levels: euthyroid ($0.5 < TSH < 4.5$), amiodarone-induced hypothyroidism (AIH; $TSH > 10$), subclinical AIH ($4.5 < TSH < 10$), and amiodarone-induced thyrotoxicosis (AIT; TSH <). The AIT group was further subdivided into two groups: those with $TSH < 0.1$ and those with subclinical AIT ($0.1 < TSH < 0.5$). Outcomes included mortality, heart failure (HF), acute coronary syndrome (ACS), atrial fibrillation (AF), and ischemic stroke (IS).

Results: Of 43 880 records, 13 444 patients met the inclusion criteria (mean age: 73.8 ± 10.7 years; 55.9% male). During follow-up, 65.6% maintained normal TSH, 23.4% developed subclinical AIH, 7.1% developed AIH, and 3.8% developed AIT; 1.8% had subclinical AIT and 2.1% had AIT. AIH patients were older than previously reported. AIT patients were younger (71.3 ± 10.9 years) and predominantly male. AIT was associated with a higher risk of mortality (OR = 1.64; 95% CI, 1.24-2.17), particularly in the subclinical group. An increased risk of HF was observed in both AIH (OR 1.61, 95% CI 1.23-2.12) and subclinical AIH (OR 1.3, 95% CI 1.11-1.51).

Conclusions: This extensive study underscores the importance of risk assessment and management in patients receiving amiodarone. The average age of patients who developed thyroid disorders was higher than previously reported, particularly among those with hypothyroidism. The study emphasizes the need for vigilance not only in symptomatic patients with overt thyroid dysfunction but also in those with subclinical hypo- and hyperthyroidism. Although the drug remains a key treatment for arrhythmias, its potential complications, particularly thyroid dysfunction and associated cardiovascular risks, require frequent monitoring for early detection. Further research is needed to explore strategies that balance the therapeutic benefits of amiodarone against its risks and to evaluate appropriate alternative treatment modalities.

RC1.6 - ECE_2341 - Initiation and cessation of levothyroxine therapy: results from a largepopulation based cohort

Adrian Heald[1], Mike Stedman[2], Peter Taylor[3], Suhani Bahl[4], Anish Patil[5], Lakdasa Premawardhana[4], David Halsall[6], Ian Halsall[6], Antonio Bianco[7], Anna Bloomfield[8], Onyebuchi Okosieme[4] and Colin Dayan[9]
[1]*Department of Diabetes and Endocrinology, Salford Royal Hospital, Salford, United Kingdom;* [2]*Res Consortium, Andover, United Kingdom;* [3]*Cardiff University, Cardiff, United Kingdom;* [4]*Cardiff University School of Medicine, Cardiff, United Kingdom;* [5]*Salford Royal Hospital, Salford, United Kingdom;* [6]*Addenbrooke's Hospital, Cambridge, United Kingdom;* [7]*Medicine-Endocrinology, University of Chicago, Chicago, United States;* [8]*University of Lancaster, Lancaster, United Kingdom;* [9]*University of Birmingham, Birmingham, United Kingdom*

Introduction: Community prescriptions for levothyroxine (LT4) increased from 9-million annually in 2000 to 30-million in 2024. Understanding the outcomes of patients discontinuing treatment, particularly those on low LT4 doses, may inform as to the causes of this increase.

Methods: This study utilised patient-level primary care data 2010-2024, encompassing 2.85 million patients with recorded thyroid function tests (TFTs) and LT4 prescriptions.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Cohort definition: Patients with prescriptions for LT4 were divided into two classes: those on medication at the start of the period (2010)(Class A) and those who started LT4 medication during the period 2011-2023 (Class B). Codes for other thyroid disorders, including Thyrotoxicosis, were excluded.

Dose classification: A cut-off of an average prescribed LT4 of 80 mcg/day was derived from the recommended 1.6 mcg/d/kg +BMI to distinguish between lower doses (<80 mcg/day) and higher doses (>=80 mcg/day).

Results: In the period 2011-2023 of the total 1 097 586 with recorded TFT-results, 106 117 received LT4.

Treatment growth: The number of patients prescribed LT4 in GMCR increased from 17.0/1000 population in 2011 to 28.3/1000 population in 2023, an Annual Average Rate of Increase (AARI) of 4.4%. The use of low doses (<80 mcg/day) grew faster (AARI = 7.9%) than higher doses (>=80 mcg/day, AARI = 2.2%). The largest increases were observed in the elderly (80+years) and males for both dose categories.

Cessation: Of 58 070 patients who started LT4 post-2010 (Class B), 5100 (Class B2) stopped medication and had subsequent thyroid function measurement. Patients who stopped (Class B2) had a significantly lower median dose (50 mcg/day (Interquartile Range (IQR) 43-57 mcg/day) compared to those continuing (Class B1: 76 mcg/day (IQR 68-84 mcg/day). Median age at diagnosis for those who stopped was 45-years vs those continuing at 49-years). The median duration on medication for low-dose patients who stopped was 12-months.

TFT outcomes post-cessation (low dose patients <80 mcg/day): For patients who stopped (Class B2, $n = 4646$), the median serum TSH 12-months after stopping (3.5 mIUL (IQR 3.2-3.miU/L)) was lower than the median TSH 3-months before starting LT4 (6.9 mIU/L (IQR 6.6-7.2 miU/L), $P = .005$). Similarly, median FT4 12-months after stopping (13.4 pmol/L (IQR 13.3-13.6 pmol/L)) was higher than before starting (12.9 pmol/L (IQR 12.7-13.1 pmol/L), $P = .02$). TSH after treatment for 55% of patients who had stopped LT4 remained within the reference range.

Conclusions: LT4 use has increased by two-thirds, notably those started on very low doses, older individuals and males. A significant subset of patients, those started on lower doses of LT4, successfully discontinued treatment and maintained euthyroid status. This suggests that initial elevation of serum TSH may have been transient.

RC2.1 - ECE_2511 - Impact of SGLT2 inhibitors on telomere length in type 2 diabetes patients with and without chronic kidney disease

Yanina Rebrova[1,2,3], Yanina Saienko[1], Kostiantyn Midlovets[1], Dmytro Krasnenkov[1] and Borys Mankovsky[1,3]
[1]*D. F. Chebotarev Institute of Gerontology of the National Academy of Medical Sciences of Ukraine, Kyiv, Ukraine;* [2]*The Scientific and Practical Medical Center of Pediatric Cardiology and Cardiac Surgery of the Ministry of Health of Ukraine, Government Institution, Kyiv, Ukraine;* [3]*Shupyk National Healthcare University of Ukraine, Kyiv, Ukraine*

Background and Aims: Telomeres are repetitive DNA–protein structures at chromosome ends that maintain genomic stability and serve as markers of biological aging. Accelerated telomere shortening is associated with cellular senescence and increased risk of chronic diseases. In type 2 diabetes mellitus (T2DM), telomere attrition is enhanced due to chronic hyperglycemia, oxidative stress, and inflammation. Chronic kidney disease (CKD) further aggravates these mechanisms, making telomere length a potential biomarker of biological age and prognosis. Sodium–glucose cotransporter-2 (SGLT2) inhibitors are established nephroprotective agents and may also modulate cellular aging by reducing oxidative stress and inflammation. However, their effect on telomere length in patients with T2DM with and without CKD remains insufficiently studied. This study aimed to evaluate the association between SGLT2 inhibitor therapy and telomere length in patients with T2DM stratified by CKD status.

Materials and Methods: The study included 100 patients with T2DM divided into two groups: with CKD ($n = 50$) and without CKD ($n = 50$). In each group, half of the patients received SGLT2 inhibitor therapy. Clinical and laboratory characteristics were assessed in all participants. Telomere length in whole blood leukocytes was measured using monochrome multiplex quantitative polymerase chain reaction and expressed as the telomere-to-single-copy gene ratio (T/S). Age-adjusted residual telomere length (ΔT/S) was calculated using linear regression. Pathologically short telomeres were defined as ΔT/S values with a Z-score < -1. Statistical analysis included Mann–Whitney U test, χ^2 test, Pearson correlation analysis, and multiple linear regression.

Results: Patients with CKD were older, had longer diabetes duration, higher HbA1c levels, lower estimated glomerular filtration rate, and higher albuminuria compared with patients without CKD. Body mass index was comparable between groups, while cardiovascular disease was more prevalent in the CKD group. Residual telomere length (ΔT/S) was significantly lower in patients with CKD ($P = .035$). Pathologically short telomeres were more frequent in CKD patients than in those without CKD (20.8% vs 2.1%, $P = .0076$). In both groups, SGLT2 inhibitor therapy was positively associated with longer telomere length (CKD: $r = 0.50$, $P < .01$; non-CKD: $r = 0.60$, $P < .01$). In multivariate analysis, SGLT2 inhibitor therapy was the only independent predictor of longer telomere length ($P < .001$; $R^2 = 0.51$).

Conclusions: CKD is associated with accelerated telomere shortening in patients with T2DM. SGLT2 inhibitor therapy is associated with longer residual telomere length regardless of CKD status, suggesting a potential slowing of cellular aging.

RC2.2 - ECE_1370 - Prevalence and outcomes of DKA in type 1 and type 2 DM patients treated and not treated with SGLT-2 inhibitors

Elena Chertok Shacham[1,2], Sireen Sharif[3] and Snait Ayalon[3]
[1]*Emek Medical Center, Internal Medicine B, Afula, Israel;* [2]*Medical Faculty, Technion, Israel Institute of Technology, Haifa, Israel;* [3]*Emek Medical Center, Research Authority, Afula, Israel*

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Diabetic ketoacidosis (DKA) is a life-threatening complication occurring in people with type 1 (T1DM) and type 2 diabetes (T2DM). Sodium–glucose cotransporter-2 (SGLT2) inhibitors have raised concern for DKA risk.

Aim: To compare the clinical characteristics, biochemical presentation, and short- and long-term outcomes of DKA in hospitalized adults with T1DM and T2DM, including the impact of SGLT2 inhibitor therapy.

Methods: A retrospective cohort of 2283 adults (838 with T1DM; 1445 with T2DM) hospitalized with DKA between 2013 and 2023 across Clalit Health Services hospitals was analyzed. Patients were stratified by SGLT2 inhibitor use within 4 months before admission. Outcomes included AKI, 30-day mortality, 1-year mortality, and readmissions. One-year mortality was assessed using Cox proportional hazards regression, 30-day mortality using logistic regression, and recurrent readmissions using a negative binomial model.

Results: 2.3% ($N = 19$) of T1DM and 16% (235) of T2DM patients were treated with SGLT-2 inhibitors. A total of 115 patients from all cohorts presented with eu DKA, characterized by lower glucose and bicarbonate levels. In T2DM, the incidence of AKI was higher among SGLT2 users (26% vs 17%; $P = .030$), but lower in euDKA cases (9.6% vs 19%; $P = .020$).

In Cox regression analysis, treatment with SGLT2 inhibitors was independently associated with reduced 1-year mortality (HR 0.55, 95% CI 0.36-0.82; $P = .004$). Predictors of increased 1-year mortality included older age, higher HbA1c, cardiovascular disease, CKD, and insulin therapy. In the negative binomial model, higher readmission rates were independently associated with T1DM, higher HbA1c, higher BMI, CKD, and pre-admission insulin use, while SGLT2 inhibitor use was not linked to increased readmissions.

Conclusions: Pre-hospital SGLT2 inhibitor therapy in patients presenting with DKA was associated with improved long-term survival and no increase in short-term mortality, supporting their continued use with appropriate clinical monitoring.

Table 1 Cox proportional hazards model for 1-year mortality in T2DM.

Variable	Hazard ratio (HR)	95% Confidence interval	*P* value
HbA1c	0.85	0.80-0.90	<.001
Age (per year)	1.05	1.04-1.07	<.001
AKI	1.09	0.79-1.48	.062
BMI	0.98	0.96-1.00	.360
Congestive heart failure	1.01	0.91-1.48	.409
Chronic kidney disease	1.15	0.89-1.49	.013
Cardiovascular disease	1.14	0.85-1.51	.004
DPP-4 inhibitor	0.97	0.70-1.36	.866
Male sex	1.12	0.87-1.44	.378
GLP-1 receptor agonist	0.82	0.52-1.32	.215
Hypoglycemia (<70 mg/dL)	1.00	0.98-1.02	.308
Metformin	1.07	0.82-1.39	.230
Pre-hospital long-acting insulin	1.66	1.28-2.16	<.001
SGLT2 inhibitor	0.55	0.36-0.82	.004

RC2.3 - ECE_2061 - Liver Kiss1 is dispensable for systemic glucose homeostasis but essential for hepatic sex-biased transcriptomic patterns

Krisztina Kukoricza[1], Guillermo Martinez[1], Esperanza Uceda-@rodriguez[2], Suvi Ruohonen[1], Andreas Landin[3], Laura Mairinoja[1], Maria Vazquez[2], Claes Ohlsson[3], Marina Mora-Ortiz[2], Leena Strauss[1], Matti Poutanen[1] and Manuel Tena-Sempere[2]
[1]*University of Turku, Turku, Finland;* [2]*University of Córdoba, Córdoba, Spain;* [3]*Gothenburg University, Gothenburg, Sweden*

Kisspeptins, encoded by the *Kiss1* gene and originally identified as metastasis suppressors, are pivotal elements for reproductive regulation, but their expression in non-reproductive tissues, including the liver, suggests broader physiological functions. However, the physiological roles of liver-born kisspeptins remain largely unknown. We report here the generation and characterization of a liver-specific *Kiss1* knockout (LiKKO) mouse. Reproductive function was unaffected in LiKKO mice, that displayed also preserved glucose homeostasis in both sexes, despite previous reports suggesting a role of liver kisspeptin in insulin secretion and glycemic control. Conversely, ablation of hepatic *Kiss1,* expressed in hepatocytes, resulted in a clear sexually-dimorphic impact, as revealed by histological, expression and transcriptomic analyses. Female, but not male LiKKO mice displayed signs of low-grade, focal hepatic inflammation. In turn, qPCR analyses documented gene expression changes preferentially in LiKKO males, with altered mRNA levels of key factors for lipogenesis, beta-oxidation and metabolic sensing, despite consistent elevation of liver Ppar-γ expression in both sexes. In good agreement, RNA-seq transcriptomic analyses revealed a much larger number of differentially expressed genes in male vs female LiKKO mice (1.474 and 132, respectively), with divergent sex-dependent changes. Thus, while female LiKKO displayed deregulation of cancer-associated gene pathways and activation of pro-inflammatory genes, LiKKO males showed transcriptional alterations related to protein processing and the unfolded protein response, and induction of anti-inflammatory genes. Notably, loss of hepatic *Kiss1* markedly amplified the intrinsic sex differences in liver gene expression, suggesting a repressive role in the control of sex-biased transcriptional patterns. Pathway analysis of genes contributing to gained sex differences in the absence of *Kiss1* highlighted immune-related processes, rather than conventional metabolic pathways. Together, our findings indicate that liver-born kisspeptins are dispensable for systemic glucose homeostasis but play a major role in modulating key liver molecular pathways, including non-metabolic functions, in a sexually dimorphic manner.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Background: Sulfonylureas (SUs) remain widely used in the treatment of type 2 diabetes (T2D), with substantial interindividual variability in glycemic response. A loss-of-function variant in the glucose-dependent insulinotropic polypeptide receptor (*GIPR*) has been identified among patients with T2D who rely on SUs for optimal glycemic control. We therefore aimed to investigate the association between *GIPR* functional variants and SU responsiveness.

Methods: Adults with T2D were enrolled from the Korea Biobank Network at Seoul National University Hospital, where comprehensive clinical data and buffy coat samples are available. Participants who had stably maintained SU treatment for at least 12 months were included. Whole-exome sequencing was performed to identify *GIPR* variants predicted to be deleterious *in silico*. The primary outcome was achievement of HbA1c < 7.0% in 1 year following SU therapy. The study was approved by the Institutional Review Board (No. H-2310-141-1479). To explore underlying mechanisms, *in vitro* experiments were conducted using insulin-secreting cell lines and human islets exposed to chronic glucolipotoxicity, assessing SU-stimulated insulin secretion following modulation of GIPR expression via RNA silencing.

Results: A total of 153 participants (mean age 60 ± 11 years, 58% male, BMI 25.5 ± 3.7 Kg/m^2, and baseline HbA1c 8.4% ± 0.9%) were enrolled. We identified a common but predicted significantly deleterious *GIPR* variant, p.E354Q (minor allele frequency ~0.2; CADD score 32). Fifty-seven participants (37.3%) carried p.E354Q, including nine homozygous individuals. In multivariable regression models adjusted for age, sex, BMI, diabetes duration, eGFR, and concomitant anti-diabetic medications, carriage of p.E354Q was independently associated with a higher likelihood of achieving HbA1c < 7.0% (OR 2.201, 95% CI 1.033-4.689; $P = .041$), and with greater HbA1c reduction (standardized $\beta = .146$; $P = .008$).

In vitro GIPR downregulation restored SU-stimulated insulin secretion under conditions of metabolic stress, but not under physiological culture conditions. Given that SU action depends on cellular ATP levels and that high-glucose reduces cellular ATP through *VDAC1* induction, we further examined these pathways. Consequently, *GIPR* silencing attenuated glucolipotoxicity-induced *VDAC1* expression and increased cellular ATP retention, supporting enhanced insulinotropic effects of SUs.

Conclusions: The functional *GIPR* variant p.E354Q contributes to a genetic predisposition to enhanced SU responsiveness in Korean individuals with T2D. The high prevalence of this variant suggests potential utility as a precision medicine marker for optimizing SU therapy.

RC2.5 - ECE_2773 - Safety and efficacy of DCCR in patients with Prader-Willi syndrome who have pre-diabetes or diabetes

Jennifer Miller[1], Neil Cowen[2], Julie Perry[2], Jing Gong[2], Michael Huang[2], Anish Bhatnagar[2] and Evelien Gevers[3]

[1]*University of Florida, Gainesville, United States;* [2]*Soleno Therapeutics Inc., Redwood City, California, United States;* [3]*Queen Mary University of London, Barts and The London Medical School, Centre for Endocrinology, William Harvey Research Institute, London, United Kingdom*

Introduction: Diazoxide choline extended-release (DCCR) is an oral, once-daily medication in development for the treatment of patients with Prader-Willi syndrome (PWS) who have hyperphagia. Here, we present an analysis of the safety and efficacy of DCCR in individuals with PWS who have evidence of prediabetes (PD) or diabetes (DM) at baseline, using data from the Phase 3 studies.

Methods: Participants were classified as having evidence at baseline of PD or DM based on their medical history, use of glucose-lowering concomitant medications, and clinical laboratory values (using the American Diabetes Association [ADA] criteria of baseline fasting plasma glucose [FPG] ≥ 100 mg/dL or HbA1c ≥ 5.7%). Efficacy outcomes included the Hyperphagia Questionnaire for Clinical Trials (HQ-CT). Safety was assessed based on hyperglycaemia-related laboratory values and adverse events (AEs).

Results: A total of 125 participants ≥4 years-old with genetically confirmed PWS who received DCCR were identified in the Phase 3 studies. Of these, 75 (60.0%) participants had evidence of PD or DM at baseline (PD/DM group). Discontinuation rates were low regardless of baseline PD/DM status, with 29.3% of participants discontinuing in the PD/DM group compared with 32.0% in the non-PD/DM group. At Week 156, both groups showed comparable, statistically significant reductions in HQ-CT score from baseline (mean [SD] reduction: 12 [9.4] and 12.9 [8.5] for the PD/DM and non-PD/DM groups, respectively; $P < .0001$ for both).

Mean (SD) HbA1c at Baseline and Week 156 was 5.7 (0.43) and 5.9 (1.18) vs 5.3 (0.24) and 5.4 (0.37), respectively, for participants with and without PD/DM. As expected, hyperglycaemia-related AEs were reported for more participants with than without PD/DM (42.7% vs 24.0%, respectively), but these events were generally manageable.

Conclusions: In the DCCR Phase 3 studies, more than half of participants with PWS had baseline evidence of PD or DM. The results of our analysis show that DCCR can be administered safely and effectively to individuals with PWS who have PD/DM, and that HQ-CT improvements are comparable between participants with and without PD/DM. Hyperglycaemia-related AEs were, as expected, reported in a greater proportion of participants with PD/DM. After 156 weeks of DCCR treatment, mean HbA1c remained in the prediabetes range for those with PD/DM, and below for those without PD/DM. Notably, DCCR-treated participants remained on study and had high treatment compliance, regardless of PD/DM status or occurrence of hyperglycaemia-related AEs.

RC2.6 - ECE_3164 - Predictive utility of OGTT-based insulin resistance and secretion indices for type 2 diabetes—a focus on HOMA-IR and ISSI-2

Huiwen Tan[1], Qingyue Zeng[2], Danting Li[2] and Nong Li[3]

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

[1]Department of Endocrinology & Metabolism, West China Hospital Sichuan University, Chengdu, China; [2]Department of General Medicine, West China Hospital Sichuan University, Chengdu, China; [3]Department of Endocrinology and Metabolism, Karamay Hospital of Traditional Chinese and Western Medicine, Karamay, China

Objective: Insulin resistance (IR) and pancreatic β-cell secretion dysfunction are the core pathophysiological mechanisms underlying the development and progression of type 2 diabetes mellitus. Although multiple assessment indices are currently available in clinical practice, controversy remains regarding their predictive efficacy and optimal selection. This study aimed to identify optimal surrogate indices for IR and pancreatic β-cell function from oral glucose tolerance test (OGTT) data and evaluate their independent and combined value in predicting dysglycaemia and type 2 diabetes (T2D).

Methods: This cross-sectional analysis included 7588 participants in Karamay classified as normal glucose tolerance (NGT, $n = 992$), prediabetes (Pre-DM, $n = 4911$), or diabetes (DM, $n = 1685$). We evaluated eight IR indices (HOMA-IR, TyG index, TyG-BMI, METS-IR, VAI, CVAI, TG/HDL ratio, and Matsuda index) and ten secretion indices [basal secretion (HOMA-β, Fins/FPG ratio), early-phase secretion (IGI, CIR), overall secretion (AUC Ins/Glu ratio, 120-minute secretion index), and disposition indices (Insulin secretion-sensitivity index-2(ISSI-2), DI_Oral, DI_Basal, DI_TyG]. Relationships with three outcomes (DM vs non-DM; dysglycaemia vs NGT; DM vs Pre-DM) were analysed using restricted cubic splines (RCS). Diagnostic performance was assessed via ROC analysis, multivariable logistic regression, and incremental value (NRI/IDI).

Results: All metabolic indices differed significantly across groups (P-trend < .001), showing rising IR and a pattern of compensatory then failing secretion from NGT to DM. Restricted cubic spline analysis revealed significant nonlinear relationships with diabetes risk for most indices. Key inflection points were identified at 1.87 for HOMA-IR and 24.38 for ISSI-2. HOMA-IR and ISSI-2 were selected as optimal indices for resistance and secretion, respectively. For diabetes prediction, fully adjusted standardised odds ratios (ORs) were 2.04 (95% CI:1.92-2.18) for HOMA-IR and 0.07 (0.06-0.08) for ISSI-2, with AUCs of 0.71 and 0.11. The indices were negatively correlated (Spearman $r = -0.43$, $P < .001$). In combined models, ISSI-2 provided substantial incremental predictive value over HOMA-IR, increasing the AUC from 0.75 to 0.90 ($P < .001$). A significant multiplicative interaction was observed ($P < .001$). Stratification by median values created four pathophysiological subtypes with markedly different diabetes prevalence, ranging from 3.6% (low resistance/high secretion) to 44.5% (high resistance/low secretion) (P-trend<.001).

Conclusions: HOMA-IR and ISSI-2 are optimal indices for assessing IR and insulin secretion, exhibiting synergistic predictive value for identifying patients at the highest risk for developing diabetes. Their nonlinear relationships with diabetes risk offer early warning thresholds. A dual-index classification strategy provides a practical tool for risk stratification and precision prevention.

RC3.2 - ECE_1307 - Digital and intelligent pathology application in PitNETs

Nidan Qiao, Haixia Cheng and Yao Zhao
Shanghai, China

Background: The diagnosis, subtyping, and prognostic prediction of pituitary neuroendocrine tumors (PitNETs) primarily rely on hematoxylin and eosin (H&E)-based assessment and transcription factor (TF) immunohistochemical classification.

Purpose: This study aimed to develop and evaluate a foundation artificial intelligence (AI) model for improving diagnostic accuracy, subtyping, and recurrence prediction in PitNETs.

Methods: A novel AI model was constructed using a state-of-the-art pathology foundation model. It comprises three modules: 1) distinguishing PitNETs from other sellar region pathologies; 2) predicting TF expression from H&E slides and generating virtual TF-stained images; and 3) predicting post-surgical recurrence. The model was trained at a primary center and its performance was validated using multi-institutional data from nine external centers.

Results: This is a multicenter cohort study. We included four cohorts: 2146 patients with PitNETs (retrospectively recorded data), 1513 patients with PitNETs (prospectively recorded data), 1205 patients with PitNETs treated at nine external institutions (external data), and 1078 patients with other sellar region pathologies. Module 1 achieved high diagnostic accuracy, with 95.6% in the internal test set and 93.5% in external validation for differentiating PitNETs from other sellar region pathologies. It not only demonstrated diagnostic performance statistically comparable to senior pathologists ($P = .069$) and superior to intermediate/junior pathologists ($P = .001$ and $P < .001$, respectively), but also successfully learned pathologist-recognized morphological features. Module 2 generated virtual TF stains from H&E slides with high morphological concordance to ground-truth, maintaining 95.9% accuracy and reducing diagnostic workload of pathologists by 68.9% in external validation. Module 3 stratified PitNETs into three recurrence-risk profiles. In multivariable analysis, the high-risk versus low-risk profile showed a hazard ratio of 6.16 (95% CI 3.01-12.6, $P < .001$). Explainable analysis implicated stromal infiltration by fibroblasts, T cells, macrophages, and microvasculature in elevated recurrence risk. By integrating the three modules, a clinical web application was deployed to facilitate clinical implementation.

Conclusions: The application of digital and intelligent pathology for PitNETs enhances diagnostic precision, reduces pathologist workload, and provides robust prognostic stratification, supporting optimized clinical management.

Introduction: Cushing's disease (CD) is a rare disorder of cortisol excess associated with increased morbidity and mortality across all age groups. Available pharmacological treatments for paediatric CD are limited. LINC 5 (NCT03708900), an ongoing, open-label, non-comparative study, evaluates the pharmacokinetics, pharmacodynamics, efficacy and tolerability of osilodrostat in paediatric patients with CD.

Methods: Patients (6-<18 years old) with confirmed CD started osilodrostat 1 mg once/twice (<60/>60 kg) daily. Dose was titrated according to weight and response. Visits were every 3 weeks (W) to assess pharmacokinetic, pharmacodynamic, efficacy and tolerability parameters. Primary endpoint: pharmacokinetic parameters of osilodrostat up to W12. Secondary endpoints: efficacy of osilodrostat assessed by proportion of patients with normal mean urinary free cortisol (mUFC) and change from baseline in mUFC at W6 and W12, and safety and tolerability of osilodrostat up to W12. Analyses were descriptive, with no formal statistical testing.

Results: Of the 13 enrolled patients with CD (median [min–max] age: 11 years [8-15]), three (23.1%) had previously undergone pituitary surgery and nine (69.2%) were ineligible for surgery. Median (min–max) osilodrostat exposure was 12 W (11.4-12.7). Median average and highest median (min–max) daily osilodrostat doses were 4.2 mg (1.5-6.8) and 8.0 mg (2.0-10.0), respectively. Median C_{max} of osilodrostat (6.36 ng/mL) was achieved at a median time of 1.03 hours after the first dose of osilodrostat 1 mg. Median elimination half-life was 3.03 hours ($n = 7$). Treatment-emergent adverse events (TEAEs) occurred in 11 patients (84.6%). Five patients (38.5%) experienced TEAEs suspected as related to osilodrostat (all mild or moderate severity). No serious TEAEs or deaths were reported. No patients discontinued osilodrostat because of TEAEs. Two patients (15.4%) experienced an adverse event related to hypocortisolism (decreased UFC, $n = 1$) and adrenal-hormone-precursor accumulation (acne, $n = 1$). No patients experienced an adverse event related to pituitary-tumour enlargement, arrhythmogenic potential or QT prolongation. Median mUFC (nmol/24 h) values decreased from 408 at baseline to 341 at W6 and 99 at W12. The proportion of patients with mUFC not exceeding the upper limit of normal increased from 0.0% at baseline to 7.7% at W6 and 53.8% at W12. There were no clinically relevant changes from baseline in the signs and symptoms of hypercortisolism, systolic or diastolic blood pressure, pulse rate, or body mass index standard deviation score.

Conclusions: Osilodrostat demonstrated pharmacokinetic, safety and efficacy profiles consistent with adult data, supporting a positive benefit–risk profile in paediatric CD.

Background: Many patients with acromegaly do not achieve biochemical control (insulin-like growth factor I [IGF-I] ≤ upper limit of normal [ULN]) or symptom remission when treated with standard-of-care (SoC) somatostatin receptor ligands (SRLs; eg octreotide long-acting repeatable [LAR], lanreotide Autogel [ATG]). CAM2029 is a long-acting octreotide subcutaneous depot approved for maintenance treatment in adults with acromegaly in Europe and the UK. CAM2029 has demonstrated improved biochemical control in patients with IGF-I ≤ 2 × ULN on baseline SoC. Here, we report the effect of CAM2029 on both biochemical control and acromegaly symptoms in this subset of patients based on the previously received SRL (either octreotide LAR or lanreotide ATG).

Methods: Patients directly enrolled on day 1 of ACROINNOVA 2 had IGF-I ≤ 2 × ULN on prior baseline SoC. CAM2029 20 mg was administered every 4 weeks (W) (±1 W) via a pre-filled pen for 52 W. The primary endpoint was long-term safety; secondary endpoints included biochemical control rate (IGF-I ≤ ULN per age and sex; W50/52 mean) and symptom control (Acromegaly Index of Severity [AIS]; range 0-18, lower scores indicate better symptoms) over time.

Results: A total of 81 patients were directly enrolled, of which 59 previously received octreotide LAR and 22 lanreotide ATG.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

CAM2029 was well tolerated, with a safety profile consistent with SoC. The observed proportion of patients with biochemical control increased from baseline (14.8%) to W50/52 (36.5%) following CAM2029 treatment (Table). Similar increases were observed from baseline to W50/52 in both the prior octreotide LAR (15.3% to 37.0%) and lanreotide ATG (13.6% to 35.0%) groups (Table). Acromegaly symptoms improved from baseline to W52 in all groups (Table).

	Any SRL	Octreotide LAR	Lanreotide ATG
Patients with mean IGF-I ≤ ULN, *n*/*N* (%)			
SoC baseline	12/81 (14.8)	9/59 (15.3)	3/22 (13.6)
W24	26/75 (34.7)	22/54 (40.7)	4/21 (19.0)
Mean W50/52	27/74 (36.5)	20/54 (37.0)	7/20 (35.0)
Mean AIS overall score (standard deviation)			
SoC baseline	(*n* = 81) 4.4 (3.6)	(*n* = 59) 4.4 (3.6)	(*n* = 22) 4.5 (3.6)
W24	(*n* = 76) 3.5 (2.7)	(*n* = 55) 3.5 (2.8)	(*n* = 21) 3.6 (2.7)
W52	(*n* = 73) 3.3 (2.9)	(*n* = 53) 3.4 (2.9)	(*n* = 20) 3.1 (2.9)

Conclusions: CAM2029 provides sustained improvements in biochemical and symptom control in patients with IGF-I ≤ 2 × ULN, regardless of previous SRL treatment. These results support CAM2029 as a long-term treatment option for acromegaly, including in patients without normalised IGF-I on octreotide LAR or lanreotide ATG.

RC3.5 - ECE_2991 - Cancer risk and GLP-1 receptor agonist use in patients with Cushing syndrome

Idit Dotan[1], Yaron Rudman[1], Ilan Shimon[1], Maria Fleseriu[2] and Amit Akirov[1]
[1]*Beilinson Hospital, Institute of Endocrinology, Petah Tikva, Israel;* [2]*Departments of Medicine and Neurological Surgery, Oregon Health & Science University, Portland, United States*

Introduction: Glucagon-like peptide-1 receptor agonists (GLP-1RAs) are commonly used for the treatment of type 2 diabetes mellitus and obesity; however, their impact on cancer in patients with Cushing syndrome (CS) remains unknown. We have previously reported a higher incidence of malignancy in patients with CS compared with matched population controls. We aimed to assess the association between GLP-1RA treatment and malignancy risk in patients with CS.

Methods: We conducted a nationwide retrospective cohort study including patients with endogenous CS diagnosed between 2000 and 2023 using the Clalit Health Services database in Israel. Patients with adrenal carcinoma or ectopic CS were excluded. Exposure to GLP-1RAs was defined as ≥3 prescription dispensations following CS diagnosis, including patients who initiated treatment prior to diagnosis. Patients treated with GLP-1RAs were compared with those never exposed (≤2 prescriptions). Time-varying analyses were performed. The primary outcome was incident malignancy following CS diagnosis. A secondary outcome included malignancy occurring after at least 6 months of GLP-1RA treatment and up to 12 months after treatment discontinuation.

Results: The cohort included 609 patients with CS (mean age ± SD, 48.05 ± 7.17 years; 65.02% women), of whom 137 received GLP-1RAs and 472 were not treated. Median GLP-1RA treatment duration was 44.80 months (IQR, 25.26-76.71). Age, sex distribution, and prevalence of malignancy prior to CS diagnosis were similar between groups. Median BMI at CS diagnosis was higher among GLP-1RA–treated patients (34.57 vs 27.74 kg/m^2), as were rates of hypertension (66.42% vs 53.39%), diabetes mellitus (48.91% vs 15.47%), and ischemic heart disease (17.52% vs 9.75%). Two-year CS remission rates were comparable. Over up to 15 years of follow-up, malignancy following CS diagnosis occurred in 10.22% of GLP-1RA–treated patients and 16.53% of non-treated patients. In a time-varying Cox model, GLP-1RA treatment was not associated with increased malignancy risk (HR 0.79; 95% CI, 0.48-1.29). GLP-1RA–treated patients experienced a reduction in median BMI during follow-up, whereas BMI remained stable in non-treated patients. In an exploratory early analysis, all-cause mortality was lower among GLP-1RA–treated patients (16.06% vs 25.21%).

Conclusions: In this large nationwide CS cohort, GLP-1 RA treatment, used in approximately 20% of patients, was not associated with an increased risk of malignancy. These findings support the oncologic safety of GLP-1RAs in this high-risk population. Observed differences in mortality should be interpreted cautiously and warrant further investigation.

RC3.6 - ECE_2932 - Voice-based machine learning model in acromegaly: single-center cohort

Seyma Aksoy[1], Emre Saygili[2], Esra Hatipoglu[1] and Mutlu Niyazoğlu[1]
[1]*Basaksehir Cam and Sakura City Hospital, Department of Endocrinology, University of Health Sciences, Istanbul, Türkiye;* [2]*Department of Endocrinology, Canakkale Onsekiz Mart Universty, Canakkale, Türkiye*

Background: Acromegaly, a rare endocrine disorder driven by excessive growth hormone (GH) and insulin-like growth factor-1 (IGF-1) production, is often characterized by insidious onset and prolonged diagnostic delays. While vocal changes are recognized clinical features, the diagnostic utility of advanced deep learning architectures for non-invasive screening remains underexplored. Although a single study has utilized machine learning for acoustic assessments in this population (Vouzouneraki K. et al.), integration of the Wav2vec 2.0 model has not yet been evaluated. This study aimed to assess the efficacy of voice analysis using Wav2vec 2.0-based machine learning as a novel digital biomarker for identifying acromegaly.

Methods: This single-center case-control study included 70 patients with acromegaly and 68 age- and sex-matched controls with non-functional pituitary adenomas. Clinical status was

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

defined by standard biochemical guidelines, assessing GH/IGF-1 levels, symptoms, comorbidities, and residual tumor presence. Voice samples were acquired using a standard mobile phone in a quiet clinical setting; participants recorded three repetitions of the Turkish words "zaman" and "simit". Acoustic signals were resampled to 16 kHz using Wav2vec 2.0 to extract high-dimensional embedding vectors (size 1024). Embedding vectors were combined with patient and control labels. These features were used to train and validate Random Forest (RF), Extreme Gradient Boosting (XGBoost), Logistic Regression (LR), and Support Vector Machines (SVM) algorithms via 80:20 test split and five-fold cross-validation.

Results: No significant demographic disparities existed between the acromegaly (mean age 45.5 years) and control (mean age 47.5 years) cohorts. In acromegaly group, the gender ratio was 57.1% female ($n = 40$) and 42.9% male ($n = 30$); in control group, it was 61.8% female ($n = 42$) and 38.2% male ($n = 26$). Within acromegaly group, 40% had active disease, 60% in remission. Median IGF-1 levels were 1.8 × upper limit of normal (ULN) (inter quantile range (IQR) 1.4-2.8) in active disease and 1.0 × ULN (IQR 1.0-1.0) in remission ($P < .01$). The patient group included both newly diagnosed and long-term following patients. Mean disease duration was 62 months (range:1 month-37 years). In the five-fold cross-validation, LR model demonstrated superior performance with an Area Under the Curve (AUC) of 0.86 (95% confidence interval (CI): 0.83-0.89), sensitivity of 0.83 (CI:0.78-0.88) and a specificity of 0.90 (CI: 0.86-0.94). Independent test set validation confirmed high accuracy in the LR model (AUC: 0.847; specificity:0.93; sensitivity:0.82).

Conclusions: Digital voice analysis leveraging the Wav2vec 2.0 model provides high diagnostic accuracy for acromegaly. Voice-based analysis serves as a promising, non-invasive digital biomarker for acromegaly.

Keywords acromegaly, digital biomarker, machine learning, Wav2vec 2.0, voice analysis

RC4.1 - ECE_2133 - Loss of Y chromosome in male infertility

Valentina Griseta[1,2], Giorgia Spaggiari[1,3], Samantha Sperduti[2], Antonio Raffaele Michele Granata[1,3], Livio Casarini[2], Manuela Simoni[1,2] and Daniele Santi[1,2,3]
[1]*Unit of Endocrinology, Department of Medical Specialties, Azienda Ospedaliero-Universitaria of Modena, Modena, Italy;* [2]*Modena, Italy;* [3]*Unit of Andrology and Sexual Medicine of the Unit of Endocrinology, Department of Medical Specialties, Azienda Ospedaliero-Universitaria of Modena, Modena, Italy*

Introduction: When alterations in semen parameters cannot be explained, the contribution of as-yet-unidentified genetic factors is advocated. The Y chromosome (chrY) includes many genes essential for spermatogenesis. It is susceptible to age-related mitotic errors that may lead to chrY loss in some of the germ cells, negatively impacting fertility. Loss of chrY has been associated with several pathological conditions, but its potential role in the pathogenesis of male infertility remains poorly investigated. This study aims to explore the association between chrY loss and male infertility.

Methods: Male partners of infertile couples attending our Unit were prospectively enrolled and divided into cases (semen parameters <5th WHO percentile) and controls (semen parameters >5th WHO percentile). In addition to semen analysis, all participants underwent blood testing for follicle-stimulating hormone (FSH), luteinizing hormone (LH), total testosterone, estradiol, prolactin and prostate-specific antigen (PSA) levels. To quantify the percentage of chrY loss, genomic DNA was extracted from peripheral blood, and X and Y chromosome copy numbers were assessed using droplet digital-PCR. Target genes on chromosome X (*AMELX* and androgen receptor gene, *AR*) and Y (*AMELY* and *USP9Y*) were selected. The analysis was performed in technical duplicate by counting the copies of *AMELY* and *AMELX*, *USP9Y* and *AR* genes by TaqMan assays, and calculating the percentage loss of chrY using the equation: (copies of Y/copies of X) × 100.

Results: This 'interim analysis' included 114 patients: 73 cases (64.0%) and 41 controls (36.0%). Age (38.0 ± 5.7 vs 35.3 ± 5.0 years) and FSH levels (7.8 ± 5.7 vs 4.9 ± 2.5 IU/mL) were significantly higher in cases than in controls ($P = .014$ and $P = .004$, respectively, Mann–Whitney's *U*-test). No differences were observed for BMI ($P = .921$), LH ($P = .252$), and estradiol levels ($P = .730$). The *AMELY/AMELX* ratio was 0.983 ± 0.034 in cases and 0.999 ± 0.001 in controls ($P = .003$, Welch's t-test). Comparable results were obtained considering the *USP9Y/AR* ratio.

Discussion: Patients with altered semen parameters had higher FSH levels, consistent with impaired spermatogenetic function. At the same time, they had greater loss of chrY compared with controls. Although these patients were also significantly older than controls, the average age of both groups remains deeply below 50, the age threshold after which the loss of chrY has been widely demonstrated in the literature. For this reason, our finding may represent a factor directly associated with poorer semen quality.

Conclusions: These results suggest that chrY loss assessment may represent a new potential etiology of male infertility, possibly independent of ageing.

RC4.2 - ECE_2674 - Efficacy of gonadotropin therapy to induce spermatogenesis and fertility in men with pathologic gonadotropin deficiency

Joshua Gialouris[1,2], Ann Conway[1,2], Amanda Idan[2], Sasha Savkovic[2], Raquel Hermosilla[2], Christopher Muir[2], Feyrous Bacha[2], Ting Zhang[1,2], Wanxin Hou[1,2], Veena Jayadev[2] and David Handelsman[1,2]
[1]*Andrology, ANZAC Research Institute, Sydney, Australia;* [2]*Andrology, Concord Repatriation General Hospital, Concord West, Australia*

Gonadotropin treatment to induce spermatogenesis for gonadotropin-deficient men is the only medically treatable cause of male infertility. However, time-dependent analyses of fertility outcomes in large cohorts are lacking. We evaluated the time to, and determinants of, fertility outcomes in men with pathologic gonadotropin-deficiency undergoing gonadotropin treatment. Consecutive infertile men ($n = 99$) with congenital or acquired pathologic gonadotropin deficiency were treated with urinary or recombinant hCG and FSH according to

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

a standardized protocol between 1983 and 2024. Kaplan-Meier and multivariate Cox regression analyses examined time to prespecified sperm density thresholds and pregnancy. Men aged 35 ± 1 years with female partners 30 ± 1 years underwent 160 treatment cycles. The proportion (%) and median time (months) to achieve sperm thresholds of >0, >2, >5, >10 and >20 million sperm/mL was 78% (5 months), 56% (12 months), 49% (14 months), 37% (21 months) and 24% (not determined) respectively. The major determinant of successful pregnancy was the presence of adverse fertility factors in the female partner (HR 0.20, 95% CI 0.10-0.40; $P < .001$), with time to pregnancy also significantly increased by the presence of adverse female factors (15 vs 43 months; $P < .0001$). The median sperm concentration associated with partner pregnancy was 2.8 (0.2, 52.6) M/mL without and 35.4 (15.1, 52.6) M/mL with adverse female factors. Most men with pathologic gonadotropin deficiency treated with hCG/FSH achieve sperm output and fertility within a year, with greatest impact on fertility outcomes being detrimental female fertility factors.

RC4.3 - ECE_1016 - Manipulation of peripheral androgen signaling in the treatment of PCOS-associated metabolic dysfunction

Caitlin MacRae[1,2], Elodie Kip[1], Benjamin Garfinkel[3] and Rebecca Campbell[1,2]
[1]Centre for Neuroendocrinology, University of Otago, Dunedin, New Zealand; [2]Maurice Wilkins Centre, Auckland, New Zealand; [3]Alnylam Pharmaceuticals, Cambridge, United States

Hyperandrogenism is the most common diagnostic criterion of polycystic ovary syndrome (PCOS), and androgen signalling through the androgen receptor (AR) is implicated in promoting reproductive and metabolic dysfunction. However, the specific physiological targets of female androgen excess in driving PCOS-associated pathology remain poorly understood. Studies in animal models of PCOS suggest liver and adipose tissue may be critical sites of androgen-induced metabolic dysfunction in mouse models of PCOS. We therefore aimed to investigate the therapeutic potential of tissue-specific AR silencing RNA (siRNA) for alleviating PCOS-like metabolic dysfunction. Two preclinical mouse models of PCOS, exposing female mice to androgens (or vehicle controls) either during the prenatal period (gestation day 16-18; prenatal androgenisation, PNA) or chronically from postnatal day 21 (peripubertal androgenisation, PPA), were treated with PBS or with proprietary, tissue-specific AR siRNA to induce AR-knockdown (ARKD). Delivery of AR siRNA, initiated at 3 weeks of age, was directed to either the liver (liver-ARKD), adipose tissue (adipose-ARKD), or both (combination-ARKD). Male and female PNA mice demonstrated mild metabolic impairments (significantly increased weight gain, impaired glucose homeostasis) compared to controls, while PPA females were significantly heavier and showed robust impairments in glucose and insulin homeostasis compared to control females. However, ARKD was unable to alleviate these effects regardless of target tissue, despite inducing a 5-fold reduction in AR gene expression as measured by qPCR. While tissue-level analysis is ongoing to investigate AR protein knockdown, lipid accumulation and metabolic gene expression, evidence to date does not support liver or adipose tissue-specific silencing of AR as a therapeutic treatment for PCOS-associated metabolic dysfunction. These data suggest that other tissues such as the brain may be responsible for androgen-induced metabolic disturbances in PCOS. Alternatively, hyperandrogenism during key developmental windows may program future androgen-independent alterations in metabolic tissue function. Further understanding of how androgens drive reproductive and metabolic programming in females will be critical for the future development of targeted treatments for PCOS.

RC4.4 - ECE_3142 - Androgen receptor PROTAC ARV-110 ameliorates cardiometabolic complications in a mouse model of polycystic ovary syndrome

Damian Romero[1,2], Jelina Basnet[1], Samar Rezq[1], Alexandra Huffman[1] and Licy Yanes Cardozo[1]
[1]Jackson, United States; [2]Pharmacology and Toxicology, University of Mississippi Medical Center, Jackson, United States

Background: Polycystic ovary syndrome (PCOS) is characterized by hyperandrogenism and metabolic dysfunction. Androgens act primarily through the androgen receptor (AR); however, AR antagonists are limited by hepatotoxicity. ARV-110 is a novel AR proteolysis-targeting chimera (PROTAC) that induces AR degradation. We hypothesized that ARV-110 would dose-dependently improve androgen-mediated metabolic dysfunction in a hyperandrogenemic mouse model of PCOS, with tissue-specific molecular effects.

Methods: Three-week-old female C57BL/6N mice were rendered hyperandrogenemic by chronic dihydrotestosterone (DHT, 8 mg) exposure for 12 weeks and treated with vehicle (VEH), low-dose ARV-110 (ARV-L, 1 mg/kg/day), or high-dose ARV-110 (ARV-H, 10 mg/kg/day) for the last 8 weeks. Body weight, body composition, adipose tissue depot mass, glucose homeostasis, renal and hepatic injury markers, and liver and kidney proteomics were assessed.

Results: DHT-VEH mice exhibited significant increases in body weight, total fat mass, and lean mass compared with controls. Both ARV-L and ARV-H attenuated DHT-induced body weight gain and fat mass expansion without reducing lean mass. DHT increased visceral (retroperitoneal and mesenteric) and subcutaneous adipose tissue depot weights, all of which were dose-dependently reduced by ARV-110.

DHT impaired glucose homeostasis, evidenced by increased fasting glucose, elevated HOMA-IR, and worsened glucose tolerance during oral glucose challenge. ARV-110 improved glucose tolerance at both doses, with ARV-H additionally attenuating fasting insulin resistance. DHT-induced hyperleptinemia was dose-dependently reversed by ARV-110, while adiponectin levels remained suppressed.

DHT increased kidney weight and markers of renal injury, which were partially or fully improved by ARV-L. In contrast, ARV-H increased renal injury markers in control mice. Hepatic analysis showed that ARV-L had minimal effects on liver weight and circulating ALT, AST, and LDH, whereas ARV-H caused marked

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

hepatomegaly, increased liver enzymes, and worsened steatosis, indicating hepatotoxicity.

Proteomic analysis revealed that in the liver, ARV-110 treatment was the primary driver of gene expression changes, with similar effects in control and DHT-treated mice, while DHT contributed modest, secondary effects. In the kidney, DHT strongly altered gene expression, and ARV-110 produced a dose-dependent modulation in DHT-treated mice without fully restoring control profiles. Pathway analysis showed that many DHT-activated translational and proteostatic pathways were reversed by ARV-110, particularly at the high dose.

Conclusion and Significance: ARV-110 improves hyperandrogenemia-driven obesity, adipose expansion, and glucose intolerance in a mouse model of PCOS. Low-dose ARV-110 provides metabolic and renal benefits with minimal toxicity, whereas high-dose ARV-110 induces hepatic and renal injury. These findings support AR PROTACs as promising, dose-sensitive therapeutic candidates for PCOS-related metabolic disease.

Uterine leiomyomas (ULs) are common, benign neoplasms, in women of reproductive age. ULs may cause severe anemia, after heavy menstrual bleeding, pelvic pain, infertility and significant morbidity, often necessitating invasive, surgical intervention. Despite their prevalence, the pathogenesis of ULs remains not fully elucidated, with roles for both hormonal and epigenetic factors, which modulate gene expression, through variations of micro-ribonucleic acids (miRNAs). Anti-Müllerian hormone (AMH) has been shown to be a potential suppressor of ULs, but its interactions with regulatory miRNAs, like miR-181a, is still unexplored in this context.

In this study, we investigated the interplay between the AMH and miR-181a, in UL pathophysiology. The expression profiles of AMH, AMHRII, and miR-181a were characterized in UL tissue versus normal myometrium. The functional relationship and downstream molecular mechanisms were examined in UL cells, focusing on SMAD and PI3K/AKT/mTOR signaling pathways, along with cellular outcomes, like proliferation and senescence.

We found that both AMH and its receptor, AMHRII, were overexpressed in ULs compared to normal myometrium, as was miR-181a. Functionally, AMH upregulated miR-181a expression in UL cells. This interaction induced a tumor-suppressive state, by activating the SMAD1/4 pathway, as well as the phosphorylation and nuclear translocation of SMAD1. Concurrently, AMH inhibited the pro-proliferative PI3K/AKT/mTOR axis, through PTEN upregulation and triggering cellular senescence. Notably, the absence of miR-181a reversed this effect of AMH, causing it to promote proliferation via the PI3K/AKT/mTOR pathway, by increasing the expression of pro-proliferative proteins, such as XIAP.

Our results revealed that AMH and miR-181a maintain a homeostatic, growth-suppressive axis in ULs. Disruption of this balance, particularly miR-181a deficiency, can convert the role of AMH, from inhibitor to promoter of proliferation. A critical protective mechanism is shown in ULs, where AMH and miR-181a cooperate to inhibit growth. This positioned AMHRII signaling and the AMH/miR-181a axis as crucial therapeutic targets for non-surgically treating UL and other benign, Müllerian-related conditions.

Background: The gonadotropin-releasing hormone (GnRH) stimulation test remains the gold standard for diagnosing central precocious puberty (CPP), however, it is invasive and time and resource consuming. Traditional sampling schedules were defined using outdated assay technologies, and their current diagnostic relevance warrants reassessment.

Purpose: To evaluate the diagnostic performance of luteinizing hormone (LH) and follicle-stimulating hormone (FSH) at specific sampling time points during the GnRH stimulation test, aiming to determine whether the protocol can be simplified without compromising diagnostic accuracy.

Materials and Methods: This multicenter, cross-sectional study included children aged ≥3 years with suspected CPP who underwent a standard GnRH stimulation test between 2015 and 2024. Serum LH and FSH were measured by electrochemiluminescence immunoassay at baseline and at 30, 60, 90, and 120 minutes following intravenous gonadorelin administration. CPP was defined as a peak LH ≥ 5 IU/L. Diagnostic performance

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

metrics were calculated for each time point, and agreement between the 60 and 120-minute protocols was assessed using the kappa coefficient (κ)

Results: Of the 209 included children (mean age 7.2 ± 1.3 years; 4.8% male), 146 (69.9%) were diagnosed with CPP. In the CPP group, mean LH peaked at 30 minutes (19.2 ± 15.3 IU/L); however, reliance on this time point alone would have missed 2 CPP cases. While LH measured at 60, 90, and 120 minutes achieved 100% sensitivity, specificity, and accuracy, the 30-minute time point demonstrated lower performance, with a sensitivity of 98.8%, a negative predictive value of 95.2%, and an accuracy of 99.1% (κ = 0.97). No additional diagnostic benefit was observed beyond 60 minutes.

Conclusions: LH measurement at 60 minutes after GnRH stimulation provides maximal diagnostic accuracy for CPP. Given the almost perfect agreement with the standard 120-minute test, a shortened 60-minute protocol can safely replace longer schedules, reducing invasiveness for the patient and resource utilization without compromising diagnostic reliability.

RC5.1 - ECE_1698 - Adherence to ESE and SfE guidance in the management of severe hyponatraemia: a multicentre audit of real-world practice

Amanda Ling Jie Yee[1,2], Samama Rafi[3], Aspasia Manta[1,2], Alexander Chandran[4], Sam Solanki[4,5], Poppy Wardley[5], Azheem Ijaz[4], Aravind Manoj[4], Zain Mahmood[4], Ahmed Iqbal[4,5], Muhammad Fahad Arshad[4,5] and Punith Kempegowda[1,2]

[1]Department of Applied Health Sciences, University of Birmingham, Birmingham, United Kingdom; [2]University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; [3]Birmingham, United Kingdom; [4]Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom; [5]University of Sheffield, Sheffield, United Kingdom

Background: Severe hyponatraemia is a high-risk endocrine emergency. The European Society of Endocrinology (ESE) and the Society for Endocrinology (SfE) guidelines recommend symptom-based use of hypertonic saline (HTS), monitored care, and prevention of overly rapid sodium correction. However, real-world adherence is uncertain.

Objectives: To evaluate adherence to ESE and SfE guidelines in severe hyponatraemia management and identify key patient safety gaps and real-world practice patterns.

Methods: We conducted a retrospective, multicentre audit of adult inpatient admissions between 1 January and 31 December 2024 with a serum sodium concentration ≤125 mmol/L. Adherence to key standards from ESE and SfE guidelines was assessed, including documentation of symptom severity, appropriate use of HTS for moderate or severe symptoms, monitoring following HTS administration, correction rates within recommended limits, location of care during HTS administration, completeness of diagnostic evaluation, and involvement of specialist endocrinology services.

Results: A total of 1121 admissions were analysed. Median age was 72.0 years (IQR 62.0-82.0), and 52.0% ($n = 583$) were female. Symptom-based assessment was documented in 87.8% ($n = 984$) of admissions; 13.9% ($n = 137$) had severe and 19.9% ($n = 196$) moderate symptoms. Based on ESE/SfE criteria, 29.7% ($n = 333$) of patients met indications for HTS, yet only 26 (7.8%) received HTS. In contrast, 7 patients with mild symptoms received HTS despite not meeting guideline criteria.

Among 33 HTS prescriptions, 54.5% ($n = 18$) were administered in monitored environments (emergency department or intensive care), and 54.5% ($n = 18$) followed bolus-based regimens. Serum sodium was rechecked within one hour of the first bolus in 66.7% ($n = 22$) of cases.

Sodium correction data at 24 hours were available in 58.9% ($n = 661$) of admissions, and overcorrection (>10 mmol/L/24 h) occurred in 4.7% ($n = 53$). Diagnostic evaluation was incomplete, with urine sodium and osmolality measured in 50.0% and 50.9% of admissions, respectively. Specialist endocrinology input was documented in 27.0% of cases. Osmotic demyelination syndrome was confirmed in one case (0.1%) and suspected in three (0.3%).

Conclusions: Management of severe hyponatraemia was suboptimal, characterised by underutilisation of HTS in eligible patients, inconsistent monitoring, and incomplete diagnostic evaluation. These findings highlight significant patient safety gaps and underscore the need for system-level interventions, including education, standardised pathways, and improved access to specialist endocrine input.

Abstract citation ID: lvag096.170

RC5.2 - ECE_2298 - Empagliflozin for paraneoplastic SIAD-related hyponatraemia: real-world multi-centre evidence

Mohammed Ahmed[1], Mark Pearce[1], Maria Michaelidou[1], Shaishav Dhage[1], Jamie Weaver[1], Tim Cooksley[1], Jan Hoong Ho[1], Laura Cove-Smith[2,3] and Safwaan Adam[1]

[1]The Christie NHS Foundation Trust, Endocrinology, Manchester, United Kingdom; [2]Manchester, United Kingdom; [3]Manchester University NHS Foundation Trust, Manchester, United Kingdom

Background: Hyponatraemia secondary to paraneoplastic syndrome of inappropriate antidiuresis (SIAD) is common and often refractory to conventional therapies such as fluid restriction. Treatment with tolvaptan is associated with significant risk of over-correction.[1] Empagliflozin has demonstrated an aquaretic sodium-raising effect in randomised trials, but real-world durability and clinically useful predictors of early response remain uncertain.[2]

Methods: We analysed 42 adults with confirmed SIAD treated with empagliflozin. Demographics, baseline biochemistry, and serial sodium measurements were extracted from clinical records. The primary aim was the assessment of early sodium correction (day 4 and week 1) and long-term sustained response. Predictors of the magnitude of sodium rise were assessed using Spearman correlation (ρ). Overall hyponatraemia outcome was categorised based on the latest available sodium measurement. Continuous variables are presented as median (IQR).

Results: The results are summarised in the table. No sodium overcorrection was observed (>12 mmol/l rise in 48 hours). One patient developed ketonuria without acidosis and other developed genital thrush. The degree of absolute sodium rise at one month was strongly associated with baseline severity of

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

hyponatraemia, with lower baseline sodium predicting a greater absolute rise ($\rho = -0.53$, $p = 0.005$).

Table. Baseline characteristics and clinical outcomes ($N = 42$).

Variable	Value
Median age (IQR), years	71 (64-74)
Female, *n* (%)	21 (50%)
BMI, kg/m^2 (IQR)	24.3 (21.6-27.9)
Baseline Na, mmol/L (IQR)	122 (118-124)
Empagliflozin dose: 10 mg/25 mg	19 (45%)/23 (55%)
Median sodium (mmol/l) rise (IQR) at:	
48 hours	4 (2-5)
Day 4	7.5 (5-12)
1 week	8.5 (3.8-12.3)
Day-4 responders (sodium rise ≥5), *n* (%)	19/24 (79%)
Week-1 responders (sodium rise ≥5), *n* (%)	26/36 (72%)
Normal sodium at 1 month (≥133 mmol/L), *n* (%)	15/26 (58%)
Sustained sodium ≥125 mmol/L, *n*/*N* (%)	
1 month	24/26 (92%)
3 months	18/19 (95%)
6 months	12/13 (92%)
12 months	5/5 (100%)
Median follow-up, days (IQR)	77 (17-194)
Overall hyponatraemia outcome, *n* (%):	
Normalised	25 (60%)
Improved	11 (26%)
Relapsed	4 (10%)
Stabilised	2 (5%)

Conclusions: Empagliflozin was effective in achieving and sustaining sodium correction in SIAD, with 86% of the cohort showing normalised or improved outcomes. These real-world data support the use of SGLT2-inhibitors as a potent and well-tolerated treatment option for SIAD.

Context: Early recognition of progressive central precocious puberty (CPP) from benign variants of puberty can be challenging. Insulin-like growth factor 1 (IGF-1) reflects both growth acceleration and early gonadal maturation and is typically elevated in progressive CPP cases.

Purpose: To validate the diagnostic performance of IGF1-SDS in the evaluation of precocious puberty and to assess an IGF1-SDS cutoff of 1.44.

Methods: Prospective multicenter study conducted from September 2024 to September 2025. Among 431 participants referred for early signs of puberty, 385 were eligible and enrolled in the study protocol, with clinical, laboratory and radiologic evaluation. Serum IGF-1 was assessed using IMMULITE assay and IGF1-SDS were calculated.

Results: 305 (79%) participants had progressive CPP, 92% were girls and 48% were diagnosed on tanner stage II. IGF1-SDS values were significantly higher in progressive CPP cases (mean 2.35 ± 0.95 versus 0.94 ± 0.69; $P < .001$) and its area under the curve (AUC) was 0.866 (95% confidence intervals (IC) 0.826-0.907). Using a predefined IGF1-SDS cutoff of 1.44, sensitivity was 82.3% (95% CI 78.0-86.6), specificity of 81.3% (95% CI 72.7-89.8), overall accuracy 82.1% (95% CI 78.2-85.9), positive predictive value 94.4% (95% CI 91.6-97.1), positive likelihood ratio 4.39 (95% CI 3.90-4.94), negative likelihood ratio 0.22 (95% CI 0.20-0.24) and diagnostic odds ratio of 19.7 (10.3-37.7).

Conclusions: IGF-1 SDS assessment in children presenting with early pubertal signs provides meaningful risk stratification between progressive and non-progressive or incomplete forms of puberty. An IGF-1 SDS value above 1.44 is associated with a significantly increased post-test probability of progressive central precocious puberty, supporting its use as a rule-in threshold. However, values ≤1.44 do not allow reliable exclusion of the disease.

[1]Istanbul, Istanbul, Türkiye; [2]Endocrinology, Istanbul, Türkiye; [3]Faculty of Health Sciences, Okmeydanı Prof. Dr. Cemil Taşçıoğlu City Hospital, Endocrinology, İstanbul, Türkiye; [4]Faculty of Health Sciences, Başakşehir Çam ve Sakura City Hospital, Endocrinology, İstanbul, Türkiye; [5]İstanbul, Türkiye; [6]Kartal Dr. Lütfi Kırdar City Hospital, Endocrinology, Faculty of Health Sciences, İstanbul, Türkiye

Aim: Micromegaly refers to a subgroup of patients who exhibit clinical features suggestive of acromegaly, have mildly elevated IGF-1 levels, normal basal GH concentrations, and GH suppression during an oral glucose tolerance test (OGTT). In this study, we aimed to present the clinical, biochemical, imaging characteristics, and pathological findings of micromegaly cases.

Methods: A total of 46 patients followed at five tertiary endocrinology centers were included in the study. Eligibility criteria comprised IGF-1 levels between 1.0 and 1.3 times the upper limit of normal (ULN), basal GH $\leq$ 2 ng/mL, and availability of pituitary MRI imaging. Demographic characteristics, comorbidities, clinical features including acral and facial changes, headache, sweating, and snoring, as well as laboratory, radiological, and pathological data were retrospectively reviewed.

Results: 27 (58.6%) were female and 19 (41.4%) were male in this study. The mean age at diagnosis was 46 years (range 19-70). Diabetes mellitus was present in 9 patients (19%) and hypertension in 19 (41%). Acral features were observed in 31 patients (67%). Enlargement of the hands and feet was reported in 14 patients (30%), headache in 15 (32%), snoring in 13 (28%), and excessive sweating in 18 (39%). Mean IGF-1 levels were 1.18-fold above the upper limit of normal. The mean basal GH concentration was 0.89 ng/mL, and the mean nadir GH level during OGTT was 0.53 ng/mL. In all patients who underwent OGTT, nadir GH values after OGTT were suppressed to below 1 ng/mL. Pituitary MRI revealed microadenomas in 22 patients (47%) and macroadenomas in 7 (15%). No pituitary lesion was detected in 14 patients (30%), while 3 patients exhibited an empty sella. All patients with macroadenomas underwent surgery. Among those with microadenomas, 9 underwent surgery, 2 received medical therapy, and 11 were managed with follow-up. Of the 16 operated patients (34%), immunohistochemistry demonstrated isolated GH positivity in 3, combined GH, PRL, and PIT-1 positivity in 3, plurihormonal staining patterns in 3, and isolated PIT-1 positivity in 1. No adenomatous tissue was identified in 2 patients, while pathology results remain pending in 4. In patients managed with follow-up, no acromegaly-specific treatment has yet been initiated; comorbidities were treated, and patients are being monitored clinically, biochemically, and radiologically for a mean duration of 3.6 years.

Conclusions: Pituitary lesions and variable hormone co-expression patterns accompanying GH positivity in micromegaly indicate that these patients should be monitored using a clinical approach similar to that applied in acromegaly.

[1]Department of Medicine IV, LMU University Hospital, LMU Munich, Munich, Germany; [2]Department of Nuclear Medicine, LMU University Hospital, LMU Munich, Munich, Germany; [3]Deggendorf Institute of Technology, Deggendorf, Germany

Background: Sleep disturbances and fatigue are common early features of CS, often persist after remission, and substantially impair quality of life. Despite their high prevalence, the objective characteristics and determinants of sleep disturbances in CS remain poorly characterised.

Aim: Our aim was to assess the diagnostic utility of actigraphy in suspected endogenous cortisol excess, to chracterise sleep patterns in patients with CS in long-term remission with persistent versus recovered adrenal insufficiency, and to examine associations between late-night salivary cortisol (LNSC) and actigraphy-derived sleep parameters.

Methods: In this prospective single-centre cohort study conducted at LMU Hospital Munich, two cohorts were enrolled: patients undergoing diagnostic evaluation for suspected CS (cohort 1) and patients with CS in remission (cohort 2), stratified by adrenal recovery status. All participants completed continuous 21-day wrist actigraphy (ActTrust 2, Condor Instruments), provided daily LNSC samples, and answered the Munich ChronoType Questionnaire.

Results: Among individuals evaluated for suspected CS, 16 were diagnosed with active disease and 13 had CS excluded. Actigraphy revealed similarly reduced sleep quality in both groups with low sleep efficiency, increased nocturnal wakefulness, and fragmented but overall largely preserved circadian rest-activity patterns. No actigraphy parameters differentiated active CS from excluded CS (all $P > .1$), except for an earlier chronotype in active CS ($P = .022$). In the remission cohort (total $n = 23$), sleep quality and circadian rest-activity patterns were similarly impaired in those with persistent ($n = 13$) and recovered ($n = 10$) adrenal insufficiency, with no significant group differences in sleep efficiency, nocturnal wakefulness, chronotype, or social jetlag (all $P > .1$). Circadian metrics were largely comparable, with only non-significant trends toward earlier acrophase and onset of the least active nocturnal period in patients with persistent adrenal insufficiency ($P = .079$ and $P = .095$, respectively). LNSC measurements showed pronounced intra- and interindividual variability across all groups, with consistent evaluations in active CS, partial evaluations in individuals with excluded CS, and frequent evaluations in patients with persistent adrenal insufficiency receiving hydrocortisone replacement, likely reflecting replacement pharmacokinetics. Correlations between LNSC and actigraphy-derived sleep parameters were weak ($r < 0.3$) and inconsistent across groups.

Conclusions: Extended actigraphy demonstrated clinically relevant sleep impairment across all patients assessed for CS but did not provide diagnostic discrimination for active disease. During remission, sleep quality remained impaired irrespective of adrenal recovery status. Given the marked variability of LNSC and its limited relationship with objective sleep measures, improved biomarkers and monitoring strategies are needed to enhance the detection and follow-up of CS.

RC5.6 - ECE_2859 - Mitochondrial metabolic dependencies shape anterior pituitary homeostasis and disease

James Kaufman-Cook[1], Yasmine Kemkem[1], Miriam Vazquez Segoviano[1], Olivia Sherwin[1], Bence Kover[1], Paul Carroll[2] and Cynthia Andoniadou[1]

[1]*King's College London, Centre for Craniofacial and Regenerative Biology, London, United Kingdom;* [2]*Guy's and St. Thomas' NHS Foundation Trust, Department of Endocrinology, London, United Kingdom*

Cell metabolism is fundamental to anterior pituitary (AP) function, enabling endocrine cells to meet the energetic and biosynthetic demands of hormone production and secretion. While pituitary cell types are presumed to rely on distinct metabolic pathways to support hormone synthesis and cell fate decisions, these dependencies remain poorly defined. Notably, mutations in mitochondrial metabolic enzymes, including succinate dehydrogenase (SDH) and isocitrate dehydrogenase (IDH), are associated with endocrine tumours, including the pituitary, implicating metabolic dysregulation in pituitary disease. However, whether altered cellular metabolism is sufficient to drive pituitary pathology *in vivo* is unknown. Understanding the metabolic dependencies that govern AP homeostasis has translational relevance for regenerative strategies and targeted metabolic therapies.

Using mouse models, we disrupted key oxidative metabolic enzymes, including Succinate Dehydrogenase B (SDHB) in the TCA cycle and electron transport chain (ETC), and NDUFS4 in Complex I of the ETC, to define the role of oxidative metabolism in pituitary homeostasis and disease.

We used complementary *Cre* drivers to mutate *Sdhb* either during embryonic pituitary development (*Hesx1*$^{Cre/+}$;*Sdhb*$^{fl/fl}$) or postnatally in the SOX2^{+} stem cell compartment (*Sox2*$^{CreERT2/+}$;*Sdhb*$^{fl/fl}$). In both models, *Sdhb* loss activated pseudohypoxic signalling in the AP, with upregulation of *Hif1a* and downstream targets, and induced metabolic reprogramming in pituitary stem cells consistent with a Warburg-like shift. Despite these tumour-associated metabolic changes, SDHB deficiency alone was insufficient to drive pituitary tumour formation. Instead, SDHB loss resulted in marked pituitary hypoplasia with preserved lineage commitment and differentiation.

Consistent with this, *Ndufs4*$^{-/-}$ mice exhibited pituitary hypoplasia with reduced AP proliferation, increased lactate dehydrogenase expression, and expansion of the SOX2^{+} stem cell compartment, without loss of endocrine cell identity. Notably, *Ndufs4* deficiency also led to the formation of ectopic, fully specified pituitary tissue connecting the anterior and intermediate lobes, characterised by a patterned SOX2^{+} stem cell epithelium.

Together, these findings reveal that intact oxidative metabolism is a critical constraint on AP growth and tissue architecture but is dispensable for lineage specification and endocrine identity. This unexpected dissociation between growth and differentiation highlights a remarkable capacity for metabolic adaptation in the AP and provides new insight into how mitochondrial dysfunction contributes to pituitary hypoplasia, ectopia, and tumour susceptibility, with implications for regenerative and metabolic therapeutic strategies.

RC6.1 - ECE_3949 - Combining bulk, single nuclei and single cell RNA sequencing of phaeochromocytomas and paragangliomas to gain insights into metastatic potential

Mark Quinn[1], Dimitria Brempou[1], Harit Kohli[1], Bertille Montibus[1], Louise Izatt[2], Paul Carroll[2], Cynthia Andoniadou[1] and Rebecca Oakey[1]

[1]*King's College London, London, United Kingdom;* [2]*Guy's and St Thomas' N H S Foundation Trust, London, United Kingdom*

Background: Phaeochromocytomas and paragangliomas (PPGLs) often display a unique pattern of metastatic spread whereby, following initial tumour resection, there is a prolonged period of remission before recurrence arises with metastatic spread. Treatment options for metastatic PPGLs are limited and outcomes are poor. Current tools used to predict metastatic risk underperform. A biomarker is urgently needed to identify patients at high risk of metastasis. This is especially relevant given the genetic drivers involved in PPGLs and the ever-increasing pool of patients identified as carries of these variants through cascade screening. RNA-sequencing has shown significant utility in increasing our understanding of PPGLs. Bulk RNA sequencing (RNA-seq) has been used to describe PPGLs in clusters and single nuclei RNA sequencing (SnRNA-seq) has helped to refine this classification even further. With this work we will combine bulk, single nuclei and single cell RNA sequencing (ScRNA-seq) to identify transcriptomic markers of metastatic disease in PPGLs.

Methods: We have collated bulk RNA-seq datasets from publicly available sources ($n = 326$) with data from our own, local tumour collections ($n = 27$) to compare the transcriptome of metastatic to non-metastatic PPGLs focusing on *SDHx* mutations. We have performed a differentially expressed gene (DEG) analysis of metastatic and non-metastatic PPGLs to identify genes that may have a role in metastatic disease. We have also performed Sn and ScRNA-seq on 8 samples including one that had metastasized at the time of resection and another that metastasized following a period of remission.

Results: Our bulk RNA-seq analyses identified the following overexpressed genes in metastatic PPGLs: *FN1, VEGFA, CDK1, PTTG1, ABCA12* and *MMP9*. Both *ABCA12* and *MMP9* were consistently overexpressed when our analyses isolated *SDHx* samples. ScRNA-seq provided a detailed picture of the tumour microenvironment (TME) of PPGLs when compared to SnRNA-seq. The cellular populations seen in PPGLs across the spectrum of genotypes were comparable. There were differences in the expression of *PTTG1*, *MMP9* and *ABCA12* in the chromaffin cells and TME of pre-metastatic and metastatic PPGLs that warrant further investigation.

Discussion: We have demonstrated that bulk RNA-seq can be used to identify genes that are overexpressed in metastatic PPGLs. Sn and ScRNA-seq allow us to explore the expression profile of tumour cells and the TME. *PTTG1* and *MMP9* have a defined role in the development of metastasis in a number of cancers. By combining these state-of-the-art techniques we show that their overexpression in the TME of PPGLs may have a role in metastatic spread.

Pheochromocytomas and paragangliomas, collectively known as PPGLs, are a group of neuroendocrine neoplasms originating from the adrenal medulla or from the sympathetic or parasympathetic extra-adrenal paraganglia. These tumors are characterized by the highest reported rate of heritability. We conducted a multicenter retrospective study to investigate the association between genetic alterations and PPGLs' clinical characteristics.

Data were collected across six Italian centers, involving a total of 346 patients: 227 (65.6%) pheochromocytomas and 119 (34.4%) paragangliomas. The cohort consisted of 56.4% females and 43.6% males, with a mean age at diagnosis of 46.6 ± 16.8 years and a mean survival from diagnosis of 10.4 ± 8.3 years. The overall mortality rate was 9%, but only 6 patients (1.7%) died because of tumor progression.

Incidental detection of PPGL was the most frequent diagnostic modality (47.2%, $n = 161$), followed by diagnosis guided by clinical symptoms (42.2%), mainly palpitations and hyperhidrosis. Genetic screening was the least common, accounting for 10.6% of cases ($n = 36$). As expected, tumor size correlated significantly with the mode of diagnosis ($P < .0001$): symptomatic patients presented with larger lesions (55.0 ± 31.2 mm), while tumors identified through genetic screening were the smallest (37.6 ± 23.7 mm).

Germline mutations were found in 44.9% of cases, more frequently in extra-adrenal than in adrenal PPGLs (64.0% vs 41.4%). Furthermore, gene mutation varied by site ($P < .0001$): NF1 and VHL predominated in adrenal locations, SDHB was the most frequent in extra-adrenal abdominal, while SDHD in the head-and-neck and PPGLs. Genetic analysis revealed a strong link between germline mutations and markers of tumor aggressiveness. Indeed, 20/141 (14.2%) of genetic PPGLs had metastatic spread compared to 12/167 (7.2%) of sporadic cases. Specifically, SDHB-mutated PPGLs showed a highest frequency of metastases (10/18 cases, $P < .0001$), while SDHD-mutated tumors were significantly associated with multifocality (4/5 cases, $P < .001$). Recurrence rate was significantly higher in genetic than in sporadic tumors (20.3% vs 8.4%, $P = .004$).

This large multicenter Italian cohort confirms that PPGLs carry a high germline mutation burden comparable to contemporary European series. Genetic status strongly correlates with aggressive clinical behavior, particularly in SDHB-mutated tumors, which showed the highest metastatic risk, while SDHD mutations were associated with multifocality and increased recurrence. Importantly, genetically screened patients presented with significantly smaller tumors, underscoring the clinical value of early genetic testing. Overall, germline alterations emerge as the major determinants of phenotype and prognosis in PPGLs.

RC6.3 - ECE_1687 - Menopause and its associated hormonal shifts define distinct cytokine and immune cell profiles

Angela Rubio Tenor[1,2,3], Jesús Roca-García[1,2,3], Alicia Santamaría-Quiles[1,2,3] and Ines Pineda-Torra[1,2,3]

[1]Cabimer, Sevilla, Spain; [2]Andalusian Public Foundation for Progress and Health ("Fundación Progreso y Salud"-"FPS"), Seville, Spain; [3]Universidad de Sevilla, Seville, Spain

Cardiovascular disease (CVD) is the leading cause of mortality for women worldwide. Atherosclerosis is the main pathology underlying ischemic CVD events, resulting from abnormal blood lipid concentrations and exacerbated inflammation. The menopausal transition represents a profound endocrine, metabolic and immune change in women's cardiovascular risk trajectory. Hormonal changes after menopause include elevated gonadotropins (FSH, LH) and decreased levels of oestrogens, progesterone and testosterone. Loss of estrogen compromises endothelial function and the atheroprotective properties of high-density lipoprotein (HDL), accelerating immune cell activation, foam cell formation, and early plaque development. The overall aim of this study was to understand how menopause and associated hormonal changes affect CV risk in women to improve prevention strategies and personalized health. Specifically, we aimed to understand the molecular and immune alterations associated with menopause.

Women with no history of CVD aged 21-35 and 57-63 years ($n = 127$) were recruited, menopausal status was recorded as well as clinical data to stablish their CV risk. Women with autoimmune diseases, pregnant or recently vaccinated were excluded. Hormone and cytokine serum profile and PBMC immunophenotyping by Cytometry by time of flight (CyTOF) was performed. Post-menopausal women were further stratified by their inflammatory status using the GlycA "inflammaging" biomarker.

CyTOF experiments revealed changes in postmenopausal women with pro-inflammatory trends in $CD4^+$ T cell subpopulations, including an increase in Th17 cells and a concomitant increase in Th2 and Tregs. Moreover, postmenopausal women exhibited a significant increase of CCL11 (eotaxin) compared to pre-menopausal women. Stratification of postmenopausal women by inflammation using GlycA revealed a pro-inflammatory profile in the high inflammation group with higher levels of CCL5, implicated in monocyte-driven atherosclerosis, and other

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

cytokines such as TNF-α, a central driver of chronic inflammation linked to CVD. Additionally, these postmenopausal women with elevated inflammation showed significantly increased oestradiol concentrations and a trend towards increased total testosterone alongside reduced levels of LH and FSH. Across the cohort, estrone showed the highest number of significant positive correlations with cytokines. When restricting the analysis to only postmenopausal women, total testosterone and estrone were positively correlated with a core set of pro-inflammatory cytokines (CCL4, CCL5, IL-9, and TNF-α).

In conclusion, our findings show that postmenopausal status is associated with a pro-inflammatory T-cell landscape and elevated CCL11. Notably, we demonstrate that high-inflammation postmenopausal women exhibit a distinct hormonal and cytokine profile, implicating an altered hormonal environment as a driver of the chronic low-grade inflammation that accelerates atherosclerotic pathology.

Background: Radiogenomics, early recognition of genomic profile exploiting radiomics, is an emerging approach for non-invasive tumor characterization, never performed in adrenocortical carcinoma (ACC). However, its clinical translation is limited by poor generalisability and small single-center cohorts. Early non-invasive genomic profiling could enhance risk stratification of ACC patients.

Methods: From 123 patients, we selected 81 patients (28 males) with histologically confirmed ACC from three tertiary referral centers (Bologna $n=5$; Birmingham, $n=31$; Paris, $n=45$) with availability of S-GRAS parameters plus sex, pre-operative contrast-enhanced venous-phase CT scan and targeted next-generation sequencing on formalin-fixed paraffin-embedded tumor tissue for *NF1* and genes of β-catenin (*CTNNB1, ZNRF3, APC*), tumor suppressor (*TP53, RB1, CDK4*) and chromatin remodeling (*TERT, MEN1*) pathways. IBSI-compliant radiomic features were independently extracted using harmonized parameters. Only reproducible, multicenter-shared features were retained, followed by correlation-based reduction to eight informative variables. Predictive models were developed to identify overall mutational status and gene-cluster alterations (β-catenin, tumor suppressor, chromatin remodeling) using: radiomics-only, clinical-only (S-GRAS parameters and sex), and combined models (best four radiomic and best four clinical features). Overall mutational status was predicted using deep learning with 10-fold cross-validation (60% training, 20% testing, 20% holdout), while cluster-specific predictions used logistic regression.

Results: Overall, a wild-type genetic profile was observed in 41 ACCs (51.0%). Alterations of tumor suppressor genes were most frequent ($n=20$ (24.7%); *TP53* = 15; *RB1* = 4; *CDK4* = 1), followed by those of β-catenin signalling ($n=17$ (21.0%); *CTNNB1* = 9; *ZNRF3* = 8; *APC* = 0), chromatin remodeling genes ($n=12$ (14.8%); *MEN1* = 8; *TERT* = 5) and *NF1* ($n=9$ (11.1%)). The eight most informative variables were Ki67 (weighted importance = 0.18), maximum intensity (0.17), ENSAT stage (0.14), intensity variance (0.14), median intensity (0.12), GLCM joint maximum (0.11), resection status (0.07) and age (0.07). Combined clinical–radiomic models outperformed single-modality approaches for overall mutational status prediction, achieving higher F1-score (0.8) compared with radiomics-only (0.73) or clinical-only models (0.75). Cluster-specific alteration prediction was feasible across all genomic groups, with the highest performance for β-catenin pathway variants hold by combined model (0.57), for tumor suppressor mutations hold by clinical-only model (0.54) and for chromatin remodeling alterations hold by radiomics-only model (0.56).

Conclusions: This multicenter radiogenomic study demonstrates that integrating radiomic features with clinical variables enables non-invasive prediction of mutational status in ACC. The use of harmonized feature extraction and cross-center validation supports the generalisability of these models. Combined clinical–radiomic approaches appear most robust and may represent a valuable tool for early recognition of ACC genetic variants.

Medicine, Uppsala Universitet, Uppsala, Sweden; [9]Wolfson Brain Imaging Centre, Cambridge University, Cambridge, United Kingdom

Background: Adrenocortical-specific PET tracers, such as 11C-metomidate (11C-MTO), show high diagnostic accuracy in adrenocortical carcinoma (ACC), but unfavorable radiochemical properties had limited its clinical implementation. Para-chloro-2-[18F]fluoroethyletomidate (18F-CETO), a new PET tracer with improved radiochemical properties, may enable broader use.

Aims: To assess the diagnostic performance of 18F-CETO-PET/CT in ACC as compared with 18F-FDG-PET/CT, and explore how their combined use correlates with ACC phenotype.

Methods: In this bicentric study, ACC patients underwent 18F-CETO-PET/CT and 18F-FDG- PET/CT. A validation cohort included patients undergoing PET/CT with either 18F-CETO or 11C-MTO. Lesions were classified as having low or high PET-uptake. Tumors underwent RNA-sequencing or immunohistochemistry to characterize adrenocortical-specific features.

Results: Twenty patients underwent combined CETO-FDG-PET/CT and 235 ACC lesions were detected; 21 18F-CETO-high/18F-FDG-low, 162 18F-CETO-high/18F-FDG-high and 52 18F-CETO-low/18F-FDG-high. For the initial tumor staging of 13 patients, compared with 18F- FDG, 18F-CETO detected more lesions in 5/13 and an equivalent number in 8/13. Contrary, at restaging 5/7 patients had fewer lesions on 18F-CETO than on 18F-FDG ($P = .002$). A similar pattern was observed in the validation cohort, that also identified 11% (8/70) patients with heterogenous 18F-CETO/11C-MTO uptake, associated with poor survival (median 9 months).

Conversely, patients with homogenously 18F-CETO-low ACC uptake showed favorable survival (median 56 months). 11C-MTO/18F-CETO-PET tracer uptake showed positive correlation to CYP11B1 mRNA expression as well as adrenocortical differentiation.

Discussion: 18F-CETO-PET/CT shows promise for phenotyping as well as staging therapy- naïve ACC, but its role in other diagnostic applications, especially for restaging, remains to be defined.

RC6.6 - ECE_2726 - Survival prediction in adrenocortical carcinoma using time-to-event machine learning with updated follow-up data: comparison of ensemble methods, deep learning, and cox regression

Emre SAYGILI[1], Otilia Kimpel[2], Marta Laganà[3], Soraya Puglisi[4], Darko Kastelan[5], Jessica Remfry[6], Rossella Libe[7] and Cristina L Ronchi[6]

[1]Faculty of Medicine, Division of Endocrinology and Metabolism, Department of Internal Medicine, Canakkale Onsekiz Mart University, Çanakkale, Türkiye; [2]Division of Endocrinology and Diabetes, Department of Medicine, University Hospital, University of Würzburg, Würzburg 97080, Germany; [3]Medical Oncology, Department of Medical and Surgical Specialties, Radiological Sciences, and Public Health, University of Brescia, ASST Spedali Civili, Brescia 25123, Italy; [4]Department of Clinical and Biological Sciences, Internal Medicine, San Luigi Hospital, University of Turin, Turin, Italy; [5]Department of Endocrinology, University Hospital Centre Zagreb, Zagreb, Croatia; [6]Department of Metabolism and Systems Science, College of Medicine and Health, University of Birmingham, Birmingham, United Kingdom; [7]Department of Endocrinology and National Reference Center for Rare Adrenal Disorders, AP-HP, Hôpital Cochin, Paris, France

Background: Adrenocortical carcinoma (ACC) is a rare aggressive malignancy with difficult-to-predict clinical outcomes. We previously demonstrated that the S-GRAS score—based on clinical-histopathological characteristics—is the most relevant prognostic tool for ACC, and subsequently developed the first ML-based survival prediction web tool using classification algorithms with binary outcome analysis.[1,2] However, classification approaches do not account for censored survival data, potentially leading to limited generalizability. This study aimed to advance prognostic modeling by applying survival-specific ML algorithms with extended follow-up data.

Methods: A total of 1062 ACC patients from our previously published cohorts were analyzed using follow-up data extended through 2025 (median 81.0 months by reverse Kaplan-Meier method).The dataset was stratified into training (70%, $n = 743$) and test (30%, $n = 319$) sets. Cox Proportional Hazards (Cox PH) regression was compared with three ML approaches: Random Survival Forest (RSF), XGBoost, and DeepSurv. All models were optimized using 5-fold cross-validation with 95% confidence intervals. Performance was assessed using Concordance Index (C-index) and time-dependent AUC for discrimination, Integrated Brier Score (IBS) for calibration, and Decision Curve Analysis (DCA) for clinical utility.

Results: All models demonstrated high discriminative performance in training: Cox PH C-index 0.773 (95% CI: 0.72-0.83), RSF 0.761 (0.70-0.82), XGBoost 0.765 (0.72-0.82), and DeepSurv 0.765 (0.72-0.81). In the test set, performance remained consistent: Cox PH 0.746, RSF 0.739, XGBoost 0.742, and DeepSurv 0.740. Time-dependent AUC exceeded 0.82 at 1-, 3-, and 5-year timepoints. Compared to our previous classification approach (training AUC 0.85, validation AUC 0.79), current models showed improved consistency between datasets. Cox PH (IBS: 0.134) and RSF (0.135) demonstrated superior calibration compared to DeepSurv (0.152) and XGBoost (0.217). DCA confirmed clinically meaningful net benefit for Cox PH and RSF across the 20-50% risk threshold range.

Conclusions: With extended follow-up and survival-specific methodology, all models achieved high discriminative ability (C-index >0.73) with more consistent performance between training and test sets compared to our previous classification-based approach, indicating improved generalizability. Cox regression and RSF demonstrated superior calibration and clinical utility, representing optimal approaches for individualized prognostic assessment in ACC. These survival models will be integrated into our web-based prediction tool to enable continuous survival probability estimation (https://acc-survival.streamlit.app).

Background: Differentiating malignant adrenocortical carcinoma (ACC) from benign adrenocortical adenoma (ACA) remains challenging. Diagnosis often relies on multimodal imaging; however, this lacks specificity. Urine steroid metabolomics (USM), a combination of multi-steroid profiling by LC-MS/MS and machine learning, has been shown to significantly improve diagnostic accuracy over imaging only. LC-MS/MS analysis is more widely available for serum steroids than urinary steroid metabolites. However, to date, the comparative utility of serum steroid metabolomics (SSM) has not been investigated.

Objectives: The primary aim was to compare the utility of SSM and USM for detecting ACC. As a secondary objective, we investigated the diagnostic accuracy of reduced steroid panels in both matrices.

Design: We included paired 24-h urine and morning serum samples from 471 patients (87 ACC, 384 ACA) from the prospective EURINE-ACT study ($n = 2017$). All samples were analysed by LC-MS/MS, measuring 14 serum steroids (androgens, glucocorticoids, core precursors) and 14 related urinary steroid metabolites. ACA and ACC were randomly selected into training and test sets. We trained serum- and urine-specific machine learning algorithms using the results from 157 patients (40 ACC, 117 ACA). USM and SSM algorithms were generated for both the 14-steroid and 8-steroid panels. Locked algorithms were then applied to the serum and urine steroid results in the test cohort ($n = 314$; 47 ACC, 267 ACA). Diagnostic performance was assessed using Receiver Operating Characteristic curve (AUROC) analysis and chi squared tests.

Results: Applying the locked USM algorithm based on the 14-steroid panel to the 24-h urine steroid profiling results of the test cohort produced an AUROC of 0.90 (95% CI 0.85-0.96). By contrast, the SSM algorithm applied to the serum steroid profiling results of the test cohort produced an AUROC of 0.77 (95% CI 0.68-0.85). Chi squared analysis revealed a significant difference between USM and SSM ($P = .005$). Application of the algorithm based on the 8-steroid panel to the 24-h urine data generated an AUROC of 0.91 (0.86-0.96); the equivalent 8-steroid serum algorithm produced an AUROC of 0.80 (0.72-0.89) ($P = .03$). USM results (8 vs 14 steroids) were not statistically different ($P = .68$).

Conclusions: SSM is diagnostically inferior to USM. The performance of an 8-steroid profile is similar to the larger, 14-steroid profile. This unequivocally answers which biological matrix is superior for use in the steroid metabolomics approach to ACC detection. Identification of a reduced profile with similar diagnostic performance will facilitate the translation of this powerful technique into routine clinical use.

RC7.2 - ECE_1530 - Targeting FAK signaling overcomes drug resistance in gastrointestinal neuroendocrine tumor cell lines

Francesco Gambera, Anna Chinnì, Alice Castenetto, Clarissa Gissi, Angeliki Ditsiou and Teresa Gagliano

Udine, Italy

Gastrointestinal neuroendocrine tumors (GI-NETs) are a rare and heterogeneous group of neoplasms originating from neuroendocrine cells dispersed throughout the gastrointestinal epithelium. Although many GI-NETs exhibit indolent clinical behavior, a significant subset develops aggressive and invasive features and becomes largely refractory to standard therapies. In the metastatic setting, treatment options are mainly limited to chemotherapy, targeted agents, and peptide receptor radionuclide therapy; however, durable clinical responses remain uncommon due to the frequent development of intrinsic or acquired resistance. Therefore, the identification of novel molecular targets able to overcome resistance mechanisms represents an urgent unmet clinical need.

Recent evidence from our laboratory suggests that focal adhesion kinase (FAK), a non-receptor tyrosine kinase that integrates signals from the extracellular matrix and growth factor receptors, plays a central role in regulating GI-NET cell proliferation and survival. Beyond its enzymatic activity, FAK also exerts kinase-independent scaffold functions that coordinate multiple oncogenic signaling pathways. The aim of this study was to investigate whether comprehensive inhibition of FAK, targeting both its kinase and scaffold functions, can modulate GI-NET sensitivity to anticancer therapies and counteract tumor-promoting microenvironmental effects.

We employed two GI-NET cell lines (GOT1 and COLO320DM) and normal human fibroblasts as experimental models to recapitulate key aspects of tumor–stroma interactions. To achieve complete functional inhibition of FAK, we used a proteolysis-targeting chimera-based FAK degrader (PROTAC-FAK), which induces selective ubiquitination and proteasomal degradation of

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

the FAK protein. Antiproliferative responses were evaluated in both two-dimensional monolayers and three-dimensional spheroid cultures, alone or in combination with etoposide and rapamycin.

Our results demonstrate that PROTAC-FAK markedly enhances the antiproliferative effects of both etoposide and rapamycin in GI-NET cells across culture systems. In addition, FAK degradation significantly impairs clonogenic growth, indicating a long-lasting suppression of tumor-initiating capacity. Importantly, PROTAC-FAK effectively counteracts the pro-proliferative influence exerted by fibroblasts, highlighting its ability to disrupt microenvironment-driven resistance mechanisms.

In conclusion, our findings indicate that dual targeting of FAK kinase and scaffold functions through PROTAC-mediated degradation potentiates therapeutic efficacy, reduces drug resistance, and mitigates tumor-promoting signals derived from the tumor microenvironment. These results support FAK as a promising combinatorial target for the treatment of GI-NETs and provide a strong rationale for further preclinical and translational studies to validate this strategy.

RC7.3 - ECE_2613 - Association between metabolic profile and tumour phenotype in lung neuroendocrine neoplasms

Violetta Rosiek, Ksenia Janas, Olga Grzelak and Beata Kos-Kudła

Endocrinology, Department of Endocrinology and Neuroendocrine Tumors, Department of Pathophysiology and Endocrinology, Medical University of Silesia, Katowice, Poland

Introduction: Data on the relationship between routinely available metabolic parameters and tumour phenotype in lung neuroendocrine neoplasms (LNENs) are limited. It remains unclear whether simple metabolic measures differ across histological subtypes, proliferative grade and disease stage in LNENs.

Aim: To evaluate associations between metabolic profile and tumour phenotype in patients with LNENs.

Methods: We analysed 158 patients with LNENs. Metabolic parameters included body mass index (BMI), fasting glucose, total cholesterol and triglycerides. Tumour phenotype was characterised by histopathological subtype (typical carcinoid [TC], atypical carcinoid [AC], large-cell neuroendocrine carcinoma [LCNEC]), Ki-67 groups (G1/G2/G3) and TNM stage (I-IV). Group comparisons were performed using Kruskal–Wallis and χ^2 tests, as appropriate. Multinomial logistic regression was used for histological subtype and ordinal logistic regression for Ki-67 groups and stage. All models included BMI, glucose, lipid parameters, age and sex.

Results: BMI differed significantly across histological subtypes, Ki-67 groups and disease stages (all $P < .01$), with progressively lower BMI observed in more aggressive tumour categories. Fasting glucose showed a weak association with disease stage but did not differ across histological subtypes or Ki-67 groups. Total cholesterol and triglycerides did not differ across tumour phenotype categories. In multivariable models, lower BMI remained independently associated with more aggressive tumour phenotype across all endpoints. In the Ki-67 model, lower BMI was associated with higher proliferative grade (OR per 1 kg/m^2 0.91, 95% CI 0.85-0.97, $P = .0039$). In the histological model, BMI independently differentiated LCNEC and AC from TC ($P < .01$). In the stage model, fasting glucose showed only a weak and borderline independent association with more advanced stage (OR per 1 mg/dL 1.014, 95% CI 1.000-1.027, $P = .042$), while lipid parameters were not independently associated with tumour phenotype in any model.

Conclusions: Among routinely available metabolic parameters, BMI consistently differs across histological subtype, proliferative grade and disease stage in LNENs, whereas glucose shows only a weak association with stage and lipid parameters provide no additional discriminatory information. These findings suggest that lower BMI reflects tumour phenotype and disease aggressiveness rather than representing a causal factor. Due to the retrospective design, the potential contribution of cancer-related weight loss, treatment effects and comorbidities cannot be disentangled.

RC7.5 - ECE_2228 - Antitumoral effects of splice-switching oligonucleotides targeting insulin receptor alternative splicing in adrenocortical carcinoma cells

Sonia Di Bari[1], Luca Bosoni[1], Rosa Catalano[1], Emanuela Esposito[1], Emma Nozza[1], Genesio Di Muro[1], Sandra Sigala[2], Laura Sophie Landwehr[3], Guido Di Dalmazi[4,5], Serena Palmieri[6], Emanuele Ferrante[6], Giovanna Mantovani[1,6] and Erika Peverelli[1,6]

[1]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; [2]Section of Pharmacology, Department of Molecular and Translational Medicine, University of Brescia, Brescia, Italy; [3]Department of Internal Medicine I, Division of Endocrinology and Diabetes, University Hospital Würzburg, Würzburg, Germany; [4]Division of Endocrinology and Diabetes Prevention and Care, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy; [5]Department of Medical and Surgical Sciences, Alma Mater University of Bologna, Bologna, Italy; [6]SC Endocrinology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy

The majority of adrenocortical carcinomas (ACC) overexpress insulin-like growth factor 2 (IGF2), which is a driving force for the neoplastic progression via the autocrine activation of its receptors insulin-like growth factor 1 receptor (IGF1R) and insulin receptor (IR). Although previous efforts focusing on IGF1R targeting have shown limited efficacy, recent evidence highlights IR as a promising therapeutic target. Alternative splicing of exon 11 of IR generates two isoforms: IR-A, mediating mitogenic effects, and IR-B, involved in metabolic regulation. Higher IR-A than IR-B expression has been observed in ACC samples and in ACC cell lines H295R and JIL-2266 (derived from primary tumors) and TVBF-7 (derived from an ACC metastasis).

The aim of this study is to manipulate IR splicing to imbalance the ratio between the two IR isoforms favoring the metabolic one (IR-B) at expense of the mitogenic one (IR-A) and to evaluate the downstream effects of the IR splice-switching in ACC cell lines and primary ACC cultured cells. To this aim we transfected cells with splice-switching oligonucleotides (SSOs) that target the CUGBP1 binding site, thereby preventing this splicing factor from promoting IR-A formation. We then measured IR-A and IR-B expression, cell proliferation, apoptosis and migration.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Our results showed that SSO transfection decreased IR-A and increased IR-B levels in all cell lines and in two ACC primary cultures.

Furthermore, consistent with the altered IR-A/IR-B ratio, cell proliferation decreased in H295R (-27.6 (IQR:13.3)%, $P < .05$), JIL-2266 (−62.5 (30.5)%, $P < .05$) and TVBF-7 (−43.3 (13.1)%, $P < .05$) as well as in primary cultured cells (−35.2% and −42.3%, $P < .01$). Apoptosis also increased (+24.3 (13.3)%, +136.2 (74)%, +100.5 (91.3)%, all $P < .05$ in cell lines; and +41.3%, +56.4% $P < .01$, in primary cultures, respectively). A decrease in cell migration was also observed in all cell lines (−53.5 (22.4)%, −37.7 (22.6)%, −64.8 (21.3)%, all $P < .05$).

In conclusion, our results demonstrated that the SSO targeting IR exerted antitumoral effects in ACC cells, supporting a therapeutic potential of modulating IR alternative splicing as a promising strategy for the development of innovative, precision-based therapies in ACC.

RC7.6 - ECE_3817 - Ten years of clinical experience with lenvatinib therapy for advanced thyroid cancer in a tertiary care center

Elisa Minaldi, Carla Gambale, Loredana Lorusso, Laura Valerio, Carlotta Giani, Virginia Cappagli, Alessandro Prete, Laura Agate, Valeria Bottici, Sandra Brogioni, Eleonora Molinaro, Antonio Matrone and Rossella Elisei
Pisa, Italy

Introduction: Lenvatinib is approved in Italy for the treatment of progressive iodine-refractory thyroid cancer. The objective of the study was to evaluate the clinical presentation at diagnosis and response to therapy in patients treated with lenvatinib and followed at our center.

Patients and Methods: We analyzed data from 207 patients treated and followed at the Endocrinology Unit of the University Hospital of Pisa between 2014 and 2025.

Results: Among 207 patients, 53.6% were males and 46.4% females. The median age at diagnosis was 59 years (IQR 50-66). Histotypes were distributed as follows: 51.7% ($n = 107$) were papillary carcinomas, 23.2% ($n = 48$) poorly differentiated, 17.9% ($n = 37$) follicular, and 7.2% ($n = 15$) oncocytic. At diagnosis, 27.5% ($n = 57$) T3a, 17.9% ($n = 37$) were T2, 15% ($n = 31$) T3b, and 13.5% ($n = 28$) T4a, according to TNM VIII edition. 55% ($n = 114$) had lymphnode metastases (87.7% N1b; 12.3% N1a) and 44.8% ($n = 86$) had distant metastases. Staging at diagnosis was: Stage I in 23.5% ($n = 42$), II in 35.2% ($n = 63$), III in 7.3% ($n = 13$), IVA in 1.7% ($n = 3$), IVB in 32.4% ($n = 58$).

After a median follow-up of 7.4 years (IQR 2.7-12.6), 60.9% had died and 39.1% were still alive. The median age at initiation of lenvatinib was 65 years (IQR 59-74), and therapy was initiated a median of 4.5 years (IQR 1.2-10.4) after diagnosis. 57.8% of patients started on 24 mg/day, 22.2% on 14 mg/day, 9.3% on 10 mg/day, and lower percentages on other doses. Overall survival (OS) after initiation of therapy was 27 months (95% CI 19.2-34.8). Older age (>61 vs ≤60 years) and higher ECOG (≥2 vs 0-1) were the only factors significantly associated with shorter OS. The Disease-specific survival (DSS) was 52.6 months (95% CI 35.9-69.4). Higher ECOG (≥2 vs 0-1) was the only factor significantly associated with shorter DSS. The median progression-free survival (PFS) after lenvatinib was 21 months (95% CI 11.7-30.3). Histology was the only factor significantly associated with PFS: poorly differentiated and oncocytic histotypes showed shorter PFS (8 and 21 months), whereas follicular and papillary histotypes were associated with longer PFS (40 and 30 months). Of 181 assessable patients, the best clinical response was 56.9% stable disease, 29.3% partial response, and 13.8% progressive disease.

Conclusions: After more than ten years of experience, the analysis confirms the good efficacy of lenvatinib in iodine-refractory advanced thyroid cancer, especially in the short term. The main challenge remains maintaining the response over time, balancing therapeutic efficacy and tolerability.

RC8.1 - ECE_3487 - High salt intake does not guarantee adequate iodine status: evidence from the lithuanian NATRIJOD study

Lina Zabuliene[1], Urte Zakauskiene[1,2], Ernesta Macloniene[1,2], Nomeda Bratcikoviene[3,4], Valdas Banys[5], Ausra Linkeviciute Dumce[2], Dovile Karosiene[2], Mykolas Urbonas[6], Algirdas Utkus[2,4] and Marius Miglinas[1,2]
[1]Institute of Clinical Medicine, Faculty of Medicine, Vilnius University, Vilnius, Lithuania; [2]Vilnius University Hospital "Santaros klinikos", Vilnius, Lithuania; [3]Faculty of Fundamental Sciences, Vilnius Gediminas Technical University, Vilnius, Lithuania; [4]Institute of Biomedical Sciences, Faculty of Medicine, Vilnius University, Vilnius, Lithuania; [5]Centro Outpatient Clinic, Vilnius, Lithuania; [6]Antakalnio Outpatient Clinic, Vilnius, Lithuania

Background: Despite established policies for salt iodization, iodine deficiency remains a public health issue in Europe. High salt consumption persists, yet it is unclear whether excessive salt intake ensures adequate iodine intake in everyday diets. Changes in dietary patterns, inconsistent use of iodized salt, and reduced consumption of iodine-rich foods may undermine the effectiveness of iodine fortification efforts. This study investigated the association between salt intake and iodine status in a nationally representative sample of adults.

Methods: The NATRIJOD study is a cross-sectional, population-based study conducted in Lithuania. The study assessed sodium, potassium, and iodine intake using 24-hour urine collections, the gold standard for evaluating population-level dietary intake. Urinary iodine concentration (UIC) was measured to classify iodine status according to WHO criteria. Salt intake was estimated from 24-hour urinary sodium excretion. Information on iodized salt use, dietary patterns, and iodine-containing supplements was collected via questionnaires. Multivariable logistic regression was used to identify factors independently associated with iodine sufficiency. A two-sided P-value <.05 was considered statistically significant.

Results: A total of 662 adults (52.0% men) with a mean age of 47.3 ± 12.0 years were included. The median UIC was 96.6 µg/L (IQR 54.4-159.5), indicating borderline iodine sufficiency at the population level. Overall, 51.7% of participants had iodine insufficiency, including 10.6% with severe deficiency.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Median salt intake was 9.08 g/24 h (IQR 6.46-12.19); 40.8% of participants consumed ≥10 g/24 h of salt. UIC increased across salt intake categories, yet iodine insufficiency remained common even among high salt consumers. Participants consuming ≥10 g/24 h of salt had a higher median UIC than those consuming 5-9.99 g/24 h (112.7 vs 91.4 µg/L, $P = .005$) and a lower prevalence of iodine insufficiency (44.1% vs 55.7%, $P = .005$).

In multivariable analysis, salt intake category was independently associated with iodine status ($P = .005$). Compared with participants consuming <5 g/24 h of salt, those consuming ≥10 g/24 h had higher odds of iodine sufficiency (OR 2.03, 95% CI 1.20-3.43; $P = .008$). Dietary factors, including bread, milk, and cheese consumption, were not independently associated with iodine sufficiency.

Conclusions: More than half of adults in Lithuania had iodine insufficiency despite high salt intake. These findings show that excessive salt consumption does not ensure adequate iodine status, highlighting the need for improved practices in using iodized salt and incorporating dietary iodine sources. To ensure sufficient iodine levels without increasing salt consumption, it is essential to strengthen iodization strategies and continue monitoring the population's iodine status.

Abstract citation ID: lvag096.187

RC8.2 - ECE_2631 - DEHP disrupts adrenal steroidogenesis via rapid membrane depolarization and subsequent calcium influx mediated by L-type voltage-dependent calcium channels

Erik Petersenn[1], Stefan Bernard[1,2], Sonja Kunz[1], Martin Bidlingmaier[1], Marily Theodoropoulou[1], Tracy Ann Williams[1], Martin Reincke[1] and Isabel Stüfchen[1]
[1]*Department of Medicine IV, Endocrinology, Diabetology and Metabolism, LMU University Hospital, Munich, Germany;* [2]*Medicine IV, Endocrinology, Diabetology & Metabolism, LMU University Hospital, Munich, Germany*

Background: Di(2-ethylhexyl) phthalate (DEHP) is among the most widely used plasticizers and ubiquitously present in everyday products. In humans, it is metabolized to mono(2-ethylhexyl) phthalate (MEHP). Due to their interference with multiple hormonal pathways phthalates are classified as endocrine disrupting chemicals. Recent *in vitro* studies suggest that DEHP impairs adrenal steroidogenesis; however, the underlying mechanisms and the differential effects of metabolites remain poorly understood.

Objective: This study aimed to investigate the effects of DEHP and its primary metabolite MEHP on steroidogenic enzyme expression and steroid secretion in adrenocortical HAC15 cells under basal conditions and upon co-stimulations with angiotensin II (AngII) or forskolin.

Methods: Cultured HAC15 cells were treated with DEHP (0.1-10 µM) for 24 and 72 hours under basal conditions, and co-stimulation with angiotensin II (AngII) (10 nM) or forskolin (10 µM). Cell viability was assessed to exclude cytotoxic effects. Gene expression of key steroidogenic enzymes and transcription factors was quantified using qPCR, and steroid hormone concentrations in cell supernatants were measured by LC-MS/MS. Co-stimulation with nifedipine (1 µM) served to investigate involvement of voltage-dependent L-type calcium channels (L-VGCCs). Voltage-sensitive fluorescent dye $DiBAC_4$ was used to detect changes in membrane potentials.

Corresponding experiments were conducted with MEHP (10 µM, 50 µM) under basal conditions. Multiple testing was corrected using the Benjamini–Hochberg method.

Results: No significant changes in cell viability were observed under any treatment condition. Exposure to DEHP for 72 h resulted in a dose-dependent upregulation of *CYP11B1*, *CYP11B2*, accompanied by a downregulation of *HSD11B2* (all $P < .001$). Steroid profiling showed concordant increases in secretion of most mineralocorticoids and glucocorticoids synthesized by the respective enzymes (eg, a five-fold increase of aldosterone, $P < .01$). Co-stimulation with forskolin for 24 h potentiated DEHP-induced enzyme expression and steroid secretion, indicating a strong additive effect (all $P < .05$). In contrast, AngII co-stimulation resulted only in a modest enhancement of DEHP effects, suggesting convergence on a shared signaling pathway, which was further supported by gene expression pattern of the key transcriptional factor *NR4A2*.

Notably, DEHP-induced effects were reversed upon co-stimulation with nifedipine ($P < .05$), indicating involvement of L-VGCCs. Consistently, DiBAC membrane potential analysis revealed depolarization within 1-5 minutes upon DEHP exposure ($P < .05$). MEHP mirrored DEHP effects at higher concentrations (50 µM).

Conclusions: The data suggest that DEHP, and similarly MEHP in higher concentration, increases steroidogenic enzyme expression and hormone secretion via membrane depolarization and L-VGCCs calcium influx, partially sharing a signaling pathway with AngII.

RC8.3 - ECE_1394 - Urinary non-persistent pollutants and thyroid cancer: a case–control study highlighting associations with phthalate metabolites and bisphenol F

Marina Lugaresi[1], Patrice Dufour[2,3], Valentina Cirello[4,5], Claudia Moneta[1], Erika Carbone[4], Laura Fugazzola[1,6], Corinne Charlier[2,3] and Catherine Pirard[2,3]
[1]*Department of Health Sciences, University of Milan, Milan, Italy;* [2]*Center for Interdisciplinary Research on Medicines (C.I.R.M.), University of Liege, Liege, Belgium;* [3]*Department of Clinical, Forensic and Environmental Toxicology, University Hospital of Liege, Liege, Belgium;* [4]*Department of Endocrine and Metabolic Diseases, Istituto Auxologico Italiano IRCCS, Milano, Italy;* [5]*Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy;* [6]*Department of Endocrinology, ASST Santi Paolo e Carlo, Milano, Italy*

Introduction: Human activities lead to the release of several chemicals into the environment with a significant impact on human health. Some of these substances are classified as endocrine disruptors due to their ability to interfere with endocrine systems, in addition to their carcinogenic potential. Considering that the incidence of thyroid cancer (TC) has been steadily increasing over last decades, a potential role of these compounds can be hypothesized. The aim of the present study was to evaluate the association between urinary concentrations of non-persistent pollutants and TC, as well as with its clinical characteristics.

Materials and Methods: wThis was a cross-sectional case-control study. Urine samples of 109 patients with TC and 100 control

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

subjects were collected at the Istituto Auxologico Italiano Hospital of Milan (Italy). Samples were analyzed for 7 bisphenols, triclosan, 4 parabens, 8 phthalate metabolites and benzophenone-3 (BP3) using gas or liquid chromatography coupled to a mass spectrometer, depending on the specific analyte.

Results: The mean age of the study population was 50 years, and females accounted for 75% of participants. Among cases, 84% had papillary thyroid cancer. Among the pollutants investigated, bisphenol A and S, methylparaben, BP3 and 4 phthalate metabolites (MEP, MnBP, 5-OH-MEHP and 5-oxo-MEHP) were detected in more than 70% of the samples. Among phthalate metabolites, urinary levels of MEP (OR = 1.16, 95% CI: 1.01-1.34), 5-OH-MEHP (OR = 1.34, 95% CI: 1.07-1.72) and 5-oxo-MEHP (OR = 1.36, 95% CI: 1.10-1.70), as well as the presence of MBzP (OR = 3.24, 95% CI: 1.74-6.19) were positively associated with TC. Moreover, the presence of bisphenol F was positively associated with TC (OR = 3.44, 95% CI: 1.81-6.55).

Conclusions: This is the first European study to evaluate the association between urinary levels of non-persistent pollutants and thyroid cancer, identifying several positive associations. Our findings are consistent with data reported in some Chinese cohorts. However, due to the cross-sectional design of the study and the short half-life of the investigated compounds, the direction of the causality could not be inferred.

RC8.4 - ECE_3813 - Exposure to per- and polyfluoroalkyl substances and Its association with blood pressure: insights from patients with endocrine and essential hypertension

Isabel Stüfchen[1], Bettina Aschenbrenner[2], Lea Grümme[2], Erik Petersenn[1], Moritz Baumgärtner[1], Tracy Ann Williams[1], Friederike Völter[1], Júnia Ribeiro De Oliveira Longo Schweizer[1], Elisabeth Nowak[1,3], Wolfgang Völkel[2], Caroline Herr[2], Stefanie Heinze[2] and Martin Reincke[1]
[1]Munich, Germany; [2]Bavarian Health and Food Safety Authority, Institute for Occupational Health and Product Safety Environmental Health, Munich, Germany; [3]Department of Medicine IV, LMU University Hospital, LMU Munich, Munich, Germany

Background: Per- and polyfluoroalkyl substances (PFAS) have been associated with an increased risk of arterial hypertension. However, their role in endocrine forms of hypertension remains insufficiently characterized.

Objective: To analyze serum PFAS concentrations, temporal trends, and their association with blood pressure (BP) in patients with primary aldosteronism (PA) and Cushing syndrome (CS), and respective controls.

Methods: This retrospective study included patients with CS ($n = 90$) and controls with excluded CS ($n = 94$) from the German Cushing Registry (CS cohort), and patients with PA ($n = 389$) and controls with excluded PA ($n = 165$) from the German Conn Registry (PA cohort) at the LMU University Hospital Munich. Serum samples collected at the timepoint of diagnosis between 2012 and 2024 were analyzed for nine different PFAS using liquid chromatography–tandem mass spectrometry (LC-MS/MS). In both cohorts, each including patients and respective controls, multiple linear regression models were used to assess the overall association between log-transformed PFAS concentrations and systolic and diastolic BP across different hormonal states. Models were further adjusted for disease status and corticosteroid concentrations as well as for age, sex, BMI, antihypertensive medication, year of sampling and smoking status.

Results: Most detected PFAS were perfluorooctane sulfonate (PFOS), perfluorooctanoic acid (PFOA), perfluorononanoic acid (PFNA), and perfluorohexane sulfonate (PFHxS) in both cohorts. Concentrations of those four were strongly intercorrelated and consistently higher in males compared to females (all $P < .05$). Summed PFAS ($\sum$PFAS) were correlated with higher age and earlier year of blood sampling in both cohorts (all $P < .05$). In crude models, higher $\sum$PFAS concentrations were associated with higher systolic BP in both cohorts (CS: $\beta = 4.26$, $P = .03$; PA: $\beta = 3.59$, $P = .01$). However, these associations were no longer statistically significant upon adjustment for age. In fully adjusted analyses, neither total PFAS nor individual compounds were independently associated with systolic or diastolic blood pressure.

Conclusions: The findings of this study suggest that within two independent, predominantly hypertensive populations, PFAS exposure correlates with age and sampling year, but does not contribute additional explanatory value for blood pressure beyond clinical and endocrine determinants.

RC8.5 - ECE_2702 - A mobile application as a tool for reducing exposure to endocrine disrupting chemicals (EDCs)

Marcin Lewicki[1] and Mateusz Górecki[2]
[1]Endocrine Protect sp. z o.o., Lublin, Poland; [2]Endocrine Protect, Lublin, Poland

Endocrine-disrupting chemicals (EDCs) are substances capable of interfering with the hormonal system and inducing adverse health effects. EDCs constitute a significant and growing challenge. Nevertheless, awareness of EDCs among patients remain insufficient. To assess the level of knowledge in this area we have conducted an original survey among patients of outpatient clinic. The survey study was carried out among 51 respondents. More than half of the participants reported a diagnosed endocrine disorder, most commonly thyroid diseases, and nearly all (96.1%) actively sought information related to endocrine health, primarily via the Internet and consultations with medical specialists. The results indicated heterogeneous levels of knowledge regarding EDCs. Approximately half of the respondents declared familiarity with the term EDC and its effects, while the remaining participants reported limited or uncertain knowledge. The survey revealed a significant gap between the growing interest in EDC-related issues and the actual level of patient knowledge. In response to the aforementioned problem, we developed a mobile application designed to enable the identification of EDCs in industrial products—particularly food and cosmetic products—using a smartphone. The application allows for rapid and user-friendly analysis of product composition with respect to the presence of harmful EDCs by scanning the product's EAN barcode or by using optical character recognition (OCR) to analyze ingredient lists directly. Additionally, it offers access to interactive, expert-prepared educational materials designed to support informed health-related choices. By combining digital technology with evidence-based content, the application seeks to enhance

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

awareness of EDC exposure and support individual efforts to reduce associated potential health risks.

Abstract citation ID: lvag096.191

RC8.6 - ECE_1563 - Study of the interaction of bisphenol A with the expression of P16, interleukin-6, apelin and PPAR gamma genes in patients with type 2 diadetes mellitus

Marwa Salah
Faculty of medicine, Internal Medicine, Endocrine, Alexandria University, Alexandria, Egypt

Background: Endocrine-disrupting chemicals have currently drawn attention for causing metabolic aberrations to obesity, insulin resistance, type 2 diabetes mellitus, and other metabolic diseases. So, the present study aimed to study the level of serum bisphenol-A, expressions of P16, interleukin-6, apelin, and peroxisome proliferator-activated receptor gamma messenger ribonucleic acids and determine the association of these markers with glycemic control in patients with type 2 diabetes mellitus.

Methods: A case-control study included 80 patients with type 2 diabetes in addition to 80 healthy controls. Serum bisphenol-A was measured by the enzyme-linked immunosorbent assay technique. In addition to measuring relative quantification of P16, interleukin-6, apelin, and peroxisome proliferator-activated receptor gamma messenger ribonucleic acids by real-time quantitative polymerase chain reaction.

Results: Serum bisphenol-A concentration among patients with diabetes was statistically significantly higher compared to controls (mean 94.10 ± 55.46, 57.03 ± 24.98, respectively, $P < .001$) and had a significant positive correlation with glycemic parameters. There was a significant increase in the relative expression of p16 (mean 10.06 ± 25.79, 1.40 ± 0.98, $P < .001$) and interleukin-6 in diabetic patients compared to healthy subjects (mean 6.68 ± 9.48, 1.45 ± 1.18, $P < .001$). On the other hand, there was a significant decrease in relative expression of apelin and peroxisome proliferator-activated receptor gamma in diabetic patients compared to controls ($P < .001$), and BPA was positively correlated to p16 ($r = 0.252$, $P = .001$) and negatively correlated with apelin ($r = -0.180$, $P = .022$).

Conclusions: Our results suggested that elevated serum bisphenol-A (BPA) levels in T2DM patients correlate significantly with poor glycemic control, pro-inflammatory markers (IL-6), increased cellular senescence (p16), and downregulated metabolic parameters (apelin and PPAR-γ). These findings establish BPA as a modifiable environmental risk factor for the development of diabetes as well as a biomarker of metabolic dysfunction.

Keywords bisphenol-A, p16, apelin, interleukin-6, PPAR-γ, type 2 diabetes mellitus

RC9.1 - ECE_1491 - Association of non-contrast CT adrenal features with histopathology and genotype in unilateral primary aldosteronism

Lukas Gold[1], Nabeel Mansour[1], Markus Kroiss[2], Moritz Schrenk[2], Felix Herr[1], Isabel Stüfchen[2], Jens Ricke[1], Wolfgang Kunz[1], Christine Schmid-Tannwald[1], Petra Zimmermann[3], Tracy Williams[2], Nicole Reisch[2], Martin Reincke[2] and Matthias Oettle[2]
[1]*Department of Radiology, LMU University Hospital, LMU Munich, Munich, Germany;* [2]*Department of Medicine IV, LMU University Hospital, LMU Munich, Munich, Germany;* [3]*Department of General, Visceral and Transplantation Surgery, LMU University Hospital, LMU Munich, Munich, Germany*

Purpose: Accurate characterization of adrenal adenomas is essential for the management of unilateral primary aldosteronism (uPA). Although non-contrast computed tomography (CT) is widely used in clinical practice, its ability to reflect histopathologic and genetic features of aldosterone-producing adenomas has not been fully elucidated.

Methods: This retrospective study includes 99 patients with uPA and available genotypic data from the German Conn Center of the Ludwig-Maximillian-University Hospital Munich. Preoperative non-contrast CT scans were reviewed by a board-certified radiologist to assess adenoma number, maximal diameter, and attenuation in Hounsfield units (HU). Postoperative histopathologic findings and genotypes were correlated with CT-derived features using Pearson correlation and independent t test. A *P*-value <.05 was considered statistically significant.

Results: The median interval between non-contrast CT imaging and surgery was 92 days (interquartile range, 106 days). Adenoma size measured on non-contrast CT correlated strongly with the size of the surgical specimen ($n = 67$; 1.77 ± 0.59 cm vs 1.66 ± 0.75 cm; Pearson $r = 0.83$, $P < .001$). However, adenomas smaller than 1.0 cm on histopathology ($n = 35$) were frequently not detected as focal lesions on non-contrast CT ($n = 25$, 71%). Patients were stratified into two groups based on genotype: KCNJ5-mutated ($n = 36$) and non-KCNJ5 adenomas ($n = 63$). The non-KCNJ5 group included ATP1A1 ($n = 17$), CACNA1D ($n = 12$), ATP2B3 ($n = 8$), CTNNB1/GNAQ ($n = 1$), SLC30A1 ($n = 1$), as well as KCNJ5 wild-type tumors ($n = 24$). Due to limited sample sizes of individual genotypes, analyses were restricted to this binary classification. In cases with a radiologically identifiable adenoma ($n = 69$), KCNJ5-mutated tumors did not differ in size on non-contrast CT compared with non-KCNJ5 adenomas (1.89 ± 0.55 cm vs 1.64 ± 0.61 cm; $P = .078$), but demonstrated significantly lower attenuation values (2.71 ± 10.2 HU vs 13.3 ± 17.6 HU; $P = .003$). Absence of a detectable adenoma on preoperative non-contrast CT at the surgical site was observed in 30 cases and was substantially more frequent in non-KCNJ5 ($n = 25$) than in KCNJ5-mutated adenomas ($n = 5$).

Conclusions: Non-contrast CT imaging serves as a useful, non-invasive tool to infer underlying histopathologic and genetic features in patients with uPA. Future studies integrating advanced imaging methods and larger genetic datasets may further enhance the precision of adenoma characterization.

University, Linköping, Sweden; [5]Department of Internal Medicine, Kalmar County Hospital, Kalmar, Sweden; [6]Wallenberg Center for Molecular and Translational Medicine, University of Gothenburg, Göteborg, Sweden

Context: Ectopic Cushing syndrome (ECS) is a rare disorder with a poor prognosis.

Objective: To investigate survival in a large ECS cohort, stratified by aetiology.

Methods: This was a nationwide cohort study based on data on all patients who had received the diagnostic code for ECS in the Swedish National Patient Register between 1997 and 2024.

Results: In total, 224 patients (53% women) diagnosed with ECS were identified. The mean age at diagnosis (± standard deviation) was 59 ± 18 years. The 1-year and 5-year survival probabilities for the entire cohort were 58% and 40%, respectively. When stratified by calendar period, the estimated 1-year survival was 57% in 1997-2006, 66% in 2007-2016, and 48% in 2017-2024. The corresponding 5-year survival estimates were 39%, 46%, and 30%, respectively.

Of 224 patients, 88 (39%) had occult ECS, 73 (33%) had pulmonary ECS, 34 (15%) had metastatic disease with unknown primary tumour, 19 (9%) pancreatic ECS, 7 (3%) thymic ECS and 3 (1%) thyroid. The 1-year and 5-year survival probabilities were 89% and 75% for patients with occult ECS, 32% and 18% for patients with ECS of pulmonary origin, 29% and 33% for tumour of unknown origin, 100% and 43% for thymic ECS, 53% and 18% for pancreatic ECS and each at 33% for thyroid.

Conclusions: In this nationwide cohort, ECS was associated with poor overall survival, with fewer than 40% of patients alive at five years. Survival differed markedly by aetiology, with better outcomes in occult, thymic and thyroid ECS and poor prognosis in pulmonary, pancreatic, and cancer of unknown primary. No clear improvement in survival over time was observed, underscoring the need for earlier diagnosis and improved management strategies in high-risk subgroups.

RC9.3 - ECE_1649 - Cortisol and steroids circadian variations are higher in Cushing syndrome patients treated with metyrapone than osilodrostat and follow daily drug levels fluctuations

Louis Thomeret[1], Fidéline Bonnet-Serrano[1,2], Juliette Blondel[3], Patricia Vaduva[1], Lucas Bouys[4], Florian Violon[1,5], Bruno Ragazzon[1], Annabel Berthon[1], Karine Perlemoine[1], Jean Guibourdenche[2,6], Léopoldine Bricaire[4], Laurence Guignat[4], Rossella Libe[1,4], Lionel Groussin[1,4], Guillaume Assié[1,4], Anne Jouinot[1,4], Alicja Puszkiel[3,6], Benoît Blanchet[3,6] and Jérôme Bertherat[1,4]
[1]CNRS, Inserm, Institut Cochin, Team " Genomics and Signaling of Endocrine Tumors", Université Paris Cité, Paris, France; [2]Hôpital Cochin, Hormonology Department, AP-HP, Paris, France; [3]Hôpital Cochin, Drug Biology and Toxicology department, AP-HP, Paris, France; [4]Hôpital Cochin, Endocrinology department, AP-HP, Paris, France; [5]Hôpital Cochin, Pathology department, AP-HP, Paris, France; [6]Université Paris-Cité, Paris, France

Introduction: Osilodrostat and Metyrapone are two 11beta-hydroxylase inhibitors used in the pharmacological treatment of Cushing syndrome (CS). However, they differ in half-lives (4 h vs 1.8 h, respectively), in half maximal inhibitory concentrations IC_{50}, and impact differently global steroidogenic profile according to previous studies. The aim of our work was to investigate diurnal fluctuations of plasma steroids concentrations, cortisol but also precursors and androgens (classical and 11-oxygenated), in patients treated by either Metyrapone or Osilodrostat for CS.

Methods: Diurnal profiles (6 samples a day) of 12 plasma steroids and drug concentrations were determined using UPLC-tandem mass spectrometry (UPLC-MS/MS) in patients treated for CS with Metyrapone ($n = 17$; median dose 1250 mg/day; various dosing regimens; median treatment duration 112 days) or Osilodrostat ($n = 28$; 10 mg/day; equivalent dose twice daily; 107 days), as well as in 13 untreated patients with CS and 16 healthy controls. Concentrations fluctuations over 24 hours were expressed by MAX-MIN range (MMR, nmol/L) and Coefficient of Variation (CV, %), reported as median [10th-90th percentiles].

Results: In treated patients, 24-hour plasma concentrations of Osilodrostat were more stable than those of Metyrapone (CV = 57.0% [36.1-101] vs 102.6% [65.2-172.2], $P < .0001$), including when compared to the subgroup of 10 Metyrapone cycles with the most regular drug intake (≥3 doses per day, ±1-dose variation; CV = 87.1% [61.0-164.0], $P = .0006$).

Diurnal plasma cortisol levels were more stable in the Osilodrostat group compared to the Metyrapone group (MMR = 126.1 [5.8-240.3] vs 230.9 [87.3-519.1] nmol/L, $P = .0003$) and to the regular-intake Metyrapone subgroup (229.4 [130.1-540.1] nmol/L, $P = .0008$). Cortisol concentrations were higher at 8:00 and lower at 20:00 and 24:00 with the use of Metyrapone compared to Osilodrostat, including in the subgroup of patients with normalized urinary free cortisol ($n_{Osilodrostat} = 25$, $n_{Metyrapone} = 8$).

Glucocorticoid precursors, mainly 11-deoxycortisol, showed higher plasma values and greater fluctuations with Metyrapone than with Osilodrostat (MMR = 62.9 [25.2-323.4] vs 16.2 [0.9-86.3] nmol/L, $P < .0001$).

Classical androgen levels were constantly higher with Metyrapone, whereas 11-oxygenated androgens were markedly decreased in both groups.

Discussion: Our study shows that Osilodrostat is associated with greater stability of plasma cortisol levels whereas Metyrapone is associated with a more physiological rhythm, a higher value in the morning and a lower value at midnight, including in the controlled patients. The findings also suggest lower increases in glucocorticoid precursors and classical androgens with Osilodrostat compared to Metyrapone. Differences in pharmacokinetic profiles could likely explain these findings, including greater plasma drug fluctuations with Metyrapone despite regular dosing.

RC9.4 - ECE_1118 - Clinical and pharmacological determinants of serum dexamethasone concentrations during the dexamethasone suppression test

Irene Tizianel[1,2], Elena Pagin[1,2], Pierluigi Mazzeo[1,2], Giulia Bovo[1,2], Giacomo Voltan[1,2], Mattia Barbot[1,2] and Filippo Ceccato[1,2]
[1]Endocrine Disease Unit, University Hospital of Padova, Padova, Italy; [2]Department of Medicine DIMED, University of Padova, Padova, Italy

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Background: The dexamethasone suppression test (DST) is recommended by the European Society of Endocrinology for the evaluation of endogenous hypercortisolism, including Cushing's syndrome (CS) and autonomous cortisol secretion (MACS) in adrenal incidentalomas. A 1 mg DST is considered normal when post-test serum cortisol is suppressed below 50 nmol/L (<1.8 μg/dL). Simultaneous measurement of serum dexamethasone allows for accurate identification of suboptimal drug exposure (<4.5 nmol/L), which may compromise test reliability. Interindividual variability in dexamethasone pharmacokinetics, influenced by patient clinical conditions and concomitant medications, represents a major challenge in clinical interpretation.

Objective: To investigate the clinical and pharmacological determinants of serum dexamethasone concentrations during the DST.

Materials and Methods: We conducted a retrospective observational study including 546 patients who underwent 1 mg DST overnight, with concurrent serum dexamethasone measurement. Serum dexamethasone concentrations were quantified using validated LC-MS/MS assays. The study population included 54 patients with CS (25 active CS and 29 with previously treated disease), 287 patients with adrenal incidentaloma (160 non-functioning adrenal incidentalomas and 127 MACS) and 205 suspected CS. Patients with known conditions potentially affecting dexamethasone metabolism, including hepatic insufficiency, were excluded. Data were analyzed to assess the relationships between serum dexamethasone levels and clinical and pharmacological variables.

Results: Patients aged ≥65 years exhibited higher dexamethasone concentrations compared with younger individuals (13.6 vs 10.4 nmol/L, $P < .001$), as did patients with BMI ≥ 25 kg/m^2 (12.2 vs 9.6 nmol/L, $P = .004$). Dexamethasone concentrations were progressively higher with decreasing renal function, when patients were categorized into four estimated glomerular filtration rate (eGFR) classes ($P < .01$); on the contrary cortisol levels after 1 mg DST overnight were progressively lower with eGFR reduction. In age-stratified linear regression analyses (cut-off 65 years), serum dexamethasone levels showed a significant positive association with creatinine concentrations ($P = .002$). Concomitant use of proton pump inhibitors, statins or calcium channel blockers was independently associated with increased serum dexamethasone levels (all drugs $P < .001$). Suboptimal dexamethasone exposure (<4.5 nmol/L) was observed in 17 patients (3.1%), of whom 11 (64.7%) showed lack of cortisol suppression following DST.

Conclusions: Serum dexamethasone levels are significantly affected by patient clinical characteristics and concomitant medications. Recognition of these factors is crucial for optimizing the reliability of hypercortisolism screening, minimizing diagnostic errors and supporting personalized evaluation. Clinicians should consider age, BMI, renal function and potential drug interactions when interpreting DST results to ensure accurate diagnosis and avoid misclassification.

RC9.5 - ECE_2071 - Replacing early morning cortisol reduces fatigue: post-hoc analysis of AddiQol in CHAMPAIN, a double-blind study comparing Chronocort and Plenadren

Irina Chifu[1], Alessandro Prete[2], Verena Theiler-Schwetz[3], Wiebke Arlt[4], Birgit Harbeck[5], Catherine Napier[6], John Newell-Price[7], Aled Rees[8], Nicole Reisch[9], Günter Stalla[10], Helen Coope[11], John Porter[11], Jo Quirke[11], Peter Treasure[11], Irmina Wlodarczyk[11], Hanna Bendfeldt[11] and Richard Ross[7]

[1]Würzburg University Hospital Straubmühlweg Heliport, Würzburg, Germany; [2]University of Birmingham, Birmingham, United Kingdom; [3]University of Graz, Graz, Austria; [4]Medical Research Council Laboratory of Medical Sciences, London, United Kingdom; [5]Amedes MVZ Hamburg, Hamburg, Germany; [6]Newcastle University, Newcastle upon Tyne, United Kingdom; [7]University of Sheffield, Sheffield, United Kingdom; [8]University of Cardiff, Cardiff, United Kingdom; [9]Ludwig-Maximilians-Universitat Munchen, Munchen, Germany; [10]Medicover, Munchen, Germany; [11]Immedica UK Ltd, London, United Kingdom

Background: Cortisol has a circadian rhythm with an early morning rise; loss of this rhythm is associated with poor health. In the CHAMPAIN study we demonstrated that twice daily Chronocort (Efmody, Immedica Netherlands B.V.), which replaces the early morning rise in cortisol, improved QoL compared to Plenadren (Takeda Ltd. UK), which only replaces daytime cortisol levels. This post-hoc analysis looked at the subdomains of the disease specific questionnaire, AddiQoL (Addison's disease Quality of Life questionnaire) and SF-36 V2, compared to other questionnaires.

Methods: CHAMPAIN was a double-blind cross-over study in 58 patients with primary adrenal insufficiency (AI) comparing Chronocort, 15 mg at night and 10 mg in the morning, with once daily Plenadren 25 mg. The primary endpoint was waking cortisol and secondary endpoints were measures of fatigue and QoL. Patients signed informed consent and the trial was registered (NCT NCT05222152; Eudract 2021-000144-21). AddiQoL has four subdomains: fatigue, emotions, symptoms, and miscellaneous and was completed every 4 weeks within 2 hours of waking. A sensitivity analysis was done on period 1 of the cross-over which was randomised parallel-arm and blinded. P was one-sided, significance at $P < .025$.

Results: In the cross-over analysis treatment effect was in favour of Chronocort for AddiQoL: Total Score (+3.214, $P = .024$), and subdomain Fatigue (+1.234, $P = .014$), but not different for Emotions (+0.861, $P = .032$), Symptoms (+0.500, $P = .157$) and miscellaneous (+0.676, $P = .033$). In the sensitivity analysis Total Score was positive (+6.3, $P = .0175$). The SF-36 V2 physical component score which includes fatigue was in favour of Chronocort (+3.2, $P = .01$) but the Mental Component Score was not different (−0.6 $P = .7$). In the sensitivity analysis the following SF-36 subdomains significantly favoured Chronocort: Physical Functioning (+5.42 $P = .004$), Role Limitations due to Physical Health (+7.59 $P = .001$), Bodily Pain (+4.99 $P = .022$), General Health Perceptions (+5.70 $P = .004$), and Vitality (+7.16 $P = .002$). The PROMIS 7b, a specific fatigue questionnaire, was in favour of Chronocort (−2.6, $P =$

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

.024). The most common adverse event was fatigue, reported by twice as many during Plenadren treatment (44.6%) compared to Chronocort (20.7%).

Conclusions: Replacing the early morning cortisol improved health related QoL in AI based on the disease specific questionnaire AddiQoL. This was primarily due to reduced fatigue which was also seen in the SF-36 physical component score and fatigue specific questionnaire PROMIS 7b and there were fewer reports of fatigue on Chronocort compared to Plenadren.

RC9.6 - ECE_3139 - Real-world effectiveness of modified-release hydrocortisone (Efmody®) in adults with classic 21-hydroxylase deficiency congenital adrenal hyperplasia: a 12-month longitudinal cohort study

Chiara Sola[1], Maria Chiara Di Carlo[1], Beatrice Bergoglio[1], Giovanna Motta[2], Mirko Parasiliti Caprino[3] and Roberta Giordano[2,4]

[1]University of Turin, Turin, Italy; [2]Division of Endocrinology, Diabetes and Metabolism, Department of Medical Sciences, University of Turin, Turin, Italy; [3]Volvera, Italy; [4]Department of Biological and Clinical Sciences, University of Turin, Turin, Italy

Background: Congenital adrenal hyperplasia (CAH) comprises a group of autosomal recessive disorders, with ~95% of cases caused by mutations in CYP21A2, the gene encoding adrenal steroid 21-hydroxylase (P450c21). Enzymatic deficiency leads to impaired cortisol biosynthesis, variable aldosterone deficiency and chronic ACTH-driven accumulation of cortisol precursors (17-hydroxyprogesterone [17-OHP] and progesterone), which are shunted toward androgen synthesis. Standard-of-care glucocorticoid (GC) formulations fall short of replicating the circadian rhythm of cortisol and controlling efficient ACTH-driven adrenal androgen production; moreover, supraphysiologic GC exposure is associated with metabolic and cardiovascular comorbidities and fertility impairment. Multiple alternative treatment approaches are being developed with the aim of tailoring therapy for improved patient outcomes. Efmody®, a modified-release hydrocortisone (MR-HC), is designed to better mimic the physiological circadian rhythm of cortisol, optimizing androgen control and minimizing metabolic burden.

Objective: To evaluate the real-world effectiveness of MR-HC in adults with classic CAH on disease control, metabolic and anthropometric outcomes and fertility parameters.

Methods: In this single-center observational cohort study, 15 adults with classic CAH were assessed at baseline (on conventional immediate-release hydrocortisone, HC) and at 3 (T1), 6 (T2), and 12 (T3) months after switching to an equivalent dose of MR-HC for hormonal, metabolic, anthropometric and fertility outcomes. Longitudinal changes in parameters were analyzed using linear mixed-effects models, including a random intercept for patient and fixed effects for time, total glucocorticoid dose, age, and sex; sex × time interactions were evaluated when clinically relevant.

Results: MR-HC was associated with a sustained reduction in 17-OHP at all follow-up time points (T1: $P = .033$; T2: $P = .059$; T3: $P = .029$). Androstenedione levels also declined (T1: $P = .023$; T3: $P = .070$), with sex-interaction analyses showing a significant reduction in females at T1 ($P = .007$) and T3 ($P = .031$). No significant changes were observed in testosterone levels. Anthropometric and most metabolic parameters remained stable; fasting glucose increased modestly at 12 months without a concomitant rise in HbA1c, and HDL cholesterol showed a nonsignificant upward trend (~+6 mg/dL). Regarding fertility, total sperm count improved in half of male patients, while no pregnancies were reported during follow-up. No adrenal crises or drug-related adverse events were observed.

Conclusions: These results support MR-HC as a physiologically aligned glucocorticoid replacement therapy in adults with CAH. Treatment with MR-HC was associated with improved biochemical androgen control, independent of dose, age or sex, without significant changes in metabolic or anthropometric parameters.

RC10.1 - ECE_2107 - How much is enough? Surgical extent of initial parathyroidectomy and long-term outcomes in MEN1-related primary hyperparathyroidism

Kosmas Daskalakis[1,2], Kostantinos Ntalaperas[1,2], Nektaria Papadopoulou[3], Marina Tsoli[3], Anna Angelousi[4], Evanthia Kassi[5] and Gregory Kaltsas[3]

[1]"Korgialenio-Benakio," Red Cross General Hospital, Athens 11526, Greece; [2]Second Department of Surgery, Athens, Greece; [3]Endocrine Oncology Unit, 1st Department of Propaedeutic Internal Medicine, Laiko Hospital, National and Kapodistrian University of Athens, Athens 11527, Greece; [4]First Department of Internal Medicine, Unit of Endocrinology, Laikon General Hospital, Athens 11527, Greece; [5]Department of Biological Chemistry, School of Medicine, National and Kapodistrian University of Athens,, Athens 11527, Greece

Context: Multiple Endocrine Neoplasia type 1 (MEN1)–associated primary hyperparathyroidism (PHPT) is typically multiglandular, which contributes to both persistent and recurrent disease following surgery. The optimal extent of initial parathyroidectomy in MEN1 remains debated.

Objective: To evaluate long-term outcomes of subtotal parathyroidectomy (SPTX) versus less-than-subtotal parathyroidectomy (LSPTX) in MEN1-related PHPT, specifically regarding persistence, recurrence, permanent hypoparathyroidism, and need for reoperation.

Methods: A retrospective cohort study was conducted including 65 MEN1 patients who underwent initial parathyroidectomy and were followed at a single tertiary referral center. Patients were stratified according to surgical extent (SPTX vs LSPTX), and rates of persistent and recurrent HPT and reoperation were analyzed. Kaplan-Meier survival curves were constructed for recurrence-free survival, and multivariable Cox regression was applied to identify independent predictors of adverse outcomes.

Results: The median follow-up was 133.1 months (range 2.4-442.2 months). Disease recurrence was observed in 72.2% of LSPTX ($n = 18$) versus 35.6% of SPTX ($n = 42$) and total parathyroidectomy with autotransplantation (TPTX-AT; $n = 3$; Chi-square test $P = .008$). Hypoparathyroidism 6 months postoperatively was recorded in 50% after SPTX and TPTX-AT (12/24) and 25% after LSPTX (2/8; Chi-square test $P = .217$). Time to reoperation was significantly shorter in the LSPTX group (median 65.9 months vs 192.7 months, log-rank $P < .001$). Cox-regression multivariable analysis identified LSPTX as

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

an independent predictor for shorter time to recurrence (HR = 6.1, 95% CI 1.64-22.86, $P = .007$).

Conclusions: In MEN1-relatedPHPT, limited parathyroidectomy (LSPTX) is associated with significantly higher recurrence rates, earlier reoperation, and independently predicts shorter recurrence-free survival. Although the risk of permanent hypoparathyroidism appeared lower after LSPTX, this difference did not reach statistical significance. These findings support subtotal parathyroidectomy as the preferred initial surgical strategy in MEN1, balancing long-term disease control with preservation of parathyroid function.

Background: Familial Hypocalciuric Hypercalcemia (FHH) is a rare autosomal dominant genetic disorder characterized by PTH-dependent hypercalcemia. It is caused by inactivating mutations of *CASR, GNA11,* or *AP2S1* (FHH type 1, 2, or 3 respectively). FHH represents the main differential diagnosis for primary hyperparathyroidism (PHPT) and is traditionally distinguished from PHPT by lower urinary calcium excretion and by less skeletal and renal complications. A better understanding of the tissue-specific effects may improve its differential diagnosis from PHPT and enhance patients care.

Objective: To characterize clinical and biological phenotypes of patients with FHH in order to optimize follow-up, establish genotype-phenotype correlations and propose new diagnostic criteria.

Patients and Methods: A prospective cohort of patients with FHH and of their disease-free relatives was established.

Results: At the time of the submission, a cohort of 27 patients with confirmed or suspected FHH from 13 families has been established (mean age: 44.4 ± 22.0 years). Five, three, and two families were diagnosed with FHH types 1, 2, and 3, respectively, while whole-genome sequencing is ongoing for three families with negative initial genetic testing. Patients with FHH have higher serum calcium concentrations than their disease-free relatives (2.68 ± 0.26 mM vs 2.37 ± 0.11 mM, $P = .0008$), while PTH levels were similar (0.72 vs 0.62 times the upper limit of normal range, $P = .3282$). Fractional excretion of calcium, which is classically used to differentiate FHH from PHPT, exceeded 1% in 45% of the patients with FHH, while the pro-FHH score, designed to distinguish FHH from PHPT was in favor of FHH for every FHH patients. Bone mineral density, bone remodeling markers, and presence of nephrolithiasis did not differ significantly between patients with FHH and their disease-free relatives. Patients with FHH exhibited enamel defects consistent with hypomineralized Amelogenesis Imperfecta, which appeared consistent across the 3 genetic subtypes and were absent in disease-free relatives. Our group identified enamel defects in murine models with loss-of-function of *Gna11*, mimicking FHH type 2. Indeed, heterozygous *Gna11* loss-of-function mice show lower enamel volume and density, raising questions about the underlying mechanisms of these defects.

Discussion and Conclusions: We describe a dental phenotype associated with FHH that appears consistent across the 3 genetic subtypes. Our cohort will be extended to confirm these findings. Further studies using mouse models will be pursued to better understand the mechanisms of enamel defects in patients with FHH. Study of rheumatological consequences of FHH must be further described. Improved diagnostic criteria to differentiate FHH from PHPT are needed.

Context: Chronic hypoparathyroidism (HypoPT) is a rare endocrine disorder characterized by hypocalcemia and hyperphosphatemia, requiring lifelong treatment with activated vitamin-D and oral calcium supplements. Palopegteriparatide, a novel long-acting prodrug of PTH (1-34), has demonstrated efficacy in randomized controlled trials, but real-world data on its long-term effectiveness and safety remain limited.

Objective: To evaluate the efficacy and safety of long-term palopegteriparatide therapy in a real-world cohort of patients with HypoPT.

Design and Setting: Multicenter prospective cohort study conducted in tertiary referral hospitals. The study is registered at ClinicalTrials.gov under the identifier NCT07299838.

Patients and Intervention: Ninety-two adults with HypoPT (79 females, 13 males), previously treated with recombinant human PTH (1-84) or conventional therapy, initiated palopegteriparatide according to the National Hellenic Guidelines for the management of HypoPT.

Results: Patients were treated for a median duration of 6.5 months (range 2-14), with significant improvements in biochemical control of calcium-phosphate metabolism. Albumin-adjusted calcium increased from 8.14 ± 0.73 to 8.99 ± 0.94 mg/dL, and magnesium from 1.79 ± 0.17 to 1.96 ± 0.17 mg/dL (both $P < .001$). Phosphate decreased from 4.74 ± 0.97 to 4.02 ± 0.63 mg/dL, Ca × P product from 38.27 ± 6.92 to 36.04 ± 6.55 mg^2/dL^2, and 24-hour urinary calcium from 245.7 ± 125.5 to 164.5 ± 88.3 mg/24 h (all $P < .001$). Daily pill burden was markedly reduced; 58% of patients achieved independence from calcium supplements and alfacalcidol after a mean of 61 days. Adverse events were mostly mild and transient.

Conclusions: In a real-world setting, palopegteriparatide effectively normalizes calcium–phosphate homeostasis, reduces hypercalciuria, and substantially decreases reliance on conventional therapy, with a favorable safety profile.

RC10.4 - ECE_2919 - Eneboparatide: mechanism of action underlying the sustained regulation of calcium in chronic hypoparathyroidism

Xavier Gaume[1], Ying Kong[2], Guillaume Ravel[3], Corentin Berardet[4], Soraya Allas[5] and Myriam Aouadi[1]
[1]Alexion, AstraZeneca Rare Disease, Discovery Biology, Écully, France; [2]Alexion, AstraZeneca Rare Disease, Global Medical Affairs, Boston, MA, United States; [3]Alexion, AstraZeneca Rare Disease, Clinical Pharmacology and Safety Sciences, Écully, France; [4]Process Development and Clinical Supply, Alexion, AstraZeneca Rare Disease, Écully, France; [5]Alexion, AstraZeneca Rare Disease, Clinical Development, Écully, France

Premise: Chronic hypoparathyroidism (cHypoPT) leads to hypocalcemia due to insufficient parathyroid hormone (PTH). cHypoPT is often treated with therapeutic doses of calcium and active vitamin D, which may cause hypercalciuria. Eneboparatide (also called long-acting PTH, or LA-PTH or AZP-3601) is a peptide in development for HypoPT. In animal models and patients with cHypoPT, eneboparatide treatment led to sustained regulation of urinary and serum calcium (sCa) despite its short circulating half-life. Here, we investigated the mechanism whereby eneboparatide provides prolonged calcium regulation *in vivo*.

Methods: PTH 1 and 2 receptor (PTH1R and PTH2R) activation was evaluated using a cell-based cyclic adenosine monophosphate (cAMP) assay. Receptor binding affinity was assessed by radioligand competition assay. Kinetics of PTH1R activation were investigated by measuring cAMP production for 24 h after ligand washout in cells expressing PTH1R. Tissue distribution was examined by quantitative whole-body autoradiography in rats. Structure-function studies evaluated the effect of amino acid substitutions, additions, and truncations on the kinetics of PTH1R activation.

Results: Eneboparatide activated PTH1R and PTH2R, establishing it as a broad-spectrum PTH receptor agonist. Eneboparatide had high affinity for PTH1R R0 conformation, leading to extended cAMP signaling up to 24 h, contrary to the transient effect of PTH (1-34). Compared with PTH (1-34), eneboparatide showed prolonged and enhanced receptor occupancy in PTH1R-expressing tissues, particularly in the kidney, with structure-function studies identifying molecular features underlying sustained PTH1R activation.

Conclusions: These data revealed the unique properties of eneboparatide needed for sustained activation of PTH1R, resulting in extended regulation of sCa via retention, particularly in the kidney, despite rapid circulatory clearance.

RC10.6 - ECE_2734 - Muscle mass and strength are independent predictors of bone health in Klinefelter syndrome, the Klin-health study

Lucia Bedatsova[1], Eliane Maalouf[2], Mohamed Faouzi[2], Gonzalez Rodriguez Elena[3,4] and Georgios Papadakis[4,5,6]
[1]Lutry, Switzerland; [2]Biostatistics Consultation Unit, Center for Primary Care and Public Health, Division of Biostatistics, University of Lausanne, Lausanne, Switzerland; [3]Center of Bone Diseases, Lausanne University Hospital, Lausanne, Switzerland; [4]Faculty of Biology and Medicine, University of Lausanne, Lausanne, Switzerland; [5]Centre Hospitalier Universitaire Vaudois (CHUV), Lausanne, Switzerland; [6]University of Lausanne, Lausanne, Switzerland

Background: Klinefelter syndrome (KFS) is frequently associated with low bone mineral density (BMD), but bone defects are not fully explained by the underlying hypogonadism.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Aim: To characterize bone health in a large prospective cohort of men with KFS and examine associations of BMD with potential predictors such as testosterone replacement therapy (TRT) status, hormonal profile and body composition indexes.

Methods: We performed a cross-sectional analysis on the baseline data of an ongoing randomized trial (NCT05586802). Participants underwent a complete phenotypic evaluation, including a fasting blood sample and Dual X-ray absorptiometry. Primary outcomes included BMD at lumbar spine (LS), femoral neck (FN), and total hip (TH), and trabecular bone score (TBS). Data on age at initiation and overall TRT duration were collected. Sex hormone levels, body composition indexes and muscle strength (hand grip), metabolic markers and calcium physiology parameters were investigated.

Results: One-hundred five men with a mean age and BMI of 36.5 ± 13.2 years and 26.3 ± 6.8 kg/m^2 were analyzed. BMD T-scores indicated osteoporosis in 11.8% and osteopenia in 78.4% of participants. Only 9 (8.6%) patients had experienced low-energy fractures. Fifty-three men were on TRT, initiated at mean age of 27.3 ± 10.2 years for a duration of 10.0 ± 9.4 years. TRT-treated patients had significantly higher BMD-TH (+0.079 g/cm^2, $P = .006$) and BMD-FN (+0.070 g/cm^2, $P = .012$) levels after adjustment for age and BMI than those without TRT, while no difference was observed for BMD-LS. Longer TRT duration was however associated with higher BMD-LS (+0.008 g/cm^2 for each additional year, $P = .017$). Plasma FSH was the only sex hormone with significant inverse associations with all bone outcomes, although this was no longer significant after adjustment for BMI. Age- and BMI-adjusted appendicular lean mass index (ALMI) was positively associated with all BMD sites (TH: +0.061 g/cm^2, $P = .000$; FN: +0.065, $P = .000$; LS: +0.049, $P = .002$) and TBS (+0.037, $P = .000$). Muscle strength showed similar associations. Fat mass percentage (FM%) correlated positively with BMD-TH ($P = .04$), but this association inversed after adjustment for age and BMI (−0.008 g/cm^2 for each additional unit of FM%, 95% CI [−014, −0.02], $P = .01$). Serum PTH levels exhibited significant negative associations (also after adjustment) with BMD at both femoral sites (TH: −0.003 g/cm^2, $P = .002$; FN: −0.003 g/cm^2, $P = .000$).

Conclusions: Lean mass and muscle strength were the most consistent predictors of bone outcomes, with an association extending beyond BMI. Active TRT and optimal calcium-phosphate metabolism as expressed by lower serum PTH confer advantages only at femoral sites.

RC11.1 - ECE_1833 - Additive effects of semaglutide and peptide YY3-36 dual agonism on HFpEF: focus on mitochondrial function in obese rats

Niklas Geiger[1,2], Palina Zytner[1,2], Michael Kohlhaas[2], Alexander Nickel[2], Takahiro Higuchi[3], Paula Arias-Loza[3], Kristina Lorenz[4], Jana Gerner[2], Annika Engelhardt[2], Thorsten Bischler[5], Panagiota Arampatzi[5], Frank Stein[6], Simon Kloock[1], Tom Lunkwitz[1], Martin Fassnacht[1], Christioph Maack[2], Vasco Sequeira[2] and Ulrich Dischinger[1]
[1]*Division of Endocrinology and Diabetes, Department of Internal Medicine, University Hospital Würzburg, Würzburg, Germany;* [2]*Comprehensive Heart Failure Center (CHFC), Department of Translational Research, University Hospital Würzburg, Würzburg, Germany;* [3]*Department of Nuclear Medicine, Department of Nuclear Medicine, University Hospital Wüürzburg, Würzburg, Germany;* [4]*Institute of Pharmacology and Toxicology, University Hospital Wüürzburg, Würzburg, Germany;* [5]*Core Unit Systems Medicine, University of Würzburg, Würzburg, Germany;* [6]*European Molecular Biology Laboratory, Heidelberg, Germany*

Intro: Glucagon-like peptide (GLP) -1 receptor agonists like semaglutide have already emerged as promising therapeutics for heart failure with preserved ejection fraction (HFpEF), but their exact mechanisms of action are still unknown. In this study with diet-induced obese HFpEF rats with chronic NO-synthase inhibition, we investigated the individual and combined effects of semaglutide and the neuropeptide (NPY)-2 receptor agonist peptide YY_{3-36} (PYY) on cardiomyocyte metabolism.

Methods: Following an eight-week feeding period with a high-fat/fructose-diet (HFD) and L-NAME, male obese Wistar rats were randomized into the following treatment groups for another 8 weeks: Semaglutide (Sema, $n = 7$), PYY ($n = 4$), semaglutide in combination with PYY (Sema+PYY, $n = 7$) and saline treated control (HFpEF, $n = 10$). Sarcomere shortening was analysed via IonOptics microscopy and mitochondrial respiration was evaluated with an Orboros Respirometer. In addition, RNA-Sequencing was performed.

Results: Cardiomyocytes of the HFpEF group showed diastolic dysfunction in echocardiography and increased diastolic intracellular Ca^{2+}, consistent with an HFpEF phenotype. Sema and PYY mono and especially Sema+PYY significantly improved diastolic sarcomere shortening ($P < .001$). Sema+PYY rescued the E/A ratio in echocardiography compared to the individual application of Sema and PYY ($P < .05$). Mitochondrial respiration and ROS-emission was significantly increased in the Sema and PYY mono group with additive effects in the combination group compared to HFpEF ($P < .001$). In line, RNA sequencing showed upregulated oxidative phosphorylation pathways in the individual and combined Sema+PYY treated group ($P < .001$).

Discussion: This study highlights the additive effects of semaglutide+PYY mitigating cardiac mitochondrial dysfunction, sarcomere shortening and E/A ratio in HFpEF rats. These results provide novel insights into molecular mechanisms following the upcoming twincretin approach.

RC11.2 - ECE_3023 - A lifestyle program to improve infertility in women with overweight or obesity tends to be particularly effective in polycystic ovary syndrome: an RCT subgroup analysis

Christophe Richer dit Laflèche[1], Melissa Filippone[1], Matea Belan[1], Farrah Jean-Denis[2], Marie-France Langlois[1,2], Hélène Lavoie[3], Marie-Hélène Pesant[1,2], Belina Carranza-Mamane[1,2] and Jean-Patrice Baillargeon[1,2]
[1]*Sherbrooke, Canada;* [2]*Centre de Recherche du Centre Hospitalier Universitaire de Sherbrooke, Sherbrooke, Canada;* [3]*Université de Montréal, Montréal, Canada*

Polycystic ovary syndrome (PCOS) is the first cause of anovulatory infertility and is closely related to obesity, which is also associated with infertility even in ovulatory women.**Aim:** Evaluate the effects of Fit-For-Fertility lifestyle intervention in women

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

with overweight/obesity (OWOB) and infertility according to PCOS status and other subgroups.

Design: Women with OWOB and infertility who could naturally conceive followed a lifestyle intervention alone for 6 months, then combined to fertility care if necessary, vs uninterrupted fertility care (control group). 128 participants were enrolled (81 PCOS, 46 non-PCOS), and 108 were followed up $\geq 6 \pm 1$ months (68 PCOS, 40 non-PCOS). Subgroup analyses of a PCOS-stratified randomized controlled trial testing the Fit-For-Fertility intervention were conducted in addition to exploratory analyses for age, parity, BMI, self-reported activity level, and smoking status subgroups. Analyses were according to intention-to-treat (ITT) and modified per-protocol (mPP; participants who completed $\geq 6 \pm 1$ months of follow-up) principles. Fertility outcomes were the occurrence of live birth, and clinical and natural pregnancy within 18-months.

Results: Mean ± SD age and BMI were 29.1 ± 4.8 years and 39.4 ± 7.8 kg/m^2 in women with PCOS and was 30.5 ± 4.9 years and 40.3 ± 7.2 kg/m^2 in women without. In ITT analyses, the intervention significantly improved natural pregnancy rates in women with PCOS (21.4% vs 5.1%, OR = 5.05, $P = .048$). In mPP analyses, the intervention significantly or marginally significantly improved live birth (54.5% vs 31.4%, OR = 2.62, $P = .057$), clinical pregnancy (57.6% vs 34.3%, OR = 2.60, $P = .056$), and natural pregnancy (27.3% vs 5.7%, OR = 6.19, $P = .027$) rates in the PCOS subgroup, which tended to respond better than the non-PCOS subgroup. Indeed, no significant intervention effects were detected in the non-PCOS subgroup (all $P > .10$), but no group*PCOS status interventions were significant (all $P > .20$). Moreover, in mPP analyses, the intervention was significantly more effective to improve live birth rates in participants <30 years old (p for interaction = 0.012; OR = 5.54, $P = .007$) and those who smoked (p for interaction = 0.04; OR = 10.5, $P = .018$), but not according to parity (P for interaction = 0.19), class III obesity (P for interaction = 0.80; BMI ≥ 40 kg/m^2 cutoff), or activity level (P for interaction = 0.14; not active vs active or moderately active).

Conclusions: In women with OWOB and infertility, a lifestyle intervention improved natural and clinical pregnancy rates and tended to improve live birth rates in women with PCOS who persevered at least 6 months. Furthermore, the intervention was significantly more effective in improving fertility outcomes in women who completed ≥6 months and were aged <30 years or smoked.

RC11.3 - ECE_1896 - Higher maternal third trimester insulin resistance is linked to central fat deposition i 7-year-old girls. An Odense child cohort study

Matias Serup[1], Camilla Viola Palm[2], Anja Fenger Dreyer[3], Anders Grøntved[4], Jan Jørgensen[2], Henrik Christesen[5], Tina Kold Jensen[6], Dorte Glintborg[3] and Marianne Andersen[3]
[1]*University of Southern Denmark, Odense, Denmark;* [2]*Gynecology and Obstetrics, Odense University Hospital, Odense C, Denmark;* [3]*Endocrinology, Odense University Hospital, Odense C, Denmark;* [4]*Sports Science and Clinical Biomechanics, University of Southern Denmark, Odense, Denmark;* [5]*H.C. Andersen Children's Hospital, Odense University Hospital, Odense C, Denmark;* [6]*Clinical Pharmacology, Pharmacy and Environmental Medicine, University of Southern Denmark, Odense, Denmark*

Introduction: Maternal Insulin resistance is evident in third trimester and may have intergenerational effects on child fat deposition. More central fat in children has been associated with increased cardiovascular risk. Furthermore, there may be sexual dimorphism regarding susceptibility to pre-gestational metabolic environment.

Objectives: To examine associations between maternal third trimester insulin resistance, glucose status and child body composition, including gynoid and android fat deposition, in 7-year-old girls and boys.

Methods: 903 mother-child pairs (girls, $n = 449$) were included from the Odense Child Cohort. third trimester insulin resistance, homeostatic model assessment-insulin resistance (HOMA-IR), fasting plasma glucose (FPG), insulin, and HbA1c and first trimester HbA1c were measured. Child Dual X-ray Absorptiometry (DXA)-assessed body composition (total, android and gynoid fat mass) were estimated at 7 years. Participants and health professionals were blinded for maternal FPG, insulin and HbA1c results.

Results: In girls, a doubling in third trimester HOMA-IR was associated with a 7.1% ($P = .02$), 1.1% ($P = .008$) and 4% ($P = .008$) increase in android, gynoid and total fat mass percentages, respectively. One mmol/L higher maternal FPG was associated with 6.1% ($P = .02$) higher fat mass percentage in girls. Associations between third trimester HOMA-IR, FPG, insulin, HbA1c and child fat mass percentage were positive in girls (All $P \leq .02$) and boys ($P = .14$, .07, .19 and .15, respectively), but only significant in girls.

Conclusions: Insulin resistance in third trimester was linked to more central fat in 7-year-old girls, suggesting higher susceptibility to insulin resistance in girls compared to boys.

Abstract citation ID: lvag096.206

RC11.4 - ECE_3635 - Efficacy and clinical Impact of nitisinone in alkaptonuria: a follow-up study from the adult metabolic disorders unit at Virgen del Rocio university hospital

Luis Baena Ariza[1], Elena Dios[1], Bothayna Oulad Ahmed[2], Silvia Torres Degayon[1], Rosa Benitez Avila[1], Alfonso Soto[1] and Eva Venegas Moreno[3]
[1]*Clinical Management Unit of Endocrinology and Nutrition, Virgen del Rocio University Hospital, Sevilla, Spain;* [2]*Torrecardenas University Hospital, Almeria, Spain;* [3]*Endocrinologia y Nutrición, Instituto de biomedicina (IBIS), Campus Del Hospital Universitario Virgen del Rocio, Sevilla, Spain*

Study objective. Cross-sectional descriptive study on the characteristics of a cohort of patients with alkaptonuria under active follow-up at the HUVR, and the effects of nitisinone treatment on homogentisic acid and tyrosine levels.

Material and methods. Demographic (age, sex) and anthropometric (weight, body mass index [BMI]) data were collected. Specific alkaptonuria involvement (ochronosis, osteoarticular involvement, genitourinary lithiasis, valvular disease) and other comorbidities (hepatic, renal, muscular, metabolic) were recorded. Tyrosine and homogentisic acid levels were measured before, as well as 6 months and 1 year after treatment initiation.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Current treatments (diet, nutritional supplements, nitisinone dosage) were also documented.

Results. Data were collected from 8 patients with alkaptonuria from 6 different families: 3 females, mean age 57 ± 13 years. BMI was 27 ± 3.3 kg/m^2: 3 normal weight, 4 overweight, and 1 grade I obesity.

Ochronosis was present in all patients, affecting the auricular pavilion in all and the conjunctiva in 7/8.

Osteoarticular involvement was the most frequent: 7/8 had axial involvement (osteoarthritis and disc disease), 3/8 had peripheral osteoarthritis, 5/8 had osteoporosis, and the remaining 3 had osteopenia. Five patients had genitourinary lithiasis (only 1 prostatic). Cardiac involvement included two valvulopathies and one left ventricular hypertrophy. Auditory involvement was present in 3 patients: 2 with hearing loss and 1 with tinnitus. Renal involvement was found in 2 related patients.

Nitisinone was used in all patients at a dose of 2 mg/day (except one patient at 1 mg/day), reducing 24-hour urinary homogentisic acid by 82.2% at one year. The mean annual increase in tyrosine was 829%, consistent with the drug's mechanism of action, necessitating a low-tyrosine diet and the use of tyrosine-free nutritional supplements. Only 2 patients experienced ocular discomfort related to tyrosine levels.

Conclusions. In our cohort, patients with alkaptonuria presented significant and limiting osteoarticular involvement in daily life, as well as a history of genitourinary lithiasis.

Nitisinone treatment markedly reduced homogentisic acid levels and consequently increased tyrosine levels, requiring a strict low-tyrosine diet, tyrosine-free supplements, and close monitoring. Disease awareness is crucial for reducing morbidity and enabling early initiation of specific treatment to mitigate pathological alkapton deposition.

RC11.5 - ECE_1788 - An atypical PKC activator promotes intestinal glucose excretion and glycemic control in diabetes mellitus

Cheol Ryong Ku[1], Yoon-A Hwang[1] and Jae Won Hong[2]
[1]*Division of Endocrinology, Department of Internal Medicine, Institute of Endocrine Research, Yonsei University College of Medicine, Seoul, South Korea;* [2]*CHA Ilsan Medical Center, Division of Endocrinology, Department of Internal Medicine, CHA University, Goyang, South Korea*

Background: Intestinal glucose excretion, defined as the uptake of circulating glucose into intestinal epithelial cells followed by luminal secretion, has emerged as an important mechanism contributing to improved glycaemic control after bariatric surgery. Despite its metabolic relevance, the molecular pathways governing this process remain incompletely understood, and pharmacological approaches capable of reproducing this effect have not yet been established.

Methods: To identify molecular pathways associated with intestinal glucose excretion, transcriptomic signatures derived from multiple experimental models exhibiting differential intestinal glucose handling were analyzed using a Connectivity Map–based drug discovery platform. Candidate pathways were prioritized based on concordant transcriptional profiles and subsequently evaluated in intestinal epithelial cell models and mouse models of diabetes. Intestinal glucose uptake and luminal excretion were quantified using tracer-based assays, while systemic metabolic effects were assessed by fasting blood glucose measurements and glucose tolerance testing. Mechanistic studies focused on glucose transporter regulation and downstream signaling pathways.

Results: Transcriptome-driven screening consistently ranked protein kinase C signaling among the top mechanisms associated with glucose-excretory intestinal phenotypes. Pharmacological activation of atypical protein kinase C using prostratin, a non–tumour-promoting phorbol ester, significantly increased intracellular glucose uptake in intestinal epithelial cells by 1.7-fold compared with controls ($P = .009$). In diabetic mice, prostratin-induced activation of intestinal atypical protein kinase C increased luminal glucose excretion by 34%, accompanied by a 23% reduction in fasting blood glucose levels ($P = .031$) and a 27% decrease in glucose tolerance test area under the curve ($P = .004$). Mechanistic analyses demonstrated that atypical protein kinase C activation regulates glucose transporter 1 trafficking, promoting basolateral glucose uptake and coordinated apical glucose secretion in intestinal epithelial cells. These metabolic effects occurred without inducing intestinal epithelial proliferation, body weight loss, or hypoglycaemia, and were independent of changes in insulin secretion.

Conclusions: These findings demonstrate that atypical protein kinase C is a key molecular regulator of intestinal glucose excretion and systemic glucose homeostasis. Pharmacological activation of atypical protein kinase C induces a glucose-excretory intestinal phenotype and improves glycaemic control in diabetic mouse models, suggesting a potential therapeutic strategy to pharmacologically mimic the metabolic benefits of bariatric surgery.

RC11.6 - ECE_1419 - Lipidomic profiling identifies phosphatidylethanolamines as novel circulating markers of Fabry nephropathy

Dimitrios Chantzichristos[1,2], Mikael Oscarson[3], Andreas Kindmark[4], Malin Levin[1], Per-Olof Bergh[5], Jan Borén[1], Elias Björnson[1] and Maria Blomqvist[1]
[1]*Department of Internal Medicine and Clinical Nutrition, University of Gothenburg, Gothenburg, Sweden;* [2]*Department of Endocrinology, Diabetes and Metabolism, Sahlgrenska University Hospital, Gothenburg, Sweden;* [3]*Karolinska University Hospital, Stockholm, Sweden;* [4]*University of Uppsala, Uppsala, Sweden;* [5]*Chalmers University of Technology, Göteborg, Sweden*

Background: Fabry disease is a rare X-linked lysosomal storage disorder caused by pathogenic variants in the *GLA* gene, resulting in α-galactosidase A deficiency. It is a multisystem disease with substantial interindividual heterogeneity, particularly regarding renal involvement. Although plasma globotriaosylsphingosine (lyso-Gb3) is an established diagnostic biomarker, robust circulating markers reflecting the severity and progression of Fabry nephropathy are still lacking.

Methods: In a nationwide, prospective, cross-sectional, controlled study (ClinicalTrials.gov: NCT05046379), we included 54 adults with well-characterized Fabry disease and 54 control

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

subjects matched for age, sex, and estimated glomerular filtration rate (eGFR). Fasting morning blood samples were collected under standardized pre-analytical conditions. Targeted lipidomics quantified 179 lipid species across multiple lipid classes using four complementary mass spectrometry platforms. Between-group differences were assessed using multivariable logistic regression adjusted for age, sex, systolic blood pressure, and apolipoprotein B, with correction for multiple testing. Within the Fabry cohort, associations between lipid species and renal function were examined using multivariable linear regression. A multianalyte prediction model was developed using gradient boosting with 5-fold cross-validation.

Results: Compared with controls, Fabry disease was characterized by widespread lipidomic remodeling, including reduced concentrations of multiple sphingomyelin isoforms, lower levels of sphingosine-1-phosphate and sphinganine-1-phosphate, altered ceramide profiles, and increased ceramide ratios. A combined lipid model incorporating significantly differentiated lipid species and ceramide ratios achieved excellent discriminative performance (cross-validated ROC–AUC ≈ 0.994 in males and ≈0.997 in females). Importantly, analyses focusing on renal involvement identified phosphatidylethanolamines (PEs) as the lipid class most strongly associated with renal function in Fabry disease. Specifically, PE 38:6, PE 36:2, and the total sum of measured PEs were inversely associated with eGFR (adjusted $P = .016$, .031, and .031, respectively), whereas no such associations were observed in controls.

Conclusions: Our analyses reveal that Fabry disease is associated with previously unrecognized systemic lipidomic alterations extending beyond lyso-Gb3. Notably, specific circulating phosphatidylethanolamine signatures were independently associated with renal dysfunction in Fabry disease, consistent with lipidomic patterns reported in nephropathy across other diseases. These findings nominate phosphatidylethanolamines as novel candidate prognostic biomarkers of Fabry nephropathy and warrant validation in independent, preferably longitudinal, cohorts.

Abstract citation ID: lvag096.209

RC12.2 - LBA_ECE_1219 - Limited agreement between FibroScan and MR-based assessment of hepatic steatosis and fibrosis in acromegaly: a proof-of-concept study

Meliha Melin Uygur[1], Ayse Nur Gul[1], Damla Tufekci[1], Gulen Burakgazi[2] and Caglayan Keklikkiran[3]

[1]Department of Endocrinology and Metabolism, Faculty of Medicine, Recep Tayyip Erdoğan University, Rize, Türkiye; [2]Department of Endocrinology, Faculty of Medicine, Recep Tayyip Erdoğan University, Rize, Türkiye; [3]Department of Gastroenterology, Faculty of Medicine, Recep Tayyip Erdoğan University, Rize, Türkiye, Rize, Türkiye

Background: Acromegaly is characterized by chronic excess of growth hormone (GH) and insulin-like growth factor-1 (IGF-1), resulting in insulin resistance and adverse cardiometabolic risk. Paradoxically, hepatic steatosis appears attenuated in acromegaly, likely due to GH-driven lipolysis and altered hepatic lipid handling. While FibroScan is widely used for noninvasive assessment of hepatic steatosis and fibrosis, its validity in acromegaly, an endocrine condition with distinct metabolic physiology, has not been systematically evaluated.

Objective: To conduct the first comparative evaluation of FibroScan and magnetic resonance (MR)–based liver assessment in patients with acromegaly and to examine the clinical utility of FibroScan in this setting.

Methods: In this cross-sectional proof-of-concept study, patients with acromegaly undergoing FibroScan and MR-based liver evaluation were included. FibroScan parameters comprised controlled attenuation parameter (CAP) for steatosis and liver stiffness measurement (LSM) for fibrosis. MR-based evaluation included quantitative liver fat assessment and MR elastography (MRE). Clinical and biochemical data, including body mass index (BMI), GH, and IGF-1, were collected. Associations between imaging modalities and clinical variables were assessed using Spearman correlation, and linear regression analyses were performed to explore predictors of MRE.

Results: A total of 8 patients were included depending on data availability (mean BMI 30.7 ± 4.3 kg/m^2). CAP values were within ranges suggestive of steatosis (248 ± 39 dB/m), whereas MR-based fat quantification consistently demonstrated low hepatic fat content ($4.25\% \pm 3.48\%$). Liver stiffness values were low by both FibroScan (3.77 ± 0.93 kPa) and MRE (2.38 ± 0.33 kPa), indicating absence of significant fibrosis.

No significant correlation was observed between CAP and MR-derived hepatic fat ($r = 0.203$, $P = .700$), indicating poor agreement for steatosis assessment. Similarly, FibroScan-derived liver stiffness showed weak and non-significant correlation with MRE ($r = 0.247$, $P = .637$), and regression analysis confirmed that FibroScan parameters were not significant predictors of MRE.

In contrast, CAP demonstrated a strong and statistically significant correlation with BMI ($r = 0.943$, $P = .005$), suggesting that CAP values may be driven by body composition rather than hepatic fat content in acromegaly.

Conclusions: In this first proof-of-concept study directly comparing FibroScan with MR-based liver assessment in acromegaly, FibroScan parameters showed limited agreement with MR findings. Notably, CAP appears to reflect BMI rather than hepatic steatosis, highlighting a potential limitation of FibroScan in this endocrine context. These findings provide novel insight into liver assessment in acromegaly and underscore the need for disease-specific validation of noninvasive diagnostic tools.

Figure 1

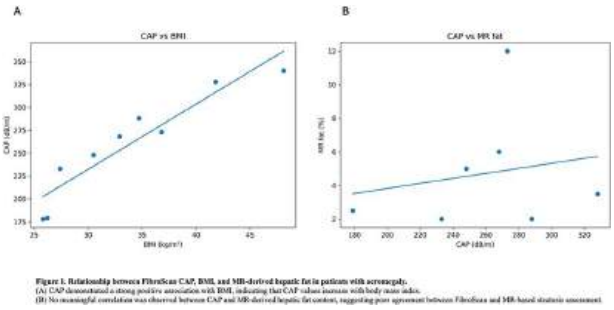

Figure 1. Relationship between FibroScan CAP, BMI, and MR-derived hepatic fat in patients with acromegaly.
(A) CAP demonstrated a strong positive association with BMI, indicating that CAP values increase with body mass index.
(B) No meaningful correlation was observed between CAP and MR-derived hepatic fat content, suggesting poor agreement between FibroScan and MR-based steatosis assessment.

RC12.3 - LBA_ECE_1400 - Profiling of CYP17A1 mutations defines the molecular basis of partial enzyme deficiencies

Kaige Li, Jibira Yakubu and Amit Pandey
University of Bern, Bern, Switzerland

Context: 17α-hydroxylase/17,20-lyase deficiency (17-OHD) is a rare form of congenital adrenal hyperplasia characterized by hypertension, hypokalemia, and sexual infantilism. Its spectrum ranges from complete deficiency to partial forms with spontaneous puberty and fertility, yet the molecular basis of this heterogeneity remains unclear.
Objective: To elucidate the pathophysiology of 17-OHD by integrating phenotyping with functional and structural characterization of seven CYP17A1 variants: T131P, L209P, G303D, L361P, I296T, R340H, and R449H.

Methods: Clinical and hormonal data were obtained from seven probands, including one with the novel T131P mutation. Variants were generated by site-directed mutagenesis in pcDNA3.1 vectors and expressed in HEK-293T cells. Enzymatic activities of 17α-hydroxylase and 17,20-lyase were measured using 14C-progesterone and 3H-17OH-pregnenolone substrates and normalized to protein expression by Western blot. In silico structural modeling localized mutations to catalytic or regulatory domains.

Results: Western blot showed mutant proteins were expressed at levels comparable to wild-type, indicating preserved stability. L209P and G303D showed near-complete loss of hydroxylase activity (<9% of WT), consistent with severe phenotypes. The T131P variant retained ~7% activity, sufficient to permit spontaneous menarche. R449H retained lyase activity, consistent with a history of fertility. Structural modeling linked activity loss to disruptions in the F-helix (L209P), I-helix (G303D), or redox partner-binding surfaces (R449H), rather than gross protein misfolding.

Conclusions: These variants cause disease through specific catalytic or regulatory defects rather than protein instability. Residual activity showed a non-linear relationship with clinical severity, with <10% supporting secondary sexual development. Structural analysis may help predict clinical outcomes and fertility potential in 17-OHD.

Introduction: Carney Complex (CNC) is a rare genetic multiple neoplasia syndrome. While *PRKAR1A* pathogenic variants are the primary cause, *PRKACA* duplications have emerged as a causing genetic alteration. With the use in routine practice of next generation sequencing and whole genome sequencing the frequency of identification of genetic alterations might have change.

Methods: Retrospective analysis of 71 probands referred for genetic screening with a clinical suspicion of CNC between 2020 and 2025. Main clinical presentation were: Primary Pigmented Nodular Adrenocortical Disease (PPNAD) ($n = 32$), cardiac myxomas ($n = 24$), lentigines ($n = 18$), schwannomas ($n = 6$). *PRKAR1A* and *PRKACA* genes were screened for point variants and copy number variants (CNV), by targeted sequencing using NGS in all, and when non conclusive by WGS in a subset.

Results: The median age at genetic screening was 33 years (range: 2-70). A genetic alteration was found in 69% (22/32) of probands with PPNAD, up to 73% (8/11) in patient under 20 and 73% (8/11) if PPNAD was associated with other CNC features. *PRKAR1A* variants were found in 28 probands: half of them carried a splice-altering variant, the remaining being mostly truncating variant or CNVs. This group showed the most diverse phenotype, including PPNAD (61%), lentigines (39%), and myxomas (29%). *PRKACA* duplications were identified in 4 probands all presenting PPNAD and no other CNC features. No genetic alteration was found for probands presenting isolated schwannomas or isolated myxomas over 35 years old.

Discussion: Our results confirm that *PRKACA* duplications are almost exclusively associated with an adrenal-limited phenotype. The high rate of negative genetic results in patients with isolated myxomas or schwannomas suggests either genetic heterogeneity or the presence of variants in non-coding regions. A genetic alteration can now be identified in 3/4 of patients with PPNAD and/or multiple features of CNC, which is more frequently than previously reported.

Background: Adrenocortical carcinoma (ACC) is a rare and aggressive endocrine malignancy with an incompletely defined genetic background. Although several predisposing genes have been identified, many cases remain genetically unexplained.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

This study aimed to identify novel germline variants (GVs) potentially involved in disease susceptibility in patients with sporadic ACC, by Whole Exome Sequencing (WES).

Methods: This retrospective analysis included patients with sporadic ACC stage I-IV. From our previously published cohort of 150 patients, we selected those who tested negative for alterations in the 17 genes most frequently implicated in adrenal tumor pathogenesis (AIP, APC, ARMC5, ARNT, BRCA1, BRCA2, CTNNB1, IGF2, MEN1, MSH2, MSH6, PDE8B, PDE11A, PRKACA, PRKACB, PRKAR1A, and TP53). Variant calling and interpretation were performed using SOPHIA Genetics pipeline. Filtering strategies prioritized genes associated with ACC predisposition and other hereditary cancer syndromes, mainly under a dominant inheritance model.

Results: Fifty-two patients were selected, with a predominance of females (75%, 39/52). Median age at diagnosis was 35 years (IQR 29-44). A personal history of malignancies other than ACC was reported in 29% of patients, while 31% had a positive family history for non-ACC malignancies. Most patients were diagnosed at stage II (63%). At a median follow-up of 45 months (IQR 22.5-77), 16 deaths were observed. Median overall survival was 176 months (95% IC 62-not reached). GVs of potential interest were identified in 6 patients (11.5%), involving the following genes: BARD1 ($n=1$), CHEK2 ($n=3$), MUTYH ($n=3$) and POLE ($n=1$). Most variants were classified as pathogenic/likely pathogenic, while one CHEK2 variant had conflicting pathogenicity interpretations according to available databases. Interestingly, patients carrying some of those alterations showed a family history of other neoplasia (breast, lung and colon rectal cancers), suggesting a potential hereditary predisposition. Somatic analyses on matched tumor samples are currently ongoing to investigate loss of heterozygosity (LOH) and second-hit mechanisms.

Conclusions: We identified GVs in a subset of patients with sporadic ACC who were selected for not being informative for the most common gene alterations. These findings support a potential role of additional genetic factors in predisposition to ACC. Their clinical significance remains to be fully defined.

RC12.6 - LBA_ECE_1193 - Mild autonomous cortisol secretion vs nonfunctional adrenal tumors and risk of psychiatric morbidity: a register-based cohort study

Hadis Mirzaei
Karolinska Institutet, Stockholm, Sweden

Background: Adrenal tumors are increasingly detected, and subtle cortisol excess may contribute to systemic disease morbidity. However, population-based data on psychiatric outcomes in relation to post–dexamethasone suppression test (DST) cortisol concentrations remain limited.

Objective: To examine the prevalence and incidence of psychiatric disorders in patients with adrenal tumors according to cortisol concentrations measured using the 1-mg dexamethasone suppression test (DST), comparing mild autonomous cortisol secretion (MACS) with nonfunctioning adrenal tumors (NFAT).

Methods: This regional population-based cohort study included patients with adrenal tumors and available DST results identified through Swedish national healthcare registries and three clinical laboratories in the Stockholm region. Overt functional adrenal tumors and primary adrenal malignancies were excluded. Patients were categorized according to post-DST cortisol concentrations (≤50 vs >50 nmol/L). Psychiatric outcomes were defined using ICD-10 diagnoses. Logistic regression and Cox proportional hazards models were used to assess prevalence and incidence outcomes, adjusted for age, sex, and socioeconomic variables.

Results: A total of 3195 patients with adrenal adenomas were included. The prevalence of psychiatric disorders at baseline was 47.3%. In crude analyses, MACS was not associated with baseline psychiatric disorders; however, after adjustment, MACS was associated with a higher prevalence (OR 1.14, 95% CI 0.95-1.37, aOR 1.35, 95% CI 1.11-1.64). During a median follow-up of 4.7 years (IQR 2.3-7.6), 334 individuals developed an incident psychiatric disorder. MACS was associated with an increased risk of incident psychiatric diagnoses (HR 1.66, 95% CI 1.34-2.06; adjusted HR 1.79, 95% CI 1.43-2.23). MACS was also associated with an increased risk of anxiety disorders (aHR 1.41, 95% CI 1.08-1.86), affective disorders (aHR 1.56, 95% CI 1.11-2.19), and substance use disorders (aHR 2.50, 95% CI 1.79-3.49). Stratified analyses suggested somewhat stronger associations among women and younger individuals, although formal interaction testing did not indicate a statistically significant effect modification.

Conclusions: Psychiatric disorders are common among patients with adrenal tumors. While post-DST cortisol concentrations were not clearly associated with baseline psychiatric prevalence, Patients with MACS showed an increased risk of incident psychiatric disorders. These findings suggest that even mild cortisol autonomy may contribute to psychiatric vulnerability over time.

P1 - ECE_2359 - Impact of P450 oxidoreductase mutation on drug metabolism: a case report

Ludmila Nicolazzi[1], Isabelle Gauchat-Bouchardy[2], Anne-Laure Rougemont[2], Nathalie Lin-Marq[2], Faiza Lamine[1], Haithem Chtioui[1] and Georgios Papadakis[1]
[1]Service of Endocrinology, Diabetology, and Metabolism, Lausanne University Hospital, Lausanne, Switzerland; [2]Service of Clinical Pathology, Geneva University Hospital, Geneva, Switzerland

Background: P450 oxidoreductase deficiency (PORD) is a rare form of congenital adrenal hyperplasia, characterized by variable degrees of primary adrenal insufficiency, ambiguous genitalia and skeletal malformations. It is caused by bi-allelic mutations in the *POR* gene, affecting the transfer of electrons to multiple cytochrome P450 (CYP) enzymes implicated in steroidogenesis but also in hepatic drug metabolism. Pharmacologic alterations have been reported in classic syndromic PORD. Data regarding pathways affected in milder PORD cases is currently scarce.

Method: We previously published the original case of a 36-year-old patient diagnosed with partial PORD due to a very mild phenotype (menstrual irregularity, infertility, ovarian macrocysts) (PMID 32242900). To evaluate the impact of POR mutations on drug metabolism beyond the classic PORD phenotype, we investigated CYP1A2, CYP2B6, CYP2C9, CYP2C19, CYP2D6, CYP3A4 metabolic pathways with CYPs genotyping in search of

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

single nucleotide polymorphisms (SNP) to classify the predicted phenotype for each enzyme as poor (PM), normal (NM), rapid (RM) or ultrarapid metabolizer (UM); *in vivo* phenotyping using the Geneva CYP450 micrococktail (PMID 34512355) to measure metabolic ratios (MR) and characterize CYP-activities as slow, normal or rapid.

Results: Genotype revealed four SNPs in *CYP1A2* gene, one SNP in *CYP2C19* gene and three SNPs in *CYP2D6* gene, resulting in UM, RM and UM, respectively. NM was expected for the remaining CYPs in the absence of significant SNPs. Nevertheless, *in vivo* phenotyping revealed low MRs for CYP1A2 (0.19), CYP2C9 (0.02), CYP2C19 (0.14), CYP3A4 (0.06), consistent with slowed drug metabolism. CYP2B6 activity was mildly reduced (MR 0.31), while the observed phenotype was normal for CYP2D6 (MR 1.89). These alterations were expected to translate into decreased metabolism of several ongoing medications of the patient including estrogens, calcium channel blockers and proton pump inhibitors.

Discussion: A discordance between genotype and phenotype was observed for five out of the six CYP enzymes, reflecting a PORD-mediated decrease in their drug-metabolizing capacity. Our case highlights the impact of PORD on drug metabolism even in its milder, non-classic forms. Following these results, patient's affected medications were reduced to the lowest clinically effective dose. She was also instructed to be cautious when initiating new medications primarily metabolized by CYP1A2, CYP2C9, CYP2C19 or CYP3A4.

Conclusions: POR mutations can alter drug metabolism, but the resulting phenotype depends also on underlying CYP polymorphisms. In these patients, pharmacologic investigations with genotyping and phenotyping approaches can help to better appreciate metabolic alterations and guide personalized treatment adjustments.

P2 - ECE_3580 - Adrenal tumor shrinkage after osilodrostat therapy in patients with acth-independent cushing syndrome

Virginia Samaritani[1,2], Lorenzo Tucci[1,2], Francesca Donnarumma[1,2], Giada Ramundo[1,2], Giulia Zema[1,2], Valentina Vicennati[1,2], Caterina Balacchi[3], Uberto Pagotto[1,2], Cristina Mosconi[3] and Guido Di Dalmazi[1,2]
[1]*Division of Endocrinology and Diabetes Prevention and Care, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy;* [2]*Department of Medical and Surgical Sciences, Alma Mater Studiorum University of Bologna, Bologna, Italy;* [3]*Radiology Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy*

Background and Aim: Adrenal tumor shrinkage after Osilodrostat therapy has been reported in ACTH-dependent hypercortisolism. However, data in ACTH-independent hypercortisolism are lacking. We describe two cases of adrenal nodule reduction following Osilodrostat therapy in patients with ACTH-independent hypercortisolism.

Case 1: A 57-year-old man was diagnosed with ACTH-independent Cushing syndrome associated with bilateral macronodular adrenal hyperplasia (urinary free cortisol [UFC]: 646 µg/day; serum cortisol after 1-mg overnight dexamethasone suppression test [1mg-ONDST]: 237 ng/mL; 23-salivary cortisol: 3.23 ng/ml). Computerized tomography (CT) showed a larger left adrenal gland (three nodules, maximum diameter 45 mm) compared with the right gland (three nodules, maximum diameter 34 mm). 18F-fluorodeoxyglucose positron emission tomography revealed higher uptake in the left adrenal gland compared to the right one (SUVmax 4.5 vs 3). The patient underwent left adrenalectomy, followed by adrenal insufficiency and recovery of adrenal function. Histology demonstrated macronodular adrenal hyperplasia (Weiss score 2). Germline DNA sequencing did not identify pathogenic *ARMC5* variants. Two years later, recurrence of ACTH-independent hypercortisolism was diagnosed (UFC: 140 µg/day; 1 mg-ONDST: 75 ng/mL). Metyrapone therapy was initiated. At treatment start, right adrenal nodules measured 26 × 20 mm, 34 × 26 mm, and 24 × 20 mm. After 43 months of therapy (weighted mean daily dose 750 mg), CT scan showed nodule growth over time (33 × 25 mm, 46 × 35 mm, and 30 × 20 mm, respectively). Metyrapone was discontinued and Osilodrostat initiated. After 7 months of Osilodrostat therapy (weighted mean daily dose 2.01 mg), CT demonstrated a reduction in the largest right adrenal nodules (38 × 28 mm vs 46 × 35 mm and 30 × 20 mm vs 33 × 25 mm).

Case 2: A 56-year-old woman was diagnosed with ACTH-independent Cushing syndrome (UFC: 441 µg/day; 1 mg-ONDST: 188 ng/mL; late-night salivary cortisol: 15.9 ng/mL). Abdominal CT revealed bilateral macronodular adrenal hyperplasia (left nodules: 32 mm, 13 mm, and 7 mm; right nodules: 20 mm and 7 mm). Osilodrostat therapy was initiated. After 16 months of treatment (weighted mean daily dose 5.10 mg), repeated CT showed a reduction in nodular size in both adrenal glands (left: 27 mm vs 32 mm and 5 mm vs 13 mm; right: 12 mm vs 20 mm and 6 mm vs 7 mm).

Conclusions: This is the first report of shrinkage of adrenal nodules in ACTH-independent Cushing syndrome. Recently, cases of adrenal shrinkage following Osilodrostat therapy have been emerging in patients with both ACTH-dependent and ACTH-independent Cushing syndrome. The underlying mechanism remains unknown. Targeted studies are needed to confirm this observation and to elucidate the potential pathophysiological mechanism.

P3 - ECE_1584 - A novel homozygous mutation of CYP17A1 gene in a 20-year old 46, XY phenotypical male with hypergonadotropic hypogonadism and gynecomastia

Karolina Kucharczyk[1], Anna Nogieć[1], Grzegorz Sokolowski[2], Anna Matrejek[1], Malgorzata Trofimiuk-Muldner[2] and Alicja Hubalewska-Dydejczyk[3]
[1]*University Hospital in Krakow, Krakow, Poland;* [2]*Department of Endocrinology, Jagiellonian University Medical College, Krakow, Poland;* [3]*Chair and Department of Endocrinology, Jagiellonian University Medical College, Krakow, Poland*

Introduction: Congenital adrenal hyperplasia (CAH) comprises autosomal recessive disorders of adrenal steroidogenesis. 17α-hydroxylase/17, 20-lyase deficiency (17-OHD) is a rare subtype (~1% of CAH) caused by pathogenic variants in *CYP17A1*. In 46, XY individuals, complete deficiency typically leads to female or ambiguous external genitalia at birth and later hypertension and/or hypokalaemia. However, partial enzyme deficiency

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

may preserve some androgen and glucocorticoid production, leading to atypical presentations and delayed diagnosis.

Case Report: A 20-year-old 46, XY phenotypic male was referred for progressive right-sided gynecomastia over five years and hypergonadotropic hypogonadism, initially suspected to represent Klinefelter syndrome. He reported impaired ejaculation with preserved erectile function and sparse facial hair. Past history included hypospadias repair in early childhood. Examination revealed normally virilized male genitalia without ambiguity, reduced penile length, and age-appropriate pubic and axillary hair.

Investigations: Biochemistry confirmed hypergonadotropic hypogonadism with low testosterone and elevated luteinizing hormone. Adrenal evaluation showed persistent ACTH elevation, markedly increased 17-hydroxyprogesterone, and low adrenal androgens, suggesting impaired steroidogenesis, while cortisol circadian rhythm was preserved. Renin was suppressed with normal aldosterone and normal blood pressure. Impaired glucose tolerance and osteopenia were also identified. Karyotype was 46, XY.

Dynamic testing demonstrated minimal testosterone response to hCG and an abnormal Synacthen steroid profile with pronounced 17-hydroxyprogesterone elevation, supporting a congenital steroidogenic defect. Imaging showed pituitary changes consistent with hyperplasia and a left adrenal lesion compatible with adenoma. Breast biopsy was benign.

Urinary steroid profiling revealed increased mineralocorticoid and progesterone metabolites with elevated 17-hydroxylated metabolites and normal cortisol metabolites, consistent with partial CYP17A1 deficiency, predominantly affecting 17, 20-lyase activity.

Genetics: Genetic testing identified a novel homozygous CYP17A1 missense variant (c.1234T>C, p.Phe412Leu; exon 7), classified as likely pathogenic and confirmed by Sanger sequencing. The variant has not been reported in major databases or the literature and is extremely rare in gnomAD (non-Finnish Europeans: 0.0000008993), with no previously described homozygous cases.

Conclusions: This case expands the genotypic and phenotypic spectrum of partial 17α-hydroxylase/17, 20-lyase deficiency. The patient presented with hypergonadotropic hypogonadism and progressive gynecomastia despite normal blood pressure, preserved circadian cortisol rhythm, and no genital ambiguity, with only subtle signs of undervirilization. These findings demonstrate that residual CYP17A1 activity can mask the classic phenotype. Therefore, 17-OHD should remain in the differential diagnosis of young men with unexplained hypogonadism, particularly when any features of disordered sex development are present.

Keywords CYP17A1, 17α-hydroxylase/17, 20-lyase deficiency (17-OHD), Congenital Adrenal Hyperplasia (CAH), Gynecomastia, Hypogonadism, c.1234T>C

P4 - ECE_2057 - Diagnostic jouney and delays in patients with pheochromocytoma and abdominal paraganglioma: from symptom onset to post-surgical outcomes

Emmanuelle Kamand[1], Elise Bouillet[2], Camille Marciniak[1], François Collet[1], Marine Mallea[1], Dupuis Hippolyte[1], Romain Vankemmel[1], Arnaud Jannin[1], Do Cao Christine[1], Guillaume Ledieu[1], Robert Caiazzo[1], Pattou François[1], Vantyghem Marie Christine[1], Cardot Catherine[1] and Stéphanie Espiard[1]

[1]CHU de Lille, Lille, France; [2]Centre Hospitalier de Tourcoing, Tourcoing, France

Background and Aim: Diagnostic delays in pheochromocytomas and paragangliomas (PPGL), their causes and consequences remain insufficiently documented, particularly from the patient perspective. While the classic Menard's triad is well-known, the full spectrum of patient-experienced symptoms remains poorly characterized. This study combines qualitative patient interviews with quantitative analysis to systematically characterize symptom burden, diagnostic delays, and post-operative outcomes.

Methods: A two-phase single-center prospective study was conducted. Qualitative interviews first identified patient experiences and symptom terminology. Based on these findings, a questionnaire capturing symptoms in patient-familiar language was developed and administered to patients operated for PPGL, assessing pre/postoperative symptoms, diagnostic pathways, and recovery patterns.

Results: Qualitative analysis revealed two symptom evolution patterns: slow progressive worsening over years and unpredictable paroxysmal crises. Patients frequently minimized their symptoms, attributing them to aging or stress, which promoted consultation delays. Many patients felt unheard by healthcare professionals unfamiliar with PPGL. In the quantitative study ($n = 83$, 70.3% response rate), chest tightness and palpitations were predominant symptoms (62.7%), while Menard's triad occurred in only 20.5%. Women reported significantly more symptoms than men (median 4.6 vs 2.9, $P = .006$). After surgery, 44% of patients reported improvement in symptoms that they had not initially attributed to their PPGL. Complete postoperative symptom resolution occurred in 60.8% overall, but was significantly higher when diagnostic delay was <5 years (81.3% vs 47.4%, $P = .006$). Weight gain was reported by 39.8% of the patients. Antihypertensive therapy was discontinued in 63.3% and antidiabetic medication in 77.4% postoperatively. The median diagnostic delay was 27 months [IQR 10-76], yet 28.8% and 22.9% reported symptom onset >10 years and 6-10 years before diagnosis, respectively. Discovery mode was incidental imaging (61.4%), symptomatic (31.3%), or genetic surveillance (7.2%). Importantly, the proportion of highly symptomatic patients was identical between incidentalomas and symptomatic presentations (35%), suggesting many incidentalomas represent unrecognized symptomatic cases. Consultation frequency correlated with symptom burden ($P < .001$). Paradoxically, diagnostic delay did not correlate with symptom count ($r = 0.19$, $P = .262$) but increased with consultation frequency ($P < .001$) and patient age ($P = .013$), suggesting repeated missed diagnoses in symptomatic patients rather than paucisymptomatic presentations.

Conclusions: Diagnostic delays in PPGL are common and impair postoperative recovery. Symptom onset often preceded diagnosis by years to decades. This study highlights mechanisms leading to these delays: patient misattribution of symptoms and repeated missed diagnoses by providers. These findings underscore the need to enhance awareness among non-specialist providers who typically first encounter these patients, to improve outcomes and reduce healthcare burden.

P5 - ECE_1585 - Long-term risk of adrenal crisis and hospitalization in chronic adrenal insufficiency—a long-term follow-up study

Irina Chifu[1], Anna Lynn Schreiber[1], Marcus Quinkler[2], Holger S. Willenberg[3], Nicole Reisch[4], Felix Beuschlein[5,6], Olaf Dekkers[7,8], Burger-Stritt Stephanie[1,9] and Stefanie Hahner[1]

[1]Würzburg, Germany; [2]Endocrinology in Charlottenburg, Berlin, Germany; [3]Division of Endocrinology and Metabolism, Department of Internal Medicine, Rostock University Medical Centre, Rostock, Germany; [4]Medizinische Klinik und Poliklinik IV, Klinikum der Ludwig-Maximilians-Universität München, München, Germany; [5]Klinik für Endokrinologie, Diabetologie und Klinische Ernährung, Universitätsspital Zürich (USZ) und Universität Zürich (UZH), Zürich, Switzerland; [6]The LOOP Zurich - Medical Research Center, Zürich, Switzerland; [7]Department of Internal Medicine, Division of Endocrinology, Leiden University Medical Center, Leiden, The Netherlands; [8]Department of Clinical Epidemiology, Leiden University Medical Center, Leiden, The Netherlands; [9]Uppsala Centre of Excellence, Department of Endocrine Oncology, Uppsala University Hospital, Uppsala, Sweden

Background: We evaluated the long-term risk for adrenal crisis (AC) and hospitalization in patients with adrenal insufficiency (AI).

Methods: Patients ($n = 423$) from a previous 2-year prospective study on AC were re-contacted by questionnaire 6 years (FU1) and 14 years (FU2) after study completion (baseline). We collected data on AC, hospitalization, glucocorticoid replacement, stress dosing, co-medication, comorbidities, and patient education on AC prevention. A total of 277 and 203 patients participated at FU1 and FU2, respectively. Incidence rate ratios for AC and hospitalization were determined using Poisson regression.

Findings: Recurrent AC was associated with prior AC ($P < .001$), secondary AI ($P < .001$), glucocorticoid dose ($P = .03$), frequent stress dosing ($P = .009$), DHEA replacement ($P = .003$) and non-endocrine comorbidities ($P < .001$). Recurrent hospitalization was associated with prior hospitalization ($P < .001$), prior AC ($P = .005$), endocrine ($P = .01$) and non-endocrine ($P < .001$) comorbidities. Patients reporting AC or hospitalization received higher glucocorticoid doses at baseline and at each follow-up. Only 44% of patients had ever attended an AC-focused education session. Among 54 reported deaths, 8 were confirmed or suspected to be AC-related, and only 30% of deceased patients possessed an emergency kit at last follow-up.

Interpretation: The persistently increased risk among patients with prior AC despite higher glucocorticoid doses suggests intrinsic vulnerability, which is further amplified with multiple comorbidities. Despite improvements over time, awareness and access to emergency remain suboptimal and require urgent enhancement. Future studies should focus on prospective, long-term assessment of individual AC susceptibility, including biomarker identification and close monitoring of patient-reported outcomes.

Background: Composite pheochromocytomas, characterized by the coexistence of pheochromocytoma with additional neural crest–derived components, are considered uncommon, and data on their clinical behaviour and prognosis are limited. This study aimed to determine whether the presence of composite histology in pheochromocytomas is associated with differences in biological features, clinical manifestation, perioperative course, and long-term outcomes compared with conventional pheochromocytomas.

Methods: We conducted a retrospective analysis of 188 patients with histologically confirmed pheochromocytomas from two tertiary centres. Patients with composite and typical tumours were compared with regard to demographic characteristics, clinical presentation, biochemical findings, imaging features, surgical and perioperative data, histopathology, and follow-up outcomes.

Results: Composite pheochromocytomas constituted 15% of all cases ($n = 28$). Patients with composite tumours were older at diagnosis (median age 56 vs 50 years, $P = .04$) and had a higher prevalence of cardiovascular comorbidities (39.3% vs 18.1%, $P = .02$) than those with typical pheochromocytomas. Preoperative systolic blood pressure was higher in the composite group (median 150 mmHg vs 140 mmHg, $P = .03$) and remained significantly elevated following adrenalectomy (130 mmHg vs 123 mmHg, $P = .04$). Laparoscopic adrenalectomy was performed less frequently in patients with composite tumours (67.9% vs 87.5%, $P = .02$), although operative and anaesthesia durations were shorter. On non-contrast CT imaging, composite tumours showed lower attenuation values (median 28 vs 35 Hounsfield units, $P = .01$) and were less commonly identified as adrenal incidentalomas. Ki-67 indices in the range of 3-5% were more frequently observed in composite tumours (23.5% vs 4.6%, $P = .02$), while rates of recurrence and metastatic disease did not differ between groups.

Conclusions: Compared with typical pheochromocytomas, composite tumours present in an older population and are associated with increased cardiovascular morbidity, higher blood pressure, lower CT attenuation values, and distinct perioperative characteristics. Although elevated Ki-67 indices were more common in composite pheochromocytomas, their relevance for long-term prognosis remains unclear.

P7 - ECE_1671 - An ACTH-secreting pheochromocytoma presenting as septic cardiogenic shock

Jaekyung Lee, Sangjun Bae and Dong Jun Lim
Division of Endocrinology and Metabolism, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, South Korea

Background: ACTH-secreting pheochromocytoma is an exceptionally rare cause of ectopic Cushing's syndrome. Concurrent catecholamine and cortisol excess can mimic septic shock and induce reversible cardiomyopathy, leading to diagnostic delay. We describe a case presenting with fulminant cardiogenic shock requiring ECMO, characterized by extreme procalcitonin elevation, paradoxical dexamethasone response, and post-operative immune reconstitution with CMV reactivation.

Case: A 42-year-old woman presented with fever and shock (BP 80/73 mmHg, HR 180 bpm). Laboratory tests showed leukocytosis 16 340/μL, CRP 6.09 mg/dL, and procalcitonin 52.29 ng/mL. Echocardiography revealed global akinesia with LVEF 12%. Despite VA-ECMO, CRRT, and broad-spectrum antibiotics, all cultures were negative. Procalcitonin declined rapidly to 1.10 ng/mL while fever and leukocytosis persisted. CT identified a 6.7-cm right adrenal mass. Biochemistry demonstrated dual hormone excess: urine metanephrine 14 306 μg/day (ref <315), ACTH >4000 pg/mL, and cortisol 122.4 μg/dL. High-dose dexamethasone (8 mg) produced a paradoxical ACTH rise from 113.7 pg/mL to 459.8 pg/mL, suggesting an ectopic source. After alpha-blockade and ketoconazole, laparoscopic adrenalectomy was performed. Pathology confirmed pheochromocytoma with positive ACTH immunostaining. Postoperatively, the patient developed pancytopenia and hypotension. CMV PCR revealed 737 534 copies/mL, consistent with viral reactivation during immune recovery after abrupt correction of hypercortisolism. Following ganciclovir and steroid replacement, she recovered completely; LVEF improved to 53.4% and hormonal levels normalized.

Conclusions: ACTH-producing pheochromocytoma may present as apparent septic shock with extreme procalcitonin elevation and reversible cardiomyopathy. Dissociation between declining procalcitonin and persistent inflammation should prompt evaluation for endocrine causes. A paradoxical ACTH rise during dexamethasone testing may represent a useful diagnostic clue. Careful surveillance for opportunistic infections is required after curative treatment due to potential immune reconstitution.

P8 - ECE_2736 - Phase I, open-label, multiple-ascending-dose study of asedebart, a novel anti-adrenocorticotropic hormone (ACTH) antibody for the treatment of classic congenital adrenal hyperplasia (CAH)

Gudmundur Johannsson[1], Anand Velusamy[2], Alessandro Prete[3,4], Henrik Falhammar[5], Marie Louise Binderup[6], Klaus Groes Larsen[6], Mimi Folden Flensburg[6], Johan Luthman[6] and Umasuthan Srirangalingam[7]
[1]Department of Endocrinology, Sahlgrenska University Hospital, Gothenburg, Sweden; [2]Department of Endocrinology, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; [3]Department of Metabolism and Systems Science, University of Birmingham, College of Medicine and Health, Birmingham, United Kingdom; [4]National Institute for Health and Care Research (NIHR) Birmingham Biomedical Research Centre, Birmingham, United Kingdom; [5]Department of Endocrinology, Karolinska University Hospital, Stockholm, Sweden; [6]H. Lundbeck A/S, Copenhagen, Denmark; [7]Department of Endocrinology, University College London Hospitals NHS Foundation Trust, London, United Kingdom

Introduction: CAH is a rare autosomal recessive disorder predominantly caused by an enzyme deficiency that results in defective cortisol biosynthesis. This impairs negative feedback on the hypothalamus-pituitary-adrenal axis, leading to elevated ACTH and thus an excess of adrenal androgens. Although supraphysiologic glucocorticoids are commonly used to manage hyperandrogenemia, they are associated with long-term adverse effects. Asedebart is a novel, high-affinity, anti-ACTH monoclonal antibody that inhibits ACTH-induced signaling and has been shown to significantly and durably reduce corticosterone and aldosterone concentrations in rats, and cortisol and aldosterone concentrations in cynomolgus monkeys. Here we present preliminary, first-in-human findings on the safety, tolerability, pharmacokinetics, and pharmacodynamics of asedebart from a Phase I trial in adult patients with classic CAH.

Methods: This open-label, multiple-ascending-dose, 2-part trial (NCT05669950) enrolled men and women, aged 18-70 years, with classic CAH and pre-glucocorticoid morning 17-hydroxyprogesterone (17-OHP) concentrations >4 times the upper limit of normal. Participants received up to 6 doses of asedebart at increasing levels, every 28-35 days. Stable glucocorticoids and mineralocorticoid replacement were given. Part A of the trial consisted of a 3 + 3 design: 3 participants received a certain dose level and were escalated to the next dose level, following a 28-day safety observation period. Part B investigated the doses of asedebart which were identified as pharmacologically relevant during Part A, in a larger number of participants. Primary endpoints included adverse events, clinical safety, maximum observed exposure (in a dosing interval), area under the concentration–time curve (in a dosing interval), and relative reductions in morning 17-OHP and androstenedione (A4) concentrations (from baseline to the day following each asedebart dose).

Results: Eleven participants (7 women and 4 men) were enrolled, with a mean age of 37 years (range 21-58 years). At the baseline visit, mean (standard deviation) concentrations were 245.3 nmol/L (2.37 nmol/L) for morning 17-OHP and 10.4 nmol/L (2.28 nmol/L) for morning A4. Clear pharmacodynamic effects were observed in the 11 participants following up to 6 intravenous infusions of asedebart at increasing doses, and morning 17-OHP and A4 concentrations were reduced by 90.5%-98.7% and 66.3%-89.3%, respectively, across all dose levels. There were no safety concerns.

Conclusions: These preliminary Phase I results show that the anti-ACTH monoclonal antibody asedebart is well tolerated and can significantly reduce adrenal androgen production, supporting continued clinical development of asedebart as a promising treatment strategy for classic CAH.

P9 - ECE_3027 - Adrenal vascular events: challenging the hemorrhage-infarction dichotomy

Augustin Maillard[1], Lucas Shorten[1], Vincent Chouraki[1], Fatima Boubziz[1], Arnaud Maillard[2], Alexis Maillard[2], Marine Mallea[1], Arnaud Jannin[1], Douillard Claire[1], Vantyghem Marie Christine[1], Vincent Sobanski[1] and Stéphanie Espiard[1]

[1]CHU de Lille, Lille, France; [2]Institute Imagine, Paris, France

Background: Adrenal hemorrhage (AH) and adrenal infarction (AI) are classically considered distinct entities. However, both share common pathophysiological mechanisms involving the unique "vascular dam" anatomy of the adrenal gland and similar triggers including stress, hypercoagulability, and hemodynamic instability. Clinical comparison between these conditions has never been systematically performed.

Objective: To determine whether adrenal hemorrhage and infarction represent a continuum through comparison of etiologies, laterality patterns, and clinical outcomes.

Methods: Retrospective cohort study of all adrenal vascular events (AVEs) in adults at a University Hospital from 2008-2022, identified through health data warehouse. Patients with underlying adrenal tumors were excluded.

Results: Among 309 patients (263 AH, 46 AI), etiological profiles differed significantly. Trauma dominated AH (62.4% vs 4.3% in AI, $P < .0001$), while prothrombotic contexts dominated AI (73.9% vs 8.7% in AH, $P < .0001$), including pregnancy (AI 30.4% vs AH 1.1%, $P < .0001$), thrombophilia (AI 15.2% vs AH 0.4%, $P < .0001$), antiphospholipid syndrome (AI 15.2% vs AH 3.8%, $P = .006$), and sepsis (AI 13.0% vs AH 3.4%, $P = .014$). Post-operative complications (AH 16.3% vs AI 8.7%, $P = .26$) and anticoagulation (AH 3.8% vs AI 2.2%, $P = 1.00$) showed no significant difference. However, etiological convergence emerged in bilateral presentations: although bilaterality rates differed (AI 56.5% vs AH 9%, $P < .001$), among the 51 bilateral AVEs (25 AH, 26 AI), prothrombotic contexts accounted for 68% overall (56% of bilateral AH, 81% of bilateral AI). Specialized endocrinological evaluation rates differed between unilateral presentations (AH: 22.3% vs AI: 52%, $P < .01$) but were similar in bilateral cases (AH: 60% vs AI: 65%, $P = .78$). Long-term follow-up of bilateral AVEs (median 4.8 years) revealed identical adrenal insufficiency rates (AH: 54% vs AI: 60%, $P = 1.0$), with 56% requiring hydrocortisone and 30% fludrocortisone replacement, irrespective of radiological classification.

Conclusions: Certain adrenal hemorrhages and infarctions represent different manifestations along a common pathophysiological spectrum. Shared prothrombotic etiologies in bilateral presentations and identical clinical outcomes support the unified concept of “adrenal vascular events” where radiological appearance reflects disease mechanism rather than distinct pathophysiology. Clinical management should prioritize systematic endocrinological evaluation based on etiology and bilaterality and not imaging classification.

Background: Commonly used screening tests for primary aldosteronism provide suboptimal diagnostic accuracy. Machine learning (ML) models that utilize steroid profiles offer an alternative approach but require improvement.

Methods: Training and validation of ML models—using a panel of 13 plasma steroids, potassium, and renin—involved three patient cohorts, a total of 1380 patients, tested after medication washout. Models were initially trained on one cohort ($n = 352$) to facilitate comparisons of a previous model also trained on that cohort; the second cohort ($n = 849$) was used for external validation. Selected best models were also tested with and without medication washout. Models were subsequently trained on the combined cohorts and externally validated on the third cohort ($n = 179$). Diagnostic performance of best models was then compared to performance of the aldosterone-to-renin ratio (ARR).

Findings: Integration of plasma steroids with potassium using a feedforward neural network (FNN) model provided improved diagnostic performance over a previously established support vector machine model according to areas under ROC curves (AUCs) of 0.940 (CI:0.918-0.963) and 0.917 (CI:0.893-0.937, $P = .0103$). Addition of renin negligibly improved model performance beyond the improvement with potassium. The FNN and other renin-independent models showed similar accuracy before and after antihypertensive medication washout, whereas renin-dependent models exhibited poorer accuracy without medication washout. Paired comparisons of combined-dataset-models with the ARR showed three further optimized renin-independent models outperformed the ARR for screening according to AUCs of 0.948 to 0.954 vs 0.839 for the ARR. Those models, which utilize five selected steroids, minimize need for medication washout

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

and at cut-offs for optimal 90% to 95% diagnostic sensitivity reduce false-positives by 53% to 72% to more effectively screen for PA than with the ARR.

Interpretation: The newly developed ML models demonstrate enhanced diagnostic performance compared to the previously established support vector machine model and the ARR. There was no difference in the diagnostic performance of renin-independent compared to renin-dependent models, though the former offer the benefit of screening patients in whom medication washout is not feasible.

P11 - ECE_3015 - Validation of the imaging criteria of ESE–ENSAT guidelines on adrenal incidentalomas in a large single-center cohort study

Katharina Kerkau[1], Schlötelburg Wiebke[2], Simon Kloock[3], Esther-Marie Krenig[2], Christine Zecha[2], Patrick Mihatsch[4], Otilia Kimpel[3], Thorsten Bley[4], Andreas Buck[2], Matthias Beissert[4] and Martin Fassnacht[3]
[1]*Clinic: Department of Medicine, Division of Endocrinology and Diabetes, University of Würzburg, University Hospital Würzburg, Würzburg, Germany;* [2]*Department of Nuclear Medicine, University Hospital Würzburg, University of Würzburg, Würzburg, Germany;* [3]*Department of Medicine, Division of Endocrinology and Diabetes, University Hospital Würzburg, University of Würzburg, Würzburg, Germany;* [4]*Department of Radiology, University Hospital Würzburg, University of Würzburg, Würzburg, Germany*

Background: Adrenal incidentalomas occur in about 2% of the adult population. Most lesions are benign and non-functioning or show mild autonomous cortisol secretion. However, malignancy must be reliably identified. In 2023, the European Society of Endocrinology (ESE) and the European Network for the Study of Adrenal Tumors (ENSAT) updated the imaging criteria for risk stratification into four imaging groups based on unenhanced CT, but real-world evidence remains limited. We aimed to validate this ESE/ENSAT algorithm.

Methods: We conducted a retrospective cohort study including all patients with adrenal mass detected by unenhanced CT at the University Hospital Würzburg (2015-2020). Lesion size, mean unenhanced attenuation (HU) and homogeneity were assessed, and lesions were assigned to ESE/ENSAT algorithm groups: group 1 (any size, HU $\leq$10); group 2 (HU 11-20 and tumor <4 cm); group 3 (HU 11-20 and tumor $\geq$4 cm) or (HU >20 and tumor <4 cm); group 4 (tumor $\geq$4 cm and HU >20). Bilateral lesions were evaluated separately. Final diagnosis was defined by histopathology or pre-defined follow-up criteria, including stable tumor size for $\geq$1 year.

Results: We included 1037 patients (580 men, 457 women) with 1308 adrenal lesions (including 271 bilateral, 262 right and 504 left). The median size was 20 mm (range 10-211) and median HU 10 (range −109-+59). 529 were identified as "true incidentalomas" and 729 as part of tumor staging for extra-adrenal malignancies. Up to now, 304/1308 lesions (23.2%) remained indeterminate, mainly due to missing follow-up imaging. According to the guidelines, 161/304 lesions would have required follow-up imaging. Final diagnosis: 672 adenomas, 77 other benign tumors, 162 metastases, 41 ACCs, 14 pheochromocytomas, 38 others. Malignancy rates increased markedly across groups: group 1: 0.2% (1/440); group 2: 5.6% (7/126); group 3: 43.8% (141/322); group 4: 79.3% (92/116). Of note, the malignancy rates were significantly different between "true incidentalomas" and lesions detected during tumor staging: group 1, 0% vs 0.4%; group 2, 0% vs 9.5%; group 3, 24.0% vs 58.4%; group 4, 70.2% vs 83.0%.

Conclusions: In a large real-world cohort, the ESE/ENSAT diagnostic algorithm provided strong malignancy risk stratification. The very low malignancy rate in group 1 supports omission of further diagnostic work-up, while groups 3-4 warrant prompt diagnostic and therapeutic escalation. Notably, malignancy risk within each imaging group was strongly influenced by the initial imaging indication, underscoring the importance of distinguishing true incidentalomas from lesions detected during oncologic staging.

P12 - ECE_3277 - Effects of modified release hydrocortisone on reproductive function in males with congenital adrenal hyperplasia. insights from CALLIOPE: a multicenter, prospective study

Davide Ferrari[1], Chiara Simeoli[2], Lorenzo Arcolesse[1], Erminio M. Crescenzo[2], Anna Chiara Conflitti[1], Mariangela Piscopo[2], Marta Tenuta[1], Daniele Gianfrilli[1], Carlotta Pozza[1], Davide Menafra[2], Donatella Paoli[1], Riccardo Pofi[1], Rosario Pivonello[2] and Andrea Isidori[1]
[1]*Department of Experimental Medicine, Sapienza University of Rome, Department of Experimental Medicine, Rome, Italy;* [2]*Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Diabetologia, Andrologia e Nutrizione, Università Federico II di Napoli, Naples, Italy*

Background: Patients with congenital adrenal hyperplasia (CAH) frequently experience impaired reproductive function, including altered spermatogenesis and the development of testicular adrenal rest tumors (TARTs). Modified-release hydrocortisone (MR-HC), by mimicking the circadian rhythm of cortisol, has shown benefits in hormonal control and quality of life. However, the specific impact of this new treatment on male reproductive function in CAH patients remains poorly explored.

Purpose: To evaluate the effectiveness of MR-HC on male reproductive function in adult patients with CAH.

Methods: Between July 2024 and May 2025, adult male patients with confirmed CAH were enrolled in the prospective, longitudinal, multicenter CALLIOPE study. Participants were assessed before and approximately 6 months after switching from conventional therapy to an equivalent dose of MR-HC. Assessments included semen analysis, hormonal profiling, and multiparametric testicular ultrasound to evaluate TARTs. Metabolic parameters were also analyzed.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Results: 32 patients (mean age 29.5 ± 7 years) were enrolled. TARTs were detectable in 20 (62.5%). After 5.7 months of MR-HC treatment (IQR 25-75: 4.11-6.21), a significant increase was observed in sperm concentration [+72.3% (95% CI: +22.79; +121.81, $P = .006$)] and total sperm count in the ejaculate [+71.84% (95% CI: +6.97;+136.72, $P = .032$)], whereas no significant changes were found in qualitative parameters (progressive motility and morphology). Ultrasound analysis showed a trend toward a reduction in total TART volume [−0.24 mL (95% CI: −0.60;+0.12 mL; $P = .055$)]. Hormonal analysis revealed unchanged Testosterone, Androstenedione and 17OH-Progesterone levels, with a significant increase in LH levels ($P = .047$), suggesting reduced suppression of the hypothalamic-pituitary-gonadal axis.

Conclusions: Our findings suggest a beneficial effect of MR-HC therapy on semen parameters and TARTs volume in adult male patients with CAH. These results highlight the need for further studies in larger cohorts with long-term follow-up to fully characterize the efficacy profile of MR-HC on reproductive function.

P13 - ECE_3363 - Aldosterone/cortisol ratio as a new marker for diagnosing mild autonomous cortisol secretion (Macs). investigating the effects of mild hypercortisolism on the renin-angiotensin-aldosterone system

Filippo Vignali[1], Lucia Zirilli[2], Sara Cerrato[1], Bruno Madeo[2], Laura Roli[3], Maria Cristina De Santis[3], Giulia Canu[3], Tommaso Fasano[3], Sara De Vincentis[1] and Vincenzo Rochira[1,2]

[1]University of Modena and Reggio Emilia, Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, Unit of Endocrinology, University of Modena and Reggio Emilia, Modena, Italy; [2]Endocrinology Unit, Department of Specialty Medicine, Azienda Ospedaliero-Universitaria of Modena, Endocrinology, Department of Specialty Medicine, Azienda Ospedaliero-Universitaria of Modena, Modena, Italy; [3]Modena, Italy

Introduction: MACS is a frequent finding in patients with adrenal incidentalomas(AI), yet its diagnosis remains challenging due to the limited specificity of the 1-mg overnight dexamethasone suppression test(ONDST) and the lack of reliable complementary biomarkers. In Cushing's syndrome(CS), cortisol excess activates renal mineralocorticoid receptors, causing sodium retention and volume expansion, which suppress aldosterone and renin levels. In MACS, the mild cortisol excess, may exert a partial suppression of the renin–angiotensin–aldosterone system(RAAS), suggesting that aldosterone–cortisol imbalance could help differentiate MACS from non-functioning adrenal incidentalomas(NFAIs).

Objectives: To evaluate the diagnostic accuracy of the ratios of aldosterone/cortisol, renin/cortisol, and aldosterone/urinary free cortisol(UFC) in differentiating MACS from NFAIs. Additionally, to investigate the effects of MACS on the RAAS.

Methods: A retrospective study was conducted on adult patients with AI, referred to the Endocrinology Unit of the AOU-Modena (2013-2025), including patients with MACS and NFAIs according to the ESE-ENSAT guidelines. Patients with CS, primary aldosteronism or major confounders were excluded. Serum cortisol (C), ACTH, aldosterone (A), renin (R), DHEAS, UFC and related ratios(A/C, C/R, A/UFC) were measured. Comparisons were made both overall and after wash-out from interfering therapies affecting the RAAS.

Results: 100 MACS (mean age 67; F/M 57/43) and 214 NFAIs (mean age 62; F/M 114/214) were initially compared without pharmacological wash-out. Serum aldosterone was significantly lower in MACS compared to NFAIs ($P < .001$), while serum cortisol was higher ($P < .001$). Renin showed no significant difference ($P = .125$). The A/C ratio was significantly lower in MACS than in NFAIs ($P < .001$), as was the A/UFC ratio ($P < .001$). ROC analysis of the A/C ratio yielded an area under the curve(AUC) of 0.767(IQR, 0.708-0.825, $P < .001$), with a cut-off <5.88 for MACS (sensitivity 69%, specificity 78.5%, negative predictive value 84.4%). This accuracy improved after wash-out (42 MACS vs 98 NFAIs), reaching an AUC of 0.784(IQR, 0.700-0.870, $P < .001$), with a cutoff <5.88 for MACS diagnosis(sensitivity 78.6%, specificity 74.5%, negative predictive value 89%). A/UFC and C/R showed similar trends, maintaining statistical significance ($P < .001$) but lower accuracy. Interestingly, ACTH, UFC, DHEAS and DHEAS ratio showed lower diagnostic performance than the A/C ratio.

Conclusions: The A/C ratio is a simple, inexpensive, and widely accessible biomarker that reliably differentiates MACS from NFAIs and outperforms other commonly used biochemical tests. A high A/C ratio (>5.88) appears to effectively exclude MACS before ONDST. These findings also provide novel pathophysiological insight, showing that even mild cortisol excess may partially suppress aldosterone secretion without altering renin, indicating RAAS dysregulation in MACS.

P14 - ECE_3701 - Incidence trends of Primary Aldosteronism in western Sweden 2006-2023

Marsel Koci[1,2], Eleftheria Gkaniatsa[1,2], Penelope Trimpou[1,2] and Oskar Ragnarsson[1,2,3]

[1]Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, Sahlgrenska Academy, Gothenburg, Sweden; [2]Department of Endocrinology, Sahlgrenska University Hospital, Gothenburg, Sweden; [3]Wallenberg Center for Molecular and Translational Medicine, University of Gothenburg, Gothenburg, Sweden

Context: Enhanced awareness of primary aldosteronism (PA) and advances in laboratory diagnostics have improved case detection. Yet population-based studies examining temporal incidence trends of unilateral and bilateral PA are scarce.

Aim: To describe incidence trends of PA and its subtypes in Western Sweden over the period 2006-2023.

Design and Methods: All individuals diagnosed with PA in the Västra Götaland County during the period 2006-2023 were included in the study. Clinical and biochemical data were collected. The annual incidence of PA was calculated by using the total number of inhabitants in Västra Götaland County.

Results: During the study period, 741 individuals were diagnosed with PA. Of these, 670 cases were confirmed by an intravenous saline infusion test, while 68 individuals were diagnosed based on biochemical criteria (aldosterone >550 pmol/L, renin <2.8 mIU/L, and potassium <3.5 mmol/L). Adrenal vein sampling

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

(AVS) was performed in 502 individuals (68%). Among those undergoing AVS, 240 were classified as having unilateral PA and 261 as having bilateral PA. Overall, the median incidence of PA was 2.27 (1.41-2.95) cases per 100 000 inhabitants. The total median incidence of PA increased from 1.02 (0.96-1.26) cases per 100 000 during 2006-2011 to 2.27 (2.05-2.56) during 2012-2017, followed by a marked increase to 3.77 (2.81-4.54) during 2018-2023. The median incidence of unilateral PA increased from 0.63 (0.45-0.73) to 0.90 (0.86-1.02) cases per 100 000 and subsequently remained stable at 0.90 (0.80-1.02) across the same time intervals. The median incidence of bilateral PA increased from 0.32 (0.25-0.48) to 0.92 (0.82-1.05), and further to 1.22 (1.19-1.26) cases per 100 000. Higher aldosterone levels at screening ($P < .0001$) and lower serum potassium levels at screening ($P < .0001$) were associated with unilateral PA. There were no significant differences in total defined daily dose (DDD) between the two subgroups ($P = .051$).

Conclusions: The incidence of PA increased markedly over time, with the most pronounced rise in recent years. Unilateral PA was more common in earlier periods, whereas bilateral PA predominated more recently, highlighting improved detection and the importance of accurate subtype classification.

Background: Intraoperative hypertensive crisis remains a major perioperative concern during pheochromocytoma resection and frequently requires urgent pharmacological management. Preoperative α-adrenergic blockade is therefore routinely employed to limit hemodynamic instability. While the choice of α-blocker has been widely discussed, the influence of blockade selectivity, duration of preoperative preparation, and final titrated dose on the occurrence and severity of hypertensive crisis has not been fully elucidated.

Methods: We performed a retrospective cohort study including 110 patients who underwent laparoscopic adrenalectomy for pheochromocytoma. The type of α-adrenergic blockade (doxazosin [DOX] or phenoxybenzamine [PXB]), length of preoperative α-blockade, and final administered dose were analysed in relation to the incidence and duration of intraoperative hypertensive crisis, defined as systolic blood pressure exceeding 200 mmHg.

Results: Patients treated with DOX experienced significantly longer hypertensive crises than those receiving PXB (median 15.0 [10.0-30.0] vs 10.0 [5.0-15.0] minutes, $P = .03$). Intraoperative vasopressor support was required more frequently in the DOX group (39.6% vs 10.9%, $P < .001$), and perioperative hospital stay was longer compared with the PXB group (median 3.0 [2.2-4.0] vs 2.0 [2.0-3.0] days, $P < .001$). Diabetes mellitus, urinary metanephrine levels exceeding ten times the upper limit of normal, and preoperative α-blockade longer than 30 days were identified as independent predictors of hypertensive crisis. Extended α-blockade was associated with prolonged crisis duration and greater vasopressor requirements, particularly among patients receiving DOX. The final titrated α-blocker dose assumed no significant association with hypertensive outcomes.

Conclusions: Selective α-adrenergic blockade with doxazosin was associated with longer intraoperative hypertensive crises, increased need for vasopressor support, and prolonged hospitalization. Moreover, extended preoperative α-blockade exceeding 30 days was linked to a higher frequency and longer duration of hypertensive crises, as well as an increased risk of postoperative vasopressor use.

P16 - ECE_2390 - Delayed Diagnosis of Pheochromocytoma Presenting with Severe Cardiac Complications in Pregnancy

Naciye Guduk Sirvan[1], Nergis Basmacı[2], Suleyman Nahit Sendur[2], Ali Devrim Karaosmanoglu[3], Cenk Sokmensuer[4], Omer Cennet[5] and Alper Gurlek[2]
[1]*Internal Medicine, Hacettepe University Hospital, Ankara, Türkiye;* [2]*Endocrinology, Hacettepe University Hospital, Ankara, Türkiye;* [3]*Radiology, Hacettepe University Hospital, Ankara, Türkiye;* [4]*Pathology, Hacettepe University Hospital, Ankara, Türkiye;* [5]*General Surgery, Hacettepe University Hospital, Ankara, Türkiye*

Background: Pheochromocytoma is a rare catecholamine-secreting tumor arising from chromaffin cells of the adrenal medulla. Its occurrence during pregnancy is rare but highly dangerous, as it can closely mimic preeclampsia or peripartum cardiomyopathy. This diagnostic overlap often leads to delayed recognition of the disease, causing significant maternal and fetal morbidity and mortality. Recent systematic reviews indicate that, even with modern management, maternal mortality remains between 4%-9% and fetal mortality between 7%-14%. Therefore, timely recognition is essential in pregnant and postpartum patients presenting with paroxysmal hypertension, palpitations, or adrenergic spells that do not respond to standard antihypertensive therapy. Early diagnosis and proper preoperative management with combined α- and β-blockade significantly reduce perioperative risk and improve outcomes for both mother and child.

Case Presentation: A 30-year-old woman at 28 weeks of gestation presented with recurrent headache, palpitations, tremor, sweating, and hypertension. She underwent emergency cesarean section due to a hypertensive crisis, which was complicated by intraoperative cardiac arrest requiring resuscitation. Postoperative echocardiography revealed a left ventricular ejection fraction (LVEF) of 25%-30% and grade 2-3 mitral regurgitation, leading to a diagnosis of peripartum cardiomyopathy. Despite beta-blocker and ACE inhibitor therapy, the patient continued to experience paroxysmal adrenergic symptoms including palpitations and diaphoresis. Abdominal computed tomography (CT) revealed a 42 × 46 mm hypodense mass in the left adrenal gland. Plasma and 24-hour

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

urinary catecholamines were markedly elevated (Table 1): epinephrine 864 ng/L, norepinephrine 1838 ng/L, metanephrine 9262 µg/day, and normetanephrine 4232 µg/day. Preoperative α-adrenergic blockade with doxazosin was followed by β-blockade for heart rate control. Laparoscopic left adrenalectomy was performed, and histopathological analysis confirmed pheochromocytoma (*chromogranin A* and *synaptophysin* positive, Ki-67 3%, PASS 9/20). The postoperative course was uneventful, and the patient's blood pressure normalized. Six months after surgery, cardiac function and symptoms had completely recovered.

Conclusions: Pheochromocytoma in pregnancy represents a rare yet life-threatening etiology of severe hypertension and cardiovascular complications, often clinically indistinguishable from preeclampsia or peripartum cardiomyopathy. A high index of clinical suspicion, prompt biochemical evaluation, and the use of non-ionizing imaging modalities are essential for diagnosis. Proper α- then β-blockade and timely adrenalectomy markedly reduce maternal and fetal morbidity.

Table 1 Laboratory results of the patient.

Parameter	Result	Reference range	Interpretation
Plasma Epinephrine (ng/L)	864	0-140	Markedly elevated
Plasma Norepinephrine (ng/L)	1838	70-750	Markedly elevated
24-h Urinary Metanephrine (µg/day)	9262	52-341	Severely elevated
24-h Urinary Normetanephrine (µg/day)	4232	88-444	Severely elevated

P17 - ECE_3008 - Operated adrenal tumours: current practice and relevance of the ESE 2023 guidelines

Morgane Mauger[1], François Tariel[2], Agathe Guenego[1], Benjamin Moreau[1], Annabelle Esvant[1], Anne Flore Herrou[1], Christèle Derrien[1], Juliette Hascoet[2], Benoit Peyronnet[2] and Patricia Vaduva[1]

[1]*Endocrinology, Diabetes, and Nutrition, Rennes University Hospital, Rennes, France;* [2]*Urology, Rennes University Hospital, Rennes, France*

Introduction: The incidence of adrenal tumours has risen steadily over the past two decades, while the prevalence of malignant, large, or secretory forms has remained stable. In 2023, the ESE/ENSAT updated recommendations for managing adrenal incidentalomas to improve the identification of patients requiring surgery.

Methods: To assess the clinical relevance of these new criteria, we conducted a retrospective study of patients who underwent adrenalectomy at Rennes University Hospital over a 20-year period. The risk of malignancy was stratified into five groups according to the 2023 guidelines based on imaging features (size, unenhanced CT attenuation, and metabolic activity). We analyzed the distribution of these groups based on histological diagnosis and evaluated the diagnostic performance (sensitivity, specificity, NPV, PPV) of this grading system.

Results: A total of 390 patients were included. Tumours were primarily discovered due to suggestive symptoms (46.6%) or incidentally (29.5%). The most frequent diagnoses were pheochromocytomas (32.8%), adrenal metastases (20.8%)—predominantly of renal origin (48.2%)—and aldosterone-producing adenomas (16.1%). Adrenocortical carcinomas accounted for 5.4% of the cohort. The risk of malignancy could be estimated in 293 patients. Among the 96 malignant tumours, 79 (82.3%) were suspicious on imaging, while 16 (16.7%)—comprising one adrenocortical carcinoma, one metastatic pheochromocytoma, and 14 metastases—were classified as indeterminate. No malignant tumours exhibited strictly benign features on unenhanced CT (≤10 HU). Only one case (a renal cell carcinoma metastasis) was classified as low risk on unenhanced CT and subsequently reclassified as benign due to a lack of ^{18}F-FDG PET/CT uptake. Conversely, only 15.7% (31/197) of benign tumours had reassuring imaging features, while 56.9% (112/197) appeared suspicious. The ESE grading system demonstrated excellent sensitivity (98.7%) and negative predictive value (96.9%) for distinguishing benign from malignant lesions. However, specificity (21.7%) and positive predictive value (41.4%) were low.

Conclusions: The 2023 ESE/ENSAT guidelines appear safe and reliable in our cohort, effectively ruling out malignancy in homogeneous tumours with unenhanced attenuation ≤10 HU, regardless of size. While combined imaging modalities offer excellent sensitivity, caution is required for fat-poor or non-hypermetabolic tumours in patients with a history of extra-adrenal cancer, particularly renal cell carcinoma.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Background: Primary aldosteronism (PA) remains underdiagnosed, even in the context of hypokalemic hypertension. Steroid profiling by liquid chromatography-tandem mass spectrometry (LC-MS/MS) enables comprehensive assessment of adrenal steroidogenesis, but the influence of potassium status and sex on biochemical phenotype and clinical risk remains incompletely defined.

Objective: To assess the impact of potassium status and sex on adrenal steroid profiles and clinical characteristics in patients evaluated for PA, and to determine whether potassium stratification identifies distinct PA phenotypes.

Methods: This cross-sectional analysis was conducted as a predefined subtrial of the PROSALDO study and included 537 patients undergoing evaluation for suspected PA. PA was diagnosed using a combination of prespecified biochemical criteria, incorporating post-saline infusion aldosterone cut-offs measured by LC-MS/MS. Participants were stratified into four groups: hypokalemic PA (HypoPA+, $n = 131$), normokalemic PA (NormoPA+, $n = 56$), hypokalemic non-PA (HypoPA-, $n = 52$), and normokalemic non-PA (NormoPA-, $n = 298$). Steroid profiling covering mineralocorticoid-, glucocorticoid-, and sex-steroid-related pathways was performed by LC-MS/MS. Analyses were conducted overall and stratified by sex, with adjusted multivariable models.

Results: HypoPA+ patients exhibited a distinct and severe clinical phenotype, with higher systolic and diastolic blood pressure and a greater prevalence of stroke (7.6%) and aneurysm of large arteries (2.3%), compared with other groups (both $P \leq .030$). Biochemically, HypoPA+ patients demonstrated markedly elevated mineralocorticoid and hybrid steroids, including aldosterone, 18-oxocortisol, 18-hydroxycortisol and 11-deoxycorticosterone (all $P < .001$). Median 18-oxocortisol concentrations were more than twofold higher in HypoPA+ than in NormoPA+ patients (0.048 vs 0.022 ng/mL; $P < .001$). Glucocorticoid-related hybrid steroids showed a similar pattern. Sex-stratified analyses showed that men had higher blood pressure, higher post-saline infusion aldosterone, 18-hydroxycortisol, 21-deoxycortisol, and 11-deoxycortisol, but lower 11-dehydrocorticosterone and corticosterone than women. Although potassium-dependent group differences were preserved in both sexes, several contrasts in the mineralocorticoid and glucocorticoid hybrid steroids were statistically significant in women but attenuated or absent in men. In multivariable models, potassium/PA stratification independently predicted aldosterone and hybrid steroid concentrations ($P \leq .009$), whereas sex, age, BMI, renin, and cerebrovascular disease were not consistent independent determinants.

Conclusions: Hypokalemia identifies a severe PA phenotype associated with increased cerebrovascular morbidity and amplified autonomous mineralocorticoid steroidogenesis. LC-MS/MS-based steroid profiling robustly characterizes a progressive increase in hybrid steroid production from hypokalemic PA to non-PA. Sex modifies absolute steroid concentrations, while potassium status remains the dominant determinant of PA-specific steroidogenic signatures. Potassium status and sex-related differences should be integrated into interpretative frameworks for steroid-based PA characterization and risk stratification.

P20 - ECE_1923 - Bioimpedance spectroscopy uncovers extracellular fluid excess in Primary Aldosteronism

Marianna Viukari[1], Antero Ylänen[2,3], Eeva Kokko[2], Niina Matikainen[1], Pasi Nevalainen[3] and Ilkka Pörsti[2,3]
[1]Endocrinology, Helsinki University Hospital and University of Helsinki, Helsinki, Finland; [2]Helsinki, Finland; [3]Department of Internal Medicine, Tampere University Hospital, Tampere, Finland

Objective: Although primary aldosteronism is characterized by intravascular volume overload, evaluation of volume status is not included in the standard diagnostic workup. Bioimpedance spectroscopy is utilized to assess fluid status and is routinely applied in dialysis patients. However, to our knowledge, this technique has not been used to compare body water balance between patients with primary aldosteronism and essential hypertension. Here we examined whether bioimpedance spectroscopy can distinguish primary aldosteronism from essential hypertension and normotensive controls by quantifying body water distribution.

Design: Patients with confirmed primary aldosteronism ($n = 77$), essential hypertension ($n = 90$), and normotensive controls ($n = 79$) were prospectively recruited for a cross-sectional comparison.

Methods: Total body water, extracellular and intracellular water volumes, and overhydration were measured using bioimpedance spectroscopy. Analyses were adjusted for sex, age, body surface area, estimated glomerular filtration rate, diuretic or spironolactone use, and comorbid diabetes or heart failure. Routine laboratory and hormonal tests were performed. Primary aldosteronism severity classification score was calculated for primary aldosteronism patients.

Results: Extracellular water was 0.69 ± 1.04 and 0.88 ± 1.04 L/m^2 higher, and overhydration 0.76 ± 1.4 and 0.92 ± 1.4 L greater, in primary aldosteronism than in essential hypertension and normotensive controls, respectively ($P < .001$ for all). Primary aldosteronism group also exhibited the highest extracellular water-to-intracellular water ratio (0.84 ± 0.1 vs 0.80 ± 0.1 and 0.73 ± 0.1, respectively; $P < .001$). Total body water indexed to body surface area did not differ significantly among groups (21.3 ± 2.2, 21.0 ± 2.8, and 21.6 ± 2.4 L/m^2, respectively, $P = .083$). Plasma N-terminal pro–atrial natriuretic peptide concentration was highest in primary aldosteronism. Primary aldosteronism severity correlated positively with extracellular water volume ($r = 0.31$), overhydration ($r = 0.43$), and the extracellular-to-intracellular water ratio ($r = 0.36$; $P < .01$ for all).

Conclusions: Bioimpedance spectroscopy detects extracellular volume overload that is pathognomonic in primary aldosteronism. Volume excess correlates with disease severity. This technique may have potential to improve diagnostic accuracy for primary aldosteronism.

[1]University of Texas Southwestern Medical Center, Dallas, United States; [2]Mayo Clinic, Rochester, United States; [3]National Institutes of Health Clinical Center and Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, United States; [4]LMU Klinikum München, Munich, Germany; [5]CHU d'Angers and Labatoire MITOVASC, Université d'Angers, Angers, France; [6]University College London Hospitals, London, United Kingdom; [7]Children's Hospital of Philadelphia, Philadelphia, United States; [8]Bicêtre Hospital, AP-HP, Université Paris-Saclay, Paris, France; [9]Neurocrine Biosciences, Inc., San Diego, United States; [10]University of Michigan Medical School, Ann Arbor, United States

Background: Chronic exposure to supraphysiologic glucocorticoid (GC) doses can adversely impact cardiometabolic health. Crinecerfont is FDA-approved as an adjunct to GC replacement to control androgens in patients with classic congenital adrenal hyperplasia (CAH), enabling GC dose reduction. Changes in GC dose and GC-related outcomes were assessed in adults with CAH who received up to 1 year of crinecerfont.

Methods: Participants from the 24-week double-blind placebo-controlled period of CAHtalyst™ Adult (NCT04490915) continued on crinecerfont 100 mg BID (CFT/CFT) or switched from placebo to crinecerfont (PBO/CFT) in the 6-month open-label (OL) period. At Month 12 (end of OL), mean % change from baseline in GC dose was assessed (1) while maintaining or improving androstenedione (A4), with decreases in GC doses set to 0 if A4 was not ≤120% of baseline or ≤ upper limit of normal; and (2) based on observed dose without imputation of A4, to understand changes in GC-related outcomes that are independent of A4.

Results: At baseline, the 182 randomized participants had a mean GC dose of 17.6 mg/m^2/d (32.3 mg/d) hydrocortisone equivalents (HCe); >70% of participants were overweight or obese; mean homeostatic model assessment of insulin resistance (HOMA-IR) was 3.2 and 43% had insulin resistance (ie, HOMA-IR >2.5). At Month 12, mean % change from baseline in GC dose while maintaining or improving A4 from baseline was −24.6% for CFT/CFT and −29.7% for PBO/CFT. The observed mean % change from baseline in GC dose (without imputation of A4) at Month 12 was −37.4% for CFT/CFT and −36.1% for PBO/CFT, with observed mean GC doses of 10.8 mg/m^2/d (19.9 mg/d) HCe and 11.0 mg/m^2/d (19.7 mg/d) HCe for CFT/CFT and PBO/CFT, respectively. Among participants who were overweight/obese at baseline (BMI ≥25 kg/m^2), 27.4% (23/84) and 38.9% (14/36) in the CFT/CFT and PBO/CFT groups, respectively, achieved >5% reduction in weight at Month 12. Among participants with insulin resistance at baseline (HOMA-IR >2.5), mean change from baseline in HOMA-IR at Month 12 was −1.1 for CFT/CFT ($n = 45$) and −2.0 for PBO/CFT ($n = 22$).

Conclusions: Adults with CAH who received up to 1 year of crinecerfont achieved substantial reductions in GC dose, and participants who were overweight or obese showed remarkable improvements in weight and insulin resistance. These results suggest that crinecerfont can reduce the risk of known complications associated with long-term supraphysiologic GC treatment in patients with CAH.

[1]Department of Nephrology and Endocrinology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark; [2]Kongens Lyngby, Denmark; [3]Department of Endocrinology, Odense University Hospital, Odense, Denmark; [4]Department of Clinical Research, University of Southern Denmark, Odense, Denmark; [5]Department of Endocrinology and Internal Medicine, Aarhus University Hospital, Aarhus, Denmark; [6]Department of Endocrinology, Odense University Hospital, Odense, Denmark; [7]Department of Clinical Medicine, Aarhus University, Aarhus, Denmark; [8]Department of Growth and Reproduction, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark

Introduction: Glucocorticoid-induced adrenal insufficiency is a known complication of long-term prednisolone therapy. Current guidelines vary on how long prednisolone should be withheld before assessing adrenal function. This study aimed to quantify how prednisolone withdrawal duration (0, 1, or 2 days) affects ACTH test outcomes, for understanding the potential impact of pause length on the interpretation of adrenal function in patients on long-term prednisolone.

Methods: This study was a sub-study of the ongoing randomized clinical trial RESCUE, investigating glucocorticoid-induced adrenal insufficiency. Forty patients (mean age 73 years ± 7.3) with polymyalgia rheumatica and/or giant cell arteritis treated with prednisolone for ≥3 months, all at a current daily dose of 5 mg, underwent 3 standard ACTH (Synacthen®) tests within median 21 days (range 15-30). The participants underwent the 1-day pause ACTH test at screening and were then alternately scheduled for the 0-day or 2-day visit. It was aimed to include 50% with insufficient ACTH response at the screening visit; defined as 30-minute cortisol <420 nmol/L (local validated cut-off). Plasma cortisol was analysed by Elecsys® Cortisol II. Serum prednisolone was measured after 1 and 2 days of prednisolone pause and analysed by LC-MS/MS, with the lowest detectable concentration limit of 1.0 nmol/l. Concentrations below the limit were listed as 0.5 nmol/L in data analysis. One-factor ANOVA with repeated measurements and paired t-tests were used to compare ACTH test results.

Results: Stimulated 30-minute cortisol increased with increasing time since last prednisolone dose ($F = 127$; $P < .0001$). After 1 vs 2 days of prednisolone pause, mean 30-minute cortisol increased by 71 nmol/L (95% CI: 53-88; $P < .001$), whereas ACTH did not differ (mean difference 0.36 pmol/L; 95% CI: −0.37-1.10; $P = .3$). Stimulated 30-minute cortisol was <420 nmol/L in 30/40 (75%),

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

19/40 (48%), and 14/40 (35%) after 0-, 1- and 2-days prednisolone pause, respectively. Mean ± SD serum prednisolone concentrations were 1.1 ± 0.6 nmol/L after 1 day and 0.9 ± 1.7 nmol/L after 2 days of prednisolone pause.

Conclusions: Extending the prednisolone pause from 1 to 2 days increased stimulated 30-minute cortisol by 71 nmol/L and reduced the proportion of tests <420 nmol/L by 13%. Serum prednisolone concentrations were very low after both 1- and 2-day prednisolone pauses, indicating minimal clinically relevant serum presence. These results characterise the effect of prednisolone withdrawal duration on ACTH test performance; determining the optimal pause may vary depending on the clinical purpose of testing.

P23 - ECE_3266 - Self-injection matters: behaviours and experiences during adrenal crisis in adults with adrenal insufficiency

Jennie Brown[1], Shashi Hirani[1], Kathleen Mulligan[1], Stanton Newman[1], Stephanie Baldeweg[2], Ashley B. Grossman[3], Philippa Sharman[4], Pat McBride[5] and Sofia Llahana[1]

[1]School of Health and Medical Sciences, City St George's, University of London, London, United Kingdom; [2]University College London Hospital, London, United Kingdom; [3]Royal Free Hospital, London, United Kingdom; [4]Addison's Disease Self-Help Group, Bristol, United Kingdom; [5]The Pituitary Foundation, Bristol, United Kingdom

Background: Adrenal crisis (AC) in patients with adrenal insufficiency has an estimated incidence of 6%-8% per year and is the leading cause of death (mortality rate 0.5 per 100 patient-years). Deaths from AC are potentially preventable by immediate administration of parenteral hydrocortisone. Limited available evidence suggests <25% of patients successfully self-inject or are assisted in the community, while preventative measures and behaviours during AC are underexplored.

Objectives: This cross-sectional study investigated factors associated with hospitalisation due to AC and length of stay.

Method: 561 adults with adrenal insufficiency who had experienced an AC within the previous 12 months completed an online questionnaire about their most recent AC. Recruitment was via 3 patient advocacy groups and 28 endocrine clinics across the UK. Participants were asked whether they: possessed and carried an emergency hydrocortisone injection kit, self-injected or required assistance, needed intervention by an ambulance or attendance at an accident and emergency (A & E) department, and whether hospitalisation due to AC occurred, including length of hospital stay.

Results: During their last AC, 18% of patients self-injected, 39% needed community assistance, 20% were injected in an ambulance/by a paramedic and 23% received their injection in A & E. Of those who self-injected, 58% were hospitalised due to AC compared with those needing assistance within the community (66%) or being injected in an ambulance or A & E (92%). Patients being injected in an ambulance/by a paramedic waited most frequently <30 minutes (49%), however 50% of patients attending A & E waited >60 minutes for their injection. Confidence ratings for self-injecting were higher in people who self-injected, compared with those needing assistance. The most common reasons for participants not self-injecting was being too unwell (57%), preferring a healthcare professional to inject (14%) and being unaware of AC symptoms or that a hydrocortisone injection was needed (11%). No significant differences in hospitalisation rates or length of stay were observed between participants who possessed an emergency steroid card, or carried an injection kit, and those who did not. Confidence in self-injection and prior injection training was also not associated with differences in hospitalisation or length of stay.

Conclusions: Patients who self-injected were around 20% less likely to be hospitalised compared to those who required assistance. These findings highlight the critical importance of early recognition of AC and prompt, independent administration of hydrocortisone in the home or community setting to reduce the need for hospitalisation.

P24 - ECE_3470 - Diagnostic value of basal and ACTH-stimulated 17-hydroxyprogesterone and 17OHP/cortisol ratio in genetically characterised 21-hydroxylase deficiency

Giordano Paolucci[1,2], Claudio Urbani[1], Luisa Pignata[1], Marianna Scordo[1], Emilio Fiore[1], Luca Manetti[1], Ferruccio Santini[1] and Massimo Tonacchera[1]

[1]Endocrinology Unit, University Hospital of Pisa, Pisa, Italy; [2]Endocrinology, University Hospital Of Pisa, Pisa, Italy

Background: 21-hydroxylase deficiency (21OHD) is the most common cause of congenital adrenal hyperplasia (CAH). Diagnosis relies on basal and ACTH-stimulated 17-hydroxyprogesterone (17OHP) measurements; however, optimal diagnostic thresholds and the utility of derived indices, such as the 17OHP/cortisol ratio, remain uncertain. Whether biochemical testing can reliably identify heterozygous *CYP21A2* carriers is also unclear.

Objective: To evaluate the diagnostic performance of basal and ACTH-stimulated 17OHP, cortisol, and the peak 17OHP-to-peak cortisol ratio (17OHPmax/CORTmax) for identifying genetically confirmed 21OHD, and to assess their ability to discriminate carriers from wild-type subjects. As a secondary aim, we characterized rare *CYP21A2* missense variants using *in silico* and structural tools.

Methods: We retrospectively analyzed 104 patients (83 women) who underwent a standard 250-µg ACTH test and *CYP21A2* genotyping. Based on genotype, 33 subjects had CAH (5 salt-wasting, 1 simple virilizing, 27 non-classic), 30 were heterozygous carriers, and 41 were wild-type. Basal, 30- and 60-minute 17OHP and cortisol were measured by chemiluminescent immunoassays; 17OHPmax, CORTmax, Δ17OHP, and 17OHPmax/CORTmax were derived. ROC curves were constructed using genotype as the reference standard. Three rare missense variants (p.Arg150Pro, p.His204Tyr, p.Leu289Phe) were assessed with prediction scores (CADD, PolyPhen-2, SIFT, GERP), structure-based tools (HOPE, Missense3D), mapping on the CYP21A2 crystal structure, and ACMG/AMP classification (VarSome).

Results: Basal 17OHP discriminated CAH from unaffected subjects (carriers + wild-type) with good accuracy (AUC 0.92); a cut-off >2.815 µg/L yielded 84.9% sensitivity and 85.9% specificity. Diagnostic performance improved for stimulated values: peak 17OHP >9.645 µg/L achieved 93.3% sensitivity and 95.7%

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

specificity, outperforming Δ17OHP and cortisol-based parameters. The 17OHP_max/CORT_max ratio showed the best discrimination (AUC 0.99); a cut-off >0.35 provided 96.6% sensitivity and 94.4% specificity, while raising it to >0.63 increased specificity to 98.6% with 89.7% sensitivity. No basal or stimulated parameter, including 17OHP_max/CORT_max, reliably separated carriers from wild-type subjects (AUCs <0.80). All three rare variants were extremely uncommon in gnomAD and classified as variants of uncertain significance (VUS) by ACMG criteria; structural mapping suggested a potential effect of p.Leu289Phe near the active site, whereas p.Arg150Pro and p.His204Tyr showed only subtle predicted structural impact.

Conclusions: In a genotyped cohort, ACTH-stimulated 17OHP and, particularly, the 17OHPmax/CORTmax ratio provided excellent diagnostic accuracy for 21OHD, outperforming basal 17OHP. However, heterozygous carriers could not be reliably identified biochemically, underscoring the need for *CYP21A2* genotyping in the diagnostic "grey zone." Integrated *in silico* and structural analyses are helpful but not sufficient to definitely classify rare missense variants.

Background: Various associations between health, disease status, stress and cortisol have been inconsistent due to the poor reliability of diurnal cortisol metrics, hindering research in this area. Salivary cortisol is a reliable, non-invasive marker of bioavailable cortisol. Well-defined reference ranges derived from healthy young adults under non-stressful conditions remain limited.

Objective: To characterize the diurnal pattern of salivary cortisol and identify factors influencing daily- cortisol-production in healthy young adults under non-stressful conditions. Reference values for individual Area-Under-the-Curve with respect to ground (AUC-g) were established to define the physiological range of diurnal-cortisol-production.

Study-Design: Cross-sectional study conducted under both controlled (hospital) and home conditions.

Methods: A total of 131 healthy medical students (median age: 19 years; 47 males, 84 females) were included in the final analysis. Salivary cortisol samples were collected at four predefined timepoints (08:00, 12:00, 18:00, and 22:00) across three consecutive weekdays. Morning serum cortisol and plasma adrenocorticotropic hormone(ACTH) levels were obtained on Day-1. Salivary and serum cortisol concentrations were measured using electrochemiluminescence immunoassay (ECLIA)(Cobas-e801analyser). Plasma ACTH levels were determined using chemiluminescence immunoassay(CLIA)(LIAISON-platform). On Day-1, morning salivary sampling was performed in a hospital-setting, whereas all remaining salivary samples, including those collected on Days-2 and 3 and the non-morning samples on Day-1, were obtained by participants at home following standardized instructions. Perceived stress was prospectively assessed using the 14-item Perceived-Stress-Scale (PSS-14) via structured questionnaires. Lifestyle factors and the occurrence of acute stress events were recorded in real-time during the sampling period using a smartphone-based application. Diurnal-cortisol-production was quantified by calculating AUC-g. Linear regression analyses and linear mixed-effects models were applied.

Results: Diurnal-cortisol-production was higher on Day-1 compared with Days-2 and 3 (median AUC-g 3.78 vs 3.34 and 2.96, respectively; $P < .001$). Analysis of Days-2 and 3 together showed a median AUC-g of 3.18, with a 95% reference interval of 1.61-7.14. Day-1 morning saliva cortisol (median 0.74 µg/dl) was higher than Day-2 (median: 0.51 µg/dl) and Day-3 (median: 0.53 µg/dl)($P < .001$), probably reflecting anticipatory stress related to hospital attendance on Day-1. Females exhibited higher morning salivary and serum cortisol levels and greater PSS than males. Lifestyle-factors, including sleep duration, exercise, smoking, alcohol and coffee consumption, were not significantly associated with diurnal-cortisol-production.

Conclusions: In healthy young adults, salivary diurnal-cortisol-production demonstrates modest sex-related differences and limited influence from everyday lifestyle factors. A clear understanding of ordinary cortisol circadian patterns under non-stressful, everyday conditions can enhance the reliability of future research exploring biological, clinical, and psychological associations of cortisol-regulation.

P26 - ECE_1581 - Salivary cortisone identifies clinically relevant mild autonomous cortisol secretion

Marcus Imamovic, Tommy Olsson and Per Dahlqvist

Department of Public Health and Clinical Medicine, Umeå University, Umeå, Sweden

Objective: Adrenal incidentalomas are frequently detected on imaging. A substantial proportion of these are cortisol secreting adenomas without overt Cushingoid features, ie, mild autonomous cortisol secretion (MACS). MACS is associated with cortisol excess

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

comorbidity, including hypertension, diabetes, and osteoporosis. Current diagnostic criteria rely on serum cortisol after 1 mg dexamethasone suppression testing (DST), although total serum cortisol is influenced by cortisol binding globulin levels and may overestimate biologically active cortisol. Salivary cortisone correlates with serum free cortisol and may represent a more physiological measure. Previous studies have shown that post DST salivary cortisone cut-offs at 2.7-3.5 nmol/L have high sensitivity and specificity for diagnosing Cushing's syndrome. We evaluated whether post DST salivary cortisone is associated with cortisol excess comorbidity in patients with adrenal incidentalomas.

Design and Methods: We performed a retrospective cross-sectional study on patients with newly detected adrenal incidentalomas, ≥10 mm, undergoing post DST salivary cortisone testing at our tertiary centre (February 2016-April 2025). Patients with Cushing's syndrome, primary aldosteronism, pheochromocytoma, adrenal malignancy, and on oral glucocorticoids were excluded. Optimal post DST cut-offs were identified by receiver operating curve analyses using the dichotomous variable of having all three comorbidities: hypertension, diabetes, and osteoporosis [Y/N]. Associations with hypertension, diabetes, osteoporosis, and combined comorbidity outcomes were analysed by logistic regression adjusted for age, sex and smoking.

Results: Ultimately, 254 patients were included. The optimal post DST salivary cortisone cut-off was 3.22 nmol/L (area under the curve 0.80), with 83% sensitivity and 79% specificity. A salivary cortisone cut-off of 6.39 nmol/L was needed to yield a 95% specificity. Patients with post DST salivary cortisone above 3.22 nmol/L were older and had higher prevalence of hypertension (79% vs 58%), diabetes (32% vs 20%), and osteoporosis (25% vs 9%) compared to those below the cut-off. In adjusted regression analyses, salivary cortisone above 3.22 nmol/L was associated with higher odds of osteoporosis (OR 2.46, $P = .05$) and combined morbidity (all three comorbidities OR 12.6, $P < .05$). At >6.39 nmol/L, strong associations were observed for hypertension (OR 8.67, $P < .05$), osteoporosis (OR 7.54. $P < .01$), and multiple comorbidities (≥2 comorbidities OR 3.61, $P < .05$; all three comorbidities OR 29.6. $P < .05$).

Conclusions: Post DST salivary cortisone identifies patients with clinically relevant cortisol excess comorbidity. Salivary cortisone may serve as a physiologically meaningful alternative to serum cortisol in the evaluation of adrenal incidentalomas.

Background: Cushing's syndrome(CS) is characterised by sustained cortisol excess and profound immune disturbance. However, the direct effects of endogenous cortisol overproduction on macrophage phenotype and cellular metabolism remain incompletely understood. In particular, the immunological consequences of mild autonomous cortisol secretion(MACS) associated with cortisol-producing adrenocortical adenomas (CPA) in the absence of overt CS are poorly defined. We hypothesised that macrophage activation, polarisation, and bioenergetic function are altered in both CPA-CS and CPA-MACS.

Methods: Human macrophages were polarised toward a pro-inflammatory (M1-like) state using TNFα and IFNγ, followed by exposure to 10% serum from 18 patients (12 CPA-MACS, 6 CPA-CS) and 10 age- and sex-matched controls with endocrine-inactive adenomas(EIA). Cytokine secretion and gene expression were measured by ELISA and RT-qPCR. Mitochondrial function, ATP production, glycolytic activity, and phagocytosis were assessed after 48 hours. Associations with cortisol secretion and tumour characteristics were examined.

Results: Pro-inflammatory IL6 secretion was reduced in macrophages treated with CPA-MACS (0.72-fold, $P = .071$) and CPA-CS serum (0.50-fold, $P = .004$) compared with EIA, while IL6 mRNA showed a similar trend. The M2 marker CD163 modestly increased in CPA-CS (1.32-fold, $P = .258$) but not in CPA-MACS, correlating with post-dexamethasone cortisol levels and tumour size. TGFβ concentrations were significantly elevated in CPA-CS ($P = .012$), and the IL6/CD163 ratio increased (2.41-fold, $P = .003$), indicating a cortisol-dependent shift toward an anti-inflammatory phenotype. Mitochondrial viability increased in CPA-MACS ($P = .059$) and CPA-CS ($P = .005$), accompanied by reduced ATP production and maximal respiration ($P < .05$) and enhanced glycolytic activity($P < .01$) in CPA-CS. Phagocytosis was impaired in both CPA-MACS ($P = .014$) and CPA-CS ($P = .076$). Glucocorticoid receptor blockade with RU486 partially restored mitochondrial respiration, spare capacity, and bioenergetic balance.

Conclusions: Serum from patients with CPA-MACS and CS suppresses inflammatory macrophage responses, promotes alternative polarisation, disrupts mitochondrial metabolism, and impairs phagocytosis. These findings demonstrate that mild autonomous cortisol excess significantly modulates macrophage immunometabolism, potentially contributing to systemic immune dysfunction and altered tissue homeostasis.

Martin Bidlingmaier[2], Christine Schmid-Tannwald[1], Clemens Cyran[1], Martin Reincke[2] and Isabel Stüfchen[2]
[1]Department of Radiology, LMU University Hospital, Munich, Germany; [2]Munich, Germany

Background: Primary aldosteronism (PA) is increasingly recognized as a spectrum disorder with recent studies suggesting low-renin hypertension (LRH) as a potential precursor stage. Adrenal morphology across distinct biochemical stages of this spectrum remains insufficiently characterized. This study aimed to systematically define adrenal imaging phenotypes across PA and LRH compared with normal-renin hypertension (NRH) and normotensive controls.

Methods: This retrospective study included 196 patients evaluated for suspected PA with available imaging data. PA was defined by aldosterone-to-renin ratio (ARR) >12 ng/mU with hypokalemia or post-confirmatory aldosterone >42.5 ng/L ($n = 95$). NRH was defined by normokalemia and either a baseline direct renin concentration >12 mU/L or a baseline plasma aldosterone concentration below limit of quantification (28 ng/L) together with an ARR <12 ng/mU ($n = 42$); remaining patients were classified as LRH ($n = 59$). Aldosterone was measured by LC-MS. Fifty age- and sex-matched normotensive individuals served as controls. Imaging features were analyzed on CT or MRI differentiating between diffuse adrenal enlargement, micronodules (<10 mm), adenoma/indeterminate lesions (≥10 mm), and nodular hyperplasia. Image segmentation was performed independently and blinded by two radiologists. Lesions were evaluated by size and attenuation (HU) or MRI signal drop.

Results: Adrenal morphometry, including body and limb width, was comparable across groups including normotensive controls. The overall prevalence of adrenal enlargement was high and similar in all groups, suggesting it to be common and not specific to any hypertension subtype. Imaging pathologies including micronodules, adenoma/indeterminate lesions, and nodular hyperplasia were rare in controls (2.0%), less frequent in NRH (14.3%), and increasingly prevalent in LRH (35.6%) and PA (42.1%) ($P < .001$). The same difference held for lesions ≥10 mm ($P < .001$). Most lesions were unilateral, more often affecting the left adrenal gland, whereas bilateral involvement and nodular hyperplasia were observed exclusively in PA and LRH.

Conclusions: Radiomorphological findings support LRH as an early stage within the PA spectrum, characterized by a progressive increase in adrenal imaging abnormalities preceding overt biochemical PA.

[1]Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Diabetologia, Andrologia e Nutrizione—Università Federico II di Napoli, Naples, Italy; [2]Andrology Unit, Department of Clinical Medicine, Life, Health and Environmental Sciences, University of L'Aquila, L'Aquila, Italy; [3]Dipartimento di Sanità Pubblica, Università degli Studi di Napoli Federico II, Naples, Italy; [4]Dipartimento di Psicologia e Scienze della Salute, Università Telematica Pegaso, Naples, Italy; [5]UNESCO Chair for Health Education and Sustainable Development, Federico II University, Naples, Italy

Management of congenital adrenal hyperplasia (CAH) due to 21-hydroxylase deficiency (21OHD) involves chronic glucocorticoid (GC) replacement in patients with adrenal insufficiency while controlling androgen excess. Treatment with conventional GCs is characterized by regimens with unphysiological peaks and troughs, often associated with GC overexposure and/or poor androgen control. In this scenario, the recently approved twice daily modified-release hydrocortisone (MR-HC) represents a useful tool for a more accurate reproduction of physiological cortisol circadian rhythm, particularly mimicking overnight cortisol increase for better control morning surge of adrenocorticotropic hormone (ACTH) and androgens.The current study aimed at investigating the impact of the switch from conventional GCs to MR-HC on disease control, GC daily dose, hormonal and biochemical profiles in 61 CAH patients treated for 12 months with MR-HC. Thirty-nine (63.9%) females and 22 (36.1%) males, 45 with classic-form [29 (47.5%) with salt-wasting and 16 (26.2%) with simple-virilizing] and 16 (26.2%) with non-classic form, with a median age of 30.9 ± 9.4 yrs, were enrolled. Patients were switched from conventional GC regimens [immediate or dual-release hydrocortisone (IR/DR-HC) or cortisone acetate (CA)] (25.43 ± 8.9 mg/day HC equivalents) to MR-HC (24, 91 ± 8,1 mg/day). The primary outcome was the change from baseline to 12 months of MR-HC in the percentage of patients with good disease control, defined as a morning 17OH-progesterone (17OHP) <12 ng/ml and androstenedione within the reference ranges, according to the phase 3 study. Secondary outcomes included changes in GC total daily dose, hormonal and biochemical parameters. At month 12, the percentage of patients with controlled disease significantly increased: controlled patients were 59% vs 32.8% at baseline ($P = .006$). Particularly, a significant decrease in 17OHP [6.33 ± 11.36 vs 12.77 ± 15.93 ULN at baseline ($P = .002$)] and androstenedione [0.87 ± 1.33 vs 0.95 ± 0.76 ULN at baseline ($P = .025$)] was observed at month 12. Furthermore, a reduction in morning ACTH [10.85 ± 10.3 vs 156 ± 180 pg/mL at baseline ($P = .001$)] was observed at month 12, while morning cortisol increased [10.14 ± 15.35 vs 84.3 ± 49 ng/ml at baseline ($P = .001$)] compared to baseline. Lastly, baseline MR-HC dose was reduced by 4.8% [23.27 ± 8.1 mg/day vs 24.91 ± 8,13 mg/day at baseline ($P = .005$)] at month 12. Data from the current real-world experience showed that MR-HC significantly improved disease control while reducing GC daily dose in 21OHD CAH patients.

Introduction: Primary aldosteronism (PA) is the most frequent cause of endocrine hypertension, associated with increased cardiovascular and renal risk. Previous studies indicate that approximately 15%-30% of patients with PA have concomitant mild autonomous cortisol secretion (MACS). However, the steroidogenic profile of patients with PA and MACS remains incompletely characterized.

Methods: This study involved analysis of 15 adrenal steroids using liquid chromatography–tandem mass spectrometry (LC-MS/MS) in patients with PA ($n = 96$) with MACS ($n = 18$) and without ($n = 78$), comparing with patients with adrenal adenomas with ($n = 202$) and without MACS ($n = 40$). MACS was defined by a post–1 mg overnight dexamethasone suppression test (DST) serum cortisol concentration >50 nmol/L. Baseline adrenal steroid concentrations were analyzed using linear regression models adjusted for age and sex.

Results: Patients with MACS showed significantly higher baseline concentrations of cortisol ($P = .0003$) than patients with adenomas without MACS. Among mineralocorticoid precursors, the hybrid steroids 18-oxocortisol ($P = .006$) and 18-hydroxycortisol ($P < .0001$) were significantly increased, indicating enhanced hybrid steroidogenesis in this subgroup compared with patients without MACS. 11-deoxycorticosterone levels were also significantly increased ($P = .003$). Patients with MACS exhibited lower concentrations of the adrenal androgen DHEA ($P = .016$). No significant differences were observed for aldosterone ($P = .56$), androstenedione ($P = .29$), 11-deoxycortisol ($P = .75$), or corticosterone ($P = .21$). In the subgroup analysis restricted to patients with PA, those with MACS exhibited significantly higher baseline concentrations of the hybrid steroids 18-oxocortisol ($P = .0088$) and 18-hydroxycortisol ($P = .0003$), as well as increased 11-deoxycorticosterone ($P = .0119$), compared with PA patients without MACS. No significant differences were observed for androstenedione ($P = .332$), 11-deoxycortisol ($P = .952$), corticosterone ($P = .485$), or cortisol ($P = .301$).

Conclusions: Patients with PA and MACS present a distinct steroid profile with selective excess of hybrid steroids and mineralocorticoid precursors, accompanied by reduced adrenal androgen production as compared to PA patients without MACS. LC-MS/MS-based steroid profiling provides additional biochemical information for identification and characterization of cortisol cosecretion in PA beyond the dexamethasone suppression test.

P31 - ECE_2346 - Adrenal reprogramming after menopause under repeated weight fluctuations

Linghui Kong[1], Coralie Frimat[2], Nicolo Faedda[1], May Fayad[1], Xiaomin Li[1], Isabelle Giscos-Douriez[1], Fabio Fernandes-Rosa[1], Bruno Feve[3,4,5], Antoine Ouvrard-Pascaud[6], Maria-Christina Zennaro[1,7] and Sheerazed Boulkroun[1]
[1]Université Paris Cité, Inserm, PARCC, Paris, France; [2]Inserm U1096, UFR santé, Rouen, France; [3]Centre de Recherche Saint-Antoine UMR_S938, Sorbonne Université-Inserm, Paris, France; [4]Institut Hospitalo-Universitaire de Cardio-Métabolisme et Nutrition (ICAN), Paris, France; [5]Service d'Endocrinologie-Diabétologie, Centre de référence des maladies rares de l'insulino-sécrétion et de l'insulino-sensibilité (PRISIS), Hôpital Saint-Antoine, Assistance Publique Hôpitaux de Paris, Paris, France; [6]Inserm U1096, UFR Santé, Rouen, France; [7]Service de Génétique, Assistance Publique Hôpitaux de Paris, Hôpital Européen Georges Pompidou, Paris, France

Overweight and obesity represent major public health challenges and only 20% of overweight individuals achieve sustainable weight loss, leading to repeated cycles of weight loss and gain. Weight cycling is associated with an increased risk of developing metabolic syndrome. Furthermore, the menopausal transition is associated with a 60% increase in the incidence of metabolic syndrome, which is associated with increased cardiovascular mortality. Aldosterone, produced by the adrenal gland, plays a role in regulating metabolic processes and exhibits a pathophysiological link to visceral adiposity.

Our objective was to investigate the role of the adrenal gland in postmenopausal cardiometabolic complications related to weight cycling.

We developed an experimental model in which female mice were either ovariectomized (OVX, mimicking post-menopause) or not (non-OVX, pre-menopause) and exposed to three cycles of high fat diet/standard diet (Yoyo) or maintained on standard diet throughout. After each dietary phase, blood samples were collected for metabolic profiling and steroid measurements, and multiple tissues (adrenal, heart, adipose tissue …) were collected for further analyses.

Yoyo dieting induced a greater weight gain in OVX mice compared with non-OVX controls. This was accompanied by reduced metabolic adaptability during weight cycling. Adrenal steroidogenic responses to the yoyo diet differed according to ovarian hormone status and evolved progressively across cycles. OVX mice on the yoyo diet displayed increased adrenal gland weight, consistent with dynamic changes in adrenocortical proliferation. Histology and immunofluorescence revealed marked adrenal cortex dysplasia, including loss of zona glomerulosa (ZG) and zona fasciculata (ZF) zonation. OVX triggered a time-dependent gonadal-like transcriptional reprogramming in the adrenal cortex, followed at later stages by structural remodeling and fibrosis. Yoyo diet did not substantially modify OVX-induced adrenal remodeling and triggered only limited transcriptional responses in non-OVX mice.

Collectively, these findings indicate that OVX reprograms adrenal plasticity, compromising normal metabolic and endocrine adaptability. Although repeated dietary cycling does not initiate this remodeling, it induces dysregulation of adrenal steroid hormone production and perturbs adrenocortical proliferative dynamics.

P32 - ECE_3469 - Noninvasive differentiation of adrenal adenomas, pheochromocytomas, and malignant tumors using CT radiomics

Karolina Węgrzyn[1], Anna Grochowska[2], Katarzyna Sitarz[3], Alicja Hubalewska-Dydejczyk[1] and Marta Opalinska[1]
[1]Chair and Department of Endocrinology, Jagiellonian University Medical College, Krakow, Poland; [2]University Hospital in Krakow, Krakow, Poland; [3]Department of Clinical Genetics and Rare Diseases, Medical University of Silesia, Katowice, Poland

Background: Non-contrast computed tomography (CT) remains the standard imaging modality for characterizing adrenal lesions and guiding subsequent clinical management. Conventional assessment relies on tumor size, density, and lipid content; however, these parameters may lack sufficient specificity, occasionally resulting in unnecessary surgical interventions or delayed malignancy diagnosis. Radiomics offers advanced quantitative image analysis capable of capturing tumor heterogeneity beyond visual assessment. This study aimed to evaluate whether CT-derived texture features can improve differentiation of adrenal lesions.

Methods: In this single-center retrospective analysis, adrenal incidentalomas from patients treated at the Clinic of Endocrinology, Oncological Endocrinology, and Nuclear Medicine, University Hospital Krakow (2017-2025) were reviewed. Lesions were assessed in a native CT scan and confirmed histopathologically. Eighty-two focal adrenal lesions from 80 patients (58 women, 22 men) were included: 22 adenomas, 35 pheochromocytomas, 16 carcinomas, 3 oncocytomas, 2 borderline oncocytic tumors, and 3 oncocytic carcinomas. Manual segmentation of lesions on native-phase imaging was performed, followed by extraction of first- (GLRLM_GreyLevelNonUniformity) and second-order texture parameters (IntensityBasedRobustMeanAbsoluteDeviation (IBRAMD) and IntensityHistogramEntropyLog10 (IHEL 10) using Local_Image_Feature_Extraction (LIFEx) software. Diagnostic performance was assessed via receiver operating characteristic (ROC) analysis for individual features and multivariable logistic regression for combined models. Statistical analyses were conducted using STATISTICA 13.3.

Results: When integrated with tumor density, selected texture parameters GLRLM, IBRMAD, and Intensity IHEL10 demonstrated significant discriminatory potential. These parameters differentiated adenomas from pheochromocytomas ($P < .01$), adenomas from carcinomas ($P < .01$), and pheochromocytomas from adrenal carcinomas ($P < .01$ for GLRLM; $P = .97$ for IBRMAD; $P = .85$ for IHEL10). For adenomas from pheochromocytomas the texture-based feature HU + GLRLM achieved the highest discriminative ability, with an AUC of 0.95 (SE = 0.03; 95% CI: 0.89-1.00; $P < .001$). For adenomas from carcinomas the texture-based feature HU + GLRLM achieved the highest discriminative ability, with an AUC of 1 (SE = 0.00; 95% CI: 1.00-1.00; $P < .001$). For pheochromocytomas from carcinomas the texture-based feature HU + GLRLM achieved the highest discriminative ability, with an AUC of 0,89 (SE = 0.04; 95% CI: 0,8-0,97; $P < .001$). Diagnostic accuracy remained high across different tumor subtypes, with minimal differences between individual parameters.

Conclusions: Preliminary data suggest that CT texture features, particularly when combined with conventional density metrics, may enhance non-invasive differentiation of adrenal adenomas, pheochoromocytomas, and malignant lesions. These findings support the potential integration of radiomic analysis into routine adrenal imaging workflows and guide clinical decision-making.

P33 - ECE_1435 - Diagnostic value of hair cortisol in mild autonomous cortisol secretion

Merve Korkmaz Yilmaz[1,2], Semih Tek[3], Aslihan Pekmezci[1], Mutlu Niyazoglu[1] and Esra Hatipoglu[1]
[1]Department of Endocrinology and Metabolism, University of Health Sciences, Basaksehir Cam and Sakura City Hospital, Istanbul, Türkiye; [2]Endocrinology and Metabolism, University of Health Sciences, Basaksehir Cam and Sakura City Hospital, Istanbul, Türkiye; [3]Department of Medical Biochemistry, University of Health Sciences, Basaksehir Cam and Sakura City Hospital, Istanbul, Türkiye

Background: Mild autonomous cortisol secretion (MACS) is a subtle but clinically relevant form of cortisol excess associated with increased cardiometabolic risk. Conventional biochemical tests largely capture short-term hypothalamic–pituitary–adrenal (HPA) axis activity and may not reflect cumulative exposure. Hair cortisol concentration (HCC) has been proposed as a marker of long-term exposure, but evidence in MACS remains limited.

Objective: To compare HCC between MACS and healthy controls, assess diagnostic performance, and examine associations with hormonal and metabolic parameters.

Methods: In this cross-sectional study, 73 MACS patients and 60 rigorously screened controls were included. MACS was defined according to European Society of Endocrinology guidelines. HCC was measured from the proximal 3-cm hair segment. Assessments included the 1-mg overnight dexamethasone suppression test (DST), 2-day low-dose DST, 24-hour urinary free cortisol, and late-night salivary cortisol. Correlation and receiver operating characteristic (ROC) analyses were performed.

Results: HCC was higher in MACS than controls (median 3.6 vs 1.75 ng/g; $P < .01$). In MACS, HCC correlated with waist circumference ($\rho = 0.27$; $P = .02$) and late-night salivary cortisol ($\rho = 0.25$; $P = .03$), but not with DST-based measures or urinary cortisol. ROC analysis showed modest discrimination (AUC = 0.60); the 2.7 ng/g cut-off yielded limited sensitivity and specificity.

Conclusions: HCC is elevated in MACS and reflects aspects of chronic cortisol exposure not captured by conventional testing. Although its standalone diagnostic value is modest, HCC may serve as a complementary biomarker. Prospective studies should clarify its role in risk stratification and disease progression.

Keywords mild autonomous cortisol secretion, hair cortisol concentration, adrenal incidentaloma, chronic cortisol exposure, HPA axis

Objectives: Lateralization is a key determinant of treatment selection in primary aldosteronism. Although adrenal venous sampling is the reference standard, its use is limited by invasiveness and availability. A primary aldosteronism severity classification has been proposed to reflect integrated biochemical and clinical burden. This study aimed to evaluate the association between disease severity, lateralization results, and treatment outcomes in a large multicenter cohort.

Methods: We conducted a retrospective multicenter cohort study including patients with confirmed primary aldosteronism who underwent adrenal venous sampling at eight tertiary hospitals. Disease severity was classified as mild, moderate, or severe using the primary aldosteronism severity classification. We assessed the relationships between severity category, adrenal venous sampling results, treatment allocation, and clinical and biochemical outcomes based on international consensus criteria. Logistic regression analyses were performed to identify factors associated with complete treatment response.

Results: A total of 848 patients were included, of whom 6.1% were classified as mild, 67.5% as moderate, and 26.4% as severe. Increasing disease severity was associated with a stepwise rise in lateralization indices and a higher prevalence of lateralizing primary aldosteronism on adrenal venous sampling (23.1% in mild, 50.5% in moderate, and 75.9% in severe; $P < .001$). Complete clinical success was observed in 40.0% of patients with moderate disease and 31.7% of those with severe disease, while partial clinical success predominated in severe disease (55.0%). In contrast, biochemical surgical outcomes were consistent across severity categories ($P = .380$), with complete biochemical success achieved in 72.5% and 71.7% of patients with moderate and severe disease, respectively. Among patients with bilateral PA treated medically, clinical outcomes varied by disease severity ($P = .010$), with complete clinical response decreasing from mild to severe disease (35.1%, 26.8%, and 9.1%). Biochemical medical outcomes were comparable across severity groups ($P = .996$).

Conclusions: Disease severity classification demonstrates a strong association with adrenal venous sampling–defined lateralization and treatment selection. Severity-based stratification may provide clinically useful guidance for lateralization assessment and individualized management in primary aldosteronism

P35 - ECE_2543 - Major adverse cardiovascular events in subjects with CYP11B2-positive aldosterone-producing adrenal lesions: a cross-sectional autopsy study

Antero Ylänen[1,2], Juhani Isojärvi[1], Antti Virtanen[3], Helena Leijon[4], Tiina Vesterinen[4], Eeva Kokko[1], Ilkka Pörsti[1,2], Marianna Viukari[5], Markus Kallio[5], Pasi Nevalainen[1,2] and Niina Matikainen[5]
[1]Faculty of Medicine and Health Technology, Tampere University, Tampere, Finland; [2]Department of Internal Medicine, Tampere University Hospital, Tampere, Finland; [3]Forensic Medicine Unit, Finnish Institute for Health and Welfare, Helsinki, Finland; [4]HUS Diagnostic Center, HUSLAB, Department of Pathology, Helsinki University Hospital and University of Helsinki, Helsinki, Finland; [5]Endocrinology, Helsinki University Hospital and University of Helsinki, Helsinki, Finland

Background: In addition to overt primary aldosteronism (PA), mild forms of autonomous aldosterone overproduction are linked to an increased risk for major cardiovascular events (MACE) in population studies. Aldosterone synthase (CYP11B2)–positive adenomas and nodules represent the hallmark of autonomous aldosterone secretion. However, the significance of CYP11B2–positive histopathological features for cardiovascular outcomes remains unclear.

Methods: We analysed the incidence of composite MACE, its components, and histopathological signs of cardiovascular disease using clinical registry and autopsy data from 401 consecutive individuals without known PA who experienced sudden death. Presence of aldosterone-producing adenomas/nodules (APA/APN) was assessed in bilateral adrenal samples with immunohistochemical CYP11B2 staining. This trial was registered at ClinicalTrials.gov (NCT05446779).

Findings: CYP11B2 staining identified APAs or APNs in 25 (6.2%) subjects. Their prevalence was similar in individuals younger than and older than 50 years. The MACE endpoint was identified more frequently in individuals with APA/APN than in those without (19 [76.0%] vs 178 [47.3%], $P = .006$), despite a similar profile of traditional vascular risk factors and biomarkers between the groups. In logistic regression analysis, the presence of APA/APN emerged as an explanatory factor for MACE (OR 4.76, 95% CI 1.61-14.10), alongside moderate or severe coronary artery disease (OR 6.99, 95% CI 3.89-12.53) and higher heart weight (OR 1.08, 95% CI 1.05-1.11). In addition, the presence of APA/APN was an explanatory factor for each MACE component and was associated with autopsy findings of aortic atherosclerosis and myocardial infarction.

Interpretation: Our findings link the presence of an adrenal APA/APN to autopsy–verified vascular disease and MACE, including sudden cardiac death, myocardial infarction, and stroke, in subjects without clinical PA. These associations persisted even after accounting for lifetime cardiovascular risk factors. Our results imply that previously undetected autonomous aldosterone secretion is a clinically relevant risk factor for cardiovascular morbidity and mortality and underscore the importance of adopting screening guidelines for secondary hypertension.

P36 - ECE_3718 - Absorption, metabolism, excretion, and absolute bioavailability of [14C]-labeled atumelnant for treatment of congenital adrenal hyperplasia and adrenocorticotropic hormone-dependent Cushing syndrome

Xiaoli Wang[1,2], Rosa Luo[3], Daria Stypinski[4], Deepak Dalvie[1], Ankita Sharma[1], Mukund Padmanabhan[1], Eduardo De La Torre[1], Alejandro Ayala[1] and Lise Kjems[1]

[1]Princeton, NJ, United States; [2]Crinetics, San Diego, United States; [3]A2-Ai LLC, Ann Arbor, MI, United States; [4]DS Clinical Pharmacology Consulting LLC, Manson, WA, United States

Atumelnant (CRN04894) is a first-in-class, once-daily, oral, selective melanocortin type 2 receptor antagonist. Atumelnant has shown clinical activity in normalizing adrenocorticotropic hormone (ACTH)-mediated pathological elevations of adrenal steroid hormones, demonstrating potential treatment benefits for patients with congenital adrenal hyperplasia (CAH) and ACTH-dependent Cushing syndrome (ADCS). This study characterized the in-human pharmacokinetic (PK) properties (ie, absorption, metabolism, excretion, and absolute bioavailability) of atumelnant to support its clinical development for treatment of CAH and ADCS.

This was an open-label, 2-part, nonrandomized, single-dose study. Part A characterized the absorption, metabolism, excretion, and mass balance of [^{14}C]-CRN04894 in 8 healthy male participants. All participants received a single 85-mg oral dose containing 125 μCi [^{14}C]-CRN04894 and were domiciled for ≤21 days or ≥8 days with early discharge criteria of (1) >90% of radioactive dose recovered in urine and feces and (2) <1% of radioactive dose recovered in combined excreta in 2 consecutive days. Plasma, blood, urine, and feces were collected and analyzed for total radioactivity and atumelnant levels. Metabolite profiling and identification were conducted on plasma, urine, and feces samples.

Part B determined the absolute bioavailability of atumelnant in 7 healthy male participants. All participants received a single 80-mg oral dose of atumelnant in the fasted state, followed by a single intravenous bolus of 22 μg/0.5 μCi [^{14}C]-CRN04894 1 hour later. Plasma was collected for ≤96 hours and analyzed for total radioactivity, [^{14}C]-CRN04894, and atumelnant concentrations.

CRN04894 was the predominant circulating drug-related component in plasma, accounting for 79.2% of total radioactivity. The major circulating metabolite was an oxidative inactive metabolite, M629a, with 14.7% of total radioactivity in plasma. The mean mass balance based on total administered radioactive dose recovered from urine and feces was 87.6%. Fecal excretion was the primary route of elimination, accounting for 76.3% recovered radioactive dose. CRN04894 and its metabolites did not partition into red blood cells (blood/plasma ratio, 0.56). Geometric mean absolute bioavailability after a single 80-mg dose was 56.7%. The mean half-life of oral CRN04894 in plasma was 27.2 hours in Part A and 21.4 hours in Part B. Treatment-emergent adverse events were mild and not considered to be related to atumelnant, indicating a favorable safety profile from both parent and metabolite M629a.

Atumelnant has suitable PK properties for chronic once-daily oral treatment of patients with CAH and patients with ADCS.

P37 - ECE_3830 - Management of adrenal cysts—a United Kingdom single centre case series

Mariyam Shazra[1], Rathna B. Veerni[2] and Rupa Ahluwalia[1]

[1]Norwich, United Kingdom; [2]Radiology, Norfolk and Norwich University Hospitals NHS Foundation Trust, Norwich, United Kingdom

Adrenal cysts are rare, representing 1%-2% of adrenal incidentalomas. Most are benign, non-functional, and asymptomatic. Despite rising incidental detection on cross-sectional imaging, there is limited data on the role of routine radiographic surveillance in management of asymptomatic adrenal cysts.

We report a case series highlighting real world experience of management of adrenal cysts within a U.K. endocrinology centre.

Thirteen patients with adrenal cysts seen within our department over a 32-month period (March 2023-November 2025) were identified following an electronic database search. Mean presenting age at diagnosis was 50 years (range 32-73 years), with 5 patients presenting in their 30s, suggesting a younger age at presentation. Patients were predominantly female (8/13, 61.5%) consistent with published data of 3:1 female-to-male ratio. Initial diagnosis following incidental detection occurred in 10 (76.9%), while remaining 3 patients were symptomatic (abdominal pain or distension). Notably, 61.5% were left-sided adrenal cysts. Cyst sizes ranged from 11-290 mm; 38.4% exceeded 5 cm, yet only 15.3% of large cysts were symptomatic. Two of the largest cysts (160 mm and 290 mm) occurred in patients with bilateral lesions. Among the three symptomatic patients, adrenal cyst sizes at presentation were 15 mm.(pheochromocytoma), 150 mm., and 290 mm.

Median unenhanced CT attenuation was 17 HU, with 61.5% demonstrating non-enhancement. Majority of our patients required secondary imaging to confirm diagnosis (CT adrenals: 23.1%, MRI adrenals: 53.8% or MRI Abdomen: 23.1%). All patients underwent multiple follow up scans as part of radiographic surveillance (range 2-6 scans). Cyst size during follow up imaging increased in five patients, decreased in three, and remained stable in five. Radiological follow up ranged from 2-40 months (mean 14 months) and from 0.07-31 months (mean 10.17 months) from time of endocrinology review. The largest cyst in our cohort had significant spontaneous reduction in size (290 mm to 170 mm). All patients underwent biochemical functional assessment for secretory status (overnight 1mg dexamethasone suppression test, renin & aldosterone studies (for hypertension and/or unprovoked hypokalaemia), 2 × 24 hour urinary metanephrines measurement). Only one patient had a confirmed secretory adrenal cyst (elevated plasma metanephrines in known multiple endocrine neoplasia type 2A mutation) requiring adrenalectomy. One patient requiring surgical intervention was 33-week pregnant with a large retroperitoneal cyst identified during evaluation for shortness of breath; cyst drainage confirmed an adrenal origin. Eleven patients (84.6%) were managed conservatively. At data collection, six patients (46.1%) were discharged, while seven (53.8%) had active endocrinology follow-up.

P38 - ECE_3225 - Ambulatory 24-hr tissue adrenal steroid profiling for personalised hormone replacement in patients with adrenal insufficiency

Ileana R. Botusan[1], Eder Zavala[2], Thomas Upton[3], Katarina Berinder[1], Paal Methlie[4], Katerina Simunkova[4], Dimitra Argyro Vassiliadi[5], Marianne Grytaas[6], Georgina Russell[3], Stylianos Tsagarakis[5], Stafford Lightman[3], Eystein Sverre Husebye[4], Olle Kämpe[1], Marianne Øksnes[6] and Sophie Bensing[1]

[1]Department of Medicine, Karolinska Institutet, Karolinska University Hospital, Solna, Stockholm, Sweden; [2]Division of Diabetes, Endocrinology & Gastroenterology, University of Manchester, Manchester, United Kingdom; [3]University of Bristol, Bristol, United Kingdom; [4]Department of Clinical Science, Faculty of Medicine, University of Bergen, Haukeland University Hospital, Bergen, Norway; [5]Evangelimos Hospital, Athens, Greece; [6]Medicine, University of Bergen, Haukeland University Hospital, Bergen, Norway

Background and Aim: Patients with primary adrenal insufficiency (PAI) lack endogenous corticosteroids and rely on lifelong replacement therapy, which fails to replicate normal circadian and ultradian rhythms. Using the ambulatory U-RHYTHM system, we previously mapped adrenal hormone dynamics in healthy individuals. Here, we characterize tissue corticosteroid profiles in PAI patients on different glucocorticoid therapies and quantify deviations from normal physiological patterns.

Materials and Methods: 41 patients with PAI were included independently of their glucocorticoid replacement therapy (GRT) regime: hydrocortisone, cortisone acetate or modified release hydrocortisone. All were 21 hydroxylase autoantibody positive, confirming an autoimmune cause. The median duration of PAI was 6.5 years (IQR: 3.25-19.75). Data were compared with a previously published cohort of 214 healthy controls. Free steroid hormones were sampled from abdominal subcutaneous tissue by microdialysis in ambulatory settings every 20 minutes over 24 hours, using the novel portable fraction collector U-RHYTHM. Steroid hormones were analyzed by ultrasensitive liquid chromatography tandem mass spectroscopy (LC-MS/MS). Normal cortisol ranges were defined in the healthy cohort using rolling means of cortisol and interquartile variability (25^{th}-75^{th} percentiles). The PAI cohort was then compared against this standard to calculate "time in range." To objectively quantify the differences in hormonal dynamics between the cohorts we further derived computational biomarkers including area under the curve, maximum hormone concentration and rate of increase after dose.

Results: Patients were analyzed according with their GRT regime: hydrocortisone, cortisone acetate, or modified-release hydrocortisone. Mean daily hydrocortisone equivalent doses were 21.6, 27.7, and 17.2 mg, respectively. Across all groups, time in range was low (<35%), with >25% of the day at extreme hormone levels (<5th or >95th percentile). In the early morning, PAI patients showed very low cortisol and cortisone and no pre-awakening rise, whereas healthy controls' levels started to increase 4 hours before awakening. Hormonal peaks in PAI were delayed compared with controls, highlighting marked deviations from normal physiology. Morning hormone surge in PAI showed reduced overall exposure, faster transitions, and altered peak morphology compared with healthy controls.

Conclusions: Here, we show for the first time the full individual 24h hormonal profiles resulting from different glucocorticoid replacement regimes, which we propose as a tool for precision management of GRT in PAI.

P39 - ECE_2323 - Sensitive diagnostic thresholds in the management of primary aldosteronism

Piotr Kmieć, Jowita Fiszer, Julia Tarnowska, Sonia Zembrzuska and Renata Świątkowska-Stodulska

Department of Endocrinology and Internal Medicine, Medical University of Gdańsk, Gdańsk, Poland

Introduction: The conventional binary approach to primary aldosteronism (PA) work-up has been proven inadequate due to the continuous nature of aldosterone secretion. PA also remains vastly underdiagnosed. Therefore, a sensitivity-oriented approach to PA has been implemented in our tertiary endocrine center in December, 2023. It included a requirement for universal screening of eligible patients, permissive aldosterone-to-renin-ratio thresholds dependent on prescribed medications as well as a low saline infusion test cutoff.

Design and Methods: A single-center, retrospective analysis of two 12-month periods: before and after implementation of a systematic diagnostic approach toward PA. The number of screenings, confirmatory tests, adrenal vein sampling procedures, and therapy outcomes were compared.

Results: In the "before" period (November, 2022 through October, 2023), 61% of normokalemic patients with an indication for screening were tested, which increased to 82% in the second ("after") period (March, 2024 through February, 2025), $P < .001$, see table below. Confirmatory testing almost doubled (37 out of 275 vs 102 out of 432 screened patients, respectively). Among all patients with an indication for PA work-up, confirmed PA cases prevalence increased from 2.9% to 10.9%, whereas among those who underwent work-up: from 4.7% to 13.2%. A shift in suppression test interpretation was evident in higher positivity: 51% vs 29.7%, $P = .03$. In patients with suspected autonomous aldosterone secretion not meeting formal PA criteria mineralocorticoid receptor antagonists (MRAs) were often prescribed. Overall, the rate of newly-prescribed MRAs among patients who underwent work-up more than tripled (Table). Clinical and biochemical outcomes were favorable, however, in the second period, adverse effects occurred in two patients and repeat testing ruled out PA in three others.

Period	Before	After	*P*
Normokalemic patients who had an indication and underwent PA work-up among all	264/433(61%)	402/490 (82%)	<.001
PA suppression tests among all patients who underwent work-up	37/275 (13.5%)	102/432 (23.6%)	<.001
Suppression test positivity	11/37 (29.7%)	52/102 (51%)	.03
PA diagnoses among all	13/275 (4.7%)	57/432 (13.2%)	<.001

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Continued

Period	Before	After	P
patients who underwent work-up			
Newly-initiated MRA among patients off MRA who underwent PA work-up	13/259 (5%)	63/393 (16.1%)	<.001
Planned and performed adrenalectomies in PA patients	3/13 (23.1%)	10/57 (17.5%)	.7
Partial or complete clinical and/or biochemical success in MRA-treated patients	10	50	1
MRA not initiated / discontinued / loss to follow-up	1	9	

Conclusions: This before-and-after study provides real-world data on sensitivity-oriented PA management. The approach significantly improved testing rates and led to a more frequent implementation of targeted pharmacotherapy.

P42 - ECE_3478 - Variable interferences for aldosterone measured by Liaison and iSYS chemiluminescence immunoassays dictate need for different cut-offs for the seated saline suppression test

Graeme Eisenhofer[1], Carmina Teresa Fuss[2], Stefanie Hahner[2], Jun Yang[3], Tracy Williams[4], Martin Reincke[4], Felix Beuschlein[5], Andrea Horvath[6], Jacques Lenders[7] and Christina Pamporaki[1]

[1]University Hospital Carl Gustav Carus, Technische Universität Dresden, Dresden, Germany; [2]University Hospital, University of Würzburg, Wurzburg, Germany; [3]Hudson Institute of Medical Research, Monash University, Melbourne, Australia; [4]Ludwig Maximilian University Munich, Munich, Germany; [5]University Hospital Zurich, Zurich, Switzerland; [6]New South Wales Health Pathology, University of New South Wales, Sydney, Australia; [7]Radboud University Medical Center, Nijmegen, The Netherlands

Background: Protein-based interferences with chemiluminescence immunoassays (CLIA) of plasma aldosterone, particularly at low concentrations during confirmatory tests, are a previously unrecognised problem. We therefore hypothesized that cut-offs for measurements of aldosterone for the seated saline suppression test (SSST) require tailoring according to the particular immunoassay.

Methods: Multicenter study involving 609 patients with suspected primary aldosteronism (PA) who underwent SSSTs with aldosterone measured by liquid chromatography-mass spectrometry (LC-MS/MS) compared to iSYS or Liaison CLIAs in 285 and 286 respective patients and a different LC-MS/MS method in 38 patients. Cut-offs for plasma aldosterone were derived from receiver-operating characteristic curves after classification of patients with ($n = 181$) and without PA ($n = 336$) by methods independent of confirmatory tests. Classifications could not be achieved by methods independent of confirmatory tests in 92 patients.

Findings: Plasma aldosterone measured by the two CLIAs showed considerable differences compared to near identical measurements by the two LC-MS/MS methods. Paired comparisons indicated higher ($P < .0001$) plasma concentrations of aldosterone measured by both Liaison and iSYS CLIAs than by LC-MS/MS for patients with and without PA. Differences were most prominent for suppressed aldosterone measured by the Liaison CLIA in patients without PA in whom concentrations were 130% higher than measured by LC-MS/MS and 40% higher than by the iSYS CLIA. Youden-index derived cut-offs for suppressed aldosterone were 300 and 272 pmol/L for respective Liaison and iSYS CLIAs compared to 169 pmol/L by LC-MS/MS. At those cut-offs, respective diagnostic sensitivities for Liaison and iSYS immunoassays and LC-MS/MS were 90%, 91% and 98% with specificities of 86%, 94% and 90%. Improved disease confirmation according to specificities of 95% for positive predictive values of 87%, 92% and 90% were provided by cut-offs of 436, 297 and 243 pmol/L for respective measurements by Liaison and iSYS CLIAs and LC-MS/MS. At those cut-offs, sensitivities were, however, reduced to 64%, 85% and 78% for those respective measurement methods.

Conclusions: Cut-offs for CLIA-based measurements of aldosterone during the SSST must be established according to the specific immunoassay and are variably higher than those for LC-MS/MS. Severe protein-based interferences with the Liaison CLIA render this method inferior for confirmatory testing than the other methods.

P43 - ECE_1371 - Hemostasis is altered in patients with mild autonomous cortisol secretion and affected by metyrapone treatment

Helena Niziolek[1], Dino Mehic[2], Tim Dreier[2], Anna Tosin[1], Clemens Baumgartner[1], Paul Fellinger[1], Luise Bellach[1], Alexandra Kautzky-Willer[1], Michael Krebs[1], Peter Quehenberger[3], Michael Leutner[1], Johanna Gebhart[2] and Peter Wolf[1]

[1]Division of Endocrinology and Metabolism, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria; [2]Division of Hematology and Hemostaseology, Department of Internal Medicine I, Medical University of Vienna, Vienna, Austria; [3]Department of Laboratory Medicine, Medical Unviersity of Vienna, Vienna, Austria

Research Question: Hypercoagulation and impaired fibrinolysis were reported in a state of hypercortisolism, but evidence for patients with mild autonomous cortisol secretion (MACS) is limited. This study aims to characterize hemostasis in patients with MACS compared to patients with non-functional adrenal adenoma (NFA) and to investigate the effects of medical treatment.

Material and Methods: Patients with MACS ($n = 25$, 21 females) were compared to patients with NFA ($n = 25$, 21 females) of comparable age and BMI (median age: 63 (55-67) vs 61 (54-68) years; median BMI: 27 (24.2- 30.5) vs 28.5 (27.5-32.2) kg/m^2). A sub-cohort of 14 patients with MACS was re-investigated prospectively following 12 weeks of treatment with evening doses of metyrapone (500 mg at 6 p.m. & 250 mg at 10p.m.) as part of an exploratory secondary analysis of the AdrenalCLOCK study.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Hemostatic parameters (activated partial thromboplastin time, von Willebrand factor antigen, protein S, plasminogen, α2-antiplasmin, prothrombin time, international normalized ratio, plasminogen activator inhibitor-1, fibrinogen, FVIII, FIX and protein C) were measured by routine laboratory techniques. Dynamics of thrombin and plasmin generation were measured using calibrated fluorescence detection in citrated platelet-poor plasma. Mann-Whitney-U test was applied for cross-sectional analysis, while Wilcoxon signed-rank tests were performed for pre-post metyrapone comparison.

Results: Levels of fibrinogen Clauss [362 (329-414) vs 331 (307-376) mg/dL, $P = .03$], von Willebrand factor antigen [121 (94-170) vs 99(77-128) %, $P = .04$] and factor VIII [109 (78-132) vs 76 (65-101)%, $P = .02$] were increased in MACS compared to NFA. While no differences between MACS and NFA were determined for thrombin generation potential, patients with MACS had a slower plasmin generation reflected by a reduced plasmin velocity in MACS compared to NFA [13.12 (11.59-16.53) vs 16.44 (13.13-18.75) nM/min, $P = .03$]. Treatment with metyrapone increased plasmin peak height [52.69 (47.04-59.61) vs 39.88 (34.49-46.57) nM; $P = .0353$) and endogenous plasmin potential [657.40 (430.26-738.44) vs 454.75 (317.17-524.26) nM/min, $P = .0203$) at follow up compared to baseline, while protein S activity [104 (85.25-109.75) vs 83(79.25-98.25)%, $P = .0035$] decreased.

Conclusions: MACS is associated with changes in hemostasis, which are affected by short-term treatment with evening doses of metyrapone. Future studies are warranted to derive potential clinical implications of medical treatment.

P44 - ECE_1661 - Salivary 18-hydroxycortisol as a non-invasive biomarker for subtyping Primary Aldosteronism

Seung Shin Park[1,2], Soyeon Park[3], Min Jeong Park[4], Seungho Lee[5], Woochul Kim[5], Su-Jin Kim[5], Man Ho Choi[3] and Jung Hee Kim[1,2]

[1]Department of Internal Medicine, Seoul National University Hospital, Seoul, South Korea; [2]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, South Korea; [3]Center for Advanced Biomolecular Recognition, Korea Institute of Science and Technology, Seoul, South Korea; [4]Department of Internal Medicine, Korea University Medical Center, Seoul, South Korea; [5]Department of Surgery, Seoul National University Hospital, Seoul, South Korea

Introduction: Primary aldosteronism (PA) is the most common cause of secondary hypertension, and accurate subtyping into lateralized or non-lateralized disease is essential for optimal management. Although adrenal venous sampling (AVS) remains the gold standard for lateralization, it is invasive, technically demanding, and not widely available. Steroid profiling using liquid chromatography–tandem mass spectrometry (LC–MS/MS) has emerged as a promising alternative, but the potential role of salivary steroid profiling in PA subtyping has not been systematically evaluated. We aimed to investigate whether salivary steroid measurements, particularly 18-hydroxycortisol (18-OHF), could predict lateralization in patients with PA.

Methods: This single-center study included 74 patients with confirmed PA who underwent AVS at Seoul National University Hospital between 2017 and 2023. Lateralized PA was defined by a lateralization index ≥4 or confirmed clinical success after adrenalectomy in indeterminate cases. Morning salivary samples were collected and analyzed using LC–MS/MS. Salivary concentrations of cortisol, cortisone, tetrahydrocortisol, 20α-dihydrocortisol, 18-OHF, and dehydroepiandrosterone sulfate were compared between lateralized and non-lateralized PA. Diagnostic performance was assessed using receiver operating characteristic (ROC) analysis. Incremental value beyond conventional biochemical parameters was evaluated using net reclassification improvement (NRI). Correlations between salivary and serum steroid concentrations were also examined.

Results: Among the 74 patients, 38 had lateralized PA and 36 had non-lateralized PA. Compared with non-lateralized PA, patients with lateralized PA had higher plasma aldosterone (34.9 vs 21.7 ng/dL, $P = .021$), lower plasma renin activity (0.2 vs 0.5 ng/mL/h, $P < .001$), and more frequent hypokalemia (71.1% vs 27.8%, $P < .001$). Among salivary steroids, only 18-OHF differed significantly, with higher levels in LPA (0.66 vs 0.25 ng/mL, $P < .001$). Salivary 18-OHF predicted lateralization with an area under the ROC curve of 0.756 (95% CI, 0.642-0.870). A cutoff value of 0.29 ng/mL yielded a sensitivity of 78.9% and specificity of 69.4%. When added to a conventional model including plasma aldosterone, renin, and serum potassium, salivary 18-OHF significantly improved classification (category-free NRI 0.52, 95% CI, 0.084-0.929 $P = .014$). Salivary and serum 18-OHF levels showed a strong correlation ($\rho = 0.73$, $P < .001$).

Conclusions: Salivary 18-OHF is a promising non-invasive biomarker for subtyping PA. It provides clinically meaningful discrimination of lateralized disease and offers incremental diagnostic value beyond conventional biochemical parameters. Salivary steroid profiling may serve as a practical adjunct to current diagnostic strategies and help reduce reliance on invasive AVS. Larger studies are needed to validate its clinical utility.

P45 - ECE_2394 - Hypertension in adrenal insufficiency: prevalence, disease specific factors and insights into regulation of the renin-angiotensin-aldosterone system

Irina Chifu[1], Laura Heger[1], Marcus Quinkler[2], Hanna F. Nowotny[3], Georgiana Constantinescu[4,5], Christina Pamporaki[4], Birgit Harbeck[6], Nicole Reisch[3] and Stefanie Hahner[1]

[1]Department of Medicine I, Division of Endocrinology and Diabetology, University Hospital Wuerzburg, Wuerzburg, Germany; [2]Endocrinology in Charlottenburg, Berlin, Germany; [3]Department of Medicine IV, Ludwig Maximilian University, Munich, Germany; [4]Department of Internal Medicine III, University Clinic Carl Gustav Carus at TU Dresden, Dresden, Germany; [5]Grigore T Popa University of Medicine and Pharmacy, Iasi, Romania; [6]III. Department of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Retrospective analyses consistently show higher cardiovascular (CV) mortality and morbidity in patients with adrenal insufficiency (AI) compared to controls. However, factors driving the increased CV risk remain poorly understood.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Objective: Assess the prevalence of hypertension (HT) by 24-hour blood pressure (24h-BP) measurements and associations with disease-related parameters in patients from our multicentric AI registry.

Methods: We measured 24h-BP in 281 patients (71% primary AI (PAI), 68% female, mean age 50 ± 14 years, 24% under antihypertensive treatment). HT was diagnosed according to ESC/ESH thresholds. Results were correlated with hormone replacement regimens, salivary- and urinary cortisol, key effectors of the renin-angiotensin-aldosterone system (RAAS) (Angiotensin I/II, Aldosterone, angiotensin-converting-enzyme activity (ACE-Q)) and routine clinical and biochemical parameters.

Results: 24h-BP was elevated in 59% of all patients (PAI 57% vs SAI 74%, $P = .006$) and in 52% of patients without antihypertensive treatment (PAI 52% vs SAI 53%, $P = 0.88$). Nighttime-HT was more prevalent than daytime-HT (48% vs 38%) regardless of antihypertensive therapy and 33% of the cohort were non-dippers. Logistic regression in patients not receiving antihypertensive therapy showed significant associations of male sex, BMI, and renal function with 24h-HT, and of higher glucocorticoid (GC) doses with daytime-HT. In the subgroup with available RAAS data, evening GC intake and ACE-Q were additionally associated with 24h-HT and nighttime-HT. Linear regression in patients with 24h-HT demonstrated associations between mean systolic BP and higher 24h urinary cortisol, salivary cortisol AUC, and GC replacement dose.

Conclusions/Outlook: Nighttime hypertension and non-dipping are frequent in our cohort. While classical risk factors appear dominant, the observed associations with GC replacement and cortisol profiles indicate unphysiological steroid exposure under conventional treatment contributes to BP elevations.

P48 - ECE_1392 - Machine learning model based on preoperative peripheral serum steroids for predicting clinical outcomes after adrenalectomy in primary aldosteronism

Ruyi Li[1,2], Lei Ye[1,2] and Weiqing Wang[1,2]
[1]*Department of Endocrine and Metabolic Diseases, Shanghai Institute of Endocrine and Metabolic Diseases, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China;* [2]*Shanghai National Clinical Research Center for metabolic Diseases, Shanghai Key Laboratory for Endocrine Tumor, Shanghai, China*

Background/Introduction: A 2021 study from our research group indicated that *KCNJ5* mutation contributes to complete clinical success after adrenalectomy in aldosterone-producing adenoma (APA). Previous studies have shown that APA patients harboring *KCNJ5* mutations possess a distinct steroid hormone profile. Building on these background, we hypothesize that the subset of APA patients who achieve clinical complete remission after surgery may be characterized by a distinct peripheral blood steroid hormone profiles.

Purpose: We aimed to develop and validate interpretable machine learning (ML) models using peripheral serum steroids to predict surgical outcomes in APA patients and to formulate individualized diagnosis and treatment plans.

Methods: LC-MS/MS was used to detect 24 types of steroid hormones in the preoperative peripheral serum of the enrolled patients with APA. Lasso regression was used to select features and eight ML algorithms such as extreme gradient boosting (XGBoost) were used to construct the model. Model prediction performance was compared using evaluation indicators such as the area under the receiver operating characteristic curve (AUC). The SHapley Additive exPlanation (SHAP) method was used to rank the feature importance and explain the final model.

Results: Among the 338 patients who were followed up for at least six months after surgery, the preoperative peripheral serum levels of 18-oxocortisol (585.00 vs 133.50 pg/mL, $P < .001$), 18-hydroxycortisol (4291.02 vs 1690.50 pg/mL, $P < .001$), and 18-hydroxycorticosterone (875.21 vs 450.00 pg/mL, $P < .001$) in the complete remission group (164 cases) were significantly higher than those in the no complete remission group (174 cases). Among the eight ML models, the XGBoost model performed the best, showing the highest AUC, accuracy, sensitivity, F1 score, and a low Brier score. The XGBoost model accurately predicted the clinical outcomes of surgery in patients with APA in both the training set [AUC: 0.963, 95% confidence interval (CI) (0.944-0.983)] and the test set [AUC: 0.878, 95% CI (0.811-0.946)]. The calibration curve showed high agreement between the predicted and observed probability. SHAP analysis identified variables that contributed to the model predictions. 6 variables were included in the final XGBoost model: 18-oxocortisol, 18-hydroxycortisol, 18-hydroxycorticosterone, sex, cortisone, and deoxycorticosterone.

Conclusions: We developed and validated an explainable ML model by using preoperative circulating steroids for predicting the surgical outcomes in APA patients. The final XGBoost model exhibited excellent prediction ability in both training set and test set validation. The model provides a basis for clinicians to identify individualized treatment plans.

P49 - ECE_2309 - Bilateral adrenal vein thrombosis and adrenal hemorrhage with acute adrenal insufficiency in a patient with Waldenström's macroglobulinemia

Michał Olejarz[1], Remigiusz Domin[1], Ewelina Szczepanek-Parulska[1] and Marek Ruchala[1]
[1]*Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences, Poznan, Poland*

Acute adrenal failure is an endocrine emergency that can be a life-threatening condition if not diagnosed and treated promptly. One of the rare and underrecognized causes of acute adrenal failure is adrenal hemorrhage secondary to adrenal vein thrombosis.

A 66-year-old male presented to the emergency department because of abdominal pain radiating to the left shoulder, nausea, and constipation. His past medical history included Waldenström's macroglobulinemia, depressive disorder, hypothyroidism (following thyroidectomy because of papillary thyroid carcinoma), and two episodes of pulmonary embolism.

Laboratory analysis revealed increased CRP (68 mg/l), hyponatremia (Na 125 mmol/l), thrombocytopenia (108 × 10^3/μl),

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

and anemia (11,1 g/dl). Abdominal radiograph revealed moderately distended loops of the descending colon, suggesting subileus. Subsequently, an abdominal CT was performed, which revealed bilateral adrenal vein thrombosis and bilateral adrenal hemorrhage. The distention of the colon was attributed to fecal impaction and did not require surgical intervention.

Because of acute adrenal failure, the patient was started on high doses of intravenous hydrocortisone supplementation, which was subsequently tapered to a standard supplementation dose later.

A week before the admission, the patient had a skin biopsy because of a suspicious skin lesion, which resembled cutaneous vasculitis. Before the biopsy, the patient was switched from oral rivaroxaban to subcutaneous low molecular weight heparin. Thus, we evaluated the patient using the 4T clinical score for heparin-induced thrombocytopenia (HIT), which indicated a high probability of HIT. Heparin was stopped, and rivaroxaban was reintroduced.

The patient's condition improved rapidly after treatment, and the follow-up CT revealed no rebleeding. We tested the patient for anti-platelet factor 4 (anti-PF4) antibodies, which were negative. Eventually, we received the result of the skin biopsy, which was suggestive of monoclonal cryoglobulinemia.

Bilateral adrenal vein thrombosis with secondary bilateral adrenal hemorrhage is potentially life-threatening and needs to be diagnosed and treated promptly. There is a handful of case reports linking it to HIT. Thus, HIT should be considered if heparin was administered recently and the 4T clinical score is high. Anti-PF4 antibodies have an excellent sensitivity and negative predictive value. Thus, a negative anti-PF4 antibody test makes the diagnosis of HIT highly unlikely.

In this case, eventually, the adrenal vein thrombosis was most probably caused by an acquired prothrombotic state associated with the underlying lymphoproliferative disorder and monoclonal cryoglobulinemia.

P50 - ECE_3013 - What was the cause of recurrent arrhythmogenic syncopes?

Zora Lazurova[1], Adriana Sudzinova[2], Martin Javorsky[1], Kleanthia Efthymiou[1], Jana Katuchova[1] and Peter Bohus[1]

[1]Medical Faculty, Department of Pathology, University of Pavol Jozef Safarik, Kosice, Slovakia; [2]1st Department of Internal Medicine, Institute of Cardiovascular Diseases of East Slovakia, Kosice, Slovakia

We present a case of 32 years old male with no previous history of any diseases. A non obese smoker, without any chronic medication was admitted to the hospital due to recurrent syncopes, without any prodromes. Patient was hemodynamically stable, blood pressure was 120-140/80-90 mmHg, apart from mild systolic murmur, physical examination was unremarkable. ECG revealed atrial flutter with rapid heart rate and short paroxysms of non-sustained ventricular tachycardia. Moreover, signs of left ventricular hypertrophy have been described. In laboratory screening, severe hypokalemia (1.5 mmol/l) and metabolic alkalosis was present, other results were within normal ranges. Transthoracic echocardiography revealed left ventricular hypertrophy (IVS 17 mm) with diastolic dysfunction. After massive potassium replacement and betablocker administration, the conversion to sinus rhythm was noticed. In differential diagnosis of severe hypokalemia, hormonal screening was performed, with identification of severe primary hyperaldosteronism (plasmatic renin activity less then 0.3 ng/ml/hod and aldosterone 2050 g/dl), with no suppression in captopril test. Due to cardiac condition, the saline test was not peformed. On the CT, there was a left adrenal nonhomogenous tumour mass documented with typical features for adrenocortical carcinoma. Furthermore, pathological paraoartic lymph nodes and methastasis in the liver (15 mm) were described. Baseline cotisol levels were normal, however In dexamethasone test there was insignificant suppression, revealing a cortisol cosecretion. Surgical removement was indicated, after preoperative treatment with high doses of spironolactone and potassium surrogation. Histopathology confirmed aldosterone-producing adrenocortical cancer with Ki67 index 35% (in hot spots 50%-60%). After surgery there was normalization of aldosterone levels and the adjuvant therapy by etoposid and cisplatin in combination with mitotan was administered.

P51 - ECE_2502 - Efficacy and Safety of the clonidine suppression test in identifying false-positive normetanephrine results in the diagnosis of pheochromocytoma and paraganglioma

Alicja Duquenne[1,2,3], Agata Toboła[1], Dorota Leszczynska[1], Małgorzata Waszkiewicz-Hanke[1], Magdalena Ostrowska[1,2], Konrad Kowalski[4], Radosław Samsel[5], Wojciech Zgliczyński[1] and Piotr Glinicki[1,2]

[1]Centre of Postgraduate Medical Education, Department of Endocrinology, Warsaw, Poland; [2]Centre of Postgraduate Medical Education, EndoLab Laboratory, Warsaw, Poland; [3]Centre of Postgraduate Medical Education, Doctoral School of Translational Medicine, Warsaw, Poland; [4]Masdiag Laboratory, Warsaw, Poland; [5]Department of Surgery, Clinic of Surgical Oncology and Neuroendocrine Tumors, Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw, Poland

Background: Measurement of free plasma metanephrines using liquid chromatography–tandem mass spectrometry (LC–MS/MS) represents the gold standard for the biochemical diagnosis of pheochromocytoma–paraganglioma (PPGL). However, despite optimal pre-analytical preparation, false-positive results occur in up to 20% of patients.

Purpose: To evaluate the efficacy and safety of the clonidine suppression test (CST) in distinguishing false-positive elevations of plasma normetanephrine.

Methods: The study included 11 patients (median age 59 years; 8 females) with plasma normetanephrine concentrations exceeding age-adjusted cut-offs. Indications for diagnostic evaluation included paroxysmal symptoms, suspected PPGL recurrence, adrenal incidentaloma with unenhanced CT attenuation >10 Hounsfield units, and suspected carotid paraganglioma. All patients received oral clonidine 300 µg. Plasma normetanephrine levels (LC–MS/MS) were measured at baseline and 180 minutes post-administration. Patients were continuously monitored, with vital signs assessed every 30 minutes and adverse events recorded.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Results: The median reduction in plasma normetanephrine was 42 pg/mL. In all patients, concentrations decreased below age-adjusted cut-offs, and in 10 of 11 patients, levels fell to <80% of the respective cut-off. The most common adverse effects were somnolence, xerostomia, and fatigue. Median reductions in hemodynamic parameters were: systolic blood pressure −48 mmHg, diastolic blood pressure −31 mmHg, and heart rate −15 bpm.

Conclusions: The clonidine suppression test appears to be a safe and effective tool for confirming isolated elevations of plasma normetanephrine in the diagnostic evaluation of PPGL.

P52 - ECE_1432 - Hair cortisol as a marker of glucocorticoid replacement adequacy in adrenal insufficiency

Merve Korkmaz Yilmaz[1,2], Semih Tek[3], Gizem Karatas Kiliccioglu[1], Aysel Unver Ozkahraman[1], Mutlu Niyazoglu[1] and Esra Hatipoglu[1]

[1]Department of Endocrinology and Metabolism, University of Health Sciences, Basaksehir Cam and Sakura City Hospital, Istanbul, Türkiye; [2]Endocrinology and Metabolism, University of Health Sciences, Basaksehir Cam and Sakura City Hospital, Istanbul, Türkiye; [3]Department of Medical Biochemistry, University of Health Sciences, Basaksehir Cam and Sakura City Hospital, Istanbul, Türkiye

Background: Achieving physiologic glucocorticoid replacement in adrenal insufficiency (AI) remains a major clinical challenge, with both under- and over-replacement contributing to substantial morbidity. Although useful, conventional serum- and urine-based markers reflect mainly short-term cortisol exposure and may not fully capture the patient's clinical status. In contrast, hair cortisol concentration (HCC) integrates long-term cumulative exposure and may address these limitations; however, HCC has been evaluated only sparsely in AI, and its clinical utility remains uncertain.

Methods: In this cross-sectional study, 64 adults with hydrocortisone-treated AI and 64 matched healthy controls were evaluated. HCC was measured from the proximal 3-cm hair segment. Clinical symptoms, anthropometry, metabolic markers, and hydrocortisone dosing parameters were recorded. Group comparisons, Spearman correlations, ROC analyses, and multivariable linear regression were performed. Patients were classified as undertreated based on VAS-fatigue or VAS-pain ≥7, and as overtreated based on SBP ≥140 mmHg, DBP ≥90 mmHg, HbA1c ≥6.5%, FPG ≥126 mg/dL, or ≥5% weight gain.

Results: HCC was higher in AI patients than controls (4.3 vs 1.75 ng/g, $P < .01$) and higher in primary vs secondary AI (6.5 vs 3.8 ng/g, $P = .037$). HCC correlated positively with BMI, waist circumference, systolic and diastolic blood pressure, and hydrocortisone dose, and inversely with fatigue, pain, and total duration of therapy (all $P < .05$). In multivariable models, AI type remained the only independent predictor of HCC. HCC showed strong discrimination for undertreatment (AUC 0.906 for severe fatigue and 0.898 for severe pain; optimal cutoffs 4.9 and 3.5 ng/g). For glucocorticoid excess, the strongest performance was observed for systolic hypertension (AUC 0.837; cutoff 7.9 ng/g). Undertreated patients had markedly lower HCC (2.1 ng/g), whereas overtreated patients exhibited substantially higher levels (14.1 ng/g; $P < .001$).

Conclusions: HCC may serve as a sensitive biomarker of long-term glucocorticoid exposure in adrenal insufficiency, capturing both metabolic strain associated with overtreatment and symptom burden associated with underreplacement. Its strong bidirectional discrimination suggests that HCC may be a practical adjunct to clinical assessment and could support more individualized hydrocortisone titration. Longitudinal studies are warranted to determine whether HCC-informed dosing improves clinical outcomes.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Background: Unilateral primary aldosteronism (UPA) is characterized by a severe clinical phenotype and can be cured by adrenalectomy. Adrenal venous sampling (AVS) is required to distinguish UPA and bilateral primary aldosteronism (BPA). Establishing accurate cutoff values that would warrant AVS is crucial. Recently, new chemiluminescent enzyme immunoassay (CLEIA)-based kits with high level of traceability, close correlation, and equivalent concentration with LC–MS/MS for plasma aldosterone concentration (PAC) are available in Japan. The Japan Endocrine Society Clinical Practice Guideline for the Diagnosis and Management of Primary Aldosteronism 2021 (JES2021) introduced "provisionally positive" range for screening aldosterone-to-renin ratio (sARR), post-captopril challenge test (CCT) aldosterone-to-renin ratio (ARR), and post-saline infusion test (SIT) plasma aldosterone concentration (PAC) to address the concern about the differing PAC values between RIA and LC–MS/MS-equivalent CLEIA. Therefore, we aimed to identify appropriate cutoff values for screening and confirmatory testing to predict UPA by CLEIA-measured PAC.

Methods: A retrospective cohort analysis was conducted as part of the JPAS-II study of 443 patients diagnosed with PA using CLEIA-measured PAC, of whom 179 were confirmed by AVS as having UPA. All patients were diagnosed according to JES2021.

Results: The sARR, screening PAC, post-CCT ARR, post-CCT PAC, and post-SIT PAC were significantly higher in patients with UPA than in those with BPA ($P < .05$). Receiver operator characteristic curve analysis yielded an sARR cutoff value of >183 pg/mL/ng/mL/h (sensitivity: 0.95, specificity: 0.25). The post-CCT ARR (AUC: 0.824 ± 0.022) and post-CCT PAC (AUC: 0.845 ± 0.021) were superior predictors of UPA to post-SIT PAC (AUC: 0.782 ± 0.037). When the cutoff values were designed to maximize sensitivity without a significant reduction in specificity, cutoff values for post-CCT ARR of >153 pg/mL/ng/mL/h (sensitivity: 0.85, specificity: 0.55), post-CCT PAC of >69 pg/mL (sensitivity: 0.85, specificity: 0.67) and for post-SIT PAC of >48 pg/mL (sensitivity: 0.80, specificity: 0.61) were obtained. The cutoff values determined for sARR, post-CCT ARR, and post-SIT PAC were within the "provisionally positive" range defined in JES2021. Importantly, these cutoff values contributed to a diagnosis of UPA when the presence of hypokalemia or adrenal tumor was also considered.

Conclusions: LC–MS/MS-equivalent CLEIA-measured cutoff values for post-CCT ARR of >153 pg/mL/ng/mL/h, for post-CCT PAC of >69 pg/mL and for post-SIT PAC of >48 pg/mL are considered to indicate AVS. Among patients with "provisionally positive" test results on sARR, post-CCT ARR, and post-SIT PAC in JES2021, AVS should be considered when clinical features suggest PA, such as hypokalemia and adrenal tumor.

P55 - ECE_2714 - Role of CACUL1/ARMC5 complex in primary bilateral macronodular adrenal hyperplasia

Rania Nait Challal, Isadora Pontes Cavalcante, Oriane Genard, Alexandre Quesnoy, Lamia Sefraoui, Anna Vaczlavik, Karine Perlemoine, Fidéline Bonnet-Serrano, Marthe Rizk, Annabel Berthon, Jérôme Bertherat and Bruno Ragazzon
Institut Cochin, Institut Cochin, INSERM U1016, Université Paris Cité, Paris, France

Introduction: Primary bilateral macronodular adrenal hyperplasia (PBMAH) is a rare cause of ACTH-independent hypercortisolism. Inactivating mutations of the tumor suppressor gene *ARMC5* have been identified in approximately 25% of cases. ARMC5, an armadillo repeat–containing protein with a BTB domain, interacts with Cullin-3 (CUL3) and acts as its adaptor for ubiquitination and degradation of specific substrates involved in several cellular processes. Using a proximity-dependent biotinylation approach (APEX2) in living cells coupled with mass spectrometry, we identified CACUL1 (CDK2-associated and Cullin domain-containing protein 1) as an interacting partner of ARMC5. CACUL1 is a nuclear protein involved in chromatin organization and transcriptional regulation, but its function in adrenal cortical cells has not been defined. The aim of this study was to characterize the ARMC5/CACUL1 interaction and to investigate its impact on ARMC5 subcellular localization, cAMP/PKA signaling pathway and steroidogenic gene expression.

Materials and Methods: Protein interactions and subcellular localization were investigated by co-immunoprecipitation and immunofluorescence after modulation of CACUL1 and/or ARMC5 expression using different constructs (wild-type, PBMAH-associated pathogenic missense variants and fragments of ARMC5) in two cellular models (HEK293 and H295R cells). Effects of ARMC5/CACUL1 modulation (siRNA/overexpression) on cAMP/PKA/steroidogenesis were assessed using CREB phosphorylation analysis, CRE-luciferase reporter assays and RT-qPCR of steroidogenic genes.

Results: We show that CACUL1 is insensitive to ARMC5/CUL3 ubiquitination. Moreover, ARMC5 interacts with CACUL1 through its BTB domain as CUL3, supporting that CACUL1 is not a target of the ARMC5/CUL3 complex. Interestingly, CACUL1 overexpression induced a nuclear translocation of ARMC5 wild-type but not ARMC5 pathogenic missense identified in PBMAH patients, which remain cytoplasmic. As CACUL1 is a partner of ARMC5, we wonder whether CACUL1 modulation could alter cAMP/PKA pathway and steroidogenic gene expression. Accordingly, we observed modification of CREB phosphorylation and CRE-luciferase activity depending on CACUL1.

Discussion: CACUL1 appears to be involved in the development of PBMAH, in association with *ARMC5* alterations and through the cAMP/PKA pathway activity and transcriptional control of steroidogenesis. Further characterization of the ARMC5/CACUL1 complex will be required to better understand the pathophysiological mechanisms underlying PBMAH.

P56 - ECE_2749 - Modified-release hydrocortisone impact on metabolism and hormonal control in patients with congenital adrenal hyperplasia: an observational cohort study

Pierluigi Mazzeo, Irene Tizianel, Giulia Bovo, Chiara Sabbadin, Filippo Ceccato and Mattia Barbot
Endocrinology unit, Padova University Hospital, Department of Medicine—DIMED, Padova, Italy

Background: Congenital adrenal hyperplasia (CAH) is a genetic disorder characterized by impaired cortisol secretion and

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

androgen excess. The mainstay of CAH treatment is glucocorticoid (GC) replacement, necessary to avoid adrenal crises and manage androgen excess. The delicate balance between GC under- and overtreatment is crucial to prevent metabolic and cardiovascular (CV) complications. The new modified-release hydrocortisone (MRHC) formulation improves hormonal control compared to conventional GC; however, there are few data on its metabolic impact.

Aim of the Study: to evaluate the hormonal control and metabolic impact of MRHC treatment in patients with CAH.

Patients and Methods: 38 patients with CAH due to 21OH-deficiency (33 patients with classic form and 5 with non-classic CAH, median age 31years) were included; clinical, metabolic and hormonal data were analyzed at baseline, after 12 and 18 or 24 months after switching to MRHC. At baseline, 15 patients were previously treated with long-acting GC, while 23 with immediate-release or dual-release hydrocortisone.

Results: During MRHC treatment, hormonal control improved, with a significant reduction in 17-OH-progesterone (median values 418 nmol/L vs 38 nmol/L at 18/24 months, $P = .001$) and androstenedione levels (19.5 nmol/L vs 8.5 nmol/L, $P = .003$). Additionally, we observed a decrease in total testosterone levels in women (2.9 nmol/L vs 0.6 nmol/L, $P = .001$) and a significant increase of the proportion of patients with good disease control (28% at baseline vs 62% at 18/24 months, $P = .014$). Furthermore, we reported a slight but significant worsening in lipid profile, with increases of total cholesterol (165 mg/dL vs 176 mg/dL, $P = .004$), and LDL-cholesterol levels (90 mg/dL vs 107 mg/dL, $P = .008$); in addition, there was also a slight elevation of homocysteine levels (10.2 µmol/L vs 12.1 µmol/L, $P = .017$). However, after performing a subgroup analysis, we observed that only patients previously treated with immediate or dual-release hydrocortisone had a worsening of lipidic profile; instead, it remained stable in patients who took long-acting GC at baseline. In addition, we noticed a slight improvement of SCORE2 and VAI scores, which were used to evaluate the CV risk profile of our patients. During MRHC treatment no adrenal crises were reported, and it was discontinued only in two cases due to insomnia and polyuria.

Conclusions: MRHC treatment showed an improvement in hormonal control, while maintaining a good safety profile. Nevertheless, a potential negative effect on metabolic parameters was observed. Although these changes do not appear to affect negatively the CV risk profile, clinicians should carefully assess the overall impact of available therapeutic options to optimally personalize treatment for each patient.

P57 - ECE_3262 - Distinctive dynamic adrenal steroid fingerprints in Liver Cirrhosis

Min Jeong Park[1,2], Soyeon Park[3], Seung Shin Park[4], Hyewon Yang[5], Man Ho Choi[3], Eun Ju Cho[4] and Jung Hee Kim[4]

[1]*Department of Internal Medicine, Korea University College of Medicine, Seoul, South Korea;* [2]*Korea University College of Medicine, Seoul, South Korea;* [3]*Center for Advanced Biomolecular Recognition, Korea Institute of Science and Technology, Seoul, South Korea;* [4]*Department of Internal Medicine, Seoul National University College of Medicine, Seoul, South Korea;* [5]*Department of Internal Medicine, Nowon Eulji Medical Center, Eulji University, Seoul, South Korea*

Introduction: Adrenal insufficiency is often overestimated when assessed by immunoassay in patients with liver cirrhosis (LC) due to reduced cortisol-binding globulin and hypoalbuminemia, which lower total serum cortisol concentration. Steroid profiling using liquid chromatography tandem mass spectrometry (LC-MS/MS) enables accurate and simultaneous quantification of multiple adrenal steroids. We aimed to characterize serum and salivary adrenal steroid phenotypes in patients with LC compared to non-LC controls using LC-MS/MS methods.

Methods: Between 2023 and 2024, patients with LC ($n = 33$) and controls ($n = 34$) were prospectively enrolled, and serum and salivary samples were collected during short Synacthen tests at a single center. LC–MS/MS was applied for the analysis of serum and saliva samples. We measured a panel of 27 serum and 13 salivary steroids, including cortisol (F), cortisone (E), 11β-hydroxy androstenedione (11-OHA4), 11-ketoandrostenedione (11-KA4), and 18-hydroxycorticosterone (18-OHF).

Results: Patients with LC had a higher percentage of male (72.7 vs 47.1%, $P = .04$) and were of similar age (58 vs 60 years, $P = .12$) than controls. Serum and salivary peak F/E were lower in patients with LC compared to control (serum F/E: 6.40 [5.37-8.11] vs 8.98 [7.25-10.31], $P < .001$; salivary F/E: 0.25 [0.20-0.34] vs 0.37 [0.24-0.43], $P = .043$), which indicated decreased 11β-hydroxysteroid dehydrogenase type 1 (11β-HSD1) in LC. In contrast, concentrations of 11-OHA4 (7.29 [5.34-10.02] vs 3.13 [2.18-5.88], $P < .001$) and 11-KA4 (1.05 [0.69-1.24] vs 0.45 [0.07-0.67], $P < .001$), which are metabolites of androgen pathways, were higher in patients with LC than in controls. Elevation of 18-OHF (1.08 [0.65-1.59] vs 0.65 [0.45-0.93], $P = .001$) was observed in patients with LC compared to controls, which may reflect renin-angiotensin-aldosterone system activation secondary to cirrhosis.

Conclusions: Patients with LC exhibited a distinctive inactivation of cortisol to cortisone along with an elevation of 11-oxygenated and mineralocorticoid pathway metabolites, indicating cirrhosis -associated remodeling of adrenal steroidogenesis. Accurate diagnosis of adrenal insufficiency in LC requires consideration of cirrhosis-specific alterations of steroid metabolism.

Background-Aim: Steroid hormones and their metabolites play a central role in endocrine physiology and disease. Although several hundred steroidal compounds have been described in human biological fluids, routine clinical and research assays still focus on

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

limited subsets, providing only a partial view of steroid metabolism. Advances in LC-MS/MS have expanded analytical capabilities; however, comprehensive steroid profiling across multiple biological matrices remains challenging. The aim of this study was to develop and validate a novel high-coverage LC-MS/MS targeted steroidomics platform enabling an integrated assessment of steroid metabolism across different biological matrices.

Methods: A novel LC-MS/MS platform was developed for the detection and relative quantification of 210 steroidal compounds, including 147 free steroids and 64 phase II metabolites, across serum, saliva, and 24-hour urine. Distinct sample preparation workflows were optimized for free and conjugated steroids using supported liquid extraction and solid phase extraction, respectively. Enzymatic hydrolysis was applied for the analysis of total urinary steroids. Chromatographic separation was optimized by testing six LC columns with different stationary phase chemistries and by using ammonium fluoride as an aqueous mobile phase modifier to enhance ionization efficiency and improve chromatographic performance, particularly for sulfated compounds.

Results: The platform was applied to samples from healthy individuals, including paired serum, saliva, and 24-hour urine collections. In serum, up to 92 free steroids in males and 83 in females were detected, together with 33 and 31 conjugated metabolites, respectively. Saliva showed a lower but still informative coverage, with up to 53 free steroids in males and 42 in females, accompanied by a limited number of conjugated compounds. Urine provided the broadest steroidal coverage. In non-hydrolyzed 24-hour urine, up to 87 free steroids in males and 91 in females were detected, together with 42 conjugated metabolites in both sexes. Following enzymatic hydrolysis, the number of detectable free steroids increased to 107 compounds in both males and females, highlighting the contribution of phase II metabolism to urinary steroid excretion.

Conclusions: This novel high-coverage LC-MS/MS platform enables an unprecedented and integrated mapping of steroid metabolism across multiple biological matrices. By markedly expanding the detectable steroid repertoire, this approach provides a more complete representation of steroid biosynthesis, metabolism, and clearance. Clinically, the combined analysis of serum, saliva, and urine may improve phenotypic characterization and diagnostic accuracy in disorders of steroid metabolism, supporting the implementation of targeted steroidomics in endocrinology and enabling the development of matrix-specific analytical panels for clinical and translational research.

P59 - ECE_3327 - Anastomosing hemangioma mimicking a paraganglioma: a case of false positive finding on 68Ga-DOTATOC PET/CT

Athanasios Fountas[1], Aikaterini Themis Vyllioti[1], Dimitra Zerva[1], Akrivi Kostopoulou[2], Ioannis Karoumpalis[3], Sofia Chatziioannou[4], Pinelopi Lampropoulou[5], Kostas Lymperopoulos[6], Chrysanthi Aggeli[7], Giorgos Zografos[7] and Athina Markou[1]

[1]Unit of Endocrinology and Diabetes Center, "G. Gennimatas" General Hospital of Athens, Athens, Greece; [2]Department of Pathology, "G. Gennimatas" General Hospital of Athens, Athens, Greece; [3]Department of Gastroenterology, "G. Gennimatas" General Hospital of Athens, Athens, Greece; [4]Department of Nuclear Medicine and Molecular Imaging, Attikon NTUA University Hospital, Athens, Greece; [5]Department of Radiology and Medical Imaging New imaging methods, "G. Gennimatas" General Hospital of Athens, Athens, Greece; [6]Department of Radiology and Medical imaging CT/MRI/US, "G. Gennimatas" General Hospital of Athens, Athens, Greece; [7]First Department of Surgery, "G. Gennimatas" General Hospital of Athens, Athens, Greece

Introduction: In recent years, ^{68}Ga-DOTATOC/DOTATATE PET/CT has become paramount in the diagnostic localization of paragangliomas. Despite its enhanced affinity and sensitivity, this imaging method is not without challenges. Herein, we present a case of a presumed paraganglioma, based on ^{68}Ga-DOTATOC PET/CT finding, but proven to be an anastomosing hemangioma.

Case Presentation: A 50-year-old man, with a history of arterial hypertension, Crohn's disease and a 3 cm left retroperitoneal lesion, presented to the Emergency Department with palpitations and pallor. Atrial fibrillation with rapid ventricular response was found and treated appropriately. An abdominal CT scan was performed revealing a 4 cm mass next to the celiac trunk and the superior mesenteric artery, in contact with the left adrenal and the left renal artery. Further imaging with MRI showed a 3.8 cm retroperitoneal lesion with increased T2 signal intensity and no signal suppression on T1 out-of-phase sequence. Differential diagnosis included a left renal vein aneurysm and a paraganglioma. Renal vein ultrasound did not confirm the presence of an aneurysm while endoscopic ultrasound showed a highly vascular lesion with increased contrast uptake in the arterial phase, being contiguous with the celiac ganglia making paraganglioma the most likely diagnosis. However, 24hour urine metanephrine and normetanephrine levels were normal. In order to exclude the possibility of a biochemically silent paraganglioma a ^{68}Ga-DOTATOC PET/CT was performed which showed significant radiotracer uptake (SUVmax 12.8) by the lesion. Taking into account the PET/CT, MRI and ultrasound findings an endoscopic resection of the abdominal mass was decided and performed after preparation with hydration and α-blockade. The surgery and the peri-operative period were uneventful. Surprisingly, the histology was indicative of an anastomosing hemangioma.

Conclusions: Anastomosing hemangiomas are rare benign vascular lesions, often discovered incidentally, and, on imaging, they may mimic other vascular lesions and neuroendocrine tumors. Hemangiomas may, scarcely, express somatostatin receptors 2 leading to false positive uptake on somatostatin receptor functional imaging. To our knowledge, our patient is the second reported case of anastomosing hemangioma showing significant radiotracer uptake on ^{68}Ga-DOTATOC PET/CT.

P62 - ECE_3790 - Overnight Dexamethasone in Primary Aldosteronism Screening (ODEPRASC): initial results of a diagnostic interpretability study

Piotr Kmieć[1], Dominika Okroj[1], Małgorzata Zdrojewska[1], Ewa Zalewska[1], Jowita Fiszer[1], Sonia Zembrzuska[1] and Renata Świątkowska-Stodulska[1]

[1]Department of Endocrinology and Internal Medicine, Medical University of Gdańsk, Gdańsk, Poland

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Introduction: The recommendation to withdraw medications that interfere with the renin–angiotensin–aldosterone system (RAAS) prior to work-up partially underlies the underdiagnosis of primary aldosteronism (PA). Research by others showed that:

1. an aldosterone (Ald)-to-renin ratio (ARR) of 10 pg/uIU in patients on RAAS-interfering medications was equivalent to 20 pg/uIU in those switched to non-interfering drugs,
2. PA work-up accuracy among HT patients off interfering drugs improved significantly when 48-hour cosyntropin suppression was combined with objective diagnostic cutoffs.

The current study aims to generate thresholds offering a 25% higher interpretability in PA screening than baseline ARR determination despite RAAS-interfering medications by applying overnight cosyntropin suppression.

Methods: In this prospective, single-center, cross-sectional study development and confirmatory cohorts are recruited among patients with an adrenal incidentaloma. ARRs are determined before and after overnight intake of 1 mg dexamethasone (DXM) on and off interfering medications. Exclusion criteria include renin above the upper reference limit (chemiluminescence immunoassay).

Results: So far, data of 67 patients have been available for initial analyzes (39 women and 28 men, mean age 61.5+-10.2 years) out of 511 screened for participation. Possible mild autonomous cortisol secretion was recorded in eleven patients (highest post-DXM cortisol: 88.3 nmol/l). Baseline PA screening was negative in 22, positive in 19, and equivocal in 26 patients (39%). Post-DXM measurements allowed classifing the basally equivocal ARRs as positive in 12 more patients (for a total of 31 out of 67, ie, 46%), negative in 24 (36%), and equivocal in 12 (18%). One positive ARR pre-DXM shifted to a negative result post-DXM (eplerenone therapy), the opposite was observed in two patients. Among the recruited patients, the presence of PA could be verified in 61 patients: by ARR re-testing off interfering medications ($n = 33$) or by PA suppression tests (27 saline infusion tests, one oral salt loading test). PA was diagnosed in 21 patients (34.4%) and ruled out in 40 patients (65.6%). The definitive diagnosis status allowed comparing diagnostic accuracy measures, which revealed clear clinical benefit of applying overnight DXM intake on ARR interpretation, in particular a 24.5 percentage point reduction in equivocal ARR rate (from 24 to 9 out of 61 patients).

Conclusions: The 2025 Endocrine Society guideline places greater emphasis on ARR in the PA work-up while restricting the use of suppression tests. The approach proposed here could be highly advantageous as demonstrated in a 24.5% reduction in equivocal ARR results among patients on interfering medications (ClinicalTrials.gov ID NCT06740838).

P63 - ECE_2054 - Diagnostic accuracy of 68Ga-pentixafor PET/CT in identifying functional Primary Aldosteronism Lesions with different features in CT images

Shiman Li[1], Fan Yang[2], Yuxing Lou[1], Wei Zhang[2], Chuanjiang Chen[1] and Ping Li[2]

[1]*Department of Endocrinology, Endocrine and Metabolic Disease Medical Center, Nanjing Drum Tower Hospital Clinical College of Nanjing University of Chinese Medicine, Nanjing, China;* [2]*Nanjing, China*

Background: Numerous studies have confirmed the value of ^{68}Ga-pentixafor PET/CT for PA subtyping. However, some diagnostic errors remain. The features of adrenal lesions on CT images vary across patients with PA. To date, no study has investigated whether the diagnostic performance of PET/CT varies among adrenal lesions with different imaging features.

Aim: To define the features of the adrenal lesions in CT images of patients with PA associated with better ^{68}Ga-pentixafor PET/CT diagnostic performance.

Methods: This single-center, retrospective study was conducted at a tertiary hospital in China. Consecutive PA patients who underwent both adrenal CT and ^{68}Ga-pentixafor PET/CT imaging were included. PET/CT image interpretation involved visual analysis, and semiquantitative parameters, including the SUVmax, liver-to-lesion ratio (LLR), and lesion-to-adrenal ratio (LAR), were recorded. According to the outcome after surgery or the results of AVS, patients were classified as having unilateral PA or bilateral PA, and their lesions were categorized as functional or nonfunctional. Based on adrenal CT imaging features, the lesions were classified as adenomas or nonadenomas. ROC curve analysis was performed to evaluate the accuracy of PET/CT for identifying adrenal lesions with different imaging features.

Results: A total of 93 patients with postoperative follow-up data or successful AVS were analyzed (45.2% female; mean age 49.3 ± 11.6 years). A total of 136 adrenal lesions, including 81 typical adenomas and 55 nonadenomas, were detected by CT. Visual analysis yielded a positivity rate of 90.1% in the adenoma group, which was significantly higher than the 18.2% for in the nonadenoma group ($P < 0.001$). Semiquantitative analysis revealed that all the parameters were significantly greater in the adenoma group than in the nonadenoma group ($P < .001$). Furthermore, the AUCs of the four PET/CT indices for identifying functional lesions in the adenoma group ranged from 0.828 to 0.915, which were consistently greater than those in the nonadenoma group (0.541-0.613). Notably, visual analysis demonstrated superior diagnostic efficacy within the adenoma group, yielding a sensitivity of 97.3%, specificity of 85.7%, and accuracy of 96.3%. In contrast, the diagnostic sensitivity of visual analysis in the nonadenoma group was only 33.3%.

Conclusions: The diagnostic performance of ^{68}Ga-pentixafor PET/CT is better for PA patients with adenomas than for those with nonadenomas by CT. Therefore, ^{68}Ga-pentixafor PET/CT could serve as a primary subtype modality in patients with adenoma lesions on CT. Further multicenter prospective studies are warranted to validate these findings.

P65 - ECE_3078 - Glucocorticoids: hub between infection susceptibility and inflammation

Samira Kaziakhmedova[1,2] and Charlotte Steenblock[1,2]

[1]*Technical University of Dresden Medical School, Dresden, Germany;* [2]*University Clinic Dresden, Dresden, Germany*

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Infections represent the second leading cause of mortality in patients with Cushing's syndrome, highlighting a clinically significant consequence of chronic endogenous hypercortisolism. While it is well established that sustained glucocorticoid excess induces a generalized immunosuppressive state, current understanding is largely based on descriptive immunophenotyping, with limited mechanistic insight into how prolonged glucocorticoid exposure alters immune competence and host-pathogen interactions. In particular, the effects of chronic hypercortisolism on innate immunity, pathogen recognition pathways, and immune responses to viral and bacterial infections remain poorly defined. This study aims to establish and translationally characterize a murine model of chronic hypercortisolism that faithfully recapitulates the metabolic, endocrine, and immune alterations observed in patients with Cushing's syndrome. Such a model is essential for elucidating the mechanisms underlying infection susceptibility in these patients. Seventeen-week-old mice were administered dexamethasone in drinking water (0.0167 mg/mL) for 14 or 21 days. Metabolic assessments included glucose and insulin tolerance tests performed prior to study termination. At the experimental endpoint, plasma was collected for measurement of adrenocorticotropic hormone (ACTH), corticosterone, and circulating cytokines. Lung and spleen tissues were analyzed by flow cytometry to quantify innate immune populations, focusing on monocytes and neutrophils using Ly6C and Ly6G markers. Adrenal glands were harvested for histological evaluation of tissue atrophy and for quantitative PCR analysis to assess transcriptional changes within the hypothalamic-pituitary-adrenal (HPA) axis. Prolonged dexamethasone exposure resulted in significant metabolic impairment, including reduced glucose tolerance, closely resembling metabolic abnormalities observed in patients with hypercortisolism. Endocrine profiling revealed high ACTH levels after 21 days of dexamethasone treatment. Flow cytometric analysis did not demonstrate glucocorticoid-dependent changes in lung innate immune cell composition, though further investigation is warranted. Histological and molecular analyses confirmed glucocorticoid-induced adrenal suppression. In conclusion, this translational murine model successfully reproduces key clinical features of Cushing's syndrome, including metabolic dysregulation and alteration of the HPA axis. As such, it provides a valuable bridge between experimental endocrinology and clinical practice. Insights gained from this in vivo model will be validated in human samples, with the ultimate goal of identifying immune biomarkers for infection risk stratification and developing targeted interventions to reduce infectious morbidity in patients with chronic hypercortisolism.

P66 - ECE_3926 - Adrenal crisis in pre-hospital and emergency care: healthcare professionals' knowledge, attitudes and practices, and implications for endocrine nursing

Heather Reid[1,2], Charlotte Rowe[1] and Sofia Llahana[1]
[1]City St George's University, London, United Kingdom; [2]Emergency Department, King's College Hospital, London, United Kingdom

Background: Adrenal crisis is a life-threatening endocrine emergency requiring rapid symptom recognition and prompt treatment with parenteral hydrocortisone. Effective management across pre-hospital and emergency department settings relies on timely triage, patient prioritisation and coordination of care, clinical assessment, prompt recognition of deterioration, and escalation for hydrocortisone administration and intravenous fluids. However, adrenal crisis often presents with non-specific features such as hypotension, vomiting, or confusion. In high-pressure emergency environments, limited familiarity with adrenal insufficiency, inconsistent protocols, and uncertainty around management may contribute to delayed or suboptimal care. Understanding current knowledge, attitudes, and practices across professional groups is essential to inform interventions that support patients with adrenal insufficiency and healthcare professionals to navigate emergency settings safely.

Aim: To explore the knowledge, attitudes, and clinical practices of pre-hospital and emergency department healthcare professionals in recognising and managing adrenal crisis.

Methods: A cross-sectional online survey was distributed to paramedics, nurses, medical doctors, and advanced clinical practitioners working in pre-hospital and emergency care settings across the United Kingdom. Participants were recruited through professional networks and social media between October and December 2025. The survey examined knowledge of adrenal crisis, clinical experience, perceived confidence in recognition and management, and learning needs.

Results: A total of 211 emergency care clinicians (89 paramedics, 85 nurses and 37 medical doctors) completed the survey. General awareness of adrenal crisis was high; however, gaps were identified in applied treatment knowledge. Most participants (75.1%; $n = 139/185$) correctly identified intravenous or intramuscular as the appropriate route for hydrocortisone administration in an AC. Knowledge of hydrocortisone dosing varied: 88.0% ($n = 125/142$) identified the correct initial hydrocortisone dose, but only 55.6% ($n = 45/81$) identified the recommended ongoing dose over 24 hours. Confidence in recognising and managing adrenal crisis was low to moderate overall, with paramedics reporting higher confidence than nurses and medical doctors. Perceived competence in medication administration and the adequacy of training were also higher among paramedics and differed significantly by role (all $P < .01$). There was strong agreement that greater awareness of the NHS Emergency Steroid Card is needed, although fewer respondents felt it is routinely recognised in practice.

Conclusions and Implications for Practice: Despite good general awareness of adrenal crisis, significant gaps remain in applied knowledge and clinical confidence among pre-hospital and emergency clinicians. Targeted, multidisciplinary education and clearer clinical pathways are needed to support timely, guideline-concordant management of adrenal crisis across acute care settings.

Bartholomew's Hospital, London, United Kingdom; [3]Faculty of Medicine, University of Belgrade, Belgrade, Serbia; [4]Clinic of Endocrine Surgery, University Clinical Centre of Serbia, Belgrade, Serbia

Introduction: Studies have shown a wide range between the time of initial CT finding of adrenal lesions (AL) until the final diagnosis. Such discrepancies affect treatment outcomes, potentially adding to healthcare system burden. Service models in other countries, such as the United Kingdom, where nurses have expanded competencies by running nurse-led clinics, have shown positive outcomes. In Serbia, there is currently no nurse-led clinics and the role of endocrine nurses in AL is not yet structured.

Aim: The aim of this audit is to review the current effectiveness of the diagnostic pathway for patients with AL, managed at tertiary endocrine unit, and to identify potential gaps in the service where specialist nurse involvement could improve coordination and the diagnostic process.

Method: A retrospective audit was conducted using the endocrine unit database over the past 10 years and randomly selected 23 patients with non-functioning adrenal lesions (NAL) and non-randomly 27 patients with functioning confirmed AL on CT imaging. Data was collected anonymously: age, sex, date of the incidental finding, diagnostic tests performed, confirmed diagnosis and treatment received.

Results: Fifty patients, 12 males and 38 females, aged 21-77, had an incidental AL finding on imaging (MRI, CT) except for two with overt signs and symptoms of Cushing's syndrome and Primary hyperaldosteronism. All patients underwent diagnostic tests-overnight dexamethasone test, 24-hour urine metanephrines and cortisol, plasma renin and aldosterone, and cortisol profile. Final diagnoses included NAL-23, phaeochromocytoma-10, adrenocortical carcinoma (ACC)-6, Cushing's syndrome-4, mild autonomous cortisol secretion-4, and primary hyperaldosteronism-3. The median time from initial AL visualization to tertiary center referral was 5.9 months, whereas the median time from tertiary care assessment to final diagnosis was 1.6 months. The total median time from initial AL visualization to final diagnosis in our cohort was 7.5 months. For ACC, the median time from AL visualization to final diagnosis was 13.4 months. This is comparable to international data for ACC, where reported median diagnostic intervals span from 8.7 months to 4 years in some cases.

Conclusions: Our findings place Serbia close to the international median for ACC but still highlight significant delays, predominantly before tertiary referral, which is particularly important as delayed diagnosis may negatively affect outcomes. Our results reflect the gaps in primary care recognition and referral pathways. Targeted primary care education, combined with nurse-led AL clinics at the tertiary level, could lead to earlier triage, and a more efficient diagnostic pathway, thus improving patient outcomes.

P68 - ECE_3385 - "Out in no man's land": illness perceptions and diagnostic experiences in adults with adrenal insufficiency

Charlotte Rowe, Shashi Hirani, Kathleen Mulligan, Stanton Newman and Sofia Llahana
London, United Kingdom

Background: Adrenal insufficiency is a rare, chronic endocrine condition requiring lifelong treatment with glucocorticoids replacement and effective self-management. Delayed diagnosis and challenges for daily treatment and Illness perception refers to patients' belief and expectations about their illness, encompassing physical, cognitive and emotional representations, and can be described within the Common Sense Model (CSM) theoretical framework (Leventhal, 2012). The CSM differentiates between cognitive and emotional illness representations, and captures the individual's overall understanding and global sense of coherence around their illness. Cognitive representations are described across five classes 1) identity, 2) consequences, reflecting an individual's beliefs about illness severity and its impact on physical, mental and social functioning, 3) timeline, relating to temporal expectations of the illness duration, 4) control-cure, referring to beliefs about whether the illness can be cured, or controlled by treatment, and 5) cause, reflecting beliefs about the underlying mechanisms of the illness.

Objective: To explore the dimensions of illness perception amongst adults with adrenal insufficiency and how these perceptions map onto the CSM.

Methods: This qualitative study investigated illness perceptions of adults with adrenal insufficiency. Semi-structured focus group interviews were conducted with 61 participants from the UK, USA and Canada, across 13 groups of 3-6 participants (10 from UK and 3 from USA and Canada). The sample included 13 males, 46 females and 2 non-binary, mean age 46.26; 20 participants were diagnosed with secondary adrenal insufficiency, 32 with primary, and 9 with tertiary. Data were transcribed verbatim, de-identified, and analysed using deductive thematic analysis and mapped onto CSM domains.

Results: Participants frequently described their identity in relation to the physical symptoms they experienced, as well as the type of adrenal insufficiency, and associated comorbidities. A wide range of perceived consequences were reported, including physical, social, and emotional.

The journey to diagnosis was often described as complex and prolonged, and participants reported experiences of misdiagnosis, and symptom misattribution by healthcare professionals. Participants often described emotional reactions when considering their diagnosis and many reported a feeling of unfairness. Treatment was largely perceived as unpredictable, unreliable and not fully effective and long-lasting.

Conclusions: This study highlights the need for access to training and support for individuals with adrenal insufficiency and their families, particularly around medication management and responding to an adrenal crisis. While support is available via patient advocacy groups these findings emphasised that clinical information and peer support should be integrated across services throughout the lifespan.

[1]Section Endocrinology, Erasmus MC, Internal Medicine, Rotterdam, The Netherlands; [2]Section Endocrinology, Università di Genova, Internal Medicine and Medical Specialties (DIMI), Genova, Italy

Introduction: Patients with pituitary adenomas are thought to have an increased risk of vertebral fractures (VFs), due to either hormone excess or hypopituitarism. However, evidence comparing bone health across different pituitary adenoma types is scares. We aimed to assess the differences in associations between bone mineral density (BMD) and bone quality, measured by Trabecular Bone Score (TBS), and their relationship with fracture prevalence across various pituitary adenomas.

Methods: This retrospective, multicenter cohort study included patients with acromegaly, Cushing's disease, prolactinomas, and non-functional pituitary adenomas (NFPA). BMD at the femoral neck (FN) and lumbar spine (LS, L1-L4), TBS, fracture prevalence and incidence were analyzed. Moderate-severe VFs (Genant grade ≥2) were considered as clinically significant. Bone quantity, quality and VFs were compared between adenoma types and assessed with univariable and multivariable regression models.

Results: Our combined Italian and Dutch cohort included 335 patients (133 acromegaly, 69 Cushing's disease, 83 prolactinomas, 50 NFPAs; mean age 60 years (SD 13.8); 53.1% female). VFs were observed in 35 patients (10.5%, 12 acromegaly, 12 Cushing's disease, 1 prolactinomas, 10 NFPAs), of which 6 VFs were incident. After adjusting for FN BMD (T-score), age, prolactinomas showed significantly lower odds of VFs (OR 0.05, 95% CI: 0.002-0.31) compared to the other pituitary adenomas. Secondary hypogonadism was similar across pituitary adenoma types, except in NFPAs, where nearly all patients (96%) had secondary hypogonadism. FN BMD was strongly associated with VFs in most groups, except for acromegaly. Here, TBS was more strongly associated with fracture risk (log odds: TBS −5.03 vs FN BMD −4.73). Overall TBS and LS BMD had a weak correlation (rho = 0.28) independently of pituitary adenoma type. In all patients, age negatively affected bone health, with each 10-year increase associated with a 0.186 decrease in BMD T-score and a 0.346 decrease in TBS T-score. Additionally, higher baseline TBS was linked to better BMD, while higher baseline vitamin D levels were positively associated with improved TBS.

Conclusions: In this large cohort of pituitary adenoma patients, vertebral fracture (VF) prevalence and incidence were lower than previously reported, and similar across most pituitary adenoma types. TBS proved to be a valuable marker for assessing fracture risk in acromegaly, while age and vitamin D levels were key factors influencing bone health in all pituitary adenoma patients. Our results highlight the importance of incorporating TBS, age and Vitamin D levels into the bone health assessment of pituitary adenoma patients.

P71 - ECE_1542 - Beneficial for weight, detrimental for bone: semaglutide and PYY3-36 exacerbate metabolic osteoporosis (MetOP) in a novel two-hit MetOP rat model

Simon Kloock[1], Palina Zytner[1], Niklas Geiger[1], Vasco Sequeira[2], Angelika Schmitt-Böhrer[3], Jasmin Felker[1], Humma Sarwar[4], Anita Ignatius[4], Martin Fassnacht[1], Melanie Haffner-Luntzer[4] and Ulrich Dischinger[1]

[1]Department of Internal Medicine, Division of Endocrinology and Diabetes, University of Wuerzburg, University Hospital Wuerzburg, Wuerzburg, Germany; [2]Comprehensive Heart Failure Center, University of Wuerzburg, University Hospital Wuerzburg, Wuerzburg, Germany; [3]Department of Psychiatry, Psychosomatics and Psychotherapy, Center of Mental Health, University of Wuerzburg, University Hospital Wuerzburg, Wuerzburg, Germany; [4]Institute of Orthopaedic Research and Biomechanics, University of Ulm, Ulm, Germany

Background: Metabolic syndrome–associated osteoporosis (MetOP) arises from the convergence of metabolic, vascular, and stress hormone disturbances. Modern gut hormone–based therapies are beneficial in the treatment of the metabolic syndrome, but the skeletal consequences remain poorly understood. This study (1) establishes and sex-specifically characterizes a "two-hit" rat model of MetOP combining a Western diet (WD) with nitric oxide synthase inhibition (L-NAME), and (2) evaluates the effects of semaglutide, peptide YY3-36 (PYY3-36), and their combination on bone health in this model.

Methods: (1) Male and female Wistar rats were fed WD and treated with L-NAME for 16 weeks to induce MetOP. Femoral trabecular bone architecture was assessed by micro-computed tomography and histomorphometry. Bone RNA-sequencing, alongside serum analyses of bone turnover markers and steroid hormones (LC/MS-MS) were performed. (2) Female MetOP rats (treated with WD and L-NAME for eight weeks) were randomized to receive semaglutide, PYY3-36, or semaglutide+PYY3-36 for another eight weeks. The read-out was similar to (1) but also included gene-expression analysis of the hypothalamus to describe alterations of the hypothalamus-pituitary-adrenal (HPA) axis as an indicator of metabolic stress.

Results: (1) WD+L-NAME induced a robust osteoporotic phenotype in both sexes, characterized by significantly reduced bone-volume-to-tissue-volume-ratio (BV/TV) in the distal femur, altered osteoclast numbers, and transcriptional suppression of bone formation pathways. While WD predominantly affected extracellular matrix–related gene expression, male rats exhibited markedly elevated circulating sclerostin, implicating Wnt-signaling inhibition. (2) Semaglutide and semaglutide +PYY3-36 significantly reduced body weight. Semaglutide monotherapy caused a modest decline in BV/TV, whereas PYY3-36 and especially semaglutide+PYY3-36 exacerbated trabecular deterioration, including significantly increased trabecular separation. Osteoclast numbers increased under semaglutide and PYY3-36, while osteoblast numbers showed a trend towards reduction across treatments. Transcriptomic analyses revealed downregulation of osteoblast and cell cycle genes with semaglutide, and upregulation of angiogenesis and extracellular matrix pathways with PYY3-36. Hypothalamic analyses suggested modulation of the NPY2 receptor and a trend towards reduced HPA-axis activity with semaglutide+PYY3-36.

Conclusions: A WD+L-NAME "two-hit" model reliably induces MetOP and reveals sex-specific molecular signatures involving Wnt-signaling and extracellular matrix regulation. In this vulnerable context, semaglutide further reduced bone-mineral content, especially in combination with PYY3-36. These findings may limit the progression of PYY3-36 to clinical application and underscore the importance of evaluating long-term bone safety of gut hormone–based therapies in patients with osteoporosis.

Autosomal dominant hypocalcemia type 1 (ADH1) and type 2 (ADH2) are rare disorders caused by activating variants of the calcium-sensing receptor (*CASR*) and G-protein subunit alpha-11 (*GNA11*) genes, respectively. The CaSR and its signal transducer GNA11 play a critical role in calcium homeostasis by regulating parathyroid hormone secretion and urinary calcium reabsorption in response to variations in blood ionized calcium. Activating variants in *CASR* or *GNA11* increase signaling sensitivity to calcium, leading to hypocalcemia and hypercalciuria.

The CLARIFY disease monitoring study [NCT05227287] is an ongoing global, multicenter, longitudinal, observational study to characterize disease burden, management, and progression in children and adults with ADH1/2 over a 5-year period. Of 95 participants enrolled, 74% (70) were adults (≥18 years; 65 ADH1, 5 ADH2). Adult participants had a mean ± SD age of 44 ± 16 years (median 41; range 18-80); 53% (37) were female. We report baseline (Day 1), self-reported quality-of-life (QoL) findings from adult participants assessed by a sponsor-developed ADH1/2 questionnaire and the 36-Item Short Form Health Survey (SF-36 v2). The ADH1/2 questionnaire captured data on clinical manifestations, symptoms, and treatment. Responses indicated that neuromuscular symptoms most frequently affected QoL ([percentage of participants (n)]: muscle cramps/spasms [76% (53)], paresthesia [70% (49)], joint pain [57% (40)], followed by chronic fatigue [50% (35)]). Symptoms reported to have greatest overall impact on daily functioning were muscle cramps/spasms [44% (31)], paresthesia [37% (26)], chronic fatigue [30% (21)], and joint pain [23% (16)]. The most impaired activities of daily living were exercising regularly [36% (25)], climbing stairs [21% (15)], and performing house cleaning and home maintenance [20% (14)]. Compared with the US general population for SF-36 assessment, ADH1/2 negatively affected all physical and mental domains [mean ± SD physical (47.2 ± 9.7) and mental component scores (47.1 ± 10.1)]. Burden of disease was further emphasized by 42% (29) of participants ever requiring hospitalization for treatment of hypocalcemia [16% (11) with 1-2 hospitalizations; 26% (18) with ≥3 hospitalizations] and 28% (19) ever requiring intravenous calcium to manage ADH1/2 [6% (4) with 1-2 infusions; 22% (15) with ≥3 infusions]. This study represents the largest cohort of adults with ADH1/2 described to date. Baseline findings reveal major and underrecognized disease burden driven by chronic neuromuscular symptoms, physical limitations, and symptomatic hypocalcemia. Continued follow-up of these QoL measures aims to elucidate factors contributing to disease burden and inform improved monitoring and management strategies for ADH1/2.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Sarcopenia is associated with aging and osteoporosis contributing to the risk of falls and fragility fractures. Circulating myokines has been proposed as muscle-related biomarkers. The myokines growth differentiation factor 15 (GDF15), a stress-induced signaling molecule, and follistatin-like 1 (FSTL1) were measured in severe osteoporotic patients, investigated by lumbar spine, femur and total body DXA and handgrip test. Eighty-nine severe osteoporotic patients [84 females, 5 males; aged 74 (71-79) years, BMI 24.5 (22.9-27.6) kg/m^2] were prospectively enrolled; all experienced at least one fracture (total 356 fractures, 277 vertebral fractures, 17 femur fractures). All individuals were vitamin D repleted [96.5 (79.5-116.7) nmol/L]. Low muscle mass, evaluated as appendicular skeletal muscle index (ASMI), was diagnosed in 34 individuals (38.2%), while sarcopenia, defined as reduced ASMI and low muscle strength by handgrip test, was diagnosed in 14 individuals (15.7%). Dynapenia was detected in 26 individuals (29.2%). In the analyzed series, serum GDF15 and FSLT1 positively correlated with each other and with sclerostin levels suggesting a bone-muscle crosstalk. Serum GDF15 levels, but not FSTL1, positively correlated with ASMI ($r = 0.249$, $P = .021$), while handgrip values did not correlate with any myokines levels. Similarly, GDF15 levels, but not FLST1, showed a trend to positively correlate with lumbar spine T-scores ($r = 0.202$, $P = .071$) and with the bone mineral content (BMC) at dorsal spine ($r = 0.264$, $P = .019$) and pelvis ($r = 0.219$, $P = .052$). Moreover, GDF15 levels emerged as a marker of frailty as they positively correlated with the number of fractures in each individual ($r = 0.202$, $P = .057$), in particular with pelvis and lower limb fractures. Twenty-two individuals were evaluated after 18 months treatment with teriparatide 20 mcg/day (TPT). TPT increased lumbar spine T-score (-3.39 ± 1.17 vs -2.92 ± 1.14, $P < .0001$), while it did not prevent the reduction of ASMI (5.64 ± 0.58 vs 5.35 ± 0.63 kg/m^2, $P = .0033$), though handgrip values remained unchanged. Moreover, TPT induced significant increases of GDF15 levels by a mean of 29% ($P < .0001$), while FSTL1 levels were unaffected. TPT-induced GDF15 levels positively correlated with ASMI ($r = 0.592$, $P = .0047$). Considering that TPT did not prevent the 5% aging-related reduction of skeletal muscle mass, the TPT-increased GDF15 levels might come from osteoblasts/osteocytes stimulation.

In conclusion, in severe osteoporotic patients, low skeletal muscle mass and dynapenia are common, and sarcopenia occurs in about 1 out of 6 individuals. GDF15 emerges as a marker of frailty but osteoporosis and sarcopenia are associated with lower levels and anabolic TPT treatment increases GDF15 levels. GDF15 role in bone-muscle crosstalk deserves further investigation.

P74 - ECE_2384 - Epidemiology of low bone density and osteoporosis in chronic hypoparathyroidism: baseline prevalence and medication usage from National US claims

David Vizcaya[1], Aliya Khan[2], Ying Kong[3], Yingqi Gu[4], Ellen Colman[3], Sigridur Björnsdottir[5,6] and Luke McGuinness[4]

[1]Epidemiology and Real-World Science, Alexion, AstraZeneca Rare Disease, Barcelona, Spain; [2]Division of Endocrinology and Metabolism, McMaster University, Hamilton, ON, Canada; [3]Global Medical Affairs, Alexion, AstraZeneca Rare Disease, Boston, MA, United States; [4]Epidemiology and Real-World Science, Alexion, AstraZeneca Rare Disease, Dublin, Ireland; [5]Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden; [6]Department of Endocrinology, Metabolism and Diabetes, Karolinska University Hospital, Stockholm, Sweden

Background: Bone health is compromised in chronic hypoparathyroidism (cHypoPT). Recent clinical guidance recommends skeletal assessment, notably in postmenopausal women and men aged ≥50 years. This study aims to report low bone density and osteoporosis prevalence at baseline and real-world osteoporosis drug usage in cHypoPT.

Methods: This is a retrospective study using the US claims database IQVIA PharMetrics Plus. Disease diagnoses were determined by ICD-10-CM codes. cHypoPT was defined by meeting ≥1 of the following criteria during 2018-2024: (1) 2 HypoPT codes separated by 30-365 days, with no prior neck surgery; (2) 1 HypoPT and 1 hypocalcemia code separated by 30-365 days, with no prior neck surgery; or (3) 1 HypoPT or 1 hypocalcemia code and ≥365 days after neck surgery. The baseline was any time prior to or on index date. In the cHypoPT cohort, low bone density was identified by the presence of ≥1 of selected M85 codes and osteoporosis by the presence of ≥1 code of M80 or M81 lists. Osteoporosis medication exposure at baseline was obtained from pharmacy claims. Recent treatment usage covers 365 to 31 days before the index date, and current usage spans 30 days before to 90 days after the index date. Analyses were stratified by age, sex, and postmenopausal status (including natural and induced ones), which was determined by menopause code or age ≥50 years.

Results: Out of 33 311 patients with cHypoPT, 76% (25 306) were female with a median age of 57 years (interquartile range of 44-65 years) at index. Among 17 407 postmenopausal women, 16% (2761) and 24% (4167) had low bone density and osteoporosis, respectively. In 7897 premenopausal women, 3% (202) had low bone density, and 2% (159) had osteoporosis. In 5290 men aged ≥50 years, 8% (440) had low bone density, and 10% (541) had osteoporosis. In 2460 men aged <50 years, 4% (94) had low bone density, and 4% (99) had osteoporosis. Though 15% of the total cohort had concomitant osteoporosis, the use of osteoporosis medication around the index date was low; 7% and 0.1% had exposure to ≥1 class of antiresorptive and anabolic therapies, respectively.

Conclusions: This large cHypoPT cohort shows notable prevalence of concomitant low bone density and osteoporosis, especially in postmenopausal women and men aged ≥50 years, and limited osteoporosis medication use despite substantial disease burden, underscoring the need for skeletal health awareness and assessment in cHypoPT.

[1]Vestfold Hospital Trust, Tønsberg, Norway; [2]University of Oslo, Oslo, Norway; [3]Medimaps, Geneva, Switzerland; [4]Oslo University Hospital, Oslo, Norway

Introduction: Greater bone mineral density (BMD) reduction and higher bone turnover after gastric bypass (GB) compared with sleeve gastrectomy (SG) may partly explain the increased fracture risk after GB. Trabecular bone score (TBS), a marker of bone microarchitecture, correlates with fracture risk. However, the long-term comparative effect of GB vs SG on TBS in people with obesity (PwO) and type 2 diabetes (T2D) is unknown.

Methods: Post-hoc analysis of a two-armed RCT conducted at Vestfold Hospital Trust (Norway). Adults with BMI ≥35 kg/m^2 and T2D were randomised (1:1) to GB or SG and followed for 5 years. Blood-tests were obtained at all visits; DXA at baseline, 1 and 5 years for participants <150 kg. This analysis reports DXA-derived areal BMD, TBS (Medimaps v4.0, valid for tissue thickness <30 cm) retrospectively analysed from lumbar scans obtained from DXA, and bone turnover markers (Procollagen type 1 N-terminal propeptide [P1NP] and C-telopeptide of type I collagen [CTX-1]). Outcomes were assessed according to intention-to-treat principles utilising generalised linear mixed models for repeated measures. Statistical analyses were performed using Stata (version 18).

Results: A total of 109 participants (mean (SD) age 47.7 (9.6) years, BMI 42.3 (5.3) kg/m^2, 66% women) were randomised to GB ($n = 54$) and SG ($n = 55$). Ninety-three (85%) completed 5-year check-up. Available DXA-scans and valid TBS were 97 and 78 at baseline, 94 and 93 at 1-year and 73 and 71 at 5-year, respectively. GB resulted in greater reduction in BMD in the femoral neck (estimated treatment difference = ETD (−4.7% [95% CI −6.7 to −2.7]), the total hip (−4.5% [−6.5 to −2.5]), and the lumbar spine (-6.0% [−8.0 to −4.0]), and greater increase in P1NP (11.7 µg/L [3.1 to 20.4] and CTX-1 (0.17 µg/L [0.09 to 0.25] than SG. Compared with baseline, TBS was 14.7% [12.6 to 16.7] and 15.9% [13.9 to 17.9] higher at 1-year, ETD (1.2% [−1.6 to 4.1], and 6.7% [4.4 to 9.0] and 7.2% [4.9 to 9.4] higher at 5-year, ETD (0.5% [−2.8 to 3.7], after GB vs SG, respectively.

Discussion: GB was, compared with SG, associated with greater reduction in BMD, larger increase in bone turnover, but similar increase in TBS in PwO and T2D suggesting different effects of the procedures on bone density vs microarchitecture. Our findings should be interpreted with caution and require confirmation in future studies using other bone microarchitecture assessment techniques.

P76 - ECE_3978 - Denosumab or Zoledronate in primary hyperparathyroidism with osteoporosis: two-year calcium and skeletal outcomes

Katarina Mlekus Kozamernik and Tomaz Kocjan
Endocrinology, Department of Endocrinology, Diabetes and Metabolic Diseases, Univerzitetni Kliničnі center Ljubljana, Ljubljana, Slovenia

Background: Primary hyperparathyroidism (PHPT) is associated with reduced bone mineral density (BMD). In patients managed conservatively, antiresorptive therapy is used, but its effects on calcium homeostasis and skeletal outcomes remain incompletely characterized.

Objective: To assess two-year changes in serum calcium and BMD with denosumab or zoledronate in postmenopausal women with PHPT and osteoporosis.

Methods: In this randomized, open-label pilot study, 40 postmenopausal women with PHPT and osteoporosis (mean age 73.0 ± 7.8 years) received either zoledronate 5 mg intravenously once yearly (ZOL) or denosumab 60 mg subcutaneously every six months (DMAB) (ClinicalTrials.gov NCT04085419). Serum total calcium was measured at 3, 6, 12, 18, and 24 months. BMD at the lumbar spine (LS), total hip (TH), femoral neck (FN), and one-third radius (1/3R) was assessed at baseline, 12 months, and 24 months.

Results: Serum calcium declined early, remaining below baseline at 3 and 6 months, before returning to baseline levels thereafter, with no sustained between-group differences. BMD changes did not differ between therapies at any site. Over the first year, denosumab increased BMD at the lumbar spine and total hip, whereas zoledronate increased BMD at the lumbar spine only. No additional BMD gains were observed during the second year, and FN and 1/3R BMD remained unchanged.

Conclusions: In conservatively managed postmenopausal women with PHPT and osteoporosis, two years of treatment with zoledronate or denosumab produced similar, modest, transient reduction in serum calcium and site-specific BMD gains that were largely limited to the first year of treatment.

João, Porto, Portugal;* [3]*Unidade Local de Saúde de Matosinhos, Matosinhos, Portugal;* [4]*Faculdade de Medicina da Universidade do Porto, Porto, Portugal;* [5]*FMUP—Faculdade de Medicina Universidade do Porto, Porto, Portugal;* [6]*EMCB/ UFP—Escola de Medicina e Ciências Biomédicas/ Universidade Fernando Pessoa, Gondomar, Portugal;* [7]*Universidade Fernando Pessoa, Porto, Portugal*

Introduction: Despite the benefic impact on weight management and obesity-related complications, metabolic/bariatric surgery (BS) presents deleterious effects on bone health. The differential outcomes of the two main bariatric techniques on bone metabolism and body composition still need to be clarified.

Methods: Prospective single-centre study of female participants who underwent BS between November/2019 and December/2022, followed between one and two years after surgery. We

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

compared the impact of Sleeve gastrectomy (SG) and Roux-and-Y gastric bypass (RYGB) on the variation of bone mineral density (BMD), body composition (evaluated with DEXA) and bone metabolism markers [such as osteocalcin and beta-crosslaps (CTX)] after BS. Linear regression analysis adjusted for age, surgery type, diabetes mellitus status, BMI, and femoral neck BMD at baseline, were performed to find predictors of BMD variation after surgery. Logistic regression analysis was adjusted for the same variables, being conducted to find predictors of osteopenia or osteoporosis 2 years after surgery.

Results: Of the 162 included women, 99 (61.1%) underwent RYGB and 63 (38.9%) SG. Total femur BMD significantly decreased one and two years after BS, with a steeper reduction in the RYGB group. Two years after surgery, RYGB led to a greater BMD decline in femoral neck (-0.09 ± 0.07 vs -0.12 ± 0.07 g/cm^2, $P = .049$). RYGB group also presented more fat loss at both time points, with no differences in lean mass reduction at one (-6.3 ± 3.4 vs -6.3 ± 2.9 kg, $P = .38$) and two years (-7.4 ± 3.4 vs -7.4 ± 3.0 kg, $P = .11$). Urinary calcium in 24hour urine increased after SG and decreased after RYGB, one and two years after BS. Osteocalcin and CTX increased at both time points, with a significantly higher increase in RYGB group. RYGB was predictor of BMD reductions in total femur and femoral neck. Logistic regression revealed a trend for RYGB to be a predictor of osteoporosis/osteopenia 2 years after BS [OR 2.97 (0.89-9.89), $P = .077$] and for higher BMC at baseline to be a protective factor [OR 0.09 (0.01-1.45), $P = .089$]. Five patients developed fragility fractures after BS (two in the radius, one in the proximal humerus, another in the fibula and the last one fractured two ribs). Nine patients developed osteoporosis after BS, with 8 of them presenting ≥50 years at diagnosis.

Conclusions: RYGB showed a greater impact in bone metabolism and body composition than SG, with noticeable effects in the hip bone and fat mass reduction, even after adjustments. This reinforces the importance of proper calcium and vitamin D supplementation after BS.

P78 - ECE_2391 - The effects of eneboparatide vs PTH(1-34) delivered by daily injection or continuous infusion on blood calcium levels and bone metabolism in thyroparathyroidectomized (TPTX) rats

Cagri Aksu[1,2], Xavier Gaume[3], Xueyi Zhang[4], Myriam Aouadi[3] and Thomas Gardella[1,2]

[1]Endocrine Unit, Massachusetts General Hospital, Boston, MA, United States; [2]Harvard Medical School, Boston, MA, United States; [3]Alexion, AstraZeneca Rare Disease, Discovery Biology, Écully, France; [4]Alexion, AstraZeneca Rare Disease, Bioinformatics and Data Science, Boston, MA, United States

Background: Eneboparatide is a long-acting parathyroid hormone (PTH) in development for the treatment of chronic hypoparathyroidism. Eneboparatide binds with higher affinity to the R0 conformation of the PTH 1 receptor vs PTH(1-34), producing sustained elevations in blood calcium in vivo despite a short circulating half-life. Here, we present further statistical analyses of previously presented data assessing whether repeated injection of eneboparatide into thyroparathyroidectomized (TPTX) rats at doses normalizing serum calcium produces different effects on bone than PTH(1-34) administered intermittently or continuously.

Methods: Male Sprague-Dawley rats aged 9 weeks (2 weeks after TPTX surgery) received daily subcutaneous (sc) injections of eneboparatide at doses of 1.0, 2.0, or 4.0 nmol/kg, daily sc injections of PTH(1-34) at 50, 100, or 150 nmol/kg, or continuous infusion of PTH(1-34) via ALZET minipump at 1.5, 2.0, or 3.0 nmol/kg/day ($n = 8$/group) for 16 days. TPTX controls received vehicle injections or infusion. Tail vein blood ionized calcium (Ca^{++}) was analyzed pre- and postinjection on days 1, 7, 14, and 15. Rats were euthanized 24 hours post-last injection, and blood and femurs were collected for analysis of bone turnover biomarkers and microcomputed tomography parameters. Differences between the effective dose of each treatment and vehicle were analyzed using *t* tests. Equivalency of eneboparatide and vehicle was analyzed using the two one-sided tests (TOST) procedure.

Results: Doses normalizing blood Ca^{++} to baseline values expected in non-TPTX rats were 1.0 nmol/kg for eneboparatide daily injection, 50 nmol/kg for PTH(1-34) daily injection, and 3.0 nmol/kg/day for PTH(1-34) continuous infusion. Continuous infusion of 3.0 nmol/kg/day PTH(1-34) significantly increased bone turnover biomarkers CTX1 ($P = .014$), TRAP5b ($P = .025$), and P1NP ($P = .035$) and reduced trabecular bone volume/tissue volume (BV/TV; $P = .003$), number ($P = .005$), and thickness ($P = .004$) and cortical thickness ($P = .012$). Daily injection of 50 nmol/kg PTH(1-34) significantly increased TRAP5b ($P < .001$), P1NP ($P < .001$), trabecular BV/TV ($P < .003$), and trabecular thickness ($P < .001$). Daily injection of 1.0 nmol/kg eneboparatide did not change the thickness of trabecular bone (TOST: P's $< .001$) or cortical bone (TOST: P's $< .01$) but significantly reduced cortical bone porosity ($P = .003$). No significant differences were observed on TRAP5b, P1NP, or CTX1 (P's $> .05$), although equivalency tests were inconclusive.

Conclusions: Our analyses confirm that at doses similarly normalizing blood Ca^{++} levels in TPTX rats, continuous infusion of PTH(1-34) was bone catabolic, daily injection of PTH(1-34) was bone anabolic, and daily injection of eneboparatide was bone neutral. The unique mechanism of eneboparatide may lead to less detrimental impact on bone when used as treatment for hypoparathyroidism.

Background: Permanent postoperative hypoparathyroidism (PpoHypoPT) is a clinically significant complication of total thyroidectomy, associated with renal morbidity and long-term deterioration in quality of life. Early identification of patients at risk among those who initially develop postoperative hypoparathyroidism (poHypoPT) may enable optimized management strategies. This

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

study investigates preoperative, intraoperative, and early postoperative determinants of progression to PpoHypoPT.

Methods: We conducted a retrospective analysis involving 295 patients who developed poHypoPT following total thyroidectomy between 2015 and 2022. PpoHypoPT was defined as persistent dependence on calcitriol to maintain asymptomatic normocalcaemia or failure to achieve serum PTH >15 pg/mL at any point during follow-up, despite supplementation with calcifediol and calcium. Patients recovering PTH >15 pg/mL without calcitriol were classified as having transient poHypoPT (TpoHypoPT). Clinical characteristics, perioperative biochemical parameters, intraoperative findings, and postoperative PTH kinetics (immediate and 24-hour values) were compared. Independent predictors were identified using multivariate logistic regression.

Results: Of the 295 patients with poHypoPT, 52 (17.6%) progressed to PpoHypoPT, corresponding to an overall incidence of 6.8% among 767 total thyroidectomies. PpoHypoPT was associated with older age, lower postoperative calcium levels and reduced immediate and 24-hour postoperative parathyroid hormone (PTH) concentrations. It was also associated with the identification of fewer than three parathyroid glands during surgery. Central neck dissection did not increase risk. In multivariate analysis, age, number of identified parathyroid glands, preoperative PTH, and the 24-hour PTH/baseline PTH ratio were independent predictors. Identification of fewer than three parathyroid glands was the strongest predictor of PpoHypoPT (OR 4.81). PTH at 24 hours showed the highest diagnostic performance (AUC 0.798). A 24-hour PTH threshold of 6.5 pg/mL optimally predicted PpoHypoPT (with a sensitivity of 56.3% and a specificity of 89.2%). Conversely, a PTH24h decline of less than 86.3% from baseline predicted the recovery of parathyroid function (sensitivity: 54.3%; specificity: 86.5%).

Conclusions: The incidence of PpoHypoPT after total thyroidectomy was 6.8%, occurring in 17.6% of patients with poHypoPT. Intraoperative identification of fewer than three parathyroid glands was found to be the most powerful predictor of permanent dysfunction. Higher preoperative PTH levels were also associated with increased risk, underscoring the potential relevance of preoperative vitamin D optimization. Early postoperative PTH dynamics, particularly PTH24h below 6.5 pg/mL or a reduction of over 86% from baseline, provide robust markers of the progression to permanent hypoparathyroidism.

P80 - ECE_3377 - Phenotyping hypercalciuria in primary hyperparathyroidism before and after parathyroidectomy: a large single-center study

Sara Capra[1,2], Nicolò Bisceglia[1,2], Anna Piazza[1,2], Cristiana Cantone[1,2], Virginia Samaritani[1,2], Matteo Malagrinò[1,2], Enrico Saudelli[1,2], Giulia Vandi[1,2], Andrea Repaci[1], Uberto Pagotto[1,2] and Guido Zavatta[1,2]

[1]*Division of Endocrinology and Diabetes Prevention and Care, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy;* [2]*Department of Medical and Surgical Sciences (DIMEC), Alma Mater Studiorum University of Bologna, Bologna, Italy*

Introduction: Hypercalciuria is a common complication of primary hyperparathyroidism (PHPT) and represents an indication for parathyroidectomy. However, the rate and extent of hypercalciuria remission after surgery remain unclear.

Objective: To evaluate the remission of hypercalciuria after parathyroidectomy.

Design: Single-center, longitudinal, retrospective study.

Methods: Among 390 hypercalcaemic PHPT patients undergoing parathyroidectomy (1989-2025), after excluding persistent disease, missing biochemical data, and malignancy, 272 patients with preoperative and 12 ± 6-month postoperative laboratory evaluation were selected. Patients were stratified into four groups by baseline biochemistry: mild hypercalcemia (10.5-11.0 mg/dL) with hypercalciuria (A) or normocalciuria (B), and significant hypercalcemia (>11 mg/dL) with hypercalciuria (C) or normocalciuria (D). Hypercalciuria was defined as ≥250 mg/day in women and ≥300 mg/day in men.

Results: Study population was: mean age at parathyroidectomy 60 ± 12 years, 83.5% women ($n = 227$), 24% ($n = 56$) with BMI ≥30 kg/m^2 and 9.6% ($n = 26$) with eGFR<60 mL/min. At diagnosis, 43.7% ($n = 119$) had nephrolithiasis, of whom 20.2% ($n = 55$) had bilateral lithiasis. At baseline, patients with hypercalciuria had lower serum phosphate levels (2.48 ± 0.04 vs 2.74 ± 0.06 mg/dL; $P < .0001$) and higher BMI (27 vs 25 kg/m^2, $P = .026$), but similar PTH levels ($P = .534$), serum calcium levels ($P = .254$) and prevalence of nephrolithiasis ($P = .130$). Postoperatively, a significant reduction in urinary calcium was observed exclusively in patients with baseline hypercalciuria (group A: 389 ± 113 to 202 ± 92 mg/day, $P < .0001$; B: 164 ± 50 to 187 ± 178 mg/day, $P = .462$; C: 475 ± 143 to 190 ± 139 mg/day, $P < .0001$; D: 176 ± 62 to 162 ± 114 mg/day, P = .333), with the maximum variation in group C ($P < .0001$). We found a significant increase in the proportion of patients with normocalciuria at 12 months (70.7% group A and 76.8% group C, $P = .501$ between groups). Mean postoperative calciuria did not differ among groups ($P = .882$). On multivariate regression analysis, baseline serum calcium was inversely associated with postoperative calciuria (β = −29.3, 95% CI −54.1 to −4.5; $P = .021$), whereas sex, nephrolithiasis, baseline PTH, baseline calciuria, serum phosphate levels, BMI, and eGFR showed no significant associations. In patients with persistent hypercalciuria, urinary calcium remained unchanged (Δ = 1.34 mg/day, $P = .971$); no differences were observed between patients with persistent vs normalized postoperative calciuria in preoperative nephrolithiasis prevalence ($P = .463$), histological diagnosis ($P = .438$), age ($P = .546$), eGFR ($P = .103$) or sex ($P = .653$).

Conclusions: Parathyroidectomy significantly reduces urinary calcium excretion in PHPT with hypercalciuria, particularly in patients with more severe disease. Further studies are needed to explain why one in four patients remain hypercalciuric and to identify biomarkers that predict persistent hypercalciuria. Lower baseline serum calcium emerged as the sole independent predictor.

[1]Motol and Homolka University Hospital, Prague, Czech Republic; [2]Institute od Endocrinology, Prague, Czech Republic; [3]University Hospital Brno, Brno, Czech Republic; [4]University Hospital Olomouc, Olomouc, Czech Republic

Introduction: Parathyroid carcinoma (PC) is an extremely rare malignant disease, while atypical parathyroid tumor (APT) represents a neoplasm of uncertain malignant potential. Preoperative differentiation between PC, APT, and benign parathyroid adenoma remains challenging. Suspicion of malignancy is based on imaging modalities, biochemistry, and intraoperative findings. Radical *en bloc* resection with ipsilateral hemithyroidectomy is considered the gold standard for PC. Hereditary forms have been reported in up to 30% of PC cases, predominantly associated with pathogenic variants in *CDC73*, and in approximately 7%-36% of APT cases. The aim of the study was to compare clinical presentation, surgical management, and germline genetic background in patients with PC and APT, with a particular focus on hereditary forms.

Methods: We retrospectively evaluated patients with PC or APT who underwent parathyroid surgery between 2010 and 2025. Diagnoses were established by expert endocrine pathologists according to the 2022 WHO classification. The extent of surgery, including concomitant thyroid resection, was determined by preoperative imaging, biochemistry, and/or intraoperative findings. Germline genetic testing was performed postoperatively from peripheral leukocytes using whole-exome sequencing.

Results: The cohort included 30 patients with PC (14 men, 16 women) and 20 patients with APT (9 men, 11 women). Age at diagnosis (PC: 63.4 ± 14.3 years; APT: 59.9 ± 14.0 years), tumor size (PC: 2.89 ± 0.93 cm; APT: 2.88 ± 1.15 cm), and calcium levels (PC: 3.6 ± 0.5 mmol/L; APT: 3.3 ± 0.7 mmol/L) were comparable between groups. Concomitant thyroid surgery was performed significantly more often in patients with PC than in those with APT (76% vs 25%, $p < 0.01$). Postoperative germline genetic testing was available for 27 patients (17 PC, 10 APT). Pathogenic germline variants in *CDC73* were identified in two patients (one PC, 6%; one APT, 10%). No pathogenic or likely pathogenic variants were detected in other selected genes (*CASR, CCND1, CDKN1B, CDKN2B, FLCN, GCM2, MEN1, PIK3CA, PTEN, RB1, RET,* and *TP53*). Several variants of uncertain significance were identified.

Conclusions: Concomitant thyroid surgery was performed significantly more often in patients with parathyroid carcinoma than in those with atypical parathyroid tumor, reflecting a higher perioperative suspicion of malignancy. The prevalence of hereditary disease was lower than expected in both entities, suggesting that vast majority of cases in our cohort were sporadic. Larger multicenter studies are needed to further define the clinical impact of hereditary forms.

P82 - ECE_2073 - Parathyroidectomy and risk of diabetes progression in primary hyperparathyroidism patients comorbid with diabetes: a target trial emulation in a population-based cohort

Xiaodong Liu[1], Lanlan Li[2], Xi Xiong[3], Chenhao Pan[4], Yan Luk[5], Paul Chi-Ho Lee[2], Carlos Wong[6], Brian Lang[5], Matrix Fung[5] and David Lui[2]

[1]Surgery, The University of Hong Kong, Hong Kong, Hong Kong; [2]Division of Endocrinology and Metabolism, Department of Medicine, The University of Hong Kong, Hong Kong, Hong Kong; [3]Department of Non-communicable Disease Epidemiology, The London School of Hygiene & Tropical Medicine, London, United Kingdom; [4]Department of Orthopaedics and Traumatology, The University of Hong Kong, Hong Kong, Hong Kong; [5]Division of Endocrine Surgery, Department of Surgery, The University of Hong Kong, Hong Kong, Hong Kong; [6]Department of Infectious Disease Epidemiology & Dynamics, London School of Hygiene and Tropical Medicine, London, United Kingdom

Background: Primary hyperparathyroidism (PHPT) was reported to increase diabetes risk due to insulin resistance. However, it is not known if parathyroidectomy could reduce the progression of diabetes among PHPT patients who already had diabetes. This study aimed to estimate the impact of parathyroidectomy on diabetes progression in PHPT patients comorbid with diabetes.

Methods: Patients diagnosed with PHPT who had coexisting diabetes were retrieved from a territory-wide electronic health database in Hong Kong between January 2006 and December 2023. The primary outcome was the risk of diabetes progression (defined by the occurrence of acute hyperglycemic crises, HbA1c increase ≥0.5% from baseline, or intensification of glucose-lowering therapy). We adopted the framework of target trial emulation and fitted marginal structural models with inverse probability of treatment weighting, modelling surgery as a time-varying exposure. Differences in cumulative incidence between patients with and without surgery were estimated. The Cox proportional hazards model was used to assess the association between parathyroidectomy and diabetes progression. Estimates of hazard ratios (HR) with 95% confidence intervals (CI) were calculated.

Results: A total of 2051 patients with a median follow-up period of 3.4 years were included. 1213 cases with diabetes progression were identified, including 162 in surgical patients and 1051 among non-surgical patients.The 10-year cumulative incidence of diabetes progression demonstratrd a lower incidence in surgical group compared with non-surgical group. Compared to non-surgical management, parathyroidectomy was associated with a lower risk of diabetes progression (HR 0.61; 95% CI, 0.47-0.79, $P < .001$). Results were consistent in subgroup and sensitivity analyses. There was no association between parathyroidectomy and the negative controls, including gastrointestinal bleeding, chronic obstructive pulmonary disease, pneumonia, and urinary tract infection. Parathyroidectomy was associated with lower risks of positive controls: chronic kidney disease (HR 0.59; 95% CI: 0.44-0.78; $P < .001$) and fractures (HR 0.49; 95% CI: 0.28-0.87; $P = .001$). Furthermore, we found that the impact of parathyroidectomy on lowering risk of diabetes progression was more prominent in PHPT patients with abnormal eGFR levels (≤60 mL/min/1.73 m^2 vs >60 mL/min/1.73 m^2: HR, 0.42 [95% CI, 0.25-0.72] vs HR, 0.74 [95% CI, 0.56-0.99]; interaction $P = .005$) and insulin use (with vs without: HR, 0.34 [95% CI, 0.16-0.73] vs HR, 0.73 [95% CI, 0.55-0.98]; interaction $P = .001$).

Conclusions: Parathyroidectomy was associated with a lower risk of diabetes progression in PHPT patients comorbid with diabetes, adding to the list of metabolic benefits for PHPT patients comorbid with diabetes for treatment decisions.

P83 - ECE_2243 - Detection of osteitis fibrosa cystica in hyperparathyroidism using [18F]fluorocholine PET/CT

Aida Orois[1], Manel Mateu-Salat[1], Mireia Mora[1], Amparo Cobo[2], Oscar Vidal[3], Martí Manyalich[3], Maite Rodrigo[4], Nerea Anton[1], David Fuster[2] and Felicia Alexandra Hanzu[1]

[1]Endocrinology and Nutrition, Hospital Clínic de Barcelona, Barcelona, Spain; [2]Nuclear Medicine, Hospital Clínic de Barcelona, Barcelona, Spain; [3]Surgery, Hospital Clínic de Barcelona, Barcelona, Spain; [4]Pathological Anatomy, Hospital Clínic de Barcelona, Barcelona, Spain

Background: Osteitis fibrosa cystica (OFC) is a rare skeletal manifestation of hyperparathyroidism, characterized by osteolytic lesions known as brown tumours. Although its prevalence has declined with early detection of hyperparathyroidism, OFC remains clinically relevant in severe or delayed cases.

Objective: To evaluate the role of [18F]fluorocholine PET/CT in detecting OFC and describe its clinical and imaging features.

Methods: A retrospective review of 274 patients who underwent [18F]fluorocholine PET/CT for hyperparathyroidism at Hospital Clínic de Barcelona (2020-2024) was performed. Clinical, biochemical, and imaging data were analysed, focusing on patients with OFC lesions.

Results: Six cases of OFC were identified. Lesions were located in the jaw, skull, humerus, iliac bone, femur, and ribs, showing characteristic uptake patterns on PET/CT. Compared to patients without OFC, those with OFC had significantly higher PTH levels (median 600 vs 154 pg/mL, $P = .0226$) and worse renal function (median eGFR 54.2 vs 86 mL/min/1.73 m^2, $P = .0256$). None of the OFC patients had osteoporosis, contrasting with its high prevalence in non-OFC cases. Follow-up imaging revealed variable timelines for lesion resolution after parathyroidectomy.

Conclusions: [18F]fluorocholine PET/CT is a valuable tool for detecting OFC in hyperparathyroidism, enabling differentiation from malignant bone lesions and guiding management. OFC appears associated with severe biochemical derangements and distinct skeletal phenotype, underscoring the need for early recognition and tailored follow-up.

P84 - ECE_2846 - Clinical and pathological significance of oxyphil cells content in sporadic parathyroid adenomas: a double center study

Anna Dal Lago[1], Elena Ruotolo[2], Liborio Torregrossa[3], Andrea Satta[4], Paolo Piaggi[5,6], Laura Pierotti[1], Simone Della Valentina[1], Giacomo De Leo[1], Chiara Sardella[7], Romina Mirsepanj[2], Silvia Carrara[8], Sabrina Corbetta[8,9] and Filomena Cetani[1,7]

[1]Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy; [2]Department of Clinical and Community Science, University of Milan, Milan, Italy; [3]Department of Surgical, Medical and Molecular Pathology and Critical Area, University Hospital of Pisa, Pisa, Italy; [4]Pathology Unit, Istituto di Ricerca e Cura a Carattere Scientifico (IRCCS) Istituto Auxologico Italiano, Milan, Italy; [5]Department of Information Engineering, University of Pisa, Pisa, Italy; [6]NIDDK, National Institutes of Health, Phoenix, Arizona, Phoenix, United States; [7]Endocrine Unit 2, University of Pisa, Pisa, Italy; [8]Bone Metabolism Disorders and Diabetes Unit, Istituto di Ricerca e Cura a Carattere Scientifico (IRCCS) Istituto Auxologico Italiano, Milan, Italy; [9]Department of Biomedical, Surgical and Dental Sciences, University of Milan, Milan, Italy

Primary hyperparathyroidism (PHPT) is the third most common endocrine disorder and is caused in over 90% of cases by chief cell adenoma (CCA), while up to 8.4% are attributable to oncocytic parathyroid adenomas (OPA). The significance of oxyphil cells (OCs) remains incompletely understood, with limited evidence regarding differences in presentation, biochemical severity, and outcomes between OPA and CCA.

We conducted a retrospective, bicentric case–control study including patients with sporadic PHPT who underwent selective parathyroidectomy for single-gland disease between 2019 and 2024 at the Universities of Pisa and Milan. Patients with OPA (>75% OCs at histology) were compared with control groups of CCA with different percentages of OCs content (0%; ≤75%; 1%-50% and 51%-75%). All histopathological slides were systematically reviewed.

A total of 213 parathyroid tumors (PAds) from 166 females and 47 males (mean age 58.9 ± 11 years) with PHPT were included; all tumors were diagnosed as single adenoma according to the WHO 2022 classification. OCs were frequent in PAds showing a heterogenous distribution among the analyzed samples. The distribution of OCs content was as follows: 0% in 42 PAds, 1%-50% in 81, 51%-75% in 28, and 76%-100% in 62 cases.

Across all analytical approaches, a significant association was observed between OCs percentage and adenoma size. PAds with >75% OC, identified as OC-PAds, were significantly larger than those without OCs (2.12 ± 0.89 cm vs 1.74 ± 0.67 cm, $P = .018$). Also, the continuous correlation 0-100% of OCs underlined a size increase (Spearman $r = 0.200$, $P = .003$). Consistently, OC-PAds were larger than those with ≤75% OCs (2.12 ± 0.89 vs 1.84 ± 0.74 cm, $P = .021$). These results indicate that PAds with higher OC content are approximately 15%-22% larger.

No significant associations were found between OCs percentage and age, body mass index, dietary calcium intake, clinical manifestations of PHPT (including nephrolithiasis, fractures, and osteoporosis), or biochemical severity (PTH, serum total and ionized calcium, 25-hydroxyvitamin D, phosphate, 24-h urinary calcium and bone turnover markers). Only a significant difference in 24-hour urinary phosphate excretion was observed across groups ($P = .006$), with highest values in tumors containing 50%-75% OCs. Moreover, a higher rate of postoperative recurrence was observed in patients with OC-PAds compared with those with ≤75% OC ($P = .045$).

In conclusion, OC-rich PAds appear to represent a morphological variant associated with increased tumor size but not with greater clinical or biochemical severity of PHPT. The association with postoperative recurrence suggests a potential prognostic relevance that merits further investigation.

P85 - ECE_3433 - Should vitamin D supplementation be recommended in hypoparathyroidism? preliminary results from a routine care trial on cellular and humoral immunity in patients with hypoparathyroidism

Christina Berr[1], Henrike Buchschuster[2], Jakob Wieke[2], Phillip Löhr[2], Christian Pfob[3], Thomas Pusl[1], Andreas Rank[2] and Mathias Lutz[2]

[1]Department of Endocrinology, I. Medical Clinic, University Hospital; University of Augsburg, Augsburg, Germany; [2]Hematology and Oncology, Department of Medicine II, Faculty of Medicine, University of Augsburg, Augsburg, Germany; [3]Nuclear Medicine, Faculty of Medicine, University of Augsburg, Augsburg, Germany

Background: Patients with hypoparathyroidism demonstrate increased infection susceptibility and hospitalization rates compared to the general population. In hypoparathyroidism, reduced parathyroid hormone levels impair renal 1-alpha-hydroxylase activity, limiting conversion of 25-hydroxyvitamin D to 1,25-dihydroxyvitamin D. While cholecalciferol modulates humoral and cellular immunity in healthy individuals, its therapeutic efficacy may be compromised in this setting. Although current guidelines on hypoparathyroidism recommend cholecalciferol supplementation for vitamin D deficiency, the added value of its addition to active vitamin D remains still unclear. This ongoing prospective trial investigates the impact of guideline-based cholecalciferol supplementation on immune cell profiles and infection rates in hypoparathyroid patients with vitamin D deficiency. Here, we present preliminary findings from this study.

Methods: Patients with hypoparathyroidism and simultaneous vitamin D deficiency are receiving guideline-based colecalciferol supplementation. Before and after three months of colecalciferol supplementation aiming at mid-normal 25-hydroxyvitamin D serum levels. Humoral immunity is assessed by measuring immunoglobulin levels and cellular immunity is evaluated using a comprehensive flow cytometry (FACS) panel. Clinical, endocrinological and functional parameters are recorded and infection frequency is assessed via a standardized questionnaire at both time points mentioned above.

Results: Up to now, fifteen patients have been enrolled in our trial. Preliminary FACS results in a small subcohort show trends towards changes in immune cell markers following colecalciferol supplementation. The expression of CD366 (TIM-3) on conventional CD4+ and CD8+ T cells decreased, suggesting reduced T cell exhaustion. Additionally, the activation marker CD226 on regulatory T cells and conventional CD4+ T cells increased, indicating potential enhanced immune activation. These results suggest a possible improvement in immune function following colecalciferol supplementation, with the results of the entire trial cohort still to be awaited.

Discussion: Preliminary FACS results suggest that colecalciferol supplementation may lead to improved immune function in patients with hypoparathyroidism and simultaneous vitamin D deficiency. The decrease in T cell exhaustion and increase in T cell activation markers point to a potential restoration of immune responsiveness. However, these findings are based on a small subcohort and sample evaluation and patient recruitment is ongoing.

P86 - ECE_3759 - Levels of serum inflammation markers before and after parathyroidectomy in patients with primary hyperparathyroidism

Lingqiong Meng[1] and Xiangbing Wang[2]

[1]Internal medicine, University of Arizona, Phoenix, United States; [2]Department of Medicine, Rutgers University-Robert Wood Johnson Medical School, New Brunswick, United States

Background: Our previous studies suggest that patients with primary hyperparathyroidism (PHPT) are accompanied by increased cardiovascular risk factor (CRF). Vitamin D binding protein (DBP) and inflammation markers, including interleukin-6 (IL-6) and monocyte chemoattractant protein-1 (MCP-1) are reported to be associated with elevated CRF. Yet, the association of levels of DBP and inflammation markers and CRF in PHPT patients remains not clear.

Objective: To investigate the effects of PTX on levels of CRF, DBP and inflammatory cytokines in patients with PHPT.

Methods: Seventy patients with PHPT and 70 age and BMI-matched healthy subjects were included as controls. Forty patients had minimally invasive PTX, and 28 patients returned 3 months after PTX. Biochemical markers, blood pressure and body weight were measured before and after PTX.

Results: Patients with PHPT had lower serum DBP and higher IL-6, C-reactive protein (CRP), and MCP-1 ($P < .05$) than controls. And their circulating levels of IL-6 and MCP-1 were positive correlated with iPTH (intact parathyroid hormone). Multiple regression analysis indicated that the preoperative iPTH explained a significant portion of the variance of IL-6 and MCP-1 ($P < .05$). The levels of MCP-1 and iPTH decreased by 20% and >50%, respectively, 15-20 min after removal parathyroid adenoma ($P < .05$). Three months after PTX, levels of DBP and MCP-1 became normalized ($P < .05$) to the similar level of normal controls ($P > .05$). Serum IL-6 was also markedly reduced ($P < .01$) but remained higher than controls ($P < .05$). The systolic blood pressure was 5 mm lower after PTX, but not significant ($P > .05$), while BMI and diastolic blood pressure remained no change ($P > .05$).

Conclusions: These findings confirmed that PTX decreases levels of inflammatory cytokines, MCP-1 and IL-6, and increases DBP in patients with PHPT. We suggest that besides its benefits on calcium and bone metabolism, PTX may also decrease CRF by reducing levels of MCP-1, IL-6 and increasing levels of DBP in patients with PHPT. Further long-term follow up study of effect of PTX on CRF including BMI, blood pressure, HDL and LDL are under investigation.

of Medicine and Health, Örebro University, Örebro, Sweden; [4]Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden; [5]Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; [6]ANOVA; Karolinska University Hospital, Stockholm, Sweden; [7]Department of Endocrinology, Skåne University Hospital, Malmö, Sweden; [8]Faculty of Medicine and Health, Örebro University Hospital, Örebro, Sweden; [9]Department of Endocrinology and Diabetes, Uppsala University Hospital, Uppsala, Sweden; [10]Department of Endocrinology and Diabetes, Uppsala University Hospital, Uppsala, Sweden

Hyperthyroidism, including toxic nodular goiter (TNG), adversely affects bones and is a recognized cause of osteoporosis. However, the extent to which it contributes to fractures remains uncertain, as studies have yielded conflicting results. This study aimed to determine whether TNG is associated with a higher incidence of fractures than controls.

Methods: We followed 621 patients with overt hyperthyroidism due to TNG for a median of 13.8 years and searched for fractures in national registries. For each case with TNG, up to 10 controls without hyperthyroidism from the general population were matched for sex, age, and county of residence. We used Cox regression stratified on the matching sets to compare rates of fragility fractures as well as osteoporosis and corticosteroid treatments between case and control groups. Analyses were performed in all as well as stratified by sex and by age (≤52 and >52 years).

Results: Higher rates of total fragility fracture were observed in women ≤52 years (2.15 (1.11-4.15). In women aged >52 years, patients with TNG had higher hip fracture rates (1.41 (1.08-1.84)). When considering all patients in both the case and control groups, total fragility fracture rates did not differ significantly (HR 1.08; 95% CI 0.89-1.32).

Conclusions: In women >52 years with TNG, hip fracture rates were higher than in the reference population. Furthermore, younger women with TNG had higher rates of all fractures. These data suggest that TNG might be a more prominent risk factor for osteoporotic fractures than previously thought.

Background: Human aging involves progressive loss of cellular integrity and homeostatic capacity, ofter preceding disease. Bioelectrical impedance–derived phase angle (PhA) is a integrative, noninvasive marker of cell membrane integrity, hydration distribution, and tissue quality. In parallel, published multi-omics and plasma proteomics evidence suggest that major molecular shifts occur with age in a nonlinear fashion, with discrete midlife and later-life inflection periods.

Objective: To characterize the age- and sex-specific trajectory of PhA across the lifespan in a very large cohort and to contextualize its nonlinear pattern against reported midlife accelerations in DNA stability loss.

Methods: Cross-sectional PhA at 50 kHz was analyzed in 184 830 individuals (121 403 women; 63 427 men), spanning 10-89 years, using standardized bioelectrical impedance procedures. Mean PhA was evaluated across 5-year age strata and modeled as a nonlinear function of age with sex stratification.

Results: PhA showed a marked age-related decline with evident nonlinearity. In men, PhA increased from early adolescence to a peak in early adulthood (approximately ~7.1-7.2° at 20-29 years), followed by a progressive decline; in women, values reached a lower early-adulthood plateau (approximately ~6.1° across 15-29 years) before declining. The downward slope appeared to steepen across two midlife-to-late-life transitions centered around ~40-44 years and ~60-64 years, consistent with a two-step acceleration pattern. Sex differences were largest from adolescence through midlife (men higher), narrowed progressively with age, and converged in the eighth decade, with near-equal values around 80-84 years (~4.6°) and a small sex-dependent divergence in the oldest stratum (85-89 years, ~4.2-4.3°).

Conclusions: In a large lifespan cohort assessed within a predictive health framework, PhA exhibits a nonlinear age-related decline with midlife accelerations that conceptually parallel reported nonlinear deterioration in multi-omics-determined physiologic stability. These convergent trajectories support PhA as a practical functional biomarker of biological aging and highlight midlife as a critical window for interventions aimed at preserving cellular integrity and resilience.

P91 - ECE_2885 - Cardiovascular safety of Romosozumab therapy in men with osteoporosis

Hadar Duskin-Bitan[1,2,3], Doron Netzer[3,4], Lilach Dolev[3], Arnon Cohen[2,3], Doron Comaneshter[3] and Gloria Tsvetov[1,2]

[1]Rabin Medical Center, Endocrinology & Metabolism Institute, Petah Tiqva, Israel; [2]Gray Faculty of Medicine, Tel Aviv University, Petah Tiqva, Israel; [3]Clalit Health Services, Division of Community Medical Services, Tel Aviv, Israel; [4]Ariel University, Adelson School of Medicine, Ariel, Israel

Aims: Romosozumab is an osteo-anabolic treatment for patients with severe osteoporosis. A signal for increased cardiovascular risk was observed in patients receiving romosozumab, especially in male patients. Real-world safety data in men is currently limited. The aim of our study was to evaluate the cardiovascular risk in patients treated with romosozumab compared to teriparatide in men and women.

Methods: A retrospective cohort study using Clalit Health Services database, to assess the incidence of major adverse cardiovascular events (MACE) in patients with severe osteoporosis using osteo-anabolic medications.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Results: The cohort included 6063 patients: 1794 patients received romosozumab (66, 3.7% men), and 4269 patients received teriparatide (404, 9.5% men). In the romosozumab group, the mean age was 73 and 73 for women and men, respectively. In the teriparatide group, the mean age was 71 and 74 for women and men, respectively. At baseline, men in both the romosozumab and teriparatide cohorts had higher proportions of smoking compared to women (26% and 19% vs 13% and 14%, $P < .001$), ischemic heart disease (IHD, 26% and 32% vs 7% and 13%, $P < .001$), and congestive heart failure (CHF, 11% and 9% vs 3% and 5%, $P < .001$) respectively. In the teriparatide group, men had significantly higher proportions of diabetes mellitus (DM) and cerebrovascular accidents (CVA). BMI was lower in men compared to women treated with romosozumab. During the follow up period, we observed an increased risk for IHD CHF and CVA in men treated with romosozumab compared to other patients' groups. Men patients treated with romosozumab had higher risk for hospitalization and death compered to women treated with romosozumab. In a multivariate analysis, adjusted for age, obesity, DM, hypertension, dyslipidemia, renal function, smoking, recent steroid use, and previous bisphosphonates treatment, we observed an increased hazard ratio for IHD (2.2, 95%CI 1.5-3.3), hospitalization in cardiovascular departments (1.6, 95%CI 1.1-2.3) and death (1.4 95% 1-1.9) in men vs women, treated with romosozumab compared to teriparatide.

Conclusions: We observed an increased risk for IHD and death in men vs women, treated by romosozumab compared to teriparatide.

P93 - ECE_3738 - Elevated parathyroid hormone due to macro-PTH: a diagnostic trap

Agata Rzepecka[1,2], Sonia Kaniuka-Jakubowska[2,3] and Renata Świątkowska-Stodulska[2,4]
[1]*Department Endocrinology and Internal Medicine, Medical University of Gdansk, Poland, Gdansk, Poland;* [2]*Department of Endocrinology and Internal Medicine, University Clinical Centre, Gdansk, Poland, Faculty of Medicine, Medical University of Gdansk, Gdansk, Poland;* [3]*Gdansk, Poland;* [4]*Department Endocrinology and Internal Medicine, Medical University of Gdansk, Poland, Gdansk, Poland*

Introduction: Parathyroid hormone (PTH) is a key regulator of calcium and phosphate homeostasis and an essential marker in the evaluation of hyperparathyroidism and chronic kidney disease. In routine practice, PTH is measured using immunometric assays together with serum calcium, phosphate, and vitamin D concentrations. However, circulating PTH includes not only the biologically active intact hormone but also inactive immunoreactive forms, which may lead to falsely elevated results. Despite improved analytical specificity of modern assays, immunoassay interference remains an underrecognized diagnostic problem. Macro-parathyroid hormone (macro-PTH) is a rare high-molecular-weight complex formed by PTH bound to immunoglobulins. It is biologically inactive and not associated with clinical or biochemical features of primary hyperparathyroidism, yet it may closely mimic this condition in routine laboratory testing. Failure to recognize macro-PTH may therefore result in misdiagnosis and unnecessary additional diagnostic procedures. Polyethylene glycol (PEG) precipitation is a simple laboratory technique that enables identification of macro-hormone complexes by selectively removing high-molecular-weight proteins from serum samples. Despite its low cost and diagnostic value, it is not routinely used in the evaluation of discordant PTH results.

Case Presentation: A 47-year-old woman was referred for evaluation of long-standing suspected primary hyperparathyroidism. For over ten years, persistently elevated PTH concentrations were documented, while total serum calcium remained within the normal range. PTH values ranged from 85 to 563 pg/mL, whereas serum calcium ranged between 8.8 and 9.6 mg/dL. Renal function was preserved, phosphate levels were normal or mildly reduced, and vitamin D deficiency was corrected. PTH was measured using a second-generation chemiluminescent immunoassay (DiaSorin) on the LIAISON XL analyser. The patient had no nephrolithiasis, fragility fractures, or symptoms of hypercalcaemia. Her medical history included autoimmune hypothyroidism treated with levothyroxine. Neck ultrasonography intermittently showed small hypoechoic lesions near the lower pole of the left thyroid lobe, while repeated 99mTc-MIBI scintigraphy with SPECT-CT revealed no pathological uptake. Fine-needle aspiration with PTH measurement in needle washout was negative. Given the marked biochemical–clinical discrepancy, PEG precipitation was performed, resulting in a marked reduction in PTH concentrations (recovery 8%-10%), confirming macro-PTH and excluding primary hyperparathyroidism.

Conclusions: Macro-PTH is an important diagnostic pitfall. PEG precipitation should be considered in cases of persistent PTH elevation inconsistent with clinical and biochemical findings to avoid misdiagnosis and unnecessary interventions

P94 - ECE_3841 - Kidney function trajectories and incremental therapeutic benefit of Palopegteriparatide after rhPTH(1-84) exposure in chronic hypoparathyroidism: a real-world cohort

Dimitra Lygerou[1], Ariadni Androvitsanea[1], Grigoria Betsi[2], Maria Sfakiotaki[2], Vasiliki Daraki[2], Ioannis Petrakis[1], Andreas Antonakis[1], Konstantina Kydonaki[1], Georgios Alexandros Kavvadias[1], Konstantinos Stylianou[1] and Paraskevi Xekouki[2]
[1]*Nephrology, University Hospital of Heraklion, Heraklion, Greece;* [2]*Endocrinology, University Hospital of Heraklion, Heraklion, Greece*

Background: In chronic hypoparathyroidism (HypoPT), long-term mineral management raises concerns regarding renal outcomes. We evaluated (i) eGFR trajectories in the full cohort and stratified by CKD status, and (ii) whether Palopegteriparatide provided incremental therapeutic benefit beyond an intermediate rhPTH(1-84) phase in rhPTH(1-84) -exposed patients.

Methods: Single-center real-world cohort of adults with chronic HypoPT treated with Palopegteriparatide. Outcomes were assessed at three phases: baseline, rhPTH(1-84) (pre-Palopegteriparatide), and last follow-up on Palopegteriparatide. eGFR (CKD-EPI) was analyzed overall and by CKD status (defined as eGFR <60 mL/min/1.73 m^2). In the rhPTH(1-84) -exposed

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

subgroup ($n = 11$), elemental calcium, alfacalcidol, serum phosphate, and eGFR were analyzed across all three phases to assess incremental Palopegteriparatide effects. Friedman tests (3 timepoints) and paired Wilcoxon tests (pairwise contrasts) were used.

Results: Part 1 (eGFR trajectories, whole cohort): All patients had complete 3-phase eGFR data ($N = 20$). Median eGFR was 71.5 (53.5-97.8) at baseline, 72.5 (57.5-98.7) on rhPTH(1-84), and 70.5 (56.0-89.0) on Palopegteriparatide (Friedman $P = .0753$). In CKD patients ($n = 7$), eGFR increased from 40.0 (37.0-53.0) at baseline to 40.0 (37.0-57.0) on rhPTH(1-84) to 56.0 (49.2-56.5) on Palopegteriparatide (Friedman $P = .0062$; baseline vs Palopegteriparatide $P = .0156$). In non-CKD patients ($n = 13$), eGFR remained stable (Friedman $P = .4006$). Part 2 (incremental therapeutic effect after rhPTH(1-84), $n = 11$): Elemental calcium decreased from 3000 (3000-4250) to 500 (0-1250) on Natpar and to 0 (0-500) mg/day on Palopegteriparatide (Friedman $P = .0001$). Alfacalcidol decreased from 3.00 (1.50-3.00) to 0.50 (0.12-0.50) and to 0.00 (0.00-0.12) µg/day (Friedman $P = .0004$). Serum phosphate decreased from 5.70 (4.60-6.10) to 4.50 (4.20-4.75) and further to 3.70 (3.40-4.20) mg/dL (Friedman $P = .0003$; rhPTH(1-84) vs Palopegteriparatide $P = .0217$). eGFR did not significantly change across phases in this subgroup (Friedman $P = .1146$).

Conclusions: Overall kidney function remained stable across phases, supporting renal safety. Importantly, patients with baseline CKD showed an increase in eGFR after transition to Palopegteriparatide, while non-CKD patients maintained stable eGFR. In rhPTH(1-84) -exposed patients, Palopegteriparatide was associated with further optimization of mineral management—near-complete withdrawal of conventional supplementation and additional phosphate improvement—suggesting incremental therapeutic benefit beyond rhPTH(1-84) in selected patients.

P95 - ECE_1772 - Optimizing post-thyroidectomy care through a PTH and calcium–guided algorithm

Ana Gheorghe Milea[1,2,3], Johannes H.W. de Wilt[4], Han J. Bonenkamp[4], Antonius van Herwaarden[5], Carmen Emanuela Georgescu[1,2] and Romana Teodora Netea-Maier[3]

[1]*Department of Endocrinology, Clinical County Emergency Hospital Cluj-Napoca, Cluj-Napoca, Romania;* [2]*Department of Endocrinology, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania;* [3]*Department of Internal Medicine, Radboud University Medical Center, Nijmegen, The Netherlands;* [4]*Department of Oncological Surgery, Radboud University Medical Center, Nijmegen, The Netherlands;* [5]*Department of Laboratory Medicine, Radboud University Medical Center, Nijmegen, The Netherlands*

Introduction: Thyroidectomy is a fundamental therapeutic intervention in the management of a broad spectrum of both benign and malignant thyroid disorders. However, it entails significant risks, including iatrogenic hypoparathyroidism, the most frequent complication associated with bilateral thyroid surgery.[1] Since 2019, our institution has implemented a standardized post-thyroidectomy protocol using parathyroid hormone (PTH) and calcium measurements to stratify hypocalcemia risk and guide calcium and alfacalcidol supplementation.

Objective: This study aimed to assess the effectiveness of this structured approach in reducing the incidence of unscheduled referrals due to hypocalcemia within three weeks after total thyroidectomy and evaluate the utility of early postoperative PTH levels in predicting the development of permanent hypoparathyroidism (PhP).

Methods: A retrospective observational cohort study was conducted at Radboud University Medical Center Nijmegen, including 373 adult patients who underwent total/ completion thyroidectomy between January 2014 and April 2025. Patients were assigned to either the post-protocol cohort (PPC) ($n = 154$) or the historic cohort ($n = 219$), depending on whether surgery occurred after or before protocol implementation, and subsequently compared.

Results: Unscheduled referrals were significantly more frequent in the historic cohort than in the PPC (19.2% vs 11% respectively, $P = .034$), and the introduction of the protocol was associated with a significant reduction in the odds of these referrals. Early postoperative PTH levels were a significant predictor of unscheduled referrals ($P = .003$), postoperative hypocalcemia ($P < .001$) and PhP ($P < .001$). A postoperative PTH cutoff of 1.7 pmol/L was identified as a clinically meaningful threshold for PhP prediction, demonstrating 100% sensitivity.

Conclusions: Subject to assay availability and workflow efficiency, these findings support the widespread implementation of this standardized protocol to mitigate post-thyroidectomy emergency consultations and readmissions.

Background: Primary hyperparathyroidism (PHPT) is uncommon in children and adolescents, but it frequently presents with significant end-organ involvement at diagnosis. In this setting, identifying a hereditary etiology is clinically relevant because it may anticipate multiglandular disease, recurrence, and the need for tailored surgical strategies and long-term surveillance. Pathogenic variants in *CDC73* (encoding parafibromin) underlie hyperparathyroidism–jaw tumour syndrome and are strongly linked to aggressive parathyroid disease, including atypical parathyroid tumours and parathyroid carcinoma. Consequently, defining the clinical, biochemical, renal, and histopathological correlates of *CDC73* variants in early-onset PHPT may refine risk stratification and inform follow-up intensity.

Methods: We performed a retrospective analysis of 49 patients diagnosed with PHPT at age ≤21 years. Genetic testing with NGS was available in 39 individuals. Carriers of pathogenic *CDC73* variants were compared with patients without detected mutations with respect to biochemical severity, renal involvement, and histopathology.

Results: Genetic testing was available in 39/49 patients; 11/39 (28%) carried a pathogenic variant in a PHPT-associated gene, including 7/39 (17.9%) with a pathogenic *CDC73* variant with a median age of 16 years (IQR 15.5-18). Among surgically treated patients (37/49), histopathology was available in 36/37 (97%). Overall, adenoma was the predominant finding (30/36, 83%), whereas atypical parathyroid tumour accounted for 4/36 (11%) and parathyroid carcinoma for 2/36 (6%) with patients with atypical parathyroid tumours were diagnosed at a younger age than those with adenoma (15.3 ± 1.0 vs 17.4 ± 2.9, $P = .048$). When histology was analysed by diagnostic category (adenoma vs atypical tumour vs carcinoma), a significant association emerged between genetic status and histological spectrum ($P = .0008$), reflecting a disproportionate representation of atypical tumours and carcinoma among *CDC73* carriers. Non-adenoma histology (atypical tumour/carcinoma) was documented in 6 patients, and 5/6 (83%) were *CDC73*-positive. In direct comparisons, *CDC73* carriers exhibited a more severe biochemical phenotype, with higher albumin-corrected serum calcium (13.7 ± 1.9 vs 11.6 ± 1.3 mg/dL, $P = .0017$), higher ionized calcium (1.9 ± 0.3 vs 1.6 ± 0.2 mmol/L, $P = .021$), and higher 24-hour urinary calcium excretion (813 ± 357 vs 392 ± 189 mg/24h, $P = .005$) than mutation-negative patients. Renal stone disease was also more frequent in *CDC73* carriers (Pearson $\chi^2 = 4.83$; $P = .028$; Fisher's exact $P = .041$).

Conclusions: In young patients with PHPT, pathogenic *CDC73* variants are associated with greater biochemical severity, increased renal stone burden, and a markedly higher prevalence of non-adenomatous parathyroid pathology. These findings support targeted genetic testing and structured, long-term multidisciplinary follow-up in *CDC73* carriers.

X-linked hypophosphatemia (XLH) is the most common genetic phosphate disorder leading to hypophosphatemia and bone mineralization defects. Recent recommendations from international panels of experts have proposed management of women with XLH during pregnancy; the main items are: 1) preconception genetic counseling; 2) supplementation with phosphate/calcitriol aimed to normalize serum phosphate; 3) monitoring of mineral metabolism. However, evidence supporting the recommendations are limited. We aimed contributing through a survey-based study.

Sixty-three women with XLH (aged 43.1 ± 14.6 years) were enrolled on September-December 2025. Thirty-six women (57.1%) experienced a total of 58 pregnancies, delivering 46 newborns, while 12 (20.7%) ended in miscarriages, predominantly in the first trimester. Thirty-four (72.7%) pregnancies were managed by cesarean delivery. None experienced fractures/pseudofractures during pregnancy or delivery, except one femur fracture after miscarriage. Symptomatic kidney stones occurred in two pregnancies.

Considering the above three major statements, we found that: 1) 36% of pregnant women with XLH received preconception genetic counseling; 2) 7 women (19.4%) received phosphate/calcitriol supplementation during pregnancy; of them, 6 women were on conventional therapy at time of conception and were older than the untreated women (35.0 vs 28.9 years, $P = .0022$); 3) only 9 (25.0%) women were referred to a bone specialist during pregnancy and biochemically monitored; of them, 6 women received conventional treatment. Monitored women compared with not monitored women underwent a similar number of orthopaedic surgeries (3.1 vs 3.3), more often received preconception genetic counseling (88.9% vs 18.5%, $P = .0003$), had a lower number of spontaneous conceptions (1.17 vs 1.74, $P = .0679$), 3 women needed in vitro fertilization with 7 embryo transfers exiting in 3 newborns, were older at first conception (35.2 vs 30.1 years, $P = .0014$), 1 women experienced worsening of bone and joint pain (vs 9 unmonitored women), delivered a lower number of newborns (1.0 vs 1.5, $P = .0488$), did not differ in prevalence of miscarriages (33.3 vs 33.3%), in gestational weeks of deliveries (38.1 vs 38.0), in prevalence of cesarean sections (88.9% vs 75.0%). Monitored pregnant women had a lower prevalence of XLH affected newborns (44.4% vs 80.0%), with a lower prevalence of psychomotor development delay (11.1% vs 63.0%; $P = .0178$).

In conclusion, a gap between recommendations and the real-life data is evident, suggesting that women with XLH received inadequate attention during their fertile life and were referred to bone specialists when subfertility emerges. However, conventional therapy during pregnancy may prevent bone and joint pain worsening, while the effects on delivery and offspring are not clear.

P98 - ECE_2985 - Primary hyperparathyroidism in young women—a retrospective cohort study of outcome in surgically treated patients

Mathias Alstrup[1], Jacob Lilja-Fischer[1], Christine Holm Egebæk[1], Lars Rejnmark[2] and Lars Rolighed[1]
[1]Department of Otorhinolaryngology, Head- and Neck surgery, Aarhus University Hospital, Aarhus N, Denmark; [2]Department of Endocrinology and Internal Medicine, Aarhus University Hospital, Aarhus N, Denmark

Background: Primary hyperparathyroidism (PHPT) predominantly affects postmenopausal women but is occasionally also seen in young women.

Methods: We performed a retrospective cohort study of women aged 15-49 years who underwent parathyroidectomy (PTX) for PHPT at Aarhus University Hospital between 2015 and 2023. Clinical, genetic, surgical, biochemical, and reproductive data were obtained through manual review of electronic medical records.

Results: A total of 215 women were included, median age of 42.7 years. Genetic testing was performed in 81% and 7% were pathogenic (MEN1, MEN2, MEN4 or CDC73). Most patients had mild to moderate PHPT (PTH 13 pmol/L and Ca^{2+} 1.45 mmol/L). During PTX, mean PTH reduction was 85%. In sporadic PHPT, the majority had single gland disease (94%). Operations were safe with very few permanent complications (recurrent laryngeal nerve palsy in 1 patient, and hypoparathyroidism in 2 MEN1 patients). Temporary nerve palsy was seen after PTX in 3 patients and 2 patients had a re-operation due to hematoma. In sporadic PHPT ($N = 200$), cure rate was 95%. The remaining 11 patients had missed adenoma ($n = 1$) or multi-gland disease ($n = 10$) and were cured at another operation. Five women (2%) were cured with PTX during pregnancy, without maternal, fetal, or obstetric complications. Pregnancy patterns did not suggest an increased risk of infertility in PHPT.

Conclusions: PTX in young women with PHPT is safe and effective, with excellent surgical and biochemical outcomes. Genetic evaluation is important due to high prevalence of hereditary disease. Surgery during pregnancy appears safe when performed in specialized centers.

P99 - ECE_3689 - "Surgical vs conservative management of primary hyperparathyroidism: renal and skeletal outcomes from a single-centre registry"

Anyat Ali[1], Elhassan Awadin[2], Ahmed Elabasy[1], Osman Abdalrazag[3] and Suresha Muniyappa[4]
[1]*Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, Northern Ireland;* [2]*Royal Bolton Hospital, Bolton, Northern Ireland;* [3]*Barnsley Hospital, Barnsley, United Kingdom;* [4]*Doncaster Royal Infirmary, Doncaster, Northern Ireland*

Background: Primary hyperparathyroidism (PHPT) may be managed with curative parathyroidectomy or conservative medical treatment with surveillance. This service evaluation assessed management patterns, biochemical outcomes, and end-organ complications among patients with PHPT recorded in the parathyroid registry at Doncaster and Bassetlaw Teaching Hospitals (DBTH), with particular focus on renal and skeletal outcomes.

Methods: A retrospective review of 175 patients recorded in the DBTH parathyroid registry was undertaken. Twenty-two patients (12.6%) underwent parathyroidectomy, while 153 (87.4%) were managed conservatively. Data collected included postoperative calcium outcomes, cinacalcet use, DXA scan, osteoporosis prevalence among those scanned, and rates of renal failure. Outcomes were compared descriptively between surgical and non-surgical groups as part of this service evaluation.

Results: Among surgically treated patients, 81.8% achieved postoperative normocalcaemia, while 18.2% had persistent or recurrent hypercalcaemia requiring ongoing medical management. Cinacalcet use was higher in the surgical group with persistent disease compared with the conservatively managed cohort (18.2% vs 9.8%). DXA scanning was performed in 59.1% of surgical patients and 58.2% of those managed conservatively. Among patients who underwent DXA scanning, osteoporosis was more prevalent in the surgically managed group (53.8%) compared with the conservatively managed group (43.8%), likely reflecting selection of patients with more advanced skeletal disease for surgery. Renal failure was less common in patients who underwent parathyroidectomy (9.1%) compared with those managed conservatively (17.6%). Most surgically managed patients had preserved renal function (90.9%), whereas renal impairment affected nearly one in five patients in the non-surgical cohort. Overall, conservative management accounted for the majority of PHPT care within the service. However, a substantial proportion of conservatively managed patients demonstrated renal impairment or osteoporosis, highlighting the cumulative burden of long term disease.

Conclusions: Parathyroidectomy was associated with favourable outcomes in patients with end-organ involvement, particularly lower rates of renal impairment compared with conservative management, supporting surgery in appropriately selected patients. We recommend that all patients who are fit for surgery and meet guideline criteria for parathyroidectomy should be referred for surgical assessment. Interpretation of skeletal outcomes is limited by incomplete availability of DXA scan data within the registry, as some assessments may have been performed outside the local service.

Implications: This audit supports current PHPT management practices at DBTH while identifying key quality improvement priorities, including optimisation of surgical outcomes, structured postoperative biochemical surveillance, and proactive renal risk assessment in conservatively managed patients. These findings inform patient counselling, support guideline concordant care and guide future service development.

P100 - ECE_3782 - Baseline eGFR predicts lower palopegteriparatide maintenance dose requirements in chronic hypoparathyroidism

Dimitra Lygerou[1,2], Ioannis Petrakis[1], Grigoria Betsi[3], Maria Sfakiotaki[3], Vasiliki Daraki[3], Ariadni Androvitsanea[1], Nicos Papadakis[1], Myrto Konidaki[1], Konstantinos Stylianou[1] and Paraskevi Xekouki[3]
[1]*Nephrology, University Hospital of Heraklion, Heraklion, Greece; ;* [3]*Endocrinology, University Hospital of Heraklion, Heraklion, Greece*

Background: In chronic hypoparathyroidism (HypoPT), conventional therapy with oral calcium and active vitamin D may contribute to hypercalciuria, adverse renal outcomes, and ectopic calcifications. Real-world determinants of palopegteriparatide (TransCon PTH; Yorvipath) maintenance dose requirements across baseline kidney function remain incompletely characterized.

Methods: Single-center observational cohort of adults with chronic HypoPT treated with palopegteriparatide. Baseline and last follow-up data were collected for palopegteriparatide dose, elemental calcium, alfacalcidol, serum phosphate, serum creatinine, and eGFR (CKD-EPI 2021). CKD was defined as baseline eGFR <60 mL/min/1.73 m^2. Data are presented as median (IQR). Between-group and paired comparisons used non-parametric tests. Associations between maintenance dose and baseline eGFR (continuous), disease duration, and ectopic calcifications were explored using Spearman correlation and robust multivariable linear regression.

Results: Twenty patients were analyzed (70% female), median age 67.0 (45.3-73.3) years; 80% had post-surgical HypoPT and disease duration was 16.5 (9.0-31.3) years. Median time on palopegteriparatide was 7.5 (3.0-13.0) months. Baseline CKD was present in 8/20 (40%); CKD patients were older (74.0 [72.3-79.5] vs 49.5 [34.3-66.5] years; $P = .0020$) and had longer disease duration (31.0 [15.0-37.0] vs 11.5 [3.8-19.5] years; $P = .0337$). At last follow-up, palopegteriparatide maintenance dose was lower in CKD vs non-CKD: 15.0 (12.0-22.5) vs 28.5 (24.0-42.0) μg ($P = .0114$). From baseline to last follow-up, conventional therapy decreased markedly (elemental calcium 3000 [1500-3125] to 0 [0-500] mg/day, $P = .00013$; alfacalcidol 1.75 [0.88-3.0] to 0.0 [0.0-0.06] μg/day, $P = .00018$), serum phosphate improved (5.3 [4.48-5.88] to 4.1 [3.48-4.35] mg/dL, $P = .00013$), and eGFR remained stable (71.5 [53.5-98.0] to 70.5 [55.8-89.0] mL/min/1.73 m^2; $P = .452$). Baseline eGFR correlated positively with maintenance dose (Spearman ρ=0.701, $P = .00058$) and remained an independent predictor after adjustment for disease duration ($\beta = .237$ μg per 1 mL/min/1.73 m^2; $P = .025$; VIF ~1.76). Ectopic calcifications (65%) were also associated with lower dose (18.0 [12.0-24.0] vs 33.0 [28.5-42.0] μg; $P = .0035$).

Conclusions: Lower baseline eGFR—modeled as a continuous measure or categorized as CKD—was associated with

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

lower palopegteriparatide maintenance dose requirements in chronic HypoPT. Ectopic calcifications may further identify patients maintained on lower doses and warrant longitudinal confirmation. Conventional therapy was substantially reduced, phosphate homeostasis improved, and overall kidney function remained stable during Yorvipath treatment.

P102 - ECE_2592 - Effect of testosterone replacement therapy on fracture risk in men with hypogonadism: a systematic review and meta-analysis of randomized-controlled trials

Panagiotis Anagnostis[1,2], Efstathios Divaris[3], Maria Zidrou[1], Evanthia Kassi[4] and Symeon Tournis[5]
[1]3rd Department of Internal Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece; [2]Aristotle University of Thessaloniki, Thessaloniki, Greece; [3]Department of Endocrinology, Diabetes and Metabolism, 424 General Military Hospital, Thessaloniki, Greece; [4]Endocrinology Unit, 1st Department of Propaedeutic Internal Medicine, National and Kapodistrian University of Athens, Centre of Expertise in Rare Endocrine Diseases, C.E.R.E.D – Disorders of Calcium and Phosphate Metabolism, LAIKO General Hospital of Athens, Athens, Greece; [5]Laboratory for Research of the Musculoskeletal System "Th. Garofalidis", Medical School, National and Kapodistrian University of Athens, Athens, Greece

Objective: Testosterone replacement therapy (TRT) is the treatment of choice in men with hypogonadism. Although its beneficial effect on bone mineral density is well-established, the evidence regarding its impact on fracture risk remains inconclusive. The purpose of this study was to systematically review and meta-analyze the highest quality available evidence regarding the effect of TRT on fracture risk in hypogonadal men.

Study Design: A systematic literature search was conducted in PubMed, Scopus and Cochrane databases from inception through 30 September 2025. Only randomized-controlled trials were eligible for inclusion. Outcomes were summarized using odds ratio (OR) and mean difference (MD), respectively, with a 95% confidence interval (95% CI). The I2 index was used in order to quantify heterogeneity.

Results: Initial search yielded 1145 results after removal of duplicates, seven of which underwent full-text assessment. Finally, two studies were included in the qualitative and quantitative analysis ($n = 2711$). TRT was associated with increased risk of clinical fractures compared with placebo (OR 1.58, 95% CI 1.23-2.04, $P < .0001$, I2 = 0%). However, no difference between groups was observed when the analysis was restricted to major osteoporotic fractures (hip, spine, wrist, and arm) (OR 0.61, 95% CI 0.11-3.46, $P = .58$, I2 64%). This was also the case for vertebral (OR 0.87, 95% CI 0.34-2.26, $P = .80$, I2: 11%) and hip fractures (OR 0.99, 95% CI 0.33-2.93, $P = .98$, I2: 0%), when analyzed separately.

Conclusions: This is the first meta-analysis showing that TRT is associated with an increased incidence of predominantly non-major fractures, while the risk of major osteoporotic fractures, including hip and vertebral fractures, was not increased.

P103 - ECE_3282 - Is hypothyroidism associated with an increased risk of fractures in females with Ehlers–Danlos syndrome?

Jędrzej Jedliński[1,2], Ivan Rychlik[3], Aleksandra Żuk-Łapan[1,2], Jan Domański[1,2], Michalina Andrzejak[1,2], Bernadetta Kałuża[1,2] and Edward Franek[1,2,4]
[1]Department of Internal Medicine, Endocrinology, and Diabetology, National Medical Institute of the Ministry of the Interior and Administration, Warsaw, Poland; [2]Students Scientific Group of the Medical University of Warsaw at the Department of Internal Medicine, Endocrinology, and Diabetology, National Medical Institute of the Ministry of the Interior and Administration, Warsaw, Poland; [3]Department of Internal Medicine, Third Faculty of Medicine, Charles University, and Královské Vinohrady University Hospital, Prague, Czech Republic; [4]Department of Human Epigenetics, Polish Academy of Sciences, Mossakowski Medical Research Institute, Warsaw, Poland

Background: Ehlers–Danlos syndrome is a group of genetic conditions involving abnormal synthesis of connective tissue, particularly collagen, which manifests as musculoskeletal abnormalities including joint hypermobility and increased risk of fractures. Thyroid hormones play an important role in bone turnover, and their deficiency slows osteoblast and osteoclast activity. The aim of this study was to assess the risk of fractures in females with Ehlers–Danlos syndrome concomitant with hypothyroidism.

Material and Methods: We assessed thyroid hormone levels in 30 female patients with classical or hypermobile Ehlers–Danlos syndrome. The patients were divided into two groups: Group 1—patients with no history of fractures ($n = 17$) and Group 2—patients with a history of fractures ($n = 13$).

Results: The two groups did not differ in terms of the rates of hypothyroidism (7.69% vs 29.41%, $P = .16$), autoimmune thyroiditis (25.38% vs 23.53%, $P = .61$), or the levels of thyroid stimulating hormone (1.69 ± 0.77 vs 2.44 ± 1.64 [μIU/ml], $P = .21$), free triiodothyronine (3.54 ± 0.8 vs 3.26 ± 0.49 [pg/ml] $P = .52$), free thyroxine (1.33 ± 0.15 vs 1.35 ± 0.28 [ng/dl], $P = .63$), or thyroid peroxidase antibody levels (49.38 ± 139.92 vs 26.26 ± 31.05 [IU/ml], $P = .89$). Univariate logistic regression analysis showed no correlation between either hypothyroidism (OR 5 [0.506–49.44], $P = .17$) or autoimmune thyroiditis (OR 1.69 [0.26–11.07], $P = .58$) and the risk of fracture.

Conclusions: Female patients with Ehlers–Danlos syndrome showed no association between hypothyroidism or autoimmune thyroiditis and an increased risk of fractures.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Background: In primary hyperparathyroidism (PHPT), the impact of antiresorptives on bone mineral density gain (ΔBMD) after parathyroidectomy (PTx) remains controversial.

Materials and Methods: We retrospectively identified 112 patients with PHPT who underwent PTx in our Hospital from 9/2021 to 12/2024 (cases) and 64 PHPT patients treated conservatively (controls). We included 82 cases with densitometry (DXA) and blood tests performed just before and 12 months after PTx, and 17 controls with comparable assessments. All DXAs were performed with the same machine, allowing the estimation of Least Significant Change (LSC) for each skeletal district. According to pre-PTx antiresorptive exposure (bisphosphonates/denosumab), cases were classified as: naïve (never treated; $n = 32$), short-exposure (<6 months; $n = 23$), chronic-exposure (>6 months; $n = 27$).

Objectives: Primary: to evaluate whether antiresorptive therapy pre-PTx influences median annualized ΔBMD post-PTx, also analyzing the percentage of responders (patients with significant ΔBMD according to LSC in at least one skeletal site). Secondary: to investigate correlations between bone turnover markers (BTMs) and ΔBMD post-PTx.

Results: Cases were younger than controls (65 vs 78 years), with higher albumin-adjusted calcium (10.6 vs 10.4 mg/dL) and PTH levels (137 vs 102 pg/mL), and lower phosphate (2.8 vs 3.1 mg/dL) at baseline. Overall, PTx resulted in significant ΔBMD at spine (+5.3%) and femur (+2.9%), with stability at radius (−1.6%). Responders were 84.1%. Across subgroups, ΔBMD at 3 sites was comparable, with numerically greater gains in short-exposure at spine (ΔBMD = 4.1%; vs naïve = 1.6% and chronic = 2.2%) and femur (ΔBMD = 2.4%;vs naïve = 1.3% and chronic = 1.2%). All three surgical subgroups showed significantly greater ΔBMD compared with controls at spine (ΔBMD = −0.9%) and femur (ΔBMD = −0.3%). The number of responders was comparable, with a prevalence of short (91.3%) vs chronic-exposure (81.5%) and naïve (81.2%). However, femoral responders were significantly higher in short-exposure (90.9%;vs naïve = 56.2% and chronic = 51.9%). In all groups, a reduction in BTMs (ΔCTX,ΔBAP) was observed. ΔCTX was numerically greater in short (−75.9%) vs chronic-exposure (−70.7%) and naïve (−68.1%). In chronic-exposure higher ΔBMD at spine was associated with greater ΔCTX ($P = .017$; rho = −0.464). In the other subgroups no robust correlations were found.

Conclusions: Parathyroidectomy appears to significantly increase BMD and reduce BTMs regardless of antiresorptive exposure; however, short-term antiresorptive treatment pre-PTx could lead to greater BMD gains and higher proportion of patients achieving a significant skeletal response. This effect may be mediated by an early widening of post-PTx anabolic window, initiated before surgery because of antiresorptive therapy. Larger prospective studies are needed to define the optimal sequencing of PTx and antiresorptives to maximize post-surgical BMD recovery.

Abstract citation ID: lvag096.304

P105 - ECE_3425 - Pseudohyperparathyroidism of lactation successfully treated with carbergoline

Genevieve Tellier[1], Rhiannon Berkeley[1], Mei-Ju Hwang[1,2] and Anthony Wilton[1]

[1]Endocrinology, Ysbyty Gwynedd, Bangor, United Kingdom; [2]Breast Surgery, Ysbyty Gwynedd, Bangor, United Kingdom

Physiological changes in maternal calcium metabolism occur in normal lactation to facilitate sufficient supply of calcium for foetal skeletal formation. These changes have been described as a brain-breast-bone circuit and entail increased secretion of prolactin by the suckling reflex or milk expression. The increased prolactin suppresses hypothalamic gonadoptrophin releasing hormone secretion with a sequential decrease in gonadotrophins and oestradiol. The latter upregulates the receptor activator of the nuclear factor beta-ligand (RANKL) which downregulates osteoprotegerin with resultant stimulation of octeoclastic activation and bone resorption. Hyperprolactinaemia also stimulates release of 5-hydroxytryptophan which increases parathyroid hormone related protein (PTHrP) production by breast epithelial cells. Excess activity of these processes can result in hypercalcaemia with suppressed parathyroid hormone levels.

Case Report: A 19 year old 3-week postpartum primigravida patient presented to primary care with a 7-day history of abdominal pain and fatigue. Pregnancy had been asymptomatic and delivery uncomplicated. The finding of hypercalcaemia at adjusted calcium levels ranging from 2.79-2.90 mmol/L coincidental with parathyroid hormone level of 1.3 pmol/L led to secondary care referral.

A history of painful engorged breasts secondary to suckling had led her to milk expression with no symptomatic relief. Expert breast examination confirmed very engorged breasts with typical lactational changes. Investigations confirmed adjusted 3.01 mmol/L, parathyroid hormone 1.1 pmol/L, vitamin D 39 nmol/L, prolactin 6941 mU/L and alkaline phosphatase 176 U/L. Unfortunately PTHrP assay was not available. The finding of low parathyroid hormone level excluded primary hyperparathyroidism and other diagnoses for hypercalcaemia were also excluded.

Subsequent serial investigations recorded increases in adjusted calcium, prolactin and alkaline phosphatase following milk expression. Agreement to convert to breast milk substitute was obtained but ongoing severe breast discomfort and lactation led us to treat with a single dose of 0.5 mg of cabergoline which resulted in rapid resolution of symptoms and biochemical abnormalities.

Discussion: Initial reports of lactational hypercalcaemia were in patients with gigantomastia who were treated with bilateral mastectomies. Subsequent reports described the same phenomenon in women with normal size breasts practising milk expression. Treatments by means of cessation of breastfeeding, IV fluids, bisphosphonates, calcitonin and bromocriptine were of limited success. We believe that cabergoline should be considered as first-line therapy in lactational hypercalcaemia as in addition to its efficacy it excludes other causes of hypercalcaemia in this rare but troublesome condition. We also suggest describing the phenomenon as a breast-brain-hypothalamic-pituitary-bone circuit.

[1]Poznań, Poland; [2]Department of Endocrinology, Metabolism and Internal Diseases, Poznan University of Medical Sciences, Poznań, Poland; [3]Departament of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences, Poznań, Poland

Background: Surgery is the only curative treatment for primary hyperparathyroidism (PHPT). Accurate preoperative localization of parathyroid lesion is essential to facilitate minimally invasive surgical approaches. Although 99mTc-MIBI scintigraphy with SPECT/CT (MIBI) remains the standard imaging modality, parathyroid hormone washout (PTHw) has emerged as a promising adjunct, particularly when radiation exposure is a concern.

Aim: The aim of this study was to assess the diagnostic performance and concordance of PTHw and MIBI in patients with PHPT and to compare different cutoff values for PTHw positivity.

Methods: This retrospective study included 54 patients who underwent surgery for PHPT. All patients had ultrasound-guided fine-needle aspiration with PTHw measurement and 99mTc-MIBI scintigraphy with SPECT/CT performed. PTHw was considered positive when the PTH concentration in the washout fluid exceeded the corresponding serum PTH level. An additional analysis was conducted using a PTH washout-to-serum PTH ratio (PTHw/PTHser) cutoff >3.

Results: The sensitivity of PTHw was 92.59% (95% CI, 82.45-97.08%), compared with 87.04% for MIBI (95% CI, 75.58%-93.58%). All patients had localization of lesion confirmed in at least one imaging technique. Concordant positive findings were observed in 79.63% of cases. In paired analyses, detection performance did not differ significantly between MIBI and PTHw (McNemar test, $P = .55$), with 11 discordant results, including 4 MIBI-positive and 7 PTHw-positive cases. When analysis was restricted to histopathologically confirmed parathyroid adenomas (excluding hyperplasia and other diagnoses), positive localization was observed in 37 of 41 cases with PTHw and in 36 of 41 cases with MIBI. Median ionized calcium levels were significantly higher in the PTHw-positive group compared with the PTHw-negative group (6.22 [IQR 6.03-6.68] vs 5.76 [IQR 5.68-5.85]; $P = .03$; $r = 0.75$). In MIBI-positive cases maximal lesion diameter was significantly larger than in MIBI-negative cases (12 mm[IQR 9.50-16.50] vs 9 mm[IQR 7-10.50]; $P = .02$; $r = 0.55$). Univariate logistic regression demonstrated a consistent trend toward higher MIBI detection with increasing lesion size (OR = 1.32; $P = .06$). Application of a PTHw/PTHser cutoff >3 reduced sensitivity to 79.63% (95% CI, 67.10%-88.23%).

Conclusions: PTHw and MIBI demonstrate comparable sensitivity for preoperative localization in PHPT but show limited concordance at the patient level, highlighting their complementary rather than interchangeable roles. Larger adenomas were more frequently detected by MIBI. A PTHw/PTHser cutoff >1 maximized sensitivity and appears preferable to a cutoff >3, although specificity could not be assessed owing to the study design. Larger prospective studies are warranted to validate these findings.

Abstract citation ID: lvag096.306

P107 - ECE_1433 - Pulse methylprednisolone therapy suppresses bone turnover without short-term loss of bone mineral density

Fatima Siddiqui[1,2], Lawrence Law[3], Amal Al-Aamri[4], Siok Bee Chionh[1,3], Pei Chia Eng[3,5] and Chin Meng Khoo[1,3]

[1]Department of Medicine, Yong Loo Lin School of Medicine, Singapore, Singapore; [2]Department of Medicine, National University Hospital, Singapore, Singapore; [3]Division of Endocrinology, Department of Medicine, National University Hospital, Singapore, Singapore; [4]Nizwa Hospital, Nizwa, Oman; [5]Department of Metabolism, Digestion and Reproduction, Imperial College London, London, United Kingdom

Introduction: Chronic glucocorticoid (GC) therapy is a leading cause of secondary osteoporosis, but the skeletal effects of intermittent high-dose intravenous pulse GC regimens are unclear. These regimens are widely used for treatment of autoimmune and inflammatory conditions and may reduce cumulative GC exposure. In this study, we evaluated the impact of pulse methylprednisolone (MP) on bone mineral density (BMD), bone turnover markers in adults without osteoporosis.

Methods: We conducted a systematic review and meta-analysis in accordance with PRISMA guidelines. Pubmed, EMBASE, Scopus and Google Scholar were searched to September 2025 for longitudinal, cohort, case-control or randomised studies in all adults receiving pulse MP with BMD and/or bone markers measured before and after pulse MP therapy. Outcomes included BMD, trabecular bone score (TBS), bone turnover markers, calcium, vitamin D and parathyroid hormone axis. Risk of bias was assessed using ROBINS-E. Pooled mean differences (MD) were estimated using random- or fixed-effects models; a 4% BMD change was prespecified as the least significant change.

Results: Nine studies with a total of 257 participants (73% women, mean age of 40 years old) were included. Pulse MP after a mean follow up of 5.3 months did not reduce BMD at the lumbar spine (MD 0.01 g/cm^2; 95% CI −0.02 to 0.03), femoral neck (MD −0.01 g/cm^2; 95% CI −0.03 to 0.01), or total hip (MD −0.03 g/cm^2; 95% CI −0.06 to 0.01) with all changes below the least significant change threshold. TBS was similarly unchanged (MD −0.02; 95% CI −0.10 to 0.07). In contrast, P1NP (MD −36.95 ng/mL; 95% CI −56.86 to −17.03) and CTX (MD −0.19 ng/dL; 95% CI −0.32 to −0.07) decreased, indicating suppression of both bone formation and resorption. Serum 25-hydroxyvitamin D increased modestly, while calcium and parathyroid hormone remained stable. Heterogeneity was low for BMD and higher for turnover markers; no major publication bias was detected.

Conclusions: In adults without osteoporosis, intravenous MP suppresses bone turnover without causing short-term BMD loss. IV MP may be less detrimental to bone health than chronic long-term GC regimens when clinically appropriate. Future studies comparing pulse GC and chronic GC regimens are needed to clarify long-term skeletal safety of pulse GC therapy.

P108 - ECE_1756 - Clinical outcomes after parathyroidectomy in elderly patients with primary hyperparathyroidism

Christine Holm Egebæk[1], Jacob Lilja-Fischer[1], Mathias Alstrup[1], Torben Harsløf[2] and Lars Rolighed[1]

[1]Department of Otorhinolaryngology – Head & Neck Surgery, Aarhus University Hospital, Aarhus N, Denmark; [2]Department of Endocrinology and Internal Medicine, Aarhus University Hospital, Aarhus N, Denmark

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Introduction: Primary hyperparathyroidism (PHPT) is increasingly detected in older individuals and often associated with osteoporosis. Benefit from parathyroidectomy (PTX) in elderly patients is debated. We evaluated biochemical outcomes, bone mineral density (BMD) and survival after PTX in elderly patients.

Methods: Retrospective cohort study of patients aged ≥75 years undergoing PTX for PHPT between 2014 and 2019. Patients were grouped as <80 or ≥80 years. Biochemical outcomes and changes in BMD at the spine and hip were assessed pre- and postoperatively. We evaluated percent change (Δ% BMD) and adjusted Δ% BMD with linear regression and accounting for body mass index, creatinine, and anti-osteoporotic therapy.

Results: 171 patients (114 <80 and 57 ≥80 years) were included and 116 (68%) had osteoporosis. Cure rate was 95%, one had nerve palsy, and another had hypoparathyroidism after PTX. There was no disease or procedure related mortality. BMD improved by 3.3% in the spine but not in the hip (0.0%). The increase was higher in patients < 80 years ($P = .03$). The difference between age-groups disappeared when we adjusted for BMI, creatinine, and osteoporotic treatment. For patients in osteoporosis treatment, BMD improved significantly in spine and hip (4.8% and 1.6%) compared with patients without osteoporosis treatment (1.5% and 0.0%).

Conclusions: PTX in a selected group of elderly patients with PHPT is safe and biochemically effective with low complication rates. The positive BMD changes are mitigated by increasing age and decreasing kidney function. Further, simultaneous medical treatment seems to improve the BMD benefit from PTX.

Keywords parathyroidectomy, primary hyperparathyroidism, elderly, bone mineral density

P109 - ECE_2168 - Teriparatide treatment of osteoporosis in solid organ transplant recipients – a single-center experience

Talia Diker Cohen[1,2], Ilana Shraga-Slutzky[1,2], Keren Kaminer[1,2], Alexander Gorshtein[1,2], Idit Dotan[1,2] and Gloria Tsvetov[1,2]

[1]Rabin Medical Center, Beilinson Campus, Institute of Endocrinology, Diabetes and Metabolism, Petah Tikva, Israel; [2]Gray Faculty of Medicine and Health, Tel Aviv University, Tel Aviv, Israel

Background: Solid organ transplant (SOT) recipients are at high risk for osteoporosis and fragility fractures due to pre-existing organ dysfunction and chronic immunosuppressive therapy, particularly glucocorticoids. Evidence supporting the efficacy and safety of anabolic osteoporosis therapy in this population is limited, and fracture data are scarce.

Methods: We conducted a retrospective cohort study at a large transplant center, including adult kidney, lung, liver, and heart transplant recipients treated with teriparatide for post-transplant osteoporosis for ≥6 months. Bone mineral density (BMD), incident fractures, biochemical parameters, renal function, and adverse events were assessed during treatment and follow-up.

Results: Thirty-nine SOT recipients (33% men; mean age 61.3 ± 11.6 years) were included, with kidney ($n = 20$), lung ($n = 10$), and liver ($n = 9$) transplants. Ninety percent had prior fragility fractures, and 79% had multiple fractures. Median teriparatide duration was 22.3 months. Significant BMD increases were observed at the lumbar spine (+11 ± 15%, $P = .01$), femoral neck (+8 ± 14%, $P = .05$), and total hip (+11 ± 16%, $P = .05$). Six patients sustained fractures after teriparatide initiation; only two occurred during active treatment, while four occurred after discontinuation. Hypercalcemia occurred in one patient and led to treatment cessation. Estimated glomerular filtration rate declined modestly during the first six months of therapy but stabilized thereafter and did not differ from contemporaneous untreated transplant controls. No cases of graft rejection were observed.

Conclusions: In this large real-world cohort of SOT recipients with severe osteoporosis, teriparatide therapy was associated with significant improvements in BMD, low rates of treatment-limiting adverse events, and no apparent excess risk to graft function. These findings support the selective use of anabolic therapy in high-risk transplant recipients and highlight the need for prospective studies to define optimal patient selection and treatment sequencing.

P110 - ECE_3936 - Effect of parathyroidectomy on bone mineral density in patients with primary hyperparathyroidism

Ozge Sahin Kimyon[1], Simge Saydam[1], Zeynep Elüstü Belten[1], Selin Celik[1], Muge Yurdacan Sahin[2], Evin Bozkur[1], İlkay Çakir[1], Meral Mert[1], Sema Ciftci[1] and Hamide Piskinpasa[1]

[1]Department of Endocrinology and Metabolism, University of Health Sciences, Bakırkoy Dr. Sadi Konuk Training and Research Hospital, Istanbul, Türkiye; [2]Department of General Surgery, University of Health Sciences, Bakırkoy Dr. Sadi Konuk Training and Research Hospital, Istanbul, Türkiye

Background: Primary hyperparathyroidism (PHPT) is characterized by bone loss, predominantly affecting cortical bone. Parathyroidectomy (PTX) is the definitive treatment and is associated with subsequent skeletal recovery. The aim of this study was to evaluate trabecular and cortical bone mineral density (BMD) changes following PTX in patients with PHPT.

Methods: This retrospective cohort study included patients who underwent PTX for PHPT between 2019 and 2024. Patients with persistent or recurrent hyperparathyroidism after surgery were excluded. Patients with available preoperative and at least one-year postoperative dual-energy X-ray absorptiometry (DXA) measurements were included. BMD measurements of the lumbar spine, femoral neck, total hip, and distal radius were analyzed, and osteoporosis prevalence at each skeletal site was assessed. Preoperative and postoperative clinical, laboratory, and BMD parameters were compared.

Results: A total of 86 patients (76 females/10 males; mean age 55.3 ± 8 years) were included. At baseline, osteoporosis was present in 70.9% of patients, most commonly affecting the distal radius (51.2%), followed by the lumbar spine (22.1%). The mean interval between surgery and follow-up DXA was 31.9 ± 19.8 months. After PTX, osteoporosis persisted in 70.9% of patients who had osteoporosis at any skeletal site

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

preoperatively. Persistence rates were 21.1% at the lumbar spine, 75.0% at the femoral neck, 16.7% at the total hip, and 81.8% at the distal radius. A history of low-trauma fracture was present in five patients preoperatively and in one patient postoperatively. Comparison of preoperative and postoperative DXA parameters revealed statistically significant increases in lumbar spine BMD (0.940 ± 0.122 vs 0.994 ± 0.123 g/cm^2, $P <$ .001), femoral neck BMD (0.806 ± 0.098 vs 0.847 ± 0.110 g/cm^2, $P <$ .001), and total hip BMD (0.875 ± 0.148 vs 0.906 ± 0.116 g/cm^2, $P =$ .004). In contrast, no significant change in BMD was observed at the distal radius (0.665 ± 0.113 vs 0.673 ± 0.116 g/cm^2, $P =$ .390).

Conclusions: In patients with PHPT, parathyroidectomy results in significant increases in bone mineral density, particularly at trabecular-rich and mixed skeletal sites. In contrast, no significant BMD improvement was observed at the distal radius, a site rich in cortical bone. The limited recovery at the distal radius likely reflects the lower remodeling capacity and more stable nature of cortical bone compared with the dynamic remodeling of trabecular bone. However, further studies with larger sample sizes are needed to confirm these findings.

P112 - ECE_3242 - Specific cord serum microRNAs and sclerostin are associated with bone mineral density (BMD) assessed by REMS, in infants up to the first year of life: results from the REMS-bone study

Anna-Mariia Shulhai[1], Virginia Beretta[1], Letteria Anna Morabito[2], Domenico Corica[2], Giorgia Pepe[2], Federica Grassi[1], Tommaso Aversa[2], Francesca Bossi[1], Andrea Dall'asta[1], Malgorzata Wasniewska[2], Serafina Perrone[1] and Maria Street[1]

[1]Pediatric Clinic, Medicine and Surgery, University of Parma, Parma, Italy; [2]University of Messina, Messina, Italy

Background: The REMS-bone study-clinical trial(NCT06750523) aimed to evaluate bone status from intrauterine life and to investigate factors that may affect BMD in infancy. MicroRNAs(miRNAs) are key post-transcriptional regulators involved in bone formation, remodeling and mineralization. To date, there is no data on cord serum miRNAs and BMD. The aim of this study was to measure specific miRNA, known to be involved with bone metabolism, in cord serum and assess any possible relationships among these, bone metabolism markers and BMD in infants during the first year of life.

Methods: This was a prospective longitudinal cohort study including 88 full-term healthy AGA infants. Hsa-miR-199a-5p, hsa-miR-335-5p,hsa-miR-494-3p,hsa-miR-369-3p, hsa-miR-379-5p,hsa-miR-503-5p,hsa-miR-140-5p,hsa-let-7a-5p, and hsa-let-7c-5p were assayed in cord serum. Expression was established using qRT-PCR, normalized by hsa-miR-16-5p and analyzed using the $2-\Delta\Delta Ct$ method. Bone-related proteins,including osteocalcin, collagen type I(CrossLaps), sclerostin(SOST), Dickkopf-1(DKK-1), irisin, and HMGB1, were assayed by ELISA methods. BMD was assessed by Radiofrequency Echographic Multi Spectrometry(REMS), a non-invasive, radiation-free technology for bone quality assessment. This method was validated in newborns and infants alongside this study. BMD z-scores were calculated at 48 hours after birth, at 1,3,6 and 12 months of life. Associations between miRNA expression levels, markers of bone metabolism and BMD z-scores across time points were evaluated by correlation and multivariable linear regression analyses.

Results: miR-199a-5p, miR-335-5p, miR-494-3p, miR-369-3p, miR-379-5p, miR-503-5p and miR-140-5p were expressed in cord serum. Cord serum DKK-1 was 3.71 ± 1.63 ng/ml, CrossLaps $0.86 + 0.22$ ng/ml, SOST 222.05 ± 108.83pg/ml, osteocalcin 21.42 ± 4.71ng/ml, irisin 7.270 ± 7.30ug/ml and HMGB1 14.037 ± 18.32ng/ml. No differences were found between sexes. MiR-199a-5p and miR-369-3p were associated with irisin levels(r:−0.320, *P*:.044 and r:−0.387, *P*:.013, respectively) and might be irisin suppressors. MiR- 503-5p was associated with DKK-1 (r:−0.363, *P*:.013), suggesting a potentially protective role for bone health. MiR-140-5p was associated with BMD z-score at 1 month(r:0.333, *P*:.039) and at 12 months(r:0.552, *P*:.002), suggesting a potential role in later BMD. Pathway enrichment analysis showed that miR-140-5p was involved in TGF-beta,Jak-STAT,Wnt and mTOR signaling pathways and osteoclast differentiation. Among proteins, only sclerostin showed a negative association with BMD z-score at 6 months(r:-0.391, *P*:.030). This association was further supported by a multivariable regression model, which showed miR-140-5p and sclerostin as significant predictors of BMD z-scores at 12 months(F:5.536, *P*:.006).

Conclusions: Cord serum miRNAs were associated with bone metabolism markers and BMD during infancy. In particular, miR-140-5p was associated with BMD at 1 year of life. These findings support the hypothesis that miRNAs may act as mediators in the prenatal programming of postnatal bone development.

Abstract citation ID: lvag096.311

P113 - ECE_2153 - Severe PTH-independent hypercalcemia in secondary adrenal insufficiency during critical illness

Aakansha Sinha[1], Zaiem Zarkasi[1] and Aye Aye Thant[1,2]

[1]Diabetes and endocrinology, Wythenshawe hospital, Manchester, United Kingdom; [2]Diabetes and Endocrinology, Wythenshawe Hospital, Manchester University NHS Foundation Trust, Manchester, United Kingdom

Introduction: Hypercalcemia in critically ill patients is most often attributed to immobilization or malignancy, but less common endocrinological causes may be overlooked. Adrenal insufficiency (AI) is a recognized cause of parathyroid hormone (PTH)-independent hypercalcemia, reported in approximately 5%-6% of patients with primary AI, and less frequently in secondary AI, where severe hypercalcemia is rarely described. Azole antifungals, including fluconazole, can inhibit adrenal steroidogenic enzymes and precipitate adrenal insufficiency in susceptible individuals. We report a critically ill burn patient with severe refractory hypercalcemia, in whom recognition of relative adrenal insufficiency led to rapid biochemical resolution with glucocorticoid replacement.

Case Presentation: A 40-year-old previously healthy man was admitted following a 40% total body surface area burn. His hospital course was prolonged (107 days) and complicated by

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

extracorporeal membrane oxygenation (ECMO), bilateral pneumonia, sepsis, and a subarachnoid hemorrhage. On day 58 of admission, he developed severe hypercalcemia with an adjusted calcium of 3.93 mmol/L, rising to 4.20 mmol/L (normal range 2.20-2.60 mmol/l). Despite aggressive intravenous hydration and bisphosphonate therapy. PTH was suppressed at 0.7 pmol/L, consistent with PTH-independent hypercalcemia. Renal function was mildly deranged with EGFR of 58 mL/min/1.73 m^2 and creatinine of 132 µmol/L. Despite severe physiological stress, a morning cortisol level was inappropriately low at 242 nmol/L, suggesting relative AI. Intravenous hydrocortisone was commenced, resulting in rapid normalization of serum calcium within 48 hours to 2.32 mmol/l. Further evaluation revealed suppressed ACTH (<4 pg/mL), raising concern for secondary AI. Although prior subarachnoid hemorrhage suggested possible pituitary injury, pituitary MRI was unremarkable. CT TAP showed bilateral extensive consolidation but no malignancy. A temporal association was noted with concurrent fluconazole therapy for Candida parapsilosis, inhibit the steroidogenesis as a contributing factor. Hydrocortisone was subsequently transitioned to oral maintenance therapy. The patient will undergo outpatient endocrine follow-up for education, dynamic testing with a short Synacthen test, and anterior pituitary hormone assessment.

Conclusions: This case highlights severe hypercalcemia as an important metabolic red flag for adrenal insufficiency. In critically ill patients, particularly those with major burns or on ECMO, a "normal" or mid-range cortisol level may represent an inadequate stress response. Severe-refractory PTH-independent hypercalcemia should prompt assessment of the hypothalamic–pituitary–adrenal axis. Clinicians should remain vigilant for secondary AI in patients with intracranial pathology or exposure to azole antifungals, as early recognition and glucocorticoid replacement can be rapidly life-saving.

Abstract citation ID: lvag096.312

P114 - ECE_2811 - Impact of conventional treatment on chronic complications among subjects with hypoparathyroidism

Roman Králik[1], Martin Kuzma[1], Juraj Payer[1], Jana Lešková[2], Peter Vanuga[2] and Martin Straka[2]
[1]*5th Department of Internal Medicine, University hospital Bratislava, Bratislava, Slovakia;* [2]*Endocrinology, National endocrinology and diabetology department, n.o, Ľubochňa, Slovakia*

Background: Chronic hypoparathyroidism (hypoPT) is a rare disease associated to long-term disturbances in calcium-bone metabolism, renal burden and decreased quality of life. These complications arise from the disease itself and from its conventional treatment.

Aim of the Study: To assess the burden of chronic complications, mainly bone changes, aortic and renal calcifications, sarcopenia and quality of life among HypoPT patients on conventional treatment (vitamin D analogues and calcium supplementation).

Methods: A case-control study of hypoPT patients ($n = 38$, mean age 52.6yrs, females $n = 32$, males n6, mean hypoPT duration 168 months) regardless of ethiology (postsurgical $n = 29$, non-surgical $n = 9$) exclusively on conventional treatment with alfacalcidol and calcium compared to healthy controls across two tertiary centres in Slovakia. Measurement of serum calcium-phosphate metabolism, urea, creatinine, 25-hydroxyvitamin D, glomerular filtration rate (GFR), pro collagen type 1N peptide (P1NP), C-terminal telopeptide of type 1 collagen (CTX), 24-hour urine calcium and phosphate in both groups was performed. Chronic complications screening: renal ultrasound, aortic calcification screening on abdominal X ray, areal bone mineral density (aBMD at lumbar spine a proximal femur), trabecular bone score (TBS), 3Ddensitometry (3D-DXA), SF-36 questionnaire (QoL) and muscular ultrasound (for sarcopenia).

Results: HypoPT patients showed lower calcium, parathormone, CTX levels ($P < .001$) and greater phosphate levels ($P < .001$),aBMD measurements (all sites $P < .05$), cortical surface BMD, trabecular vBMD (total and neck), and cortical neck thickness than controls (all $P < .05$). Significantly lower physical health and emotional health SF-36 scores in the hypoPT group were observed. No association between QoL and disease duration was observed. A significant negative association of PTH levels with all aBMD measures ($P < .05$), cortical thickness and cortical surface BMD ($P = .008$) was observed. No differences in TBS, aortic calcifications, nephrolithiasis or sarcopenia measures were found.

Conclusions: Chronic hypoPT patients on conventional therapy (alfacalcidol and calcium) showed typical biochemical features of hypoparathyroidism—hypocalcemia, hyperphosphatemia, suppressed bone turnover. Compared with controls, hypoPT patients had higher aBMD at all sites and increased 3D-DXA metrics (higher trabecular and cortical vBMD and greater cortical thickness), changes that inversely correlated with PTH levels. There were no differences in TBS, aortic calcifications, nephrolithiasis or sarcopenia. QoL was impaired, especially physical and emotional domains – with greater physical role limitation linked to higher daily calcium dose, disease duration showed no association. Overall, conventional therapy increases bone density/structure measures but does not mitigate the clinical and perceived burden, indicating it cannot replicate PTH's physiological effects on bone and well-being.

P116 - ECE_1381 - Simulating hypoparathyroidism: a web-based tool for interactive and personalized therapeutic decision-making

Marta Gallach Martínez[1,2], Laura Rambla Aguilar[3], Isabel Huguet[3], Marina Jara Vidal[1], Luyi Zeng[3], César Gonzalvo Díaz[1], Inmaculada Moreno-Ruiz[3], Cristina Lamas[1], Cristina Sevillano-Collantes[3] and José Joaquín Alfaro Martínez[1]
[1]*Complejo Hospitalario Universitario de Albacete, Albacete, Spain;* [2]*Endocrinología y Nutrición, Complejo Hospitalario Universitario de Albacete, Albacete, Spain;* [3]*Hospital Universitario Infanta Leonor, Madrid, Spain*

Introduction: Hypoparathyroidism is a rare endocrine disorder characterized by parathyroid hormone (PTH) deficiency, leading to hypocalcemia and hyperphosphatemia. The most common etiology is postsurgical iatrogenesis. As no standardized treatment algorithms exist, its management requires individualized

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

therapeutic adjustments and it largely depends on the patient's biochemical response and clinical expertise. Due to the low prevalence of this condition, opportunities for systematic clinical exposure and experience acquisition are limited. To address this challenge, an online simulator has been developed to recreate clinical scenarios and predict biochemical responses to therapeutic modifications.

Methods and Materials: A mathematical model was developed using R and implemented as a web-based application through the Shiny framework, derived from expert knowledge in calcium-phosphate metabolism. Expected serum calcium responses to therapeutic modifications were estimated across predefined hypoparathyroidism scenarios and used to model calcium changes based on baseline levels and dose adjustments. Urinary calcium excretion was modeled as dependent on serum calcium levels, treatment regimen, and individual patient-specific factors. Each simulated patient was assigned a minimum urinary calcium excretion value corresponding to a serum calcium level of 7,5 mg/dL, from which calciuria increased proportionally with rising serum calcium. Symptoms, clinical signs, and electrocardiographic abnormalities were incorporated when hypo or hypercalcemia occurred. To enhance realism, a random variability component was incorporate, allowing results to fluctuate within ±5%. The simulator is available at www.morpho.org.es/SimuladorHipopara.

Results: The simulator includes 42 simulated patient cases with heterogeneous clinical characteristics. Serum calcium evolution depends on baseline calcium levels and the therapeutic regimen applied. Users can modify doses of calcium carbonate, calcitriol and thiazide diuretics. Following each therapeutic adjustment, updated serum calcium levels, urinary calcium excretion, and clinically coherent data reflecting a subsequent follow-up visit are generated. The simulator allows iterative decision-making, with the objective of maintaining biochemical and clinical parameters within appropriate target ranges while minimizing adverse outcomes.

Conclusions: This web-based simulator represents a valuable educational tool that facilitates structured training in the management of hypoparathyroidism. By allowing the safe exploration of multiple clinical scenarios and therapeutic strategies, it facilitates the understanding of the dynamic relationship between treatment adjustments and biochemical outcomes. The simulator promotes active learning and clinical reasoning in a controlled environment, potentially enhancing confidence and competence. This digital tool may complement traditional educational approaches and contribute to improving consistency and quality in clinical practice.

P118 - ECE_3489 - Cinacalcet use in primary hyperparathyroidism – a retrospective look at patient outcomes in a london hospital

Bara Taufik, Suhrab Sayfi and Ian Seetho
Department of Diabetes & Endocrinology, Northwick Park Hospital, London, United Kingdom

Introduction: Cinacalcet, a calcimimetic first approved for use in 2004, has become a mainstay of treatment in those awaiting or unable to undergo surgery for primary hyperparathyroidism. In this retrospective study, we aimed to map clinical outcomes in patients who had been prescribed cinacalcet for a suspected or confirmed diagnosis of primary hyperparathyroidism, between 1st October 2022 and 30th September 2024, and to compare our practice with NICE guideline *NG132*, published in 2019.

Methodology: All instances where cinacalcet was dispensed from a pharmacy within the trust were logged – biochemical, demographic and clinical data were then gathered. Any patients with chronic or end-stage renal disease were excluded.

Results: Eighty-four patients were identified—fifty-five female (65%) and twenty-nine male—with ages ranging from twenty-five to ninety (mean age sixty-seven). 37% ($n = 31$) were referred for parathyroidectomy (mean age fifty); 16% ($n = 14$) went on to have surgery (mean age 56). Two patients had recurrence of hypercalcaemia post-operatively, and were subsequently restarted on cinacalcet; the remainder were cured. Seventy-one of the eighty-four patients were prescribed cinacalcet after *NG132* was published—of these, 49% ($n = 35$) were prescribed cinacalcet in adherence with the guidelines; in those where cinacalcet was prescribed outwith the guidelines, all but one was prescribed cinacalcet while awaiting surgery.

Conclusions: Cinacalcet was prescribed in adherence with NICE guideline *NG132* in just under half of cases; the overwhelming majority of prescriptions outwith the guidelines were for use as bridging therapy while awaiting parathyroid surgery – this is consistent with evidence elsewhere within the literature, and should be a key consideration to take into account for future guidelines, given the well-documented use of cinacalcet peri-operatively. Surgical outcomes were very favourable, with 85% of patients cured following surgery.

P120 - ECE_1946 - Bone and dental complications in adult XLH patients—a single-centre cohort cross-sectional pilot study

Marko Stojanovic[1], Ana Djinic Krasavcevic[2], Iva Milinkovic[2], Jelena Bajic[1], Bojana Caric[3], Valentina Stankovic[3], Mirjana Doknic[1], Sandra Pekic Djurdjevic[1], Zvezdana Jemuovic[1], Ivana Cekic[1], Ivan Jevtic[1], Boris Kurcubic[1] and Marina Nikolic Djurovic[1]
[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Center of Serbia, Belgrade, Serbia; [2]Department of Periodontology and Oral Medicine, School of Dental Medicine, University of Belgrade, Belgrade, Serbia; [3]Department of Endocrinology-, Banja Luka, Bosnia—Herzegovina., University Clinical Center of Republika Srpska- Banja Luka- Faculty of Medicine-University of Banja Luka, Banja Luka, Bosnia and Herzegovina

Introduction: X-linked hypophosphatemia (XLH) is a rare genetic disease of autonomous FGF-23 over-secretion, hallmarked by hypophosphatemia and osteomalacia with progressive skeletal deformities and dental complications.

Aim: Assessing bone and dental complications in a cohort of adult XLH patients on conventional treatment through cross-sectional pilot study

Patients and Methods: We analysed 11 adult XLH patients (9 females), 37.3 ± 4.0 years old, treated with active vitamin D and phosphate supplementation. History of fragility fractures was assessed. BMD was analysed by DXA (Hologic Discovery QDR) at L1-L4 spine (LS), femoral neck (FN) and mid-distal radius (MDR)

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

and expressed as Z-score (Zsc). Serum osteocalcin (OC), and beta-cross-laps (BCL) were analysed as bone turnover markers, expressed as index denominated by the upper limit of normal age, gender and menopausal status reference values (ULN). Seven patients underwent comprehensive dental-periodontal examination including radiographic analysis.

Results: 6 patients (54.5%) had a history of fragility fractures (femur in 5, radius and tibia in 1 each). Average LS Zsc was +1.2 ± 0.4 (BMD 1.156 ± 0.055); average FN Zsc: −0.7 ± 0.4 (BMD 0.755 ± 0.051); average MDR Zsc: −1.3 ± 0.6 (BMD 0.617 ± 0.038). Serum OC-ULN was 0.68 ± 0.16 and BCL-ULN 1.63 ± 1.38). Majority of patients (4/7) lost 4-17 teeth due to periodontitis and infections. One was fully edentulous. All of dentate patients had severe periodontal inflammation, with bleeding on probing (BOP) of 57-85% and plaque index (PI) of 80%-92%. Advanced periodontal disease was established with periodontal probing depth (PPD) of 2.8-3.4 mm, and clinical attachment level (CAL) of 1.8-4.0 mm. Radiographic analyses revealed 1-14 endodontically treated teeth in all patients. One patient, otherwise asymptomatic, was diagnosed with apical periodontitis in two intact teeth. Enlarged pulp chambers were observed in five dentate patients, affecting 3-20 teeth. Only 2 patients (19 and 21 years old and timely diagnosed with XLH in early childhood) had no extracted teeth.

Conclusions: Prior fragility fractures were common in our pilot cohort of XLH patients on conventional treatment (54.5%) with femur as most affected site. BMD was decreased at mid-distal radius (Zsc: −1.3 ± 0.6). Bone formation and bone resorption were unbalanced (2.71 ± 0.79-fold) in favour of resorption. Advanced periodontal disease, including asymptomatic apical periodontitis in intact teeth was prevalent, with 4-17 teeth lost per patient (one being edentulous at the age of 45) due to periodontitis and infections, except in patients with timely diagnosis and follow-up from childhood. Comprehensive and multidisciplinary follow-up of bone and dental complications is mandated in XLH patients.

P121 - ECE_3185 - Knowledge, attitudes, and practices regarding medication-related osteonecrosis of the jaw among oral surgery specialists and endocrinologists: a cross-sectional study

Rutie Mamlok Sherf[1], Dror Cantrell[2], Amir Laviv[3], Nirit Tagger-Green[4] and Michael Joachim[5]
[1]*Shamir medical center, Endocrine and Diabetes Institute, Zerifin, Israel;* [2]*Shamir medical center, Internal Medicine C, Zerifin, Israel;* [3]*Department of Oral and Maxillofacial Surgery, Tel Aviv University, Tel Aviv, Israel;* [4]*Department of Periodontology and Oral Implantology, Tel Aviv University, Tel Aviv, Israel;* [5]*Shamir medical center, Oral and Maxillofacial Surgery Unit, Zerifin, Israel*

Background: Medication-related osteonecrosis of the jaw (MRONJ) is a rare but serious complication associated with antiresorptive and antiangiogenic agents used in osteoporosis management. Although the incidence among osteoporosis patients treated with oral bisphosphonates is very low (0.001%-0.01%), risk increases with prolonged therapy, particularly beyond four years, and following invasive dental procedures. However, discrepancies between international and national guidelines regardinng MRONJ have led to inconsistency in clinical practice and treatment approaches. Despite growing awareness, studies reveal significant knowledge and practice gaps among healthcare professionals globally.

Objective: This study aims to evaluate MRONJ-related knowledge, attitudes, and preventive practices among endocrinologists and oral surgery specialists, addressing the impact of divergent guidelines on clinical decision-making and interdisciplinary collaboration.

Methods: A cross-sectional survey (January-March 2025) among oral and maxillofacial surgeons, periodontists, and endocrinologists evaluated MRONJ knowledge, risk factor awareness, clinical management, and interprofessional communication, with data analyzed using descriptive statistics and chi-square tests ($P < .05$).

Results: 112 specialists completed the survey (52 endocrinologists, 60 oral surgery specialists; Both groups demonstrated excellent medication knowledge regarding bisphosphonates and denosumab, with correct response rates exceeding 90% and 94.6%, respectively, but exhibited low levels of romosuzumab recognition (8.9%). Oral surgery specialists reported significantly higher MRONJ case experience (86.7% vs 48.1%, $P < .001$) and self-rated knowledge scores (3.60 ± 0.93 vs 3.12 ± 0.89, $P = .005$). Oral surgery specialists showed higher recognition of MRONJ risk factors: specifically smoking (46.7% vs 21.2%, $P = .004$) and prior MRONJ (25.0% vs 3.8%, $P = .002$). Endocrinologists utilized bone markers more frequently (34.6% vs 13.3%, $P = .007$). Management approaches varied considerably, particularly regarding drug holidays and timing procedures between doses, with case-dependent decisions most common for bisphosphonates (35.9%) and timing-based approaches preferred for denosumab (46.4%). Oral surgery specialists reported a slightly higher frequancy of communication between specialists as compared to endocrinologists (2.9 ± 1.4 vs 2.5 ± 1.3, $P = .154$).

Conclusions: There are significant gaps in knowledge and therapeutic approaches between endocrinologists and oral surgery specialists regarding MRONJ. Enhanced interprofessional education and standardized protocols could optimize MRONJ prevention and management.

P123 - ECE_2918 - Epicardial adipose tissue-derived extracellular vesicles in heart failure impair β-cell function and survival

Federica Bistolfi[1], Cristina Grange[1], Francesca Pedrolli[1], Iacopo Gesmundo[1], Guglielmo Gallone[1], Antonino Loforte[2], Gaetano Maria De Ferrari[1], Mauro Rinaldi[2], Stefania Bruno[1], Maria Felice Brizzi[1], Giovanni Camussi[1] and Riccarda Granata[3]
[1]*Department of Medical Sciences, University of Turin, Turin, Italy;* [2]*Department of Surgical Sciences, University of Turin, Turin, Italy;* [3]*Department of Molecular Biotechnology and Health Sciences, University of Turin, Turin, Italy*

Epicardial adipose tissue (EAT) is a metabolically active fat depot adjacent to the myocardium that undergoes pathological remodeling in cardiovascular disease, adopting a pro-inflammatory and catabolic phenotype that contributes to cardiac dysfunction. One mechanism by which EAT may exert systemic effects is through the release of extracellular vesicles (EVs) that reflect its molecular

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

and metabolic state and deliver bioactive signals to distant target organs. Pancreatic β-cells are highly vulnerable to inflammatory and metabolic stress, yet the effects of EAT-derived EVs (EPI-EVs) on β-cell function and survival in heart failure (HF) remain largely unexplored. Thus, we aimed to investigate the role of EPI-EVs on pancreatic β-cell function and survival in HF. EVs were isolated from EAT samples obtained from patients undergoing cardiac surgery and classified into four groups: control without HF, HF with preserved ejection fraction (HFpEF), HF with reduced ejection fraction (HFrEF), and advanced HFrEF. EPI-EVs, isolated by sequential ultracentrifugation, were characterized by nanosight, transmission electron microscopy, Western blotting and sensitive flow cytometry, confirming the presence of specific EV markers (CD9, CD63 and CD81), as well as adipose tissue specific genes, adiponectin and FABP4. To evaluate functional effects, rat insulinoma INS-1E β-cells were exposed to EPI-EVs (15×10^3/cell) for 24 hours. Cell viability was assessed by MTT assay, and gene expression by real-time PCR. EPI-EVs induced a progressive reduction in β-cell viability that was associated with the severity of cardiac disease. At the molecular level, EPI-EVs elicited a stress and inflammatory response, as indicated by increased mRNA expression of the endoplasmic reticulum stress marker *Chop* and the inflammatory cytokines *Il1b* and *Ifng*. In addition, EPI-EVs consistently downregulated the key β-cell transcription factor *Pdx1* across all HF groups, indicative of functional impairment and early loss of mature β-cell identity. These findings suggest a novel mechanism of heart-pancreas communication mediated by EPI-EVs, whereby cardiac disease associated alterations in EAT may contribute to β-cell stress and metabolic dysregulation in HF.

P127 - ECE_1305 - Dementia risk in type 1 and type 2 diabetes: a nationwide population-based comparison with the general population

Ji Eun Jun[1], Seohyun Kim[2], In-Kyung Jeong[1] and Jae Hyeon Kim[2]
[1]*Kyung Hee University Hospital at Gangdong, Seoul, South Korea;* [2]*Samsung Medical Center, Seoul, South Korea*

Objective: We aimed to compare the risk of all-cause dementia, Alzheimer's disease (AD), and vascular dementia (VaD) among individuals with diabetes and non-diabetic participants using a nationwide Korean cohort.

Methods: This population-based retrospective cohort study used data from the Korean National Health Insurance Service (2013-2024). A total of 1 322 651 adults aged ≥40 years without prior dementia were included. Participants were classified as non-diabetic, type 2 diabetes (T2DM) with oral hypoglycemic agents (OHA), T2DM with insulin, or type 1 diabetes (T1DM). Incident dementia was identified using ICD-10 codes and antidementia prescriptions. Multivariable Cox proportional hazards models adjusted for demographic, lifestyle, and clinical factors estimated adjusted hazard ratios (aHRs) for dementia.

Results: During follow-up, 4.3, 12.7, 17.9, and 21.1 dementia cases per 1000 person-years occurred in non-diabetic, T2DM with OHA, T2DM with insulin, and T1DM groups, respectively. Compared with non-diabetic participants, adjusted HRs for all-cause dementia were 1.29 (95% CI 1.26-1.32) for T2DM with OHA, 2.14 (2.00-2.28) for T2DM with insulin, and 2.35 (2.12-2.59) for T1DM. Similar gradients were observed for AD and VaD. Dementia risk was highest in individuals with T1DM and insulin-treated T2DM, with no significant difference between the two groups.

Conclusions: Patients with diabetes had a higher risk of dementia compared with non-diabetic individuals. Among diabetic subgroups, both T1DM and insulin-treated T2DM were associated with markedly elevated dementia risks. Proactive cognitive screening and stabilization of glycemic variability—potentially aided by continuous glucose monitoring—may help mitigate dementia risk in these high-risk groups.

Background: Type 1 diabetes is a lifelong condition characterized by glycemic instability and progressive microvascular complications that may substantially increase the risk of physical injury. Episodes of hypoglycemia and diabetes-related complications, including neuropathy and retinopathy, can impair cognition, sensation, balance, and vision, potentially increasing vulnerability to trauma. Prior limited data suggest an elevated risk of trauma and hospitalization among adults with type 1 diabetes; however, nationwide evidence assessing vulnerability to trauma among youth and young adults remains limited.

Objective: To quantify the risk of trauma-related hospitalization and severe injury in young adults diagnosed with type 1 diabetes during adolescence compared to a healthy control group.

Methods: This nationwide historical cohort study cross-referenced data from the Military Health Examinations Database (MHED) and the National Trauma Registry (INTR). The study population included individuals assessed before military recruitment between 2008 and 2020 at ages 16.5-18 years. The exposure group consisted of individuals with a type 1 diabetes diagnosis code. Analysis was conducted across two cohorts: the total population and a "Medically non-combat eligible" cohort to minimize bias from military service risks. Primary outcomes included hospitalization for injury and injury severity (ISS).

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Results: In the total population analysis ($n = 868\,982$), 2898 individuals had type 1 diabetes. The rate of trauma-related hospitalization was 1.28% ($n = 37$) in the type 1 diabetes group compared to 1.91% ($n = 16\,561$) in the non-diabetic population ($P = .013$). When restricting the analysis to the medically non-combat eligible cohort ($n = 255\,461$) to ensure comparable risk exposure, the type 1 diabetes group showed no statistically significant difference in injury rates compared to the non-diabetic control group ($n = 3690$, 1.46%; $P = .411$). Gender-stratified analyses within the non-combat cohort further confirmed no significant risk elevation for either females (0.84%; $P = .483$) or males (1.58%; $P = .384$).

Conclusions: Individuals with type 1 diabetes were not at increased risk of serious injury related hospitalization. These findings suggest that adolescents and young adults with type 1 diabetes may effectively mitigate trauma risk, potentially through heightened self-awareness, education, and preventive behaviors.

P129 - ECE_2172 - SGLT2 inhibitors and cardiovascular effects in kidney transplant recipients with diabetes mellitus

Idit Dotan[1,2], Amir Polansky[1,2], Idan Bergman[2,3], Gida Ayada[2,3], Tanya Babich[2,4], Amit Akirov[1,2], Tali Steinmetz[2,5] and Talia Diker Cohen[1,2]

[1]Rabin Medical Center, Beilinson Campus, Institute of Endocrinology, Diabetes and Metabolism, Petah Tikva, Israel; [2]Gray Faculty of Medicine and Health, Tel Aviv University, Tel Aviv, Israel; [3]Rabin Medical Center, Beilinson Hospital, Internal Medicine C, Petah Tikva, Israel; [4]Hod Hasharon, Israel; [5]Rabin Medical Center, Beilinson Campus, Institute of Nephrology, Petah Tikva, Israel

Objectives: SGLT2 inhibitors (SGLT2i) reduce major adverse cardiovascular events and mortality in patients with type 2 diabetes mellitus (T2DM), but kidney transplant recipients (KTRs), a high-risk group, were excluded from major trials. We aimed to evaluate the cardiovascular effects of SGLT2i in KTRs with diabetes.

Methods: In this retrospective matched-cohort study at a large transplant center, KTRs with diabetes treated with SGLT2i were compared to matched controls receiving other antihyperglycemic agents. Major outcomes were: (1) a composite of acute coronary syndrome (ACS), stroke/transient ischemic attack (TIA), or all-cause mortality; and (2) a composite of heart failure hospitalizations or all-cause mortality.

Results: A total of 480 patients (240 per group; 20% women; median age 63-64 years) were followed for up to three years. The incidence of ACS, stroke/TIA, or death was 7.9 vs 13.6 events per 100 person-years in the SGLT2i and control groups, respectively (adjusted HR 0.64, 95% CI 0.42-0.97, $P = .039$). Heart failure hospitalizations or death occurred less frequently in SGLT2i users (5.7 vs 11.6 events per 100 person-years), though the difference was not statistically significant after adjustment (HR 0.82, 95% CI 0.50-1.32, $P = .410$).

Conclusions: SGLT2i use was associated with a lower risk of major cardiovascular events in KTRs with diabetes, consistent with benefits observed in non-transplant populations. Given the elevated cardiovascular risk in KTRs, these findings support further investigation of SGLT2i therapy in this population.

P130 - ECE_1089 - Euglycemic diabetic ketoacidosis revealing atezolizumab-induced type 1 diabetes in a patient with type 2 diabetes

Oğuzhan Kara[1], Seda Nur Yalçın[1], Nisa Babacanlar[1], Mustafa Can Senoymak[1], Mina Karakullukcu[2] and Arif Yonem[1]

[1]Endocrinology Clinic, Department of Endocrinology and Metabolism, Sultan 2. Abdulhamid Han Training and Research Hospital, Istanbul, Türkiye; [2]Department of Medical Oncology, Sultan 2. Abdulhamid Han Training and Research Hospital, Istanbul, Türkiye

Introduction: Although diabetic ketoacidosis (DKA) is typically associated with type 1 diabetes mellitus (T1DM), certain antidiabetic agents have been linked to atypical forms of DKA. In particular, SGLT2 inhibitors promote urinary glucose excretion and may precipitate ketosis despite near normal blood glucose levels, a condition known as euglycemic DKA. Immune checkpoint inhibitors (ICIs) enhance antitumor immune responses while potentially triggering autoimmune reactions against pancreatic β-cells. Consequently, new-onset type 1 diabetes may develop in patients previously diagnosed with type 2 diabetes mellitus (T2DM). In this case, a patient with T2DM receiving an SGLT2 inhibitor and treated with atezolizumab for small cell lung cancer (SCLC) presented with euglycemic DKA, which was subsequently attributed to atezolizumab-induced type 1 diabetes.

Case Presentation: A 52-year-old woman with a 4-year history of T2DM and a diagnosis of SCLC 3 months prior presented to the emergency department with polydipsia and increased appetite. On physical examination mildly decreased skin turgor was noted, while other systemic examinations revealed no significant abnormalities. Laboratory studies showed arterial blood gas pH: 7.06, HCO_3^-: 8 mmol/L, urine ketone 3+, and urine glucose 3+. Blood glucose was 196 mg/dL. These findings were consistent with euglycemic DKA. The patient had etoposide–carboplatin–atezolizumab chemotherapy initiated approximately two months ago for extensive stage SCLC, with a pre-treatment HbA1c level of 7.0%. During the treatment course, the patient was using metformin and empagliflozin, and the third dose of atezolizumab had been administered 10 days prior. The patient was managed with intravenous isotonic fluids, 5% dextrose, insulin infusion, and potassium replacement. Oral antidiabetic medications were discontinued. The patient resolved from DKA by hospital day 2, continuing with basal-bolus insulin therapy thereafter. Follow-up evaluation for ICI-associated T1DM revealed negative anti-insulin and islet cell antibodies, but anti-GAD antibody was positive at 182 IU/mL and C-peptide level was 0.22 ng/mL. The patient's HbA1c was 7.72%. Based on these findings a diagnosis of atezolizumab-induced new-onset T1DM was made. Basal-bolus insulin therapy was continued and the patient was discharged after achieving clinical stabilization.

Conclusions: This case highlights the potential for euglycemic DKA in patients with preexisting T2DM who are treated with SGLT2 inhibitors and concurrently receive ICIs. Clinicians should maintain a high index of suspicion for ICI-induced new-onset T1DM, even in patients previously diagnosed with T2DM, particularly when presenting with atypical DKA. Early recognition and

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

prompt initiation of insulin therapy are crucial to prevent morbidity and ensure safe continuation of oncologic treatment.

P131 - ECE_1459 - Proportion of diabetes of the exocrine Pancreas among adult patients classified as type 2 diabetes mellitus and evaluation of gut-pancreatic hormones for its detection

Ankitesh Kumar[1,2], Sv Madhu[1], Nishant Raizada[1] and Shuchi Bhatt[3]
[1]Endocrinology, University College of Medical Sciences, New Delhi, India; [2]Endocrinology, Sitaram Bhartia Institute of Science and Research, New Delhi, India; [3]Radiology, University College of Medical Sciences, New Delhi, India

Introduction: Diabetes of the exocrine pancreas (DEP), or type 3c diabetes mellitus, is frequently misclassified as type 2 diabetes mellitus (T2DM) with significant clinical implications. It is characterised by altered gut-pancreatic hormone responses that may help differentiate DEP from T2DM.

Methodology: This cross-sectional observational study included 310 adults with apparent T2DM attending an endocrinology clinic. Patients with type 1 diabetes mellitus (anti GAD antibody positive), major comorbidities, prior pancreatitis, prior pancreatic or upper gastrointestinal surgery, pregnancy, or incretin-based therapy were excluded. All participants underwent clinical and biochemical evaluation with fecal elastase-1 testing; CT with pancreatic protocol was performed in those with fecal elastase-1 <200 µg/g to confirm DEP according to Ewald criteria. Pancreatic polypeptide (PP) response to a mixed meal was assessed in all participants, while mixed-meal testing for peptide-YY (PYY), ghrelin, and C-peptide was performed in a predefined subgroup. Statistical analyses included non-parametric tests, receiver operating characteristic analysis, and ANCOVA for age, sex, and BMI.

Results: DEP was diagnosed in 51 of 310 participants (16.45%), with 71% being asymptomatic for clinical features of exocrine insufficiency. Compared with T2DM, DEP patients had a lower BMI, worse glycaemic control, and a higher prevalence of diabetic neuropathy, while rates of retinopathy and nephropathy were similar. PP levels at baseline and 30 mins did not differ between DEP and T2DM (AUC <0.55). Hormonal analyses in a subgroup of 80 patients (40 DEP, 40 T2DM) showed significantly lower fasting and post-mixed meal C-peptide levels in DEP, with good diagnostic accuracy (AUC 0.76 and 0.69) and high sensitivity (95% and 92%) but modest specificity (50% and 47.5%) at 0 and 30 minutes, respectively. PYY response at 30 minutes and PYY fold rise (0-30 minutes) were also reduced in DEP ($P = .003$ and $P = .015$), with an AUC 0.69 and 0.66 respectively, with specificity of 87.5% for PYY (30 minutes) and sensitivity of 82.5% for fold rise. Ghrelin responses did not differ significantly between groups and showed no discriminatory value. Differences in PYY and C-peptide parameters remained significant after adjustment for age, sex, and BMI.

Discussion and Conclusions: DEP accounted for 16.45% of adults with apparent T2DM and was frequently clinically silent. PP lacked diagnostic utility. Whereas reduced c-peptide and impaired postprandial PYY responses characterised DEP in a subgroup, while ghrelin didn't differ. A diagnostic strategy combining fecal elastase-guided imaging with selective hormonal assessment may improve recognition and classification of DEP, with important implications for clinical management.

P132 - ECE_3255 - Disulfiram attenuates high-fat diet–induced metabolic dysfunction in a rat model of metabolic syndrome

Ondřej Šeda[1], Hana Malínská[2], Irena Marková[2], Martina Hüttl[2], Blanka Chylíková[1] and Lucie Šedová[1]
[1]First Faculty of Medicine, Charles University, Institute of Biology and Medical Genetics, Prague, Czech Republic; [2]Center for Experimental Medicine, Institute for Clinical and Experimental Medicine, Prague, Czech Republic

Disulfiram (DSF) is a traditional drug used in the treatment of alcohol dependence, but recently its effects on limiting tumor proliferation, inflammation, and various aspects of metabolic syndrome have been described. The aim of this study was to analyze the effect of DSF administration in a model of metabolic syndrome, the inbred PD strain of laboratory rats.

Methods: Adult male PD rats were fed for 7 weeks a standard diet (STD, $n = 7$), high-fat diet (HFD; ssniff E15186-347, $n = 9$), or HFD supplemented with DSF (0.25 g/kg; $n = 9$), followed by comprehensive metabolic phenotyping (oral glucose tolerance test, insulin, lipid profile, leptin, Fibroblast Growth Factor 21, and hepatic triacylglycerols (TAG) and cholesterol) and transcriptome profiling of liver and visceral adipose tissue (Affymetrix GeneChip Rat Gene 2.1 ST array; multiple comparison adjustment -FDR <0.05, fold change >20%).

Results: As expected, HFD induced marked metabolic deterioration, including increased body weight and adiposity, impaired glucose tolerance, elevated plasma and hepatic TAG, hyperinsulinemia and hyperleptinemia, and reduced HDL cholesterol. Co-administration of DSF with HFD normalized body weight, plasma TAG, total cholesterol, and fasting insulin; glucose tolerance, leptinemia, and hepatic TAG were significantly improved vs HFD but remained above STD levels. Transcriptomic analyses mirrored these physiological effects: HFD caused extensive gene-expression remodeling in both tissues (liver: 895 significantly altered transcripts; visceral adipose: 411), whereas DSF largely blunted the HFD-driven transcriptional changes. Consistent with partial normalization, the disulfiram-treated group displayed substantially fewer residual differences relative to STD (liver: 220 transcripts; adipose: 108) compared with HFD alone. There was a strong counteracting pattern of DSF actions in liver including genes related to lipid/cholesterol metabolism regulators *like Dhcr7, Fads1, Pcsk9, Acacb* and others.

Conclusions: DSF significantly mitigated the adverse metabolic effects of HFD and broadly reversed the accompanying tissue transcriptomic perturbations, supporting DSF as a candidate for repurposing to counteract diet-induced metabolic dysfunction.

P133 - ECE_1408 - Rhein antagonizes glucocorticoid receptor signaling to activate SIRT1-dependent thermogenesis in brown adipose tissue and ameliorate obesity

Hannah Hui
Hong Kong, Hong Kong

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Rhein, a natural anthraquinone derivative, has emerged as a promising therapeutic agent for combating obesity, while its detailed mode of action is unknown. In this study, we unravel that Rhein acts as an antagonist of glucocorticoid receptor (GR) and thereby enhances SIRT1 protein stability followed by brown adipose tissue (BAT) activation. Rhein-treated mice were resistant to diet-induced obesity, reduced adiposity and exhibited improved glucose tolerance, insulin sensitivity. Notably, Rhein augmented BAT thermogenic activity, and thereby enhanced the whole body energy expenditure of the mice. Mechanistically, Rhein enhances SIRT1 expression which in turn boosts mitochondrial biogenesis and thermogenic function in BAT. Adipocyte-selective ablation of SIRT1 almost completely abolished Rhein's anti-obesity and thermogenic effects, confirming SIRT1 as a critical mediator. Furthermore, we identified ARGLU1, a GR co-activator, as a direct Rhein-binding protein. Rhein antagonized GR/ARGLU1 signaling, thereby relieving GR-mediated suppression of JNK activity. Activated JNK subsequently phosphorylated and stabilized SIRT1 protein, establishing a novel Rhein-ARGLU1-GR-JNK-SIRT1 regulatory axis in BAT. Importantly, Rhein effectively counteracted corticosterone-induced obesity, SIRT1downregulation and BAT whitening in vivo. Our findings reveal Rhein as a potent BAT activator that ameliorates metabolic dysfunction through modulation of GR signaling, offering new therapeutic strategies for obesity and glucocorticoid-related endocrine disorders.

P134 - ECE_3275 - Metabolic dysfunction-associated steatotic liver disease is associated with vascular dysfunction in type 1 diabetes

Jonathan Mertens[1], Hilde Heuten[2], Eveline Dirinck[2], Sven Francque[3] and Christophe De Block[1]
[1]*Endocrinology, diabetology and metabolism, Antwerp University Hospital, Edegem, Belgium;* [2]*Cardiology, Antwerp University Hospital, Edegem, Belgium;* [3]*Gastroenterology and hepatology, Antwerp University Hospital, Edegem, Belgium*

Introduction: Metabolic dysfunction-associated steatotic liver disease (MASLD) is linked to atherosclerotic cardiovascular disease (ASCVD). Markers of arterial stiffness & subclinical atherosclerosis (carotid-femoral pulse wave velocity [cfPWV], carotid-intima media thickness [CIMT]) and endothelial dysfunction (flow-mediated dilation [FMD], nitroglycerine-induced dilation [NID]) might aid in ASCVD risk reclassification. This study examined the association between MASLD and markers of vascular dysfunction in type 1 diabetes (T1D).

Methods: We performed cross-sectional vascular assessments in non-smoking adults with T1D without ASCVD. MASLD was determined by ultrasound-assisted transient elastography. FIB-4 was calculated as an index for fibrosis. ASCVD risk was predicted using the validated Steno Type 1 Risk Engine. Subjects were included in a 2:1 control-to-case ratio and matched for age and diabetes duration.

Results: We examined 105 subjects, 30 had MASLD. Mean age was 51.7 ± 15.7 years, mean diabetes duration was 29.9 ± 14.3 years. Fifty percent were male, mean HbA1c was 55.1 ± 9.5 mmol/mol. MASLD was associated with lower NID (15.3 ± 6.3 vs 20.1 ± 7.5%, $P = .003$). NID and cfPWV were more often impaired in people with MASLD (53.3% vs 28.4%, $P = .018$, 56.7% vs 35.1%, $P = .043$, respectively). In adjusted multivariable logistic regression, MASLD was associated with increased cfPWV (OR 8.30, 95% CI 1.25-55.2, $P = .029$), as were age, sex and mean arterial pressure. cfPWV and CIMT strongly correlated with 5-year ASCVD risk (cfPWV $\rho = 0.76$, CIMT $\rho = 0.81$, $P < .001$), as did FIB-4 ($\rho = 0.74$, $P < .001$). CIMT (0.93), cfPWV (0.88) and FIB-4 (0.88) yielded the highest AUROC to identify significant ASCVD risk.

Conclusions: cfPWV is the most robust vascular marker associated with MASLD in people with T1D. cfPWV, CIMT and FIB-4 correlated strongly to incident 5-year ASCVD risk.

P135 - ECE_1009 - Deletion of FGFR1 in hypothalamic neurons alters energy homeostasis and negates the metabolic effects of α-klotho

Hu Huang[1,2]
[1]*Kinesiology, Physiology, East Carolina University, Greenville, United States;* [2]*Kinesiology, Physiology, East Carolina Dibetes and Obesity Institute, Greenville, United States*

Background: The global obesity epidemic highlights the need for novel therapeutic targets. While central administration of α-Klotho shows promise in ameliorating metabolic dysfunction in rodent models, the underlying molecular and cellular mechanisms remain poorly defined. Given that α-Klotho signals through fibroblast growth factor receptors (FGFRs), we hypothesized that FGFR1 in specific hypothalamic neuronal populations is critical for metabolic homeostasis.

Methods: To investigate the metabolic role of FGFR1 in the arcuate nucleus of adult mice, we employed an AAV-mediated CRISPR/Cas9 system, coupled with transgenic models, to achieve cell-type-specific deletion of FGFR1 in mature glutamatergic, GABAergic, and AgRP neurons.

Results: We found that selective deletion of FGFR1 in GABAergic neurons, but not in glutamatergic neurons, induced a profound disruption of energy balance, resulting in obesity characterized by excessive weight gain and increased adiposity. Targeted deletion of FGFR1 specifically within AgRP neurons recapitulated most of these phenotypes. Furthermore, FGFR1 deletion in AgRP neurons blocked α-Klotho signaling and abolished the ability of α-Klotho to modulate AgRP activity and eliminated its therapeutic benefits on glucose and energy metabolism.

Conclusions: Our findings establish FGFR1 signaling in arcuate nucleus GABAergic and AgRP neurons as an essential component of the pathway through which α-Klotho regulates systemic energy homeostasis, identifying it as a critical molecular target for anti-obesity therapeutics.

Conflicts of interest: The authors declare no conflicts of interest.

P137 - ECE_2819 - Classification of diabetes subtypes in the All New Diabetics in Scania (ANDIS) study and comparison with Swedish National Diabetes Register (NDR) diagnoses

Shobitha Vollmer[1], Alice Maguolo[2], Axel Lindström[2], Sonia García-Calzón[3], Emma Ahlqvist[2], Katarina Fagher[1] and Charlotte Ling[2]

[1]Epigenetics and Diabetes Unit, Department of Clinical Sciences Malmö, Lund University, Skane University Hospital, Malmö, Sweden; [2]Lund, Sweden; [3]University of Navarra, Pamplona, Spain

Objective: Classifying diabetes in registry-based studies is challenging. Since 2008, adults with newly diagnosed diabetes have been registered in the All New Diabetes in Scania (ANDIS) study. Our aims are: 1) classify ANDIS individuals into diabetes subtypes using baseline and follow-up clinical data; 2) compare clinical characteristics across diabetes subtypes; 3) compare ANDIS diabetes subtypes with Swedish National Register (NDR)-reported diagnoses.

Methods: Baseline clinical data for 18 985 adults with newly diagnosed diabetes were included from ANDIS, with follow-up data, including ICD-10 codes for diagnoses and mortality, medication dispensations and laboratory results, obtained from NDR, the National Board of Health and Welfare, and regional healthcare databases. Using a new method adapted to registry-based data following ADA and EASD guidelines, individuals were classified to diabetes subtypes based on available clinical data, including autoantibodies, C-peptide levels and insulin treatment. These subtypes were compared with NDR-reported diabetes diagnoses.

Results: Individuals were classified as having type 1 diabetes (T1D, $n = 630$; 3.3%), type 2 diabetes (T2D, $n = 17\,475$; 92%), LADA ($n = 689$; 3.6%), type 3c ($n = 86$; 0.5%) or unspecified diabetes ($n = 105$; 0.5%). Individuals classified as T1D differed markedly from those with T2D regards to age, BMI, comorbidities and complications. LADA showed clinical characteristics largely overlapping with T2D, whereas type 3c individuals were often older, leaner, with more comorbidities and higher HbA1c. Only 87.4% of individuals had an NDR-reported diagnosis, of which 2957 had different diagnoses in NDR compared with our classification. Chi-squared test comparing our classification with NDR showed significant difference.

Discussion: Most individuals were classified as having T2D with the remaining classified into T1D, LADA, type 3c or unspecified, consistent with expected prevalences of these subtypes in literature. Baseline characteristics compared across subtypes highlighted clinical differences in diabetes onset and complications attributable to differing aetiologies. Comparison with NDR-reported diagnoses demonstrated substantial improvement with our classification as NDR does not distinguish between T1D and LADA or include type 3c. Most mismatched diagnoses were due to individuals classified as T2D in NDR but LADA in our cohort or unknown in NDR but T2D in ours, reflecting the management of preserved insulin secretion and the impact of missing data, overlapping diagnoses or fear of misclassification in clinical settings respectively.

Conclusions: We demonstrate that systematic classification following established guidelines and adapted to registry-based data can reliably distinguish diabetes subtypes in large cohorts and reveal heterogeneity that may be overlooked in registries, improving individualised analysis and research practices in diabetes precision medicine.

P138 - ECE_2898 - Robo4: a key endothelial link between atherosclerosis and MASLD?

Christina-Maria Flessa[1], Ioannis Kyrou[2], Maria-Eleni Chondrogianni[1,3], Narges Nasiri Ansari[1], George Agrogiannis[4], Maria Lianou[1], Antonios Chatzigeorgiou[5], Harpal S. Randeva[2] and Eva Kassi[1,3]

[1]Department of Biological Chemistry, Medical School, National and Kapodistrian University of Athens, Athens, Greece; [2]University Hospitals Coventry and Warwickshire NHS Trust, Coventry, CV2 2DX, United Kingdom; [3]Endocrine Unit, 1st Department of Propaepeudic Internal Medicine, Laiko Hospital, National and Kapodistrian University of Athens, Athens, Greece; [4]First Department of Pathology, Medical School, National and Kapodistrian University of Athens, Athens, Greece; [5]Department of Physiology, Medical School, National and Kapodistrian University of Athens, Athens, Greece

Introduction: Endothelial dysfunction plays a critical role in all stages of atherogenesis. Metabolic dysfunction–associated steatotic liver disease (MASLD) is closely associated to increased cardiovascular risk. Robo4 is an endothelial-specific receptor that regulates cell migration, angiogenesis, and vascular integrity and is expressed in liver sinusoidal endothelial cells, positioning it as a possible molecular link between cardiovascular disease (CVD) and hepatic disease.

Aim: To investigate the role of Robo4 expression in the atherosclerosis process and in MASLD development.

Materials and Methods: Robo4(-/-) mice were crossed with ApoE(-/-) mice, an established model of atherosclerosis that develops MASLD following high-fat diet (HFD) feeding. Robo4(-/-), ApoE(-/-), and ApoE(-/-)/Robo4(-/-) mice were fed HFD for 15 weeks starting from their 6th week of age to accelerate atherosclerotic plaque formation and liver disease development. After sacrifice, aortas and livers were harvested for histomorphometric analysis of aortic root and liver sections. RNA was isolated from aortic and hepatic tissues and qPCR was performed to assess the expression of genes involved in inflammation, endothelial activation, extracellular matrix remodeling, lipid uptake and synthesis, and MASLD susceptibility, including MMP-2, MMP-9, TIMP-1, TIMP-2, IL-6, MCP-1, ICAM-1, VCAM-1, PNPLA3, TM6SF2 in liver and aorta, and CD36, ApoB, IL-1α, IL-1β, TNF-α, CCL-7, AGPAT-2, and GPAT-3 in liver.

Results: Histomorphometry of the aortic root showed atherosclerotic plaques in 100% of ApoE(-/-) mice, 66% of ApoE(-/-)/Robo4(-/-) mice, and none in Robo4(-/-) mice. Aortic MCP-1 mRNA was increased in ApoE(-/-)/Robo4(-/-) vs Robo4(-/-), while TIMP-1 and TIMP-1/MMP-2 were higher in ApoE(-/-) compared to Robo4(-/-) ($P < .05$). ApoE(-/-)/Robo4(-/-) aortas showed reduced VCAM-1 and TM6SF2 and increased PNPLA3 mRNA compared to ApoE(-/-), approaching significance ($p \leq 0.09$). Notably, liver histomorphometry revealed more severe MASLD in Robo4(-/-) mice, with significantly higher NAS scores than ApoE(-/-)/Robo4(-/-)

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

and ApoE(-/-) mice ($P = .03$ and $P = .002$, respectively). Hepatic TM6SF2 mRNA was increased in Robo4(-/-) mice compared to ApoE(-/-)/Robo4(-/-) ($P \leq .09$) and ApoE(-/-) mice ($P < .05$). Robo4(-/-) livers exhibited reduced MMP-9, CD-36, TIMP-1, TIMP-1/MMP-2, CCL-7, PNPLA3 levels vs ApoE(-/-)/Robo4(-/-) ($P < .05$), with AGPAT-2 and GPAT-3 also reduced, approaching significance ($P \leq 0.09$). Taken together, it appears that Robo4 loss mainly affects the lipoprotein and triglyceride handling during atherogenesis and MASLD progression.

Conclusions: Robo4 loss reduces atherosclerosis but paradoxically exacerbates MASLD, in an established ApoE(-/-) mouse model of atherosclerosis and MASLD, highlighting tissue-specific roles in cardiovascular–metabolic disease crosstalk. Further studies are needed to delineate the precise mechanisms mediating these effects.

P140 - ECE_2381 - Phoenixin—a novel modulator of proliferation and differentiation of rat brown preadipocytes

Joanna Fiedorowicz, Małgorzata Krążek, Tatiana Wojciechowicz and Marek Skrzypski
Department of Animal Physiology and Biochemistry, Poznań University of Life Sciences, Poznań, Poland

Phoenixin (PNX) is a neuropeptide derived from the SMIM20 protein that plays a significant role in reproduction and metabolism. Recent studies show that PNX is involved in white adipogenesis, but its role in brown adipogenesis remains unknown. This study examined SMIM20 and GPR173 (putative PNX receptor) expression during rat brown preadipocytes differentiation and in brown adipose tissue (BAT) from young (5-6 weeks) and adult (16-18 weeks) rats, as well as PNX effects on brown preadipocytes proliferation and differentiation.

Brown preadipocytes were isolated from intracapsular BAT of male Wistar rats (100-120 g). Gene expression was analyzed by real-time PCR and protein levels by Western blot. Cell proliferation was assessed using BrdU incorporation, lipid accumulation via Oil Red O staining, and intracellular cAMP levels by ELISA.

During brown preadipocytes differentiation, *Smim20* mRNA expression decreased while PNX protein levels increased. *Gpr173* mRNA was upregulated during differentiation, though this was not reflected at the protein level. In BAT, *Smim20* mRNA expression was higher in young vs adult rats, whereas PNX protein levels showed the opposite pattern. *Gpr173* mRNA expression was elevated in adults, while protein production remained unchanged. Furthermore, PNX increased brown preadipocytes proliferation after 24 hours (100 nmol/L) and 48 hours (10 and 100 nmol/L), accompanied by elevated intracellular cAMP levels and enhanced ERK1/2 phosphorylation, but not AKT. In addition, PNX did not induce preadipocytes proliferation in the presence of H89 (PKA inhibitor), U0126 (ERK1/2 inhibitor), ESI-09 (noncyclic nucleotide EPAC antagonist). These findings indicate that PNX promotes brown preadipocytes proliferation via PKA-, Epac-, and ERK1/2-dependent mechanisms. Furthermore, PNX (100 nmol/L) upregulated UCP1 expression at both the mRNA and protein levels in brown preadipocytes differentiated for 7 days. Among transcription factors modulating brown adipogenesis (*Pparγ, Pgc1a, Prdm16, Cebpα, Cebpβ*), only *Pparγ* mRNA expression was significantly increased by 100 nmol/L PNX treatment, with corresponding elevation in PPARγ protein levels during 7 days of differentiation of brown preadipocytes. Moreover, PNX (100 nmol/L) enhanced *Fgf21* mRNA expression, while 10 and 100 nmol/L PNX stimulated FGF21 protein production in brown preadipocytes differentiated for 7 days. PNX did not affect lipid accumulation. These results demonstrate that PNX enhances UCP1 and FGF21 production in rat brown adipocytes.

Overall, the results indicate that PNX may regulate energy homeostasis by modulating the proliferation and differentiation of brown preadipocytes in rats.

Background: Immune checkpoint inhibitors (ICIs) are increasingly used as first-line therapy for melanoma and are associated with immune-related adverse events (irAEs), particularly involving the endocrine system. ICI-associated diabetes mellitus (ICI-DM) is an uncommon but potentially life-threatening complication, often presenting abruptly and requiring lifelong insulin therapy.

Objective: To evaluate the incidence, clinical characteristics, and associated endocrine phenotypes of ICI-DM in patients with melanoma treated with ICIs.

Methods: This retrospective study included adults (>18 years) with melanoma who received ICIs as first-line therapy between 2023 and 2026. Eligible patients were those who developed new-onset DM following initiation of immunotherapy or experienced deterioration of pre-existing diabetes requiring insulin therapy. The diagnosis of ICI-DM was further supported by the presence of pancreatic autoantibodies, diabetic ketoacidosis (DKA), and/or reduced or absent C-peptide levels.

Results: Among 853 patients treated with ICIs, 29 patients (15 males) with a median age of 72 years (range: 44-85) met the criteria for ICI-DM. These cases accounted for 10.9% (29/265) of all endocrine-related irAEs observed in the study population. Twenty-three patients (79.3%) received anti– Programmed Death-1 (PD-1)/ Programmed Death Ligand-1 PD-L1 monotherapy (PD-L1), while 4 patients (13.8%) were treated with a combination of anti–PD-1/PD-L1 and anti– Cytotoxic T-Lymphocyte-Associated protein 4 (CTLA-4) therapy. No cases of ICI-DM were observed in

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

patients treated with anti–CTLA-4 alone. The median body mass index was 26.6 kg/m^2 (range: 18.6-36.9). Eighteen patients (62.1%) developed new-onset ICI-DM, while 11 patients (37.9%) had pre-existing diabetes progressing from oral antidiabetic agents to basal–bolus insulin therapy. Five patients (17%) had a medical history of hypothyroidism. Concomitant endocrine irAEs were observed in 19 patients (65.5%). Specifically, ir- hypothyroidism occurred in 8 patients (27.6%), ir-thyroiditis in 2 patients (6.9%), and ir- hypophysitis with corticotrope axis insufficiency in 9 patients (31.0%). Among patients with new-onset ICI-DM, 9 patients (31.0%) presented with DKA at diagnosis. Anti–glutamic acid decarboxylase antibodies were detected in 3 of 17 tested patients (17.6%), while reduced or undetectable C-peptide levels were documented in 7 of 23 patients (30.4%), indicating significant β-cell dysfunction.

Conclusions: ICI-DM occurred in the 3.3% of melanoma patients treated predominantly with PD-1/PD-L1 inhibitors and represented approximately the 11% of all endocrine irAEs. Most cases presented as new-onset insulin-dependent DM, and nearly one-third manifested with DKA, highlighting the need for early recognition and prompt management. The frequent coexistence of other endocrine irAEs suggests a broader autoimmune endocrine phenotype.

P142 - ECE_2889 - Diazoxide choline extended-release (DCCR) improves hyperphagia in both children and adults with Prader-Willi Syndrome

Evelien Gevers[1], Jennifer Miller[2], Lynne Bird[3], Heidi Shea[4], Ashley Shoemaker[5], Jennifer Abuzzahab[6], Parisa Salehi[7], Theresa Strong[8], Lisa Matesevac[8], Jessica Bohonowych[8], Jing Gong[9], Michael Huang[9] and Anish Bhatnagar[9]

[1]Centre for Endocrinology, Queen Mary University of London, Barts and The London Medical School, William Harvey Research Institute, London, United Kingdom; [2]University of Florida, Gainesville, United States; [3]Rady Children Hospital of San Diego, San Diego, California, United States; [4]Endocrine Associates of Dallas, Plano, United States; [5]Vanderbilt University, Nashville, United States; [6]Childrens Minnesota, St. Paul, United States; [7]Seattle Children's, Seattle, United States; [8]Foundation Prader Willi Research, Walnut, California, United States; [9]Soleno Therapeutics Inc., Redwood City, California, United States

Introduction: Prader-Willi syndrome (PWS) is a rare genetic condition characterized by hyperphagia, excess body fat accumulation, hypotonia, and behavioural/psychological complications. DCCR (diazoxide choline extended- release) is an oral, once-daily medication in development for the treatment of patients with PWS who have hyperphagia. To assess DCCR efficacy in improving hyperphagia, we compared data of both children and adults with PWS from a DCCR-treated cohort to a matched untreated historical cohort.

Methods: Pooled data from the multicentre, Phase 3 DCCR studies (C601/C602) were compared with patient-level data from untreated participants in the Paving the Way for Advances in the Treatments & Health (PATH) for PWS Natural History Study (NHS). The two cohorts (DCCR-treated/untreated) were matched for age, hyperphagia severity, and body weight. Hyperphagia was assessed using the Hyperphagia Questionnaire for Clinical Trials (HQ-CT), a 9-item scale (0-36), with higher scores representing more severe hyperphagia. Participants were included in the analysis if they had at least one HQ-CT assessment performed approximately 6 months post-baseline. Participants were classified as children (<18 years) or adults (≥18 years).

Results: A total of 123 participants from C601/C602 studies (DCCR-treated cohort) and 229 PATH participants (untreated cohort) were included. Children (<18 years) and adults, respectively, comprised 80.5% ($N = 99$) and 19.5% ($N = 24$) of participants in the C601/C602 cohort, and 56.3% ($N = 129$) and 43.7% ($N = 100$) in the PATH cohort. Mean (standard deviation) baseline HQ-CT total scores in children and adults, respectively, were 22.1 (6.7) and 19.4 (6.4) in the DCCR-treated cohort, and 18.5 (5.3) and 17.9 (4.6) in the untreated cohort.

DCCR-treated children and adults had significantly greater reductions in HQ-CT total scores, indicating an improvement in hyperphagia, compared with untreated historical controls at week 26, and this benefit was sustained through week 52 (Table 1).

Table 1 LS mean difference in reductions in HQ-CT total scores in DCCR-treated vs untreated controls.

	Week 26	Week 52
Children (<18 years)	−5.8 (95% CI: −7.8, −3.9) $P < .0001$	−6.4 (95% CI: −8.5, −4.3) $P < .0001$
Adults (≥18 years)	−6.3 (95% CI: −10.1, −2.5) $P = .0015$	−4.3 (95% CI: −8.0, −0.6; $P = .0236$

Conclusions: Results of our analysis demonstrate that DCCR administration significantly reduced hyperphagia in both children and adults with PWS. HQ-CT total score improvements at 26 weeks (first available time point) were sustained at least through 52 weeks. Findings demonstrate that DCCR has prolonged efficacy across different age groups and strengthen its role as an effective treatment for hyperphagia in people with PWS.

P143 - ECE_1310 - EDL6D an SHBG mimetic peptide: a new approach for treating the metabolic dysfunction-associated fatty Liver Disease

Anna Alvarez-Guaita[1], Beatriz Perez-Gonzalez[1], Maria Teresa Salcedo Allende[2], Lidia Fuertes Rioja[1], Lorena Ramos Perez[1], Cristina Hernandez[1], Rafael Simo Canonge[1] and David M Selva[1]

[1]Diabetes and Metabolism, Vall d'Hebron Research Institute, Barcelona, Spain; [2]Pathology, Hospital Vall d'Hebron, Barcelona, Spain

Metabolic dysfunction-associated fatty liver disease (MASLD) is linked to low plasma levels of sex hormone-binding globulin (SHBG). Previous studies showed that SHBG overexpression reduces liver fat accumulation by inhibiting lipogenesis. In the present work, we have developed an SHBG mimetic peptide (EDL6D) that could be used as a new treatment to prevent and treat MASLD development and arrest its progression to MASH. We have first tested the EDL6D effects in in vitro experiments using HepG2 cells treated daily with 30 mM fructose. We next have

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

studied the preventive and therapeutic effects of EDL6D using wild-type mice developing MASLD induced by high fat diet and 30% fructose in the drinking water over 8 and 20 weeks respectively. Our results clearly showed that the treatment with EDL6D was able to reduce liver fat accumulation and regress MASLD by reducing the mRNA expression and protein levels of key lipogenic enzymes (ACLY, ACC and FAS) as well as PPARγ. Moreover, EDL6D was able to prevent the development of mild fibrosis, which can be attributed to its capacity to downregulates the intrahepatic production of collagen 1A1 (Col1A1) and transforming growth factor beta 1 (TGF-β1). In summary, we have shown that EDL6D, an SHBG mimetic peptide reduces de novo and exerts an important anti-inflammatory effect preventing fibrosis development in MASLD mouse models. These results suggested that EDL6D could be used as a new treatment to prevent and treat MASLD development and arrest its progression to MASH.

P145 - ECE_1652 - Chemosensory dysfunction as identifier of metabolic–microbiome phenotype in patients with type 2 diabetes

Stylianos Kopanos[1], Sebastian Büscher[2], Julia Hassa[3], Timm Weber[4], Sarah Büyükdag[1], Tobias Purschke[1], Michael Wehmeier[5], Gabriele Anton[4], Tobias Busche[3], Annika Hoyer[2] and Joachim Feldkamp[1]

[1]Academic Department of General Internal Medicine, Endocrinology, Diabetes and Infectiology, Bielefeld University, Medical School and University Medical Center East Westphalia-Lippe, Bielefeld, Germany; [2]Medical School OWL, Bielefeld University, Biostatistics and Medical Biometry, Bielefeld, Germany; [3]Medical School East Westphalia-Lippe & Center for Biotechnology (CeBiTec), Bielefeld University, Bielefeld, Germany; [4]Medical School OWL, Bielefeld University, Biobank OWL (BOWL), Bielefeld, Germany; [5]Microbiology and Transfusion Medicine, University Medical Center OWL, Institute of Medical Laboratory Diagnostics, Bielefeld, Germany

Background: Type 2 diabetes mellitus (T2DM) is associated with multisystem metabolic dysfunction. Chemosensory impairment remains underrecognized despite its relevance for nutrition and metabolic control, while gut microbiome dysbiosis may mechanistically link metabolic disease and sensory dysfunction.

Methods: In this prospective clinical study, 146 adults (66 T2DM, 80 non-diabetic controls) underwent standardized assessment of taste and smell, neuropathy scoring (MNSI), and metabolic phenotyping. Stool samples from 146 participants were analysed using 16S rRNA gene sequencing. Group comparisons used non-parametric tests with false discovery rate correction. Multivariable regression models adjusted for age, sex, obesity, and COVID history were applied. Microbiome analyses included diversity, dispersion testing, and differential abundance analyses.

Results: Participants with T2DM demonstrated significantly lower taste (mean 8.21 vs 11.88; Δ −3.67, $P = .0087$) and smell scores (2.35 vs 3.98; Δ −1.64, $P = .009$) and higher neuropathy burden (MNSI 7.67 vs 1.98; Δ +5.68, $P = .0011$). Impaired taste and smell were more prevalent in T2DM (taste: $\chi^2 = 19.44$, $P < .001$; smell: $\chi^2 = 9.30$, $P = .0023$). After adjustment, diabetes independently predicted impaired smell (OR 2.74, 95% CI 1.14-6.58, $P = .024$) and impaired taste (OR 2.94, 95% CI 1.30-6.64, $P = .010$), while obesity independently contributed to impaired taste (OR 2.21, 95% CI 1.01-4.83, $P = .048$). Gut microbiome analysis revealed altered community structure with unequal dispersion ($F = 22.6$, $P < .0001$) and differential abundance, including depletion of Faecalibacterium, Anaerostipes, Agathobacter, and Blautia and enrichment of Enterobacteriaceae and *Escherichia–Shigella* (all $P < .01$).

Conclusions: Chemosensory dysfunction delineates a distinct metabolic–microbiome phenotype in T2DM, integrating glycaemic burden, neuropathy, and gut dysbiosis, supporting its potential role as a clinically relevant marker for metabolic disease severity.

P146 - ECE_2616 - Socioeconomic and psychobehavioural determinants of obstructive sleep apnea and risk of type 2 diabetes in Hispanic/Latino adults: a longitudinal analysis of the HCHS/SOL study

Manal Taimah[1], Paula Holland[1] and Guillermo Perez Algorta[2]

[1]Lancaster University, Lancaster, United Kingdom; [2]Division of Health Research, University of Lancaster, Lancaster, United Kingdom

Background: Type 2 diabetes mellitus (T2DM) and obstructive sleep apnea (OSA) are frequently comorbid conditions and represent major global public health challenges. OSA is characterised by recurrent episodes of partial or complete upper airway obstruction during sleep, and its coexistence with T2DM is associated with increased cardiovascular risk, mortality, and healthcare utilisation. Hispanic/Latino populations experience a disproportionate burden of both conditions. This study examined the association between OSA, socioeconomic, psychological, and behavioural factors, and incident T2DM in Hispanic/Latino adults.

Methods: Using a biopsychosocial framework, we conducted a longitudinal analysis of the Hispanic Community Health Study/Study of Latinos, including baseline (2008-2011) and follow-up (2014-2016) data from 3105 adults without T2DM or prediabetes at baseline. OSA was assessed using the apnea–hypopnea index derived from home sleep testing. Incident T2DM was identified through self-report and biomarker data (fasting glucose and HbA1c). Generalised estimating equation models examined the association between baseline OSA and incident T2DM, adjusting for age, sex, waist-to-hip ratio (WHR), employment status, depressive symptoms, and smoking. Effect modification by sex, age, and WHR was assessed.

Results: The mean age was 44.1 years (SD = 14), and 61.9% of participants were women. Participants with OSA were older, predominantly male, and more likely to be employed, with significantly higher prevalence of hypertension, dyslipidemia, and central obesity. OSA was associated with more frequent snoring and excessive daytime sleepiness, while depressive symptoms and behavioural factors showed limited differences. Over six years of follow-up, baseline OSA was associated with a nearly twofold higher risk of incident T2DM (OR = 1.99, 95% CI: 1.38-2.87). Elevated WHR independently predicted T2DM risk (OR = 1.88, 95% CI: 1.25-2.82). Associations were consistent across sex, age, and WHR subgroups (Figure 1).

Conclusions: These findings support integrated screening for OSA among individuals with metabolic risk and underscore the need for culturally tailored public health interventions to reduce

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

disparities. OSA was found to be an independent risk factor for T2DM, underscoring the importance of multidisciplinary, equity-focused prevention approaches. Future longitudinal research should examine bidirectional associations between OSA and T2DM and include diverse ethnic populations to enhance generalisability.

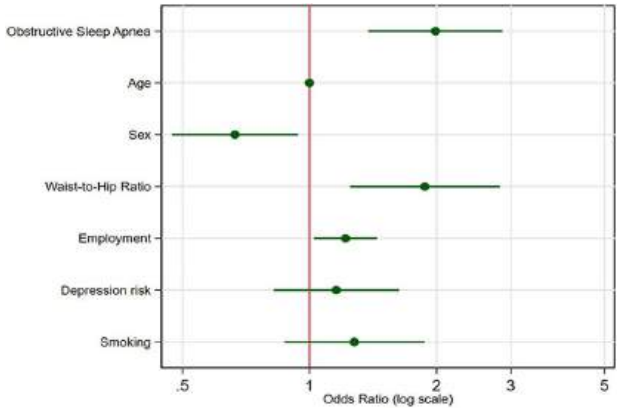

Figure 1 Adjusted associations between obstructive sleep apnea and Incident type 2 diabetes mellitus, fully adjusted generalised estimation equation model.

P147 - ECE_3952 - Extreme chronic hyponatraemia due to wheatgrass juice consumption followed by fatal osmotic demyelination syndrome upon discontinuation: a case report

Gergő Csitári[1] and Viktória Besir[1]
[1]*DBC-SZIEOK, Budapest, Hungary*

Hyponatraemia constitutes the most frequent electrolyte derangement encountered in clinical practice, encompassing hypovolaemic, hypervolaemic and euvolaemic aetiologies. Management of severe chronic hyponatraemia mandates precise correction rates, as overly rapid sodium repletion—even within guideline thresholds of ≤10 mmol/L per 24 hours—precipitates osmotic demyelination syndrome (ODS), characterised by central pontine and extrapontine myelinolysis with potentially irreversible neurological devastation.

We report the case of a 51-year-old female admitted for evaluation of extreme hyponatraemia (serum sodium 98 mmol/L) following prehospital trauma assessment. Relevant history comprised panic disorder, untreated anxiety-depression, suspected eating disorder and prior refusal of hospitalisation for severe metabolic acidosis (pH 7.02, 2015) and grand mal seizure (2019). Recurrent emergency presentations for headache, abdominal pain, diarrhoea, dizziness and gait instability culminated in admission after collapse.

Unremarkable head CT notwithstanding, emergency oxyologists—disregarding internal medicine consultation—administered 1500 mL 0.9% saline and 1 g intravenous sodium chloride bolus. Laboratory data from four months prior (117 mmol/L) confirmed chronicity. Within 12 hours, serum sodium increased 16 mmol/L, prompting free water intake and 5% dextrose infusion for deliberate relowering; extensive diuresis supervened despite intervention. Pharmacological agents and ethanol were excluded; on day 3, chronic exclusive consumption of 5 L daily wheatgrass juice—intended for weight loss and diuretic effects—was disclosed.

Neurological decline progressed from disorientation and dysthymia to mild ataxia. Day 9 witnessed pseudobulbar palsy, dysarthria and hemiplegia; repeat CT remained negative, but MRI confirmed pontine and basal ganglia demyelination diagnostic of ODS. Despite nasogastric feeding, quadriparesis advanced to locked-in syndrome and respiratory decompensation, culminating in death.

This case underscores the imperative of <8 mmol/L per 24-hour correction in high-risk chronic hyponatraemia, irrespective of initial acuity perception. Excessive wheatgrass juice—a purported "detoxification" agent lacking robust evidence—may induce profound water intoxication mimicking psychogenic polydipsia. Multidisciplinary vigilance for occult aetiologies, rigorous repletion limits and proactive relowering constitute essential prophylaxis against ODS, even when overcorrection appears contained.

P148 - ECE_2198 - Estrogen receptor beta activation orchestrates lipid remodeling and fatty acid oxidation to prevent lipotoxicity

Debora Rocha[1], Eloisa Vilas-Boas[2], Everton Vogt[1], Mariana de Carvalho[1], Maiara Queiroz[1], Camille Caldeira[1] and Alicia Kowaltowski[1]
[1]*Chemistry, Biochemistry, São Paulo, Brazil;* [2]*Faculty of Pharmaceutical Sciences, São Paulo, Brazil*

Non-selective hormone replacement with estradiol improves metabolic homeostasis during menopause. However, this treatment is not recommended for individuals with genetic predisposition to hormone-responsive cancers. In contrast, selective activation of estrogen receptor beta (ERβ) has shown promising results, promoting antitumor effects and modulating metabolic outcomes, although mechanisms in which these changes occur remain poorly understood. We investigated the effects of ERβ activation using diarylpropionitrile (DPN), a selective ERβ agonist, in both an in vivo post menopause model and in vitro models of metabolic overload. Female Wistar rats were submitted to ovariectomy (OVX) and later treated with DPN (1mg/kg, s.c.) for 15 days. ERβ agonist treatment recovered fasting glucose and lipid profiles, improved pancreatic islet morphology, and reduced retroperitoneal white adipose tissue. Serum ketone bodies and free fatty acid levels were also recovered to control levels, suggesting a modulation of liver lipid oxidation. Indeed, ERβ activation promoted expressive liver lipidome remodeling. To isolate the direct effects mechanistically, hepatocytes were submitted to nutrient overload and treated with DPN. In vitro, DPN also recovered ketone body secretion and promoted an increased dependence on complete fatty acid oxidation as well as decreased metabolic flexibility, as assessed by modulated extracellular flux analysis. In line with that, lipid species related to fatty acid metabolization were modulated by the treatment. Overall, these findings demonstrate the potential of ERβ as an alternative target for hormone replacement therapy, under conditions in which hepatic lipid remodeling to prevent lipotoxicity is desirable.

P149 - ECE_2587 - Semaglutide and empagliflozin improve glycaemic control and body composition in type 1 diabetes (T1DM): results from the ENDIS trial

Maja Navodnik Preložnik and Aleksandra Šauperl
Departement of Angiology and Endocrinology, General Hospital Celje, Celje, Slovenia

Background: SGLT2 inhibitors and GLP-1RAs are not approved for the treatment of T1DM; however, accumulating evidence suggests potential benefits. In the ENDIS trial, we previously demonstrated improvements in endothelial function with empagliflozin and semaglutide. Here, we present prespecified subanalyses focusing on glycemic control, body weight, and body composition.

Methods: A total of 89 adults with T1DM, all users of continuous glucose monitoring systems (majority treated with insulin pump therapy), were randomized into three matched groups receiving empagliflozin ($n = 30$), semaglutide ($n = 30$), or standard care ($n = 29$). At baseline, participants were well controlled, with a mean HbA1c of 7.4%, mean body mass index (BMI) of 27 kg/m^2, time in range (TIR) of 62%-70%, and coefficient of variation (CV) of 33%-35%. Outcomes were assessed after 12 weeks of treatment.

Results: Both active treatments led to comparable improvements in glycaemic control. HbA1c was reduced by −0.4% (IQR 0.8) in the semaglutide group ($P = .016$) and by −0.1% (IQR 0.6) in the empagliflozin group ($P = .052$). Significant weight loss was observed with both agents, being more pronounced with empagliflozin (−8.0 kg, IQR 4.0; $P < .001$) compared with semaglutide (−4.2 kg, IQR 4.0; $P < .001$). Waist circumference decreased similarly in both groups (empagliflozin −3.5 cm, IQR 6.0; semaglutide −3.2 cm, IQR 6.0; both $P < .001$). Glycaemic variability was low at baseline due to the use of advanced technologies and was not significantly altered by either treatment (ΔCV −1.5% vs −1.2%; both $P > .1$). Total daily insulin dose was significantly reduced in both treatment groups (empagliflozin −2.7 IU, $P = .009$; semaglutide −6.0 IU, $P < .001$).

Both interventions resulted in a comparable reduction in fat mass. In the empagliflozin group, fat mass decreased from 19.5 kg to 17.6 kg (27.2% to 24.0%; $P = .004$), while in the semaglutide group it decreased from 19.8 kg to 15.8 kg (24.8% to 23.2%; $P = .001$). Lean body mass was modestly reduced in both groups. Semaglutide was associated with a slight increase in total and extracellular body water. Empagliflozin did not lead to clinically relevant increases in β-hydroxybutyrate; mild ketonaemia (≤1.1 mmol/L) occurred only during intercurrent illness.

Conclusions: n adults with T1DM, empagliflozin and semaglutide significantly improve glycaemic control, body weight, and waist circumference, primarily through reductions in fat mass, while lowering insulin requirements and without clinically relevant increases in ketone bodies.

P150 - ECE_1744 - Empagliflozin for the treatment of postprandial hypoglycaemia—a randomized placebo-controlled superiority study and meta-analysis

Matthias Hepprich[1,2], Deborah Zeiter[3], Justus Fischer[4,5], Stefanie Dobler[6], Monica La Vista[3], Lia Bally[7], David Herzig[8], Marco Cattaneo[5] and Marc Donath[2,9,10]
[1]Endocrinology and Nutrition Center, Endocrinology and Nutrition Center, Basel, Switzerland; [2]Medical Faculty,University of Basel, Basel, Switzerland; [3]Endocrinology and Diabetes, Kantonsspital Olten, Olten, Switzerland; [4]Internal Medicine, Kantonsspital Bruderholz, Binningen, Switzerland; [5]Clinical Trial Unit, University of Basel, Basel, Switzerland; [6]Internal Medicine, Spital Dornach, Dornach, Switzerland; [7]Inselspital Bern, Diabetes, Endocrinology, Nutritional Medicine and Metabolism UDEM, Bern, Switzerland; [8]Inselspital Bern, Bern, Switzerland; [9]Research Center, University Of Montreal/NPRI, University Hospital, Montréal, Canada; [10]Clinical Trial Unit, Baden Cantonal Hospital Heliport, Baden, Switzerland

Background: Postbariatric hypoglycaemia (PBH) significantly impairs quality of life and remains difficult to treat, with current therapies offering limited benefit. Although empagliflozin reduced hypoglycaemic episodes in an acute trial, its longer-term effects on hypoglycaemia and quality of life are unknown. We hypothesised that empagliflozin would reduce hypoglycaemic episodes and improve quality of life in individuals with PBH.

Methods: In this multicentre, randomized, double-blind, placebo-controlled trial, 40 adults (18-75 years) with frequent PBH were assigned to empagliflozin 10 mg daily or placebo for 28 days. Primary outcomes were changes in SF-36 mental and physical health scores and frequency of hypoglycaemic events measured by blinded continuous glucose monitoring (CGM). Secondary outcomes included patient-reported symptoms, metabolic measures, and safety. Analyses were performed in the full analysis set with per-protocol sensitivity analyses. A post-hoc random-effects meta-analysis combined these findings with prior studies.

Findings: Empagliflozin did not improve physical or mental quality-of-life scores compared with placebo. The number of CGM-detected hypoglycaemic episodes tended to be higher with empagliflozin ($P = .054$), supported by sensitivity analyses showing an increased risk (incidence rate ratio 1·86, 95% CI 1·07-3·23). Time spent in hypoglycaemia (<3·0 mmol/L) was significantly greater with empagliflozin (0·90% vs 0·40%). Despite this, participants reported fewer symptomatic episodes, with no differences in hypoglycaemia awareness or fear. Secondary metabolic and safety outcomes were similar between groups. Meta-analysis suggested reduced glycaemic variability but no reduction in hypoglycaemia exposure.

Interpretation: Empagliflozin did not improve quality of life or reduce hypoglycaemia in PBH and may increase unrecognized hypoglycaemic exposure, raising safety concerns.

Androgen excess is a major diagnostic feature in polycystic ovary syndrome (PCOS), affecting 10-15% of women globally, and has been linked to the increased risk of metabolic disease in PCOS. Testosterone (T; classic androgen pathway) and 11-ketotestosterone (11KT; 11-oxygenated androgen pathway) are equipotent activators of the androgen receptor. Both circulate in similar concentration in premenopausal women whereas 11KT is predominant after menopause and in PCOS. *In vitro*, the enzyme aldo-keto reductase 1C3 (AKR1C3) activates precursors from classic and 11-oxygenated pathways to T and 11KT. Furthermore, AKR1C3 expression is upregulated by insulin, linking androgen excess and insulin resistance. Here, we investigated the contribution of AKR1C3 to female systemic and intra-adipose androgen production.

Using single-nucleus RNA-Seq (62 donors, 43 female), we established that, within adipose tissue, AKR1C3 primarily resides in adipocytes, with increased expression in women vs men and in obese vs lean individuals; androgen receptor expression mirrored this pattern. Using subcutaneous and visceral adipose tissue explants from women undergoing elective surgery ($n = 30$; BMI 20.8-56.8 kg/m^2, age range 32-74 years), we found that both subcutaneous and visceral adipose tissue preferentially activates 11-oxygenated androgens (8-10-fold higher 11KT over T). Pharmacological AKR1C3 inhibition selectively disrupted 11-oxygenated androgen activation in female adipose tissue explants, with only minor impact on T generation.

Treatment with an oral AKR1C3 inhibitor ($n = 9$) or placebo ($n = 12$) for 12 weeks in premenopausal women with normal circulating androgens resulted in selective inhibition of 11-oxygenated androgen activation, with only minor effects on circulating T. Similarly, in a single dose study in 16 postmenopausal women, a different, chemically unrelated AKR1C3 inhibitor yielded a significant decrease in circulating 11KT, with no discernible effects on T.

Next, we used a validated computational model that incorporates enzyme kinetic parameters obtained from *in vitro* experiments with multiple enzymes involved in androgen metabolism. We fitted the model to serum androgen concentrations measured by tandem mass spectrometry in 91 treatment-naïve women with PCOS (age 19-48 years) and 66 women without PCOS (age 22-48 years). Results showed a 2.6-fold increased systemic AKR1C3 activity in PCOS and predicted preferential effects of AKR1C3 inhibition on 11KT.

Taken together, we show that pharmacological targeting of AKR1C3 preferentially blocks 11-oxygenated androgen activation, both systemically and in adipose tissue. AKR1C3 inhibition provides a promising, novel strategy to alleviate 11KT excess in women and potentially also address related metabolic dysfunction. Future studies will quantify the impact of AKR1C3 inhibition in women with PCOS.

P152 - ECE_1208 - Metabolomic disparities between men and women with diabetes and obesity; differential predictors of tirzepatide response determined by obesity status

Ipsita Mishra[1] and Nirupama Chayani[2]

[1]IMS & SUM II, Phulnakhara, Soul Balance,Diabetes and Endocrine Centre of Excellence, Endocrinology,Diabetes and Metabolism, Cuttack, India; [2]DRIEMS, Mahaveer Lab, Microbiology, Cuttack, India

Background: Tirzepatide, a dual GIP/GLP-1 receptor agonist, demonstrates unprecedented efficacy for weight loss and glycemic control in type 2 diabetes (T2DM) and obesity. However, significant inter-individual variability in therapeutic response exists. We aimed to identify sex-specific metabolomic predictors of tirzepatide-induced weight loss response) in men and women with T2DM, stratified by obesity status(Class I: BMI 30-34.9 kg/m^2 vs Class II/III: BMI ≥35 kg/m^2).

Methods: A prospective cohort study of 220 adults (110 men, 110 women) with T2DM and obesity (mean BMI 37.1 ± 5.2 kg/m^2) initiating tirzepatide (10-15 mg weekly) were included. Baseline fasting serum samples were analyzed using untargeted high-resolution mass spectrometry (LC-MS/MS) and targeted quantification. Metabolomic data were analyzed using multivariate logistic regression and Random Forest models to identify baseline metabolites predictive of a "High Responder" status (≥15% TBWL) at 9 months. Models were developed separately for men and women and stratified by obesity class (Class I vs Class II/III).

Results: Overall, women were significantly more likely to be High Responders (62.7% vs 41.8% of men, $P = .003$).

In Men (Class II/III Obesity; BMI ≥35): High Responder status was negatively predicted by a cluster of branched-chain amino acids (BCAAs) and their catabolites. Specifically, elevated baseline valine, leucine,and 3-hydroxyisobutyrate were associated with non-response(OR: 0.72 per 1-SD increase, 95% CI: 0.59-0.88, $P = .001$).The predictive model for this group achieved an AUC-ROC of 0.81 (95% CI: 0.70-0.91).

In Men (Class I Obesity; BMI 30-34.9): The BCAA signature was not predictive ($P = .34$).Higher levels of specific long-chain

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

acylcarnitines (eg, C16:0, C18:1) were associated with non-response (OR: 0.79, 95% CI: 0.64-0.95, $P = .014$).

In Women (Class II/III Obesity; BMI ≥35). High baseline levels oflipid species i,e several lysophosphatidylcholines (LPCs) (eg, LPC 18:2, LPC 20:4) and dicarboxyl-acylcarnitines were positively associated with High Responder status (OR: 1.31 per 1-SD increase, 95% CI: 1.12-1.53, $P < .001$) with an AUC-ROC of 0.84 (95% CI: 0.74-0.93).

In Women (Class I Obesity; BMI 30-34.9): The predictive signature was less robust (AUC-ROC: 0.69), but trended towards an association with baseline bile acid profiles rather than lipids.

Conclusions: The metabolic pathways predicting tirzepatide response are fundamentally different between sexes and are further modified by obesity class.Men with high baseline BCAA signatures in the context of severe obesity are poor responders.Conversely, women with severe obesity and a favorable baseline lipid profile are likely to achieve significant weight loss. These findings highlight the potential for sex-stratified, metabolomics-based precision medicine to guide the use of incretin therapies.

P153 - ECE_2699 - MHC class II+ adipocyte in control of white adipose tissue browning

Yifan Zhao[1], Tuo Deng[2] and Hannah Hui[1]
[1]*Hong Kong, China;* [2]*Central South University, The Second Xiangya Hospital, Changsha, China*

Activation of beige adipocyte within white adipose tissue (WAT), a process called WAT browning, is emerging as a therapeutic approach to combat obesity and metabolic diseases. However, due to the incomplete understanding on the regulatory mechanism of beige adipocyte, efficient and safe strategy to enhance this process is currently lacking. We found that a subcluster of white adipocyte with MHCII antigen presenting activity (namely MHCII+ adipocyte) potentiates adipose inflammation and systemic insulin resistance in obesity via altering the immune cells in the visceral WAT. We found both the number and the activity of MHCII+ adipocytes are increased during WAT browning. Furthermore adipocyte-selective deletion of MHCII gene boosts WAT browning, suggesting MHCII+ adipocyte acts as a negative regulator of WAT browning. The mice with specific MHCII+ adipocyte depletion also exhibited impaired WAT browning, confirming the negative action of MHCII+ adipocyte on beige adipocyte activation. Meanwhile, we found a subcluster of adipose stem cell high in CD74 expression (CD74+ ASC) is present in iWAT. These CD74+ ASCs readily differentiate to MHCII+ adipocytes in vitro. Single cell RNA sequencing (scRNA-Seq) analysis showed that the adipose tissue precursor cells were significantly reduced in adipocyte-selective MHCII gene. In contrast the number of immune cells including T cells and myeloid cells was not significantly altered. These results suggest that MHCII+ adipocytes regulate beige adipocyte activation independent of its antigen presenting activity.

P154 - ECE_2916 - Ghrelin gene-derived peptides induce browning and regulate thermogenesis in mouse and human adipocytes

Iacopo Gesmundo[1], Giuseppina Granato[1], Ramesh Kasarla[1], Federica Bistolfi[1], Francesca Pedrolli[1], Maria Alessandra Bocchiotti[2], Ahmed M. Mansour[3], Andrea Margara[4], Andrea Armani[5], Massimiliano Caprio[5], Mario Morino[6], Ezio Ghigo[1] and Riccarda Granata[7]
[1]*Department of Medical Sciences, University of Turin, Turin, Italy;* [2]*Department of Plastic Surgeon Gynecological and Obstetrician, City of Health and Science of Turin, Turin, Italy;* [3]*Faculty of Medicine, Alexandria University, Alexandria, Egypt;* [4]*Plastic Surgery Service, Humanitas Gradenigo Hospital, Turin, Italy;* [5]*Department for the Promotion of Human Sciences and Quality of Life, San Raffaele Roma Open University, Rome, Italy;* [6]*Department of Surgical Sciences, University of Turin, Turin, Italy;* [7]*Department of Molecular Biotechnology and Health Sciences, University of Turin, Turin, Italy*

Obesity arises from an imbalance between energy intake and expenditure. Whereas white adipose tissue (WAT) primarily functions as an energy storage depot, brown adipose tissue (BAT) dissipates energy as heat through the action of uncoupling protein 1 (UCP1). In addition, white adipocytes can undergo reversible transdifferentiation into thermogenic beige adipocytes through browning. Identifying novel factors that promote browning, and thermogenesis may therefore offer therapeutic strategies to combat obesity and its associated metabolic disorders. Ghrelin gene-derived peptides, acylated ghrelin (GHRL), des-acyl ghrelin (DAG), and obestatin (OBE), are key regulators of energy balance and lipid metabolism. However, their role in WAT browning and BAT thermogenesis has not been fully established. Here, we investigated the effects of GHRL, DAG, and OBE on the induction of browning and thermogenesis in differentiated 3T3-L1 mouse adipocytes and in human adipocytes obtained during bariatric surgery from obese, nondiabetic individuals. Human samples included abdominal subcutaneous and visceral adipose tissue fragments (hSAT and hVAT), as well as hSAT-derived mature adipocytes and preadipocytes. In 3T3-L1 adipocytes DAG and OBE, but not GHRL, significantly increased UCP1 mRNA and protein levels and upregulated the expression of brown and beige markers (*Pgc1a, Prdm16, Tmem26, Cd137,* and *Dio2*), as well as batokines (*Igf1, Il6, Adipoq, Ngf, Gdf15,* and *Fgf21*). In contrast, the adipogenic gene *C/ebp* was upregulated by GHRL but downregulated by DAG and OBE. Moreover, DAG and OBE increased intracellular cAMP levels and CREB phosphorylation, and enhanced isoproterenol-stimulated lipolysis, whereas GHRL had no effect. DAG and OBE also promoted GLUT4 translocation, increased glucose uptake, and activated the AMPK-SIRT1 pathway, as indicated by increased AMPK phosphorylation and elevated SIRT1 expression. Functionally, DAG and OBE stimulated thermogenesis, as evidenced by increased mitochondrial respiration and enhanced mitochondrial biogenesis. Finally, DAG and OBE, but not GHRL, upregulated brown/beige markers across all human samples and increased mitochondrial respiration in hSAT-derived beige adipocytes. Collectively, these findings indicate that DAG and OBE promote adipose tissue browning and thermogenesis,

P156 - ECE_1204 - A4D—alarm for diabetes study: N-glycosylation of plasma proteins as a predictive biomarker for type 2 diabetes onset in at-risk individuals

Maja Baretić[1,2], Valerija Bralić Lang[2,3], Tamara Poljičanin[4], Domagoj Kifer[5], Olga Gornik Kljaić[5] and Martiana Džepina[6]
[1]*Internal Clinic, Department of Endocrinology and Diabetes, University Hospital Centre Zagreb, Zagreb, Croatia;* [2]*University of Zagreb, School of Medicine, Zagreb, Croatia;* [3]*Family medicine practice Valerija Bralić Lang, Zagreb, Croatia;* [4]*Zagreb County Health Centre, Zagreb, Croatia;* [5]*Faculty of Pharmacy and Biochemistry, University of Zagreb, Zagreb, Croatia;* [6]*Medilab One Ltd, Zagreb, Croatia*

Background and Aims: The potential for early identification of individuals at risk for type 2 diabetes mellitus (T2DM) through biomarkers could shift from preventive to predictive medicine. Predictive healthcare strategies could direct resources toward individuals highly likely to develop T2DM soon. Biomarkers, such as N-glycans- oligosaccharide structures attached to plasma proteins, exhibit significant changes years before disease onset, making them promising predictive tools. This study investigates the association between plasma protein N-glycosylation patterns and the onset of T2DM within 24 months in individuals with initially normal glycated haemoglobin (HbA1c).

Materials and Methods: This prospective cohort study involved 1, 484 participants recruited from primary healthcare practices in Croatia. Inclusion criteria included ages 55-69 years, normal HbA1c levels, and a positive family history of diabetes in first-degree relatives. Individuals with known diabetes or those newly diagnosed during screening based on ADA criteria, those with autoimmune or malignant diseases, acute inflammatory processes, and those treated with corticosteroids or antipsychotic therapy were excluded. Plasma protein N- glycan profiles were analysed at baseline and after 12 months, while HbA1c levels were measured throughout the study period.

Results: Statistically significant differences in glycan profiles were observed between individuals who developed T2DM within 24 months ($n = 93$, 44% females, median age 61 [53-71] years, median BMI 30.46 [19.7-42.9] kg/m^2) and those without a diagnosis of T2DM ($n = 1392$, 64% females, median age 60 [47-75] years, median BMI 27.67 [18.-50.3] kg/m^2). Several glycan groups exhibited distinct alterations between groups, including GP 18, GP 20 (both disialylated biantennary glycans), GP 26 (disialylated triantennary glycans), GP 29 and GP 32 (both trisialylated triantennary glycans), and GP 36, GP 37, GP 38, and GP 39 (tri- and tetrasialylated tetraantennary glycans). Lower levels of GP 18, GP 29, GP 36, GP 37, GP 38, and GP 39, alongside higher levels of GP 20, GP 26, and GP 32, were associated with an increased predisposition to T2DM development within two years.

Conclusions: N-glycosylation profiling shows strong potential as a prognostic marker for the onset of T2DM, offering a novel approach for early risk stratification. These findings underscore the significance of glycosylation changes in disease progression and its potential role in monitoring lifestyle interventions, more frequent screening, and early introduction of pharmacotherapy. As T2DM can often be delayed or prevented through timely action, glycan-based risk assessment may enhance early preventive strategies for at-risk populations, alarming for diabetes.

P158 - ECE_2781 - Dapagliflozin alters the levels of leptin and TNF-α in patients with type 2 diabetes and metabolic dysfunction-associated fatty liver disease

Fedir Laniush, Myroslava Borovets and Alina Urbanovych
Endocrinology, State non-profit enterprise "Danylo Halytsky Lviv National Medical University", University Clinic State non-profit enterprise "Danylo Halytsky Lviv National Medical University", Lviv, Ukraine

Background: Metabolic dysfunction-associated fatty liver disease (MAFLD) affects one third of the adult population. It often coexists with type 2 diabetes (t2D) with a prevalence 70% among these patients. MAFLD is known to increase macro- and microvascular complications in T2D, such as cardiovascular events, chronic kidney disease, and retinopathy. Both MAFLD and T2D are linked with systemic changes in immune response and inflammation. Dapagliflozin has multiple beneficial effects on glycemia, renal function, and cardiovascular system. This study aimed to evaluate whether dapagliflozin improves liver function in MAFLD and alters proinflammatory cytokines levels.

Materials and Methods: : We conducted a study of 135 patients with T2D and MAFLD with no other medication taken previously but metformin. The average T2D duration was 2.04 ± 1.21 years; BMI 31.4 ± 4.3 kg/m^2; HbA1c level 8.35 ± 1.27%. We added dapagliflozin as the second medication for the next 6 months. The investigated parameters were ALT, AST, the De Ritis ratio, leptin, IL-2, IL-6, and TNF-α.

Results: After 6 months of metformin and dapagliflozin therapy, ALT level decreased from 43.11 ± 4.47 to 25.13 ± 3.19 U/L ($P < .05$); AST from 37.93 ± 3.30 to 25.13 ± 1.95 U/L ($P < .05$). The De Ritis ratio increased from 0.9 ± 0.05 to 1.06 ± 0.14 ($P < .05$). Leptin level declined from 26.09 ± 3.81 ng/ml to 15.45 ± 3.44 ($P < .05$); TNF-α level from 11.24 ± 0.96 to 3.87 ± 0.38 pg/mL ($P < .05$). IL-2 and IL-6 levels did not show a significant decrease after 6 months ($P > .05$).

Conclusions: Using dapagliflozin in T2D patients has multiple benefits including MAFLD improvement. It decreases the levels of transaminases as well as leptin and TNF-α which generally defines a reduction in systemic and local inflammation in liver. It prevents a liver from further dysfunction and fibrosis.

P159 - ECE_1751 - A Prothymosin-α biomarker signature predicts early fetal growth independent of maternal glycaemia

Maria Mirabelli[1], Marta Greco[1], Daniela Foti[2] and Antonio Brunetti[2]
[1]*Department of Health Sciences, Magna Græcia University, Catanzaro, Italy;* [2]*Department of Experimental and Clinical Medicine, Magna Græcia University, Catanzaro, Italy*

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Background: Gestational diabetes mellitus (GDM) is the most common endocrine complication of pregnancy and is associated with adverse neonatal outcomes. Alterations in fetal growth (FG) may occur early in gestation, often before the biochemical diagnosis of GDM. Maternal glycaemia alone does not fully explain FG variability, and fetal overgrowth can also occur in pregnancies without GDM, suggesting additional determinants. Maternal inflammation and placental angiogenic imbalance are potential contributors: pro-inflammatory cytokines such as IL-6 and TNF-α can influence maternal, placental and fetal insulin sensitivity, while angiogenic factors including VEGF and EGF regulate placental vascular development and nutrient transfer. Prothymosin-α (ProT-α), an immunomodulatory protein and emerging biomarker of obesity-related insulin resistance (IR) has not been well studied in GDM or FG. We therefore examined whether ProT-α, alongside inflammatory and angiogenic mediators, is associated with early FG trajectories independently of maternal glycaemia.

Methods: Forty-six women with singleton pregnancies underwent a 75-g OGTT at 24-28 weeks' gestation (WG). GDM was diagnosed according to IADPSG criteria (GDM $n = 8$; normal glucose tolerance $n = 38$). Plasma glucose and serum insulin were measured at fasting, 1h and 2h post-load. Circulating ProT-α, cytokines and angiogenic factors were assessed at the time of OGTT and, in a subset of very high-risk women, also at earlier screening. FG was evaluated using ultrasound-derived abdominal circumference and estimated fetal weight (EFW) percentiles at 20 WG and, when available, again at 24 WG, with near-perfect concordance between time points. Associations were explored using Spearman correlations and multivariable linear regression to identify independent predictors of FG.

Results: Women with GDM were older ($P = .020$) and tended to have higher pre-pregnancy BMI. As expected, glucose concentrations were significantly higher in GDM group at fasting, 1h and 2h (all $P < .01$). Compared with women with normal glucose tolerance, those with GDM exhibited lower circulating levels of IL-8 ($P = .034$), TNF-α ($P = .046$) and IL-1α ($P = .007$), alongside reduced ProT-α concentrations. In multivariable regression, 2h glucose ($\beta = .545$, $P = .010$), VEGF ($\beta = .380$, $P = .021$) and EGF ($\beta = .374$, $P = .047$) were independently associated with higher EFW percentiles, whereas IL-10 ($\beta = -.416$, $P = .030$) and ProT-α ($\beta = -.431$, $P = .022$) were independent negative predictors.

Conclusions: Early FG is better identified by an integrated glycaemic, immune, and angiogenic biomarker profile than by maternal glycaemia alone. The inverse association between ProT-α and EFW percentiles supports its potential as an immunometabolic biomarker for early FG risk, particularly in GDM and/or maternal IR pregnancies.

P161 - ECE_2089 - Glucose tolerance in a longitudinal perspective

Daniela Vejrazkova, Markéta Vaňková, Petra Lukasova, Martin Hill, Josef Vcelak and Bela Bendlova
Department of Molecular Endocrinology, Institute of Endocrinology, Prague, Czech Republic

Background: Given the alarming increase in the incidence of type 2 diabetes mellitus (T2DM) worldwide and enormous societal burden of health complications associated with this metabolic disorder, such as dyslipidemia, hypertension, or central obesity, it is essential to focus on its prevention.

Aims: Our aim was to evaluate the long-term follow-up of 384 Czech adults who were not diabetic at study entry, but two-thirds of whom had an increased risk of developing T2DM due to family or personal history. We intended to determine anthropometric and biochemical markers that could serve as a suitable early predictors of deterioration in glucose metabolism.

Methods: 308 women and 76 men underwent detailed anthropometric and biochemical examinations including a 3-hour oral glucose tolerance test (OGTT) at the beginning and at the end of the monitoring. In both sexes, median of follow-up period was 10.2 years and median of age at study entry 38.4 years. During the baseline examination and re-examination, we ensured maximum adherence to a uniform protocol in terms of methodology.

Results: Based on the initial OGTT, prediabetes, ie, increased fasting glucose and/or impaired glucose tolerance in the 120th minute of the test was detected in 48 participants (13%) with no significant difference between the sexes. During the follow-up, the number of people with prediabetes/T2DM increased to 133 (35%), of which 98 (32%) were women and 35 (46%) were men. This was already a statistically significant difference ($P = .02$). A comparison of the group that remained healthy during monitoring with the group that developed prediabetes/T2DM pointed already during the baseline examination to higher blood pressure ($P = .001$), higher fat accumulation in the waist area ($P < .001$), less healthy lipid spectrum especially with regard to triglycerides ($P < .001$), higher liver GGT ($P < .001$) along with lower hepatic insulin extraction ($P = .01$) and also to lower IGF-1 levels ($P < .001$) in those whose metabolism deteriorated. These characteristics were already at the start of monitoring accompanied by higher fasting glycemia ($P < .001$) and insulinemia ($P < .001$) in the impaired group compared to the group that remained healthy, as well as by higher area under the curve of insulin measured during the 3-hour OGTT ($P < .001$), which is a manifestation of lower insulin sensitivity.

Conclusions: In addition to older age and male gender, we present other metabolic markers that can be considered predictive of (pre)diabetes and that warn of increased risk many years in advance.

P162 - ECE_1279 - Real-world outcomes of hybrid closed-loop insulin therapy in children and young people with type 1 diabetes in a UK district general hospital

Manish Shah, Nazik Elamin and Gunjan Jain
Paediatrics, East & North Hertfordshire NHS Trust, Stevenage, United Kingdom

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Introduction: NHS England has expanded access to hybrid-closed-loop (HCL) insulin delivery systems for children and young-people (CYP) with type-1 diabetes mellitus (T1DM) through a five-year national implementation programme. Since January-2023, our district general hospital has adopted HCL therapy for CYP with T1DM. This study evaluates the real-world impact of HCL systems on glycaemic control, including HbA1c, time-in-range (TIR), and hypoglycaemia.

Method: CYP with T1DM initiated on HCL therapy between January-2023 and June-2024 were identified using electronic patient records. HbA1c values were obtained from clinical records, and continuous glucose monitoring (CGM) metrics were extracted from Glooko platform. Patients with incomplete datasets, insufficient CGM uploads, or lost follow-up were excluded. Paired pre- and post-HCL HbA1c measurements and early post-initiation CGM metrics were analysed.

Results: Of 120 CYP commenced on HCL therapy, 72 had complete data suitable for analysis. Median age at HCL initiation was 13.5 years (IQR 4-20), 53% were female, and median diabetes duration was 7 years (IQR 3-9). Omnipod-5 was the most commonly used system (75%). All participants used CGM and multiple daily injections prior. Mean HbA1c improved significantly from 72.34 ± 26.37 mmol/mol pre-HCL to 56.01 ± 8.41 mmol/mol at up to 18 months post-initiation (mean paired reduction 16.49 mmol/mol; 95% CI −22.88 to −10.10; $P < .001$). Early CGM outcomes were favourable. Mean 90-day time-in-range (3.9-10.0 mmol/L) was 65.55 ± 9.52%. Mean time below range (<3.9 mmol/L) was 1.53 ± 1.06%, and time in very-low range (<3.0 mmol/L) was 0.39 ± 0.60%.

Variable	Measure	Total
Age, year	Median, IQR	13.5 (4-20)
Gender, Male	n(%)	34 (47%)
Gender, Female	n(%)	38 (53%)
Diabetes Duration pre-HCL, Years	Median, IQR	7 (3-9)
Pre-HCL HbA1c, mmol/mol	Mean ± SD	72.34 ± 26.37
Post HCL Measures		
First 90-day Time-In-Range, TIR, % (3.9-10 mmol/L)	Mean ± SD	65.55 ± 9.52
First 90-day Time-Below-Range, TBR, %(<3.9 mol/L)	Mean ± SD	1.53 ± 1.06
First 90-day Time In Very Low-Range, %(<3 mol/L)	Mean ± SD	0.39 ± 0.60
Post-HCL Mean HbA1c (Paired), mmol/mol	Mean ± SD	56.01 ± 8.41
Pre-Post HbA1c difference, mmol/mol	Mean ± SD	16.49 ± 27.47

Conclusions: Hybrid closed-loop insulin delivery systems delivered substantial and clinically meaningful improvements in glycaemic control within a district general hospital setting, with achievement of recommended CGM targets and low exposure to hypoglycaemia. These real-world data demonstrate that HCL technologies can be implemented safely and effectively outside specialist tertiary centres. Our findings highlight the capability of DGH-based multidisciplinary teams to deliver high-quality, technology-enabled diabetes care, reinforcing the scalability and sustainability of HCL systems within national diabetes pathways. Continued longitudinal evaluation will clarify long-term outcomes and inform service planning.

P163 - ECE_3273 - Contemporary mortality rates in type 1 diabetes in the era of advanced therapeutic care: a large-scale healthcare registry study

Adi Vinograd[1], Shiraz Vered[2], Noah Levek[3], Neriya Levran[4], Liat Lev-Shalem[2], Gilad Twig[5,6] and Orit Pinhas-Hamiel[4,5]
[1]Ministry of Health, Israel center of disease control, Ramat-Gan, Israel; [2]Maccabi Healthcare, Tel Aviv-Yafo, Israel; [3]Juvenile Diabetes Center, Maccabi Healthcare, Raanana, Israel; [4]Pediatric Endocrine and Diabetes Center, Edmond and Lily Safra Children's Hospital, Ramat Gan, Israel; [5]Tel-Aviv, Israel; [6]Division of Endocrinology, Diabetes and Metabolism, Medical Center Dr. h Sheba Medical Center, Tel Hashomer, Ramat Gan, Israel

Introduction: Technological advances enhancing glycemic control in type 1 diabetes have emerged over the past two decades, warranting an updated assessment of mortality in more recent cohorts.

Objective: To quantify all-cause mortality odds among individuals with type 1 diabetes compared with matches controls without diabetes and to assess temporal trends in mortality.

Methods: All individuals reported to the Type 1 Diabetes Registry of Maccabi Healthcare Services, between 2000 and 2022, and diagnosed before age 35 years, were included. Propensity score matching (1:4) was performed by sex and age to construct diabetes-free comparison cohort. Follow-up continued until 2023, death, or transfer to another provider, whichever occurred first. Logistic regression models were applied to estimate mortality odds.

Results: The study comprised 4299 individuals with type 1 diabetes and 17 196 matched controls (45.6% female; age 17.4 ± 9.1 years). During 204 102 person-years of follow-up, 112 deaths occurred, with incidence rates of 131.0 and 43.3 per 10^5 person-years among individuals with and without type 1 diabetes, respectively. Among decedents, age and BMI at death were comparable between groups. Type 1 diabetes was associated with higher mortality (OR of 3.90 (95% CI, 2.69-5.65) compared with matched controls, and this association remained consistent after adjustment. The association persisted when analyses were limited to individuals without pre-existing comorbidities or to those with a lean BMI. Females with type 1 diabetes exhibited higher mortality odds (aOR = 8.37; 95% CI, 3.18-22.04) than males (aOR = 2.49; 95% CI, 1.40-4.42), relative to matched controls. Individuals diagnosed earlier (2000-2010) had higher mortality odds than those diagnosed later (2011 and 2022), relative to period-matched controls.

Conclusions: Type 1 diabetes was associated with higher mortality odds, particularly among females. This association was attenuated among individuals diagnosed in more recent years.

Practical Implications: These findings highlight the importance of continued efforts and resources to improve overall diabetes management and glycemic control, which may contribute to

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

further reductions in mortality, particularly among females and individuals diagnosed in earlier calendar periods.

P165 - ECE_3802 - Beyond obesity: prevalence and correlates of underweight in 7-year-old children (WHO COSI 2008-2025)

Radka Taxová Braunerová, Markéta Vaňková, Tereza Svobodová, Tereza Metelcová and Josef Vcelak
Molecular Endocrinology, Institute of Endocrinology, Prague, Czech Republic

Background: Childhood obesity represents a major global public health concern; however, underweight and thinness also pose significant risks to growth, development, health, and well-being. Many countries face a double burden of malnutrition, characterized by the coexistence of overweight and underweight within the pediatric population, yet data on childhood underweight in Europe remain limited. This study, part of the WHO Childhood Obesity Surveillance Initiative (COSI), aimed to evaluate factors associated with underweight in 7-year-old children.

Methods: We analyzed 11 307 Czech children aged 6.5-7.9 years from the COSI project (2008-2025). Anthropometric measurements included waist circumference, height, weight, and BMI. Underweight was defined as BMI-for -age standard deviation (SD) <−1, indicating children below the WHO reference range for normal weight. Children's guardians completed questionnaires on dietary habits, physical activity, family characteristics, and school environment. Data were analyzed using Chi-square tests (NCSS 2019) and multivariate regression with the O2PLS method (SIMCA).

Results: Overall, 18% of children were underweight, with no significant differences between boys and girls. An increasing trend in underweight prevalence was observed between 2008 and 2025, more pronounced in boys, although not statistically significant. Compared with normal-weight and overweight peers, underweight children consumed more fruits, vegetables, and high-fat milk, but also more chips. They participated less frequently in organized sports while reporting lower screen time. Mothers of underweight children had higher educational levels.

Conclusions: Underweight affects nearly one-fifth of 7-year-old czech children, highlighting that undernutrition remains a relevant public health issue alongside obesity. The coexistence of healthier dietary patterns with higher consumption of energy-dense foods, along with lower physical activity but reduced screen time, highlights the complexity of factors related to underweight. Higher maternal educational level among underweight children suggests that socioeconomic determinants should be considered when addressing undernutrition in childhood. Continued surveillance and targeted interventions are needed to address both undernutrition and overweight in children.

Funding: Supported by the Ministry of Health of the Czech Republic in cooperation with the Czech Health Research Council under project No. AZV NU23-09-00252 and project MH-CZ-DRO (EU00023761).

P166 - ECE_1502 - Insulin autoimmune syndrome—something to always keep in mind!

Angelos Theocharis[1], Sofia Chatzi[1], Angeliki Angelidou[1], Kanella Kantreva[1], Maria Gabriella Stathi[1], Elisavet Kontou[2], Alexandra Tsirogianni[2], Marinella Tzanela[1] and Georgia Ntali[1]
[1]Department of Endocrinology "D.Ikkos"—Diabetes Center, Endo-ERN, Nosokomeio Evangelismos, Athina, Greece; [2]Department of Immunology and Histocompatibility, Nosokomeio Evangelismos, Athina, Greece

Background: Insulin autoimmune syndrome (IAS), or Hirata's disease, is a rare hypoglycemic disorder characterized by spontaneous hypoglycemia without evidence of exogenous insulin administration, a high serum concentration of total immunoreactive insulin, and the presence of insulin autoantibodies in high titer. The majority of cases occur in the Asian population, and treatment is generally successful with watchful waiting or steroids.

Case Report: A 70-year-old female was admitted to the emergency room due to expressive aphasia. A capillary blood glucose of 35 mg/dL (confirmed later in laboratory) was detected so iv glucose solution was initiated resulting in clinical improvement and establishment of Whipple's Triad. The patient reported episodes of sweating, tremors, and palpitations that occasionally awakened her during the previous two weeks. She was a non-diabetic and had no history of exposure to insulin, insulin secretagogues or any drug known to precipitate hypoglycaemia. She had history of breast cancer but was disease-free. However, she reported a viral infection a month before the appearance of the symptoms and the occasional use of a supplement containing a-lipoic acid. After her admission endogenous hyperinsulinemic hypoglycemia was established as high insulin levels were measured in two occasions (episode 1: Glucose 45 mg/dl, Insulin 64,1 μU/ml, C-peptide 8,92 ng/ml—episode 2: Glucose 35 mg/dl, Insulin 61,3 μU/ml, C-peptide 13,3 ng/ml). Insulin autoantibodies (IAA) were markedly elevated: 65,2 U/ml (reference range 0,1-0,3 U/ml) (measured with radioimmunoassay methodology). A confirmatory test with chemiluminescence assay demonstrated again high levels of IAA >175IU/ml (<20). Findings in imaging with abdominal CT, MRI and 68Ga-DOTATATE PET/CT were unremarkable. Oral methylprednisolone 32 mg was initiated with subsequent resolution of the hypoglycemia. A continuous glucose monitoring (CGM) was placed to allow her to predict and respond to an imminent drop of blood glucose values and the patient was discharged. The dosage of methylprednisolone was gradually lowered. 6 months after the initial diagnosis IAA were still elevated 50,1 U/ml (reference range 0,1-0,3 U/ml). At the most recent follow-up the patient was asymptomatic under 4 mg of methyloprednisolone.

Conclusions: Insulin autoimmune syndrome, although rare, should always be considered as a diagnosis in a patient with hypoglycemia and endogenous hyperinsulinemia. Differential diagnoses of IAS include insulinoma and exogenous intake of insulin and sulphonylureas. Most cases of IAS are self-limiting, with gradual decrease of antibody titre and resolution of symptoms after removal of the trigerring factor.

P167 - ECE_1564 - Glycemic control in type 2 diabetes patients in the context of humanitarian crisis in Ukraine: rescue therapy

Yeva Ilkiv[1,2], Viktoriia Yerokhovych[1], Oksana Sulaieva[3], Iuliia Komisarenko[1], Vitalii Gurianov[1], Ilona Rudnieva[1] and Nazarii Kobyliak[1,3]
[1]*Bogomolets National Medical University, Kyiv, Ukraine;* [2]*D. F. Chebotarev Institute of Gerontology of the National Academy of the Medical Sciences of Ukraine, Kyiv, Ukraine;* [3]*Medical Laboratory CSD, Kyiv, Ukraine*

Background/Introduction: Ukraine's situation is potentially the biggest migration crisis in Europe. As humanitarian crises become more widespread, chronic diseases such as type 2 diabetes mellitus (T2DM) are becoming increasingly important. Limited access to healthcare facilities, interrupted supply of hypoglycemic medications and economic hardship are just some of the many challenges faced by patients with T2DM. Therefore, it is necessary to develop strategies to improve glycemic control in humanitarian crises in order to provide effective and high-quality care to patients.

Purpose: to assess the effectiveness of different groups of antidiabetic drugs (ADD) under the conditions of a humanitarian crisis caused by war.

Methods: A total of 582 people with T2DM from all regions of Ukraine participated in the study. According to the hypoglycemic drugs taken by patients during martial law, the following treatment regimens were identified: 1—metformin, 2—sulfonylurea drugs, 3—metformin with sulfonylurea derivatives, 4—metformin with iDPP-4, 5—metformin with iSGLT-2, 6—triple combination of drugs. To assess the risk of elevated glycated hemoglobin (HbA1c) and the effectiveness of therapy with hypoglycemic drugs, patients were divided into two groups: group I—individuals without experience of military operations, occupation, forced resettlement ($n = 391$), group II—responders with experience ($n = 191$). For defining prognostic factors impacting T2D progression, logistic regression analysis and machine learning algorithms were applied.

Results: In group I, almost the same effect of all regimens was noted, which is close to 50% ($P = .740$); in group II the most effective was the variant with triple combination with sulfonylurea derivatives ($P = .012$). Univariate analysis for group II showed that the combination of metformin with sulfonylurea ($P = .04$) and the triple combination ($P = .001$) were more effective. Multivariate analysis show that the best results in terms of reducing HbA1c were obtained in respondents who took a triple combination ($P = .007$). The area under the curve was AUC 0.768 (95% CI 00.698—0.838).

Conclusions: sulfonylurea drugs demonstrated a significant positive effect for the control of diabetes in emergency situations, and their availability allows less well-off patients to purchase them and use during martial law and occupation.

P168 - ECE_1580 - Regulation of hypothalamic ketone metabolism and neuroinflammation by empagliflozin under metabolic stress

Joo Yeon Kim, Ji Hyun Bae, Min Jin Lee, Ah Reum Khang, Yang Ho Kang, Dong Hee Kim and Dongwon Yi
Yangsan, South Korea

Background and Aims: Sodium–glucose cotransporter 2 (SGLT2) inhibitors are widely used antidiabetic agents that improve systemic glucose homeostasis and induce weight loss primarily through enhanced urinary glucose excretion. Beyond their peripheral metabolic effects, emerging evidence suggests that SGLT2 inhibitors may also modulate central metabolic regulation in the brain. The hypothalamus is a key integrative center for energy balance and undergoes metabolic and inflammatory remodeling in response to chronic nutritional excess, such as high-fat diet (HFD)–induced obesity. In this context, astrocytes play a pivotal role by exhibiting metabolic reprogramming, including increased ketone body production, which can influence neuronal activity and neuroinflammatory responses. However, the effects of SGLT2 inhibition on hypothalamic ketone metabolism and neuroinflammation under metabolic stress remain poorly understood. The study investigates whether empagliflozin (EMPA), a selective SGLT2 inhibitor, modulates hypothalamic ketone metabolism and neuroinflammatory responses in an HFD-induced metabolic stress condition.

Materials and Methods: Mice fed a HFD were treated with EMPA, and hypothalamic expression of genes related to ketone body synthesis and inflammation was analyzed. Complementary in vitro experiments were performed using lipid-overloaded astrocytes treated with EMPA to assess inflammatory activation and metabolic alterations. Astrocyte–neuron co-culture and conditioned media experiments were conducted to evaluate the indirect effects of EMPA-treated astrocytes on neuronal viability under lipotoxic conditions.

Results: EMPA significantly attenuated HFD-induced upregulation of ketogenesis-related genes in the hypothalamus and reduced markers of glial inflammation. In vitro, EMPA suppressed inflammatory responses and improved metabolic homeostasis in lipid-overloaded astrocytes. Importantly, neurons exposed to conditioned media from EMPA-treated astrocytes exhibited enhanced survival under lipotoxic stress, indicating astrocyte-mediated neuroprotective effects.

Conclusions: EMPA modulates hypothalamic metabolic adaptation to nutritional excess by limiting maladaptive astrocytic ketone production and reducing inflammatory signaling. This central metabolic remodeling may contribute to neuronal protection and improved energy homeostasis, suggesting a previously underappreciated brain-centered mechanism underlying the actions of SGLT2 inhibition. These findings support further investigation into brain–periphery crosstalk in obesity and metabolic disease.

P169 - ECE_2756 - Central-peripheral circadian misalignment: increased corticosterone levels in the inactive phase disrupt adipose BMAL1 and promote lipid accumulation in the obese rat model

Mariarosaria Negri[1,2], Feliciana Amatrudo[2], Nunzia Magnacca[1], Maria Anna Marciano[3], Cristina De Angelis[1], Chiara Simeoli[1], Erminio M. Crescenzo[1], Annamaria Colao[1,4], Raffaella Crescenzo[3], Rosario Pivonello[1,4] and Claudia Pivonello[5]

[1]Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Diabetologia, Andrologia e Nutrizione—Università Federico II di Napoli, Naples, Italy; [2]Dipartimento di Psicologia e Scienze della Salute, Università Telematica Pegaso, Naples, Italy; [3]Department of Biology, Federico II University, Naples, Italy; [4]UNESCO Chair for Health Education and Sustainable Development, Federico II University, Naples, Italy; [5]Dipartimento di Sanità Pubblica, Università degli Studi di Napoli Federico II, Naples, Italy

Circadian clocks regulate metabolic homeostasis by hierarchically synchronizing central and peripheral oscillators. Although obesity is associated with circadian dysfunction, the contribution of endocrine zeitgebers to central and peripheral clocks remains understood. The current study examined the effects of high-fructose/high-fat (Western) diet (WD) on circadian BMAL1 expression in rat hypothalamus and visceral adipose tissue (VAT), concomitantly with in vitro assessment of lipid accumulation. To induce obesity, sixty-day-old male Wistar rats were fed a four-week WD and compared with control rats fed a standard diet (SD). Serum, hypothalamus, and VAT samples were collected during early inactive (ZT3–5) and early active (ZT10–12) phases. BMAL1 and appetite-regulating neuropeptides hypothalamic, as well as BMAL1 and lipid-related markers VAT expression, were monitored by WB. Serum corticosterone, leptin and tryglicerides were measured by ELISA at both timepoints. Differentiated white adipocytes were subjected to Bmal1-knockdown to evaluate the role of Bmal1 on lipid accumulation and leptin production. Compared to SD, WD induced obesity with significantly increased body weight ($P = .01$) despite reduced food intake ($P = .001$). At both ZT3–5 and ZT10–12, hypothalamic BMAL1 expression was increased in obese rats (+68.7% and +65%, respectively) and was associated with higher POMC ($P = .007$) and reduced NPY protein expression (−21.30% and −71.25%, respectively), consistent with reduced food intake. In contrast, at ZT3–5, VAT BMAL1 expression was significantly reduced in obese rats ($P = .01$) and was associated with a significant increase in leptin protein expression ($P = .01$). At ZT10–12, VAT BMAL1 expression remained similarly low in both groups, whereas leptin expression was slightly increased in obese animals (+22.86%). These findings indicate that WD-induced alterations of adipose BMAL1 are observed during the inactive phase. At ZT3–5, corticosterone ($P = .03$), leptin ($P = .01$) and tryglicerides ($P = .01$) were significantly increased in obese rats, whereas at ZT10–12 no significant differences were observed between obese and control animals. Notably, corticosterone levels at ZT3–5 were inversely and significantly correlated with VAT BMAL1 expression ($P = .008$), indicating that higher circulating corticosterone was associated with lower VAT BMAL1 specifically during inactive phase. Consistently, Bmal1-knockdown (−64%) in adipocytes increased lipid accumulation ($P = .0002$) and leptin expression ($P = .02$). These findings demonstrate that abnormal glucocorticoid secretion during the inactive phase is associated with adipose BMAL1 rhythmicity disruption, promoting lipid accumulation and contributing to central-peripheral circadian misalignment in WD-induced obesity.

P170 - ECE_3407 - Hybrid closed-loop insulin systems improve hypoglycemia and insulin sensitivity with favorable effects on FIB-4 in poorly controlled type 1 diabetes

Maria Apostolopoulou[1,2], Dimitra Pappa[2], Stefanos Tamouridis[2] and Alexandra Bargiota[1,2]

[1]Larissa, Greece; [2]Department of Endocrinology and Metabolic Diseases, University Hospital of Larissa, Larissa, Greece

Background and Aims: Obesity and insulin resistance represent a rising burden in individuals with type 1 diabetes (T1D) and are associated with metabolic dysfunction–associated fatty liver disease (MAFLD). Hybrid closed-loop systems (HCLS) lead to better glycemic control and reduced insulin requirements compared to multiple daily injections (MDI) and open-loop systems. The aim of the present analysis is to compare glycemia, body weight, total daily dose (TDD) and indices related to MAFLD and liver fibrosis in patients initially on MDI or open-loop systems and after initiation of HCLS.

Methods: We studied individuals with T1D previously on MDI and open-loop systems at baseline (tA) and 6 months (tB) after hybrid-closed loop CSII initiation (Medronic 780 G, Medrum), who visited our outpatient clinic. Continuous glucose monitoring (CGM) metrics- time in range (TIR), time above range (TAR), time below range (TBR) and time below 54 mg/dl (TBR <54), HbA1c, BMI and TDD were analyzed.

Results: A total of 53 patients were included. At tA: 36/53 on MDI, 17/53 on open-loop systems with a mean age: 43.3 ± 15.8 years, BMI: 27.3 ± 6.3 kg/m^2, HbA1c 7.8 ± 1.3%, and diabetes duration 20 ± 12 years, without known history of liver disease. At tB they had lower TBR <54 (B: 0.15 ± 0.04 vs A: 0.45 ± 0.1%, $P = .02$) and a trend towards reduced TBR (B: 0.9 ± 0.7 vs A: 1.9 ± 0.2%, $P = .07$). TDD was lower after 6 months (B: 53.5 vs A: 50.5 IU, $P = .02$), consistent with improved insulin sensitivity. TIR, HbA1c and BMI remained unchanged. In 8 patients with available liver enzyme tests at both tA and tB, FIB-4 score showed a significant reduction (B: 0.90 ± 0.48 vs A: 0.91 ± 0.51, $P = .03$), while hepatic steatosis index remained unchanged.

Conclusions: HCLS initiation led to better glucose metabolism, lower TBR <54 and lower TDD at 6 months. Preliminary findings suggest beneficial effects on markers of liver fibrosis, which warrant further investigation and longer-term follow-up.

P172 - ECE_3990 - JUV-161 reverses skeletal muscle myopathy and functional decline in a translational model of myotonic dystrophy type 1

Ashil Koranne, Hee Ju Kim, Ritwik Datta, Vengadeshprabhu Karuppagounder, Han Song, Thach Mai, Zhihua Li, Banmeet Anand, Colin Hislop, Priya Handa, Hanadie Yousef and Jeremy O'connell

Juvena Therapeutics.Inc, Redwood City, United States

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Myotonic dystrophy type 1 (DM1) is a multisystemic neuromuscular disorder caused by toxic CUG repeat expansions in the 3′ untranslated region (UTR) of the DMPK gene, leading to progressive skeletal muscle weakness, myopathy, and functional decline. Despite substantial unmet clinical need, therapeutic development for DM1 has been limited by the lack of preclinical models that faithfully recapitulate the systemic pathology and functional impairments observed in patients.

At Juvena Therapeutics, we have developed a biologics-based drug discovery platform focused on identifying stem-cell secreted proteins capable of restoring tissue health. This platform led to the identification of JUV-161, a novel secreted protein engineered to enhance muscle regeneration and functional repair. To enable translational evaluation of JUV-161 in DM1, we developed the panCUG960/+ mouse model, a murine system that integrates key genotypic, phenotypic, and functional hallmarks of human DM1 within a single animal. The panCUG960/+ mouse harbors an expanded CUG repeat in the 3′ UTR of the DMPK gene, resulting in accumulation of nuclear RNA foci and widespread splicing abnormalities. These molecular defects drive canonical DM1-associated histopathologic changes accompanied by progressive functional deficits closely mirroring the clinical trajectory in patients with DM1.

Using this translationally relevant model, we evaluated the therapeutic efficacy of JUV-161. PanCUG960/+ mice received daily subcutaneous administration of JUV-161 at a dose of 12 mg/kg for 21 days. Treatment with JUV-161 significantly improved gastrocnemius muscle mass (180 mg vs 160 mg in vehicle, $P <$ .01) and tibialis anterior muscle cross-sectional area (1.92E3 μm^2 vs 1.82E3 μm^2, $P <$ .01) in male mice. Furthermore, treated animals demonstrated significant improvement in both specific forelimb grip strength (28.5 mN/g vs 23.2 mN/g in vehicle; $P <$ .01) and all-limb grip strength (66.4 mN/g vs 56.1 mN/g in vehicle; $P <$ .001). In contrast, vehicle-treated mice showed a steady decline in grip strength over the 3-week treatment period, indicating meaningful restoration of functional capacity with JUV-161. JUV-161 treatment also significantly lowered non-fasting blood glucose levels relative to baseline compared with vehicle treatment (−8.74% vs −0.04% in vehicle, $P <$ .05).

In conclusion, JUV-161 reverses both structural and functional manifestations of skeletal muscle myopathy in a robust and disease-relevant model of DM1. These findings support JUV-161 as a promising therapeutic candidate for treating DM1 and related muscle-wasting conditions.

Abstract citation ID: lvag096.356

P173 - ECE_3329 - Beyond steatosis grade: hepatic parenchymal heterogeneity on ultrasound as a marker of metabolic deterioration

Merve Şenay Özçalık, Deniz Türküm Atikcan, Ece Gül Köse Hamidi, Ozlem Turhan Iyidir, Asli Nar and Neslihan Başçıl Tütüncü
Endocrinology and Metabolism, Baskent University, Ankara, Türkiye

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) is increasingly recognized as a multisystem disorder closely linked to cardiometabolic morbidity. Ultrasonography (US) is widely used for the detection and grading of hepatic steatosis; however, the clinical relevance of hepatic fat distribution patterns beyond steatosis severity remains insufficiently defined. We hypothesized that ultrasonographic hepatic parenchymal heterogeneity reflects more advanced metabolic impairment. This study aimed to evaluate the association between hepatic steatosis distribution patterns and metabolic abnormalities in diabetic and non-diabetic individuals.

Methods: A total of 527 adults who underwent upper abdominal ultrasonography in 2025 were retrospectively analyzed. Hepatic steatosis was graded from stage 0 to 3, and parenchymal distribution was classified as homogeneous or heterogeneous. Anthropometric measurements and biochemical parameters obtained at the time of imaging were assessed, including body mass index (BMI), waist circumference, fasting plasma glucose, HbA1c, liver enzymes, lipid profile, and spot urine albumin-to-creatinine ratio. Participants were categorized as diabetic, prediabetic, or non-diabetic based on glycemic status.

Results: The mean age of the cohort was 55.4 ± 16.8 years; 33.8% were diabetic, 16.1% prediabetic, and 50.1% non-diabetic. Hepatic steatosis was absent in 36.2% of patients, while 26.4%, 29.0%, and 8.3% had stage 1, 2, and 3 steatosis, respectively. A heterogeneous parenchymal pattern was identified in 22.4% of cases. The prevalence of heterogeneous steatosis was significantly higher among diabetic patients and increased progressively with worsening glycemic status ($P = .003$). Steatosis severity was also strongly associated with parenchymal heterogeneity ($P < .001$). Patients with heterogeneous hepatic parenchyma exhibited significantly higher BMI, waist circumference, fasting glucose, ALT, and triglyceride levels, along with lower HDL cholesterol concentrations (all $P < .01$), compared with those showing a homogeneous pattern.

Conclusions: This study shows that heterogeneous hepatic parenchymal patterns on routine ultrasonography are linked to adverse metabolic features in both diabetic and non-diabetic individuals, underscoring the importance of steatosis distribution beyond severity alone.

Abstract citation ID: lvag096.357

P174 - ECE_1521 - Associations of skeletal muscle mass and muscle strength with arterial stiffness in patients with type 2 diabetes mellitus

Naoki Koike[1,2], Yuji Doi[1], Ryosuke Kemmotsu[1], Moe Kusushita[1], Yasuna Sakai[1], Tomonori Okita[1], Hiroyuki Sho[1], Ryoko Inui[1], Yoko Irie[1], Yukiko Tabuchi[1], Tunehiko Yamamoto[3] and Tetsuyuki Yasuda[1]
[1]Osaka, Japan; [2]Osaka International Medical & Science Center(Osaka Keisatsu Hospital), Osaka, Japan; [3]Hyogo, Japan

Background: Arterial stiffness is a major determinant of cardiovascular disease in patients with type 2 diabetes mellitus (T2DM). Brachial–ankle pulse wave velocity (baPWV) is a widely used, noninvasive measure of arterial stiffness and a strong predictor of cardiovascular events. Sarcopenia-related traits, including reduced skeletal muscle mass and muscle strength, are highly prevalent in T2DM; however, their vascular relevance remains incompletely understood. In particular, evidence linking skeletal muscle characteristics to baPWV as an intermediate vascular

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

phenotype in T2DM is limited. We therefore examined the associations of skeletal muscle mass index (SMI) and handgrip strength with baPWV in patients with T2DM.

Methods: This single-center, retrospective cross-sectional study included consecutive patients with T2DM admitted to our hospital between 2021 and 2024. Skeletal muscle mass was assessed by bioelectrical impedance analysis, and SMI was calculated as appendicular skeletal muscle mass divided by height squared. Muscle strength was evaluated using handgrip strength. Arterial stiffness was assessed using baPWV. Multivariable linear regression analyses were performed with baPWV as the dependent variable. To avoid multicollinearity, SMI and handgrip strength were entered into separate models adjusted for age, sex, mean arterial pressure, diabetes duration, smoking status, history of cardiovascular disease, glycated hemoglobin, estimated glomerular filtration rate, and body mass index.

Results: A total of 281 patients were analyzed (mean age 64.1 ± 15.1 years; 68.4% men). In univariate analyses, both SMI and handgrip strength were significantly and inversely correlated with baPWV. These associations remained significant after multivariable adjustment for established cardiovascular risk factors. Higher SMI was independently associated with lower baPWV ($\beta = -115.1$ cm/s per 1 kg/m^2, $P = .003$). Likewise, greater handgrip strength was independently associated with lower baPWV ($\beta = -12.2$ cm/s per 1 kg, $P < .001$).

Conclusions: Both SMI and handgrip strength were independently associated with arterial stiffness in patients with T2DM. Consistent with observations in the general population, these findings suggest arterial stiffness as a potential vascular link between skeletal muscle health and cardiovascular risk in T2DM. Future large-scale prospective studies are warranted to confirm these associations and clarify their clinical implications.

P176 - ECE_3752 - Evaluation of ChatGPT-5 utility in managing diabetes-related comorbidities

Özge Baş Aksu, Fatma Tuğçe Şah Ünal and Rifat Emral
Department of Endocrinology and Metabolism, Ankara University Faculty of Medicine, Ankara, Türkiye

Objective: With the increasing prevalence of AI-generated healthcare content, evaluating its reliability and quality is critical. This study assessed the readability, content quality, and reliability of ChatGPT-5 responses to clinical case scenarios for diabetes comorbidity management.

Methods: Five major diabetes comorbidities—dyslipidemia, obesity, metabolic dysfunction-associated steatotic liver disease [MASLD], hypertension, and nephropathy—were represented by clinical cases. Five questions were evaluated for each case, assessing risk assessment, treatment goals, treatment recommendations, second-line strategies, and follow-up plans. Three independent endocrinologists assessed ChatGPT-5 responses using the Modified DISCERN (mDISCERN) for reliability and the Diabetes Comorbidity Management Scale (DCMS) for content quality. Reliability was categorized as poor (0-2, 0%-40%), moderate (3, 60%), or strong (4-5, 80%-100%). Content quality was classified as low (0-11, <50%), moderate (12-17, 52%-74%), or high (18-23, 78%-100%). Readability was measured using the Flesch-Kincaid Grade Level (FKGL), Gunning Fog Index, and Flesch Reading Ease (FRE) tests. Inter-rater agreement was determined by the intraclass correlation coefficient (ICC).

Results: ChatGPT-5 achieved moderate reliability (mDISCERN: 3.2 ± 0.4; 64%) and high content quality (DCMS: 19.1 ± 1.7; 83%). Inter-rater agreement was excellent for DCMS (ICC = 0.89; 95% CI: 0.68-0.98; $P < .001$) and moderate for mDISCERN (ICC = 0.57; $P = .019$). The highest performance was observed in nephropathy (87%) and obesity (88%) cases, while MASLD cases demonstrated the lowest performance (75%). Among evaluated domains, risk assessment (96%) and treatment goals (90%) received the highest scores, whereas treatment recommendations (70%) and second-line strategies (73%) received the lowest. Readability analysis indicated that responses required education above the high-school level (FKGL: 11.3; FRE: 27.5).

Conclusions: ChatGPT-5 demonstrates high performance, particularly in risk assessment and goal-setting for diabetes comorbidity management, but shows limitations in specific treatment recommendations and in complex cases. Clinicians may use it as a supportive tool to confirm risk assessments and establish treatment goals; however, expert judgment remains essential for detailed treatment planning and complex clinical scenarios.

P177 - ECE_1410 - Glucagon-like peptide-1 receptor agonists vs sodium–glucose cotransporter-2 inhibitors and risk of incident asthma in patients with diabetes: a real-world cohort

Wan-Ting Huang[1], Yi-Tzu Wu[2], Wei Chuan Chang[1], Ching-Hui Loh[3,4] and Huei-Kai Huang[1,3,5]
[1]Center for Clinical Epidemiology and Biostatistics, Hualien Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Hualien, Taiwan; [2]Hualien Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Hualien, Taiwan; [3]School of Medicine, Tzu Chi University, Hualien, Taiwan; [4]Center for Aging and Health, Hualien Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Hualien, Taiwan; [5]Hualien, Taiwan

Background: Diabetes mellitus is characterized by metabolic dysregulation and systemic low-grade inflammation and is associated with an increased risk of asthma. Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) have potential pulmonary and immunomodulatory effects, but existing evidence regarding their association with asthma remains inconsistent and has largely focused on patients with pre-existing asthma. The risk of incident asthma associated with GLP-1 RA use in patients with diabetes therefore remains unclear.

Objectives: To investigate the association between GLP-1 RAs and the risk of incident asthma in patients with diabetes mellitus, using sodium–glucose cotransporter-2 inhibitors (SGLT2is) as an active comparator.

Methods: Using the TriNetX U.S. Collaborative Network (2015-2024), we conducted a real-world cohort study of adults with diabetes initiating GLP-1 RAs or SGLT2is under a new-user, active-comparator design within a target trial emulation framework. Patients with prior exposure to either drug class, concomitant use, or pre-existing asthma or chronic pulmonary diseases

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

were excluded. Cohorts were balanced using propensity score matching on demographics, comorbidities, medication history, and laboratory data. For each GLP-1 RA agent, a separate matched cohort was constructed and analyzed. Cox proportional hazards models were applied to estimate the risk of incident asthma.

Results: After propensity score matching, 204 650 patients were included in each cohort. Overall, GLP-1 RA use was associated with a higher risk of incident asthma compared with SGLT2i use (hazard ratio [HR], 1.18; 95% confidence interval [CI], 1.14-1.22). Age- and sex-stratified analyses showed consistent trends toward a higher asthma risk among GLP-1 RA users across strata. In analyses of individual GLP-1 RAs, significantly increased risks of incident asthma were observed for exenatide (HR, 1.28; 95% CI, 1.09-1.50), liraglutide (HR, 1.25; 95% CI, 1.16-1.35), and dulaglutide (HR, 1.08; 95% CI, 1.03-1.14). In contrast, tirzepatide was associated with a significantly lower risk of incident asthma compared with SGLT2is (HR, 0.57; 95% CI, 0.51-0.65).

Conclusions: GLP-1 RA use was associated with an overall increased risk of incident asthma compared with SGLT2is; however, the association varied across individual GLP-1 RA agents, with several agents showing increased risks and tirzepatide demonstrating a lower risk. These findings highlight clinically relevant heterogeneity within the GLP-1 RA class regarding asthma risk and suggest a potential safety signal that warrants further investigation.

P178 - ECE_1547 - Sustained glycaemic benefits of a single intermittently scanned continuous glucose monitoring use in non-insulin-treated patients with type 2 diabetes: a randomised study

Ohk-Hyun Ryu
Endocrinology and Metabolism, Internal Medidine, Hallym University, College of Medicine, Chuncheon, South Korea

Background: Intermittently scanned continuous glucose monitoring (isCGM) has been shown to improve glycaemic control and promote behavioural change in people with diabetes. However, most evidence derives from insulin-treated populations or repeated CGM use. The potential for a single, short-term isCGM exposure combined with structured education to induce sustained glycaemic and behavioural benefits in non-insulin-treated patients with type 2 diabetes remains unclear.

Objectives: To evaluate the effects of a single 2-week isCGM use with structured education on glycaemic control, diabetes self-care, and treatment satisfaction, to assess the additional impact of short message service (SMS)-based feedback, and to identify factors associated with short-term glycaemic improvement.

Methods: Patients with type 2 diabetes managed with oral antidiabetic drugs or lifestyle modification (HbA1c 7.0%-8.9%) were enrolled. All participants wore an isCGM device (FreeStyle Libre) for two weeks and received standardised education on CGM interpretation and lifestyle-based glucose management. Participants were randomly assigned to a CGM-only group or a CGM plus SMS-feedback group.

HbA1c was measured at baseline, 10-12 weeks, and 24 weeks. Diabetes self-care behaviours and diabetes treatment satisfaction (DTSQ total score) were assessed at baseline and at 10-12 weeks only. Multivariable linear and logistic regression analyses were performed to identify determinants of HbA1c improvement at 10-12 weeks.

Results: Sixty-two participants completed the study (31 per group). Baseline characteristics were comparable between groups. At 10-12 weeks, HbA1c decreased significantly from baseline in the overall cohort; however, no significant difference was observed between the CGM-only and CGM + SMS groups ($-0.38\% \pm 0.63\%$ vs $-0.41\% \pm 0.70\%$, $P = .833$). Improvements in diabetes self-care domains and DTSQ scores were observed in both groups without between-group differences.

In multivariable analysis, higher scan frequency was independently associated with greater HbA1c reduction at 10-12 weeks ($\beta \approx -.26\%$ per scan-frequency category increase, $P = .021$), whereas intervention assignment was not. At 24 weeks, HbA1c remained significantly lower than baseline in the overall cohort, with no difference between groups.

Conclusions: A single short-term use of isCGM combined with structured education resulted in clinically meaningful and sustained reductions in HbA1c over 24 weeks in non-insulin-treated patients with type 2 diabetes. SMS-based feedback did not provide additional benefit beyond CGM use alone. Frequent glucose scanning emerged as a key determinant of short-term glycaemic improvement, highlighting the central role of patient engagement in CGM-based diabetes management.

P179 - ECE_2834 - Secondary prevention of type 1 diabetes using oral vitamin D receptor agonists: fifteen-year outcomes from the PRECAL study

Dimitrios Papadimitriou[1], Eleni Dermitzaki[1], Rodis Paparodis[2], Ioanna Grivea[1] and George Mastorakos[3]
[1]*Pediatric Endocrinology, Pediatrics, University of Thessaly, Larisa, Greece;* [2]*Hellenic Endocrine Network, Athens, Greece;* [3]*Endocrinology, Aretaieion University Hospital, Athens, Greece*

Background: Type 1 diabetes (T1D) affects approximately 1 in 300 individuals, with a steadily increasing incidence, particularly in early childhood. Population-based screening for T1D-associated autoantibodies (T1Abs) at key ages has demonstrated high sensitivity, yet an effective, scalable strategy for secondary prevention remains unavailable. Vitamin D has immunomodulatory properties, and early-life supplementation has been associated with a markedly reduced risk of T1D. In the absence of widely available antigen-specific immunotherapies, vitamin D receptor agonists represent a potential intervention to modify disease progression following seroconversion https://pubmed.ncbi.nlm.nih.gov/39834215/.

Methods: Following an initial pilot trial of T1Ab negativization under oral calcitriol https://pubmed.ncbi.nlm.nih.gov/23302101/, the PRECAL study (ISRCTN17354692) was initiated as a prospective, interventional, non-randomized clinical trial https://pubmed.ncbi.nlm.nih.gov/37238410/. We now report 15-year outcomes in 103 children (age 0.65-16.37 years) identified as being at high risk for T1D. Ninety-seven were T1Ab-positive, while six were T1Ab-negative but carried high-risk HLA-DQ/DR genotypes. At enrollment, 9 children had impaired glucose tolerance, 4 met criteria for pre-T1D, and 10 had newly

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

diagnosed T1D. Participants received oral calcitriol (0.05 μg/kg/day) or paricalcitol (0.15 μg/kg/day). Autoantibodies, glycemic indices, C-peptide, calcium–phosphate metabolism, vitamin D metabolites, and renal imaging (when indicated) were monitored every 3-6 months.

Results: Eighty-one participants had evaluable follow-up data. Fifty-four children achieved complete negativization of T1Abs within a median of 0.56 years (range 0.32-1.9). All HLA-positive/T1Ab-negative participants remained diabetes-free during follow-up. Among children with pre-T1D, two progressed to overt T1D, while the remainder either negativized T1Abs or remained progression-free. Of those presenting with new-onset T1D, six experienced partial or complete remission lasting up to two years, and one remains in remission after 2.9 years despite persistent autoantibody positivity. Relapse of autoantibodies occurred in seven children and resolved after treatment re-initiation. Transient hypercalciuria or hypercalcemia occurred in ten cases, including one reversible nephrocalcinosis, managed with dose adjustment or discontinuation.

Conclusions: Oral calcitriol and paricalcitol were effective in inducing T1Ab negativization and delaying or preventing progression to clinical T1D in a substantial proportion of high-risk children, with acceptable safety. These findings support vitamin D receptor agonists as promising candidates for secondary prevention of T1D, particularly when initiated soon after seroconversion.

P180 - ECE_3664 - Disease burden and long-term outcomes in a monocentric cohort of adults with glycogen storage diseases

Luis Baena Ariza, Elena Dios, Silvia Torres Degayon, Rosa Benitez Avila, Alfonso Soto and Eva Venegas Moreno
Clinical Management Unit of Endocrinology and Nutrition, Virgen del Rocio University Hospital, Sevilla, Spain

Study Objective: Cross-sectional descriptive study on the characteristics of a cohort of patients with glycogen storage diseases under active follow-up at the Adult Metabolic Disorders Unit of Virgen del Rocio University Hospital (HUVR).

Material and Methods: Demographic (age, sex) and anthropometric (weight, body mass index [BMI]) data were collected. Variables recorded included specific glycogenosis type, associated comorbidities (cardiac, hepatic, renal, muscular, metabolic), degree of metabolic control, and current treatment (diet, oral nutritional supplements, cornstarch).

Results: We included 10 patients: 4 females, mean age 35 ± 4 years, median age at diagnosis 3 years (range 1-30). BMI was 26 ± 5.9 kg/m^2: 6 normal weight, none overweight, and 4 with grade I obesity.

The identified glycogenoses were: 4 type IIIa (AGL gene), 2 type IXb (PHKB gene), 1 type IXa (PHKA2 gene), 1 type Ib (SLC37A4 gene), 1 type II (Pompe disease, GAA gene), and 1 type V (McArdle disease, PYGM gene).

The most frequent comorbidity was hypertrophic cardiomyopathy, present in 3/4 type IIIa patients, followed by Crohn's-like inflammatory bowel disease in 2 patients (one type Ib and one type IXb). Only one patient (type V) had renal involvement.

Muscular involvement was observed in 8 patients (excluding the type Ib and one type IXa), with persistent elevation of muscle enzymes in 5 of them (all 4 type IIIa and the type V). Three patients had hepatic fibrosis and 2 had hepatic steatosis.

Laboratory analysis showed a mean LDL-c of 120 ± 34 mg/dL and mean triglycerides of 131 ± 57 mg/dL. Lactate levels remained <2 mmol/L in all patients. During follow-up, there was one death (one type IIIa patient).

Hypoglycemia was present in 7 out of 10 patients, all effectively prevented with daily cornstarch intake.

All patients followed a fractionated diet, and 6 additionally required protein supplements to meet daily protein intake targets.

Conclusions: Our cohort showed a higher prevalence of glycogenosis type III than reported in the literature (4/10), confirming its characteristic muscular and cardiac involvement. Compared to other metabolic disorder cohorts at our center, the degree of obesity was lower, despite a high proportion of hypoglycemia.

The lipid profile was acceptably within target and untreated, compared to literature descriptions. The age at diagnosis was heterogeneous, though most cases were concentrated in early childhood.

P182 - ECE_3446 - Roflumilast effectiveness in Greek COPD patients with obesity: a subgroup analysis of the ARGO real-life study

Konstantinos Porpodis[1], Stavros Tryfon[2], Efthymia Papadopoulou[2], Nikolaos Angelis[3], Vasiliki Paraskeva[4], Maria Bertoli[4], Polyanthi Papanastasiou[4], Alexandros Gkinis[4] and Konstantinos Kostikas[5]
[1]*Pulmonary Department, George Papanikolaou Hospital, School of Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece;* [2]*Pulmonary Department (NHS), George Papanikolaou General Hospital of Thessaloniki, Thessaloniki, Greece;* [3]*Private Pulmonary Site, Thessaloniki, Greece;* [4]*Medical Department, ELPEN Pharmaceutical Co. Inc., Athens, Greece;* [5]*Respiratory Medicine Department, University of Ioannina, Ioannina, Greece*

Background: Chronic obstructive pulmonary disease (COPD) is a heterogeneous disease frequently coexisting with obesity, which may adversely affect symptoms, severity and disease management. The relationship between body weight and COPD is non-linear, with increased mortality risk observed at both extremes of body mass index (BMI). This subgroup analysis of the ARGO study aimed to evaluate roflumilast effectiveness on dyspnea, health-related quality of life (HRQoL) and lung function in patients with severe COPD and obesity in a real-world setting.

Methods: ARGO was a multicenter, non-interventional, observational study conducted in Greece (NCT05426915). Among 750 patients with severe COPD, 299 obese patients were stratified according to World Health Organization (WHO) obesity classes (Class I-III). Patients were evaluated at baseline (V_0) and after 3 (V_1), 6 (V_2), and 12 (V_3) months of treatment with roflumilast. Dyspnea was assessed using the modified Medical Research Council (mMRC) scale, HRQoL using the validated Greek version of the Clinical COPD Questionnaire (CCQ) and lung function by Forced Expiratory Volume in 1 second (FEV_1) % predicted.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Results: Across all obesity classes, dyspnea severity demonstrated a notable shift from higher (mMRC grades 4-3) to lower (grades 2-1) levels during follow-up. The same trend was observed in the total study population. HRQoL improved significantly in all obesity subgroups, exceeding the minimal clinically important difference (MCID > 0.4) at 3, 6 and 12 months of follow-up ($P < .001$). Mean CCQ scores progressively decreased from baseline to 12 months in Obesity Class I (3.40 ± 1.05 to 2.14 ± 1.08), Class II (3.62 ± 0.96 to 2.45 ± 0.97), and Class III (4.28 ± 1.04 to 2.45 ± 1.13). Lung function also showed clinically meaningful improvement, with FEV_1 increase (MCID≥0.1L) at 6 and 12 months across all obesity classes. Similar improvements in CCQ ($\Delta V_0–V_3 = -1.24$, $P < .001$) and FEV_1% predicted ($\Delta V_0–V_3 = +5.7$, $P < .001$) were observed in the total study population.

Conclusions: The ARGO study showed that treatment with roflumilast contributes to the reduction of dyspnea severity and leads to a clinically significant improvement in HRQoL and lung function both in obese patients with severe COPD, irrespective of obesity class, and in the total study population.

P185 - ECE_1552 - Preserved arginine-stimulated glucagon secretion despite profound β-cell failure in immune checkpoint inhibitor–induced type 1 diabetes: a case series

Ryosuke Kemmotsu[1,2], Yuji Doi[3], Naoki Koike[3], Moe Kusushita[3], Yasuna Sakai[3], Hiroyuki Sho[3], Tomonori Okita[3], Ryoko Inui[3], Yukiko Tabuchi[3], Masahiro Hatazaki[1] and Tetsuyuki Yasuda[3]

[1]Department of Diabetes and Endocrinology, Osaka Acute and General Medical Center, Osaka Prefectural Hospital Organization, Osaka City, Japan; [2]Department of Diabetes, Endocrinology and Metabolism, Osaka International Medical & Science Center(Osaka Keisatsu Hospital), Osaka, Japan; [3]Osaka International Medical & Science Center(Osaka Keisatsu Hospital), Osaka, Japan

Background: Immune checkpoint inhibitor–induced type 1 diabetes (ICI-T1D) is characterized by abrupt and near-complete β-cell failure and represents a rare immune-related adverse event. Pathological studies suggest relative preservation of pancreatic α-cells in ICI-T1D, yet human functional data on α-cell responsiveness remain limited. We evaluated arginine-stimulated glucagon secretion (ASGS) in patients with ICI-T1D.

Methods: Five consecutive patients who developed insulin-dependent diabetes after immune checkpoint inhibitor therapy underwent an intravenous arginine stimulation test (30 g) under fasting conditions while continuing basal insulin therapy. Plasma glucose, C-peptide, and glucagon (sandwich ELISA) were measured at 0, 15, 30, 60, 90, and 120 minutes. Peak glucagon, peak-to-baseline increment (Δglucagon), and incremental area under the curve from 0 to 120 minutes ($iAUC_{0–120}$) were calculated. Six tests were performed, including repeat testing five months apart in one patient.

Results: The cohort included four men and one woman aged 61-76 years treated with PD-1/PD-L1 inhibitors with or without CTLA-4 blockade for solid malignancies. Most patients presented with diabetic ketoacidosis or severe hyperglycemia. Testing was performed early after onset (10-17 days in three patients) and in long-standing ICI-T1D (approximately 6 years in two patients). Baseline plasma glucose ranged from 107 to 194 mg/dL. C-peptide was undetectable (<0.01 ng/mL) in four of six tests and minimally detectable in the remaining two. In contrast, glucagon increased in all tests from baseline levels of 5.9-71.7 pg/mL to peaks of 95.6-202 pg/mL at 15-30 minutes. Δglucagon ranged from 89.7 to 168.0 pg/mL, and median $iAUC_{0–120}$ was 5453 pg/mL·min (range 4556-7665). In the longitudinally assessed patient, peak glucagon responses were similar at both time points.

Conclusions: In this case series of ICI-T1D, arginine-stimulated glucagon secretion was consistently observed despite profound β-cell failure, suggesting relative preservation of α-cell responsiveness to non-glycemic stimulation. These functional findings align with pathological observations of α-cell preservation in ICI-T1D. Larger longitudinal and comparative studies, including assessment under hypoglycemic conditions, are warranted to clarify determinants, temporal dynamics, and clinical relevance of α-cell function in ICI-T1D.

P186 - ECE_1909 - Discordance between glycated haemoglobin (Hba1c) and glucose management indicator (Gmi) in type 1 diabetes mellitus—a comphrehensive analysis of multiple factors

Kaushiki Kirty[1], Kamal Abouglila[2] and Srikanth Mada[1]

[1]Endocrine and Diabetes, University hospital of North Durham, Durham, United Kingdom; [2]Durham, United Kingdom

Introduction: With the management of type 1 DM becoming more technology-centric, especially since the emergence of the COVID-19 pandemic, it is important for clinicians to be aware of the practical issues in the interpretation of data from continuous glucose monitoring systems (CGM). Glucose management indicator (GMI) is a measure of mean glucose from CGM and is increasingly being used as a substitute for Glycated haemoglobin (HbA_{1C}).

Background: Several studies have shown varying rates of concordance between HbA_{1C} and GMI. One of the first and very high-impact studies, which shows minimal discordance, has looked at a future where CGM metrics might be the major glucose management tool. On the other hand are studies, that show significantly higher rates of discordance, recommending caution in substituting accepted markers such as HbA_{1C} with CGM metrics. In these uncertain times, it is important that clinicians have confidence that parameters derived from CGM are an acceptable surrogate for standard biomarkers such as HbA_{1C}.

Materials and Methods: We carried out a retrospective, consecutive study of 66 patients of type 1 DM to assess the concordance rates between HbA_{1C} and GMI to assess if HbA_{1C} is a robust marker to predict glycaemic control in a real-world setting of patients using Freestyle LIBRE and to analyse factors that are associated with the significant discordance levels seen between the measurements.We analysed the data downloaded from the online LIBRE systems as well as the medical records stored on the CDDFT trust database. The patients were analysed in a sequential manner as they appeared on the LIBRE database. The HbA_{1C} and GMI were calculated in mmol/mol. The formula for calculating GMI was as follows: GMI = 12.71 + 4.70587x (mean glucose in mmol/L/) (1)

Results and Conclusions: Out of 66 patients, 28 were women and 38 were men. Clinically significant discordance (a difference of

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

5.5 mmol/mol being equal to a discordance of 0.5% and 11 mmol/mol being a discordance of 1%) was found in 33.33% of the patient population (22 patients out of 66). Linear regression performed using an online tool showed that there is no significant discordance between HbA_{1C} and GMI in our patient population. Prediction interval plot had R-squared (R^2) equal to 0.7435, showing that 74.3% of the variability of GMI is explained by HbA_{1C}. Correlation (R) was found to be 0.8623. This showed that there is a very strong direct relationship between HbA_{1C} and GMI.

P188 - ECE_1049 - Clinical and ultrasound markers in familial partial lipodystrophy type 1: contribution to the phenotypic definition of Köbberling syndrome

Everardo J. Díaz-López[1,2], Antia Fernández-Pombo[1,2], Teresa Prado-Moraña[1,2], Ana I. Castro[1], Silvia Cobelo-Gómez[2], Sofía Sánchez-Iglesias[2] and David Araújo-Vilar[1,2]

[1]*Division of Endocrinology and Nutrition, University Clinical Hospital of Santiago de Compostela, Santiago de Compostela, Spain;* [2]*Unidade de Enfermedades Tiroideas e Metabólicas (UETeM)-Molecular Pathology Group, Department of Psychiatry, Radiology, Public Health, Nursing and Medicine, Center for Research in Molecular Medicine and Chronic Diseases (CIMUS), Santiago de Compostela, Spain*

Introduction: Familial Partial Lipodystrophy Type 1 (FPLD1), also known as Köbberling syndrome, is an underrecognized polygenic disorder characterized by selective loss of subcutaneous fat in the limbs, accompanied by redistribution of fat to the trunk. Clear diagnostic criteria to differentiate FPLD1 from common obesity remain lacking.

Methods: We studied 70 women divided into three groups: FPLD1 ($n = 46$), Mendelian lipodystrophies ($n = 9$), and common obesity ($n = 15$). All participants underwent biochemical testing, anthropometric measurements, handgrip dynamometry, and musculoskeletal ultrasound. In patients with suspected FPLD1, a next-generation sequencing (NGS) panel was performed to exclude pathogenic variants in genes associated with FPLD.

Results: Women with FPLD1 were older on average (61.7 ± 10.4 years) than those with other lipodystrophies (54.8 ± 10.2 years) or common obesity (52.5 ± 10.8 years; $P = .008$) and exhibited a later onset of body fat redistribution (26.7 ± 14.7 vs 14.1 ± 8.2 and 21.6 ± 15.1 years; $P = .044$). Menstrual activity was less frequent in the FPLD1 group (23.9%) compared to women with obesity (66.7%; $P = .010$). Renal disease was observed exclusively in FPLD1 (23.9%; $P = .033$), whereas hepatic steatosis was present in 65.2% of FPLD1, 100% of Mendelian lipodystrophies, and 20% of obesity cases ($P < .001$).

The waist-to-height ratio was higher in FPLD1 (0.695 ± 0.077) than in common obesity (0.751 ± 0.097; BMI-adjusted $P < .001$). Handgrip strength was lower in FPLD1 (22.2 ± 5.6 kg) compared to obesity (25.4 ± 6.6 kg; $P < .001$). The adiponectin-to-leptin ratio showed intermediate values in FPLD1 (1.28 ± 2.52) relative to other lipodystrophies (3.12 ± 2.32) and obesity (0.58 ± 0.70; BMI-adjusted $P = .007$).

Ultrasound revealed that total abdominal subcutaneous adipose tissue (SAT) was significantly lower in FPLD1 than in obesity (33.5 ± 9.6 mm; BMI-adjusted $P = .007$), and this difference persisted 2 cm above the measurement site. Femoral SAT was also greater in FPLD1 compared to Mendelian lipodystrophies, but markedly reduced compared to women with obesity (8.1 ± 5.2 mm vs 3.55 ± 2.51 and 20.75 ± 9.28 mm, respectively; $P < .001$ BMI-adjusted).. The upper abdominal/femoral SAT ratio demonstrated excellent discriminatory performance for FPLD1 (cutoff ≥ 0.62; sensitivity 97%, specificity 91.7%, AUC 0.83, 95% CI 0.70-0.95) and correlated positively with HOMA-IR ($r = 0.307$; $P = .025$).

Conclusions: FPLD1 defines a distinct adipose–metabolic phenotype, characterized by an increased waist-to-height ratio, reduced femoral fat, and partial preservation of abdominal subcutaneous tissue. The upper abdominal/femoral SAT ratio demonstrated strong discriminatory value, supporting its potential as a simple, noninvasive diagnostic tool for this syndrome.

P191 - ECE_2909 - Maternal obesity interacts with stress-coping phenotypes to program offspring metabolic health

Naama Netsach Pe'er, Adam Merai, Louis Avitan, Michaella Ben-Shachar, Albert Pinhasov and Tovit Rosenzweig

Department of Molecular Biology, and The Adelson School of Medicine, Ariel University, Ariel, Israel

Maternal obesity is an increasing global health concern with long-term consequences for both maternal well-being and offspring health. This study investigated the effects of high-fat diet (HFD)-induced maternal obesity on maternal behavior, oxytocin secretion, and offspring metabolic and behavioral outcomes, using a mouse model of stress resilience (dominant; Dom) and stress vulnerability (submissive; Sub).

Female Dom and Sub mice were maintained on either a standard diet (STD) or HFD before and during pregnancy. Maternal behavior was assessed during pre- and postnatal periods, serum oxytocin levels were measured on gestational day (GD) 19, and delivery outcomes were recorded. Offspring were examined at early postnatal stages for epigenetic alterations and in adulthood for metabolic parameters and behavioral traits, including anxiety-like behavior and sociability.

Maternal HFD exposure differentially affects maternal behavior depending on stress-coping phenotype. In Dom dams, HFD impaired maternal behavior, whereas in Sub dams, it paradoxically improved maternal care. Serum oxytocin levels were consistently higher in Dom dams compared with Sub dams, regardless of diet. Maternal HFD was associated with increased rates of stillbirths and delivery complications in both Dom and Sub mice.

Metabolic assessments revealed pronounced sex- and phenotype-specific effects. Glucose tolerance tests (GTT) demonstrated significant interactions between maternal diet, offspring diet, sex, and stress phenotype. In female offspring, impaired glucose tolerance was primarily driven by offspring HFD, with maternal HFD exerting only a minor effect, limited to Dom females. In contrast, male offspring exhibited a strong susceptibility to maternal HFD. Sub male offspring displayed the most severe glucose intolerance, with additive detrimental effects of maternal and offspring HFD exposure. Area-under-the-curve (AUC) analysis confirmed that maternal HFD did not affect

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

glucose homeostasis in females, while markedly exacerbating glucose intolerance in Sub males. Notably, glucose tolerance in Dom males remained largely unaffected, even following combined prenatal and postnatal HFD exposure.

Alterations in serum insulin and leptin levels, as well as hepatic steatosis, mirrored glucose intolerance patterns, with the most severe metabolic phenotype observed in Sub male offspring exposed to HFD both prenatally and during adulthood.

These findings demonstrate that maternal obesity programs offspring's metabolic health in a sex-specific and stress-phenotype-dependent manner. Stress vulnerability emerges as a critical modifier of susceptibility to HFD-induced metabolic dysfunction, highlighting the importance of behavioral and psychosocial factors in developmental metabolic programming.

P192 - ECE_1332 - Early changes in serum calcitonin during tirzepatide therapy in adults with obesity

Nicholas Angelopoulos[1], George Simeakis[2], Ioannis Androulakis[1], Andreas Rizoulis[1], Rodis Paparodis[1,3,4], Anastasios Boniakos[1], Dimitra Zianni[1], Valentina Petkova[1], Paraskevi Mentzelopoulou[1] and Sarantis Livadas[1]

[1]Hellenic Endocrine Network, Athens, Greece; [2]Endocrine Department, 401 General Military Hospital of Athens, Thyroid Cancer Outpatient's Clinic, Athens, Greece; [3]Loyola University Medical Center, Maywood, United States; [4]Edward Hines Jr VA Hospital, Hines, United States

Background: Glucagon-like peptide-1 (GLP-1) receptor agonists have been associated with calcitonin elevation and C-cell hyperplasia in rodent models, raising concerns regarding thyroid safety. Human data, particularly for the dual GIP/GLP-1 receptor agonist tirzepatide, remain limited. This study aimed to evaluate the temporal pattern of serum calcitonin changes during tirzepatide therapy in adults with obesity and no known thyroid disease.

Methods: In this prospective observational study, 76 adults with obesity (mean age 48.7 ± 10.8 years; 73.7% female; mean BMI 40.6 ± 8.2 kg/m^2) initiated tirzepatide for weight loss. Serum calcitonin was measured at baseline, 3 months, and 6 months using electrochemiluminescence immunoassay. Non-parametric paired analyses and linear mixed-effects models were applied due to skewed distributions. Secondary analyses assessed whether early calcitonin changes predicted subsequent elevations above predefined clinical thresholds (≥12 pg/mL). Weight loss outcomes were recorded to confirm treatment effectiveness.

Results: Median serum calcitonin increased modestly from 2.05 pg/mL (IQR 1.00-3.60) at baseline to 2.12 pg/mL (IQR 1.10-4.00) at 3 months and remained stable at 2.25 pg/mL (IQR 1.23-3.70) at 6 months (overall time effect, $P < .001$). The increase occurred early, with no further significant rise between 3 and 6 months ($P = .43$). Among participants with baseline calcitonin <12 pg/mL, two developed transient elevations above this threshold during early follow-up; no additional cases emerged at 6 months. Early change in calcitonin (baseline to 3 months) strongly correlated with 6-month change ($\rho = 0.73$, $P < .001$) and demonstrated excellent discriminatory ability for identifying individuals exceeding thresholds (AUC = 0.991). Tirzepatide therapy resulted in clinically meaningful weight loss (median −15.0% at 6 months).

Conclusions: Tirzepatide therapy is associated with an early, modest increase in serum calcitonin that does not progress with continued treatment over 6 months. Calcitonin elevations were infrequent, non-cumulative, and largely predictable from early changes. These findings support baseline and early follow-up calcitonin assessment, while suggesting that prolonged routine monitoring may not be necessary in patients without additional thyroid risk factors.

[1]Endocrinology and Metabolism, Çanakkale Onsekiz Mart University Faculty of Medicine, Canakkale, Türkiye; [2]Physiology, Çanakkale Onsekiz Mart University Faculty of Medicine, Canakkale, Türkiye; [3]Histology and Embryology, Ankara University Faculty of Medicine, Ankara, Türkiye; [4]Medical Pathology, Çanakkale Onsekiz Mart University Faculty of Medicine, Canakkale, Türkiye; [5]Medical Biochemistry, Çanakkale Onsekiz Mart University Faculty of Medicine, Canakkale, Türkiye; [6]Endocrinology and Metabolism, Canakkale Mehmet Akif Ersoy State Hospital, Canakkale, Türkiye

Background: While lipotoxicity in organs such as the liver, skeletal muscle, and pancreas has been well described, myocardial steatosis remains less well characterized. This study aimed to investigate cardiac steatosis in a high-fat diet (HFD)-fed rat model and to evaluate the effects of pioglitazone, a PPAR-γ agonist, on myocardial lipid accumulation, endoplasmic reticulum (ER) stress, and ultrastructural changes.

Methods: A total of 32 male Wistar rats were fed either a normal chow diet (NCD) or a HFD for 17 weeks and treated with pioglitazone during the final 4 weeks. Cardiac tissue was evaluated using histopathological analysis, Oil Red O staining, transmission electron microscopy (TEM), and quantitative real-time PCR to assess myocardial lipid accumulation, ultrastructural alterations, ER stress, and apoptosis-related gene expression. Circulating NT-proBNP levels were measured as a marker of cardiac stress.

Results: Epididymal white adipose tissue mass was significantly greater in HFD-fed rats compared with NCD-fed rats (5.13 ± 1.59 g vs 3.26 ± 0.94 g, $P < .001$), reflecting the impact of a HFD on adipose tissue expansion. In TEM analysis, HFD feeding resulted in significant myocardial lipid accumulation, accompanied by marked ultrastructural alterations, including mitochondrial crista disruption, ER dilation, increased intercellular space, and inflammatory cell infiltration. Pioglitazone treatment attenuated ER stress signaling, reduced intracellular lipid droplet accumulation, decreased inflammatory cell presence and partially preserved mitochondrial and ER morphology. These changes were associated with a significant reduction in circulating NT-proBNP levels, particularly in HFD–fed rats. Pioglitazone markedly decreased NT-proBNP concentrations

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

(1769 ± 312 pg/mL vs 851 ± 116 pg/mL, $P < .001$) in HFD-fed rats, whereas untreated HFD-fed rats showed no significant change over time ($P = .084$). Additionally, PCR analysis showed that HFD-fed rats treated with pioglitazone, the HFD-associated induction of unfolded protein response (UPR)/ER stress markers was significantly attenuated, with reduced expression of CHOP, ATF4, PERK, XBP1, sXBP1 and eIF2α compared with untreated HFD rats, indicating attenuation of ER stress activation.

Conclusions: Pioglitazone partially mitigates diet-induced myocardial steatosis by reducing cardiomyocyte lipid accumulation, attenuating ER stress, and preserving ultrastructural integrity. These findings may support a cardioprotective role of PPAR-γ activation through modulation of myocardial lipotoxicity.

P195 - ECE_2145 - NADH oxidase–mimetic nanozymes restore hepatic NAD+ homeostasis and ameliorate experimental MASH

Gregori Casals[1,2,3], Muling Zeng[4], Eudald Casals[5], Jie Tang[6], María Rodríguez[6], Manuel Maclas[1,7], María Rodríguez-García[1], Wladimiro Jiménez[1,2,7], Manuel Morales-Ruiz[1,2,7] and Guillermo Fernández-Varo[1,2]

[1]Department of Biochemistry and Molecular Genetics, Hospital Clínic of Barcelona, FRCB-IDIBAPS, Barcelona, Spain; [2]CIBEREHD, Madrid, Spain; [3]Department of Fundamental and Clinical Nursing, Faculty of Nursing, University of Barcelona, L'Hospitalet de Llobregat, Spain; [4]Institut de Ciència de Materials de Barcelona, ICMAB (CSIC), Bellaterra, Spain; [5]Premium Research SL, Guadalajara, Spain; [6]School of Biotechnology and Health Sciences, Wuyi University, Jiangmen, China; [7]Department of Biomedicine, University of Barcelona., Barcelona, Spain

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) is characterized by significant alterations in hepatic redox homeostasis, including a marked depletion of nicotinamide adenine dinucleotide (NAD^+). Reduced NAD^+ availability compromises mitochondrial function, lipid handling, and cellular stress responses, thereby facilitating the transition from simple steatosis to steatohepatitis (MASH) and accelerating disease progression. Therefore, restoring hepatic NAD^+ levels emerges as a major and promising therapeutic challenge. This study aimed to identify inorganic nanozymes with long-lasting NADH oxidase–like activity capable of restoring NAD^+ availability, and to evaluate their therapeutic relevance in MASLD.

Methods: We first screened inorganic nanozymes for NADH oxidase–like activity by monitoring UV–Vis spectral changes associated with NADH consumption. The panel included gold, cerium oxide, and iron oxide nanozymes. Absorbance decreases at 340 nm, and concomitant increases at 260 nm were used to quantify NADH oxidation activity. Gold nanozymes (AuNZs) were subsequently incorporated into a mesoporous silica ($mSiO_2$) framework to improve colloidal stability and biocompatibility. MASH was induced in 16 Wistar rats by a methionine- and choline-deficient diet for 3 weeks. Animals were randomly administered intravenously (iv) with AuNZs@$mSiO_2$ (0.25 mg/kg; $n = 8$) or vehicle ($mSiO_2$; $n = 8$) at weeks 1 and 2. Tissue biodistribution of nanozymes was assessed by mass spectrometry and their therapeutic efficacy was then evaluated through liver histology, serum biochemistry, hepatic gene expression profiling by PCR Array and RT-PCR, and targeted assessment of liver metabolism.

Results: Among all nanozymes tested, only AuNZs catalyzed the oxidation of NADH to NAD^+. This activity was strongly size-dependent, with 4 nm AuNZs displaying markedly higher catalytic rates than 10 nm particles. The NADH oxidase-like activity remained stable under physiological pH and ionic strength, and no NADPH oxidase activity was detected, confirming strict substrate specificity for NADH. After intravenous administration to rats with MASH, nanozymes accumulated efficiently in the liver, restored the mitochondrial hepatic NADH/NAD^+ redox balance, significantly reduced hepatic steatosis by 15% ($P < .001$) and serum alanine aminotransferase (ALT) levels by 40% ($P < .01$), and improved the expression of genes involved in metabolic pathways related to oxidative phosphorylation, lipid metabolism and transport, inflammatory response, and adipokine signaling.

Conclusions: Nanozymes with NADH-oxidizing activity can restore hepatic NAD^+ redox balance and represent a promising therapeutic approach for MASLD.

P196 - ECE_3434 - Sustained remission of severe insulin autoimmune syndrome following rituximab therapy: a two-year follow-up case report

Nektaria Papadopoulou-Marketou, Eirini Biliou, Anna Angelousi, Evanthia Kassi and Gregory Kaltsas

Endocrinology Unit, 1st Department of Propaedeutic Internal Medicine, National And Kapodistrian University Of Athens, ENETS–EURACAN Centre of Excellence for Neuroendocrine Tumors, Laiko General Hospital, Athens, Greece

Background: Insulin Autoimmune Syndrome (IAS), or Hirata disease, is a rare but important cause of endogenous hyperinsulinemic hypoglycemia. It is characterized by the triad of spontaneous hypoglycemia, inappropriately elevated insulin and C-peptide levels, and the presence of insulin autoantibodies (IAA), in the absence of exogenous insulin use. While many cases are self-limiting, severe or steroid-refractory presentations may necessitate immunosuppressive treatment.

Case Series: Case 1: A 28-year-old woman presented with recurrent episodes of loss of consciousness and adrenergic/neuroglycopenic symptoms. Point-of-care glucose was 30 mg/dL. Biochemistry revealed insulin >3000 μU/mL and C-peptide 7.1 ng/mL. Imaging (MRI, EUS, Ga-68 DOTATATE PET/CT) was negative for insulinoma. Strongly positive insulin autoantibodies (>175 U/mL) confirmed IAS. Initial treatment with high-dose diazoxide and steroids was poorly tolerated. Rituximab (2 × 1 g one week apart) led to rapid and sustained remission: insulin declined to 958 μU/mL at 1 month and 110 μU/mL at 28 months. CD19/CD20+ cells were fully depleted by 3 months. The patient remained asymptomatic with dietary management and discontinued all medications. Genetic testing revealed HLA-DRB1*0406 and a heterozygous MAPK8IP1 variant.

Case 2: A 79-year-old man was hospitalized with recurrent hypoglycemia and documented Whipple's triad. Fasting glucose was 38 mg/dL, with C-peptide 33.27 ng/mL and insulin >1000 μU/mL. Imaging (MRI, octreoscan) and selective arterial calcium injection (SACI) testing showed no pancreatic lesion or

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

lateralization. IAA were positive (2.6 U/mL; ref <1.1), confirming IAS. He had a history of polymyalgia rheumatica. Diazoxide was initially prescribed but stopped due to edema and GI intolerance. Prednisolone (40 mg) improved hypoglycemia but caused disabling myopathy. Rituximab was administered with complete resolution of hypoglycemia and disappearance of IAA at 1-year post-treatment.

Conclusions: These cases illustrate the diagnostic challenges of IAS and the limitations of standard therapy. Rituximab achieved sustained remission in both patients with steroid-refractory IAS, irrespective of age or autoimmune background. B-cell depletion may represent a valuable treatment option in selected severe cases. Long-term follow-up with biochemical monitoring is essential to assess durability of response.

P197 - ECE_1137 - The levels of advanced glycation end-products and glutathione in the plasma in patients with type 2 diabetes mellitus and different stages of cardiovascular autonomic neuropathy

Olha Monashnenko[1,2] and Borys Mankovsky[3]
[1]Center of Cardiology and Cardiac Surgery of the Ministry of Health of Ukraine, Kyiv, Ukraine; [2]Kyiv, Ukraine; [3]D.F. Chebotarev Institute of Gerontology of the National Academy of the Medical Sciences of Ukraine, Kyiv, Ukraine

Background and Aims: Cardiovascular autonomic neuropathy (CAN) is a progressive complication of type 2 diabetes mellitus (T2DM), associated with oxidative stress and accumulation of advanced glycation end-products (AGEs). This study aimed to evaluate AGEs and glutathione (GSH) levels in T2DM patients with different stages of CAN: no CAN, early CAN, and established CAN.

Materials and Methods: We examined 79 subjects divided for three groups. The first group included 16 patients with T2DM without CAN (age—63.2 ± 10.9 years, BMI—32.7 ± 6.2, mean diabetes duration—6.7 ± 4.2 years, HbA1c—7.6% ± 1.6%, (data are presented as mean ± SD). The second group included 22 patients with T2DM with early CAN (1 abnormal autonomic test) (age 60,7 ± 12.6 years, BMI —30.8 ± 4.7, mean diabetes duration—6.8 ± 4.6 years, HbA1c -7.5% ± 1.8%). The third group included 41 patients with T2DM and established CAN (2 and more abnormal autonomic tests) (age —63.5 ± 9.3 years, BMI—31.3 ± 4.7, mean diabetes duration—7.7 ± 4.9 years HbA1c—7.3% ± 1.7 %). AGEs and GSH levels in the plasma were measured using standardized laboratory methods of fluorometry and spectrophotometry. CAN was diagnosed by standard battery of tests. Statistical analysis was performed using unpaired Student's t-test (with Welch's correction for unequal variances).

Results: We found a trend towards decreased GSH levels in patients with established CAN group compared to the early CAN group and to the no CAN group (1077.24 ± 104.11 μg/mLto 1109.51 ± 141.74 and to 1136.27 ± 98.83 respectively, $P = .09$). The highest AGEs levels were observed in the **early CAN group** (90.76 ± 19.8), though intergroup differences were not statistically significant ($P > .05$ for all comparisons). The **established CAN group** showed levels comparable to the **no CAN group** (85.64 ± 16.76 vs 84.0 ± 11.12).

Conclusions: Early CAN is associated with **elevated AGEs levels**, which may serve as a marker of initial metabolic dysregulation. **CAN progression** correlates with a **declining GSH trend**, supporting the role of oxidative stress in its pathogenesis. Further studies with **larger cohorts** and additional biomarkers are needed to validate these findings and explore clinical implications.

P200 - ECE_1716 - Longitudinal clinical and metabolic profile of male patients with LMNA-related lipodystrophy syndromes

Dupuis Hippolyte, Quitterie Blois and Marie Christine Vantyghem
Endocrinology, Daibetology, Oncoendocrinology and Metabolism, Lille University Hospital, Lille, France

Introduction: Laminopathies are rare disorders caused by variants in the *LMNA* gene. They display clinical heterogeneity, ranging from frequent forms of partial lipodystrophy (FPLD2) with diabetes to rarer cardiac or muscular forms. A female predominance is observed in FPLD2 due to a phenotype easier to identify with severe metabolic complications. Diagnosis in male subjects is more challenging, and the disease course has been poorly studied.

Aims: To describe the clinical and metabolic follow-up of male subjects carrying a pathogenic *LMNA* variant and to compare carriers of the *R482-LMNA* mutation associated with FPLD2, with carriers of other *LMNA* variants.

Methods: This retrospective, single-center cohort included 33 *LMNA*-mutated men (median age at V1 42(28-51); BMI 25(23-28)) who were followed for a mean duration of 8 years in a referral centre. Clinical, biological and anthropometric (assessed with metabolic MRI & DEXA) data were compared between the first (V1) & the last visit (V2), and between the *R482-LMNA* carriers ($n = 10$) and those carrying other variants (*non-R482* group, $n = 23$).

Results: During the follow-up, in the treated whole group, a significant decrease in triglyceride, alanine aminotransferase, leptin, intra- and total abdominal fat was observed, along with a trend toward improvement in insulin-resistance parameters and femoral Z-score. At V1, *R482* carriers exhibited more metabolic complications (higher blood pressure, HbA1c, liver steatosis, intra/total abdominal fat ratio, & lower leptin levels) than *non-R482* patients, who presented with cardiac complications (implantable cardiac device (ICD), heart failure) in 40% of cases vs 0% in the *R482* group. Longitudinal analysis nevertheless revealed a substantial incidence of diabetes in the *non-R482* group and a significant increase in ICD in the *R482* group.

Conclusions: This study confirms the phenotypic diversity of laminopathies in men and highlights the need for repeated cardiometabolic evaluation and diabetes screening regardless of the pathogenic variant.

Background: Individuals born small-for-gestational-age (SGA) often achieve catch-up growth, yet rapid or excessive catch-up and calorie-focused nutritional support have been linked to higher lifetime risks of obesity and type 2 diabetes. Recombinant human growth hormone (GH) is a standard therapy for those who fail to catch up, but its long-term metabolic safety remains uncertain because GH can counterregulate insulin action while potentially supporting beta-cell function; however, long-term adult metabolic outcomes remain incompletely defined. We examined how early-life GH treatment and subsequent dietary exposure shape adult growth and energy/glucose homeostasis.

Methods: Pregnant C57BL/6 mice were fed either normal chow or a protein-restricted diet (PRD; 9 kcal% protein) during pregnancy and lactation. SGA pups from PRD dams were treated with recombinant human GH or vehicle via subcutaneous injection from postnatal weeks 3-8. Growth and adiposity were traced until adulthood, while energy expenditure was assessed by indirect calorimetry. Glucose metabolism was evaluated by glucose and insulin tolerance tests, complemented by *ex vivo* assessment of glucose-stimulated insulin secretion and islet insulin content. In a separate cohort, mice were switched to a high-fat diet (HFD; 60 kcal% fat) from 8 weeks of age.

Results: Offspring from protein-restricted dams demonstrated reduced body length, a key feature of SGA, which GH treatment rescued. Under normal chow, GH did not alter adult fat mass or energy expenditure. GH also did not impair glucose homeostasis; glucose tolerance was even improved with increased islet insulin content and enhanced secretory capacity. By contrast, exposure to an HFD after completion of GH treatment attenuated GH-mediated recovery of body length in adulthood and increased visceral adiposity in GH-treated offspring born SGA. Glucose tolerance showed a trend toward impairment in female but not in male mice after post-treatment exposure to HFD.

Conclusions: These findings support the metabolic safety of GH therapy in SGA and highlight the importance of dietary management in clinical applications.

Funding: This study was supported by the National Research Foundation of Korea (NRF) grants funded by the Korea government (MSIT) (2020R1A4A3078962, RS-2024-00406845, and RS-2025-00515235), by a grant of the Korea Health Technology R&D Project through the Korea Health Industry Development Institute (KHIDI) funded by the Ministry of Health & Welfare, Republic of Korea (RS-2024-00404132), and by grant No. 16-2018-010 from the SNUBH research fund.

P203 - ECE_2857 - Diagnostic predictors of endogenous hyperinsulinemic hypoglycaemia

Christina Romberg[1,2], Matthias Hepprich[2,3], Sandrine A. Urwyler[1,2], Julie Celine Refardt[2,4] and Emanuel Christ[1,2]
[1]Basel 4056, Switzerland; [2]Department of Clinical Research, University Hospital Basel, Basel, Switzerland; [3]Department of Endocrinology, Diabetes and Metabolism, Sankt Clara Hospital, Basel 4058, Switzerland; [4]Department of Internal Medicine, Section of Endocrinology, Erasmus Medical Centre, Rotterdam 3015, The Netherlands

Background/objective: The gold standard for diagnosing endogenous hyperinsulinemic hypoglycaemia (EHH) is the prolonged fasting test. While neuroglycopenic symptoms are crucial for the evaluation of the fasting test, the respective relevance of measuring insulin, C-peptide, proinsulin and beta-hydroxybutyrate remains unclear. Therefore, we aimed to explore the relevance of these parameters based on a literature review.

Methods: We conducted extensive literature research in the databases Embase and Medline to identify case reports and original studies that report data on the fasting test eg, fasting duration, blood glucose and insulin levels at the end of the fast, as well as data on C-peptide, proinsulin and beta-hydroxybutyrate, where available. Histology was seen as the diagnostic gold standard in the patients.

Results: Data of 522 individual patients and 36 individual controls with data on the fasting tests were identified. Whereas blood glucose, insulin and C-peptide are measured and reported in most cases, proinsulin and beta-hydroxybutyrate appeared in only 51% and 50% respectively. In combination with blood glucose, C-peptide reached higher diagnostic accuracy (AUC 0.97) than insulin (AUC 0.93), however, proinsulin and beta-hydroxybutyrate seem to be even better (both AUC = 0.99).

Conclusions:

- The fasting test is an excellent diagnostic test with very high sensitivity and specificity
- There is considerable variation in reporting and conducting fasting tests worldwide.
- Measurements of glucose and C-peptide at the end of the fasting test are sufficient to establish the diagnosis.
- Proinsulin and beta-hydroxybutyrate show very high diagnostic accuracy for diagnosing EHH but are not measured on a regular basis.

Abstract citation ID: lvag096.376

P204 - ECE_2482 - Clinical consequences of insulin overbasalization in hospitalized patients with type 2 diabetes mellitus: evidence for a basal insulin ceiling effect and long-term predictors

Feride Özkara Akkuş, Abdulkadir Sarı, Özge Baş Aksu, Mustafa Sahin, Rifat Emral and Demet Çorapçıoğlu
Endocrinology and Metabolic Diseases, Ankara Üniversitesi Tıp Fakültesi Hastaneleri, Ankara, Türkiye

Background: In the management of type 2 diabetes mellitus (T2DM), basal insulin titration is essential for achieving fasting plasma glucose (FPG) targets. However, escalation beyond a certain threshold—referred to as insulin overbasalization—may result in a clinical plateau where further dose increases fail to improve glycaemic control while promoting adverse metabolic effects. Although international guidelines recommend an upper limit of 0.5 U/kg/day, this threshold is frequently exceeded in routine practice. Data on the metabolic consequences in hospitalized patients admitted for glycaemic regulation remain

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

limited. This study evaluated the association between overbasalization and long-term metabolic parameters.

Methods: This retrospective, observational study included 100 adult patients with T2DM followed at Ankara University Faculty of Medicine between 2020 and 2025. Fifty overbasalized patients (basal insulin >0.5 U/kg/day with HbA1c >8%) were matched for age, sex, and BMI with fifty non-overbasalized patients. All patients had received insulin therapy for at least 12 months. Anthropometric and metabolic changes were assessed over a 12-month follow-up after hospitalization. ROC analysis was performed to identify predictors of overbasalization.

Results: Baseline demographic characteristics and HbA1c levels were comparable between groups. The overbasalization group had a significantly longer duration of insulin therapy (11.5 ± 6.6 vs 9.4 ± 6.7 years, $P = .016$) and a higher prevalence of hypertension ($P = .035$). During follow-up, overbasalized patients experienced a significant increase in body weight ($+3.5 \pm 11.1$ kg, $P = .028$), whereas the non-overbasalized group achieved a significant reduction (-3.2 ± 9.8 kg, $P = .024$). Improvements in HbA1c and FPG were observed exclusively in the non-overbasalization group (−1.5% and −44.5 mg/dL, respectively, $P < .001$). In the overbasalized cohort, basal insulin dose was not associated with glycaemic improvement but showed a negative association with BMI changes. ROC analysis identified insulin treatment duration as the sole significant predictor of overbasalization (AUC 0.663, $P = .005$; 95% CI 0.554-0.771), with a cut-off of 9.5 years.

Conclusions: In hospitalized patients with T2DM, insulin overbasalization is associated with weight gain and limited glycaemic benefit, consistent with a basal insulin "ceiling effect". Prolonged reliance on basal dose escalation despite inadequate control may reflect elements of clinical inertia in inpatient diabetes management. These findings highlight the importance of timely treatment intensification strategies with non-insulin agents rather than continued basal insulin escalation after approximately 9.5 years of therapy.

Background: Vitamin D is increasingly recognized as a key modulator of growth, metabolism, and body composition in early life. However, the long-term impact of maternal vitamin D status and its multiple circulating forms on childhood anthropometry remains poorly understood. The KLOTHO cohort provides a unique opportunity to investigate these associations using detailed multi-form vitamin D profiles.

Methods: Within the prospective KLOTHO cohort, serum concentrations of eight vitamin D metabolites [$25(OH)D_2$, $25(OH)D_3$, $1\alpha,25(OH)_2D_2$, $1\alpha,25(OH)_2D_3$, 3-epi-$25(OH)D_2$, 3-epi-$25(OH)D_3$, D_2, D_3] were quantified at birth by liquid chromatography–tandem mass spectrometry (LC–MS/MS). Anthropometric measurements were assessed at 10-11 years of age (height, weight, BMI, waist circumference, and skinfold thickness). Associations between $\log_{10}$-transformed metabolite levels and anthropometric outcomes were evaluated using Spearman's correlation and multivariable linear regression adjusted for available covariates (sex, birth weight, maternal BMI, and season). False discovery rate (FDR) correction was applied (q Results: Among 98 children with complete follow-up data, vitamin D metabolites at birth were significantly associated with anthropometric indices at 10-11 years. Specifically, total $25(OH)D_3$ and its epimer 3-epi-$25(OH)D_3$ correlated positively with height ($\rho = 0.28$, $q = 0.04$) and negatively with BMI and triceps skinfold thickness ($\rho \approx -0.25$ to -0.30, $q < 0.05$). In the adjusted models, $25(OH)D_3$ remained consistently associated with adiposity markers ($\beta_std = -.27$, $P = .008$), although this association did not remain statistically significant after false discovery rate correction ($q = 0.06$).

Conclusions: Multi-form vitamin D assessment at birth reveals distinct metabolic patterns associated with later childhood growth and adiposity. These findings suggest that specific vitamin D metabolites, particularly $25(OH)D_3$ and its epimer, may be associated with long-term influences on somatic growth trajectories, underscoring the potential importance ofearly vitamin D sufficiency for metabolic health.

Inc., Athens, Greece; [13]1st Cardiology Clinic, Hippokration General Hospital, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece

Background: The 2019 European Society of Cardiology (ESC) and European Atherosclerosis Society (EAS) dyslipidaemia guidelines, updated in 2025, identify non-High Density Lipoprotein Cholesterol (non-HDL-C) as a secondary therapeutic target providing complementary information on a patient's atherogenic lipid burden, particularly relevant in populations at increased cardiovascular risk, such as patients with dyslipidaemia and diabetes mellitus (DM). This sub-analysis of ZEUS study evaluated non-HDL-C target attainment and changes in HbA1c after 12 months of treatment with fixed-dose combination (FDC) of ezetimibe/rosuvastatin in Greek patients with dyslipidemia and DM under routine clinical practice.

Methods: ZEUS was a multicenter, prospective, non-interventional observational study (NCT03947866) enrolling 570 Greek adult patients with dyslipidaemia, of whom 113 had a concomitant diagnosis of DM. Among patients with DM, the majority were classified as very-high cardiovascular risk (78.76%), followed by high (18.58%) and moderate (2.65%) cardiovascular risk. Cardiovascular risk classification and lipid target assessment were performed according to the 2019 ESC/EAS guidelines. Due to the small sample size of patients classified as moderate cardiovascular risk, no robust conclusions could be drawn.

Results: Dyslipidaemic patients with DM, baseline mean (±SD) non-HDL-C levels were 143.10 mg/dL (±43.94) in very-high cardiovascular risk subgroup and 175.57 mg/dL (±48.02) in high-risk. After 12 months of treatment with the FDC of ezetimibe/rosuvastatin, non-HDL-C levels significantly decreased ($P < .001$) across these categories to 78.72 mg/dL (±18.12) in very-high-risk and to 83.63 mg/dL (±18.44) in high-risk patients with DM. According to the 2019 ESC/EAS guidelines, non–HDL-C target achievement rates at month 12 were 49.44% and 57.14%, respectively. Mean HbA1c, reduced significantly ($P = .03$) in very-high-risk patients with DM from 6.73% (±1.05) to 6.32% (±0.72) and in high-risk patients from 6.60% (±0.77) to 6.06% (±0.65), $P = .01$.

Conclusions: This subgroup analysis of ZEUS study in patients with DM showed that twelve-month treatment with FDC of ezetimibe/rosuvastatin led to statistically significant reductions in non-HDL-C and HbA1c across all cardiovascular-risk groups. The observed rates of non–HDL-C target achievement highlight the need for more complete application of guideline-recommended lipid management in routine clinical practice, particularly in patients at increased cardiovascular risk.

[1]Department of Cell Biology, Physiology, and Immunology, University of Cordoba, Cordoba, Spain; [2]Maimonides Biomedical Research Institute of Cordoba (IMIBIC), Cordoba, Spain; [3]Reina Sofia University Hospital (HURS), Cordoba, Spain; [4]Laboratory of Cellular Metabolism and Metabolic Regulation, VIB Center for Cancer Biology, VIB, Leuven, Belgium; [5]Laboratory of Cellular Metabolism and Metabolic Regulation, Department of Oncology, KU Leuven and Leuven Cancer Institute (LKI), Leuven, Belgium; [6]Spatial Metabolomics Expertise Center, VIB Center for Cancer Biology, VIB, Leuven, Belgium

Prostate cancer (PCa) is a hormone-dependent tumour and one of the most prevalent endocrine-related cancers in men worldwide. PCa progression is influenced by its interaction with the surrounding tumour-microenvironment, highlighting the role of periprostatic-adipose-tissue (PPAT) through the secretion of bioactive molecules (eg, adipokines); however, the nature/influence of this complex cell communication and signalling remains to be fully elucidated. To address this, we perform multiomic and bioinformatic approaches (integration of transcriptomic-proteomic-metabolomic data) into PPATs and their secretome using a well-characterized cohort of PPAT samples [75 PCa patients vs 21 control-subjects with benign prostatic hyperplasia (BPH)]. Different prostate cell models [normal-like prostate (PNT2) and PCa (PC3/DU145/LNCaP/22Rv1) cells] were used to test the role of lipocalin-2/receptors axis in PCa cell-behaviour via multiple functional and molecular analyses, including gain- and loss-of-function assays by overexpressing LCN2 and its associated receptor SLC22A17, as well as silencing the latter, to precisely characterize the modulation of this axis. As a result, a signature of significantly dysregulated adipokines profile was identified in the PPATs of PCa compared with those of BPH patients. Subsequent unsupervised clustering analyses allowed the identification of two distinct molecular phenotypes of PCa patients with a unique fingerprint of adipokines alterations that presented distinctive clinical/metabolic features (ie, BMI/diabetes/dyslipidemia), being lipocalin-2 the only adipokine showing consistent differences at the transcriptomic/proteomic levels. Lipocalin-2 treatment did not affect proliferation/apoptosis/colony-formation in PCa cells, but migration was significantly increased in PNT2 and decreased in DU145 cells, wherein a differential lipocalin-2 receptor expression profile (especially

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

SLC22A17) may directly contribute to these differential effects. This is further supported by our functional modulation experiments, which reinforce the critical role of the LCN2/SLC22A17 axis in PCa cell aggressiveness. Notably, expression of SLC22A17 receptor, but not LRP2, was significantly downregulated in different PCa patient cohorts and was associated with significantly poorer disease-free survival in PCa patients. Molecularly, lipocalin-2 treatment was associated with alterations in critical oncogenic/metabolic pathways, including neutrophil-degranulation, inflammation and autophagy, suggesting a connection with inflammasomes. Further analyses revealed a weight-dependent association between lipocalin-2 and individual inflammasome components. Additionally, arachidonic acid in the PPAT-secretome positively correlated with lipocalin-2 levels, specifically in obese PCa-patients, suggesting a metabolic link to lipocalin-2-mediated effects. In conclusion, these results demonstrate a profound dysregulation of the PPAT-derived adipokine profile in PCa, which is associated with obesity-related comorbidities, highlighting the multifaceted role of lipocalin-2/SLC22A17-receptor axis as a potential key player in the interaction between PPAT-PCa microenvironment, by influencing inflammation and tumour-cell behaviour.

P211 - ECE_2319 - Hematological toxicity of radioligand therapy based on personalized dosimetry: interim results of the multicenter DUONEN study

Marta Opalinska[1], Maclej Kolodziej[2], Grzegorz Kamiński[2], Marek Dedecjus[3], Aldona Kowalska[4], Marek Saracyn[2], Piotr Garnuszek[5], Wioletta Lenda-Tracz[1], Danuta Gąsior-Perczak[4], Anna Borkowska[1], Joanna Januszkiewicz-Caulier[3], Anna Budzyńska[2], Agata Kubik[2], Krzysztof Kacperski[2], Patrycja Szubstarska[2], Wioletta Chalewska[3], Izabela Cieszykowska[5], Renata Mikolajczak[5] and Alicja Hubalewska-Dydejczyk[1]

[1]Chair and Department of Endocrinology, Jagiellonian University Medical College, Krakow, Poland; [2]Department of Endocrinology and Isotope Therapy, Military Institute of Medicine—National Research Institute, Warsaw, Poland; [3]Department of Endocrine Oncology and Nuclear Medicine, National Institute of Oncology, Warsaw, Poland; [4]Collegium Medicum Jan Kochanowski University in Kielce, Kielce, Poland; [5]Radioisotope Centre POLATOM, National Centre for Nuclear Research, Otwock, Poland

Introduction: RTL targeted somatostatin receptors is increasingly available. Individual dosimetry performed during RLT of NET may enable to achieve better results of therapy with maintaining its safety. In theory, administering higher doses of RLT allows for greater radiation delivery to the tumor, potentially improving long-term treatment outcomes, but it also increases the risk of side effects, particularly myelotoxicity.

Aim: To evaluate the hematologic toxicity of personalized dosimetry in patients undergoing radioligand therapy.

Materials and Methods: Adult patients with advanced, unresectable well-differentiated (G1/G2) GEP-NETs progressing on long-acting SSA are randomized into four arms of personalized RLT:

A: [^{177}Lu]Lu-DOTATATE at a fixed 7400 MBq per cycle.

B: Combination of [^{177}Lu]Lu-DOTATATE and [^{90}Y]Y-DOTATATE (initially 3700:1850 MBq), with [^{90}Y]Y-DOTATATE dose adjusted by individual dosimetry to maximize tumor radiation.

C: Same as B, but [^{90}Y]Y-DOTATATE is fixed and [^{177}Lu]Lu-DOTATATE is adjusted by dosimetry.

D: [^{177}Lu]Lu-DOTATATE starting at 7400 MBq, with subsequent doses adjusted by individual dosimetry.

Critical doses to the kidneys and bone marrow for all patients in arms B-D have cumulative limits of <23 Gy for the kidneys and <2 Gy for the red bone marrow over 4 cycles.

Results: 55 patients already started RLT (arm: A-15, B-16, C-14, D-10 cases). In average, the RTL doses in the arm D were increased, in arm C decreased while in arm B remained similar across whole therapy.

Hematologic toxicities were assessed during and after RLT. Nadir values were generally recorded during RLT, with most patients showing partial or complete recovery over time. Persistent reductions (diagnosed if nadir was diagnosed during follow-up) were observed most frequently in neutrophils (18%) and platelets (14%), whereas hemoglobin and total white blood cells were less affected (12% and 8%, respectively).

Persistent anemia (Hb≤10 g/dL) was most frequently observed in group D (33%) and group C (18%). Thrombocytopenia (PLT < 150 x10^3/μL) persisted in 22%-27% of patients in groups C and D, although severe PLT < 50 x10^3/μL were observed only in one patient in arm C. Additionally, leukopenia (WBC < 4.0 x10^3/μL) and neutropenia (NEU < 2.0 x10^3/μL) were present in approximately 10%-22% of patients, with a slightly higher incidence in group D. Groups A and B showed lower rates of persistent hematologic impairments after treatment.

Conclusions: Dosimetry based RLT was associated with manageable hematologic toxicity, but a small subset of patients may experience clinically significant or life-threatening cytopenias.

The study is funded by the Medical Research Agency(Project number 2019/ABM/01/00077-00).

P212 - ECE_1407 - Periprostatic adipose tissue boosts prostate cancer progression via androgen receptor-mediated lipolytic reprogramming

Hannah Hui

Hong Kong, Hong Kong

Periprostatic adipose tissue (PPAT), a specialized fat depot surrounding the prostate gland, is linked to poor prostate cancer (PCa) prognosis. However, the mechanisms underlying the crosstalk between PPAT and PCa progression remain poorly understood. We found that PCa tumors, particularly aggressive ones, actively stimulated androgen receptor (AR) expression in PPAT, with upregulation of AR and its signaling in PPAT a hallmark of PCa aggressiveness. Adipocyte-specific AR overexpression was sufficient to promote PCa growth in vitro and in vivo. Mechanistically, AR directly suppressed E3 ligase *RNF213*, which stabilized hormone-sensitive lipase (HSL) to drive lipolysis. Consequently AR-driven lipolysis liberated free fatty acids (FFAs) to boost PCa cell growth and remodel the tumor microenvironment. Clinically, PPAT in high-risk PCa patients exhibited elevated lipolytic activity and reduced RNF213 expression. The PPAT conditioned medium (CM) of high-risk PCa patients

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

enhanced PCa cell proliferation, which was reversed by blocking fatty acid uptake. Targeting this axis with the antilipolytic drug Acipimox significantly attenuated PCa growth in vivo. Our findings reveal a critical feed-forward loop between PCa and PPAT, orchestrated by adipocyte AR signaling. This self-reinforcing cycle accelerates disease progression, and targeting PPAT lipolysis presents a promising therapeutic strategy.

P213 - ECE_3504 - Epidemiological profile of 134 patients with multiple endocrine neoplasia type 1 (MEN1)

Nektaria Papadopoulou-Marketou, Kosmas Daskalakis, Charikleia Christakou, Maria Eleni Chondrogianni, Marina Tsoli, Evanthia Kassi and Gregory Kaltsas
Endocrinology Unit, 1st Department of Propaedeutic Internal Medicine, National And Kapodistrian University Of Athens, ENETS–EURACAN Centre of Excellence for Neuroendocrine Tumors, Laiko General Hospital, Athens, Greece

Introduction: Patients with Multiple Endocrine Neoplasia type 1 (MEN1) exhibit marked clinical heterogeneity regarding tissue involvement, metastatic potential, disease stage at diagnosis, and overall mortality.

Aim: To evaluate the clinical manifestations and mortality associated with various neuroendocrine tumors (NETs) in a cohort of patients with MEN1.

Methods: We conducted a retrospective analysis of 134 patients with clinical and/or genetically confirmed MEN1 followed at the ENETS–EURACAN Centre of Excellence, Laiko General Hospital, Athens.

Results: Of 134 patients, 53.5% were male and 46.5% female. The mean follow-up from diagnosis to last data collection was 14.8years. At study conclusion, 121 patients (90.3%) were alive and 13 (9.7%) had died.

Genetic testing was performed in 58.9% of patients (79/134), with MEN1 mutations identified in 75 individuals, most frequently in exons 9 (22.8%), 10 (22.8%), and 3 (15.2%). The most common initial manifestation was primary hyperparathyroidism (88%), occurring before age 25 in 39.4%, between 25-40 in another 39.4%, and after age 40 in 19.2% of patients.

Gastroenteropancreatic NETs (GEP-NETs) were identified in 82 patients (75.9%). Firty-eight (50%) had G1, 23 (37.5%) G2 tumors (13% of which were stage III-IV), and one G3 tumor (2.7%, stage IV). Functioning GEP-NETs occurred in 15 patients (9 gastrinomas and 6 insulinomas).

Pituitary adenomas (pitNETs) were found in 67 patients (60.9%); 46 were microadenomas (57.5%) and 15 macroadenomas (18.8%).

Adrenal adenomas were observed in 30 patients (28.3%): 17 were unilateral (14.2%) and 19 bilateral (15.8%). Only 30% were functioning: 26.7% secreting cortisol, followed by aldosterone (3.3%).

Other neoplasias included meningiomas (11.8%), breast cancer (4.0%), and differentiated thyroid cancer (7.1%).

Pulmonary NETs (LungNETs) were found in 11 patients: 8 typical carcinoids (TC),3 atypical carcinoids (AC). Thymic carcinoids (ThC) were diagnosed in 5 patients: 2 with G2 tumors developed ACTH-dependent Cushing's syndrome.

Distant metastases from GEP-NETs, occurred in 16 patients (12.9%), all with G2 tumors >2 cm, mainly hepatic. Pancreatectomy was performed in 27 patients (24.1%); 38.0% received somatostatin analogs, and 13.4% PRRT. All patients with AC and/or ThC developed metastates, and 5 died. Additionally, seven patients died due to metastatic G2 PanNETs, and one from sepsis.

Conclusions: In one of the largest Greek MEN1 cohorts, we described the clinical phenotype, morbidity, and mortality of affected individuals. The study highlights the clinical and neoplastic heterogeneity of the syndrome and underscores the need for systematic, individualized follow-up in specialized centers with expertise in neuroendocrine tumors.

P215 - ECE_1904 - Computed tomography texture analysis of pheochromocytomas and abdominal paragangliomas: relationship with clinical, laboratory, and histopathological data

Natalya Tarbaeva, Almaz Manaev, Dmitry Beltsevich, Liliya Urusova, Kseniya Vysotskaya, Anna Roslyakova, Anastasia Chevais, Nadezhda Platonova, Ekaterina Troshina, Galina Melnichenko and Natalia Mokrysheva
Endocrinology Research Centre, Moscow, Russia

Objectives: Pheochromocytomas and paragangliomas (PPGLs) are heterogeneous chromaffin-cell tumors with diverse clinical course. Predicting the biological behavior of these tumors remains a critical challenge.

Aims: This study aimed to evaluate the feasibility of texture analysis of computed tomography (CT) images for predicting the clinical, biochemical, and histopathological features of PPGLs.

Materials and Methods: We conducted a retrospective single-center study. Preoperative four-phase contrast-enhanced CT images of 230 patients with a verified diagnosis of PPGL were analyzed. Clinical manifestations, including the presence and duration of arterial hypertension, carbohydrate metabolism disorders, dyslipidemia, and atherosclerosis were evaluated. In the first stage, comparative and correlation analyses were performed between hormonal parameters and contrast-enhanced CT findings. In the second stage, patients were stratified into two groups based on morphological characteristics: PASS scores <4 ($n = 155$) and PASS scores ≥ 4 ($n = 56$). Logistic regression analysis was conducted to assess the potential of predicting group classification based on clinical, laboratory, and contrast-enhanced CT imaging data.

Results: PPGLs characterized by isolated normetanephrine secretion demonstrated significantly greater contrast enhancement in both arterial and venous CT phases compared with other secretion types ($P < .001$). Correlation analysis revealed statistically significant moderate positive correlations between plasma free normetanephrine levels and the volume of viable tumor tissue without necrosis. In contrast, plasma free metanephrine levels showed moderate negative correlations with maximum

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

venous phase attenuation, the degree of venous contrast enhancement, and the 90th percentile of X-ray density within functioning tumor tissue during the venous phase of CT. Significant associations were observed between tumor size and the presence or absence of necrosis ($P < .001$), as well as between tumor structure and size ($P = .004$). CT imaging features demonstrated moderate predictive ability for PASS score–based group classification, with an AUC of 0.647 (95% CI: 0.471-0.797), sensitivity of 0.923 (95% CI: 0.727-1.000), specificity of 0.400 (95% CI: 0.250-0.548), positive predictive value of 0.333 (95% CI: 0.176-0.500), and negative predictive value of 0.941 (95% CI: 0.800-1.000).

Conclusions: Texture analysis of contrast-enhanced CT images provides a noninvasive, quantitative approach to aid in the characterization of the biochemical and histopathological features of PPGLs. Our study underscores the importance of further development of texture analysis methods to enhance diagnostic accuracy and improve prediction of the disease course.

P216 - ECE_3577 - A Taiwanese founder effect: distinct clinical phenotype of SDHD c.3G>C pathogenic variant in pheochromocytoma and paraganglioma

Wan-Chen Wu[1] and Pei-Lung Chen[2]
[1]*Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan;* [2]*National Taiwan University Hospital, Taipei, Taiwan*

Background: Germline mutations in *SDHD* (PGL1) are classically characterized by a high prevalence of head and neck paragangliomas (HNPGLs) and a strong paternal transmission pattern. While Western cohorts often exhibit an HNPGL-dominant phenotype with low rates of adrenal pheochromocytoma (PCC), we have identified a unique clinical profile in Taiwanese patients carrying a suspected founder variant at the start codon of *SDHD*.

Methods: We retrospectively analyzed 19 patients with confirmed germline *SDHD* pathogenic variant (PV). Phenotypes were classified into four groups: (1) Head and neck (H&N)—isolated carotid or other HNPGLs; (2) Extra-adrenal—sympathetic PGLs outside the H&N and adrenal regions; (3) Adrenal—unilateral or bilateral PCC; and (4) Multifocal—involvement of ≥2 of the above sub-groups.

Results: A striking founder effect was evident, with 18 of 19 patients (94.7%) harboring the *SDHD*, c.3G>C (p.0) variant; one patient carried the c.3G>A variant. The median age at diagnosis was 36.7 years (IQR 25.5-44.0). Distinct from Western reports, isolated H&N disease was found in only 31.6% ($n = 6$) of patients. In contrast, adrenal involvement (21.1%, $n = 4$) and multifocal presentations (42.1%, $n = 8$) were highly prevalent. Clinical symptoms were reported in 57.9% of the total cohort, rising significantly to 75.0% in the adrenal group and 87.5% in the multifocal groups. Biochemical evaluation revealed marked catecholamine excess with norepinephrine-predominant in the adrenal and multifocal groups (median 24-hr urine norepinephrine levels of 1052.2 and 669.7 μg/24h, respectively, compared to only 38.0 μg/24h in the H&N group). Metastatic disease occurred in four patients (21.1%). Paternal transmission was molecularly confirmed in three families (fathers carry the *SDHD* variant and mothers test negative). Interestingly, carrier screening identified two HNPGL cases (a father and a sister of index patients who both presented with bilateral adrenal PCCs), further illustrating the remarkable phenotypic heterogeneity of the *SDHD*, c.3G>C variant even within the same pedigree.

Conclusions: The *SDHD* c.3G>C founder variant in Taiwan is associated with a high degree of phenotypic diversity, specifically a high incidence of adrenal PCC and multifocal PGLs. These findings diverge from the HNPGL-centric paradigm, suggesting that for patients with this specific genotype, comprehensive systemic surveillance and aggressive cascade family screening are mandatory to detect both secretory and non-secretory tumors early.

P218 - ECE_3111 - Immunocytochemical studies in the diagnosis of thyroid and parathyroid tumors in outpatient endocrine practice

Marcin Nosal[1], Barbara Budzynowska[2] and Ewa Ogłodek[1]
[1]*Collegium Medicum, Jan Dlugosz Uniwersity, Częstochowa, Poland;* [2]*Gdów, Poland*

Background: Immunocytochemistry is an underutilized yet valuable diagnostic tool in outpatient endocrinology. Its use improves diagnostic accuracy in selected thyroid and parathyroid lesions, particularly in non-referral settings with limited access to advanced diagnostics. Early and precise diagnosis is essential for optimal surgical planning and for reducing diagnostic delay, especially in rare endocrine malignancies.

Materials and Methods: Between 2021 and 2025, 698 fine-needle aspiration biopsies (FNABs) of thyroid lesions were performed in a single-physician outpatient endocrine clinic in southern Poland. Until 2022, patient qualification followed the 2018 recommendations of the Polish Society of Endocrinology; from 2023 onward, the updated 2022 guidelines were applied. In clinically ambiguous cases, immunocytochemical staining was used as an adjunct diagnostic method. This analysis focuses on the diagnostic value of calcitonin and parathyroid hormone (PTH) immunostaining in medullary thyroid carcinoma (MTC) and parathyroid tumors.

Results: Medullary thyroid carcinoma accounts for approximately 1%-2% of all thyroid malignancies and may correspond cytologically to Bethesda categories III-VI, occasionally mimicking Hürthle cell neoplasms. Although serum calcitonin is a key diagnostic marker, its interpretation may be limited by preanalytical instability, the hook effect, or ectopic secretion. In the presented case, only mildly elevated calcitonin levels were detected, potentially delaying diagnosis. Immunocytochemical staining for calcitonin enabled definitive identification of MTC, later confirmed histopathologically, and allowed appropriate surgical management including lymphadenectomy. Parathyroid adenomas present similar diagnostic challenges. Cytological findings are often nonspecific, and serum calcium may remain normal, particularly in early or normocalcemic hyperparathyroidism. In addition, PTH instability may result in false-negative laboratory results. In the analyzed case, a lesion initially suspected to be thyroid in origin showed elevated PTH with normal calcium and low vitamin D. Immunocytochemical staining confirmed parathyroid origin, which was later verified histologically.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Conclusions: Immunocytochemical detection of calcitonin and parathyroid hormone is a reliable, cost-effective diagnostic tool that improves accuracy in thyroid and parathyroid pathology. Its use is especially valuable in outpatient settings, facilitating earlier diagnosis, supporting surgical decision-making, and improving overall patient management.

P219 - ECE_2258 - Periprostatic adipose tissue-secreted miR-6798-5p in obesity acts as a oncomiR regulating prostate cancer aggressiveness through the TAGLN2 gene

Laura Arroyo-Millán[1,2], Francisco Porcel-Pastrana[1,2], Ignacio Gil-Duque[1,2], Antonio Prats-Escribano[1,2], Miguel E. G-Garcia[1,2], María Ortega-Bellido[1,2], Antonio Jesús Martínez-Fuentes[1,2,3], Manuel D. Gahete[1,2,3], André Sarmento-Cabral[1,2,3] and Raul M. Luque[1,2,3]

[1]Department of Cell Biology, Physiology and Immunology, University of Córdoba, Cordoba, Spain; [2]Maimónides Institute of Biomedical Research of Córdoba (IMIBIC), Reina Sofía University Hospital (HURS), Cordoba, Spain; [3]CIBER Pathophysiology of Obesity and Nutrition (CIBERobn), Cordoba, Spain

The periprostatic adipose tissue (PPAT) that surrounds two-thirds of the prostate has been postulated as a putative active player in the pathological interaction between obesity (OB) and prostate cancer (PCa); however, molecular bases underlying this PPAT-OB-PCa communication is scarce. This study was aimed at assessing for the first time the dysregulation of the whole human PPAT-secreted miRNome of PCa patients under normo-weight and OB, and to identify miRNAs with a potential critical role in the pathophysiological association between PPAT-OB-PCa. To that end, conditioned media (CM) from a discovery cohort of PPAT explants derived from PCa-patients with normo-weight ($n = 16$) or OB ($n = 12$) was determined and compared using an Affymetrix-miRNA array, showing that the expression of 33 miRNAs was significantly altered, wherein five exhibited a high discriminating capacity. Then, a systematic validation using a validation cohort [PCa-patients with normo-weight ($n = 15$) or OB ($n = 25$)] demonstrated that miR-6798-5p was profoundly altered in PCa-patients with OB. Functional assays, both *in vitro* [proliferation, migration, colony, and tumoursphere formation in various PCa cell models (LNCaP, 22Rv1, DU145, and PC-3)] and *in vivo* (tumours growth, MKI67 and mitosis number in a preclinical model), demonstrated the impact of miR-6798-5p modulation (overexpression and/or inhibition) on critical cancer hallmarks, suggesting a oncomiR role in PCa cells. Remarkably, an induced obesogenic milieu (high glucose and insulin) further amplified the miR-6798-5p-associated oncogenic effects *in vitro*. Mechanistically, proteomic and enrichment analyses revealed critical changes in protein expression upon miR-6798-5p modulation (ie miR-6798-5p overexpression promoted transcriptional activity and TP53 repression, while its inhibition reactivated ribosome biogenesis and rRNA processing pathways) through the regulation of TAGLN2 (an actin-binding protein). Altogether, our data demonstrates that the PPAT-secreted miR-6798-5p acts as a oncomiR in the interplay between OB and PCa, promoting tumour aggressiveness via TAGLN2 repression and translational reprogramming, and highlights that miR-6798-5p inhibition might be a promising therapeutic strategy in PCa.

P221 - ECE_3118 - Sequential [68Ga]Ga-PSMA-11 and [18F]FDG PET/CT in TENIS syndrome: a prospective comparison

Klaudia Zajkowska, Paulina Cegla, Marta Wojewódzka-Mirocha, Paweł Ochman, Agata Sackewicz, Joanna Januszkiewicz-Caulier and Marek Dedecjus

Department of Endocrine Oncology and Nuclear Medicine, Maria Skłodowska-Curie National Research Institute of Oncology, Warsaw, Poland

Background: In patients with differentiated thyroid carcinoma (DTC) and biochemical evidence of persistent or recurrent disease with negative iodine scintigraphy (TENIS syndrome), [^{18}F]FDG PET/CT is regarded as the imaging gold standard. Prostate-specific membrane antigen (PSMA) is expressed by the neovasculature of several solid tumours, including DTC. Emerging evidence suggests that PSMA-targeted PET/CT may be useful in TENIS syndrome, demonstrating metastatic lesions in various anatomical sites, including those not visualised on [^{18}F]FDG PET/CT. The aim of this study was to compare the diagnostic performance of [^{68}Ga]Ga-PSMA-11 PET/CT and [^{18}F]FDG PET/CT in TENIS syndrome and to assess the optimal sequential imaging pathway.

Methods: Forty patients with TENIS syndrome were prospectively enrolled and randomly assigned to one of two diagnostic arms. In the first arm (PSMA–FDG), patients underwent [^{68}Ga]Ga-PSMA-11 PET/CT as the initial examination, followed by complementary [^{18}F]FDG PET/CT in cases with a negative result. In the second arm (FDG–PSMA), patients were first examined with [18F]FDG PET/CT and subsequently with [^{68}Ga]Ga-PSMA-11 PET/CT if the initial scan was negative. The two groups did not differ significantly with respect to serum thyroglobulin, disease stage or previous treatments. Endpoints were patient-level detection rates for each tracer and for each imaging pathway, as well as the incremental value of the complementary examination.

Results: In the PSMA–FDG arm, [^{68}Ga]Ga-PSMA-11 PET/CT was positive in 10/20 patients. Among the 10 patients with a negative PSMA scan, complementary [^{18}F]FDG PET/CT was positive in 2/

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

10. In the FDG–PSMA arm, [^{18}F]FDG PET/CT was positive in 16/20 patients. Among the four patients with a negative FDG scan, complementary [^{68}Ga]Ga-PSMA-11 PET/CT was positive in 1/4. Overall, the PSMA–FDG arm led to detection of pathological lesions in 12/20 (60%) patients, whereas the FDG–PSMA arm yielded positive findings in 17/20 (85%) patients. Patient-level detection rates were 45.8% (11/24) for [^{68}Ga]Ga-PSMA-11 PET/CT and 60% (18/30) for [^{18}F]FDG PET/CT. Complementary PET/CT after an initial negative result yielded additional clinically relevant information in 15% (3/20) of patients.

Conclusions: In patients with TENIS syndrome, [^{68}Ga]Ga-PSMA-11 PET/CT demonstrated inferior diagnostic performance compared with [^{18}F]FDG PET/CT, supporting the role of [^{18}F]FDG PET/CT as the reference imaging modality in this setting. A sequential FDG–PSMA strategy yielded a higher patient-level detection rate than the reverse pathway. Although complementary PSMA imaging may add incremental value after a negative FDG scan, [^{68}Ga]Ga-PSMA-11 should be considered an adjunct to, rather than a substitute for, [^{18}F]FDG PET/CT in TENIS syndrome.

Background: Metastatic pheochromocytoma and paraganglioma (mPPGL) are rare neuroendocrine tumors with heterogeneous clinical behavior, variable treatment responses, and limited prognostic data.

Methods: We performed a retrospective single-center analysis of patients with mPPGL. Demographic characteristics, timing of metastatic disease, treatment modalities, genetic findings, clinical outcomes, and survival data were collected and analyzed descriptively.

Results: Twelve patients with mPPGL were included (6 males and 6 females), with a median age at diagnosis of 49.5 years (range, 20-68) and a median follow-up duration of 86 months (range, 11-272). Nine patients had primary pheochromocytoma, whereas two had primary intra-abdominal paraganglioma and one had primary intrathoracic paraganglioma. Metastatic disease was present at initial diagnosis in 4/12 patients (33.3%), while 8/12 (66.7%) developed metastases during follow-up, with a median time to metastasis of 56 months (range, 10-171). The most frequent metastatic sites were bone, liver, lymph nodes, and lungs, often with multifocal involvement. Genetic testing was performed in 10/12 patients (83.3%). Pathogenic or likely pathogenic variants were identified in 6/12 patients (50%), including SDHB ($n=1$), SDHD ($n=1$), MEN2A ($n=1$), RET ($n=1$), as well as somatic mutations in RET ($n=1$) and ATRX ($n=1$).

All patients received multimodal treatment, including surgery ($n=11$), ^{131}I-MIBG ($n=10$), chemotherapy (CVD) ($n=7$), somatostatin analogues ($n=2$), peptide receptor radionuclide therapy (PRRT) ($n=1$), and temozolomide ($n=1$). At the last follow-up, complete response was observed in 2/12 (16.7%), partial response in 1/12 (8.3%), stable disease in 3/12 (25%), and progressive disease in 6/12 patients (50%). During long-term follow-up, 7/12 patients (58.3%) died. The cause of death was disease related in 5/7 patients (71.4%), while one patient experienced sudden death of unknown cause, and in one patient the cause of death was undocumented. Median overall survival was 86 months (range, 12-272).

Conclusions: Despite marked clinical heterogeneity and high disease-related mortality, a subset of patients with mPPGL can achieve durable disease control, highlighting the importance of individualized multimodal treatment in specialized centers.

P223 - ECE_3069 - SMAC-2 and SMAC-3 cells: characterization of two new ACC patient-derived cell lines

Andrea Abate[1], Mariangela Tamburello[1], Claudia Bonera[1], Guido Tiberio[2], Sara Baldelli[3], Mattia Carini[3], Alessia Inglesi[4], Maria Scatolini[4], Deborah Cosentini[5], Marta Laganà[5], Marta Leporati[6], Luigi Poliani[7], Domenico Cosseddù[6], Duilio Brugnoni[3], Alfredo Berruti[5] and Sandra Sigala[1]

[1]Department of Molecular and Translational Medicine, University of Brescia, Brescia, Italy; [2]Surgical Clinic, University of Brescia at ASST Spedali Civili di Brescia, Brescia, Italy; [3]ASST Spedali Civili di Brescia, Central Clinical Laboratory, Brescia, Italy; [4]Molecular Oncology Laboratory, Fondazione Edo ed Elvo Tempia, Ponderano, Italy; [5]Oncology, University of Brescia at ASST Spedali Civili di Brescia, Brescia, Italy; [6]Laboratory Medicine, AO Ordine Mauriziano, Torino, Italy; [7]Pathology Unit, University of Brescia at ASST Spedali Civili di Brescia, Brescia, Italy

Background: AdrenoCortical Carcinoma (ACC) is an aggressive, rare and heterogeneous malignancy that demands a broad spectrum of preclinical models. In this context, generating new cell lines is crucial. This work reports the establishment and characterization of two new patient-derived ACC cell lines, named SMAC-2 and SMAC-3 cells.

Materials and Methods: Cell cultures were established from two patients diagnosed with ACC and operated on. Mutational status was investigated by NGS and Sanger methods. Gene expression was analysed by qRT-PCR, while protein expression was evaluated by immunofluorescence. Hormonal secretion was investigated by LC-MS/MS. Cell proliferation was evaluated by BrdU-incorporation assay while cell viability was assessed by WST-1 assay.

Results: SMAC-2 originated from the primary adrenal tumor mass of a metastatic EDP-M-treated ACC in a female patient with Cushing's syndrome and hyperandrogenism, whereas SMAC-3 was derived from a male patient with a mitotane-treated local recurrence without clinical signs of hypercortisolism. Both lines harbored *TP53* mutations; SMAC-2 additionally carried a pathogenic *CTTNNB1* alteration and a *CDKN2A* deletion, while SMAC-3 showed a mutation in *MSH2*. Basal hormone profiling

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

revealed a cell line–specific fingerprint. Also, gene and protein expression of steroid hormone receptors presented a model-specific pattern. In line with the clinical manifestation of the original patient, SMAC-2 secretes high levels of cortisol. SMAC-3 is also able to secrete cortisol at baseline, although in a low amount. The reference drug in ACC, mitotane displayed in both cell lines a low potency in terms of reduction of cell viability and cell proliferation. Interestingly, treatment with low concentrations of mitotane (IC10, calculated based on cell viability) resulted in a significant reduction of cortisol in both cellular models. Experiments in a wide range of passages were carried out to study the stability of the two cell lines.

Conclusions: SMAC-2 and SMAC-3 therefore exhibit distinctive molecular and functional features that enlarge the panel of available ACC experimental models and constitute valuable tools for preclinical studies alongside existing cell lines.

P224 - ECE_2759 - Steroid hormones and endocrine disruptors in the prediction of prostate cancer aggressiveness

Jana Vitku[1], Tereza Skodova[1], Lucie Kolatorova[1], Anežka Varausová[1], Lukas Gadus[2,3], Ludmila Michnova[4] and Jiri Heracek[2,3]

[1]Department of Steroids and Proteofactors, Institute of Endocrinology, Prague, Czech Republic; [2]Department of Urology, Military University Hospital Prague, Prague, Czech Republic; [3]First Faculty of Medicine, Department of Urology, Charles University, Prague, Czech Republic; [4]Department of Pathology, Military University Hospital Prague, Prague, Czech Republic

Introduction: Prostate cancer (PCa) is a hormone-dependent disease in which steroid hormones and potentially also endocrine disruptors (EDs) may play an important role.

Aims: The study aimed to analyze steroid hormones (28 unconjugated, 17 conjugated) and EDs (15 unconjugated, 16 conjugated) in prostate tissue (cancerous and non-cancerous) and plasma in patients ($n = 163$) who underwent robotic radical prostatectomy for PCa, and to relate these profiles to tumor aggressiveness.

Methods: Quantification was performed using liquid chromatography–tandem mass spectrometry (LC-MS/MS). Cancerous and non-cancerous tissues from the same patients were compared using a paired t-test. Subsequently, individual steroids and EDs were compared between patient groups stratified by Gleason score, representing tumor aggressiveness, using ANOVA models. Finally, multivariate prediction models (bidirectional orthogonal projections to latent structures, O2PLS) were applied to evaluate complex relationships between steroids and EDs and PCa aggressiveness.

Results: Steroid hormones and EDs did not significantly differ between cancerous and non-cancerous tissue within the same patient, except for 17-hydroxyprogesterone ($P = .022$) and conjugated estriol ($P = .009$), both of which showed lower concentrations in cancerous tissue compared with non-cancerous tissue.

In the OPLS model constructed from prostate tissue samples, higher levels of conjugated pregnenolone, dehydroepiandrosterone (DHEA), 17-hydroxyprogesterone, corticosterone, 21-deoxycortisol, and both conjugated and unconjugated dihydrotestosterone were associated with lower Gleason score, suggesting a potential protective role. In contrast, higher Gleason score (ie greater cancer aggressiveness) was associated with increased levels of oxygenated DHEA metabolites (7α-hydroxyDHEA and conjugated 7-oxoDHEA), estrone, 5α-dihydroprogesterone, and glucocorticoids (cortisol and cortisone), indicating a shift toward alternative steroidogenic pathways, enhanced glucocorticoid activity, and increased estrogenic signaling in aggressive disease. Notably, both conjugated and unconjugated butylparaben were positively associated with higher Gleason score, suggesting that ED exposure may contribute to PCa progression. This tissue-based model explained a substantial proportion of Gleason score variability (32.5%, 26.7% after cross-validation), confirming the key role of intraprostatic steroid metabolism in PCa. In contrast, the OPLS model constructed from plasma samples explained considerably less variability in Gleason score (14.9%, 11.4% after cross-validation). Although some of the same steroids contributed to the model, their associations with Gleason score were predominantly negative.

Conclusions: This study provides the first integrated multisteroid and multiED analysis in prostate cancer tissue and plasma, highlighting the dominant role of intraprostatic steroid metabolism in determining tumor aggressiveness.

P226 - ECE_3536 - Serum biomarkers as tools for disease recurrence detection and monitoring in patients with neuroendocrine tumors

Edyta Tkacz[1], Anna Kurzyńska[2], Agnieszka Stefańska[1], Małgorzata Szumińska[1], Karolina Węgrzyn[2], Anna Sowa Staszczak[2], Justyna Brodowicz[3], Katarzyna Gawlik[3], Bogdan Solnica[3], Marta Opalinska[2] and Alicja Hubalewska-Dydejczyk[2]

[1]Department of Endocrinology, Oncological Endocrinology, Nuclear Medicine and Internal Medicine, University Hospital in Krakow, Krakow, Poland; [2]Chair and Department of Endocrinology, Jagiellonian University Medical College, Krakow, Poland; [3]Department of Clinical Biochemistry, Jagiellonian University Medical College, Krakow, Poland

Introduction: A diverse group, which are neuroendocrine neoplasms (NENs) is characterized by variable secretory activity. Nevertheless, the spectrum of reliable biomarkers suitable for biochemical detection and monitoring is currently limited. Factors involved in angiogenesis, inflammatory processes, and extracellular matrix remodeling, such as tumor necrosis factor-aplha (TNF-α), fascin, matrix metalloproteinase 7 (MMP-7) and lipocalin-2, have been shown to contribute to tumor progression and metastasis in a multiple type of cancers. However, their clinical relevance in neuroendocrine tumors (NET) has not been fully clarified yet. The present study assessed serum concentrations of selected factors in patients with NETs in comparison with healthy controls.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Methods: The study involved eighty participants: 60 patients with advanced, histologically confirmed NETs and 20 healthy volunteers without a history of any malignancy. Serum levels of TNF-α, fascin, MMP-7, and lipocalin-2 were measured using enzyme-linked immunosorbent assay (ELISA) kits following the manufacturer's protocols. All samples were obtained under fasting conditions and analyzed in duplicate. Analysis of all measured factors was performed separately for pancreatic (Pan NETs), small intestine (Si NETs), and other NET cohort (rectum, stomach, lung), in comparison with healthy control groups. Statistical analysis of quantitative variables was performed using the ANOVA Kruskala-Wallisa test, ANOVA for independent groups test, with a significance threshold set at $P < .05$. Calculations were performed using Statistica 13 software.

Results: Serum concentrations of TNF-α, fascin, MMP-7, and lipocalin-2 were higher in NET patients compared with the control group: 16.91 vs 13.01 pg/mL ($P = .000025$); 23.81 vs 10.39 ng/mL ($P = .07$); 2.80 vs 1.65 ng/mL ($P = .000013$); and 196.97 vs 103.49 ng/mL ($P = .000002$), respectively. Only the difference in fascin levels did not reach statistical significance. In a comparative analysis of all measured factors, only MMP-7 showed an association with tumor origin. MMP-7 concentrations were significantly higher in patients with small intestine NETs compared with those with pancreatic NETs or other NET subtypes (3.39 vs 2.45 vs 2.8 ng/mL; $P = .002$).

Conclusions: The study confirmed significant differences in the serum concentrations of the analyzed factors between patients with neuroendocrine tumors (NETs) and healthy controls. The strongest associations with the presence of NETs were observed for TNF-α, MMP-7, and lipocalin-2. Additionally, MMP-7 concentrations varied depending on the primary tumor site. Further studies in larger, long-term cohorts are needed to fully determine the clinical relevance and potential utility of these analyzed factors.

P227 - ECE_3750 - Machine learning identifies hidden phenotypes and predicts somatostatin analogue response in gastroenteropancreatic neuroendocrine tumours

Fernando Vidal-Ostos De Lara[1], Sofiya Khoruzha Aleksandrovych[1], Jose Ignacio Busteros Moraza[2], Remedios Gomez Sanz[3], Bernard Theillac[4], Raquel Niddam Sanchez[1], Edinson Caviedes Sanchez[5], María Laura Villalobos Leon[5] and Concepcion Blanco Carrera[5]

[1]Endocrinology and Nutrition, Principe de Asturias University Hospital, Alcalá de Henares, Spain; [2]Pathological Anatomy, Principe de Asturias University Hospital, Alcalá de Henares, Spain; [3]General Surgery, Principe de Asturias University Hospital, Alcalá de Henares, Spain; [4]Nuclear Medicine, Principe de Asturias University Hospital, Alcalá de Henares, Spain; [5]Oncology, Principe de Asturias University Hospital, Alcalá de Henares, Spain

Introduction: Gastroenteropancreatic neuroendocrine tumours (GEP-NETs) display marked clinical heterogeneity. Conventional TNM staging and histological grading inadequately capture prognostic diversity, and reliable prediction of somatostatin analogue (SSA) response remains limited. Machine learning approaches may uncover hidden phenotypes and improve treatment selection.

Material and Methods: We conducted a retrospective cohort study of 115 GEP-NET patients diagnosed and treated in a multidisciplinary unit (2001-2024). Demographic data, tumour characteristics (location, size, TNM stage, grade), biomarkers (Ki-67, chromogranin A, angioinvasion), treatment details, and outcomes were collected. We applied unsupervised K-means clustering (18 variables) to identify phenotypes and supervised Random Forest classification to predict SSA response in 65 patients receiving SSA as first-line therapy. Model performance was compared using AUC-ROC, C-index, cross-validation (5-fold), and feature importance analysis (SHAP values).

Results: K-means clustering identified four distinct GEP-NET phenotypes: (1) "Indolent Incidental" ($n = 28$, 24%): small pancreatic NETs, no metastases, 5-year overall survival (OS) 95%; (2) "Gastric Indolent" ($n = 30$, 26%): gastric NETs, well-differentiated, 5-year OS 92%; (3) "Carcinoid Intestinal" ($n = 35$, 30%): multifocal small-bowel carcinoids with 46% metastatic disease, 5-year OS 68%; (4) "Aggressive Metastatic" ($n = 22$, 19%): large T3-T4N1M1 tumours, 5-year OS 32%. Machine learning clustering improved prognostic discrimination (C-index 0.71) compared to conventional TNM staging (C-index 0.62), a relative improvement of 14% ($P < .001$ by log-rank test). For SSA response prediction, Random Forest achieved superior performance (AUC 0.79, 95% CI 0.68-0.90) compared to standard logistic regression (AUC 0.68, 95% CI 0.54-0.82). Top predictive variables were: histological grade (importance 0.24), baseline chromogranin A (0.19), tumour location (0.15), angioinvasion (0.12), and tumour size (0.10). A simplified clinical nomogram (0-5 point risk score) stratified patients into risk categories predicting SSA response probability: low risk 95%, intermediate risk 65%, high risk 15%.

Conclusions: Machine learning identifies four GEP-NET phenotypes reflecting distinct biological behaviours superior to conventional TNM staging. Random Forest prediction of SSA response enables personalized treatment selection and avoids unnecessary SSA exposure in resistant patients. This approach integrates non-linear variable interactions missed by traditional statistical methods. Further external validation in multicentric cohorts is warranted to implement these tools in routine clinical practice.

Introduction: Growth hormone (GH) treatment is approved for cancer survivors with GH deficiency. Alongside daily GH, long-acting GH (LAGH) has been recently approved for the treatment of GHD. Given its different mechanistic action to daily GH, the safety of LAGH in this group needs further study.

Methods: The Global Registry for Novel Therapies in Rare Bone and Endocrine Conditions (https://globe-reg.net/) was initiated in 2022 to collect real world data on safety and effectiveness of GH therapy. In late 2025, a non-interventional, retrospective and prospective study, SAFE-Survivors was launched with the aim of using GloBE-Reg to study cases of all ages who receive daily GH or LAGH following a cancer diagnosis; longitudinal data shall be analysed at 12, 24, 60, and 120 months after initiation of GH. The study will recruit for 10 years and this report presents the preliminary analysis of the first data tranche.

Results: Since its launch in late 2022, 44 centres from 24 countries in 5 continents have enrolled 5075 cases with a median current age of 12.2 (10^{th}, 90^{th} centile: 6.3, 18.1). Of these, 2928 (58%) had growth hormone deficiency (GHD). Among this cohort, 92 (3%) cases from 16 centres received GH following a cancer diagnosis. Of these, 10 (11%) were receiving LAGH, 2 had stopped GH and the remainder were on daily GH. In the first data tranche at study launch, data was available for 74 (80%) cases from 11 centres. The median age at start of therapy and the current age was 11 yrs (6.4, 14.8) and 14.5 yrs (9.8, 19.2), respectively. This cohort consisted of 64 reports of intracranial tumours including craniopharyngiomas (n,23) and pituitary tumours (n,8). Therapy data was available in 64 cases and the broad groups were surgery only (10), radiation only (3), chemotherapy only (3) and combined (48). Median follow-up after GH initiation was 28 months(4.5, 96) with data at 12, 24, 60 and 120 months in 23, 19, 9 and 3 cases respectively.

Conclusions: This initial analysis offers an early view of the long-term safety of LAGH in comparison to daily GH treatment in cancer survivors with GHD. No new cancers or recurrences were found in this cohort. However, this is based on a small sample and short follow up time and requires further data clarification. Increased patient recruitment and data collection of the GloBE-Reg over time will be crucial to fully assess safety and guide clinical practice.

P230 - ECE_3166 - Seminal microbiota as an endocrine modulator: lactobacillus-dependent reprogramming of hormonal networks in male idiopathic infertility

Fudulu Alina[1], Adrian Albulescu[1], Anca Botezatu[1], Dinu Draganescu Daniela[2], Suzana Vladoiu[2,3], Cristina Stancu[2,4], Andrei Muresan[2], Dinu Draganescu Daria[5] and Corin Badiu[2,6]
[1]Department of Molecular Virology, Ştefan S. Nicolau Institute of Virology, Bucureşti, Romania; [2]Research Department , Endocrinology IV, C.I. Parhon National Institute of Endocrinology, Bucureşti, Romania; [3]"C.I.Parhon" National Institute of Endocrinology, Bucharest, Romania; [4]Laboratory of Molecular, Cellular and Structural Endocrinology Research, Endocrinology IV, C.I. Parhon National Institute of Endocrinology, Bucureşti; [5]University Medical Center, Groningen, The Netherlands; [6]Endocrinology, Endocrinology IV, "C Davila" University of Medicine and Pharmacy, Bucharest, Romania

Background: Despite its prevalence, many cases of male infertility remain idiopathic, prompting the search for novel etiological factors. Emerging research suggests the seminal microbiome can regulate hormones and immunity, yet its role in male reproduction is unclear. The study aimed to investigate how *Lactobacillus* abundance modulates the correlation network of key reproductive and adrenal hormones.

Methods: We included patients with male idiopathic infertility ($n = 27$), and a fertile control group ($n = 21$). Seminal microbiota was determined by 16S rRNA gene sequencing (V3-V4 region) and bioinformatic analysis provided relative taxonomic abundances. Serum levels of key reproductive hormones—including Follicle-Stimulating Hormone (FSH), Luteinizing Hormone (LH), Testosterone, Estradiol (E2), Inhibin B, Dehydroepiandrosterone Sulfate (DHEA-S), Sex Hormone-Binding Globulin (SHBG), Prolactin (PRL), and Cortisol—were quantified using ELISA kits according to the manufacturer's protocols. Pearson correlation analyses were performed to assess hormonal interrelationships using GraphPad Prism 10.4.1.

Results: Subjects were classified into "Low-Lactobacillus" and "High-Lactobacillus" groups, based on a predefined cutoff (<80%) of *Lactobacillus* spp. abundance. In the Low-Lactobacillus environment, the endocrine network was characterized by a highly significant positive correlation between FSH and LH ($r = 0.91$, $P < .0001$), indicating a strong activation of the hypothalamic-pituitary-gonadal axis. Furthermore, a strong positive correlation was observed between DHEA-S and free Testosterone ($r = 0.77$, $P = .0012$), as well as between SHBG and total Testosterone ($r = 0.72$, $P = .0056$). A significant negative correlation was present between Inhibin B and FSH ($r = -0.60$, $P = .0298$). The High-Lactobacillus context revealed DHEA-S emerging as a central factor. It exhibited a very strong positive correlation

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

with Inhibin B (r = 0.80) and with SHBG (r = 0.75), but strong negative correlations with E2, total Testosterone, and FSH (r = −0.66 to −0.69, all $P < .0001$). A novel, strong positive coupling was observed between total Testosterone and E2 (r = 0.73, $P < .0001$). Despite network-wide shifts, two key correlations remained stable and significant regardless of *Lactobacillus* abundance: PRL—Cortisol (r ≈ 0.60) and Inhibin B—FSH (r ≈ −0.60 to −0.65).

Conclusions: *Lactobacillus* abundance acts as a switch between distinct endocrine states. A deficient microbiome corresponds to classic HPG axis activation, while a Lactobacillus-rich environment shifts the network toward a DHEA-S-centered profile. Thus, the microbiota influences not just hormone levels, but the very architecture of endocrine interactions.

P232 - ECE_1750 - Can AI make a difference in patient satisfaction and consultation efficiency using an AI-based documentation tool in endocrinology practice?

Roxana Novac[1], Repede Vlad[2] and Razvan Valcu[2]
[1]*CLINICA DR. NOVAC, Bacau, Romania;* [2]*Apolloiq, Taunton, United Kingdom*

Background: Administrative documentation during medical consultations may reduce physician–patient interaction and impact patient satisfaction. Artificial intelligence (AI)–based tools designed to capture and structure medical conversations may improve consultation workflow and communication.

Aim: To evaluate patient satisfaction and consultation efficiency in standard endocrinology consultations compared with consultations assisted by an AI-based documentation application.

Methods: Twenty patients were included in a prospective observational study. Each patient underwent two endocrinology consultations: one standard consultation without AI assistance and one consultation supported by an AI-based application that listened to the physician–patient conversation and generated structured medical documentation.

After each consultation, patient satisfaction was assessed using validated questionnaires: the Client Satisfaction Questionnaire (CSQ-8) and the Patient Satisfaction Questionnaire Short Form (PSQ-18). Consultation duration and estimated time saved were recorded.

Results: AI-assisted consultations were associated with a mean time saving of approximately 10 minutes per consultation compared with standard visits. Patient satisfaction scores were higher following AI-assisted consultations, particularly in domains related to communication quality, perceived physician attentiveness, and overall consultation experience. Patients reported feeling more listened to, benefiting from continuous eye contact with the physician due to the absence of manual note-taking. The AI application also supported a more complete medical history by minimizing the loss of relevant anamnesis details.

Conclusions: The use of an AI-based documentation tool during endocrinology consultations was associated with improved patient satisfaction and increased consultation efficiency compared with standard practice. These findings support the potential role of AI-assisted documentation as a complementary tool in routine endocrinology care.

P234 - ECE_3795 - Impact of in utero exposure to sesamol on folliculogenesis

Manon Fiévet[1,2], Gabrielle Sulimowski[1], Louisa Menu[1], Annica Frau[1] and Denis Nonclercq[3]
[1]*Faculty of Medicine, Pharmacy and Biomedical Sciences, Health Institute, Laboratory of Histology, University of Mons, Mons, Belgium;* [2]*Faculty of Medicine, Pharmacy and Biomedical Sciences, Health Institute, University of Mons, Mons;* [3]*Faculty of Medicine, Pharmacy and Biomedical Sciences, Health Institute Laboratory of Histology, Laboratory of Histology, University of Mons, Mons, Belgium*

The growing popularity of vegetarian and vegan diets has significantly increased our exposure to phytoestrogens, which are potential endocrine disruptors. Sesamol, obtained by roasting sesame seeds, is classified as a phytoestrogen. As hormonal variations play a decisive role in the formation and differentiation of the reproductive system, pregnancy represents a period of increased sensitivity to endocrine disruptors. Through its ability to cross the placental barrier and interact with estrogen receptors, sesamol could impact the development of the reproductive system of babies exposed in utero.

The aim of this study is to investigate the consequences of prenatal exposure to sesamol on folliculogenesis and blood hormone levels in F1 offspring. Pregnant rats were orally exposed to different doses of sesamol (30 or 100 mg/kg/day) from the 14th to the 19th day of gestation. Histological analysis of the ovaries was performed in newborn (aged 4 days) or adult (aged 120 days) animals from the F1 offspring.

In newborn rats, in utero exposure to sesamol does not affect the relative proportion of pre-antral follicles. However, morphometric analysis of the ovaries revealed an increase in apoptosis of oocytes present in primordial follicles, resulting in a rise in the number of atretic follicles. The proliferation rate of follicular and thecal cells was also assessed by anti-BrdU immunohistochemistry. Our results show that sesamol has no impact on the proliferation rate of these cells at this stage of life.

In adulthood, the proportion of the different types of follicles is not affected by the treatment. By contrast, sesamol induces a significant increase in the number of S-phase cells in the granulosa of antral follicles. An increased frequency of polyovular follicles is also observed in treated animals. The alteration of the zona pellucida and the corona radiata in these abnormal follicles could impact the process of gamete recognition and fertilisation. ELISA tests carried out on blood serum samples showed that exposure to sesamol has no significant impact on testosterone and oestrogen levels. By contrast, a significant increase in AMH concentration was observed in animals exposed to a dose of 100 mg/kg/day.

In conclusion, prenatal exposure to sesamol induces morphological alterations in the ovaries, such as an increase in oocyte apoptosis within primordial follicles and a resurgence of polyovular follicles. The increased synthesis of AMH associated with these morphological alterations could have an impact on fertility.

P235 - ECE_3659 - Exposure to microplastics (MP) and nanoplastics (NP) during the perinatal life alters hormone levels in Wistar rat dams and offspring

Patricia Cristina Lisboa[1], Nathalia Medeiros Nehme[2], Nelyana de Oliveira Serpa[3], Egberto Gaspar de Moura[2] and Iala Milene Bertasso[2]

[1]Ciências Fisiológicas, Universidade do Estado do Rio de Janeiro, Rio de Janeiro br, Brazil; [2]State University of Rio de Janeiro, Rio de Janeiro, Brazil; [3]Federal University of Rio de Janeiro, Rio de Janeiro, Brazil

Currently, plastic production in the world is around 400 million tons/year. Due to improper disposal, waste is generated that accumulates in the environment, such as MP (particles smaller than 5 mm) and NP (particles smaller than 100 nm), which have already been found in air, soil, water and food. Additionally, MP and NP have been detected in various human tissues, such as the placenta and breast milk, and may affect the endocrine system of offspring. Here, we studied if exposure to MP and NP during pregnancy and lactation can cause hormonal dysfunction in dams and offspring of both sexes and different ages. Experimental design was approved by ethics committee (CEUA/032/2022). From gestational day 7 until postnatal day 21 (weaning), Wistar rat dams received vehicle (filtered water; control group; $n = 9$), 10 µm polystyrene microparticles (25 µg/kg body weight, MP group; $n = 8$) or 100 nm polystyrene nanoparticles (25 µg/kg body weight, NP group; $n = 8$). Hormone levels of dams, male and female pups were evaluated by multiplex assay at weaning (21 days-old), puberty (45 days-old) and adulthood (120 days-old). Corticosterone, T4, TSH, leptin and insulin were analyzed at all ages, while gonadotropins and sex steroids were evaluated at adulthood. Data were analyzed by one-way ANOVA with Dunnett's post-test; $P < .05$ as significant. NP dams had lower plasma T4 (-10%, $P = .033$), while MP dams did not show hormonal changes. At weaning, male offspring had lower plasma corticosterone (MP −65%, $P < .0001$; NP −55%, $P = .0001$), while females did not show hormone alterations. At puberty, no changes were observed in either sex. In adulthood, male offspring presented higher plasma FSH (MP +53%, $P = .0280$; NP +51%, $P = .0437$), while females presented higher plasma TSH (MP +54%, $P = .0328$; NP +50%, $P = .0483$). Thus, perinatal exposure to both MP and NP alters the hormonal homeostasis of dams and offspring at weaning and in adulthood, while at puberty, no changes were found.

P237 - ECE_1934 - Influence of blood phosphatidyl-ethanol, quantitative LC-MS/MS assessment of alcohol intake on metabolic and cortisol parameters

Dupuis Hippolyte, Charlotte Altet, Florian Hakim, Antoine Danais, Espiard Stephanie and Marie Christine Vantyghem

Endocrinology, Daibetology, Oncoendocrinology and Metabolism, Lille University Hospital, Lille, France

Fifty-years ago, the first cases of alcohol-induced pseudo-Cushing syndromes were described (1977 Smals & Rees, *The Lancet*, 1977; Wright, *JCEM*, 1978), Chronic alcohol consumption remains a pitfall in the evaluation of Cushing syndrome, and its impact on the corticotropic axis is often underestimated, sometimes leading to unnecessary investigations. From a pathophysiological standpoint, alcohol may either directly stimulate the corticotropic axis, through alcohol-related stress, anxiety, and depressive disorders, resulting in abnormal glucocorticoid feedback and loss of circadian rhythm, or indirectly affect liver steroid metabolism via 11beta-hydroxysteroid-dehydrogenase type 1, which activates cortisone into cortisol. In this complex clinical setting, phosphatidylethanol (PEth), measured by LC-MS/MS, recently emerged as a direct and specific biomarker of alcohol intake.**Objectif:** To evaluate the relationship between chronic alcohol intake, assessed by PEth, and clinical, biological, and body-composition parameters reflecting glucocorticoid exposure.

Methods: This **retrospective cross-sectional study,** conducted in accordance with the French MR-003 methodology, included 1346 patients who underwent PEth measurement between 2020 and 2025. Among them, 136 patients had at least one cortisol assessment and were considered for the study; 23 patients were excluded due to ongoing corticosteroid therapy. The final cohort comprised 113 patients, divided into two groups: 42 patients (26 men) with a PEth ≥ 200 µg/L (excessive alcohol intake) and 71 patients (33 men) with a PEth < 200 µg/L.

Results: Sex ratio, age, BMI, blood pressure, fasting blood glucose and C-peptide, liver enzymes, Low-density-lipoprotein-cholesterol and triglycerides, body fat and lean mass percentages, vertebral, femoral, and whole-body T-scores (DEXA), Controlled-Attenuation-Parameter and liver stiffness assessed by ultrasound elastography (Fibroscan), liver steatosis percentage, and intra- and total-abdominal fat (MRI) did not differ significantly between groups. Mean corpuscular volume (MCV), gamma-glutamyl-transferase, and Hight-density-lipoprotein-cholesterol (HDL) were significantly higher, while HbA1c was significantly lower, in the high-intake group. Urinary free cortisol (UFC) ($P = .09$) and 16h00 serum cortisol ($P = .07$) tended to be lower and higher, respectively, in the high-intake group. No significant differences were observed between 08h00 and 00h00 cortisol and ACTH, 1-mg Dexamethasone Suppression test, or THF + αTHF/THE ratio between the two groups.

A negative correlation was found between PEth and HbA1c ($P = .007$), while positive correlations were observed between PEth and HDL ($P = .038$), MCV, and UFC ($P = .0001$).

Conclusions: These results suggest that high alcohol intake could increase UFC and alter the cortisol nychthemeral rhythm without significantly affecting metabolic parameters. However, these findings are limited by missing data inherent to this real-life setting.

Keywords phosphatidylethanol, alcohol, cortisol, Cushing, metabolism

The evolution of human fertility over the last 50 years has shown considerable problems due to a growing number of couples who find it difficult to procreate without medical assistance. The World Health Organization (WHO) suggests that around one in every six people of reproductive age worldwide experience infertility in their lifetime, and it has an impact on their families. Worldwide, an increase in the prevalence of this reproductive disorder has been increasingly linked to lifestyle factors, such as exposure to endocrine-disrupting chemicals (EDCs). Several food additives present in our food may enhance the risk of infertility in both sexes. Therefore, it is crucial to understand the impact of human exposure to these substances to protect the health of the population. On this basis, a pre-pubertal exposure to potassium sorbate (12.5, 45, and 78 mg/kg BW doses) and an extended three-generation reproductive toxicity were evaluated in immature female Wistar rats. The work aimed to study their effects on the sexual maturation, sexual behavior, and fertility of parents (F0) and offspring of the first, second and third generations. Results from the evaluation of their effects on sexual maturation showed compared to the control group, animals receiving potassium sorbate at the dose of 78 mg/kg BW, showed significantly decrease in percentage of animal with vaginal opening ($P < .001$) on postnatal day 46, the number total follicles ($P < .001$), relative weight of ovaries ($P < .01$) and an increase in the number of atresia follicles ($P < .001$). The evaluation of their effects on fertility revealed that exposure to potassium sorbate from PND 21 to parturition is responsible for the decrease of fertility index, gestational rate, and the increase of the resorption index and post implantation loss rate as compared to the control group. Concerning biochemical parameters evaluated in the third generation, potassium sorbate decreased the ovarian total protein (PS 78, $P < .001$) and progesterone serum concentration (PS 45 and 78). On folliculogenesis, the results showed that potassium sorbate decreased the number of primary follicles (PS 78, $P < .001$) and increased the number of atresia follicle (PS 78) at the third generation. To conclude, these results could validate at least in part the global observations on increasingly declining fertility linked to exposure to food additives and provide substantial scientific proof confirming potassium sorbate as an endocrine disruptor.

P239 - ECE_1829 - Bisphenol A, F and S disrupt thyroid growth regulation via RET and mTOR pathway activation

Niklas Geiger, Pauline Mehringer, Simon Kloock, Palina Zytner, Max Kurlbaum, Jasmin Felker, Martin Fassnacht and Ulrich Dischinger
Division of Endocrinology and Diabetes, Department of Internal Medicine, University Hospital Würzburg, Würzburg, Germany

Background: Endocrine-disrupting chemicals such as bisphenol A (BPA) and its analogues BPF and BPS are regularly detected in consumer products and the environment. Their phenolic structure enables interference with thyroid hormone synthesis, and receptor signaling. With rising human exposure, these compounds represent a growing concern for thyroid physiology and public health.

Methods: Male Wistar rats (n = 4-5 per group) were exposed to BPA, BPF, or BPS (10 or 100 µM in DMSO) via drinking water for 19 weeks. Additional groups received combined bisphenol exposure (100 µM BPA + BPF, BPA + BPS, BPF + BPS, or BPA + BPF + BPS). Controls received tap water with DMSO. Thyroid tissue was analyzed by qRT-PCR for RET, mTOR, Cxcl10 and Rps6ka4 as key components of growth-regulatory signaling. Expression of NIS (sodium-iodide symporter) and the TSH receptor was also quantified. Serum TSH, T3 and T4 were measured.

Results: Exposure to 100 µM BPA significantly increased RET and Cxcl10 mRNA expression compared to controls ($P < .05$). The combined BPA + BPF + BPS group showed the strongest induction of these mitogenic genes ($P < .05$). mTOR and Rps6ka4 mRNA expression was significantly upregulated in the combined BPA + BPS group ($P < .05$) and further amplified in the triple-exposed group ($P < .001$). NIS expression was significantly reduced in the 100 µM BPA group and in the BPA + BPF + BPS group, whereas expression of TSH receptor remained largely unchanged except for a downward trend in the triple-exposed animals ($P < .07$). Serum TSH was significantly elevated in the 100 µM BPA group ($P < .001$), serum T3 was reduced in the BPA + BPF group while serum T4 was unchanged across all groups.

Conclusions: Chronic exposure to BPA and its analogues activates thyroidal RET and mTOR signaling, particularly under combined bisphenol exposure. These findings demonstrate that BPA substitutes may synergistically impair thyroid growth regulation and hormone synthesis, underscoring their relevance as endocrine disrupting chemicals.

P240 - ECE_3604 - Assessment of selenium status and background bromide exposure in children and young adults using urinary biomarkers

Ewelina Sośnierz[1], Przemysław Śliwka[1], Dorota Kowalik-Zakrzewska[1], Sara Aszkiełowicz[1,2], Sylwester Smoleń[3], Marcin Pakosz[3], Alina Niewiadomska[4], Renata Stawerska[1,2], Anna Łupińska[1,2], Andrzej Lewiński[1] and Arkadiusz Zygmunt[1]
[1]Department of Endocrinology and Metabolic Diseases, Polish Mother's Memorial Hospital—Research Institute, Łódź, Poland; [2]Department of Developmental Age and Adult Endocrinology, Medical University of Lodz, Łódź, Poland; [3]Laboratory of Mass Spectrometry, Faculty of Biotechnology and Horticulture, University of Agriculture in Krakow, Kraków, Poland; [4]Laboratory Diagnostics Center, Polish Mother's Memorial Hospital—Research Institute, Łódź, Poland

Introduction: Selenium is an essential micronutrient, while bromide represents a non-essential halogen with potential toxicological relevance. Both are excreted in urine and can serve as biomarkers of nutritional status and environmental exposure.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Data on urinary selenium and bromide in children remain scarce. This study assessed urinary concentrations of both elements in children and young adults from Residential Care Facilities in central Poland to characterise selenium status and evaluate background bromide exposure.

Methods: Urinary concentrations of selenium and bromide were assessed in a cohort of children and young adults residing in children's homes located in Łódź to characterise micronutrient status and possible exposure to brominated compounds. A total of 289 participants were examined across two stages: 157 children in 2019 and 132 children in 2023-2024. Selenium and bromide were quantified in diluted urine samples using inductively coupled plasma–triple quadrupole mass spectrometry, and results were normalised to creatinine concentrations to correct for urine dilution. Complete data were available for 272 children.

Results: The median urinary selenium concentration was 15.75 ± 8.25 μg/g creatinine, with a minimum value of 0.31 μg/g and a maximum of 66.93 μg/g. Twenty-seven children exhibited urinary selenium values below 10 μg/g creatinine, indicating insufficient dietary selenium intake based on commonly cited biomonitoring reference ranges. The median urinary bromide concentration was 1.14 ± 1.71 mg/g creatinine, with values ranging from non-detectable (0 mg/g) to 17.38 mg/g. Three children exceeded 10 mg/g creatinine, reaching concentrations more typical for occupationally exposed adults, yet none approached concentrations associated with acute toxicity.

In both, selenium and bromide concentrations, no statistically significant differences were observed between boys and girls. Although analysis across age groups revealed a statistically significant overall effect, subsequent multiple comparison procedures did not attribute the difference to specific individual age groups. Moreover, both element concentrations showed significant negative correlations with age, height, body mass index (BMI), body surface area (BSA), and muscle mass, whereas correlations with sex, body fat, and total body water were not significant.

Conclusions: The findings indicate generally adequate selenium levels in the cohort, with a subset demonstrating potential deficiency requiring dietary attention. Bromide values were broadly consistent with environmental background exposure, with isolated higher values likely reflecting non-toxic sources. The observed negative correlations with growth-related metrics for both elements may reflect physiological dilution or altered excretion dynamics with increasing body size. Together, these data contribute novel biomonitoring reference information for selenium and bromide in children.

P241 - ECE_1540 - Adrenal accumulation and functional impact of endocrine disrupting chemicals: mass spectrometric profiling in human adrenal tumors and a bisphenol exposition trial in rats

Simon Kloock[1], Zhong-Min Li[2], Pauline Mehringer[1], Palina Zytner[1], Max Kurlbaum[1], Jasmin Felker[1], Martin Fassnacht[1], Kannan Kurunthachalam[2] and Ulrich Dischinger[1]

[1]Department of Internal Medicine, Division of Endocrinology and Diabetes, University of Wuerzburg, University Hospital Wuerzburg, Wuerzburg, Germany; [2]Wadsworth Center, New York State Department of Health, Albany, NY, United States

Endocrine disrupting chemicals (EDCs) have been increasingly recognized for their potential to interfere with adrenal gland function, yet their tissue-specific accumulation and functional consequences *in vivo* remain poorly understood. Using mass spectrometry (LC-MS/MS), we quantified multiple EDCs in human adrenal tumor tissue (non-functional adenoma, aldosterone-producing adenoma, cortisol-producing adenoma, adrenocortical carcinoma). Preliminary results show bisphenol S (BPS) to be enriched across all samples, suggesting adrenal tissue accumulation. Other EDC related substances (eg mEP) may accumulate in non-functional adenomas but not in hormone-producing adenomas, with unknown effects on tumor development and progression. Additionally, to explore causality and functional outcomes, we exposed rats to bisphenol A (BPA), bisphenol F (BPF), and BPS at concentrations of 10 μM and 100 μM via drinking water for 19 weeks. Urine analysis confirmed a dose-dependent increase in urinary bisphenol excretion. BPS was again found to accumulate in the adrenal gland in a dose-dependent manner. Major alterations in steroid profiles were not detected. These findings suggest that EDCs (especially BPS) selectively accumulate in adrenal tissue, highlighting the adrenal gland as a critical target for environmental endocrine disruptors. Further studies are going to focus on the identification of other adrenal-enriched EDCs and their impact on adrenal function, but also tumor development and progression.

P242 - ECE_3278 - Clinical features and outcomes of acromegaly patients with mild IGF-I elevation at diagnosis

Cécilia Laure[1], Carine Richa[1], Tristan Verdelet[1], Severine Trabado[2,3], Clovis Adam[4], Philippe Chanson[1,3], Luigi Maione[1,3], Jacques Young[1,3], Peter Kamenicky[1,3], Sylvie Salenave[1,3] and Fanny Chasseloup[1,3]

[1]AP-HP, Hôpital de Bicêtre, Service Endocrinologie et des Maladies Rares de l'Hypophyse (CRMR HYPO), Le Kremlin Bicêtre, France; [2]AP-HP, Hôpital de Bicêtre, Service de Biochimie, Hormonologie, Pharmacotoxicologie, Le Kremlin Bicêtre, France; [3]Inserm, Physiologie et physiopathologies endocriniennes, Université Paris-Saclay, Le Kremlin-Bicêtre, France; [4]AP-HP, Hôpital de Bicêtre, Service d'Anatomopathologie, Le Kremlin-Bicêtre, France

Background: Historically, the diagnosis of acromegaly relied on elevated IGF-1 levels and inadequate GH suppression during the oral glucose tolerance test (OGTT). Guidelines now define acromegaly as IGF-1>1.3 times the upper limit of normal (ULN), with characteristic clinical features. Consequently, management of patients referred for moderately elevated IGF-1 with subtle or absent clinical features remains challenging. Our objective was to identify the clinical, biochemical, and follow-up characteristics of acromegaly patients with mildly elevated IGF-1.

Methods: We performed a retrospective monocentric cohort study of patients evaluated in the Bicêtre Endocrinology department between 2013 and 2024 with a diagnosis of acromegaly and an initial IGF-I < 1.5 ULN.

Results: In the 436 patients included, 23 had an initial IGF-I <1.5 ULN. Among them, 21 were women (91%); the median age

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

at diagnosis was 36 years [IQR: 28; 46], and most pituitary lesions were microadenomas (57%). Thirteen patients (57%) had no dysmorphic syndrome. Median IGF-I at diagnosis was 324 ng/mL [IQR 278; 356], corresponding to a median IGF1 index of 1.35 [IQR 1.18; 1.37]. Elevated IGF-1 was identified in patients following investigation for nonspecific pituitary tumoral symptoms in 8 (35%), symptoms related to hyperprolactinemia in 5 (22%), pituitary incidentaloma in 4 (17%), clinical suspicion of acromegaly in 3 (13%) and in the context of pituitary tumor genetic predisposition (Mc Cune Albright Syndrome and AIP) in 3 patients (13%). When available, nadir plasma GH during the OGTT was >1 mUI/L in 15 patients (15/21 = 71%), including 2 with initial normal IGF-1 levels, and 4 patients had a normal GH nadir during OGTT. Surgery was performed in 16 patients; 14 had tumoral GH immunostaining, including 7 with GH and prolactin immunostaining, and 1 patient displayed isolated prolactin staining but persistent elevated IGF-1 levels during follow-up (pathology was not available in 1 patient). In the remaining patients, the diagnosis of acromegaly was retained because of acromegaly features during follow-up. Overall, complications of acromegaly were present in 10 patients (43%).

Conclusions: This study demonstrates that patients with mildly elevated IGF-1 levels exhibit distinct features compared with typical acromegaly patients, including a marked female predominance, a higher prevalence of microadenomas, and a high proportion of lacto-somatotroph adenomas. Disease presentation was rarely driven by typical acromegalic features; however, despite a subtle clinical presentation and lower GH secretion, nearly half of the patients exhibited acromegaly-related complications, highlighting the need for further investigation, including OGTT and long-term follow-up in this patient subgroup.

P243 - ECE_2216 - Giant macroprolactinoma with extensive parasellar invasion demonstrating an exceptional early response to low-dose cabergoline

Hafiz Awais Javed, Amna Zeeshan, Anupam Brahma, Jayamalee Jayaweera, Daisy Beard and Haris Marath
Endocrinology, West Suffolk Hospital, Bury St Edmunds, United Kingdom

Background: Giant macroprolactinomas are rare pituitary adenomas characterised by extensive local invasion, markedly elevated prolactin concentrations, and significant mass effect. They present major diagnostic and therapeutic challenges and have traditionally been associated with poorer outcomes due to tumour size and invasiveness. Dopamine agonists remain in first-line therapy, although the magnitude and speed of response are variable. We report a case of a giant macroprolactinoma in a young woman demonstrating an unusually rapid and profound clinical, biochemical, and radiological response to low dose cabergoline.

Case Presentation: A 20-year-old female presented with a two-month history of headaches and visual disturbance described as blind spots, along with absent of withdrawal menstrual bleeding on combined oral contraceptive pill. Formal visual field testing confirmed bitemporal hemianopia. Pituitary MRI showed a giant macroadenoma (3.9 × 3.4 × 3.0 cm) with suprasellar extension, optic chiasm displacement, hypothalamic and third ventricle deformation, bilateral cavernous sinus invasion, encasement of the right internal carotid and middle cerebral arteries, temporal lobe distortion, clival extension, and sphenoid sinus deformation.

Hormonal testing showed elevated prolactin levels (>100 000 mIU/L), consistent with a giant macroprolactinoma. Other pituitary axes were intact. She was commenced on cabergoline 250 micrograms twice weekly, with advice regarding the risk of pituitary apoplexy.

Visual, hormonal and radiological responses to cabergoline were rapid and unexpected. Prolactin declined from >100 000 mIU/L to 2129, 749, and 397 mIU/L after the second, third, and fourth dose, respectively. Visual field defects resolved after the third dose, and MRI after the fourth dose showed marked tumour regression.

Conclusions: This case illustrates the exceptional dopamine agonist sensitivity that may occur even in highly invasive giant macroprolactinomas. Proposed underlying mechanisms include high tumour dopamine D2-receptor density with rapid suppression of prolactin synthesis, inhibition of lactotroph proliferation, and induction of tumour cell apoptosis. Low-dose cabergoline should remain first-line therapy, as prompt initiation can rapidly reverse mass-effect symptoms and potentially obviate the need for surgical intervention.

Abstract citation ID: lvag096.405

P244 - ECE_3530 - Novel AIP mutation in aggressive somatotroph adenoma presenting as gigantism

Mai C. Arlien-Søborg[1], Kirstine Stochholm[1], Marta Korbonits[2], Jens Otto Jørgensen[1] and Jakob Dal[3]
[1]*Department of Endocrinology, Aarhus University Hospital, Aarhus, Denmark;* [2]*Centre for Endocrinology, Barts and the London School of Medicine and Dentistry, William Harvey Research Institute, Queen Mary University of London, London, United Kingdom;* [3]*Department of Endocrinology and Steno Diabetes Center North, Aalborg University Hospital, Aalborg, Denmark*

Background: Acromegaly and gigantism usually occur sporadic, but familial cases exist. Germline mutations in the aryl hydrocarbon receptor–interacting protein (*AIP*) gene are associated with familial isolated pituitary adenoma (FIPA) and predispose to early-onset, large aggressive growth hormone (GH) secreting adenomas that often respond poorly to somatostatin analogues.

Case: A 19-year-old male patient presented with gigantism (height 207 cm) and 2-year history of backache and reduced libido, and a rapid growth spurt from 195 cm to 207 cm. There was no family history of pituitary adenomas. He was well proportioned, with prognathism, enlarged extremities, and bitemporal inferotemporal visual field impairment. Biochemical evaluation confirmed GH excess (IGF-I SDS 6.9; nadir GH 85.5 µg/L during oral glucose tolerance testing). Prolactin was within the normal range, testosterone was suppressed (0.2 nmol/L), with undetectable LH and FSH.

Pituitary MRI demonstrated a macroadenoma (30 × 43 × 35 mm) causing displacement of the optic chiasm, anterior extension beneath the frontal lobes, and posterior extension toward the pons without invasion of the cavernous sinuses. Bone age was 3.3 years delayed. Genetic testing identified a novel likely pathogenic 4 basepair deletion *AIP* mutation resulting in a

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

frameshift: c.668_671del; p.(Trp223Serfs*79). Family screening revealed four asymptomatic carriers (age range 17-72 years) with no clinical or biochemical evidence of pituitary disease.

Preoperative treatment with pasireotide LAR 60 mg every 4 weeks led to marked improvement in visual fields but incomplete biochemical control, prompting the addition of pegvisomant 60 mg weekly. The patient subsequently underwent partial tumour resection via craniotomy. Histology confirmed an eosinophilic GH-producing pituitary adenoma with low proliferative index (Ki-67 1%). Postoperatively, combination medical therapy was resumed. Although IGF-I levels declined further, they remained above the upper limit of normal, necessitating stepwise escalation of pegvisomant and pasireotide LAR dosing.

Conclusions: This case highlights aggressive, treatment-resistant gigantism linked to a novel *AIP* mutation. Early genetic testing and multimodal management are essential, and identification of asymptomatic carriers enable early diagnosis which has been shown to improve clinical outcomes.

P246 - ECE_3578 - Osilodrostat in a block-and-replace strategy for successful management of cycling Cushing's syndrome—case series

Wiktoria Suchy[1], Mari Minasyan[2], Aleksandra Gamrat-Żmuda[2], Alicja Hubalewska-Dydejczyk[2] and Aleksandra Gilis-Januszewska[2]
[1]Department of Endocrinology, Jagiellonian University Medical College, Krakow, Poland; [2]Kraków, Poland

Introduction: Cyclic Cushing's syndrome (cCS) represents a significant clinical challenge due to unpredictable fluctuations in cortisol secretion, leading to heterogenous presentations and false-negative biochemical results. Although previously considered rare, cCS is increasingly recognized in clinical practice. Management is particularly difficult, and block-and-replace therapy with osilodrostat may provide effective cortisol stabilization. We present two illustrative cases from our clinic, highlighting the diagnostic process and practical use of osilodrostat in a block-and-replace strategy among patients with cCS.

Case presentations: A 68-year-old man with a 5-year history of recurrent hospitalizations due to infections and metabolic instability evaluated for bilateral adrenal incidentalomas. The patient presented with cushingoid features, and biochemical tests confirmed ACTH-dependent CS. Despite extensive imaging, the source of ACTH excess could not be identified. Retrospective analysis of the patient's history revealed multiple peaks of hypercortisolemia (morning serum cortisol 34.43-43.5 ug/dl) separated by spontaneous remissions (morning serum cortisol 8.02-13.3 ug/dl), correlating with episodes of hypertension and hyperglycemia, followed by hypotension and hypoglycemia. He was treated with metyrapone, temporarily in a block-and-replace regimen, however, marked cortisol variability required frequent dose adjustments. Initiation of low-dose osilodrostat (1 mg) in a continuous block-and-replace regimen (with hydrocortisone 5-10 mg daily) resulted in sustained biochemical and clinical stabilization for 13 months. Osilodrostat was discontinued prior to planned BIPSS, with the patient maintained on hydrocortisone replacement. Currently, the patient remains in an eucortisolemic phase 11 months after osilodrostat discontinuation.

A 45-year-old woman was admitted after referral by her gynecologist, presenting with numerous cushingoid features, worsening hypertension, and diabetes. Biochemical and imaging tests confirmed Cushing's disease (CD), leading to transsphenoidal surgery. She remained on hydrocortisone for six years, with several unsuccessful discontinuation attempts. Ambulatory cortisol measurements suggested normocortisolemia (morning serum cortisol 12.7-15.3 ug/dl), but during admissions for planned discontinuation, they were unexpectedly low (morning serum cortisol 3.6-7.66 ug/dl). After eventual adrenal function recovery, she experienced fluctuating control of comorbidities. BIPSS performed during peak of hypercortisolemia confirmed recurrent CD, and pituitary radiotherapy was performed. Block-and-replace therapy with osilodrostat was initiated at 4 mg daily with hydrocortisone 5-10 mg. Optimal disease control enabled dose reductions, with the patient currently stable on 1 mg of osilodrostat and 5 mg of hydrocortisone.

Conclusions: These cases illustrate the complexity of diagnosing and managing cCS. In both patients, the block-and-replace therapy with osilodrostat was well tolerated, effectively stabilized cortisol concentrations and controlled comorbidities, demonstrating its clinical value and safety in real-life management of cCS.

Abstract citation ID: lvag096.407

P247 - ECE_3541 - Block-and-replace therapy with osilodrostat in Cushing's syndrome: a real-life single-center experience

Aleksandra Gilis-Januszewska[1], Aleksandra Gamrat-Żmuda[1,2], Mari Minasyan[1], Wiktoria Suchy[1] and Alicja Hubalewska-Dydejczyk[1]
[1]Department of Endocrinology, Jagiellonian University Medical College, Krakow, Poland; [2]Doctoral School of Medical and Health Sciences, Jagiellonian University Medical College, Krakow, Poland

Background: Osilodrostat is an effective cortisol synthesis inhibitor for Cushing's syndrome (CS). The block-and-replace (BR) strategy is not currently included in clinical practice guidelines; however, limited data and clinical experience suggest efficacy in selected patients.

Objective: To describe real-life clinical experience with osilodrostat administered using a BR regimen in patients with CS treated at a tertiary referral center.

Methods: The retrospective observational analysys included 10 patients with CS treated with osilodrostat using a BR strategy between 2020 and 2025. Clinical and biochemical data were collected at baseline and during follow-up. Patients treated with block-and-replace after switching from titration were analyzed from the time of block-and-replace initiation. Treatment efficacy and safety were assessed during routine clinical practice.

Results: Ten patients (4 men, 6 women) were included: four with Cushing's disease(CD) and six with ectopic Cushing's syndrome (three small-cell lung cancers with metastases, one lung adenocarcinoma with metastases, one lung carcinoid tumor, and one of unknown origin). Three patients were treated before successful surgery, one after non-radical surgery, and the remaining patients were disqualified from surgery.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

In six patients, titration was initially used and BR strategy was initiated after a mean of 29.1 days (range 8-45). The median duration of BR was 66.3 days. In eight patients, BR was introduced due to severe hypercortisolism (mean morning serum cortisol 45.1 µg/dL, night cortisol 30.5 µg/dL, ACTH 335 pg/mL), with a mean potassium supplementation of 166.35 mEq/day.

Initial osilodrostat doses in the BR regimen ranged from 5 to 25 mg/day (mean 10.7 mg/day), and hydrocortisone doses from 10 to 50 mg/day (mean 19 mg/day). The maximum osilodrostat dose (10-40 mg/day) was reached within 2-8 days. A >50% reduction in cortisol levels or values <15 µg/dL was achieved in 7/8 patients within a mean of 9.6 days (mean morning cortisol 9.22 µg/dL). Potassium supplementation was reduced in seven patients (mean 80.5 mEq/day), and antihypertensive therapy was reduced in six patients within a mean of 16.8 days.

In two patients with cyclic CS (cCS), BR was used due to difficulties with titration (osilodrostat 1-2 mg/day plus hydrocortisone 5-10 mg/day). No cases of adrenal insufficiency were observed; adverse events were mild (fatigue $n=3$, headache $n=1$, myalgia $n=1$).

Conclusions: Block-and-replace therapy with osilodrostat appears to be an effective and safe option in patients with severe hypercortisolism. It allows rapid dose escalation without the risk of adrenal insufficiency and provides effective cortisol control, including prevention of hormonal fluctuations in cCs.

P248 - ECE_1382 - Analysis of selected ZBTB38 gene variants in Polish pediatric patients with growth hormone deficiency and idiopathic short stature

Katarzyna Majewska[1], Andrzej Kędzia[1], Magdalena Prauzińska[2], Jarosław Szydłowski[2] and Joanna Nowacka-Woszuk[3]

[1]Department of Pediatric Diabetes, Auxology and Obesity, Poznan University of Medical Sciences, Poznan, Poland; [2]Department of Pediatric Otolaryngology, Poznan University of Medical Sciences, Poznan, Poland; [3]Department of Genetics and Animal Breeding, Poznan University of Life Sciences, Poznan, Poland

Introduction: Human height is a complex quantitative trait regulated by genetic, endocrine, and environmental factors. The *ZBTB38* (Zinc Finger and BTB Domain Containing 38) gene is considered to be one of the common contributors to height phenotypes, and its variants have been associated with height variation and short stature across diverse populations. Recent evidence suggests that *ZBTB38* may also influence therapeutic responses in children receiving recombinant human growth hormone (rhGH) treatment. Our study aimed to investigate the polymorphic variants of the *ZBTB38* gene in the context of growth hormone deficiency (GHD) and growth failure within the Polish pediatric population.

Material and Methods: The study cohort consisted of 150 children with short stature, all from central and western Poland, including 117 with GHD and 33 with idiopathic short stature (ISS). Inclusion criteria covered a height standard deviation score (hSDS) of -2 or below, calculated for age and gender, as well as the absence of additional chronic diseases. The control group consisted of 150 healthy, normal height children. Extracted DNA was amplified by PCR to analyze *ZBTB38* gene fragments, followed by Sanger sequencing. The odds ratio test calculator was used for statistical analysis. The study was approved by the Local Ethics Committee at the Poznan University of Medical Sciences.

Results: Allele frequencies were studied for three SNPs: one intronic, rs724016A>G, and two exonic, rs62282002C>G (p.Pro300Ala) and rs16851435T>G (p.Ser319Ala). The only statistically significant result was observed for rs724016A>G when comparing patients with ISS vs controls ($P=.0105$), with the alternative allele G having a lower frequency (0.2727) in ISS than in healthy children (0.4467). No differences were observed in the distribution of analyzed variants between children with GHD and controls.

Conclusions: Our results suggest a possible involvement of *ZBTB38* gene variants in the etiology of idiopathic short stature, while arguing against their significant role in the development of GHD in the Polish pediatric population. As genotype variation exerts effects on the growth process, the integration of genetic and clinical data may enhance diagnostic precision and potentially improve therapeutic strategies for pediatric growth disorders.

P249 - ECE_2493 - Cancer risk in acromegaly

Christian Rosendal[1], Mai C. Arlien-Søborg[2], Marianne Andersen[3], Eigil H. Nielsen[1], Marianne Klose[4], Claus Feltoft[5], Olaf Dekkers[6], Jens Otto Jørgensen[2] and Jakob Dal[1,7]

[1]Research data and Biostatistics, Aaborg Universityhospital, Aalborg, Denmark; [2]Endocrinolgy, Aarhus Universityhospital, Aarhus, Denmark; [3]Endocrinolgy, Odense Universityhospital, Odense, Denmark; [4]Rigshospitalet, Copenhagen, Denmark; [5]Endocrinolgy, Herlev Hospital, Herlev, Denmark; [6]Department of Endocrinology, Leiden University Medical Center, Leiden, The Netherlands; [7]Steno Diabetes Center North Jutland, Aalborg, Denmark

Background: Cancer risk in acromegaly remains debated, with studies showing both increased and similar risk compared to the background population. We conducted a nationwide cohort study examining the risk of cancer and colorectal polyps in acromegaly patients.

Methods: Using a database of all acromegaly patients with validated diagnoses (1977-2021) ($n=809$, mean follow-up 14.6 ± 10.5 years) and controls matched on sex and birth year ($n=80\,900$, mean follow-up 15.1 ± 10.5 years), we investigated the occurrence of cancer diagnoses.

Findings: Overall cancer risk was not increased (IRR: 1.10 [0.93;1.30], $P=.27$), but patients with acromegaly had an increased risk of colorectal cancer (IRR: 1.78 [1.22;2.60], $P<.01$) which was more often localized (IRR: 2.00 [1.21;3.30], $P=.007$) as compared to controls. The incidence of benign colorectal polyps was elevated in acromegaly patients (IRR: 2.32 [1.96;2.76],

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

$P < .01$). All-cause mortality was elevated in acromegaly (MRR: 1.18 [1.02; 1.36], $P = .03$), but cancer-specific mortality was not (MRR: 0.95 [0.72;1.25], $P = .72$).

Interpretation: In a population-based setting with confirmed cases of acromegaly and a follow-up period of up to 44 years, we found that acromegaly is associated with an increased risk of colorectal cancer, whereas neither overall cancer risk nor cancer-specific mortality was increased.

[1]Department of Endocrinology and Metabolism, Amsterdam Gastroenterology Endocrinology and Metabolism (AGEM), Amsterdam UMC, University of Amsterdam, Amsterdam, The Netherlands; [2]Pituitary Center Amsterdam, Amsterdam, The Netherlands; [3]European Reference Network on Rare Endocrine Conditions (Endo-ERN), Amsterdam, The Netherlands; [4]Department of Radiology & Nuclear Medicine, Amsterdam UMC, Vrije Universiteit, Amsterdam, The Netherlands; [5]Department of (Neuro)Pathology, Amsterdam UMC, University of Amsterdam, Amsterdam, The Netherlands; [6]Department of Neurosurgery, Amsterdam UMC, University of Amsterdam, Amsterdam, The Netherlands; [7]Brain Imaging, Amsterdam Neuroscience, Amsterdam, The Netherlands

Purpose: To assess the clinical value of [18F]fluoroethyl-L-tyrosine PET ([^{18}F]FET-PET) correlated with MRI in patients with functioning pituitary adenoma (FPA) with negative or equivocal conventional MRIs during diagnosis, persistent disease and recurrence.

Methods: Retrospective observational cohort study of 34 patients with FPAs who underwent a total of 37 [^{18}F]FET-PETs (Cushing's disease: $n = 19$, acromegaly: $n = 14$, prolactinoma: $n = 3$, and TSH producing adenoma: $n = 1$) between January 2022 and April 2025. The clinical performance was assessed in the surgically treated cohort, using confirmative histopathology and/or postoperative remission as reference standard.

Results: [^{18}F]FET-PET identified a single lesion in 28 scans (76%), two lesions in 1 scan (3%), and no lesion in 8 scans (22%). [^{18}F]FET-PET and MRI were concordant positive in 14/37 scans, concordant negative in 1/37, discordant MRI+/[^{18}F]FET-PET+ different location in 2/37, discordant MRI-/[^{18}F]FET-PET+ in 8/37, discordant MRI+/[^{18}F]FET-PET- in 7/37 and partly concordant in 5/37 scans. In 14 cases surgery resulted in confirmative histopathology and/or postoperative remission, 12 of those had a positive [^{18}F]FET-PET. In 6 cases surgery did not result in confirmative histopathology and/or postoperative remission, of whom 5 had a positive [^{18}F]FET-PET. Overall, the sensitivity was 86% and the positive predictive value 71%. In three patients with acromegaly, [^{18}F]FET-PET was able to localize a lesion, despite biochemical control under continued somatostatin analogue treatment.

Conclusions: [^{18}F]FET-PET enhances lesion detection and improves personalized treatment in patients with FPA and negative or equivocal conventional MRIs throughout the disease course. Consensus on the timing of [^{18}F]FET-PET with respect to medication and biochemical status is warranted.

Background: Structural variants (SVs) that disrupt topologically associating domains (TADs) can cause disease by rewiring enhancer-promoter interactions. Duplications involving *GPR101* are known to cause X-linked acrogigantism (X-LAG)[1] by enabling aberrant expression of *GPR101*[2]. However, not all *GPR101*-containing duplications are pathogenic,[3] presenting a diagnostic challenge, especially in the prenatal setting.

Methods: We evaluated POSTRE, a tool designed to predict the regulatory impact of SVs, to distinguish pathogenic from benign *GPR101* duplications. We analyzed seven non-pathogenic duplications, and 27 known X-LAG associated pathogenic duplications. Tissue-specific enhancer maps built using H3K27ac ChIP-seq and ATAC-seq data as well as gene expression data derived from human anterior pituitary samples (research protocol 97-CH-0076) were integrated into POSTRE to enable predictions in an X-LAG relevant tissue context.

Results: POSTRE correctly classified all 34 duplications as benign or pathogenic. In addition, one X-LAG case with mild clinical features (eg severe growth hormone hypersecretion in the absence of pituitary tumorigenesis) was found to include only 2/5 *VGLL1* enhancers, whereas all 26 typical X-LAG cases had ≥4 enhancers duplicated. This suggests that milder enhancer hijacking at *VGLL1* could explain the different clinical features of X-LAG in this individual.

Conclusions: These results support incorporating POSTRE into diagnostic pipelines for interpreting SVs affecting chromatin architecture in pituitary disease. By accurately modelling

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

enhancer adoption in a cell type-specific context, POSTRE could help to reduce uncertainty in genetic counselling and offers a rapid alternative to performing chromatin conformation capture experiments.

Cushing's syndrome (CS) is a rare and severe endocrine disorder associated with substantial morbidity and impaired quality of life (QoL). Osilodrostat, a novel oral steroidogenesis inhibitor, has demonstrated efficacy and safety in clinical trials; however, real-world data remain limited. This multicenter, single-arm, phase-IV-study aimed at investigating real-world effectiveness and safety of osilodrostat in a large cohort of CS patients enrolled by 11 national referral centers. One hundred patients (71F,29M), aged 49 ± 14 years, with a disease duration of 8.8 ± 8.3 years, mainly affected by Cushing's disease (CD) (74%), were treated with osilodrostat up to 18 months. In 88% of patients disease severity was mild-to-moderate. Data collection included demographic, clinical, anthropometric, biochemical and hormonal parameters, QoL, pituitary tumor size, adverse events (AEs). 5% ($P < .05$) was considered statistically significant. 81% of patients reported normal UFC levels at their last follow-up observation, with 92% reporting normal UFC levels at least at one time point within the study-period. Time to first normalization of UFC levels, in the 80 patients who achieved normalization, was 92.1 ± 86.3 days at a median osilodrostat dose of 5(1-40) mg/day. Patients with milder forms of CS normalized UFC levels in a higher percentage of cases, more rapidly and requiring lower doses, compared with patients with moderate, severe/very-severe disease who achieved normalization in a lower percentage of cases, later and at higher doses. Osilodrostat induced significant reduction in late-night-salivary cortisol levels over time ($P < .05$). Testosterone levels early and transiently increased significantly in females ($P < .05$ at 3-6 months). However, this transient increase remained clinically silent, with hirsutism remaining stable. Osilodrostat was associated with progressive improvements in body weight, BMI, waist circumference, blood pressure, glucose metabolism, clinical signs of hypercortisolism ($P < .05$), and QoL ($P \leq .005$). Treatment effectiveness was consistent across different CS etiologies. In CD patients, the increase in ACTH levels did not significantly impact on pituitary tumor size, which remained stable in the majority of cases. AEs occurred in 29% of patients and were mild-to-moderate; hypoadrenalism was the most frequent AE (20%), mostly manageable with dose adjustment (36.4%) or temporary interruption (50%). This real-world study conducted in a large number of CS patients for a follow-up up to 18 months provides a comprehensive picture of osilodrostat use in routine clinical practice, supporting and extending evidence from controlled clinical trials, confirming that osilodrostat is a highly rapid and effective and generally well-tolerated therapy for CS management, with meaningful improvements in cardio-metabolic, clinical, and QoL parameters.

P254 - ECE_3945 - Hypertonic saline test: a salty journey from a "feared" procedure to a safe, effective diagnostic for arginine vasopressin deficiency

August Palma[1], Chris Hallett-Morley[1], Katrina Lezaron[1], Danilo Inchiappa[1], Sue Parsons[1], Denise Tapa[1], Sophie Howarth[1], James MacFarlane[1] and Mark Gurnell[1,2]
[1]Endocrinology, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; [2]University of Cambridge, Cambridge, United Kingdom

Background: Distinguishing arginine vasopressin deficiency (AVP-D) or resistance (AVP-R) from primary polydipsia (PP) is clinically challenging. The water deprivation test (WDT) is widely used but is labour-intensive, time-consuming, and yields a higher rate of equivocal results. The hypertonic saline-stimulated copeptin test (HST) offers greater diagnostic accuracy in differentiating AVP-D from PP. We describe the establishment of HST as routine care in our endocrine centre, addressing concerns about safety and feasibility.

Methods: Discussions were held at monthly endocrine service meetings before adoption. A consultant endocrinologist and specialist nurse co-developed a clinical protocol and patient information leaflet. Initially, one test per month was carried out, later increasing to two per month. Patients underwent HST as outpatients, with monitoring of symptoms and serum sodium before, during and after stimulation. Technical success was predefined as post-stimulation sodium >149 mmol/L. Copeptin levels determined diagnostic category (complete AVP-D, partial AVP-D, PP, or AVP-R).

Results: Twenty-nine patients (20 women, 9 men; median age 41 years) were studied. All achieved technical success (100%) with post-stimulation sodium >149 mmol/L. No complications were reported; all patients were discharged the same day with normal sodium levels. Mild to moderate transient symptoms were documented but resolved. Diagnoses: 3 (10.3 %) complete AVP-D, 3 (10.3 %) partial AVP-D, 22 (75.9%) PP, and 1 (3.4 %) AVP-R based on baseline copeptin.

Conclusions: Implementation of HST as an outpatient diagnostic is feasible and safe when adequate protocols, personnel training, and monitoring are in place. The 100 % technical success rate, absence of complications, and clear diagnostic outcomes support HST as a highly efficient alternative to WDT. We propose copeptin stimulation tests be considered part of the standard approach for the evaluation of hypotonic polyuria, when basal laboratory tests are indeterminate.

Background: Hypothalamic melanocortin-4 receptor (MC4R) signalling is crucial for regulating hunger, satiety, and energy expenditure. Tumour/treatment-induced or traumatic brain injury to the hypothalamus can lead to hyperphagia and acquired hypothalamic obesity (aHO), for which no approved treatments exist. We present results of an international Phase 3 trial of the MC4R agonist setmelanotide in aHO (NCT05774756).

Methods: Patients aged ≥4 years with BMI ≥95th percentile (<18 years) or ≥30 kg/m^2 (≥18 years) and aHO were included. Patients were randomized 2:1 to setmelanotide (0.5 mg subcutaneously once daily [QD], titrated to 1.5-3.0 mg QD) or placebo for up to 60 weeks. The primary endpoint was a modified intent-to-treat analysis of the percentage change in BMI at 52 weeks. Secondary endpoints included the proportion of patients with ≥5% BMI reduction and the change in maximal daily hunger score (scored 0-10 in patients ≥12 years). Safety was also assessed.

Results: Of 120 patients included, 81 and 39 received setmelanotide or placebo, respectively (female, 60.0%; mean [SD] age, 19.9 [13.8] years; BMI z-score in patients <18 years, 3.61 [1.66]; BMI in patients ≥18 years, 41.2 [9.7] kg/m^2). Fourteen patients discontinued treatment before end of trial. The primary endpoint, mean (SE) change in BMI at 52 weeks, was −16.5% (1.4%) for setmelanotide vs +3.3% (2.0%) for placebo, with a significant placebo-adjusted difference of −19.8% (95% CI: −24.6%, −15.1%; $P < .0001$). A significantly greater proportion of patients who received setmelanotide vs placebo achieved a BMI reduction of ≥5% (79.5% vs 10.4%, $P < .0001$). The mean (SE) change in the weekly average of the maximal daily hunger score was −2.73 (0.28) for setmelanotide vs −1.45 (0.40) for placebo ($P = .0086$). Overall, 81 (100%) vs 35 (89.7%) patients receiving setmelanotide vs placebo experienced AEs, the most common of which were

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

skin hyperpigmentation (55.6% vs 7.7%), nausea (50.6% vs 30.8%), vomiting (39.5% vs 17.9%), and headache (38.3% vs 30.8%). In the setmelanotide arm, one death due to seizures (treatment-unrelated) was reported and one serious treatment-related AE of hypernatremia due to vomiting and inability to tolerate desmopressin; after 2 days setmelanotide was reinitiated upon hospital discharge.

Conclusions: In the largest randomised, placebo-controlled trial in aHO to date, setmelanotide demonstrated significant effects over placebo in the primary and key secondary efficacy endpoints at 52 weeks, with no new safety signals. Setmelanotide may represent an important treatment option for patients with aHO aged ≥4 years, for which currently no approved treatments exist.

Introduction: Acquired hypothalamic obesity (aHO) is a rare complex disease characterized by hyperphagia and reduced energy expenditure, leading to accelerated and sustained weight gain. Commonly associated with pituitary hormone deficiencies, fatigue, or sleep disturbances, aHO puts patients at high risk for metabolic complications like insulin resistance, dyslipidemia, and hepatic steatosis. Non-invasive metabolic markers enable early detection and quantification of cardiometabolic risk, allowing timely, targeted interventions. In the international Phase 3 trial of MC4R agonist setmelanotide (NCT05774756), the primary endpoint of percent change in BMI at Week 52 was met. This post-hoc analysis assessed setmelanotide impact on metabolic index scores.

Methods: Patients with aHO aged ≥4 years in the Phase 3, double-blind TRANSCEND trial were randomized 2:1 to receive setmelanotide (0.5 mg subcutaneously once daily [QD], titrated up to 1.5-3.0 mg QD) or placebo for up to 60 weeks. The modified intent-to-treat (mITT) population was analyzed for changes in lipid accumulation product (LAP), triglyceride-glucose waist circumference index (TYG-WC), visceral adiposity index (VAI), fatty liver index (FLI), and metabolic syndrome z-score (MetS z-score) after 52 weeks of therapeutic dose. Only participants with baseline and week 52 values available were included.

Results: Overall, 120 participants were included in the pivotal cohort (81 setmelanotide, 39 placebo), with a mean (SD) age of 19.9 (13.8; range: 4-66) y, a mean BMI in participants ≥18 y of 41.2 (9.7) kg/m^2, and a BMI z-score in participants <18 y of 3.61 (1.66). In the mITT population ($n = 81$), baseline metabolic index scores for each marker were indicative of metabolic dysfunction. The mean (SD) change from baseline to week 52 in the setmelanotide-treated group vs placebo was greater across all indices: for LAP ($n = 68$ vs $n = 36$) the change was -36.4 (58.8) vs −2.6 (37.0), $P < .0001$; TYG-WC ($n = 63$ vs $n = 35$) was -138.3 (140.1) vs +21.2 (73.2), $P < .0001$; VAI ($n = 67$ vs $n = 35$) was −1.5 (2.8) vs −0.4 (1.7), $P = .0009$; FLI ($n = 65$ vs $n = 35$) was −24.2 (26.7) vs +4.4 (11.1), $P < .0001$; and reductions in MetS z-score ($n = 53$ vs $n = 31$) were −0.9 (1.0) vs −0.2 (0.4), $P < 0.0001$, respectively.

Conclusions: Setmelanotide treatment in patients with aHO led to significant improvements in multiple metabolic index scores vs placebo. These data suggest reductions in visceral fat burden, hepatic steatosis, and overall cardiometabolic risk. The findings highlight the broad metabolic benefits and strong clinically meaningful efficacy of setmelanotide in this population, supporting its potential as a therapeutic option for patients with aHO.

P258 - ECE_3609 - Surgical vs medical remission in Cushing's disease: a medium-term comparative analysis

Ylenia Alessi[1], Francesco Ferraù[2], Carla Paola Costa[3], Elena Sofia Blanca[3], Giordana Siracusano[3], Alessandra Piccione[3], Filippo Flavio Angileri[1], Angela Alibrandi[4], Francesca Pecori Giraldi[5] and Salvatore Cannavò[2]

[1]Department of Biomedical, Dental and Morphological and Functional Imaging Sciences, University of Messina, Messina, Italy; [2]Department of Human Pathology of Adulthood and Childhood, University of Messina, Messina, Italy; [3]Endocrine Unit, "Gaetano Martino" University Hospital of Messina, Messina, Italy; [4]Department of Economics, University of Messina, Messina, Italy; [5]Department of Clinical and Community Sciences, University of Milan, Milano, Italy

Background: Cushing's disease (CD) is a rare endocrine disorder caused by chronic cortisol excess, associated with increased cardiometabolic morbidity and mortality. Although normalization of

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

hypercortisolism represents the main therapeutic goal, clinical features and comorbidities may persist after biochemical remission. Transsphenoidal pituitary surgery is the first-line treatment, while medical therapy is used in patients with persistent, recurrent, or inoperable disease. Data comparing medium-term outcomes of surgical vs medical remission are limited.

Aims: The aim of this study was to evaluate differences in anthropometric/clinical/hormonal and metabolic parameters, including related-comorbidities, between patients achieving remission after surgical treatment and those achieving remission through medical therapy, with additional gender-specific analyses.

Methods: We retrospectively evaluated 57 patients with CD in remission (45 females): 36 treated surgically (S) and 21 under pharmacological treatment (P). Anthropometric/clinical/biochemical parameters and related-comorbidities were assessed at baseline (T0), 1 year and 2 years after remission (T1 and T2 respectively). Comparisons were performed between treatment groups and across timepoints. Gender-stratified analyses were conducted within each group.

Results: At T1, S showed a significantly greater improvement in clinical features of hypercortisolism compared with P, including a reduction in waist circumference, striae rubrae, easy bruising and facial rubor. Biochemically, S exhibited lower triglycerides, total cholesterol and HbA1c, but a higher rate of growth hormone deficiency (GHD). At T2, myopathy and facial rubor were significantly more pronounced in P, with no significant differences in other clinical/biochemical/cardiometabolic parameters. Gender-specific analyses indicated a more severe phenotype in males, particularly in P, where a higher prevalence of cardiomyopathy and diabetes mellitus was observed at T1, with the latter also trending towards significance at T2. In S, males showed a more favorable lipid profile at T2 but had a higher prevalence of GHD and hypogonadism compared to females at both T1 and T2. In contrast, females exhibited a higher prevalence of psychiatric disorders at T1 and greater central obesity at T2.

Conclusions: In patients with CD in remission, surgical treatment provides faster and more sustained improvements in clinical phenotype and metabolic profile compared to medical therapy. However, several comorbidities persist up to two years post-remission, indicating the need for long-term, multidisciplinary follow-up. Additionally, gender-specific differences reveal that males in P group experience more severe cardiometabolic comorbidities while females show greater central obesity and psychiatric disorders. These findings highlight the importance of individualized management strategies that address both treatment type and sex differences to optimize patient outcomes beyond biochemical remission.

P259 - ECE_3757 - An artificial intelligence assisted risk-stratification approach to endocrine surveillance in adult survivors of primary, non-pituitary brain tumour treated with radiotherapy

Darran Mc Donald[1,2], Liam O'connell[3], Maria Tomkins[1,2], Tara McDonnell[1,2], Niamh Mc Dermott[2], Jack Lee[2], Claire Carthy[2], Mary Moore[2], Amar Agha[1,2], Donncha O'brien[1,2], Kieron Sweeney[4], Stephen McNally[4], Mohsen Javadpour[4], Clare Faul[3], David Fitzpatrick[3], Michael W. O'reilly[1,2] and Mark Sherlock[1,2]

[1]Department of Medicine, Royal College of Surgeons in Ireland, Dublin, Ireland; [2]Department of Endocrinology, Beaumont Hospital, Dublin, Ireland; [3]St Luke's Radiation Oncology Network, Dublin, Ireland; [4]Department of Neurosurgery, Beaumont Hospital, Dublin, Ireland

Background: There is no established guidance on the optimal approach to screening for radiotherapy-induced hypopituitarism in survivors of primary, non-pituitary brain tumours arising in adulthood. While pituitary radiation dose exposure is a recognised risk factor, its incorporation into screening protocols remains uncertain. We therefore, evaluated a risk-stratification approach to endocrine surveillance based on pituitary radiation dose exposure.

Methods: Pituitary function was assessed in adult brain tumour survivors, treated with intensity-modulated radiotherapy who were attending Beaumont Hospital (the Irish National Neurosurgical Centre) between 2012 and 2022. Hormone assessments included a pituitary profile, short synacthen test and dynamic testing of GH axis with either a glucagon stimulation or insulin tolerance test in selected cases. M Vision® artificial intelligence software was utilised to contour the hypothalamic-pituitary axis. Mean radiation dose to the pituitary gland and hypothalamus were then autogenerated by the radiotherapy planning system. Participants were categorised into low (LD, <30Gy), intermediate (ID, 30-44.9Gy) and high (HD, >45Gy) dose exposure groups. Kruskal-Wallis test evaluated differences across these groups with post-hoc analysis using Dunn's test performed when significant differences were observed.

Results: Pituitary function was assessed in 140 brain tumour survivors (prospective cohort $n = 54$, retrospective cohort $n = 86$). Median age at radiotherapy was 39.7 years (IQR 30.5-49.8) with a median post-radiotherapy interval of 60.5 months (IQR 36.0-83.0). Groups comprised LD group ($n = 33$), ID group ($n = 30$) and HD ($n = 74$) survivors. The prevalence of GH deficiency was LD-35%, ID-30% and HD-78%. Gonadotropin, adrenocorticotrophic hormone (ACTH) and thyroid stimulating hormone (TSH) deficiency did not arise in the LD. Gonadotropin deficiency occurred in ID-3% and HD-18%. ACTH deficiency occurred in ID-16% and HD-15%. TSH deficiency occurred in ID-3% and HD-14%. A composite of gonadotropin, ACTH and TSH deficiency occurred in 0%, 17% and 23% in the LD, ID and HD groups, respectively. Panhypopituitarism was only observed in the HD group ($n = 3/40$, 8%). Pituitary radiation dose thresholds (lowest dose at which specific hormone deficits occurred) were GH axis >12.2Gy, gonadotropin axis >37.1Gy, ACTH axis >36.9Gy and thyroid axis >43.4Gy.

Conclusions: Integrating artificial intelligence to rapidly generate pituitary radiation dosimetry allows for the optimisation and personalisation of radiotherapy-induced hypopituitarism screening protocols. Screening is unnecessary in survivors exposed to less than 30Gy (if not GH replacement candidates), while reduced surveillance frequency appears reasonable for intermediate dose exposure (30-44.9Gy). This risk stratification approach has the potential to reduce the burden of endocrine surveillance in up to 50% of adult brain tumour survivors.

P260 - ECE_1902 - Effect of growth hormone treatment on muscle strength in adults with Prader-Willi syndrome (PWS)

Rosalie Poldervaart[1], Janneke Baan[1], Karlijn Pellikaan[1], Jacqueline Goos[1] and Laura De Graaff[1,2]
[1]Rotterdam, The Netherlands; [2]Department of Endocrinology, Radboud University Medical Center, Nijmegen, The Netherlands

Introduction: Prader-Willi syndrome (PWS) is a rare genetic syndrome characterized by hypothalamic dysfunction, intellectual disability, hypotonia and hyperphagia. Individuals with PWS display features of growth hormone (GH) deficiency, including short stature, increased fat mass, and low muscle mass and strength. Reduced muscle mass results in a low basal metabolic rate (BMR). Combined with hyperphagia, this often results in severe obesity. As obesity is the primary contributor to increased morbidity and mortality in adults with PWS, addressing it is essential for long-term health in this population.

GH treatment improves body composition and muscle strength in children with PWS. Smaller studies suggest similar improvements in body composition in adults. However, the effect of GH treatment on muscle strength in adults with PWS has not yet been demonstrated. We have studied the effect of GH treatment on muscle strength in a Dutch population of GH-naïve adults with PWS.

Methods: At the Dutch Center of Reference for PWS, 24 GH-naïve patients with PWS were included in this open-label prospective cohort study. We measured muscle strength before the start of GH treatment (0.6 mg once daily) and after 3, 6 and 12 months of therapy. Muscle strength was quantified using a handgrip dynamometer for hand and forearm strength, as well as the 30-second sit-to-stand test and the 5× sit-to-stand test for leg muscle strength. In addition, subjective improvements in muscle and side-effects were assessed. All tests were validated for adult individuals with an intellectual disability.

Results: Ten females and fourteen males were included (17 deletion and 7 mUPD, age range 22-63 years, BMI range 23-38 kg/m^2). Overall, patients, parents and caregivers reported notable improvements in muscle strength. Most remarkable subjective changes were increased walking speed and increased ability to get out of chairs, walk without help or climb the stairs. They also reported a decrease in fatigue and daytime sleepiness. Objective improvements were significant increases in muscle strength as measured by the handgrip dynamometer ($P = .042$), the 30-second sit-to-stand test ($P = .002$), and the 5× sit-to-stand test ($P = .032$).

Conclusions: GH treatment significantly improves muscle strength in adults with PWS. As improved muscle strength improves exercise tolerance, it enables a healthier lifestyle needed to reduce obesity and cardiovascular complications in this vulnerable population.

P261 - ECE_3746 - Impact of stringent IGF-I control on glycemic outcomes in acromegaly: a real-world evidence study in the United States

Suwei Wang[1], Raffaella Colzani[1], Janetricks Okeyo[1] and Nicholas Tritos[2]
[1]Crinetics Pharmaceuticals, Inc., San Diego, United States; [2]Harvard Medical School, Boston, United States

Background: Acromegaly is a chronic endocrine disorder characterized by excess secretion of growth hormone (GH), leading to elevated insulin-like growth factor 1 (IGF-I) and an increased risk of metabolic complications, including insulin resistance and diabetes mellitus (DM). While normalization of IGF-I is the standard therapeutic goal, the evidence regarding possible incremental glycemic benefits associated with achieving IGF-I levels below conventional thresholds appears to be limited. This study investigates whether more stringent IGF-I control confers additional improvements in glycemic outcomes among patients with acromegaly.

Methods: A retrospective cohort study was performed utilizing a de-identified, linked dataset from Komodo US claims and Prognos Health Laboratory records. The study population comprised adults with acromegaly who attained IGF-I ≤1.3× upper limit of normal (ULN) and had at least one post-treatment HbA1c measurement between January 2020 and November 2025. Participants were categorized into three groups based on IGF-I levels: Optimal (0.8-1.0 × ULN), Suboptimal (1.0-1.3 × ULN), and Stringent (≤0.8 × ULN). Primary endpoints included changes in HbA1c following achievement of IGF-I targets and glycemic control in patients with DM. Statistical analyses included descriptive statistics, analysis of variance (ANOVA), multivariable regression, and mixed-effects modeling.

Results: The study included 3783 patients (56.5% female; mean age 54.3 years). The Stringent IGF-I group ($n = 2176$, 57.5%) demonstrated a reduction in HbA1c (mean change −0.05, SD 0.74), compared with the Optimal ($n = 701$, 18.5%; mean change 0.02, SD 0.55) and Suboptimal ($n = 906$, 23.9%; mean change −0.0003, SD 0.68) groups (overall ANOVA, $P = .029$). Longitudinal mixed-effects modeling revealed a significant decline in HbA1c over time in the Stringent group ($P = .012$) compared with the other groups. Multivariable regression analysis confirmed that stringent IGF I control was significantly associated with greater HbA1c reduction ($\beta = -.15$, 95% CI −0.18 to −0.11, $P = .11$) and increased odds of achieving glycemic control, defined as HbA1c <6.5% (OR = 1.04, 95% CI 1.01-1.08, $P = .009$) in patients with DM over the study period. Notably, increasing age was associated with lower likelihood of achieving glycemic control (OR = 0.98, 95% CI 0.97-0.99, $P < .001$).

Conclusions: Patients who achieved stringent IGF-I control experienced greater reductions in HbA1c and a higher likelihood of glycemic control in diabetes. These findings support the implementation of more stringent IGF-I targets to improve glycemic control in patients with acromegaly.

P262 - ECE_3860 - Pituitary tumors in the course of pituitary adenoma and pheochromocytoma/paraganglioma association (3PAs). A single-center case series

Anna Bogusławska[1], Ewelina Rzepka[1], Anna Nogieć[2], Alicja Hubalewska-Dydejczyk[1] and Aleksandra Gilis-Januszewska[1]
[1]Department of Endocrinology, Jagiellonian University Medical College, Kraków, Poland; [2]Kraków, Poland

The coexistence of pituitary adenoma and pheochromocytoma/paraganglioma is extremely rare condition known as 3PAs association. Approximately 30% of reported cases harbor pathogenic germline variants, most commonly in *SDHx* genes (particularly

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

SDHB). An additional 31% of patients present clinical features suggestive of hereditary disease despite negative genetic testing

We present three cases of pituitary adenoma in the course of 3PAs.

Patient 1. A 50-year-old woman diagnosed with a prolactinoma, initially presenting with irregular menses. Pituitary MRI showed invasive macroadenoma with concomitant hyperprolactinemia (at the age of 29 years). Due to tumor progression and poor tolerance of high-dose cabergoline, transsphenoidal surgery was performed. Histopathology confirmed oncocytic acidophil stem cell adenoma GH(-),PRL(+),ACTH(-),TSH(-),FSH(-),LH(-), alfasubunit(-), MIB1<1%. In 2022, recurrence as a pituitary microadenoma was detected and dopamine agonist was reintroduced (cabergoline 0.5 mg/week). Subsequently, abdominal imaging showed right adrenal mass and CT confirmed 56 × 40 × 52 mm adrenal lesion with heterogeneous contrast enhancement. Biochemical testing showed markedly elevated urinary normetanephrines. Right adrenalectomy confirmed pheochromocytoma (PASS score 7, Ki-67 6%) and genetic testing revealed a pathogenic *SDHB* missense mutation (p.Cys192Arg). Family history revealed paraganglioma in both her son and mother.

Patient 2. A 47-year-old man, presented at the age of 36 with severe headaches and loss of libido. MRI showed pituitary macrodenoma 49 × 16 × 27 mm invading local structures which was surgically removed without hormonal assessment. Histopathology revealed adenoma hypophysis AE1/AE3, synaptophysin(+), CD56(−), TTF1(−). Due to persistent hyperprolactinemia cabergoline was implemented (0.5 mg/week). Last MRI showed residual tumour in turkish saddle. In routine abdominal ultrasound right adrenal mass was found. CT showed adrenal tumor (24 × 22 mm) with native contrast enhancement of 41 HU. Urinal metoxycatecholamines were elevated and right adrenalectomy was performed. Histopathology confirmed pheochromocytoma with PASS = 5 and Ki67<1%. Genetic testing for *SDH, MAX, VHL, MEN1, CDKN1b* mutations were negative.

Patient 3. In 2014 the patient underwent right adrenalectomy due to pheochromocytoma at the age of 50. One year later, recurrence of symptoms were noted. Biochemical and imaging studies demonstrated recurrent and disseminated disease. Additionally, PET/CT with Ga68 revealed increased tracer uptake in pituitary gland and MRI confirmed pituitary macroadenoma 11 × 11 × 8 mm. Biochemically, GH was elevated and IGF-1 within normal range. Due to disseminated process, patient died and no genetic testing was available.

3PAs syndrome should be considered in patients with pituitary adenoma and coexisting or subsequent paraganglioma/pheochromocytoma. Although SDHx mutations are uncommon in PitNETs, their presence is more likely in patients with concomitant pheochromocytoma/paraganglioma or a positive family history.

P263 - ECE_2227 - Preoperative score to distinguish silent corticotroph tumors from gonadotroph tumors before surgery

Cristina Guillen, Elena García, Jorge Frances, Francisca María Peiró-Marqués, Maria Rodríguez-Bedoya, Johana Sottile, Jorge Navarro, Javier Abarca Olivas, Joaquin Serrano and Antonio Pico

Instituto de Investigación Biomédica de Alicante (ISABIAL), Instituto de Investigación Biomédica de Alicante (ISABIAL), Alicante, Spain

Introduction: Silent Corticotroph Tumors (SCTs) are aggressive tumors that are clinically indistinguishable from Silent Gonadotroph Tumors (SGTs) before pathology results are available. Given the higher risk of recurrence in SCTs, preoperative identification is important. Our goal was to create a non-invasive, multiparametric score that combines imaging features and hormonal results to accurately predict SCT lineage.

Methods: We analyzed a retrospective cohort of 59 patients with clinically non-functioning tumors, including 27 SCTs and 31 SGTs. We compared specific T2-weighted MRI features, such as the Signal Intensity Ratio (SIR) and the presence of microcystic changes. These features were combined with baseline hormonal markers (ACTH, Cortisol, IGF-1, GH) to create a predictive score.

Results: SCTs were significantly brighter on T2-weighted MRI. The quantitative SIR was nearly double in SCTs compared to SGTs (2.43 ± 1.01 vs 1.31 ± 0.30, $P = .0049$). In qualitative terms, 75% of SCTs showed characteristic T2-microcystic areas, while only 15% of SGTs showed this ($P < .0001$). Even though they are clinically silent, basal cortisol was significantly higher in SCTs than SGTs (14.17 ± 4.6 vs 9.84 ± 4.8 µg/dL, $P = .005$). ACTH (52.0 vs 24.7 pg/mL), IGF-1 (175.1 vs 105.8 ng/mL), and basal GH levels showed a trend of almost doubling (0.42 ± 0.5 vs 0.19 ± 0.1 ng/mL, $P = .22$). Based on these findings, we propose a 4-point preoperative score: Radiology: SIR >1.5 (+1 point) OR Presence of T2-Microcysts (+1point). Hormones: Basal ACTH > 40 pg/mL (+1 point) AND IGF-1 >130 ng/mL (+1 point). A score of ≥3 points predicts the Corticotroph lineage with high diagnostic accuracy (AUC 0.98).

Conclusions: We present a combined score for the preoperative diagnosis of Silent Corticotroph Tumors. By using simple T2-MRI markers (High SIR/Microcysts) with baseline hormonal levels (High ACTH/IGF-1), doctors can reliably tell apart high-risk SCTs from less aggressive SGTs. This tool helps neurosurgeons decide on the level of resection needed and how to monitor patients afterward for this challenging condition.

Abstract citation ID: lvag096.422

P264 - ECE_3480 - The DA-resistance in prolactinomas according to current definitions

Maria Aleksandra Komisarz-Calik[1,2], Anna Bogusławska[1], Alicja Hubalewska-Dydejczyk[1] and Aleksandra Gilis-Januszewska[1]

[1]*Department of Endocrinology, Jagiellonian University Medical College, Kraków, Poland;* [2]*Doctoral School of Medical and Health Sciences, Jagiellonian University Medical College, Kraków, Poland*

Objectives: Dopamine agonists (DA) are the first-line therapy for prolactinomas; however, a subset of patients exhibits resistance or incomplete response. The approach to the concept of resistance has evolved over the years, and a precise definition of resistance is needed.

Methods: This retrospective study included 85 patients (out of 125 screened patients) with prolactinoma treated with DA, followed for a median of 52.0 months. We compared clinical, biochemical, and radiological parameters (at baseline, 6, and 12

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

months) and the incidence of resistance, using two definitions. **1) Resistance**—failure to normalize serum prolactin concentration (PRL) or achieve ≥30% reduction in tumor maximal diameter (MTD) after standard (7.5-10 mg per day of bromocriptine or 2.0 mg per week of cabergoline) or maximally tolerated DA doses. **2) Resistance**—failure to normalize PRL and inability to reduce tumor size (TV) by 50% despite the maximally tolerated DA doses. **Responsiveness** was defined as PRL normalization and either≥30% reduction in MTD or >50% TV reduction, depending on the approach. Patients who did not meet the criteria for DA resistance and responsiveness were classified as **partial responders.**

Results: The cohort comprised 54 males (63.5%), with a mean age of 41.5 ± 17.2 years. After 6 and 12 months of treatment, 24.7% and 40% achieved PRL normalization, 29.4% and 41.2% demonstrated ≥50% reductions in TV, and 16.0% and 28% achieved ≥30% reductions in MTV. At 6 months, we identified 29.5% vs 41.2% DA-resistant tumors (*P* = *.064*), at 12 months, 31.8% vs 30.6% (*P* = *.078*), and at last follow-up, 23.5% vs 23.5% (*P* = *1.000*) according to definitions 1) and 2), respectively. Incidence of responsive tumors was 7.0% vs 10.6% at 6 months (*P* = *.375*), 10.6% vs 16.5% at 12 months (*P* = *.125*), and 25.9% vs 35.3% at the last follow-up (*P* = *.039*). Partially responsive tumors constituted 63.5% at 6 months vs 48.2% (*P* = *.024*), 57.6% at 12 months vs 52.9% (*P* = *.618*), and 50.6% at the last follow-up vs 41.2% (*P* = *.185*). In both resistant groups, resistant tumors were associated with higher PRL at 6 and 12 months and at the last follow-up *(P* < *.001*).

Conclusions: Using definition 2, a higher proportion of responsive tumors was observed across all time points. The 1 definition is associated with a higher percentage of partially resistant tumors, especially at 6 months. Further studies are needed to unify the definition of DA-resistant prolactinomas.

Abstract citation ID: lvag096.423

P265 - ECE_2692 - Paradoxical growth hormone increase during OGTT in acromegaly is linked to smaller adenomas with a more aggressive biochemical profile

Mathilde Damm, Jon Rasmussen, Yeliz Bulut, Caroline Kistorp and Mikkel Andreassen
Rigshospitalet, University of Copenhagen, København Ø, Denmark

Introduction: It is estimated that a paradoxical rise in growth hormone (GH) during oral glucose tolerance test (OGTT) occurs in approximately 30% of patients with acromegaly. The phenomenon is likely related to ectopic expression of glucose-dependent insulinotropic polypeptide (GIP) receptors in the GH-secreting pituitary adenoma. The clinical significance of paradoxical GH increase remains poorly studied; however, one study has suggested that it may be associated with smaller adenomas at baseline, but higher random GH levels when adjusted for tumor size.

Aims: To compare endocrine, radiological, and metabolic characteristics at diagnosis between patients with a paradoxical GH increase and those without a paradoxical increase

Methods: This retrospective, single-center study included consecutive patients with an available baseline GH profile during an OGTT. A paradoxical GH increase was defined as a peak-to-basal GH ratio exceeding 120%

Results: A total of 109 patients with acromegaly were included; 44 (40%) exhibited a paradoxical GH increase during OGTT and 65 (60%) did not. Patients with paradoxical increase were of similar age compared with those without (mean (SD) 54 ± 15 vs 51 ± 13 years; *P* = .243). Baseline GH at t = 0 was also comparable between groups (median 16 [IQR 11-35] vs 15[5-39] µg/L; *P* = .58). The paradoxical group had higher IGF-1 levels (688 ± 275 vs 578 ± 253 µg/L; *P* = .06) and a significantly higher IGF-1 SDS (8.8 ± 3.9 vs 7.2 ± 3.8; *P* = .049). Maximum adenoma width tended to be smaller in the paradoxical group, but this was not statistically significant (median 15 [11-24] vs 19 [12-25] mm; *P* = .143). IGF-1 adjusted for adenoma size (IGF-1/maximum diameter) was significantly higher in patients with paradoxical increase (median 49 [31-70.] vs 31 [20-47]; *P* < .01. HbA1c was similar between groups (39.0 ± 4.0 vs 38.0 ± 4.8 mmol/mol; *P* = .615). Systolic blood pressure (137 ± 19 vs 134 ± 23 mmHg; *P* = .62) and diastolic blood pressure (85 ± 11 vs 84 ± 17 mmHg; *P* = .75) did also not differ between groups.

Discussion: Compared with previous reports, we observed a slightly higher prevalence of paradoxical GH increase, affecting 40% of patients. Our findings support that patients exhibiting a paradoxical GH rise have more hormonally active tumors, reflected by higher IGF-1 levels and IGF-1 SDS, and by significantly higher IGF-1 when adjusted for tumor size. With respect to glucose metabolism and blood presure we did observe any differencies between the 2 groups.

Background: Long-term biochemical control of acromegaly is essential to reduce mortality and morbidity. CAM2029 is a long-acting, octreotide subcutaneous depot for self-administration. ACROINNOVA 2 demonstrated long-term safety and efficacy of CAM2029, including patients biochemically uncontrolled on standard-of-care (SoC) somatostatin receptor ligands. Here we report results of the 52-week ACROINNOVA 2 extension.

Methods: ACROINNOVA 2 was an open-label, 52-week (W) trial (core phase) with 52W extension. Patients who completed W48 CAM2029 treatment and W52 assessment could directly continue (DC) to the extension. Patients could restart CAM2029 after completing the core phase and either after return to SoC or after >4 weeks elapsed. CAM2029 20 mg was administered every 4W ± 1W via pre-filled pen. Primary endpoint was safety. Secondary endpoints included biochemical control (insulin-like growth factor I [IGF-I] ≤upper limit of normal [ULN] per age and sex) rate and symptoms (Acromegaly Index of Severity [AIS] score).

Results: Forty-three patients were included in the ACROINNOVA 2 extension safety analysis (DC $n = 20$, restarted $n = 23$). Mean (standard deviation [SD]) CAM2029 exposure in the extension was 54.0 (9.5) weeks. CAM2029 was well tolerated with no new safety signals. CAM2029-related adverse events (AEs) were reported by 17 (39.5%) patients; the most frequent were injection site AEs (12 [27.9%]). In the efficacy analysis set ($N = 42$; DC $n = 19$, restarted $n = 23$), biochemical control rate increased from start (52.4%) to end (70.7%) of extension. Similar trends were observed for the DC and restarted groups (Table). Notably, the biochemical control rate for the restarted group decreased from end of core phase to start of extension. Upon restarting CAM2029, the biochemical control rate increased at extension end. AIS overall score was stable throughout the extension.

Efficacy analysis set	Overall	Restarted	DC
Patients with IGF-I ≤ULN, *n*/*N* (%)			
SoC baseline	23/42 (54.8)	11/23 (47.8)	12/19 (63.2)
Core phase end (W50/52 mean)	29/42 (69.0)	14/23 (60.9)	15/19 (78.9)
Extension start	22/42 (52.4)	8/23 (34.8)	14/19 (73.7)
Extension end (W102/104 mean)	29/41 (70.7)	13/22 (59.1)	16/19 (84.2)
Mean AIS overall score (SD)			
SoC baseline	($n = 42$) 4.2 (3.3)	($n = 23$) 4.5 (3.1)	($n = 19$) 3.7 (3.5)
Core phase end (W52)	($n = 41$) 3.0 (3.1)	($n = 23$) 3.0 (3.3)	($n = 18$) 2.8 (3.0)
Extension start	($n = 42$) 2.8 (2.7)	($n = 23$) 2.8 (2.5)	($n = 19$) 2.9 (2.9)
Extension end (W104)	($n = 41$) 2.5 (2.3)	($n = 22$) 2.7 (2.2)	($n = 19$) 2.3 (2.5)

Conclusions: Long-term CAM2029 improves biochemical and symptom control of acromegaly over time, and restores biochemical control when restarted in patients switched to SoC.

Background and Objective: Cushing disease (CD) is characterized by impaired glucocorticoid negative feedback. In rare cases, patients exhibit glucocorticoid-induced positive feedback (GIPF), which may represent a distinct corticotroph adenoma phenotype. We aimed to investigate the prevalence, clinical and biochemical features, and surgical outcomes of GIPF in a large multicenter cohort.

Design: Retrospective cohort study from the SPAIN-CUSHING registry.

Methods: We included 139 patients with CD who had complete overnight 1-mg dexamethasone suppression test. GIPF was defined as a paradoxical cortisol response, corresponding to an increase of at least 25% in serum cortisol levels after dexamethasone compared with baseline. Clinical, biochemical, and radiological characteristics as well as surgical outcomes were compared between groups. Recurrence was evaluated in patients undergoing transsphenoidal surgery, with recurrence-free survival assessed by Kaplan–Meier analysis.

Results: Thirteen patients (9.3%) showed GIPF. These patients had lower BMI (26.4 vs 29.8 kg/m^2, $P = .032$), higher urinary free cortisol expressed as the upper limit of normal ratio (4.7 vs 2.8 ULN, $P = .047$), and a markedly greater ACTH response to desmopressin (525.0 vs 63.1 pg/mL, $P = .022$). Tumor size, proportion of macroadenomas, and cavernous sinus invasion did not

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

differ. Despite this, after surgery remission was significantly lower in GIPF (28.6% vs 70.2%, $P = .036$), and Kaplan–Meier analysis showed reduced recurrence-free survival in GIPF patients (log-rank $P = .04$). Clinical phenotypes and comorbidities were otherwise similar.

Conclusions: GIPF occurs in up to 9% of patients with CD and is associated with poorer surgical outcomes and lower remission rates. This phenotype likely represents a distinct subtype of corticotroph adenoma, highlighting the need for closer follow-up and molecular characterization.

[1]Department of Endocrinology, Diabetes & Metabolism, Rabin Medical Center, Beilinson Campus, Petah Tikva, Israel; [2]Gray Faculty of Medical & Health Sciences, Tel Aviv University, Tel Aviv-Yafo, Israel; [3]Rabin Medical Center, Beilinson Campus, Research Authority, Petah Tikva, Israel; [4]Biostatistics Unit, Rabin Medical Center, Beilinson Campus, Petah Tikva, Israel; [5]Neurosurgery Department, Rabin Medical Center, Beilinson Campus, Skull Base Surgery Service, Petah Tikva, Israel; [6]Pacific Neuroscience Institute, Pacific Pituitary Disorders Center, Santa Monica, United States; [7]Endocrinology, Ichilov Sourasky Hospital, Tel Aviv-Yafo, Israel; [8]Departments of Medicine and Neurological Surgery, Oregon Health & Science University, Pituitary Center, Portland, United States

Objective: Cushing syndrome (CS) is associated with depression and anxiety. This study compared treated mood and anxiety disorders between patients with CS and controls, assessing differences by etiology and remission status.

Methods: A retrospective matched cohort study of patients with endogenous CS (2000-2024) from the Clalit Health Services database. Each patient was matched with five controls by age, sex, socioeconomic status, and BMI. Mood and anxiety disorders were identified through affective drug dispensations (ADD). Drug discontinuation was defined as ≥1 month without dispensations.

Results: The cohort included 540 patients with CS (mean age 47.8 ± 17.0 years; 64.4% women) and 2517 controls, with a median follow-up of 13.3 years (IQR 8.3-18.5). At baseline, patients with CS had nearly twice the odds of receiving ADD than controls (OR = 1.9, 95% CI,1.3-2.6), with a significant excess in women (12.9% vs 6.9%, OR = 1.9, 95% CI, 1.3-2.8). During follow up, drug discontinuation rates did not differ (HR = 0.7, 95% CI: 0.5-1.0), whereas the risk of new-onset ADD was twofold higher in CS (HR = 2.2, 95% CI, 1.8-2.6), persisting in patients who achieved remission (HR = 2.1, 95% CI, 1.5-2.7) and those who did not (HR = 2.3, 95% CI, 1.6-3.5). Compared to controls, the risk of new-onset ADD was similarly elevated in Cushing disease (HR = 2.4, 95% CI: 1.9-3.1) and adrenal CS (HR = 2.1, 95% CI, 1.9-3.1).

Conclusions: Endogenous CS is associated with a higher risk of treated affective disorders at diagnosis and throughout long-term follow-up, with persistence after remission, underscoring the need for ongoing psychological care.

Background: INSIGHTS-GHT is a German nationwide, product-independent registry endorsed by scientific societies that captures real-world use of growth hormone (GH) therapies in both children and adults, including long-acting GH (LAGH). LAGH reduces injection frequency and may improve adherence in replacement therapy for growth hormone deficiency (GHD). We present updated baseline utilisation and treatment patterns in paediatric/adolescent and adult patients initiating LAGH.

Methods: This interim cross-sectional analysis included registry patients with GHD who initiated LAGH from 2023 onwards. Demographics, prior GH exposure, starting dose at LAGH initiation (categorised relative to product label), and baseline IGF-I/IGFBP-3 were summarised by age group.

Results: At database analysis on December 3rd, 2025, 2218 patients were enrolled into the register study, 191 of whom received LAGH preparations.

Paediatric/Adolescent Cohort: Among 114 patients aged <18 years initiating LAGH, mean age at initiation was 9.5 ± 3.8 years; 77.2% were male and 74.5% were prepubertal. Fifty-eight percent switched from daily GH (median prior duration 2.9 years). At initiation, 80.6% received a starting dose below the product-label recommendation; the median dose was 92% of the recommended dose. In switch patients, IGF-I SDS was −2.1 (SD 1.2) before any GH and 0.1 (SD 1.6) at LAGH initiation.

Adult Cohort: Seventy-two adults initiated somapacitan treatment, the only approved LAGH for the adult indication in Germany at the time. Mean age at initiation was 42.4 (SD 16.2) years; 55.6% were male. Most patients (90.1%) had organic

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

GHD, and 45.5% had childhood-onset disease. Ninety-one percent switched from daily GH (median prior duration 10.7 years). Starting dose relative to label was below in 39.3%, in label in 53.6%, and above in 7.1%; mean dose was 87.9% (SD 30.2) of the recommended dose (median 100%; range 30%-200%).

No new safety signals were detected in either cohort. Registry data contribute to post-authorisation safety (PASS) requirements.

Conclusions: In routine practice, LAGH is commonly initiated with conservative starting doses relative to product labels in both paediatric/adolescent and adult patients, suggesting cautious titration during early adoption. Longitudinal follow-up in INSIGHTS-GHT will assess how these initial dosing strategies translate into IGF-I trajectories, effectiveness, adherence, and safety under real-world conditions.

Introduction: Lactotroph and corticotroph pituitary tumours (lactoPiT and corticoPiT) represent the most common secreting aggressive pituitary tumours (APT) and pituitary carcinomas (PC), characterised by a worse prognosis and reduced survival. Known markers of aggressiveness (invasion, Ki-67, mitotic count, p53) are not always able to predict tumour behaviour.

Studies showed that somatic mutations in *SF3B1* in lactoPiT and in *ATRX* and *TP53* in corticoPit and lactoPiT are associated with greater aggressiveness, resistance to traditional treatments, and reduced overall survival. The latest European guidelines suggest molecular screening for somatic mutations in these genes in lactoPiT and corticoPiT with suggestive features of aggressiveness to facilitate early identification and intervention.

Aim: To evaluate the recommendation of the European guidelines, to define the incidence of said somatic mutations, to investigate the association with other known markers of aggressiveness.

Methods: Clinical study on a cohort of consecutive patients affected by macro-lactoPiT and macro-corticoPiT, surgically treated between 2023 and 2025 and histologically confirmed. Somatic mutation research was performed using next-generation sequencing (NGS) with the « Solid Tumour Solution » from Sophia Genetics, including *TP53*, *ATRX*, and *SF3B1* genes on Illumina™ NextSeq500® or Novaseq® instruments.

Results: 64 patients were included (41 women and 45 corticoPiT), operated between January 2023 and October 2025. 47 of them underwent NGS, for the remaining 17 analysis is ongoing. Low quality was seen in 8 samples, results are available for 39 (26 women, 28 corticoPiT, median age 47 years (range 16-88)). Somatic mutations were found in 6/39 (15%). *ATRX* and *SF3B1* genes were not altered in those tumours. *TP53* pathogenic variants were found in two patients. Incidentally, *ATM* variants were identified in two cases, one associated with a *TP53* variant. Two patients showed *FANCA* and *NBN* variants, respectively. The last case displayed pathogenic variants in *BRCA2* and *RB1*. All mutated tumours were corticoPiT (three women). Four were invasive, four proliferative, and five had a Ki-67 score higher than 3% (median 7.2%, range 6-9.5).

Conclusions: In this cohort, we did not identify somatic mutations in *ATRX* or *SF3B1* genes, whereas *TP53* variants appeared to be more common. The broad inclusion criteria for molecular testing may be a reason for this low percentage. NGS enabled us to identify additional pathogenic variants in pituitary tumours, notably in the *ATM* gene, which has been associated with *SF3B1* variants in other malignancies. This incidental finding may represent another genetic mechanism involved in pituitary tumorigenesis, warranting further study.

P271 - ECE_3771 - Comparative analysis of masseter and temporal muscle thickness and quality in patients with Cushing's syndrome and non-functioning pituitary tumors

Anna Arecco[1], Loris Peirano[2], Claudia Campana[1], Bianca Bignotti[3], Oleksandr Starovatskyi[4], Ilaria Patelli[1], Mara Boschetti[1,5], Diego Ferone[1,5], Alberto Tagliafico[3,4] and Federico Gatto[1,5]

[1]*Endocrinology Unit, Department of Internal Medicine and Medical Specialties (DIMI), Centre of Excellence for Biomedical Research (CEBR), University of Genova, Genoa, Italy;* [2]*University of Genoa, Genoa, Italy;* [3]*Celle Ligure, Italy;* [4]*Department of Radiology, IRCCS Ospedale Policlinico San Martino, Genoa, Italy;* [5]*Endocrinology Unit, IRCCS Ospedale Policlinico San Martino, Genoa, Italy*

Background: Cushing's syndrome (CS) is bourdened by a peculiar myopathy characterized by atrophy of type 2 muscle fibres and increased intramuscular fat infiltration. Previous studies have demonstrated masseter and temporal muscles as reliable proxies of muscle mass and quality.

Aims: We compared masseter thickness (MMT), temporal thickness (TMT) as well as masseter and temporal muscle quality (simplified Goutallier score: 0 = normal, 1 = fatty infiltration) in

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

patients with CS and non-functioning pituitary tumours (NF-PitNETs) matched for sex and age. Brain/sella turcica MRIs performed at diagnosis and/or follow-up were retrospectively evaluated to define MMT, TMT and facial muscles quality. In patients with CS, available abdominal CT scans were used to evaluate iliopsoas muscle area (the gold standard to define sarcopenia) and iliopsoas density.

Results: Both groups included 43 patients (28 females, 65%) with a median age of 58 years. In the CS group, 40 subjects had an ACTH-PitNET and only 3 an adrenal CS.

Median MMT was 16.5 mm [IQR 6.54] in the CS group and 15.3 mm [IQR 3.60] in the NF-PitNET group ($P = .264$); median TMT was 5.35 mm [IQR 1.72] vs 5.80 mm [IQR 1.97], respectively ($P = .086$).

Masseter quality was poorer in the CS group compared to the NF-PitNET group, with 64.7% patients having a Goutallier grade 1 vs 26.2% in the NF-PitNET group ($P < .001$). Temporal quality was similar (Goutallier score 1: 67.4% in CS vs 34.9% in NF-PitNET group; $P = .003$).

Male patients had significantly higher MMT and TMT than females in the NF-PitNET group ($P = .002$ for both muscles), while in the CS group only TMT was higher in male patients ($P = .007$). Muscle quality was not affected by gender in both groups ($P > .05$).

In CS patients, no difference was found in masseter ($P = .236$) and temporal quality ($P = .151$) between controlled (UFC < 1.0xULN) and active CS patients (UFC ≥ 1.0xULN).

No correlation was found between MMT, TMT and cortisol or UFC values ($P > .05$).

Of note, in CS patients, iliopsoas area had a significant direct correlation with both MMT (rho = .529, $P = .024$) and TMT (rho = .498, $P = .016$). Iliopsoas density was lower in subjects with poor masseter quality ($P = .005$) and temporal quality ($P = .006$).

Conclusions: CS patients have poorer masseter and temporal muscle quality than the NF-PitNET group. MMT and TMT correlated with iliopsoas area; poorer masseter and temporal muscle quality were associated with lower iliopsoas density. These findings support the role of facial muscle evaluation by brain/sella turcica MRI to investigate muscle mass and quality in patients with CS.

Introduction: Endogenous Cushing's syndrome (CS) is a rare disease caused by excess cortisol production. LINC 7 (NCT05633953), a retrospective observational study, assessed osilodrostat safety and effectiveness in adrenal (adenomas, carcinomas, bilateral adrenal nodular disease [BND]) and ectopic adrenocorticotropic hormone secretion (EAS) aetiologies of CS. This analysis evaluated osilodrostat safety and effectiveness by CS aetiology and severity.

Methods: Patients with CS who initiated osilodrostat under the French Autorisation Temporaire d'Utilisation scheme or, once approved, in routine clinical practice were followed up retrospectively for ≤36 months (Tabarin *et al. J Clin Endocrinol Metab* 2025). Patients were specified as having: (1) mild benign adrenal CS (M_bACS; any cortisol measure [ACM; mean urinary free cortisol, late-night salivary cortisol, or morning serum cortisol] at baseline ≤2 times the upper limit of normal [ULN], with adrenal adenoma or BND); (2) mild malignant CS (M_mCS; baseline ACM ≤2xULN, with adrenocortical carcinoma or EAS); or (3) moderate-severe CS (MSCS; baseline ACM >2xULN, all aetiologies). Analyses are descriptive only.

Results: 91/103 patients had ACM data available at baseline (M_bACS, $n = 20$; M_mCS, $n = 19$; MSCS, $n = 52$). Initial median (min–max) osilodrostat dose was 4 (1-10), 4 (1-40), and 10 (2-60) mg/day, respectively; at week (W)24, this was 4 (1-12), 15 (3-40), and 20 (0-120) mg/day. At W12 and W24, ACM ≤ULN was achieved in $n = 8/9$ and $n = 4/4$ patients with M_bACS, respectively; equivalent values were $n = 7/10$ and $n = 7/7$ for M_mCS and $n = 15/28$ and $n = 9/15$ for MSCS. Among patients with hypertension ($n = 75/91$ [82.4%]), mean baseline systolic blood pressure (SBP; mmHg) was 139.9 (M_bACS, $n = 17$), 141.1 (M_mCS, $n = 15$), and 148.4 (MSCS, $n = 34$). By W24, SBP had decreased in M_mCS (130.5, $n = 6$) and MSCS (134.9, $n = 7$) and was 142.0 in M_bACS ($n = 2$). Mean baseline fasting plasma glucose (mg/dL) was higher in MSCS (127.9, $n = 27$) than in M_bACS (103.4, $n = 14$) or M_mCS (98.4, $n = 11$) and decreased in all groups (W24: MSCS, 82.2, $n = 5$; M_bACS, 80.7, $n = 3$; M_mCS, 81.0, $n = 7$). Hypocortisolism-related adverse events occurred in $n = 4/20$ (M_bACS), $n = 6/19$ (M_mCS), and $n = 18/52$ (MSCS) patients, most commonly adrenal insufficiency (M_bACS, $n = 4$; M_mCS, $n = 6$; MSCS, $n = 16$). Deaths were most commonly neoplasm related (M_mCS, $n = 4/10$; MSCS, $n = 4/14$); none were reported in M_bACS.

Conclusions: Osilodrostat effectively reduced cortisol levels, leading to improvements in cardiometabolic parameters, regardless of CS aetiology or severity and with an expected and manageable safety profile.

P273 - ECE_2259 - A combined approach with clinical, laboratory, and expert team input reduces volume status misclassification: secondary analysis of a large European cohort of hospitalized patients with hyponatremia

Laura Potasso[1], Julie Celine Refardt[2] and Mirjam Christ-Crain[1]

[1]Endocrinology, Diabetes and Metabolism, University Hospital of Basel, Basel, Switzerland; [2]Department of Internal Medicine, Erasmus Medical Center, Rotterdam, The Netherlands

Introduction: Hyponatremia affects up to 30% of hospitalized patients and represents a frequent clinical challenge. Proper management requires accurate assessment of volume status, typically based on clinical evaluation and laboratory data. Despite its central role in both European and American guidelines, little is known about the effectiveness of volume status assessments. The aim of the present analysis was to evaluate the accuracy of a merely clinical vs a combined approach (clinical, laboratory, and team input) for volume status assessment hospitalized patients with hypotonic hyponatremia.

Methods: This preplanned secondary analysis of a multicentre, prospective, randomized-controlled European trial (NCT03557957) included hospitalized adults with plasma sodium <130 mmol/L from nine centers. Volume status at admission was classified as hypovolemic, euvolemic, or hypervolemic using either clinical assessment (patient history and physical examination) or a combined approach, which also included guideline-based laboratory indices, and team input if classification was uncertain. Treatment response served as the reference standard. Baseline characteristics of misclassified vs correctly classified patients were compared using chi-square or Mann–Whitney U tests, as appropriate.

Results: Among 2034 patients, misclassification was more frequent with clinical assessment than with a combined approach (333/2034, 16.4% vs 230/2034, 11.3%, $P < .001$). Clinical assessment showed high misclassification in hypovolemic (167/516, 32.4%) and hypervolemic patients (50/318, 15.7%), less in euvolemic (116/1033, 11.2%). Misclassified hypovolemic patients had higher body mass index (BMI, median 25.5 vs 23.6 kg/m^2, $P = .002$), misclassified hypervolemic patients more often chronic renal failure (+8.5%, $P = .03$), and misclassified euvolemic patients more often heart failure (+9.6%, $P < .001$) than correctly classified patients.

The combined approach as compared to clinical approach reduced misclassification across all volume states, most notably in hypovolemic (88/516, −14.6%), but also in euvolemic (108/1033, −1.2%) and hypervolemic patients (34/318, −5%). Misclassified euvolemic patients more frequently had liver cirrhosis (+4.1%, $P = .01$) or heart failure (+11.7%, $P < .001$) compared with correctly classified ones, in contrast to hypervolemic patients, where heart failure predominated in correctly classified patients (+34.9%, $P < .001$). Finally, liver cirrhosis was more prevalent in misclassified hypovolemic patients (+5.6%, $P = .01$) as compared to correctly classified ones.

Conclusions: In hospitalized patients with hyponatremia, combining clinical evaluation, laboratory data, and expert team input reduces misclassification of volume status. Special attention should be given to patients with comorbidities such as heart failure or liver disease, who are at higher risk of misclassification.

Background: Patients with acromegaly may experience waning biochemical and symptom control towards the end of dosing intervals with injectable somatostatin receptor ligands (SRLs). CAM2029, a long-acting octreotide subcutaneous depot, demonstrated stable insulin-like growth factor I (IGF-I) and symptom control across 4-week (W) and >28-day dosing intervals in ACROINNOVA 1 (NCT04076462). We report descriptive data for IGF-I and symptom stability over the final dosing interval for patients receiving long-term CAM2029 in ACROINNOVA 2 (NCT04125836).

Methods: Patients were directly-enrolled (baseline IGF-I ≤2× upper limit of normal [ULN]) or continued from ACROINNOVA 1 (baseline IGF-I ≤ULN; prior-CAM2029 or prior-placebo). CAM2029 20 mg was administered every 4W (±1W) for 52W (prior-placebo, W24-52). The final dose was received at W48, with IGF-I and Acromegaly Index of Severity (AIS) assessments at W48 (pre-CAM2029), W50 (IGF-I levels only) and W52/end of core phase (EOCP). Some patients had delayed W52/EOCP assessments; patients were grouped by on-time (≤28 days post-W48 dose) and later assessment (>28 days post-W48 dose).

Results: Of 135 patients enrolled, 122 completed W48 treatment and W52/EOCP IGF-I assessments and are included in the current analysis. Mean IGF-I levels (standard deviation [SD]) were stable across W48 (1.09 [0.46] × ULN), W50 (0.98 [0.36] × ULN) and W52/EOCP (1.06 [0.46] × ULN). Mean AIS overall scores (SD) were stable from W48 (3.2 [3.0]) to W52/EOCP (3.4 [3.1]). Eighty-six patients had on-time W52/EOCP assessments (mean interval 25.0 days) and 36 patients had later W52/EOCP assessments (mean interval 33.2 days). The table reports IGF-I × ULN values and AIS overall scores for patients with on-time or later assessments, overall and by subgroup.

P275 - ECE_3525 - Predictors for early response to fluid restriction in patients with SIAD—analysis of a randomized, controlled, parallel-group trial with blinded outcome assessment

Michelle Müller[1,2], Laura Potasso[1,2], Julie Celine Refardt[1,2,3] and Mirjam Christ-Crain[1,2]

[1]Department of Endocrinology, Diabetology and Metabolism, University Hospital Basel, Basel, Switzerland; [2]Basel, Switzerland; [3]Department of Internal Medicine, Section of Endocrinology, Erasmus Medical Centre, Rotterdam, The Netherlands

Introduction: Fluid restriction is the current first-line therapy for hyponatremia induced by the syndrome of inappropriate antidiuresis (SIAD), but, up to 50% of patients do not achieve a sufficient sodium correction. Reported predictors of non-response are urine osmolality >500 mOsm/kg H_2O, a Furst Ratio >1 (UNa+UK/SNa) as well as a urine sodium (>130 mmol/L) and plasma urea (>5 mmol/L). This study aimed to validate current prognostic factors and potentially identify new predictors.

Materials and Methods: This predefined secondary analysis was based on an international, prospective study that included patients with moderate to severe hyponatremia (plasma sodium <130 mmol/L). Response to treatment with fluid restriction was defined as an increase in plasma sodium of >3 mmol/L within the first 24 hours, while non-response was defined as an increase of ≤3 mmol/L. Baseline laboratory parameters—particularly urine sodium, urine osmolality, and plasma urea—were analyzed using multivariate logistic regression.

Results: Of 853 patients with SIAD, 278 were treated with fluid restriction within the first 24 hours and had complete laboratory data. Among these patients, 103 (37%) were classified as responders and 175 (63%) as non-responders. We confirmed urine osmolality ($P = .001$) and urine sodium ($P = .028$) as predictors of non-response to fluid restriction in multivariate logistic regression analysis. In our cohort alternative cut-offs of urine osmolality >700 mOsm/kg H_2O (PPV 0.89, NPV 0.39, LR+ 4.71) and urine sodium >110 mmol/L (PPV 0.85, NPV 0.42, LR+ 3.24) showed better predictive performance than the previously proposed thresholds. In contrast, no other previously proposed markers were associated with treatment non-response in multivariate logistic regression analyses.

Conclusions: Our data confirm urine osmolality and urine sodium as a predictor of non-response to fluid restriction. We propose alternative cut-offs (urine osmolality >700 mOsm/kg H_2O and urine sodium >110 mmol/L) for better identification of non-responders.

P276 - ECE_3213 - Biomarkers for progression allowing individualized management of patients with non-functioning pituitary tumors

Medha Suman[1], Tobias Hallén[2], Thomas Skoglund[2], Linus Koster[2], Oskar Ragnarsson[2] and Gudmundur Johannsson[2]

[1]Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, Gothenburg, Sweden; [2]Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, Sahlgrenska University Hospital, University of Gothenburg, Gothenburg, Sweden

Introduction: Post surgical tumor progression is observed in more than 50% of non-functioning pituitary tumors (NFPTs). There is no reliable method to predict individual tumor behaviour after surgery. Therefore, life-long surveillance with magnetic resonance imaging (MRI) is needed in all patients to monitor tumor growth. Biomarkers are needed to identify patients at risk of progression who may benefit from early re-operation, radiotherapy and/or medical treatment. In parallel, a deeper understanding of the biological mechanisms driving tumor progression is crucial for the development of novel therapeutic approaches.

Aims: In this project, we aim to investigate genome-wide DNA methylation and protein expression profiles in NFPTs to understand the interplay between the two molecular events and to potentially reveal driver events or pathways associated with tumor progression. Unravelling the underlying biology has potential for biomarker discovery and the development of novel therapeutic interventions.

Methods: We conducted an integrated analysis of DNA methylation and protein expression across 734 065 CpG sites and 457

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

differentially expressed proteins in NFPTs using hypernetwork models. We used our local retrospective cohort that included progressive ($n = 25$), and indolent ($n = 15$) NFPTs. The biomarkers identified in this study will be validated in another cohort that includes 88 NFPT cases.

Results: Of the 457 proteins, 101 proteins in progressive and 171 proteins in indolent NFPTs formed highly connected protein clusters that displayed coordinated epigenetic regulation. Some of the top hypernetwork proteins were encoded by genes *MCM6*, *SAFB*, *HDGFL2*, *PSMD6* and *LAMB2*. Several of these proteins were primarily involved in metabolic pathways and previously reported in other tumors with role in cell proliferation and migration. All these proteins were significantly upregulated in progressive NFPTs. Area under receiver curve analysis revealed that several of these proteins could predict the progressive tumor behaviour with over 80% accuracy.

Discussion: Hypernetwork analysis identified proteins involved in higher-order interactions between DNA methylation and protein expression that were not ranked high in conventional differential protein expression analysis. These proteins could potentially be functionally involved in driver events in tumor biology and warrant further investigation as candidate biomarkers for identifying individuals at risk of tumor progression after surgery.

P277 - ECE_1345 - Metabolic profiling of patients with active acromegaly and in remission by ultrahigh performance liquid chromatography-tandem mass spectrometry (UHPLC-MS/MS): exploring pathophysiology and biomarkers

Amy Coulden[1,2], Catherine Winder[3], Wanchang Lin[3], Warwick Dunn[3], Gabriela Da Silva Xavier[1] and Niki Karavitaki[1,2]

[1]Department of Metabolism and System Science, College of Medicine and Health, University of Birmingham, Birmingham, United Kingdom; [2]Department of Endocrinology, Queen Elizabeth Hospital Birmingham, University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; [3]Centre of Metabolomics Research, Biochemistry, Cell and Systems Biology, Institute of Systems, Molecular and Integrative Biology, University of Liverpool, Liverpool, United Kingdom

Background: Patients with acromegaly have multi-systemic co-morbidities (metabolic, cardio-/cerebrovascular, respiratory, musculo-skeletal) and increased mortality driven by metabolic and cardiovascular complications. Biochemical control is a main aim of treatment approaches and normalization of IGF-1 is considered indicative of biochemical remission. Nonetheless, acromegaly-related co-morbidities may persist even after apparent biochemical remission. Biomarkers reliably reflecting acromegaly activity and its sequelae in the body function are needed.

Aims: a) Explore global perturbations in the metabolism of patients with active acromegaly and acromegaly in biochemical remission, b) identify biomarkers discriminating patients from matched controls.

Methods: Non-targeted plasma metabolomic assessment was performed in plasma samples from 39 patients with active acromegaly, 39 with acromegaly in biochemical remission and 35 age-, sex- and BMI-matched controls by ultrahigh performance liquid chromatography-tandem mass spectrometry (UHPLC-MS/MS)**;** assays were detecting more than 800 water-soluble metabolites (HILIC assay) and 1000 lipid metabolites (C_{18} reversed phase assay). No participants were on medical treatment for the acromegaly or on antidiabetic medications. Analyses were performed with the MetaboAnalyst platform.

Results: 257 and 309 metabolites were different between active acromegaly and controls and between remission and controls, respectively ($P < .01$, Benjamini-Hochberg corrected). 74 water-soluble and 97 lipid metabolites were different in both comparisons and were investigated further. Eight pathways were enriched using the water-soluble metabolites ($P < .05$, Benjamini-Hochberg corrected), including amino acid metabolism (branched chain amino acids and arginine metabolism), purine metabolism and the pentose phosphate pathway. 26 (lyso)glycerophospholipids, 21 acyl carnitines, 15 fatty acids and oxidised fatty acids, 12 sterol lipids and 8 ceramides/sphingolipids were enriched based on lipid classes. 11 of the metabolites which were significantly different in both comparisons had AUROC ≥ 0.95 providing a panel to discriminate between active disease and control samples. In patients with active disease, 109 metabolites were correlated with IGF-1 levels ($-0.4 <$ correlation coefficient > 0.4; $P < .01$); no water-soluble metabolic pathways were enriched, whereas 36 glycerophospholipids (including 8 glycerophosphoinositols), 11 phosphosphingolipids, 9 sterol lipids, and 3 glycosphingolipids were statistically significant. Only 20 metabolites were different between patients with active acromegaly and on remission.

Conclusions: The metabolic profile of patients with acromegaly but also of those in remission is distinct from that of matched controls challenging the value of IGF-1 as biochemical marker of successful treatment. Correlations of IGF-1 levels with specific metabolites propose pathways involved in the pathophysiology of acromegaly. A number of metabolites can reliably discriminate disease status. Larger scale studies are needed to further explore these findings.

P278 - ECE_2785 - Diagnostic usefulness of fractional uric acid excretion as a supplementary criterion for SIAD

Emanuele Ferrante[1], Alessandro Maria Berton[2], Roberta Mungari[1], Michela Sibilla[2], Emanuele Varaldo[2], Nunzia Prencipe[2], Valeria Lanzi[1], Arianna Cremaschi[1], Silvia Grottoli[2], Gianluca Aimaretti[2], Ezio Ghigo[2] and Giovanna Mantovani[3]

[1]Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Division of Endocrinology, Diabetology and Metabolism, Medical Sciences Department, University of Turin, Turin, Italy; [3]Department of Clinical Sciences and Community Health, Dipartimento di Eccellenza 2023-2027, University of Milan, Milan, Italy

Background: The syndrome of inappropriate antidiuresis (SIAD) is the most frequent cause of hypotonic euvolemic hyponatremia. However, the differentiation between extracellular hypovolemia and euvolemia can be difficult and SIAD remains a diagnosis of exclusion. Other than essential criteria, a fractional uric acid excretion (FE-UA) >12% has been proposed as supplementary diagnostic criterion, independently of diuretics use.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

This study aimed to evaluate the diagnostic performance of FE-UA in SIAD and to validate the guideline-proposed thresholds.

Methods: biochemical parameters (serum and urine), including FE-UA, were prospectively analyzed in consecutive hyponatremic patients at diagnosis who were referred to two different Endocrinology Divisions in Northern Italy from November 2020 to December 2025. Patients who had already received treatment for hyponatremia, receiving hypouricemic drugs, or with hyponatremia due to primary polydipsia were excluded.

Results: 101 patients [66 females (65.3%), 35 males (34.7%), median age: 73 (61-80)] were included in the study. 86 patients (85.1%) had a diagnosis of SIAD, and 15 (14.9%) were classified as non-SIAD. 23 patients (22.8%) were on diuretics (17 in the SIAD group, 6 in the non-SIAD group), while 6 patients (5.9%) were on SGLT2-inhibitors (3 in the SIAD group and 3 in the non-SIAD group). In the whole group, median sodium was 129 (126-132) mmol/L, p-Osm 268 (258-276) mOsm/Kg, u-Osm 421 (318-541) mOsm/Kg and FE-UA 10.9% (7.5-13.6).

FE-UA median levels were significantly different between the two groups of patients (11.1% (8.6-15.4) vs 0.2% (0.07-6.79) in SIAD and non-SIAD groups, respectively, $P < .001$). Logistic regression showed a strong association between diagnosis and FE-UA levels (OR: 1.49, 95%CI: 1.23-1.79, $P < .001$). ROC analysis showed good discriminative performance, with an area under the curve (AUC) of 0.857 (95%CI: 0.737-0.976). The empirical optimal cut-off, determined using Liu Method, was 6.8%, at which the sensitivity and specificity were 87% and 80%, respectively. A cut-off of 12.5% showed a specificity and a positive predictive value (PPV) of 100% (95%CI: 89.4-100%), while a value of 2.5% showed a sensitivity and a negative predictive value (NPV) of 100% (95%CI: 63.1-100%). The diagnostic performance remained unchanged after excluding patients receiving diuretics and/or SGLT2 inhibitors, and the empirical optimal cut-off remained unchanged.

Conclusions: FE-UA showed a good diagnostic performance for SIAD. Values ≥12.5% reliably confirmed, whereas values <2.5% excluded the diagnosis. Diagnostic accuracy and optimal cut-off values were not influenced by diuretic and/or SGLT2 inhibitor use, supporting FE-UA as a robust supplementary diagnostic criterion for SIAD.

P279 - ECE_1060 - Association between SUDOSCAN-derived cardiac autonom neuropathy score and cardiovascular risk scores in patients with acromegaly

Nijat Nasirov[1], Humeyra Rekalı Şahin[2], Onour Chasan[1], Melike Cevikdizici[2], Ümmü Mutlu[1], Fulya Calikoglu[2], Hulya Hacisahinogullari[2], Nurdan Gul[2], Ozlem Soyluk Selcukbiricik[2], Ayse Kubat Uzum[2] and Gulsah Yenidunya Yalin[1]

[1]Department of Internal Diseases Division of Endocrinology and Metabolism Disorders, Istanbul University Istanbul Faculty of Medicine, Istanbul, Türkiye; [2]Department of Internal Diseases Division of Endocrinology and Metabolism, Istanbul University Istanbul Faculty of Medicine, Istanbul, Türkiye

Background: Acromegaly is associated with increased cardiovascular risk due to excess growth hormone and insulin-like growth factor-1 secretion. Cardiac autonomic neuropathy (CAN) represents an early manifestation of the associated cardiometabolic alterations. SUDOSCAN, a non-invasive device, quantifies electrochemical skin conductance (ESC) and estimates autonomic dysfunction. However, its clinical utility in acromegaly has not been systematically evaluated. This study aimed to assess the relationship between the SUDOSCAN-derived CAN risk score and cardiovascular risk algorithms SCORE2 and Framingham in patients with acromegaly.

Methods: A total of 72 participants, acromegaly patients (n: 36) and age and sex matched healthy control group (n:36) were evaluated in a cross-sectional design. Autonomic function was assessed with the Ewing test battery and SUDOSCAN (Impeto Medical, Paris, France). Ewing protocol included five standard cardiovascular reflex tests; heart rate response to deep breathing, valsalva maneuver, heart rate response to standing (30:15 ratio), blood pressure response to standing, and sustained handgrip test. Each test was scored (normal: 0, borderline: 0.5, or abnormal: 1) generating a total Ewing score (range 0-5). SUDOSCAN measurements were performed under standardized conditions by the same trained investigator. ESC values were obtained for hands and feet, and the device generated CAN risk scores adjusted for age, sex, and BMI. Cardiovascular risk was estimated using SCORE2 and Framingham algorithms. Statistical analyses included Mann–Whitney U, Spearman correlation, multivariate linear regression, and ROC analysis.

Results: Baseline demographic features, metabolic parameters (glucose, HbA1c, non-HDL cholesterol, triglyceride) and Ewing scores were similar between groups. SUDOSCAN-derived CAN risk scores were significantly higher in acromegaly patients (median 22.5 [14-35.5] vs 17 [10-25.8], $P = .023$). CAN scores correlated strongly with SCORE2 ($r = 0.773$, $P < .001$) and moderately with Framingham ($r = 0.471$, $P = .007$) and Ewing ($r = 0.458$, $P = .005$) scores. In multivariate regression, SCORE2 remained an independent predictor of CAN score ($\beta = .376$, $P = .02$). ROC analysis demonstrated excellent discriminative ability of SCORE2 (AUC = 0.937, 95% CI: 0.859-1.000) and good performance for Framingham (AUC = 0.865, 95% CI: 0.694-0.960) in identifying abnormal CAN scores, no significant predictive value was observed in the control group.

Conclusions: SUDOSCAN-derived CAN scoring correlates strongly with established cardiovascular risk algorithms and Ewing test parameters in acromegaly patients. Incorporating sudomotor-based autonomic assessment into cardiovascular risk stratification may enhance early identification of autonomic dysfunction and provide a practical adjunct to conventional scoring systems in this population.

[1]Institut de Recerca de l'Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; [2]Department of Endocrinology, Hôpital de la Conception, Marseille, France; [3]Department of Endocrinology, University Hospital of Padova, Padova, Italy; [4]Department of Endocrinology, Hôpital COCHIN, Paris, France; [5]Hospital General Universitario Gregorio Marañón, Madrid, Spain; [6]Department of Endocrinology, University Hospital Zagreb, Zagreb, Croatia; [7]Department of Endocrinology, Centro Hospitalar Universitário do Santo António, Porto, Portugal; [8]Department of Endocrinology, Erasmus University Medical Center Rotterdam, Rotterdam, The Netherlands; [9]Unit of Endocrinology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico di Milano, Milan, Italy; [10]Institute of Medicine at Sahlgrenska Academy, Department of Internal Medicine and Clinical Nutrition, University of Gothenburg, Gothenburg, Sweden; [11]ESTEVE Pharmaceuticals, S.A., Barcelona, Spain

Background: Ketoconazole ESTEVE is approved for the treatment of endogenous Cushing's syndrome (CS) with a requirement to collect safety data in this indication.

Methods: The primary objective of this prospective open-label Post-Authorisation Safety Study (PASS), using the European Registry on Cushing's Syndrome (ERCUSYN), is to document liver and cardiac safety in patients treated with Ketoconazole ESTEVE for CS. Overall safety, treatment pattern, and effectiveness are secondary objectives. Data from the last annual interim report are presented.

Results: At the cut-off date (31 August 2025), 134 patients were enrolled. One hundred and thirty-two patients were included in the full analysis set, 129 were evaluated for safety, and 130 for efficacy. Mean (SD) age of the patients was 46.9 (15.25) years. The majority of patients were female (78.8%) and were diagnosed with pituitary-dependent CS (73.6%). Ketoconazole ESTEVE was mainly used as monotherapy (87.1%), with a mean (SD) exposure of 1.4 (1.8) years and a median average daily dose of 400 mg.

Fifty-two cases (40.3%) of liver function test (LFT) abnormalities observed, occurred at the mean time of 1.7 months, with the median resolution time of 53.5 days. The proportion of patients with hepatotoxicity (ALT$\geq 5\times$ULN; ALP$\geq$2x ULN (without known bone fractures); or ALT$\geq$3x ULN and TB $>$ 2x ULN) decreased since the last report to 6.2% (8/129), with no new hepatotoxicity events being reported during this reporting period. Mean time to occurrence was 5.1 months, and the mean resolution time was 13.9 days. Co-administration of a known hepatotoxic drug was suspected in 6 of these patients. In all 8 patients, liver injury resolved after discontinuation of ketoconazole, 5 of these events were hepatocellular. No QTc prolongation cases were reported.

Effectiveness analysis suggests improved clinical outcomes in most patients treated with Ketoconazole ESTEVE, with 20.0% (26/130) of patients reaching remission and 60.0% (78/130) partial remission. Additionally, UFC or plasma cortisol levels were normal at the last visit in the majority of treated patients (72.2%, 65/90) with available data.

Conclusions: The results confirm the established safety and efficacy profile of Ketoconazole ESTEVE, with no new or unexpected safety signals detected.

P283 - ECE_3680 - Prevalence and risk factors for radiotherapy-induced hypopituitarism in survivors of primary, non-pituitary brain tumours treated with intensity-modulated radiotherapy

Darran Mc Donald[1,2], Liam O'connell[3], Maria Tomkins[1,2], Tara McDonnell[1,2], Niamh Mc Dermott[2], Jack Lee[2], Claire Carthy[2], Mary Moore[2], Amar Agha[1,2], Donncha O'brien[4], Kieron Sweeney[4], Stephen McNally[4], Mohsen Javadpour[4], Clare Faul[3], David Fitzpatrick[3], Michael W. O'reilly[1,2] and Mark Sherlock[1,2]
[1]Department of Medicine, Royal College of Surgeons in Ireland, Dublin, Ireland; [2]Department of Endocrinology, Beaumont Hospital, Dublin, Ireland; [3]St Luke's Radiation Oncology Network, Dublin, Ireland; [4]Department of Neurosurgery, Beaumont Hospital, Dublin, Ireland

Background: Hypopituitarism is a well-recognised late-effect of cranial radiotherapy. However, there is limited evidence quantifying the risk of hypopituitarism in adult survivors of primary, non-pituitary brain tumours, treated with modern radiotherapy techniques. Intensity-modulated radiotherapy (IMRT) is an advanced form of photon-based radiotherapy that precisely delivers radiation to brain tumours, with relative sparing of surrounding structures, including the hypothalamic-pituitary axis (HPA).

Methods: We evaluated the prevalence of, and risk factors for, radiotherapy-induced hypopituitarism in adult survivors of brain tumours that were distant from the HPA and treated with IMRT in Beaumont Hospital (the Irish National Neurosurgical Centre) between 2012-2022. Two patient cohorts were assessed (i) a retrospective cohort of survivors previously referred for endocrine surveillance; and (ii) a prospective cohort of consecutively treated survivors without prior surveillance. Prospectively recruited patients underwent a glucagon stimulation test and baseline pituitary assessment. Retrospectively recruited patients underwent annual synacthen testing and a pituitary profile, with growth hormone (GH) assessments performed in selected cases. Fischer's exact test compared prevalence rates between both cohorts. Multivariate logistic regression models evaluated the impact of independent variables on hypopituitarism risk.

Results: Pituitary function was assessed in 140 brain tumour survivors (prospective cohort $n=54$, retrospective cohort $n=86$). Median age at radiotherapy was 39.7 years (IQR 30.5-49.8) with a median post-radiotherapy interval of 60.5 months (IQR 36.0-83.0). The prevalence of hypopituitarism was 55% ($n=51/93$). GH deficiency was most common (54%; $n=50/93$), followed by adrenocorticotrophic hormone (ACTH) deficiency (12%; $n=17/138$), gonadotropin deficiency (11%; $n=15/138$) and thyroid-stimulating hormone (TSH) deficiency (9%; $n=12/137$). Hypopituitarism, ACTH, gonadotropin and TSH deficiency were more significantly prevalent in the retrospective compared to prospective cohort ($P<.05$). The composite endpoint of gonadotropin, ACTH or TSH deficiency occurred in 16% ($n=22/134$). The prevalence of this endpoint was significantly lower than a prior study in our institution using older 2 and 3-dimensional radiotherapy (16 vs 34%;$P<.01$). Multivariate logistic regression analysis revealed higher pituitary doses were independently associated with developing deficits across all hormone axes.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Longer follow-up interval was significantly associated with gonadotropin and TSH deficiency. Age, sex, tumour type and adjuvant chemotherapy were not associated with any hormone deficits.

Conclusions: This is the largest study evaluating the prevalence of radiotherapy-induced hypopituitarism in adult-onset-brain tumour survivors. The prevalence of the most clinically significant pituitary hormone deficits (ACTH, TSH and gonadotropin) is lower than previously reported, likely reflecting advances in modern radiotherapy techniques. Pituitary radiation dose exposure is an independent risk factor for radiotherapy-induced hypopituitarism.

Background: Stereotactic radiosurgery (SRS) is an effective salvage therapy for progressive non-functioning and medically refractory hormone-secreting pituitary adenomas, albeit requiring precise and confident target delineation. This, however, can be difficult on often equivocal postoperative MRI scans. While functional imaging is gaining importance in the diagnostic workup of challenging pituitary tumours, its value for radiosurgical planning in pituitary adenomas is largely unknown.

Methods: In this single-centre retrospective study, we report clinical outcomes of [68Ga]DOTATOC PET/MRI-guided SRS at a tertiary pituitary centre. Furthermore, we assessed the impact of [68Ga]DOTATOC PET on radiosurgical target delineation by comparing MRI-only contours, generated by an experienced radiosurgeon blinded to PET data, with clinically used PET/MRI-based plans using overlap and dose metrics.

Results: Twenty-three patients (57% women, median age 40 years) received PET-guided SRS at our centre; 44% had functioning adenomas. Visual PET uptake was present in all suspected residual tumours. At a median follow-up of 20.5 months [IQR: 11.8-50] for 20 patients without previous sellar irradiation, local tumour control was 94%. In tumours treated for uncontrolled hypersecretion ($n = 7$), 86% achieved biochemical normalization or improvement ($n = 6$). Only two patients (10%) developed additional pituitary deficits after SRS. Overall toxicity was predominantly low grade; 40% reported at least one adverse event (mostly headache, exclusively grade 1 according to the Common Terminology Criteria for Adverse Events [CTCAE]). One patient (5%) developed an oculomotor nerve disorder (CTCAE grade 3).

In simulation contouring, MRI-only and PET/MRI gross tumour volume (GTV) sizes did not show significant differences (5.57 cm^3 [3.29-7.95] vs 4.97 [3.22-7.33], $P = .8$). Spatial agreement was moderate (median GTV Dice coefficient 0.795 [0.753-0.838]), with MRI-only contouring missing a median of 18.7% [12.6-25.6%] of the PET/MRI GTV. Applying the PET/MRI-based dose distribution to the MRI-only planning target volume reduced coverage from 98.7% to 88.4% ($P < .001$), illustrating that even minor target delineation differences can markedly affect radiosurgical planning.

Conclusions: [68Ga]DOTATOC PET/MRI appears to identify residual adenoma more precisely than MRI-defined targets, suggesting that functional imaging may enhance radiosurgical planning. While early clinical outcomes are encouraging, the clinical value of functional imaging in guiding stereotactic radiosurgery requires validation in larger prospective multicentre trials.

Aggressive evolution of PitNETs is uncommon and remains difficult to characterize. Defining aggressiveness and malignancy is challenging, and subsequently hard to predict, and to understand. The aim of this study was to provide a molecular definition of aggressiveness using genomic approaches.

Methods: Tumor samples from 206 patients with PitNETs were included. Associations between 9 clinical features of aggressiveness and PitNETs' omics were explored. Omics included transcriptome, DNA methylation, chromosomal alterations and mutations. Clonal tumor evolution was monitored in 7 patients.

Results: Among the 9 clinical features of aggressiveness evaluated, only rapid progression, progression after radiotherapy, Ki67/MIB1 proliferation index ≥10%, temozolomide treatment, metastases and specific death were associated with distinct molecular signatures. In contrast, tumor maximal diameter ≥40 mm, cavernous and sphenoid invasion were not linked to specific omic signatures. The omic signatures associated with these features of aggressiveness overlapped but remained distinct between corticotroph and mammo-somato-thyrotroph lineages. For each lineage, a common signature of aggressiveness emerged, associating proliferative transcriptome signature and DNA hypermethylation. Alterations in specific cancer-related genes were associated with aggressive features. *USP8* and *GNAS* alterations were associated with a better outcome. Integrative analysis of gene alteration, methylome, and transcriptome signatures identified a subset of molecularly aggressive PitNETs, enabling the development of a histomolecular risk stratification strategy. Molecular signatures remained globally stable during the course of the disease, despite evolution towards aggressiveness and potential clonal divergence.

Conclusions: This systematic analysis of clinical and histopathological features of aggressiveness using an integrated multiomic approach refines the concept of aggressiveness in PitNETs with a molecular definition. High risk PitNETs with pejorative outcome can be individualized according to a histomolecular risk assessment workflow. Prospective cohort studies are needed to validate this approach in clinical practice.

P286 - ECE_1919 - Tirzepatide in patients with hypothalamic obesity secondary to craniopharyngioma: a single-center case series

Elisa Sala[1], Giulia Carosi[1], Giulia Del Sindaco[1], Giacomo Noschese[1,2], Alessandra Mangone[1,2], Roberta Mungari[1], Arianna Cremaschi[1], Emanuele Ferrante[1] and Giovanna Mantovani[1,2]

[1]Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy

Background: hypothalamic obesity is a severe condition affecting patients with craniopharyngioma, resulting from hypothalamic damage and characterized by rapid weight gain, hyperphagia, and dysregulation of energy expenditure. Lifestyle interventions show limited efficacy, and pharmacological options remain scarce. Currently, setmelanotide can be prescribed in pediatric patients with hypothalamic obesity; however, no pharmacological therapy is specifically approved for adults. To date, only one published case report has suggested potential benefits of tirzepatide in a patient with surgically treated craniopharyngioma.

Methods and Results: we report a single-center case series including 3 adult patients (2 females, 1 male; mean age 45 ± 6.4 years) with hypothalamic obesity secondary to transsphenoidal surgery for adamantinomatous craniopharyngioma. Body mass index (BMI) at diagnosis was 25 (patient 1, F), 20 (patient 2, F), and 29 (patient 3, M) kg/m^2. Before starting tirzepatide, prescribed according to clinical practice 14, 24, and 5 months after surgery, BMI was increased to 30, 36, and 39 kg/m^2, respectively (median weight increase: 36 kgs (29-48 IQR); median percentage increase: 51% (34-80 IQR)). Changes in body weight, metabolic parameters, appetite-related symptoms, body image perception assessed by the Body Uneasiness Test (BUT-A), and safety outcomes were evaluated during follow-up.

Tirzepatide treatment was associated with a weight reduction in female patients, corresponding to a 10% of body weight loss after 4 months in patient 1 (final dose: 5 mg/w) and a 5% of body weight loss after 2 months in patient 2 (final dose: 5 mg/w). In the male patient, an initial weight gain of 5 kg was observed during the first month of therapy (2.5 mg/w), followed by weight stabilization over the subsequent 2 months (dose: 7.5 mg/w). All patients reported a reduction in hyperphagia and food-seeking behavior. Treatment was well tolerated, and no adverse events were reported. Weight changes were accompanied by improvements in metabolic parameters in patient 1, after 4 months follow-up: HOMA-IR decreased from 4.5 to 2.6, and glycated hemoglobin levels were reduced from 37 to 33 mmol/mol. Moreover, body image perception improved, with the Global Severity Index of the BUT-A decreasing from a pathological

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

value of 1.6 at baseline to 1.1 after four months, below the pathological threshold (>1.2).

Conclusions: In this single-center case series, tirzepatide was associated with clinically relevant weight improvements in patients with hypothalamic obesity secondary to craniopharyngioma surgery. Despite the small sample size, these findings suggest that tirzepatide may represent a promising therapeutic option for this challenging condition.

P288 - ECE_3351 - Pharmacological steroid secretion inhibition in Cushing's disease: the risk of acute kidney injury

Brian Randazzo[1], Giacomo Fabio Antonio Grifoni[1], Vittoria Favero[1,2], Andrea Saladino[3], Edoardo Porto[3], Renato Cesare Cozzi[2] and Iacopo Chiodini[1,2]
[1]Department of Biotechnology and Translational Medicine, University of Milan, Milano, Italy; [2]Endocrinology Unit, ASST Grande Ospedale Metropolitano Niguarda, Milan, Italy; [3]Milan, Italy

Background: Medical therapy has an established role in treating Cushing's disease (CD) when surgery is delayed, contraindicated or unsuccessful, with the aim of normalizing 24-hour urinary free cortisol and/or late-night salivary cortisol. However, the normalization of these hormonal parameters may become excessive in some cases, such as cyclic disease or during stress conditions, leading to adrenal insufficiency (AI). Several studies have linked AI to acute kidney injury (AKI), but to date, AKI associated with medical therapy-induced AI has not been systematically described.

Cases Presentation: Case 1. A 54-year-old man with CD treated with Osilodrostat since May 2022 (2 mg/day). In July 2025, due to worsening metabolic control, the dose was up-titrated to 4 mg/day. Two weeks later, he developed asthenia, weight loss and hypotension. Biochemical evaluation showed low cortisol levels. At the same time, serum creatinine increased from a baseline of 1.34 mg/dL up to 3.57 mg/dL, and eGFR reached a nadir of 18 mL/min/1.73 m^2.

Osilodrostat was discontinued and the patient received intravenous hydrocortisone and isotonic saline, followed by a replacement therapy with oral hydrocortisone for few days. His clinical symptoms improved rapidly, and renal function progressively recovered, with serum creatinine decreasing to 1.58 mg/dL within a month.

Case 2. A 79-year-old woman with a long-term persisting CD, treated with Pasireotide since 2018. In April 2024 she underwent knee arthroplasty and block and replace treatment was prescribed for surgery. Surgery was uneventful and rehabilitation started. Three weeks later she developed nausea, vomiting, asthenia, hypotension; laboratory evaluation showed hyperkalaemia (6.4 mEq/L) and serum creatinine of 6.2 mg/dL. Pasireotide therapy was suspended, while intravenous steroids and supportive therapy were administered. Oral hydrocortisone was then started, with clinical benefit and gradual complete recovery of renal function.

Conclusions: These two cases highlight the need for close monitoring of CD patients on medical therapy. Although the primary goal of treatment is to normalize cortisol secretion, therapy-adjusted cortisol levels may not be sufficient in conditions that require increased physiological demand (eg stress and surgery). In this setting, patients may develop AKI as a sign of AI. Prompt discontinuation of the culprit agent, administration of intravenous hydrocortisone and fluid resuscitation, yielded full clinical and renal recovery in both patients, supporting a multimodal strategy over isolated measures.

These observations underscore the need for evidence-based, standardized protocols to guide the prevention and management of AI in Cushing patients medically treated.

P289 - ECE_1810 - Differential skeletal recovery after surgical vs medical remission in Cushing's disease: a 5-year observational study

Giacomo Voltan[1,2], Pierluigi Mazzeo[1,2], Irene Tizianel[1,2], Carlo Mogno[1,2], Giulia Bovo[1,2], Filippo Ceccato[1,2], Mattia Barbot[1,2] and Valentina Camozzi[1,2]
[1]Endocrinology Unit, University Hospital of Padova, Padova, Italy; [2]Department of medicine—DIMED, University of Padova, Padova, Italy

Background: Skeletal fragility is a major and often irreversible complication of Cushing's disease (CD). Although remission of hypercortisolism may allow partial bone recovery, long-term data comparing surgical and medical remission are scarce. In particular, whether sustained eucortisolism achieved through medical therapy results in skeletal recovery comparable to surgical cure remains unresolved.

Methods: We conducted a 5-year retro-prospective observational study including 58 patients with CD and sustained normalization of 24-h urinary free cortisol (UFC), achieved after transsphenoidal surgery (surgical remission, $n = 36$) or during long-term medical therapy (medical remission, $n = 22$). Baseline assessment was performed during active disease. Endocrine, metabolic and skeletal evaluations, including DXA-derived bone mineral density (BMD) and fragility fracture assessment, were performed at 2 and 5 years after first UFC normalization. A complete 5-year follow-up was available in 33 patients (22 surgical, 11 medical).

Results: At baseline, patients were comparable for age and biochemical severity, whereas disease duration before UFC normalization was significantly longer in medically treated patients (12 vs 1 months, $P = .001$). Lumbar spine BMD significantly increased in the overall cohort at 2 years (0.863 vs 0.830 g/cm^2, $P = .018$) and further at 5 years (0.960 vs 0.830 g/cm^2, $P = .001$). This improvement was robust and consistent in surgically cured patients at both 2 ($P = .039$) and 5 years ($P = .002$), while only a non-significant trend was observed in the medical remission group. No significant changes were detected at femoral neck or total hip in either group.

The prevalence of densitometric osteoporosis decreased from 68% at baseline to 57% at 5 years. Despite biochemical remission, incident fragility fractures occurred during follow-up (3 at 2 years and 3 at 5 years). In multivariate regression analysis adjusted for age, sex, disease duration and baseline UFC, baseline

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

lumbar spine BMD emerged as the only independent predictor of 5-year lumbar spine BMD (β = .573, $P = .002$).

Conclusions: In Cushing's disease, long-term skeletal recovery remains incomplete and strongly site-specific, predominantly affecting trabecular bone. Surgical remission is associated with a significantly greater lumbar spine BMD recovery compared with medical remission, despite sustained UFC normalization in both groups. Persistent fracture occurrence indicates that biochemical control alone does not fully restore skeletal integrity. Early diagnosis and baseline bone status critically determine long-term bone outcomes, supporting the need for prolonged skeletal surveillance and targeted bone-protective strategies, particularly in patients managed with long-term medical therapy.

P290 - ECE_2273 - Continuing imbalance in sex distribution among pediatric patients with growth hormone deficiency in Poland

Katarzyna Majewska[1], Magdalena Tchorzewska-Skrobich[1], Paulina Wais[2], Monika Naskręcka[3] and Andrzej Kędzia[1]

[1]Department of Pediatric Diabetes, Auxology and Obesity, Poznan University of Medical Sciences, Poznan, Poland; [2]Poznan, Poland; [3]Department of Applied Mathematics, Poznan University of Economics and Business, Poznan, Poland

Introduction: Short stature, by statistical definition, affects nearly 2.5% of children and therefore represents a substantial pediatric problem. Both boys and girls are diagnosed with short stature when their height falls below −2 SD appropriate for their age and sex. Consequently, similar proportions of both sexes meet these criteria. A specific group of children with short stature are those with growth hormone deficiency (GHD), as they require long-term therapy with recombinant human growth hormone (rhGH) to achieve growth improvement. Reports indicating sex disparity, with more males than females diagnosed with GHD, date back over three decades and were confirmed by numerous studies worldwide. This study aimed to investigate the current gender distribution among Polish pediatric patients with GHD compared to all children undergoing diagnostic procedures due to short stature in a single specialist center.

Methods: The study used a retrospective analysis of medical records collected between 2014 and 2024. The cohort comprised 336 children with short stature from central and western Poland, aged 3 to 17 years, who were admitted to a single specialist center for diagnostic procedures. Sex distribution was analyzed among all short stature patients, and within subgroups based on growth hormone (GH) peak levels: ≥10 ng/mL, <10 ng/mL, and <5 ng/mL.

Results: There were significantly more boys than girls among all children with short stature who underwent diagnostic procedures (66.1% vs 33.9%, respectively; $P < .001$). Similar findings, with significant male prevalence, also applied to all subgroups based on GH status: ≥10 ng/mL, <10 ng/mL, and <5 ng/mL ($P < .001$ in each subgroup). The sex distribution did not significantly differ across all analyzed subgroups. No significant differences were observed in hSDS or peak GH levels between girls and boys.

Conclusions: The prevalence of males in our study was similar across all analyzed groups, regardless of GH results, and including all patients with short stature analyzed together. Apparently, the number of boys referred for diagnostic procedures is significantly higher than the number of girls, and in consequence, proportionally more boys are diagnosed with GHD. Our observation supports the thesis that girls with short stature are generally underinvestigated, likely because of the social acceptance of girls and women being short, in contrast to boys and men. This disparity has persisted for decades, even though, according to current guidelines, girls should have the same diagnostic and treatment options as boys.

P291 - ECE_1177 - Effect of carbohydrate quality index on plasma IGF-1 levels in acromegaly patients receiving somatostatin analogue therapy

Sena Nur Demirtas[1], Fulya Calikoglu[2], Humeyra Rekalı Şahin[2], Ümmü Mutlu[2], Hulya Hacisahinogullari[2], Cemile İdiz[2], Nurdan Gul[2], Ozlem Soyluk Selcukbiricik[2], Ayse Kubat Uzum[2] and Gulsah Yenidunya Yalin[2]

[1]Department of Internal Medicine, Nutrition and Dİetetics Program, Istanbul University, Institute of Graduate Studies in Health Sciences, Istanbul, Türkiye; [2]Department of Internal Diseases Division of Endocrinology and Metabolism Disorders, Istanbul University Istanbul Faculty of Medicine, Istanbul, Türkiye

Background: Acromegaly is characterized by chronic excess secretion of growth hormone (GH) and insulin-like growth factor-1 (IGF-1). Somatostatin analogues (SSAs) constitute the mainstay of medical treatment. Emerging evidence suggests that nutritional factors may influence IGF-1 regulation. However, studies evaluating this relationship are limited.

Objective: To investigate the effect of improving dietary carbohydrate quality, quantified by the Carbohydrate Quality Index (CQI), on serum IGF-1/upper-limit ratio (IGF-1/ULR) and metabolic parameters in acromegaly patients on stable-dose SSA treatment.

Methods: Acromegaly patients who had been receiving a stable dose of long-acting SSA treatment for at least six months were enrolled in this study (*n*: 24; M: 15, F:9). Dietary intake was assessed using a validated food frequency questionnaire, and CQI was calculated based on dietary fiber intake, glycemic index, whole-grain ratio, and solid-to-total carbohydrate ratio. Patients received a structured nutrition education program and were followed up for three months by weekly schedules regarding their nutritional intake. A total of 20 patients completed the study protocol (M:13,F:7). At the end of the nutritional intervention period CQI was recalculated. Patients were divided in two groups by median split based on final CQI (CQI ≥ 12 vs CQI <12). The change in baseline and final results of anthropometric measurements, biochemical parameters and IGF-1/ULR were compared. ΔIGF-1/ULR was defined as the change in IGF-1/ULR levels before and after the nutritional intervention. Statistical analyses included paired t-tests, Pearson correlations, and multivariable regression.

Results: CQI was improved significantly in all of the patients ($P <$ .001); characterised by higher fibre intake, lower glycaemic index, and increased whole-grain ratio ($P = .005$, $P = .007$, $P < .001$,

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

respectively). Significant reductions were observed in fasting glucose, LDL and triglyceride levels ($P = .02$, $P = .03$ and $P = .01$). No significant changes were detected in IGF-1/ULR levels and ΔIGF-1/ULR levels were similar between CQI groups ($P > .05$). Total energy intake correlated positively with baseline IGF-1/ULR ($r = 0.48$, $P = .031$), and negatively with ΔIGF-1/ULR ($r = -0.53$, $P = .017$). Multiple regression analysis did not reveal independent predictors of IGF-1 change.

Conclusions: A three-month CQI-oriented dietary intervention improved carbohydrate quality and metabolic parameters; however did not produce significant effects on the change in IGF-1/ULR levels in SSA-treated acromegaly patients. Role of high CQI diets in modulating the IGF-1 axis should be investigated in larger cohorts with longer-term studies.

P292 - ECE_1639 - Volume status of patients with hyponatremia across the age span—a secondary analysis of a large prospective international study

Emanuele Varaldo[1,2,3], Laura Potasso[1,2], Julie Celine Refardt[1,2,4] and Mirjam Christ-Crain[1,2]

[1]Department of Endocrinology, Diabetology and Metabolism, University of Basel, Basel, Switzerland; [2]Department of Clinical Research, University of Basel, Basel, Switzerland; [3]Division of Endocrinology, Diabetology and Metabolism, Department of Medical Sciences, University of Turin, Torino, Italy; [4]Department of Internal Medicine, Section of Endocrinology, Erasmus Medical Center, Rotterdam, The Netherlands

Introduction: Hypotonic hyponatremia is the most common electrolyte disorder observed in hospitalized patients, with its prevalence increasing with age. It is generally classified into hypovolemic, euvolemic, and hypervolemic forms based on extracellular fluid volume status. The aim of our study was to evaluate the characteristics of volume status and the etiologies of different forms of hypotonic hyponatremia across the age span in adult patients hospitalized with hyponatremia.

Methods: This secondary analysis of a prospective, randomized, controlled, international trial (NCT03557957) included hospitalized adult patients with plasma sodium <130 mmol/L from nine European centers. Participants were classified into three age groups (<65, 65-79, and ≥80 years). At study inclusion, physicians assessed volume status as hypervolemic, euvolemic, or hypovolemic. A reassessment at the end of hospitalization provided a definitive classification based on the patient's full clinical course and hospital management. For this analysis, only patients with a documented volume status reassessment before discharge or death were included.

Results: A total of 1992 patients (F/M 1050/942, median age 73 [63-81] years) were included. Plasma sodium levels and the prevalence of profound hyponatremia did not differ across age groups ($P = .198$ and $P = .774$, respectively). Euvolemic hyponatremia ($n = 1073$) was the most prevalent across all age groups and sexes, primarily due to SIAD ($n = 853$). However, a significant difference in the distribution of volume status subtypes was observed ($P = .007$), mainly driven by a higher prevalence of hypervolemic forms in both males and females aged ≥80 years. Moreover, a higher prevalence of SIAD was observed in patients aged 65 years or older compared to younger patients ($P = .033$). In the hypovolemic subgroup ($n = 613$), the leading causes differed by age: among patients <65 years, gastrointestinal sodium losses accounted for 41.3% of cases, whereas in patients aged ≥80 years, diuretic use was the cause in nearly 50% of cases. In the hypervolemic subgroup ($n = 306$), heart failure was the leading cause, accounting for 70.3% of patients, followed by liver insufficiency (11.8%), with heart failure increasing and liver insufficiency decreasing across age groups.

Conclusions: Euvolemic hyponatremia is the most prevalent form in hospitalized patients of all age groups. It is commonly due to SIAD, which is more frequent in individuals aged 65 years or older. Moreover, the underlying causes of both hypervolemic and hypovolemic hyponatremia varies across different age groups.

Background: Acquired hypothalamic obesity (aHO) represents a rare, complex disease, manifesting as loss of satiety and reduced energy expenditure due to disrupted hypothalamic signalling within the melanocortin-4 receptor pathway. Clinically, aHO presents as hyperphagia, accelerated and sustained weight gain, and profound metabolic dysregulation. Childhood-onset craniopharyngioma (CO-CP), a slow growing tumour of the pituitary region, is a leading cause of aHO, with hypothalamic injury from the tumour and/or treatment causing a secondary chronic

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

disease burden. Despite high survival, transition to adult care often limits access to multidisciplinary support, further reducing quality of life and increasing premature mortality. This qualitative study aimed to highlight the persistent, under-recognised health burden of aHO across life stages, drawing on the experiences of individuals with CO-CP from the Netherlands, Germany, and the UK.

Methods: Individuals with CO-CP diagnosed between 3-14 years, now aged 6-68 years, were recruited from charities/medical centres in the Netherlands ($n = 12$), Germany ($n = 11$), and the UK ($n = 10$). A mixed-methods approach combined online and in-person interviews with individuals ($n = 33$) and family members ($n = 11$), with insights from healthcare professionals ($n = 9$).

Results: Across all three countries, aHO emerged as a dominant and persistent consequence of CO-CP and/or its treatment. Reported core symptoms for aHO included weight gain (79%), fatigue and reduced stamina (76%), extreme hunger [hyperphagia] (36%), as well as other symptoms of hypothalamic dysfunction such as pituitary hormone dysfunction (100%), and visual impairment (76%). Furthermore, fear of Addisonian crises (91%), social stigma (88%), relationship struggles (82%), challenges at work/school (88%) and emotional dysregulation (64%) were reported as the most frequent daily struggles. Furthermore, despite centralised, structured paediatric care with early tertiary referral pathways across all three countries, the transition to adult care was reported as abrupt, inconsistent and fragmented with significant needs and gaps in adult follow-up.

Conclusions: The findings of this study highlight the critical importance of recognising aHO and secondary metabolic syndrome as life-limiting fundamental, long-term neuroendocrine consequences of CO-CP with a substantial impact on patients' ability to engage fully in daily life. aHO should be a primary component of CO-CP management, research, care planning, clinical guidelines, and healthcare resource allocation. Cost-effective long-term management requires bespoke pituitary-specialist care in expert centres, targeted pharmacotherapy and patient-empowered transition from paediatric to adult neuroendocrine/metabolic care, fully supported by multidisciplinary care including endocrinologists, specialised dietitians and psychologists, and neurorehabilitation specialists, essential to address the diverse physical and mental health needs of patients with aHO across the life-span.

P294 - ECE_2059 - Oral semaglutide—a novel stimulant for the hypothalamic-pituitary-adrenal axis?

Inge Nobbenhuis[1,2], Martin Bidlingmaier[3], Kevin Cj Yuen[4] and Sandrine A. Urwyler[1,2]

[1]*Endocrinology, Diabetology & Metabolism, University Hospital Basel, Basel, Switzerland;* [2]*University of Basel, Department of Clinical Research, Basel, Switzerland;* [3]*Medizinische Klinik und Poliklinik IV, Ludwig Maximilians University Munich, Munich, Germany;* [4]*Saint Joseph's Hospital & Medical Center, Barrow Pituitary Center, Phoenix, United States*

Background: Symptoms of adrenal insufficiency (AI) are often nonspecific, hence can complicate or delay its diagnosis. The insulin tolerance test (ITT) remains the gold standard for diagnosing secondary and tertiary AI, but is elaborate, uncomfortable and carries risks for patients due to insulin-induced hypoglycemia. Consequently, there is need for a safe, feasible oral test capable of accurately assessing the entire hypothalamic–pituitary–adrenal (HPA) axis. Limited evidence indicates that glucagon-like peptide-1 receptor agonists (GLP-1 RAs) can activate the HPA axis in rodents and humans. However, the effects of orally administered GLP-1 RAs, such as semaglutide, on the HPA axis have not yet been investigated.

Patients and Methods: In this randomized, placebo-controlled, double-blind, cross-over study we investigated the acute effect of a single dose 14mg oral semaglutide vs placebo on the HPA axis. During both study visits, blood and saliva samples were drawn every 15-30 minutes until 210 minutes for measurements of serum cortisol, adrenocorticotropic hormone (ACTH) and salivary cortisol levels. Delta values for each time point were calculated (eg delta serum cortisolΔ_{30min} = serum cortisol$_{30min}$—serum cortisol$_{baseline}$).

Results: Twenty male healthy volunteers were included. Median age was 27 years (IQR 24, 31) and mean body mass index 24.5 kg/m^2 (SD ±2.3). Mean baseline serum cortisol values were similar in the semaglutide group with 394 nmol/L (± 81) and the placebo group with 371 nmol/L (±75), $P = .17$. Mean delta serum cortisol levels were significantly higher at 75 min after oral semaglutide (delta serum cortisol −34.6 nmol/L (±120)) vs placebo (−103.5 nmol/L (±76)), $P = .02$, and this effect was even more pronounced at 90 min and 120 min. Delta salivary cortisol was higher at 120 min after semaglutide (0.2 nmol/L (±9.8)) vs placebo (−5.6 nmol/L (±4.7), $P = .04$). In parallel, delta median ACTH was higher after semaglutide at 75 min and 90 min with a maximal effect at 90 min (6.95 pmol/L (IQR) (−0.98; 12.15) vs placebo −3.65 pmol/L (−6.35; 0.08), $P = .01$.

Conclusions: Oral semaglutide can stimulate serum cortisol, salivary cortisol and ACTH in healthy men, and may therefore be evaluated as a novel oral stimulation test for the entire HPA axis in assessing for AI. Possible mechanisms could include co-stimulation due to the anatomical proximity of hypothalamic GLP-1 receptors to corticotropin releasing hormone producing neurons and a relative blood glucose-lowering effect of oral semaglutide.

P295 - ECE_3019 - Wolfram syndrome in adult clinical practice: a retrospective, single-center case series

Mustafa Berkay Tastekin[1], Selin Tekin[2], Nergis Basmacı[2], Suleyman Nahit Sendur[2], Selcuk Dagdelen[2] and Tomris Erbaş[2]

[1]*Department of Internal Medicine, Hacettepe University School of Medicine, Ankara, Türkiye;* [2]*Department of Internal Medicine, Division of Endocrinology & Metabolism, Hacettepe University School of Medicine, Ankara, Türkiye*

Background: Wolfram syndrome (WS) is a rare, progressive, fatal syndrome characterized by endocrinological and neurological degeneration. WS mainly caused by pathogenic variants in WFS1 gene chromosome 4p16.1. AVP deficiency, diabetes mellitus, optic atrophy, and deafness are major components. Also, many neurological, endocrinological, and systemic

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

complications can occur. Although they are diagnosed in the pediatric age, they spend almost half of their lives in adulthood. In this study, we examined the clinical characteristics and real-life data of seven patients who applied to our center. Thus, we aimed to contribute to the management of the syndrome in the adult period of life.

Methods: In this single-center retrospective study, we described the clinical characteristics of seven patients diagnosed with Wolfram (DIDMOAD) syndrome who presented to our center between January 2000 and 2025.

Results: Four patients (51.7%) were female. The median age was 4 (IQR 4-5) at diagnosis and 30 (IQR 27-36) at the time of the study. Diabetes mellitus was the first component of the syndrome to appear and was present in all patients. At the time of diagnosis, three of the patients (42.9%) were diagnosed with diabetes mellitus with ketoacidosis. The median of the latest HbA1c values was 8.1% (7.6%-11.3%) and insulin doses were 1.44 (1.00-1.46) IU/kg/day. Statistical analysis of the difference between the HbA1c values at the time of diagnosis and the final HbA1c values showed no significant difference ($P = .67$). Arginine vasopressin (AVP) deficiency occurred in all patients, with a median age of 10 (IQR 4-13). The median age for the onset of visual impairment was 11 (IQR 9.5-22) and was observed in all seven patients. Hearing loss was observed in two patients; it emerged during infancy in one, and at the age of 22 in the other. Similarly, urological complications (neurogenic bladder, hydroureteronephrosis) were present in two patients developing at the ages of 19 and 28, respectively. Three of the patients (42.9%) showed widespread atrophy on brain MRI. In terms of hypopituitarism, isolated GH deficiency was found in one patient, gonadotropin deficiency in another, and a combination of both in a third patient.

Conclusions: More clinical trials in adult settings are essential for improving treatment and complication management; this will help patients lead productive lives in society once curative genetic therapies become available in the future.

P296 - ECE_3232 - The third phenotype: high preoperative serum IGF-1 imprints post-surgical discordant trajectory in acromegaly

Anna Pennlund[1], Thomas Olsson Bontell[1,2], Thomas Skoglund[3], Helena Carén[3], Gudmundur Johannsson[3], Daniel S Olsson[3] and Daniela Esposito[2]

[1]Gothenburg, Sweden; [2]Department of Endocrinology, Sahlgrenska University Hospital, Gothenburg, Sweden; [3]University of Gothenburg, Gothenburg, Sweden

Introduction: The 2024 consensus on acromegaly remission relies on biochemical concordance, yet a gray zone of discordant growth hormone (GH) and Insulin-like Growth Factor-1 (IGF-1) levels still exists. We postulate this represents a distinct "Third Phenotype"—neither cured nor classically active—and investigated the characteristics of this discordant group and biological predictors in a large single-center surgical cohort.

Methods: We performed a longitudinal analysis of 103 patients (1994-2019) treated at a dedicated Pituitary Center of Excellence. The final cohort ($n = 82$) had complete postoperative Oral Glucose Tolerance Test and IGF-1 data. Discordance was rigorously defined as one parameter (GH nadir or IGF-1) indicating remission while the other remained elevated. Phenotypic stability was tracked across three assay eras (RIA/Immulite/iSYS).

Results: Biochemical discordance manifested in 20% (16/82) of patients, predominantly as the High-IGF1/Normal-GH pattern (88%). The median age of discordant patients was 44 (range:30-75 years), 75% of discordant patients were men. Most patient (81%) presented with a macroadenoma at diagnosis of acromegaly and 47% had an invasive tumour. Hypertension was observed in 38%, and diabetes mellitus in 19% of patients. The phenotype demonstrated remarkable stability (94% retention of discordance type over a decade), arguing against transient assay variability. While tumor size and invasiveness were non-predictive, high preoperative IGF-1 was the defining predictor: median IGF-1 at diagnosis was significantly higher in discordant vs concordant-controlled patients (3.1 vs 2.5 × ULN, $P = .01$).

Conclusions: Biochemical discordance represents a stable biological entity rather than a methodological artifact. Approximately one fifth of patients exhibited postoperative discordance, most commonly elevated IGF-1 with a normal GH nadir. The majority of discordant patients had macroadenomas. Higher IGF-1 levels at diagnosis predicted postoperative discordance. These patients remain in a gray zone between remission and active disease, requiring careful and individualized follow-up.

P297 - ECE_1848 - Sellar metastases from solid tumors and hematological malignancies: a 20-year single-centre experience

Sandra Pekic Djurdjevic[1,2], Marko Stojanovic[1,2], Mirjana Doknic[1,2], Dragana Miljic[1,2], Emilija Manojlovic Gacic[1,3], Zvezdana Jemuovic[2], Ivana Cekic[2], Ivan Jevtic[2], Boris Kurcubic[2], Jelena Bajic[2], Aleksandar Stanimirovic[1,4], Vuk Scepanovic[1,4], Mihailo Milicevic[1,4], Marina Nikolic Djurovic[1,2] and Vera Popovic[1]

[1]Medical Faculty, University of Belgrade, Belgrade, Serbia; [2]Department of Neuroendocrinology, Clinic for Endocrinology, Diabetes and Diseases of Metabolism, University Clinical Center of Serbia, Belgrade, Serbia; [3]Belgrade, Serbia; [4]Clinic for Neurosurgery, University Clinical Center of Serbia, Belgrade, Serbia

Introduction: Malignant or metastatic origin of sellar–suprasellar lesions is comparatively rare. This often leads to diagnostic delays or misdiagnosis. Highly vascularised pituitary is however the most attractive intracranial site for hematogenic neoplastic dissemination.

Aims: Analysis of clinical, biochemical, hormonal and neuroradiological characteristics of sellar/suprasellar lesions representing solid tumor metastases and hematological malignancies in a large single-centre cohort.

Patients and Methods: We retrospectively analysed 1867 patients with sellar or suprasellar lesions diagnosed and treated at Department of Neuroendocrinology over a 20-year period (2005-2025).

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Results: Twenty patients (1.07%) were identified (12 females), diagnosed at mean age of 55.7 ± 2.1years (range, 32-69). Twelve of those (60%) had solid tumor metastases, with lung cancer as predominating origin ($n = 7$; six males). Breast cancer, renal cell carcinoma, papillary thyroid carcinoma, melanoma, and cancer of unknown primary origin were each observed in one patient. Hematological malignancies accounted for 8 cases (40%), including lymphoma ($n = 4$: intravascular large B-cell lymphoma, $n = 1$; high-grade B-cell non-Hodgkin lymphoma, $n = 3$), multiple myeloma ($n = 2$), and acute leukaemia ($n = 2$). Mean age did not differ between hematological malignancies and solid tumor metastases (54.3 ± 4.0 vs 56.7 ± 2.4 years, $P > .05$). Female sex strongly predominated in hematological malignancies, (75%) while gender distribution was neutral (50:50%) in solid tumor metastases. Predominant presenting symptoms were headache (70%), visual impairment (50%), and cranial nerve palsies due to cavernous sinus infiltration (50%). Most patients (90%) had multiple anterior pituitary hormone deficiencies. AVP-deficiency was present in 35% and was isolated in one (acute myeloid leukaemia). Symptom duration was short (15-180 days). Patients with hematological malignancies commonly exhibited elevated ESR and abnormal blood counts; elevated LDH was observed in lymphoma patients. In majority (85%) of affected patients sellar/suprasellar lesion was the presenting manifestation of underlying malignancy. In three patients, primary cancer was diagnosed 3-20 years earlier. Imaging most commonly showed intrasellar mass with suprasellar extension (55%). Exclusive intrasellar or suprasellar localisation were observed in 20% each. Pituitary stalk infiltration was present in four patients, empty sella in one, and absent posterior pituitary T1-weighted hyperintensity in one patient. Surgery was performed in 35%, while 50% of patients received immunochemotherapy and/or stereotactic radiotherapy.

Conclusions: Metastatic involvement of sellar–suprasellar region should be suspected in patients with rapid symptom onset, neurological signs, pituitary dysfunction, and atypical imaging features. Surgical decompression may provide rapid symptom relief and enable diagnosis. Lung cancer metastases and hematological malignancies were the most frequent non-pituitary sellar lesions in this 20-year single-centre cohort.

[1]Endocrinology, Policlinico Agostino Gemelli, Roma Capitale, Italy; [2]Neurosurgery, Policlinico Agostino Gemelli, Roma, Italy; [3]Neurosurgery, Ospedale Santo Spirito, Pescara, Italy; [4]Radiology, Policlinico Agostino Gemelli, Roma, Italy; [5]Radiotherapy, Policlinico Agostino Gemelli, Roma Capitale, Italy; [6]ORL, Policlinico Agostino Gemelli, Roma, Italy; [7]Mater Olbiae, Olbia, Italy

Background: Craniopharyngioma is a rare tumor of the sellar region that causes significant clinical effects due to its proximity to critical structures such as the hypothalamus.

Patients and Methods: Data of 68 patients, followed at our center between 2003 and 2025, were retrospectively reviewed. Endocrine, cognitive, and metabolic outcomes were assessed pre- and postoperatively. The extent of resection and tumor location were evaluated by a dedicated neuroradiologist. Univariable and multivariable logistic regression identified predictors of residual tumor and recurrence/progression. Survival was assessed via Kaplan–Meier analysis.

Results: We included 22 papillary craniopharyngiomas (CPs) (13 females; 9 males) with a mean age of 52.3 years (18-82) and 46 adamantinomatous craniopharyngiomas (CAs) (18 females; 28 males) with a mean age of 46.3 years (5-74). Preoperatively, hypopituitarism, diabetes insipidus (DI), obesity, and cognitive deficits were present in 31.8%, 12.1%, 24.2% and 39.4% of patients, respectively. Surgery mostly required a transsphenoidal endoscopic approach (EEA) (45.5% CPs; 50% CAs). Gross total resection (GTR) was achieved in 47% of cases. Residual tumor occurred in 53% of patients and was strongly associated with hypothalamic infiltration (71.9% vs 33.3%, $P = .007$), pituitary stalk resection (92.9% vs 42.2%, $P = .004$), and surgical approach ($P = .039$), with EEA showing the strongest association with GTR. Papillary histotype was the only independent predictor of lower residual tumor risk (OR 0.205, $P = .019$). Surgical complications were rare, mainly hydrocephalus (CPs 2; CAs 3). Postoperatively, hypopituitarism affected 79.6%, permanent DI 54.7%, and obesity 42.2% of patients; cognitive deficits were present in 10.6%. During a mean follow-up of 62 months, recurrence/progression occurred in 40% of patients. Residual tumor ($P = .026$), surgical approach ($P = .013$), and tumor location ($P = .014$) significantly predicted progression/recurrence. Recurrence after GTR occurred earlier (mean 6.5 months), whereas progression of residuals occurred later (16.5 months) but required reoperation more frequently (72%). No variable independently predicted recurrence/progression. Seven patients (10.8%) died during follow-up, including three perioperative deaths. Mortality was strongly associated with hypothalamic infiltration ($P = .018$), postoperative cognitive deficits ($P = .003$), complications ($P < .001$), and surgical approach ($P = .002$). Survival analysis showed significantly reduced survival with non-total resection ($P < .001$), pituitary stalk preservation ($P < .001$), and non-EEA approaches ($P < .001$).

Conclusions: Tumor–hypothalamus relationship is the strongest determinant of surgical radicality, postoperative morbidity, and long-term survival. EEA offers superior resection rates and lower complication rates.

[1]CI Parhon National Institute of Endocrinology, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Introduction: Giant prolactinomas are pituitary adenomas with ≥ 4 cm in at least one diameter, usually associated with very high prolactin (PRL) levels, extrasellar extension and lower response rate to treatment.

Objective: To compare the clinical characteristics and treatment response in patients with giant prolactinomas (gPRM) vs those with macroprolactinomas (mPRM) with a maximal diameter of 1- 3.9 cm from a single center of Endocrinology.

Patients and Methods: A retrospective file review identified 66 patients, of which 33 patients with gPRM M:F = 2.3:1, median age at diagnosis 37 years (16-67) and 33 patients with mPRM M:F = 1.2:1 ($P = .04$), median age at diagnosis 38 years (13-82), P = NS.

Results: In gPRM median PRL level at diagnosis was 2509.7 ng/mL (>200 up to 31 398 ng/mL) compared to , 418.74 ng/mL (133.6 up to 11430 ng/mL), $P < .01$ in mPRM, while median of the largest tumor diameter was 5 cm (4-8.6 cm) compared to 2.1 cm (1-3.7 cm), $P < .001$. Neuro-optic abnormalities were recorded in 87.9% of gPRM and 30.3% of mPRM ($P < .001$). Pituitary insufficiency affecting at least one hormonal axis (TSH, ACTH or GH) at diagnosis was found in 72.7% of gPRM and 30.3% of mPRM ($P = .001$), global pituitary insufficiency was 21.2% in gPRM and 3% in mPRM ($P = .05$). All patients received Cabergoline (CBG) treatment. Mean initial dose of CBG was 2.1 mg/week in gPRM and 1.6 mg/week in mPRM ($P = .03$), mean maximal CBG dose was 3.5 mg/week in gPRM and 2.7 mg/week in mPRM ($P = .01$). Surgery was used in 54.5% gPRM and 18.2% mPRM ($P = .002$) (none cured after surgery), radiotherapy (RT) was used in 30.3% gPRM vs 9.1% mPRM ($P = .03$), prior Bromocriptine treatment was administered in 33.3% patients in each group. Initial PRL resistance to DA was noted in 6 gPRM (18.1%) and 7 mPRM (21.2%). RT improved the response to CAB in resistant patients in 4 gPRM and in 1 mPRM. At the last evaluation, 2 gPRM (6%) and 4 mPRM are cured (12%). From gPRM only 1 patient was not controlled after complex treatment.

Conclusions: Giant prolactinomas had higher levels of PRL and increased prevalence of hypopituitarism compared to mPRM; however, gPRM demonstrated good response to first-line dopamine agonists even in patients with optic chiasm syndrome, in a similar proportion with mPRM. Radiotherapy improved the response to dopamin agonists in resistant cases in both gPRM and mPRM. Extremely large and invasive tumors are more difficult to control overall.

P301 - ECE_2849 - "Head-to-head" lncRNAs and non-canonical DNA structures in the regulation of lineage-determining transcription factors, Foxl2 and Nr5a1

Philippa Melamed[1], Hadas Gruber[1], Gil Golan[1], Lilach Pnueli[1] and Sally Camper[2]

[1]Haifa, Israel; [2]Department of Human Genetics at the University of Michigan Medical School, Ann Arbor, United States

The gonadotrope lineage-determining transcription factors (TFs) FOXL2 and NR5A1 are essential for pituitary development and reproductive function. Pathways reported to govern their transcription in the gonads are not active in the pituitary gonadotropes, and their regulation in these cells remains poorly understood. Both protein-coding genes are located "head-to-head" with sequences transcribed divergently to long non-coding RNAs (lncRNAs). This organization is highly conserved across species for *FOXL2*, but less so for *NR5A1*. The *FOXL2*-associated lncRNAs, *FOXL2NB* in human and *Foxl2os* in mouse, are expressed in a cell-type-specific manner and show correlated expression with *FOXL2* mRNA in the human fetal pituitary and during murine postnatal gonadotrope differentiation, as well as in gonadotrope cells under various experimental conditions. Although the *Nr5a1*-associated *Nr5a1os* lacks a clear human orthologue, its expression in mouse gonadotropes is similarly coordinated with *Nr5a1* during postnatal pituitary development and in experimental cells. We therefore hypothesized that these lncRNAs might play a role in regulating their adjacent protein-coding gene or, perhaps, arise merely as by-products of divergent RNA polymerase II activity.

We examined first the polyA-tailing and subcellular localization of these lncRNAs. *Foxl2os*, but not *Nr5a1os*, was found to be chromatin-associated and not-polyadenylated, consistent with a possible *cis*-regulatory function. Moreover, functional depletion of *Foxl2os*, using RNase H-dependent antisense oligonucleotides, reduced *Foxl2* mRNA levels significantly. In contrast, knockdown of *Nr5a1os* resulted in a slower response, with reduction in *Nr5a1* expression as well as H3K4me3 at the promoter, suggesting a role in maintaining an active chromatin state. To explore further the role of *Foxl2os*, we performed **T**argeted **R**NA-directed **E**xtraction of crosslinked proteins (TREX) coupled with mass spectrometry, which identified 18 proteins associated significantly with this lncRNA, including factors involved in chromatin remodeling, transcriptional elongation, and mRNA processing.

The divergent promoter regions at both *loci* contain sequences predicted to form non-canonical G-quadruplex (G4) structures. Pharmacological stabilization of G4s with pyridostatin or their targeted resolution by DHX36, a G4-specific helicase targeted by dCas9 and gRNAs, shifted the balance between the two divergent transcripts. Most notably, G4-stabilization increased *Foxl2os* while reducing *Foxl2* mRNA levels, and its unwinding favored transcription of *Foxl2* mRNA.

These findings reveal that promoter G4 structures can affect transcriptional direction, and demonstrate that, although these lncRNA facilitate expression of their neighboring genes, their expression is not inevitably linked. Our study thus exposes novel components of the regulatory organization of the *Foxl2* and *Nr5a1* genomic loci relevant for other similarly organized lncRNA-gene pairs.

Giuseppe Lembo[3], Andrea Isidori[2,5], Alessandro Landolfi[3] and Marie-Lise Jaffrain-Rea[1,4]
[1]Neuroendocrinology, Neuromed IRCCS, Pozzilli, Italy; [2]Department of Experimental Medicine, Sapienza University, Rome, Italy; [3]Cardiology, Neuromed IRCCS, Pozzilli, Italy; [4]Department of Biotechnological and Applied Clinical Sciences, University of L'Aquila, L'Aquila, Italy; [5]Policlinico Umberto I, Centre for Rare Diseases, Rome, Italy

Background: Concerns about cabergoline (CAB)–associated valvular disease in prolactinoma patients have generally been mitigated by reassuring data. However, most studies included a majority of young women with microprolactinomas. Men are generally older, more frequently affected by macroprolactinomas and often requiring higher weekly CAB dose, potentially increasing cardiovascular risk, but this issue has been poorly addressed.

Objective: To assess the cardiac safety of long-term CAB therapy in men with macroprolactinomas.

Methods: A real-life, longitudinal, single-center observational study including 35 male patients referred for treatment of macroprolactinoma between January 2005 and July 2021. Clinical, biochemical, and echocardiographic data were prospectively collected for up to 18 years. Quantitative cardiac parameters were retrieved from ecochardiography performed by a single observer (AN). Cumulative CAB exposure was calculated over time and cardiac findings were analyzed according to CAB dose, treatment duration, and additional risk factors.

Results: Median age at diagnosis was 43 (IQR 30-54) and median follow-up was 122 months (87-170). Median baseline PRL and maximal tumor diameter were 2347 ng/mL (159-82 300) and 25.0 mm (13.8-58.4), respectively. CAB was the first-line treatment in 94.3% of cases, only two patients undergoing first-line surgery. At diagnosis, no patient had relevant valvular disease, but 4 (all over 60 years old) had mild mitral or aortic sclerosis. The weekly CAB dose (CABw) was titrated according to PRL response, seven patients (20%) showing partial resistance (CABw >2 mg). In responsive patients, PRL normalization was achieved with a median CABw of 1.0 mg (0.5-1.5), after a median time of 8.5 months and an overall median CAB exposure of 27.7 mg (12-67). At last follow-up, median CABw was 0.75 mg (0.5-1.0) and overall CAB exposure was 390 mg (279-713). Clinically relevant valvular regurgitation was found at last follow-up in 3 patients (8.6%) (2 aortic, 1 mitral), regardless of CABw, cumulative CAB exposure and treatment duration. In contrast, an increase in the prevalence of aortic ($n = 8$) and/or mitral ($n = 3$) sclerosis was observed, age at diagnosis being the only independent predictor (OR 1.137 per year; $P = .005$). All cases of clinically relevant regurgitation occurred in patients with valvular sclerosis at baseline or during follow-up.

Conclusions: These data suggest that long-term CAB therapy is not significantly associated with clinically relevant valve regurgitations in men with macroproactinoma. Valvular sclerosis may develop in relation with age rather than CAB regimen. Thus, regular echocardiographic monitoring remains indicated, especially in older patients or in the presence of preexisting valvular alterations.

Background: Acromegaly is frequently associated with disturbances in calcium–phosphate metabolism, including mild hypercalcemia. These biochemical changes complicate the assessment of parathyroid function in a clinical context where the prevalence of primary hyperparathyroidism (PHPT) is increased among patients with acromegaly (approximately 6·0%). Although the coexistence of acromegaly and PHPT may occur as part of multiple endocrine neoplasia, most reported cases arise in individuals without identifiable pathogenic variants in *MEN1* or other predisposing genes. We aimed to refine the diagnosis of PHPT in acromegaly by integrating serum calcium, phosphate, and PTH concentrations into a classification model.

Methods: We conducted a retrospective diagnostic study (CEEI/IRB00003888) at two university hospitals in France. Adult patients with acromegaly evaluated between January 2013 and December 2024 were included. Eligible patients had at least one serum calcium measurement obtained while acromegaly was biochemically uncontrolled. Patients with isolated acromegaly were compared cross-sectionally with those diagnosed with PHPT. Diagnostic models were developed using support vector machine (SVM) algorithms.

Findings: A total of 396 patients with acromegaly were included, of whom 212 (54%) were women. Median age at evaluation was 43.5 years [IQR 33-55], and median IGF-I concentration was 467 ng/mL [IQR 322-655]. Isolated acromegaly was present in 372 patients (93·9%); among these, hyperphosphatemia occurred in 138 (37·1%) and mild hypercalcemia in 12 (3·2%), all of which resolved following effective treatment of acromegaly. Twenty-four patients (6·1%) had acromegaly with PHPT. All but one exhibited mild hypercalcemia (median serum calcium 2·72 mmol/L [IQR 2.66-2.86]) with elevated PTH concentrations, and low-to-normal serum phosphate. No pathogenic

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

variants in *MEN1* or other tested genes were identified. Eleven patients underwent less-than-subtotal or subtotal parathyroidectomy, with normalization of serum calcium concentrations in all cases. A SVM-derived model incorporating serum calcium, phosphate, and PTH correctly classified 220 of 221 patients with complete data (99·5%; 95% CI 98.7-100). A simplified model including calcium and phosphate correctly classified 384 of 386 patients with available measurements (99·5%; 95% CI 98.8-100), with no difference in diagnostic performance between models.

Interpretation: These findings offer a practical and readily applicable diagnostic tool to refine the biochemical evaluation of hypercalcemia in acromegaly. By distinguishing IGF-I–mediated alterations in mineral metabolism from true PHPT, this approach may help avoid unnecessary parathyroid surgery and inappropriate genetic testing in patients with isolated acromegaly, while ensuring timely and appropriate referral for specialized surgical management in patients with PHPT, in whom multiglandular involvement is frequent.

Introduction: Pituitary adenomas are common intracranial tumors, clinically affecting 1:1000 individuals and most cases remain genetically unexplained. Emerging research has highlighted the major contribution of germline pathogenic variants to tumorigenesis across many tissue types in young subjects. We investigated whether young-onset (<30 years old) pituitary macroadenomas that were negative for known genetic causes harbor pathogenic or likely pathogenic (P/LP) variants in a panel of >200 cancer-risk genes.

Methods: We retrospectively analyzed 60 subjects (36 males; 95% GH- or PRL-secreting) with sporadic pituitary macroadenomas that were negative for known germline variants (*AIP, MEN1, CDKN1B*) or duplications (*GPR101*). Whole-exome sequencing (WES) was performed on germline DNA. Bioinformatics analysis including variant calling (for small variants and CNVs), annotation and variant prioritization were performed, using secondary analysis pipelines for WES data and a certified diagnostics predictor platform (AION) for tertiary analysis. Variants in established cancer-risk genes were prioritized.

Results: P/LP germline variants in 22 different cancer-risk genes were identified in 16.7% of subjects on ClinVar/ACMG criteria. This rose to 35.0% of subject with deleterious variants when additional *in silico* and AION predictor criteria were included.

Conclusions: Our findings expand the spectrum of genes potentially associated with young-onset pituitary macroadenomas. The identification of a high rate of deleterious germline variants in cancer-risk genes in pituitary adenomas echoes similar findings in young patients across a wide range of tumors affecting other organs. These results may have relevance for genetic counseling and potentially could expand targeted management strategies in young patients with large pituitary tumors.

P306 - ECE_1924 - Impact of osilodrostat on health-related quality of life in Cushing's disease: analysis of patient-reported outcomes from the Phase III LINC 3 and LINC 4 studies

John Newell-Price[1], Beverly M.K. Biller[2], Maria Fleseriu[3], Beatrice Gueron[4], Grzegorz Binowski[5], Anna Packowska[5] and Mônica Gadelha[6]

[1]The School of Medicine and Population Health, University of Sheffield, Sheffield, United Kingdom; [2]Massachusetts General Hospital, Neuroendocrine and Pituitary Tumor Clinical Center, Boston, MA, United States; [3]Pituitary Center, Departments of Medicine and Neurological Surgery, Oregon Health & Science University, Portland, OR, United States; [4]Recordati Rare Diseases, Puteaux, France; [5]MAHTA Intl Sp z o o, Warsaw, Poland; [6]Neuroendocrinology Research Center, Endocrinology Section, Medical School and Hospital Universitário Clementino Fraga Filho, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil

Introduction: Cushing's disease (CD) is a rare disorder of cortisol excess with increased morbidity and mortality risk, impacting health-related quality of life (HRQoL). Osilodrostat, an 11β-hydroxylase inhibitor, was well tolerated and effective in CD patients in the LINC 3 (NCT02180217) and LINC 4 (NCT02697734) trials. We report HRQoL outcomes in an exploratory pooled analysis of these two trials.

Methods: LINC 3: 26-week (W) open-label osilodrostat, 8W randomised-withdrawal phase, 14W open-label osilodrostat; LINC 4: 12W double-blind, placebo-controlled period, 36W open-

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

label osilodrostat. Both studies included an optional extension. Mixed-effect models and paired t-tests assessed changes from baseline in Cushing's Quality of Life (CushingQoL), Beck Depression Inventory II (BDI-II) and EuroQol Five Dimensions Five Levels (EQ-5D-5L) total and domain/item scores. Minimal clinically important differences (MCIDs) were changes of: CushingQoL, 10.1 points; BDI-II, 17.5%; ED-5D-5L, 0.037-0.069. Patient data from baseline to W72 were pooled, excluding LINC 4 placebo-arm data. Data are reported as mean change from baseline unless otherwise stated.

Results: 185 patients were included (mean baseline total scores: CushingQoL, 44.0; BDI-II, 15.6; EQ-5D-5L, 0.7). CushingQoL total score significantly increased over time by: W12: 7.72, $n = 154$; W26: 11.45, $n = 160$; W48: 13.36, $n = 152$; W72: 15.32, $n = 128$ (all $P \leq .001$), reaching MCID at W26. All CushingQoL item scores significantly improved from baseline to W72 ($P \leq .05$), with largest changes in bruising, body image and irritability (W72: 0.93, 0.74 and 0.72, respectively; all $P \leq .001$); future worry, bruising and body image were most impaired at baseline. BDI-II total score significantly improved from baseline by: W12: −19.0%, $n = 154$; W26: −34.2%, $n = 160$; W48: −36.0%, $n = 153$; W72: −41.2%, $n = 128$ (all $P \leq .001$), reaching MCID at W12. All BDI-II item scores but one improved over time, with largest absolute changes at W72 in items with greatest burden at baseline (loss of energy, −0.46; sleep changes, −0.59; fatigue, −0.49; all $P \leq .001$). EQ-5D-5L utility score significantly improved from baseline after W26 by: W12: 0.02, $n = 154$; W26: 0.04, $n = 160$; W48: 0.06, $n = 153$; W72: 0.08, $n = 128$ ($P \leq .01$ for W26-72), reaching MCID at W26. Most-improved EQ-5D-5L domains at W72 were pain/discomfort (−0.42), anxiety/depression (−0.35) and mobility (−0.35; all $P \leq .001$); pain/discomfort and anxiety/depression were most impaired at baseline.

Conclusions: Osilodrostat significantly improved HRQoL, with consistent clinically meaningful, long-term improvements across all reported HRQoL instruments. Including LINC 3 placebo data may underestimate treatment effect.

P307 - ECE_1146 - Recurrent pituitary apoplexy: experience from a national registry

Betina Biagetti[1], Esteban Cordero[1], Pedro Iglesias[2], Rosa Camara-Gómez[3], Queralt Asla[4], Almudena Vicente[5], Elena Martinez-Saez[1], Silvana Isabel Sarria Estrada[1], Manel Puig-Domingo[6] and Marta Araujo Castro[7]
[1]Hospital Universitario Vall d'Hebron, Barcelona, Spain; [2]Hospital Puerta de Hierro, Madrid, Spain; [3]Hospital la Fé de Valencia, Valencia, Spain; [4]Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; [5]Hospital UNiversitario de Toledo, Toledo, Spain; [6]Hospital Germans Trias i Pujol, Badalona, Spain; [7]Hospital Universitario Ramón y Cajal., Madrid, Spain

Background and Objective: Pituitary apoplexy (PA) is a neuroendocrine emergency characterized by acute hemorrhage or infarction of a pituitary adenoma. While initial presentation and management are well-documented, data on recurrent PA remain scarce.

Methods: We analyzed 274 patients from the Spanish Pituitary Apoplexy Registry (2010-2023) with complete follow-up data. Recurrent PA was defined as a new acute episode with radiological evidence of new hemorrhage or infarction in a previously affected lesion. A systematic literature review complemented registry findings.

Results: Recurrent PA was identified in 9 patients (3.3%), of which 6 of 214 had non-functioning adenomas (2.8%) and 3 of 60 with functioning adenomas (5.0%). Patients with recurrence had significantly larger tumors (median 35 vs 25 mm, $P = .006$), higher rates of cavernous sinus invasion (77.9% vs 37.3%, $P = .006$), and more frequent prior cabergoline treatment (33.3% vs 6.3%, $P = .020$) compared to non-recurrent cases. Median time to recurrence was 18 months (range 2-108). Literature review identified 11 studies reporting recurrence rates of 2.6-16.7%, with larger series ($n \geq 50$) showing rates of 4-9.6%. All of them had favorable clinical course and recovery.

Conclusions: Recurrent PA is uncommon, affecting only 3% of patients with prior PA. It is associated with larger tumor size, cavernous sinus invasion, and dopamine agonist therapy. The second episodes were not more severe than the initial event, and overall prognosis was favorable. The association between dopamine agonist therapy and recurrence, observed in both prolactinomas and nonfunctioning adenomas, warrants further investigation.

P309 - ECE_2276 - Pituitary metastases: a case series

Jowita Fiszer[1,2], Magdalena Guzek[1,2], Barbara Buchalska[3], Sonia Kaniuka-Jakubowska[1,2], Wiesława Grajkowska[3], Maria Maksymowicz[4], Anna Lewczuk[1,2], Jacek Kunicki[3] and Renata Świątkowska-Stodulska[1,2]
[1]Department of Endocrinology and Internal Medicine, Medical University of Gdansk, Gdańsk, Poland; [2]Department of Endocrinology and Internal Medicine, University Clinical Centre (UCK), Gdańsk, Poland; [3]Department of Neurosurgery, Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw, Poland; [4]Department of Cancer Pathomorphology, Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw, Poland

Background: Pituitary metastases are rare lesions in this region; their exact incidence has not been clearly determined, although it is estimated at approximately 0.5%. However, given the increasing incidence of neoplastic diseases, a gradual rise in the number of diagnoses can be expected.

Purpose: The aim of this study is to present a series of cases of pituitary metastases, with particular emphasis on their clinical manifestations and their relevance in the differential diagnosis of lesions in the pituitary region.

Methodology: The presented case series includes 18 patients: 12 patients were hospitalized in Maria Sklodowska-Curie National Research Institute of Oncology and 6 were hospitalized at the University Clinical Center in Gdańsk between 2008 and 2025. In 4 patients from the University Clinical Center in Gdańsk, the diagnosis was based on clinical and radiological findings, and radiotherapy targeting the pituitary gland and brain was administered; however, no histopathological confirmation of the lesion was obtained.

Results: In 9 patients, the primary malignancy had been previously diagnosed and treated prior to admission, whereas in the remaining cases, the metastasis manifested for the first time as

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

a parasellarmass. The mean age at metastasis diagnosis was 61. The primary origin of pituitary metastases included lung cancer ($n = 7$), breast cancer ($n = 6$), renal cell carcinoma ($n = 1$), prostate carcinoma ($n = 1$), and hepatocellular carcinoma ($n = 1$). In three patients the primary of metastases was not identified. The main clinical symptoms were neurological and visual disturbances. Three patients presented symptoms of diabetes insipidus prior to neurosurgical intervention.

Conclusions: Although pituitary metastases are rare, they should be considered in the differential diagnosis of lesions in this region, particularly in patients with a history of malignancy. Importantly, a pituitary metastases are not a manifestation of end-stage disease—it may also be the first clinical presentation. The analyzed case series only suggest that diabetes insipidus is not an obligatory symptom, and nonspecific neurological complaints often predominate. It should be emphasized that the actual incidence of pituitary metastases may be underestimated, as biopsies in this region are not always performed and therefore the definitive diagnosis is not always established.

Pituitary neuroendocrine tumors (PitNETs), are generally benign neoplasms and encompasse both hormone-secreting and non-functioning lesions. Their marked clinical and biological heterogeneity, together with the limited availability of validated biomarkers, complicates early diagnosis, prognostic evaluation, follow-up strategies, and therapeutic management.

In this study, we performed a comparative proteomic analysis of growth hormone–secreting pituitary adenomas (GH-Pnets), non-functioning pituitary adenomas (NFPnets), and normal pituitary tissue.

Despite inter-patient variability, distinct proteomic differences were consistently observed between GH-Pnets, NFPnets, and controls. Functional annotation of differentially expressed proteins highlighted alterations in pathways related to cell adhesion, glycolytic metabolism, and oxidative stress responses. Notably, a substantial proportion of the identified proteins were associated with mitochondrial function, suggesting dysregulation of cellular energy metabolism and impaired protection against oxidative stress. In detail, SOD enzymes were overexpressed in GH-Pnets as compared to NFPnets.

Overall, our findings provide insight into subtype-specific proteomic features of PitNETs and support the relevance of metabolic and mitochondrial pathways in pituitary tumor biology, potentially offering a basis for the identification of clinically meaningful biomarkers and novel therapeutic targets.

P312 - ECE_3726 - Arginine vasopressin deficiency, is that all?

Emma Capparelli[1], Elisabetta Sciarroni[1], Silvia Canovetti[2], Giulia Marconcini[1], Maurizio Carbonari[1], Alessio Basolo[1], Claudio Urbani[1], Mirco Cosottini[2], Antonio Tavoni[3], Luca Manetti[1], Ferruccio Santini[1] and Isabella Lupi[1]

[1]Department of Clinical and Experimental Medicine, Unit of Endocrinology 1, Pisa University Hospital, Pisa, Italy; [2]Neurordiology Unit, Universitary Hospital of Pisa, Pisa, Italy; [3]Clinical Immunology Unit, Pisa, Italy

Background: Hypophysitis includes a broad range of chronic inflammatory disorders involving the anterior and/or the posterior lobe of the pituitary gland. Neuro-hypophysitis (NH) can manifest clinically with arginin-vasopressin defect (AVP-d) and radiologically with pituitary stalk thickening at MRI. There are primary (autoimmune) forms of NH, where the cause is unknown, and secondary forms, where an initiating event is identifiable. However, MRI or serological findings are not specific and pathology from a stalk lesion is rarely obtained, thus etiology is often not immediately apparent. AVP-d can indeed precede for years diagnosis of systemic infiltrative disease.

Aim of the Study: Determine the prevalence of secondary NH in a cohort of patients with AVP-d.

Patients and Methods: A retrospective review of patients diagnosed with AVP-d and MRI pituitary stalk thickening, from 2008 to 2024, at Pisa Endocrinology Unit, was conducted. Mean follow-up was 8 years (range 1-20). Results Twenty-eight patients were included: 19 females (F), 9 males (M), age at diagnosis 45 + 17 and 38 + 19 years, respectively. Duration of polyuria/polydipsia was less than 12 months in 20 patients (68%) and up to 48 months in 3 (10%). Secondary NH was found in 15 (53%). Five (33%), were diagnosed simultaneously with AVP-d and a systemic disease: 3 IgG4-related disease (mean age 32 years, 2F, 1 M), 2 Erdheim Chester disease (mean age 70 years, 1M, 1F). Ten (67%), were diagnosed during follow-up: 2 F (mean age 70 years) manifested Erdheim-Chester disease, and 7 (5 F, 2 M, mean age 37 years) manifested Langerhans cells histiocytosis. Partial hypopituitarism, mainly hypogonadism, was found in 10 (66%). Overtime, pituitary stalk thickening disappeared in 8 (53%), AVP-d persisted in all. The remaining 13 patients (46%; 8 F, 5 M mean age 43 + 16) did not develop other clinical manifestations thus were diagnosed as primary NH. Partial hypopituitarism, mainly hypogonadism, was found in 5 (38%). Pituitary stalk thickening spontaneously reduced in 8 (62%), AVP-d persisting in all patients except one.

Conclusions: Careful clinical evaluation and prolonged follow-up are needed to establish the etiology of NH. AVP-d is persistent

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

in both primary and secondary NH even when pituitary stalk thickening regresses.

Abstract citation ID: lvag096.464

P314 - ECE_2051 - Crooke's cell corticotroph adenoma or metastatic carcinoma? A different perspective of pitNETs: a case report

Ece Seçgin Demir[1], Nevra Karademir[2], Serhat Özçelik[1], Hande Erman[2], Naile Gokkaya[1], Ziya Mithat Bıyıklı[1], Meryem Özoğlu[1], Müge Yılmaz[1], Senem Boz Aksoy[1], Sevinç Keser[3], Mehmet Tiryaki[4], Özcan Keskin[2] and Kadriye Aydin[1]

[1]Department of Endocrinology and Metabolism, Kartal Dr. Lütfi Kırdar City Hospital, İstanbul, Türkiye; [2]Department of Internal Medicine, Kartal Dr. Lütfi Kırdar City Hospital, İstanbul, Türkiye; [3]Department of Pathology, Kartal Dr. Lütfi Kırdar City Hospital, İstanbul, Türkiye; [4]Department of Neurosurgery, Kartal Dr. Lütfi Kırdar City Hospital, İstanbul, Türkiye

Objective: Crooke's cell adenomas (CCA)/pitNETs (pituitary neuroendocrine tumours) are very rare and aggressive forms of corticotroph pitNETs causing Cushing's disease. They are associated with a low response to surgery and/or radiotherapy, but they rarely metastasize. Given the rarity of Crooke cell pitNETs, we aimed to present a case with a crooke cell pathology in pituitary surgery, who was observed to have a devastating clinical features and distant organ metastasis.

Results: A 60-year-old female patient with a history of pituitary surgery and a Cushingoid appearance was found to have a pitNET and laborotary results consistent with Cushing's disease. There is no evidence for distant organ metastasis in FDG PET-CT imaging. The patient, whose initial surgical pathology was a Crooke's cell adenoma/pitNET, underwent a second transsphenoidal surgery. As remission could not be achieved, another surgery was recommended, but the patient declined. The patient underwent stereotactic radiotherapy with a CyberKnife device at 30 Gy in 5 fractions. As remission was still not achieved, cabergoline, ketoconazole, and metyrapone treatments were initiated, but due to side effects, all treatments except metyrapone were discontinued. A decision was made to perform bilateral adrenalectomy. Preoperative CT and FDG PET-CT images revealed lesions consistent with metastasis in the liver, the biopsy result from the suspected metastatic lesions in the liver was consistent with tumor infiltration containing ACTH-positive neuroendocrine features. The patient declined further investigation and discontinued follow-up at our center.

Conclusions: Although Crooke's cell pitNETs are rare, they are aggressive. Treatment response may not be achieved after repeated surgeries and/or radiotherapy, or the disease may recur. As far as we know, less than 10 cases of CCA with distant organ metastasis have been described in the literature. The time to metastasis has been observed to be defined in years. In our case, liver metastases was observed 18 months after the first operation, and two FDG PET-CT scans taken 9 months apart revealed that a lesion that could be described as an adenoma 9 months earlier had transformed into metastatic carcinoma. We are introducing our case of aggressive Crooke's cell pitNET, which metastasized quite rapidly, to the literature.

Keywords Crooke's cell pitNET, Cushing disease, liver metastasis

P315 - ECE_2127 - Hypertonic saline test induces significant electrolytic alterations

Michela Sibilla[1], Nunzia Prencipe[1], Emanuele Varaldo[1], Iulia Petria[2], Gianluca Aimaretti[1], Silvia Grottoli[1], Giovanna Mantovani[2], Emanuele Ferrante[3], Valentina Gasco[1] and Alessandro Maria Berton[1]

[1]Division of Endocrinology, Diabetology and Metabolism, Medical Sciences Department, University of Turin, Turin, Italy; [2]Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico; Department of Clinical Sciences and Community Health, Dipartimento di Eccellenza 2023-2027, University of Milan, Milan, Italy; [3]Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy

Background: The hypertonic saline test (HST) is the new gold standard for the differential diagnosis of polyuria–polydipsia syndrome (PPS), strongly stimulating AVP secretion by increasing plasma osmolality (p-Osm). Transient hyperkalemia has been reported during HST, possibly due to an osmotic drive ("solvent drag") in Na/K balance or to hypertonic saline-induced hypercloremic metabolic acidosis that causes a shift of K from the *intra* to the *extra* cellular fluid. Other electrolytic alterations, however, have not been assessed. The aim of this study was therefore to describe possible electrolytic alterations occurring during HST.

Methods: Thirty-nine patients (28 F; age 38 [31-53] years; BMI 23.4 [21.8-26.1] Kg/m^2) with PPS ($n = 24$) or a previous diagnosis of AVP-deficiency (AVP-D, $n = 15$) underwent HST between 12/2023 and 12/2025 at two tertiary centers in Northern-Italy. Serum Na, K, Ca, glucose, copeptin, p-Osm and pH levels were measured at baseline and upon achieving hypernatremia (Na >149 mmol/L) via 3% saline bolus (250 mL at 500 mL/h) followed by continuous infusion (9 mL/Kg/h).

Results: As expected, HST induced significant increases in Na (140 [138-143] vs 150 [150-152] mmol/L, $P < .0001$), p-Osm (284 [281-289] vs 305 [298-318] mOsm/Kg, $P < .0001$) and copeptin concentrations (2.2 [1.7-2.9] vs 9.9 [2.8-26.4] pmol/L, $P < .001$). Glucose levels remained unchanged. K levels significantly increased (3.9 [3.8-4.0] vs 4.4 [4.1-4.6] mmol/L, $P < .001$) and two cases of hyperkalemia were observed (K = 6.1 and 5.7 mmol/L). Ca levels decreased significantly, both by blood gas analysis (1.22 [1.16-1.24] vs 1.14 [1.11-1.16] mmol/L, $P < .001$) and in the subset with total serum Ca measured (2.31 [2.22-2.33] vs 1.95 [1.92-2.01] mmol/L, $P = .028$), all developing mild to moderate hypocalcemia by the end of the test. Notably, pH levels remained stable (7.38 [7.34-7.39] vs 7.35 [7.33-7.36], $P = .127$).

Conclusions: This study demonstrates, in addition to the expected increase in K, also a significant decrease in Ca. This likely reflects increased urinary Ca excretion, as hypercalciuria commonly follows NaCl-induced natriuresis. Although modest, these changes underscore the importance of assessing baseline electrolyte status before HST. Additionally, ECG monitoring should be considered following the procedure in cases where significant electrolyte disturbances occur in response to HST.

P316 - ECE_2696 - Elevated risk of hip fractures in patients with Cushing's syndrome

Hiba Masri Iraqi[1], Yaron Rudman[1], Tzipora Shochat[2], Shiri Kushnir[3], Keren Kaminer[1], Idit Dotan[1], Gloria Tsvetov[1], Ilan Shimon[1], Maria Fleseriu[4] and Amit Akirov[1]

[1]Institute of Endocrinology, Beilinson Hospital, Rabin Medical Center, Petah Tiqva, Israel; [2]Biostatistics Unit, Rabin Medical Center, Beilinson Hospital, Petah-Tiqva, Israel; [3]Research Authority, Rabin Medical Center, Beilinson Hospital, Petah-Tiqva, Israel; [4]Pituitary Center, Departments of Medicine and Neurological Surgery, Oregon Health & Science University, Portland, OR, United States

Background: Glucocorticoid-induced osteoporosis is a common complication of Cushing's syndrome (CS). While the increased risk for vertebral fractures is well-established, evidence regarding hip fracture risk are limited. This study investigates the association between endogenous CS and hip fracture risk and examines the effect of remission on this risk.

Methods: A nationwide retrospective matched-cohort study was conducted using the Clalit Health Services database in Israel, including patients diagnosed with endogenous CS between 2000 and 2023. Patients with CS were matched 1:5 with controls based on age, sex, socioeconomic status, and body mass index. The primary outcome was the first diagnosis of hip fractures following the diagnosis of CS. Patients with a history of hip fractures prior to CS diagnosis were excluded.

Results: The study included 606 patients with CS and 2988 matched controls, with a mean age at diagnosis of 47.8 ± 17.14 years; 65.3% were female. Follow-up durations were 13.2 ± 6.1 years for patients with CS and 13.1 ± 6.2 years for controls. The risk of hip fracture was significantly higher in patients with CS compared to controls (3.9% vs 2.5%, HR 1.54, 95% CI 1.0-2.5). The risk was significantly elevated among patients with a pituitary source of CS (HR 2.2, 95% CI 1.0-4.7) but not in those with an adrenal source (HR 1.3, 95% CI 0.6-2.8). Analysis by remission status showed that hip fractures occurred in 4.4% of patients without remission and 3.6% of those in remission, with no significant difference between groups (HR 1.1, 95% CI 0.4-3.0).

Conclusions: Patients with CS, especially those with Cushing's disease, have an increased risk of hip fractures.

P317 - ECE_2868 - Arginine vasopressin deficiency—a single center retrospective analysis from the endocrinological perspective

Mustafa Berkay Tastekin[1], Burcin Gonul Iremli[2], Selin Tekin[2], Suleyman Nahit Sendur[2], Seda Hanife Oguz[2], E. Nazlı Gönç[3], Rahşan Göçmen[4], Figen Söylemezoğlu[5], Selcuk Dagdelen[2] and Tomris Erbaş[2]

[1]Internal Medicine, Hacettepe University School of Medicine, Ankara, Türkiye; [2]Department of Internal Medicine, Division of Endocrinology & Metabolism, Hacettepe University School of Medicine, Ankara, Türkiye; [3]Department of Pediatrics, Division of Pediatric Endocrinology, Hacettepe University School of Medicine, Ankara, Türkiye; [4]Department of Radiology, Hacettepe University School of Medicine, Ankara, Türkiye; [5]Department of Pathology, Hacettepe University School of Medicine, Ankara, Türkiye

Background: Arginine vasopressin deficiency (AVP-D) is a rare hypothalamus and/or posterior pituitary disorder due to deficient AVP secretion, causing hypotonic polyuria and polydipsia. The aim of this study is to describe the distinctive characteristics of the various etiologies of AVP-D from a single center.

Methods: We retrospectively reviewed 181 patients with confirmed AVP-D who followed up at the Hacettepe Medical School, between 1980 and 2024. Demographic data, symptoms, hormonal profile, imaging findings, treatment response and prognosis were retrieved. The study was approved by Ethics Committee.

Results: The cohort included 181 patients (104 F/ 77 M) with a median age at diagnosis of 22 (12.0-37.5) years and a median follow-up of 9 years (3-18). The average duration from the onset of symptoms to diagnosis was one year (79%). In 8.8% of the patients, the diagnostic delay was longer than 4 years. In the cohort, 36 diseases causing AVP-D were divided into 7 etiological groups. The most common etiologies were CNS neoplasia (24.3%, $n = 44$), consequence of neurosurgery (19.9%, $n = 36$) and histiocytosis—Langerhans cell histiocytosis and Erdheim Chester disease—(18.8%, $n = 34$). Other causes of AVP-D included idiopathic (16.0%, $n = 29$), hereditary (8.3%, $n = 15$) and autoimmune (7.2%, $n = 13$). Head trauma, radiotherapy and apoplexy was observed in 5.5% ($n = 10$) of cases. Hypopituitarism were identified in 71.3% ($n = 129$) of patients; 55.2% had GH deficiency, 49.2% secondary hypothyroidism, 45.9% hypogonadotropic hypogonadism, 39.8% secondary hypocortisolism and 12.2% hypoprolactinemia. At the time of diagnosis, 37.1% of the patients had hypernatremia, there was no significant difference between the groups. Thirteen patients had sodium levels above 150 meq/L. Diabetes mellitus was initially considered in 11 patients (6.1%) due to symptoms of polyuria and polydipsia. Significant differences were found between etiology groups in terms of pituitary gland size, infundibulum thickening, and optic tract involvement ($P < .001$, $<.001$ and $<.02$, respectively). In MRI, bright spots, which are not expected to be seen in AVP-D, were found in 17% in patients. Forty one patients who underwent water restriction testing, 7 (17%) of them had bright spots. There was no significant difference in the presence of bright spots between the first and last MRI during the follow-up. No difference in desmopressin dose was observed between the groups.

In summary, maintaining a wide differential diagnosis is critical when assessing AVP-D to avoid overlooking rare causes. Our study highlights that identifying the underlying cause and assessing for concurrent pituitary deficiencies are essential when managing patients with AVP-D.

Background: The diagnosis of polycystic ovary syndrome (PCOS) is controversial, historically based on common features in selected populations. Advanced analytics offers opportunities to cluster features to better define PCOS. The main objective of this study was to explore what features clearly differentiated PCOS from controls and clustering criteria thresholds using the PCOS Phenotype in Unselected Populations (P-PUP) dataset.

Methods: The study was conducted in an internationally diverse, well-characterized, and harmonized cohort from unselected populations. Unsupervised k-means cluster analysis (k = 3) was conducted using robustly selected clinical features, including body mass index (BMI), modified Ferriman-Gallwey (mFG) score, androgen measures (total testosterone [TT], free androgen index [FAI], and dehydroepiandrosterone sulfate [DHEAS]), menstrual characteristics (menstrual cycle length in days and menstrual cycle per year), antral follicle counts, lipid profiles (total cholesterol, high density lipoprotein, and triglyceride), and systolic and diastolic blood pressure. We characterized the distribution of clinical features within the clusters to differentiate groups.

Results: This analysis included 1651 reproductive-aged women. Considering the entire population together, we were able to generate three distinct clusters: the hyperandrogenic cluster (34.2%), including women with higher mFG score, TT, FAI, androstenedione, and ovarian volume, the metabolic cluster (32.1%) with higher age, BMI, waist circumference, insulin, and blood pressure, and the healthier cluster (33.7%) having higher SHBG levels coupled with lower BMI and waist circumference. The hyperandrogenic and metabolic clusters encompassed 87.2% of PCOS women diagnosed with PCOS, but did not clearly distinguish cases from controls in population-based analysis.

Conclusions: The P-PUP study, utilizing an ethnically diverse unselected population, identified three clusters in the general population, but did not clearly distinguish cases from controls. These findings highlight the challenge of clustering on clinical and biochemical features alone in PCOS and more broadly, such as in type 2 diabetes mellitus. This indicates the need to integrate clustering with genetic markers, undertake predictive and longitudinal modelling, and consider alternative personalised medicine approaches, such as risk prediction, to advance clinical utility.

P321- ECE_1361 - Reduced circulating and skeletal muscle MOTS-c expression in women with polycystic ovary syndrome: evidence for disrupted mitochondrial-derived peptide regulation

Irem Sonmezoglu Kutuk[1], Senay Akın[2], Ali Haydar Demirel[3], Sezcan Mumusoglu[4], Turkmen Turan Ciftci[5] and Bulent Yildiz[6]

[1]Department of Internal Medicine, Hacettepe University Faculty of Medicine, Ankara, Türkiye; [2]Division of Exercise and Sport Physiology, Hacettepe University Faculty of Sport Sciences, Ankara, Türkiye; [3]Center for Sport Sciences, Near East University, Nikosia, Cyprus; [4]Department of Obstetrics and Gynecology, Hacettepe University Faculty of Medicine, Ankara, Türkiye; [5]Department of Radiology, Hacettepe University Faculty of Medicine, Ankara, Türkiye; [6]Division of Endocrinology and Metabolism, Hacettepe University Faculty of Medicine, Ankara, Türkiye

Background: Polycystic ovary syndrome (PCOS) is characterized by insulin resistance and metabolic dysfunction, Mitochondrial-derived peptides (MDPs), specifically MOTS-c, have recently been identified as potent regulators of glucose homeostasis and skeletal muscle metabolism. Whether MOTS-c expression is altered in PCOS across different physiological compartments is unknown.

Objective: To assess circulating and skeletal muscle MOTS-c levels in women with PCOS and to examine their associations with metabolic and hormonal parameters.

Methods: Forty women with PCOS and 40 age- and BMI-matched healthy controls underwent detailed clinical, biochemical, and hormonal phenotyping. Serum MOTS-c concentrations were quantified by ELISA. In a representative subgroup, skeletal muscle MOTS-c expression was determined from vastus lateralis biopsy specimens using Western blotting.

Results: Women with PCOS exhibited lower circulating MOTS-c concentrations compared with controls (220.2 ± 147.6 pg/mL vs 498.3 ± 224.4 pg/mL, $P < .001$). Skeletal muscle MOTS-c expression was also reduced in the PCOS group (74.2 ± 15.2 vs 100.0 ± 8.5 arbitrary units; $P = .005$). Serum MOTS-c levels were inversely associated with total testosterone ($r = -0.224$, $P = .046$) and total cholesterol ($r = -0.228$, $P = .044$), with additional inverse trends observed for 2-hour insulin during oral glucose tolerance testing, triglycerides, and LDL cholesterol.

Conclusions: Women with PCOS display reduced MOTS-c expression in both the circulation and skeletal muscle, indicating impaired availability of this mitochondrial-derived peptide. The associations with hyperandrogenism and lipid profiles suggest a link between altered mitochondrial peptide biology and the endocrine–metabolic phenotype of PCOS. These findings identify MOTS-c as a novel marker of tissue-specific mitochondrial involvement in PCOS and warrant further mechanistic and therapeutic exploration.

P322 - ECE_3313 - The gonadotrophin response to kisspeptin administration reveals hypothalamic dysfunction in obesity-related hypogonadism in men

Kanyada Koysombat[1,2], Patrick McGown[1,2], Arthur Yeung[1], Agathoklis Efthymiadis[1,2], Sandhi Nyunt[1,2], Maria Phylactou[1,2], Megan Young[1], Bijal Patel[1,2], Elisabeth Daniels[1,2], Aureliane Pierret[1,2], Aaran Patel[1,2], Jovanna Tsoutsouki[1,2], Margarita Solodovnikoff[1], Folakemi Olujimi[1], Edouard G Mills[1,2], Anna Kowalka[1], Chioma Izzi-Engbeaya[1,2], Tricia Tan[1,2], Alexander Comninos[1,2], Ali Abbara[1,2] and Waljit Dhillo[1,2]
[1]*London, United Kingdom;* [2]*Department of Endocrinology, Imperial College Healthcare NHS Trust, London, United Kingdom*

Background: Male obesity-related secondary hypogonadism (MOSH) affects over half of men with BMI ≥ 40 kg/m^2, exacerbating morbidity and mortality. Animal models suggest decreased hypothalamic function in obesity-related hypogonadism. Kisspeptin enables direct examination of hypothalamic dysfunction in men with obesity.

Methods: We enrolled men with obesity (BMI ≥ 30 kg/m^2, $n = 35$), and healthy eugonadal men without obesity ($n = 97$). Men with obesity with symptoms of hypogonadism and fasting free testosterone ≤0.22 nmol/L were subcategorised as MOSH ($n = 7$). Endocrine profiling included LH-pulsatility assessment (10-minutely sampling for 8 hrs), responses to intravenous bolus of kisspeptin and GnRH to interrogate hypothalamic and pituitary function, respectively. Hormone concentrations were compared using Kruskal-Wallis test, and temporal endocrine profiles using mixed-effects models.

Results: Men with MOSH had higher BMI than age-matched eugonadal men with obesity (BMI 49.0 vs 34.1 kg/m^2). In addition to lower total (5.55 vs 12.93 nmol/L; $P < .0001$) and free testosterone (0.15 vs 0.31 nmol/L; $P < .0001$), men with MOSH had lower DHT 0.43 vs 0.90 nmol/L, AMH 15.0 vs 37.9 pmol/L, inhibin B 81.53 vs 156.30 ng/L (all $P < .0001$); whilst oestradiol was higher 147.3 vs 116.7 pmol/L ($P = .0038$). Total testosterone ($\beta = -.48$), free testosterone ($\beta = -.01$), and dihydrotestosterone ($\beta = -.04$) were inversely associated with BMI ($P < .0001$). Median LH pulse-frequency was increased with obesity: (BMI < 25.0 kg/m^2: 3.00 vs >40 kg/m^2: 5.00) pulses per 8 h ($P = .0004$). LH pulse-amplitude and GnRH responses did not differ. Men with obesity had augmented gonadotrophin response to kisspeptin than controls ($P < .0001$). The maximum LH-response to kisspeptin was delayed in MOSH compared to controls 315 vs 270 mins ($P = .0055$). Whilst the total area-under-the-curve (AUC) of LH rise over 6 hrs after kisspeptin did not differ, the early-phase LH rise over 1 hr was blunted in MOSH (median AUC at 60 mins: MOSH 28.4 vs lean controls 126.4 IU·h/L ($P < .0001$) vs eugonadal men with obesity 89.9 IU·h/L ($P = .0076$).

Conclusions: In contrast to existing reports, our data demonstrated an increase in LH pulse-frequency with obesity rather than a reduction in pulse-amplitude. Men with obesity had an increased response to kisspeptin consistent with decreased endogenous hypothalamic function. Notably, the LH rise after kisspeptin was delayed in men with MOSH resulting in a decreased early phase response. Pituitary responses to GnRH were preserved. Our data provides first evidence that hypothalamic dysfunction plays a key role in the pathophysiology of obesity-related hypogonadism in men.

P323 - ECE_3289 - Comparing dual-energy X-ray absorptiometry and radiofrequency echographic multi-spectrometry for bone mineral density assessment in patients with Turner syndrome: preliminary results of a pilot study

Laura Rotolo[1,2], Matteo Malagrinò[1,2], Carolina Cecchetti[2,3], Paola Dionese[1,2], Elisabetta Belardinelli[1,2], Beatrice Solmi[1,2], Guido Zavatta[1,2], Uberto Pagotto[1,2] and Alessandra Gambineri[1,2]
[1]*Division of Endocrinology and Diabetes Prevention and Care, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy;* [2]*Bologna, Italy;* [3]*Endocrinology Unit, Ospedale Morgagni-Pierantoni, Forlì, Italy*

Background: Turner syndrome (TS) is often characterized by reduced bone mineral density (BMD). Dual-energy X-ray absorptiometry (DXA) is the gold standard method for monitoring BMD in these patients. Nonetheless, its BMD measurement is affected by radiological artefacts and altered bone geometry, frequently found in TS patients. Radiofrequency Ecographic Multi-Spectrometry (REMS) is a new, validated tool to measure BMD without the interference from such radiological artefacts. However, it has not yet been applied to measure BMD in TS patients.

Aim: To compare the diagnostic classification between DXA and REMS in a cohort of TS patients.

Methods: We conducted an exploratory comparison on 34 consecutive adult TS patients (median age: 41 yo; min-max: 24, 5-71,7 yo). All patients underwent lumbar spine and femoral BMD assessment with both DXA and REMS. We classified all patients according to T-score (osteoporosis: T-score ≤ −2,5/osteopenia: T-score −2,5 − −1/normal BMD: T-score ≥ −1), Z-score (low BMD: Z-score ≤ −2/normal BMD: Z-score > −2) and using the appropriate score as per general population guidelines according to age/current hormonal replacement treatment (T-score if considered post-menopausal).

Results: We found a significant correlation between DXA and REMS for T-score at lumbar and total hip sites (R = 0.489; $P = .005$ and R = 0.464; $P = .015$, respectively), while no significant correlation was found for femoral neck T-score or Z-scores of all three sites. According to DXA BMD value, 8 patients (25.8%) were classified as osteoporotic, 13 (41.9%) as osteopenic, 10 (32.3%) with normal BMD. On the other hand, according to REMS 11 (32.4%) patients were classified as osteoporotic, 15 (44.1%) as osteopenic and 8 (23.5%) as normal BMD. Using Z-score, 7 patients (22.6%) had low BMD and 24 (77.4%) patients had normal BMD according to DXA. Using REMS, 6 (17.6%) patients showed low BMD and 28 (82.4%) patients had normal BMD. Using T- or Z-score where appropriate, the overall concordance of their diagnostic classification was 72.7% ($\kappa = 0.372$, $P = 1.000$ between discordant cases). When analysing T-score categories separately,

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

the concordance was lower (61.3%,κ = 0.576), with REMS identifying a higher prevalence of osteopenia or osteoporosis compared to DXA ($P = .010$ between discordant cases).

Conclusions: These preliminary data suggest REMS could be a promising tool for monitoring bone health in patients with TS, potentially overcoming known radiological artefacts affecting BMD measurement by DXA. While REMS showed a tendency towards identifying more cases of reduced BMD, further studies on larger cohorts are needed to validate its accuracy and to identify which patients could benefit from this method.

[1]Hellenic Endocrine Network, Athens, Greece; [2]Department of Endocrinology, KBC Bežanijska kosa, belgrade; [3]Department of Endocrinology, Diabetology and Isotope Therapy, University of Medicine, Wroclaw, Poland; [4]Ushate 'acad. IV. Penchev', Department of Endocrinology, Faculty of Medicine, Medical University, Sofia, Bulgaria; [5]Clinic for Endocrinology, Diabetes and Metabolic Diseases, belgrade; [6]Department of Endocrinology and Diabetes, Hellenic Red Cross Hospital, Athens, Greece; [7]2nd Propaedeutic Department of Internal Medicine, Research Unit and Diabetes Center, Attikon University Hospital, Athens, Greece; [8]Division of Endocrinology, Diabetes and Metabolism, Aretaieion University Hospital, Athens, Greece

Background: Women suffering from PCOS display a variety of metabolic and hormonal abnormalities. Waist to height ratio (WHtR,), is considered as a valuable predictor of cardiovascular risk and central obesity.

Aim of the Study: To assess the association of WHtR with metabolic/hormonal profile in PCOS.

Methods: Data from 2201 PCOS women, mean age 25.0 years (21-29), BMI 24.7 kg/m^2 (21.3-30.80) were analyzed. Participants were classified into three WHtR categories according to the established cut-offs (A: <0.50, B: 0.50-0.59, C: ≥0.60). Findings are presented before and after adjustment for age and BMI.

Results: A gradual statistically significant increase was observed among subgroups regarding HOMA-IR [A: 1.5 (0.9-2.3), B: 2.7 (1.6-4.0), C: 4.2 (2.6-6.3)] and the existence of impaired glucose tolerance (IGT) [A: 7.3%, B: 12.4%, C: 24.0%], (P for trend <.001). The relationship of HOMA-IR with WHtR remained statistically significant ($P < .001$) even after adjustment for age and BMI. These subgroups were also associated with a progressively adverse lipid profile, characterized by higher triglyceride [A: 78 (58-102), B: 89 (67-111), C: 96 (75-142)mg/dl] and LDL cholesterol levels [A: 108 (86-133), B: 114 (94-139), C: 118.0 (98-133)mg/dl] and lower HDL cholesterol concentrations [A: 51(43-61), B: 51 (42-57), C: 45 (40-54)mg/dl], with strong linear trends across WHtR strata. Notably, the associations with triglycerides and HDL cholesterol persisted after adjustment for age and BMI ($P < .001$). Considering, hormonal profile, subgroups based on WHtR categories were associated with a progressive increase in free androgen index (FAI) [A: 4.97 (3.07-7.66), B: 7.49 (4.54-11.11), C: 9.38 (6.00-13.90)] and the prevalence of hirsutism [A: 55.5%, B: 61.8%, C: 69.3%] (P for trend <.001). Total testosterone levels showed a modest, but significant increase across WHtR strata, whereas DHEAS, D4 and 17OP concentrations did not differ significantly. Gonadotropins exhibited an inverse association with WHtR, with lower LH and FSH levels observed in higher WHtR categories, while TSH showed only a weak trend. In multivariate analyses, sugbroups were strongly associated with increased FAI values in a graded manner, and these associations remained statistically significant after adjustment for age and BMI ($P < .001$).

Conclusions: Multivariate analysis showed that WHtR constitutes a solid denominator of insulin resistance, dyslipidemia and hyperandrogenemia even after adjustment of age and BMI. These findings suggest that WHtR captures a distinct aspect of PCOS pathophysiology as it integrates both metabolic and androgenic interaction in PCOS and emerges as a pragmatic anthropometric marker for early metabolic risk stratification in PCOS.

P325 - ECE_3527 - Metabolomic profiling reveals distinct metabolic signatures in women with functional hypothalamic amenorrhoea (FHA) and polycystic ovary syndrome (PCOS)

Sandhi Nyunt[1,2], Thomas Hopkins[3], Adrien Le Guennec[3], Arthur Yeung[1,2], Kanyada Koysombat[1,2], Jovanna Tsoutsouki[1,2], Bijal Patel[1,2], Megan Young[1], Agathoklis Efthymiadis[1,2], Aaran Patel[1,2], Tricia Tan[1,2], Alexander Comninos[1,2], Kim Jonas[3], Ali Abbara[1,2] and Waljit Dhillo[1,2]
[1]Department of Metabolism, Digestion and Reproduction, Imperial College London, London, United Kingdom; [2]Department of Endocrinology, Imperial College Healthcare NHS Trust, London, United Kingdom; [3]Department of Women and Children's Health, Kings College London, School of Life Course and Population Health Sciences, London, United Kingdom; [4]Women and Children's Health, King's College London, London, United Kingdom

Background: Reproductive endocrine disorders are tightly linked to alterations in energy balance and metabolism, with functional hypothalamic amenorrhoea (FHA) associated with reduced energy availability, and polycystic ovary syndrome (PCOS) with metabolic dysfunction and insulin resistance, further exacerbated by obesity. Metabolomics provides comprehensive analysis of small-molecule metabolites offering an integrated assessment of systemic metabolic activity. Herein, we describe the first direct comparison of metabolomic signatures in these two common causes of menstrual disturbance.

Methods: Metabolomic evaluation was conducted in healthy controls ($n = 32$), women with FHA ($n = 37$) and women with PCOS ($n = 54$). PCOS was further stratified into lean PCOS (BMI < 25 kg/m^2; $n = 30$) and obese PCOS (BMI ≥30 kg/m^2; $n = 24$). Serum was analysed using nuclear magnetic resonance (NMR) spectroscopy,

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

with metabolites categorised into amino acid, carbohydrate, and lipid pathways. Metabolites are presented as normalised expression values and compared by Kruskal-Wallis test.

Results: *Amino acid profiles:* Branched-chain amino acids (BCAA) were increased in PCOS, with higher leucine and isoleucine than healthy controls ($P < .0015$) and FHA ($P < .0099$), whilst valine was higher in PCOS than in healthy controls ($P = .0034$). Glycine was lower in PCOS than other groups ($P < .0001$), whereas tyrosine was higher in PCOS than FHA ($P = .0076$). Aromatic amino acids (AAA) including phenylalanine and tyrosine were higher in obese PCOS ($P < .036$). Carbohydrate metabolites were also altered, with lower lactate in FHA than healthy controls ($P = .01$) and lower citrate in PCOS than FHA ($P < .0001$) and healthy controls ($P = .048$). Lipid profiling demonstrated higher triglycerides in PCOS than healthy controls ($P = .001$), while total cholesterol ($P = .008$) and polyunsaturated fatty acids ($P = .009$) were higher in FHA than PCOS. Citrate concentrations were lower in obese PCOS than healthy controls ($P = .02$) and FHA ($P < .0001$) and triglyceride levels were higher than in healthy controls ($P = .003$) and FHA ($P = .02$).

Conclusions: PCOS is characterised by a distinct metabolomic signature consistent with insulin resistance, demonstrated here by elevated BCAA and AAA, reduced glycine, altered carbohydrate metabolism, and triglyceride enrichment. By contrast, FHA exhibits a metabolic profile consistent with energy conservation, reduced glycolytic activity and preserved lipid composition. Collectively, these findings indicate that PCOS and FHA represent fundamentally divergent metabolic states, with obesity acting as a key modifier of metabolic dysfunction in PCOS.

P327 - ECE_1893 - Prospective short and long-term changes in cardio-metabolic risk markers following gender affirming hormone therapy

Louise Lehmann Christensen[1], Camilla Viola Palm[2], Marianne Andersen[1], Guy T'sjoen[3], Jan Frystyk[1], Tine Taulbjerg Kristensen[1], Rikke Hjortebjerg[1] and Dorte Glintborg[1]

[1]Endocrinology, Odense University Hospital, Odense, Denmark; [2]Gynecology and Obstetrics, Odense University Hospital, Odense, Denmark; [3]Endocrinology, Ghent University Hospital, Ghent, Belgium

Introduction: Gender affirming hormone treatment (GAHT) may associate with increased cardiometabolic disease (CMD) risk. Prospective CMD risk screening is recommended, but long-term data are needed regarding changes in CMD markers.

Objectives: To evaluate prospective changes in CMD risk markers during GAHT.

Methods: Transgender persons initiating (GAHT naïve) or on current GAHT (GAHT ongoing) were included in a 36 month prospective study at a Danish center of gender identity. Participants were categorized as transmasculine (TransM, $N = 245$: GAHT naïve, $N = 129$; ongoing, $N = 116$) and transfeminine (TransF, $N = 250$: GAHT naïve, $N = 157$; ongoing, $n = 93$) persons. BMI, waist-hip-ratio, lipids, blood pressure (BP), and HbA1c were measured annually.

Results: In transM, the baseline age was median (interquartile range) 23 (20-28) years in GAHT naïve and 25 (21-29) years in GAHT ongoing with median GAHT duration of 3.1 (1.8-4.8) years. Masculinizing GAHT until 36 months in GAHT naïve and ongoing transM ($N = 84$) was followed by increased LDL and triglycerides, whereas GAHT naïve transM ($N = 53$) in addition had significantly increased waist, and HbA1c and decreased HDL. In TransF, the median age at baseline was 25 (22-30) years) in GAHT naïve and 27 (23-36) years in GAHT ongoing with median GAHT duration of 2.2 (1.3-3.7) years. In GAHT naïve, 36 months of feminizing GAHT ($N = 38$) was followed by increased weight, BMI, waist and hip and decreased t-cholesterol and triglycerides, whereas CMD risk markers were stable in transF GAHT ongoing.

Conclusions: Masculinizing GAHT was associated with long-term adverse changes in lipid status, whereas initializing feminizing GAHT was associated with metabolically unfavorable body composition changes.

P328 - ECE_1888 - Morphometric and transcriptomic profiles in porcine testicular maturation

Petra Ferjan[1], Nina Batorek Lukač[1], Mette Rosenkilde[2] and Milka Vrecl Fazarinc[1]

[1]University of Ljubljana, Veterinary faculty, Institute of Preclinical Sciences, Ljubljana, Slovenia; [2]Faculty of Health and Medical Sciences, Department of Biomedical Sciences, Laboratory for Molecular Pharmacology, University of Copenhagen, Copenhagen, Denmark

Pigs offer a unique model for studying testicular development because of their large interstitial compartment, three-stage Leydig cell differentiation akin to humans, and a functional gonadotropin-releasing hormone receptor 2 (GnRHR2), which induces luteinizing hormone –independent testosterone secretion by Leydig cells. This study aims to connect age-dependent morphometric and transcriptomic changes in porcine testis to enhance our understanding of testicular maturation and its translational relevance.

Testis samples were collected at 0, 1, 3, 6, 12, 19, 22, and 27 weeks of age (6-10 animals/group) and processed for histomorphometric, qPCR[1,2] and LC–MS/MS analyses. Preselected qPCR target genes were cell markers SOX9 (Sertoli cells), ACTA2 (peritubular myoid cells), CD68 (macrophages), UCHL1 (pre-meiotic germ cells) and SYCP1 (meiotic/post-meiotic germ cells), Leydig cell development and function markers (STAR, HSD3B1, HSD17B7, HSD17B3, PDGFRA, BHMT) and genes involved in regulation of testicular function (FSHR, LHCGR, GnRHR2). Kruskal–Wallis test with Bonferroni correction was used for statistical analysis.

Histomorphometric analysis revealed a significant increase in seminiferous tubule diameter and their luminisation from week 19, accompanied by a decreased proportion of Leydig cells and other interstitial components. Leydig cells showed a distinct developmental pattern, with the N:C index lowest at 3 weeks during mini puberty, peaking at 12 weeks, and declining after week 19, reflecting the transition from perinatal to adult Leydig cells. Transcriptome analysis showed that LHCGR, FSHR, HSD3B1, and SOX9 peaked at week 12, marking the transition toward mature testicular function. PDGFRA, marker for stem and progenitor Leydig cells, showed a marked decline in expression from week 19, while HSD17B3, a marker of immature Leydig cells, peaked at week 12. BHMT, a marker of adult Leydig cells,

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

increased significantly from week 19 onward, paralleled by an upregulation of GnRHR2. Increased expression of UCHL1, SYCP1, and ACTA2 from weeks 12 and 19 onward indicated the initiation and progression of seminiferous tubule development. Expressions of STAR and CD68 and testosterone concentrations in testicular tissue declined throughout development, reflecting the reduced proportion of Leydig cells and other interstitial components. HSD17B7 expression remained stable throughout development.

Observed changes align with the three-phase Leydig cell developmental pattern and the onset of puberty at week 19, coinciding with activation of the GnRH-II/GnRHR-II system. Collectively, these findings highlight the coordinated interplay between structural remodeling and transcriptional regulation underlying testicular development in pigs.

P329 - ECE_1941 - Role of the FGF signaling pathway in the etiopathogenesis of congenital hypogonadotropic hypogonadism

Rosa García Moreno[1], Patricia Martín Rojas-Marcos[1], Cristina Álvarez Escolá[1], Paula Muñiz Sevilla[2], Isabel González Casado[3] and Angel Campos Barros[4]

[1]*Endocrinology and Nutrition, Hospital Universitario La Paz, Madrid, Spain;* [2]*Instituto de Genética Médica y Molecular (INGEMM), IdiPAZ., Hospital Universitario La Paz, Madrid, Spain;* [3]*Pediatric Endocrinology, Hospital Universitario La Paz, Madrid, Spain;* [4]*Instituto de Genética Médica y Molecular (INGEMM), IdiPAZ. CIBER de Enfermedades Raras (CIBERER; U 753), ISCIII, Madrid., Hospital Universitario La Paz, Madrid, Spain*

Introduction: The Fibroblast Growth Factor (FGF) signaling pathway is essential for the development and migration of GnRH neurons. Besides genes encoding ligands and receptors (*FGF8, FGF17*, *FGFR1)*, several modulatory genes (*IL17RD, SPRY4, DUSP6, FLRT3)* regulate this pathway. Deleterious variants may cause normosmic congenital hypogonadotropic hypogonadism (nCHH) or Kallmann syndrome (KS).

Objectives: To characterize the phenotype and inheritance patterns of patients with CHH harboring deleterious variants in FGF-pathway genes.

Methods: Targeted NGS analysis of 84 CHH patients with custom panels including up to 482 genes implicated in CHH and hypothalamic-pituitary development.

Results: Heterozygous deleterious variants in FGF-pathway genes were identified in 19% of patients. Four familial cases showed probable autosomal dominant (AD) inheritance due to pathogenic *FGFR1* variants: 1) Mother and daughter with nCHH, presented the nonsense p.(Arg609*) variant; the mother also presented a missense *DUSP6* VUS. 2) Father and daughter with KS, presented a frameshift variant p.(Val102Profs*2). 3) Mother and son with nCHH presented a missense p.(His621Asn) variant; the son also inherited a *SOX2* VUS from his father, suggesting digenic contribution. 4) A woman with nCHH, and her brother with KS, whose mother had hyposmia and pubertal delay, presented a frameshift p.(Asn568LysfsTer67) variant. In three additional cases without family history of CHH, parental genetic studies revealed: 1) a *de novo* pathogenic *FGFR1* variant, p.(Trp691*) in a nCHH case (probably monogenic); 2) a probable digenic KS case due to a pathogenic *FGF8* variant inherited from the mother (unaffected) and a *PROKR2* VUS inherited from the father (delayed puberty); 3) a probable oligogenic CHH case, involving 2x VUS in *SPRY4* and *SMAD6* (inherited from his mother), and predicted deleterious variants in *NPFFR1*, *CHD7,* and *PLEKHA5* (from his father). Among the remaining cases, isolated variants in *FGFR1* or *FGF8* were identified in two, while five cases had VUS in *FGFR1, FLRT3,* or *ILR17D*, combined with variants in other CHH candidate genes.

Conclusions: FGF-signaling pathway genes are implicated in nCHH and KS. *FGFR1* variants may follow AD or oligogenic inheritance, whereas other pathway genes likely contribute to CHH predominantly through oligogenic mechanisms.

P330 - ECE_3180 - The role of insulin-like growth factor-I in predicting growth response during GnRH-agonists treatment for central precocious puberty

Valeria Citterio[1], Giulia Rodari[1], Eriselda Profka[1,2], Valentina Collini[2], Aurora Pedroli[2], Giovanna Mantovani[1,2] and Claudia Giavoli[1,2]

[1]*Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy;* [2]*Department of Clinical Sciences and Community Health, Dipartimento di Eccellenza 2023-2027, University of Milan, Milan, Italy*

Introduction: Central precocious puberty (CPP) is characterized by early activation of hypothalamic-pituitary-gonadal axis and is often associated with elevated insulin-like growth factor-I (IGF-I) levels and accelerated growth and bone maturation, leading to reduced adult height (HT). Treatment with GnRH-agonists (GnRHa) slows growth and bone maturation, though not always restores prepubertal growth velocity (GV). The causes of different growth response to GnRHa treatment remain unclear and although several studies have examined the role of IGF-I on GV during CPP-treatment, results are still debated.

Aims: To investigate the IGF-I response to GnRHa therapy and its potential role in growth outcomes in girls with CPP.

Methods: 69 girls with CPP (Tanner stage B2 before 8 years of age and LH peak response to GnRH test >5 mU/L) treated with GnRHa for at least 12 months were included. Auxological (HT-SDS, BMI-SDS, GV-SDS, Tanner stage), biochemical (LH, FSH, oestradiol, IGF-I-SDS) and radiological (pelvic ultrasonography and bone age) data were collected at diagnosis and during treatment.

Results: At diagnosis, median age was 7.8 years (IQR 7.2-8), mean HT was 0.4 ± 1 SDS and mean BMI 0.6 ± 1.2 SDS. Median estradiol was 5.7 pg/mL (IQR 5-16), mean basal and stimulated LH levels were 0.9 ± 1.1 mU/L and 16.2 ± 16.1 mU/L, respectively. Median IGF-I SDS was 1.8 (IQR 0.6-2.6), with 42% patients showing IGF-I levels >2 SDS. Baseline IGF-I SDS correlated positively with chronological age ($P = .0012$), bone age advancement ($P = .014$), LH peak ($P = .0056$) and HT expressed as distance to mid-parental height (deltaMPH) SDS ($P = .033$). During treatment, IGF-I levels did not show significant overall changes, though decreased in 57% and 56% patients after 6 and 12 months, respectively, and increased in the remainder. IGF-I levels at 6 months significantly correlated with deltaMPH both at 6 and 12 months of therapy ($P = .012$, $P = .004$, respectively), and with GV after 18 months ($P = .03$). Furthermore, girls with IGF-I levels ≥2 SDS at 6 months had higher GV not only at 6, but also at 12 and 18 months compared with those with IGF-I within the normal range ($P = .029$, $P = .034$, $P = .01$, respectively).

Conclusions: Present results confirm the importance of pretreatment IGF-I in supporting CPP diagnosis and firstly highlight the potential role of short-term IGF-I changes in predicting growth response to GnRHa to treatment, even in the long-term. This finding supports the role of IGF I as an early marker of treatment effectiveness, reflecting individual variability in growth response during GnRHa therapy.

P332 - ECE_2573 - Mechanistic insights into the effects of intranasal insulin in increasing postprandial energy expenditure in obese women with polycystic ovary syndrome

Colin Duncan[1], Yuan Wang[1], Riada McCredie[1], Stephen Franks[2], Paul Fowler[3], Roland Stimson[1], Mick Rae[4] and Katarzyna Siemienowicz[4]

[1]*The University of Edinburgh, Edinburgh, United Kingdom;* [2]*Imperial College London, London, United Kingdom;* [3]*University of Aberdeen, Aberdeen, United Kingdom;* [4]*Edinburgh Napier University, Edinburgh, United Kingdom*

Polycystic ovary syndrome (PCOS) is a lifelong condition associated with reproductive and metabolic consequences. Obesity worsens PCOS and women with PCOS are more likely to be obese and find weight loss difficult. Women with PCOS have a reduced adaptive thermogenesis response to food meaning they burn off fewer calories after eating. Previous studies conducted in a clinically realistic ovine model of PCOS suggested that this is due to a reduced insulin signalling in the brain resulting in less sympathetic-mediated activation of thermogenesis in subcutaneous adipose tissue (SAT). In the ovine PCOS model intranasal insulin (INI) improved the thermic response to food. We have now shown that INI improves postprandial energy expenditure (PPEE) in dose dependent manner in obese women with PCOS. To discover molecular mechanistic insight, we examined the effects of INI using microdialysis and transcriptome analysis of SAT combined with plasma proteomics.

Obese women with PCOS ($n = 12$) were fed a standard meal on two occasions with either intranasal saline placebo or 40iu INI in a random and blinded manner. The effect of INI on PPEE was assessed by indirect calorimetry over the next 150 minutes. Microdialysis fluid from anterior abdominal wall SAT was collected throughout. Sixty minutes after INI or saline placebo, a SAT biopsy was taken from the lower abdominal wall. Noradrenaline (NA) concentrations were measured by ELISA and mass spectroscopy and the proteome and transcriptome were analysed by Ingenuity Pathway analysis.

SAT NA concentrations from 30 to 60 mins in the microdialysate were at the lower limit of detection. There was a trend (mean 50% rise and 30% more samples with detectable NA) to higher NA after INI in PCOS but this was not significant. There were 439 genes nominally differentially expressed in SAT after INI with activation of 10 canonical pathways (including RHO and Sirtuin signalling) and inhibition of one (mitochondrial protein degradation). There were 423 differentially expressed plasma proteins in PCOS after INI (420 were elevated) with activation of 36 canonical pathways (including FGF signalling). Interestingly of the differentially expressed genes and proteins, only 14 were common to both. Analysis of the source of the top ten differentially expressed proteins showed that the liver was a more common source of synthesis than SAT.

These results give additional insight into the molecular effect on metabolism of INI and highlight that INI has likely effects on the liver as well as SAT.

P333 - ECE_3172 - Endocrine rhythm integrity: a novel AI-derived metric of menstrual cycle health of the cycle length

Tinatin Kutchukhidze[1,2]
[1]New Vision University, Tbilisi, Georgia; [2]University of Oxford, Oxford, United Kingdom

Background: Clinical assessments of the menstrual cycle remain largely focused on cycle length and bleeding regularity, although these measures account for less than 30% of inter-individual variability in reproductive endocrine functions. 30-40% of women with regular menstrual cycles experience unexplained infertility, indicating subclinical dysfunction not detected by standard evaluations. We introduce Endocrine Rhythm Integrity (ERI), a novel quantitative metric capturing the temporal coherence, phase synchrony, and feedback stability of Hypothalamic-Pituitary-Ovarian hormone dynamics across the menstrual cycle. ERI reframes menstrual health as a property of endocrine rhythm organisation rather than static hormone levels or cycle duration, enabling identification of clinically relevant dysfunction with hormonal "normal" cycles.

Methods: A prospective, observational clinical trial enrolled 312 reproductive-aged women (18-22 years) with self-reported regular menstrual cycles (24-35 days). Participants were stratified into fertility controls ($n+162$) and women with unexplained infertility ($n=150$). Over two consecutive cycles, participants underwent dense longitudinal hormonal profiling with serum LH, FSH, estradiol, and progesterone sampling during the luteal phase. Continuous physiological data (basal body temperature, heart rate, sleep metrics) were collected using wearable devices. An AI- based model integrating hormonal dynamics and physiological signals was developed to compute the ERI score, incorporating metrics of phase alignment signal entropy and feedback loop stability. Primary outcomes included between-group differences in ERI and its predictive performance for infertility status. Secondary outcomes assess correlations between ERI and implantation failure history.

Results: Mean cycle length did not significantly differ between fertile and infertile groups (28.9 ± 2.3 vs 28.9 ± 2.5 days, $P=.42$). In contrast, ERI scores were lower in the infertility group (0.61 ± 0.12 vs 0.78 ± 0.10; $P<.001$). Disrupted endocrine rhythm integrity was observed in 64% of infertile participants despite hormonally" normal" mid-luteal progesterone levels. ERI independently predicted infertility status after adjustment of age, BMI, and AMH (OR 2.84, 95% CL1.96-4.1; $P<.001$). Receiver operating characteristic analysis demonstrates superior discrimination of infertility by ERI (AUC 0.86) compared with cycle length (AUC 0.52) and single-time point progesterone assessment (AUC 0.64). Lower ERI scores were also associated with a higher incidence of implantation failure ($r=-0.48$, $P<.001$)

Conclusions: Endocrine rhythm integrity is an AI-Dirven mechanism that captures subtle but clinically relevant endocrine dysregulation and outperforms traditional metrics in identifying subclinical infertility.It represents a previously unmeasured dimension of menstrual cycle health that is independent of cycle regularity. These findings support a paradigm shift from static cycle assessment to dynamic endocrine rhythm evaluation in reproductive endocrinology

P334 - ECE_3358 - Comparison between Radiofrequency Echographic Multi-Spectrometry (REMS) and Dual-energy X-ray Absorptiometry (DXA) for the assessment of bone status in Klinefelter Syndrome—preliminary data

Francesca Allosso[1], Lucia Digitale Selvaggio[2], Raffaele Navarra[2], Raffaela Carotenuto[2], Giammarco Valentino[2], Claudia Cocchini[2] and Daniela Pasquali[2]
[1]Department of Advanced Medical and Surgical Sciences, University of Campania L. Vanvitelli, Naples, Italy; [2]Advanced Medical and Surgical Sciences, University of Campania L. Vanvitelli, Naples, Italy

Introduction: Klinefelter Syndrome (KS), the most frequent sex chromosome aneuploidy in males, is usually characterized by an increased risk of fragility fractures. Reduced bone mineral density (BMD) in KS has a multifactorial pathogenesis, including hypogonadism, vitamin D deficiency and alterated body composition. Dual energy X-ray Absorptiometry (DXA) is the gold standard for BMD assessment, but a new ultrasound-based technique, Radiofrequency Echographic Multi-Spectrometry (REMS), has recently emerged, showing several advantages like the absence of ionizing radiation and high reproducibility.

Aims: We conducted a cross-sectional study at the "Rare Endocrine Diseases" Unit, University of Campania L. Vanvitelli, Naples. The primary aim of our study was to compare DXA and REMS densitometric parameters in a population of KS patients. The secondary aim was to compare REMS results of KS patients with a healthy control group to evaluate potential differences in BMD, bone fragility and body composition.

Methods: We enrolled 29 patients with KS (aged $\geq$21 years) with a recent DXA scan. Anthropometric (age, weight, height, BMI, waist circumference), biochemical parameters (glycolipid profile, bone metabolism, hormonal profile), information regarding testosterone replacement therapy (TRT) were collected and densitometric parameters were obtained through DXA and REMS. Results were compared with 23 healthy male controls.

Results: All KS patients had normal testosterone levels (naturally or via TRT). Mean BMI was 27.47 ± 5.41 kg/m^2. Lumbar spine results were comparable between DXA and REMS. However, DXA showed significantly higher femoral BMD values (1.012 ± 0.149 g/cm^2 vs 0.842 ± 0.141 g/cm^2; $P<.001$) and T-score (-0.3 ± 0.9 vs -0.7 ± 0.8; $P=.047$) compared to REMS. Despite similar femoral BMD values between groups, KS patients exhibited a significantly lower REMS T-score (-0.09 ± 0.9; $P=.027$) and a higher Fragility Score (13.8 ± 3.73 vs 11.7 ± 1.43; $P=.017$) than controls, suggesting increased bone fragility. Additionally, KS patients had significantly higher body fat percentage (25.5 ± 5.19% vs 21.5 ± 3.84%; $P=.004$) and BMI (27.5 ± 5.38 kg/m^2 vs 24.8 ± 2.42 kg/m^2; $P=.021$).

Conclusions: REMS appears to be a reliable method for the early diagnosis of impaired mineral density in KS, overcoming

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

several DXA limitations as shown by the discrepancies in femoral evaluation.

Abstract citation ID: lvag096.481

P336 - ECE_3234 - Umasking hidden androgen rhythms with a real-time AI- enhanced testosterone patch

Tinatin Kutchukhidze[1,2]
[1]New Vision University, Tbilisi, Georgia; [2]New Anglia University, London, United Kingdom

Background: Hypogonadism and infertility evaluation relies on single morning serum testosterone measurements, which fail to capture the dynamic nature of androgen secretion. Up to 25-30% of men with normal testosterone levels present with symptoms of hypogonadism or unexplained infertility, suggesting the presence of subclinical androgen rhythm disorders undetectable by testing. Continuous hormonal monitoring has never been implemented in males, which is a critical gap in male reproductive endocrinology. This study introduces continues transdermal testosterone monitoring system combined with an AI- driven analysis platform as a novel method to detect previously unrecognised androgen rhythm disorders and provide real-time hormonal analysis.

Methods: A Prospective, observational study with 102 men aged 22-38 years with normal morning total testosterone (12-35 nmol/L) was conducted, including 54 men presenting with infertility or hypogonadal symptoms and 48 age-matched health controls. Participants wore a non-invasive transdermal biosensor patch cable of continuously captured testosterone every 15 minutes for 96 hours. Data were analysed in a real-time dedicated mobile application with integrated AI algorithms, which automatically quantified diurnal amplitude, peaking time, and rhythm stability using the coefficient of variation, phase delay, and AI-derived rhythmicality indices. The app provided clinicals immediate visualisation and analysis of variability of sleep, basal body temperature, and correlated endocrine fluctuations.

Results: Mean morning serum testosterone did not differ between symptomatic and control groups (22.4 ± 3.1 vs 23.1 ± 3.5 nmol/L; p+0.38). Continuous AI-assisted monitoring revealed significant differences in androgen dynamics. Men with symptoms exhibited lower diurnal amplitude(5.2 ± 1.1 vs 8.7 ± 1.4 nmol/L; $P < .001$)compared to controls. Disrupted androgen rhythmicity correlated with reduced sperm concentration ($r = 0.047$;$P = .002$). Rhythm indices, computed in real time by an AI platform, predicted subclinical dysfunction with superior accuracy(AUC 0.87) compared with static serum testosterone (AUC0.61)

Conclusions: Ai-driven Continues transdermal testosterone monitoring patches uncover hidden androgen rhythm disorders in men with normal morning testosterone levels, redefining male hypogonadism and subclinical reproductive dysfunction as disorders of dynamic endocrine regulation rather than absolute deficiency. AI-integrated system enables real- time analysis and clinical decision support, offering a foundation for rhythm-based diagnostic approaches, for transgender medicine, personalized interventions, and timing-optimized testosterone therapy.

P338 - ECE_2708 - Automated AI-assisted preantral ovarian follicle staging in a mouse model of chemotherapy-induced primary ovarian insufficiency (POI)

Malene Lundgaard Riis, David Ari Ostenfeldt, Susanne Pors, Annika Runegaard Thomsen, Jacob Lercke Skytte, Allison Butt and Line Zachariassen
Gubra A/S, Hørsholm, Denmark

Rationale: Classification and counting of ovarian follicles is a widely used as a key endpoint in evaluation of preclinical models of reproductive disorders. This has traditionally been done using manual histopathological scoring systems that are prone to inter- and intra-observer variability which can influence robustness and reproducibility of study results. The present study aimed to validate an automated deep learning-assisted digital imaging analysis pipeline, termed GHOST (Gubra Histopathological Objective Scoring Technology) for objective assessment of preantral follicle staging in a mouse model of chemotherapy-induced primary ovarian insufficiency (POI).

Methods: Female C57BL/6JRj mice, 11 weeks of age, were given an intraperitoneal injection with cyclophosphamide (10 mL/kg, 100-200 mg/mL) on day 1 and 8. At day 11, 18 and 30, the ovaries were dissected and fixed in formalin for 24 hours. The ovarian tissue was then paraffin embedded, sectioned at 5 μm with every 10^{th} section collected, and immunohistochemically stained for p63 (Abcam, Ab124762) and digitally scanned. Firstly, an oocyte segmentation model was established by sampling image tiles of 512×512 pixels (at 20x) throughout the entire study. Within each tile, p63-positive oocytes were annotated using manually drawn bounding boxes and the Segment-Anything-Model (SAM). Based on these annotation images, a U-Net was trained to segment oocytes at pixel-level. Secondly, to create data for a follicle staging model, follicle tiles of 299×299 pixels (at 40x) were extracted around each segmented oocyte and scored by histopathologist into four categories: primordial, transitional, primary and secondary follicles. A fifth category was added to contain false positives detections typically due to unspecific staining. The follicle staging model was created by using scored tiles to train InceptionV3 classification model.

Results: In total 500 tiles containing p63-positive oocytes were used to train the oocyte segmentation model, and 1000 tiles were used to train the follicle staging model. On the held-out test set, automated follicle staging into four categories (primordial, transitional, primary and secondary) showed good agreement with expert manual scoring (Cohen's kappa = 0.61), with the best agreement observed for follicles stages primary and secondary.

Conclusions: The GHOST pipeline shows high agreement with manual scoring of follicle stage by expert histopathologists. GHOST provides unbiased, fast, accurate, and reproducible histopathological scoring. This establishes GHOST as an accurate AI-based method for unbiased and automated preantral follicle staging in mouse ovaries and highlights its valuable application in preclinical studies for reproductive disorders as well as for assessing reproductive toxicology.

P339 - ECE_3904 - The BRIDGE initiative: empowering university societies through evidence-based workshops co-created with patient support groups to support women with PCOS

Sumaya Osman[1], Maiar Elhariry[2], Alaee Ziani[3], Akshat Sinha[2], Esha Kaur[4], Zalanda Shinwarie[5], Halimah Salami[1], Sumayyah Amin[1], Karin Nassar[6] and Punith Kempegowda[1,7]

[1]College of Medicine and Health, University of Birmingham, Birmingham, United Kingdom; [2]Midland Metropolitan University Hospital, Birmingham, United Kingdom; [3]Aston Medical School, Birmingham, United Kingdom; [4]Imperial College London, London, United Kingdom; [5]Birmingham, United Kingdom; [6]Keele University, Keele, United Kingdom; [7]Queen Elizabeth Hospital, Birmingham, United Kingdom

Background: Polycystic Ovary Syndrome (PCOS) affects up to 10% of individuals assigned female at birth, yet many often lack access to accurate information and appropriate support. Misinformation on social media and limited awareness contribute to stigma, confusion, and delayed help-seeking. University societies, often perceived as approachable sources of peer support, are seldom equipped with the training required to address PCOS-related concerns. The BRIDGE (Bridging Resources to Inform and Develop Groups for Effective Support) initiative was developed to address this gap by positioning student societies as informed, community-centred health hubs.

Aims: To deliver accurate, evidence-based information, practical resources, and structured training that address both the clinical and psychosocial dimensions of the condition.

Methods: RIDGE employed a multimodal educational programme grounded in Kolb's experiential learning model, delivered through two workshops (formative and summative) held four months apart. The team consisted of healthcare university students nationwide, doctors, and a patient support group. Each workshop combined simulation-based learning with anonymised real-patient PCOS scenarios, facilitated case discussions, focus groups, and input from Verity PCOS UK. Between workshops, participants designed and implemented community-based "PCOS interventions" within their student societies. Mixed-methods evaluation included pre- and post-session confidence surveys analysed using Wilcoxon signed-rank tests, and thematic analysis of focus group transcripts, with intercoder reliability assessed using Cohen's kappa (κ).

Results: Across both workshops ($n = 25$ completing all surveys), self-reported confidence in supporting peers with PCOS increased significantly from 14.7% to 76.0% ($P < .0001$). All participants reported improved knowledge of PCOS, holistic care principles, signposting skills, and the ability to challenge misinformation. Simulation cases were rated as effective by 94-100% of participants. Thematic analysis ($\kappa = 0.66–0.84$) identified key themes: enhanced PCOS awareness, the value of experiential and collaborative learning, the development of culturally sensitive and patient-centred approaches, and the recognition of logistical challenges in sustaining initiatives. Between the formative and summative sessions, participants produced diverse community interventions including peer-support programmes, podcast storytelling, awareness events, and partnerships with community leaders.

Conclusions: BRIDGE is the first initiative to equip university societies with structured, evidence-based training to support students living with PCOS. The programme significantly improved confidence, knowledge, and culturally sensitive support skills, demonstrating that simulation-based, co-produced, peer-led education can effectively counter misinformation and empower student communities. The BRIDGE model offers a scalable blueprint for addressing other stigmatised or poorly understood health conditions in higher education settings.

P340 - ECE_1053 - Research priorities for polycystic ovary syndrome: results of a priority setting partnership

Sue Channon[1], Elinor Coulman[1], Rachel Morman[2], Caroline Andrews[2], Fiona Morgan[2], Juliet Hounsome[1], Jo Watson[3] and Aled Rees[1]

[1]Cardiff University, Cardiff, United Kingdom; [2]Verity, Oxted, United Kingdom; [3]James Lind Alliance, Southampton, United Kingdom

Background: Polycystic Ovary Syndrome (PCOS) is a common endocrine disorder associated with significant metabolic, reproductive and psychological manifestations. Co-production of research priorities is vital in ensuring that research addresses questions that matter most to individuals with lived experience of PCOS and to healthcare professionals (HCPs). We sought to identify the most important areas for research for people with PCOS by establishing a James Lind Alliance (JLA) Priority Setting Partnership.

Methods: Using standard JLA methodology, we launched an online survey to collect research questions from a diverse group of stakeholders. These were synthesised into summary questions and cross-referenced with existing evidence to identify gaps in the literature. Unanswered questions were included in a second survey for shortlisting by stakeholders. A final prioritisation workshop was held to reach consensus on the top 10 research priorities.

Results: The first survey yielded 1339 questions from 523 respondents (434 people with lived experience [3% 16-20 years, 35% 21-30 years, 39% 31-40 years, 15% 41-50 years, 8% >50 years; 79.6% White, 8.9% Asian, 3.5% Mixed or Multiple, 3.5% Black], 84 HCPs, 78 others). We formed 55 summary questions, of which 51 were unanswered and included in the second prioritisation survey. We heard from 374 respondents (286 people with lived experience) in this survey, with 3452 unanswered questions selected and ranked (2.0% 16-19 years, 28.1% 20-29 years, 46.2% 30-39 years, 14.4% 40-49 years, 7.0% 50-59 years: 7.0%, 2.0% 60-69 years: 2.0%; 78.3% White, 10.2% Asian, 4.0% Mixed or Multiple, 2.7% Black). The 27 highest-ranked questions were taken forward to the final consensus workshop, where individuals with lived experience of PCOS ($n = 13$) and HCPs ($n = 12$) collaboratively determined the top 10 research priorities. The most important question identified was '*What are the optimal care pathways for women and people living with PCOS in the UK, and how can they be adequately resourced and delivered so they are all accessible to everyone with PCOS?*'. Other important areas for research included association with other health

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

conditions, healthcare practitioner knowledge, ethnicity, non-pharmacological therapies, mental health needs, subtypes, anti-obesity and anti-androgen therapies, and fertility.

Conclusions: The study identified the top research priorities for PCOS, as determined jointly by people with lived experience and healthcare professionals. These findings should inform the PCOS research agenda for researchers, funders and policymakers, with the goal of improving outcomes that are meaningful to those affected by this common disorder.

Introduction: Thyroid disorders, especially thyroid autoimmunity, are becoming more common in women of reproductive age and have been associated with fertility outcomes. Although endocrinology guidelines specify target thyroid-stimulating hormone (TSH) levels for women undergoing assisted reproductive technology, the ideal preconception TSH range for successful *in vitro* fertilization (IVF) remains uncertain.

Material and Methods: This study aimed to evaluate how baseline TSH levels within the recommended normal range affect IVF outcomes, focusing on clinical pregnancy and live birth rates. Additionally, machine learning models were used to analyze the predictive roles of factors such as maternal body mass index (BMI) and TSH levels. A retrospective cohort study was performed at the Institute of Reproductive Medicine, University of Szeged, including 996 women undergoing IVF with or without intracytoplasmic sperm injection. Data on biometric, medical history, laboratory, and procedural variables were evaluated. Pregnancy and live birth predictions were modeled using support vector machine (SVM), random forest (RF), and extreme gradient boosting (XGBoost) algorithms, with feature importance assessed for RF and XGBoost.

Results: The SVM models predicted pregnancy with an average accuracy of 72.26% but were less effective for live birth prediction. RF and XGBoost models showed an area under the curve (AUC) of 0.76 and 0.74 for pregnancy, and 0.67 and 0.61 for live birth, respectively. Significant predictors included embryo quality score, maternal age, BMI, and hormone levels, with paternal factors also influencing outcomes. Importantly, variations in maternal TSH within the normal 0.3-4.0 mIU/L range did not significantly affect IVF success.

Conclusions: The findings suggest that preconception TSH levels within the reference range do not have a substantial impact on IVF success, supporting current clinical recommendations on TSH management in this context.

P342 - ECE_2334 - Pro-inflammatory cytokine profiling in polycystic ovary syndrome phenotypes: excess abdominal adiposity vs hyperandrogenism

Martina Curcio[1,2], Fannie Lajeunesse-Trempe[3,4], Georgios K. Dimitriadis[1,5,6] and Royce Vincent[1,5]
[1]*King's College Hospital NHS Foundation Trust, London, United Kingdom;* [2]*Università Cattolica del Sacro Cuore, UCSC, Rome, Italy;* [3]*Quebec Heart and Lung Institute, Laval University, Quebec, Canada;* [4]*Nutrition Faculty, Laval University, Quebec, Canada;* [5]*Faculty of Life Sciences and Medicine, King's College, London, United Kingdom;* [6]*Eli Lilly and Company, Indianapolis, United States*

Background: Polycystic Ovary Syndrome (PCOS) is increasingly recognised as a systemic illness extending beyond the scope of the reproductive disorder. Chronic low-grade inflammation is a key driver in the development and progression of cardiovascular disease (CVD) and inflammation has been reported in both PCOS and in those with excess abdominal adiposity. We assessed inflammation in PCOS phenotypes based on either excess abdominal adiposity or hyperandrogenism.

Methods: PCOS women were classified into four groups based on central adiposity (*healthy*/waist to height ratio (WHtR) 0.40-0.49 vs *high*/WHtR ≥0.6) and biochemical androgen status (*normal*/free androgen index (FAI) <5.0 vs *hyperandrogenism*/FAI>5.0. Groups were compared for cytokines (interleukins (IL-6, IL-1β, IL-8) and tumour necrosis factor α (TNFα)), BMI, HOMA-IR, blood pressure (BP), fibrosis-4-index (FIB-4), testosterone, DHEAS and FAI. Python (v3.14) was used for statistical analysis. $P < 0.05$ was considered statistically significant. Data is reported as median (IQR).

Results: The number of women in each sub-group were as follows: 15 with healthy WHtR, 23 with high WHtR, 32 with FAI ≤5.0 and 19 with FAI >5.0. Healthy and high WHtR groups had similar age, IL-1β, IL-8, TNFα, testosterone, DHEAS, FIB-4 and diastolic BP (DBP). High WHtR had higher % of non-White ethnicities 31 vs 8%, BMI 41.7(34.3-45.3) 23.6(21.7-24.5) kg/m^2 ($P < .0001$), IL-6 4.48(2.88-7.90) vs 1.61(1.21-1.98) ng/L (0.02), IL-6/TNFα 0.37(0.32-0.49) vs 0.16(0.113-0.20) (0.01), HOMA-IR 4.19(2.88-10.32) vs 1.16 (0.68-2.08) (0.02), FAI 5.25(2.08-6.50) vs 2.70 (2.20-3.40) (0.04) and systolic BP (SBP) 124(113-134) vs 108(116-118) mmHg (0.004). FAI ≤5.0 and >5.0 groups had similar age, % ethnicity, WHtR, cytokines, FIB-4, SBP and DBP. Those with FAI >5.0 had higher BMI 39.4(30.9-45.5) vs 27.9(23.7-34.9) kg/m^2 (0.02), testosterone 1.6(1.5-2.4) vs 1.3 (0.9-1.5) nmol/L (<0.0001), DHEAS 6.4(4.5-7.4) vs 2.3(1.9-3.3) umol/L (<0.0001) and HOMA-IR 3.15(2.56-5.04) vs 2.07(1.14-3.32) (0.04). There were no significant correlations between WHtR or FAI with any of the cytokines. However, numerous women exhibited circulating pro-inflammatory cytokines above the upper limits of normal, with elevated IL-6 in 64%, IL-8 and

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

IL-1β in 48%, and TNFα in 28%. There was no difference in WHtR, FAI or IL-6 between White and non-White ethnicities.

Conclusions: In our cohort, excess abdominal adiposity was a stronger driver of IL-6, HOMA-IR and SBP with androgen excess driving primarily HOMA-IR. PCOS is associated with a heightened inflammatory burden, independent of BMI/androgen excess. These findings may suggest a role for active CVD risk stratification and prevention measures across all PCOS phenotypes.

Background: Hyperandrogenemia and insulin resistance (IR) are prevalent in PCOS. Since Androstenedione (A4) is produced by both ovaries and adrenals it is difficult to distinguish the source of hyparandrogenemia in these women. The ratio of testosterone to A4 ratio (T/A4) >1, is considered as a marker of ovarian contribution to androgen excess, whereas the ratio of Dehydroepiandrosterone sulfate (DHEAS) to A4 (DHEAS/A4) > 10 suggests a higher adrenal androgen production. Recent data suggest a potential favorable effect of T/A4 ratio in metabolism in lean women with PCOS.

Aim of the Study: To assess the association of ovarian (HO) and adrenal hyperandrogenemia (HA) with metabolic profile in PCOS.

Methods: Data from 2201 women with PCOS with a mean age of 25.0 years and BMI 24.7 kg/m^2 were analyzed. Participants were classified into HO and HA groups and findings were presented after adjustment for age and BMI.

Results: Women with T/A4 >1 displayed higher IR ($P = .004$), higher total glucose exposure during OGTT ($P = .034$) and impaired glucose tolerance (OR 5.51, $P = .018$). Furthermore, T/A4 was associated with elevated cholesterol ($P = .023$), LDL ($P < .001$), and lower HDL ($P = .002$). T/A4 > 1 was metabolically significant only in normal weight patients (HOMA-IR *P*: .012, HDL *P*:.034). Given the age-related decline in ovarian androgen levels, analyses were additionally stratified by age and it was disclosed a stronger impact of this ratio at younger ages for HOMA-IR with progressive attenuation (*P*:.029). Regarding HA, in the overall model adjusted for age and BMI, DHEAS/A4 >10 was not associated with HOMA-IR, whereas significant associations with lower total and LDL cholesterol were observed. However, these lipid associations were not consistent across BMI strata. Formal interaction analyses demonstrated that both age and adiposity significantly modified the metabolic expression of DHEAS/D4>10, since a significant age interaction was identified for HOMA-IR, while BMI-stratified analyses revealed lower HOMA-IR exclusively among women in the highest BMI tertile.

Conclusions: Collectively, these ratios resemble as functional indexes of androgen source, rather than absolute androgen burden. It seems that HA reflects heterogeneity in androgen source rather than a stable metabolically favorable phenotype. In contrast, HO is compatible with adverse metabolic profile especially in young lean women with PCOS, highlighting the ovary as the main regulator of dysmetabolism in this subset of women. Together, our findings argue against the use of T/A4 as a marker of favorable metabolic status in PCOS and instead support its role as an indicator of increased cardiometabolic risk.

P344 - ECE_3216 - Lipid accumulation product as a non–insulin-based marker of metabolic heterogeneity in polycystic ovary syndrome phenotypes

Lena Radic[1], Sanja Ognjanovic[1,2], Bojana Popovic[1,2], Dusan Ilic[1], Valentina Elezovic Kovacevic[1,2], Milica Opalic Palibrk[1], Katarina Krstic[1], Natalija Dragicevic[1], Bogdan Milenkovic[1], Uglješa Barać[1] and Djuro MacUt[1,2]
[1]Department for Endocrine Tumors and Hereditary Cancer Syndromes, Clinic for Endocrinology, Diabetes and Metabolic Diseases, Belgrade, Serbia; [2]Faculty of Medicine University of Belgrade, Belgrade, Serbia

Introduction: Polycystic ovary syndrome (PCOS) is characterized by distinct metabolic heterogeneity, with insulin resistance representing a key pathophysiological feature. Given the limitations of insulin-based measures, non–insulin-based indices such as lipid accumulation product (LAP) have been proposed as simple and reliable marker of metabolic risk. However, data on the relationship between LAP, androgen-related parameters, and phenotypic metabolic heterogeneity in PCOS remain limited.

Subjects and Methods: This cross-sectional study included 200 women with PCOS, classified into phenotypes A–D according to the Rotterdam criteria (50 patients per group), and 50 healthy controls. Anthropometric, metabolic, and hormonal parameters were assessed. LAP was calculated using waist circumference and fasting triglyceride levels. Differences in LAP across study groups were analyzed using non-parametric methods, and associations between LAP and metabolic and hormonal parameters were evaluated using Spearman correlation analysis.

Results: The mean age of the study population was 26.2 ± 6.6 years, with no significant age differences between groups. Body mass index and waist circumference differed significantly across PCOS phenotypes and controls ($P < .001$). LAP values also differed significantly across study groups ($P < .001$), with higher values observed in hyperandrogenic PCOS phenotypes

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

and lower values in phenotype D. In correlation analyses, LAP showed significant positive associations with body mass index ($r = 0.791$), waist circumference ($r = 0.885$), fasting insulin ($r = 0.369$), HOMA-IR ($r = 0.393$), triglycerides ($r = 0.760$), and free androgen index ($r = 0.411$), as well as significant negative associations with HDL-cholesterol ($r = -0.457$) and sex hormone–binding globulin ($r = -0.444$) (all $P < .001$). No significant correlation was observed between LAP and total testosterone. Similar patterns of association were confirmed when analyses were restricted to women with PCOS only.

Conclusions: LAP may represent a simple and clinically useful non–insulin-based marker for identifying metabolically unfavorable PCOS phenotypes, particularly those characterized by hyperandrogenism.

P345 - ECE_1583 - Impact of gender-affirming hormone treatment on body composition and muscle strength: 1-year follow-up data from a prospective study

Gesine Meyer[1], Anne-Sophie Fath[1], Kerstin Jacobs[1], Eva Herrmann[2] and Jörg Bojunga[1]
[1]*Endocrinology and Diabetes, Goethe University Frankfurt, University Hospital, Medical Clinic 1, Frankfurt, Germany;* [2]*Goethe University Frankfurt, Institute of Biostatistics and Mathematical Modelling, Frankfurt, Germany*

Objective: Several studies, predominantly using dual x-ray (DXA), showed rapid changes of body composition (BC) under virilising hormone treatment. However, the impact of muscle-building behaviour on these changes has not been considered so far.

Patients and Methods: Prospective measurement of BC using bioelectrical impedance analysis (BIA), hand-grip strenght and self-perception as well as workout habits using an established questionnaire (Drive for Muscularity Scale) in 42 transgender individuals ($n = 21$ transmen, $n = 21$ transwomen) before and 1 year after start of a gender-affirming hormone treatment (GAHT).

Results: During the first year pf GAHT body weight and BMI increased significantly in the entire cohort ($P = .015$, resp. $P = .024$). In transmen, BIA revealed a significant increase in lean body mass (+ 10.3%; $P < .001$) and a significant decrease in fat mass (−5.1%; $P = .02$). In transwomen lean body mass remain unchanged, while fat mass increased by 7.2%, though not significant. Hand-grip strength showed a significant increase in transmen (+8.8%; $P < .001$) and only a slight decrease in transwomen (−2.4%; n.s.). Muscularity-related cognition as well as behaviour did not change during the first year of GAHT. Differences of muscularity-related behaviour between transmen and transwomen were highly significant at both times of measurement ($P < .001$).

Conclusions: Our results of BIA are comparable to DXA measurements used in former studies, and demonstrate that virilising hormones lead to a significant increase of lean body mass and muscle strength in transmen even during the first year of treatment. According to former data, we could not see any significant changes in muscle mass or strength during the first year of a feminising hormone therapy. This is a remarkable finding, particularly considering the distinct lower degree of muscle-building behaviour in transwomen. A further measurement after five years of therapy will per performed to evaluate long-term effects.

The hypothalamic-pituitary-gonadal axis (HPG) controls pubertal development, sexual maturation, and fertility. We hereby demonstrate a new role of hypothalamic microglia in controlling the HPG axis through Rank signaling, a pathway known for its role in bone and mammary gland biology. Whole-body and microglia Rank depletion leads to hypogonadotropic hypogonadism (HH) resulting from an alteration in gonadotropin-releasing hormone (GnRH) neuron function. In addition, we identify rare gene variants of *RANK* in patients with HH. Transcriptional profiling upon Rank loss reveals defective microglia activation and morphological alterations in the median

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

eminence, decreasing the contacts and engulfment of GnRH terminal projections and impairing GnRH neuronal responses to kisspeptin. Overall, our data uncover the role of microglia in regulating GnRH neuronal function through Rank signaling, with implications for reproductive maturation and fertility.

P347 - ECE_3228 - The use of pegvisomant to inhibit growth in a child with constitutional tall stature

Magdalena Stasiak, Renata Stawerska and Arkadiusz Zygmunt
Polish Mother's Memorial Hospital—Research Institute, Department of Endocrinology and Metabolic Diseases, Łódź, Poland

Constitutionally tall stature usually requires only the exclusion of gigantism, and no pharmacological treatment is necessary. However, when such height significantly exceeds the average height in a given population, it leads to peer rejection, a lack of self-acceptance, and, consequently, the development of depressive disorders.

Pegvisomant is a potent growth hormone (GH) receptor antagonist used in the treatment of acromegaly. This drug has not yet been reported to inhibit growth in children for indications other than pituitary gigantism.

We present the case of a 13-year-old boy whose height at the time of admission to our clinic was 195 cm and body weight 77 kg. His bone age was consistent with his chronological age. His predicted height based on his parents' height was 197.5 cm, and his final height, calculated using the Khamis-Roche formula, was 209.4 cm. Due to the growth prognosis, treatment with testosterone heptanoate was initiated at a dose of 200 mg every two weeks, and then—due to the lack of satisfactory efficacy—every 10 days. During treatment, bone age accelerated by 9 months, while height increased to 197 cm. The patient refused to continue treatment due to severe gynecomastia and height gain, as well as severe acne. At that moment, the calculated final height was 208 cm.

After obtaining approval from the bioethics committee, treatment with pegvisomant was initiated, using the standard dosage used in the treatment of acromegaly. An initial dose of 80 mg of pegvisomant was administered subcutaneously under medical supervision. Subsequently, the patient received 10 mg of the drug once daily. The boy self-administered the drug under his parents' supervision. During the 4-month treatment period significant growth retardation was observed (growth increased only by 1.4 cm) together with one-year bone age progression, although IGF-1 concentrations did not decrease below the reference range. As the initiation of the treatment took place exactly at the time of the beginning of the developmental growth spur, the initial IGF-1 concentration was 451.6 ng/mL (reference range 102-486) and it decreased to 230 ng/mL during treatment. The boy reported no side effects. No complications were observed during the 18-month follow-up. The final growth after growth completion is 199 cm, which is entirely acceptable for the patient.

Pegvisomant is an effective and safe treatment for patients with constitutionally very tall stature whose prognosed height significantly exceeds the height which can be psychologically accepted by a patient.

P349 - ECE_1673 - Multi-axis endocrine regulation of bone turnover in reproductive disorders

Jovanna Tsoutsouki[1,2], Edouard G Mills[1,2,3], Agathoklis Efthymiadis[1], Kanyada Koysombat[1], Megan Young[1], Sandhi Nyunt[1], Arthur Yeung[1], Aaran Patel[1], Maria Phylactou[1,2], Aureliane Pierret[1], Ali Abbara[1,2], Waljit Dhillo[1,2] and Alexander Comninos[1,2,3]
[1]*Department of Metabolism, Digestion and Reproduction, Imperial College London, London, United Kingdom;* [2]*Department of Endocrinology, Imperial College Healthcare NHS Trust, London, United Kingdom;* [3]*Endocrine Bone Unit, Imperial College Healthcare NHS Trust, London, United Kingdom*

Background: Bone health in reproductive disorders is traditionally attributed to oestrogen deficiency, neglecting that these conditions involve complex multi-axis endocrine perturbations. We hypothesised that bone turnover regulation reflects distinct endocrine signatures across reproductive states, challenging the purely oestrogen-centric paradigm.

Methods: We conducted a comparative cross-sectional study measuring fasting bone turnover markers (BTMs; P1NP, CTX) in hormonally-untreated women aged 20-36 years with distinct reproductive-endocrine phenotypes: healthy controls ($n = 26$), hypothalamic amenorrhoea (HA; $n = 29$), congenital hypogonadotrophic hypogonadism (CHH; $n = 9$), and polycystic ovary syndrome (PCOS; $n = 56$). Between-group differences were assessed using Kruskal-Wallis tests; within-group endocrine associations were evaluated using Spearman correlations.

Results: Bone turnover was markedly elevated in CHH (CTX 0.61 ng/mL; P1NP 86.7 ng/mL) compared with controls (CTX 0.38; P1NP 57.3), HA (CTX 0.39; P1NP 58.1), and PCOS (CTX 0.34; P1NP 53.1; all $P \leq .02$ compared to CHH). Interestingly, despite comparable oestradiol levels between CHH and HA, both resorption and formation markers were significantly higher in CHH, demonstrating that current sex-steroid exposure alone does not explain bone turnover patterns.

Androgens emerged as consistent positive correlates of bone turnover across all conditions. CTX correlated with androstenedione and dihydrotestosterone in controls ($r = 0.44$, $P = .04$) and HA ($r = 0.46$, $P = .03$), and with DHEAS in PCOS ($r = 0.29$, $P = .04$). P1NP correlated with dihydrotestosterone and androstenedione in controls ($r = 0.45–0.53$, $P < .03$) and HA ($r = 0.46–0.49$, $P < .03$), testosterone in PCOS ($r = 0.36$, $P = .01$), and strongly with DHEAS in CHH ($r = 0.82$, $P = .03$).

Condition-specific endocrine determinants were evident: in HA, P1NP correlated with markers of hypothalamic function (LH: $r = 0.51$, $P = .01$; oestradiol: $r = 0.53$, $P = .008$) and associated multi-axis disruption (IGF-1: $r = 0.44$, $P = .03$; fT3: $r = 0.49$, $P = .02$). In PCOS, CTX correlated inversely with BMI ($r = −0.31$, $P = .02$), suggesting adiposity-related suppression of bone resorption.

Conclusions: This comparative study reveals that bone turnover across reproductive-endocrine disorders reflects condition-specific endocrine regulation that extends beyond purely oestrogen exposure. Androgens demonstrate consistent anabolic associations, while HA and PCOS exhibit distinct multi-axis and metabolic modulation patterns. These findings challenge the traditional oestrogen-centric framework and support precision, phenotype-

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

driven approaches to skeletal health assessment in reproductive endocrinology.

P350 - ECE_2546 - Steroid hormone levels across the menstrual cycle in women with PCOS: golden standard liquid-tandem mass spectrometry analysis

Meri-Maija Ollila[1], Sanni Parpala[1], Elisa Hurskainen[1], Marika Kangasniemi[1], Merja Häkkinen[2], Seppo Auriola[3], Matti Poutanen[4], Riikka Arffman[1] and Terhi Piltonen[5]
[1]*Department of Obstetrics and Gynaecology, Medical Research Center Oulu, Research Unit of Clinical Medicine, University of Oulu and Oulu University Hospital, Oulu, Finland;* [2]*Department of Public Health, Finnish Institute for Health and Welfare (THL), Kuopio, Finland;* [3]*Department of Health Sciences, School of Pharmacy, University of Eastern Finland, Kuopio, Finland;* [4]*Institute of Biomedicine, University of Turku, Research Centre for Integrative Physiology and Pharmacology, Turku, Finland;* [5]*Oulu, Finland*

Context: Women with PCOS are known to have alterations in the steroid hormone profile, yet there are no previous studies reporting different steroid hormone levels across menstrual cycle phases among the affected women analysed by liquid chromatography-tandem mass spectrometry (LC-MS).

Objective: To investigate the steroid hormone profile of women with PCOS according to menstrual cycle phases, with a special focus on ketosteroids.

Study Design: An age and BMI-matched case-control study including 89 women with PCOS and 80 control women, with multiple blood samples collected during different phases of the menstrual cycle.

Methods: Serum steroids were measured by LC-MS. Ovulation was detected by a urine test and confirmed by ultrasound. The baseline hormone levels were reported at the follicular phase. The changes in steroid hormone levels during the menstrual cycle between PCOS and control women were analysed using a generalized additive mixed model with five different time windows: cycle days [CD] CD 2-4, CD 6-8, and post ovulation luteinizing hormone level peak (LH)+2-3 days, LH+7-8 days, and LH +11-12 days.

Results: Serum testosterone ($P < .001$), free androgen index ($P < .001$), androstenedione ($P < .001$), progesterone ($P = .035$), 17α-hydroxyprogesterone ($P < .001$), 21-hydroxyprogesterone ($P = .035$) and estrone ($P < .001$) levels were significantly higher in women with PCOS compared to control women in the follicular phase of the menstrual cycle.

Serum levels of testosterone were 0.3 nmol/L higher (β = .33, 95% CI: 0.19-0.47, $P < .001$), androstenedione levels were 1.9 nmol/L higher (β = 1.86, 95% CI: 1.11-2.61, $P < .001$) and FAI was 0.8 higher (β = .82, 95% CI: 0.49-1.15, $P < .001$) throughout the menstrual cycle in women with PCOS compared to controls, and the levels changed non-linearly during menstrual cycle both in women with and without PCOS ($P < .001$ for all comparisons).

11-ketotestosterone (β = .06, 95% CI: −0.09-0.22, $P = .446$), 11-ketoandrostenedione β = .0003, 95% CI: −0.181-0.181, $P = .998$), and 11β-hydroxy-testosterone levels (β -.021, 95% CI: −0.092-0.051, $P = .569$) were comparable between PCOS and control women across the menstrual cycle.

Conclusions: Women with PCOS have significantly higher serum testosterone, androstenedione, and FAI levels than control women, regardless of menstrual cycle phase. In addition, in contrast to some previously published studies, levels of 11-oxygenated androgens measured were similar in women with and without PCOS with white European ethnicity, and the levels remained stable throughout the menstrual cycle.

P351 - ECE_2641 - Cortisol and stress levels in women with functional hypothalamic amenorrhoea (FHA) and polycystic ovary syndrome (PCOS)

Aureliane Pierret[1], Arthur Yeung[1], Kanyada Koysombat[1,2], Bijal Patel[1,2], Megan Young[1], Maria Phylactou[1,2], Jovanna Tsoutsouki[1], Sandhi Nyunt[1,2], Aaran Patel[1], Elisabeth Daniels[1], Ambreen Qayum[1,2], Pei Eng[1,2], Elizaveta Sheremetyeva[1,3], Edouard G Mills[1,2], Simon Hanassab[1,3], Channa Jayasena[1,2], Tricia Tan[1,2], Sophie Clarke[4], Alexander Comninos[1,2], Ali Abbara[1,2] and Waljit Dhillo[1,2]
[1]*Department of Metabolism, Digestion and Reproduction, Imperial College London, London, United Kingdom;* [2]*Department of Endocrinology, Imperial College Healthcare NHS Trust, London, United Kingdom;* [3]*Department of Computing, Imperial College London, London, United Kingdom;* [4]*University College Hospitals NHS Foundation Trust, London, United Kingdom*

Background: Menstrual disturbance affects one fifth of young women; the two commonest causes are functional hypothalamic amenorrhoea (FHA) and polycystic ovary syndrome (PCOS). Psychological stress is a key component of FHA, along with reduced energy availability and genetic susceptibility. FHA is associated with central hypercortisolism, with increased corticotrophin releasing hormone (CRH) believed to contribute to the reduction in GnRH neuronal activity. PCOS, which typically has increased GnRH neuronal activity, is also associated with psychological morbidity with increased rates of anxiety and depression. There are limited data directly comparing stress and cortisol in women with menstrual disturbance from different aetiologies.

Methods: We examined measures of stress and serum cortisol in women aged 18-35 years with FHA or PCOS, and healthy controls. Perceived stress was quantified using the validated perceived stress scale (PSS) and reported as mean (standard deviation). Group differences were calculated using one-way ANOVA with post-hoc Sidak's multiple comparisons test. 8am serm cortisol and ACTH concentrations were quantified using immunoassays and reported as median (IQR). Group differences were assessed using Krusak-Wallis with post-hoc Dunn's multiple comparisons test.

Results: We included 45 healthy controls, 37 women with FHA and 70 women with PCOS ($n = 46$ non-obese; $n = 24$ obese). PSS scores were similar between healthy women [13.08 (4.25)] and those with HA [16.62 (4.11), $P = .2048$], but significantly higher in PCOS [18.81 (6.642)] compared to healthy women ($P = .0005$). PSS scores did not differ with obesity in women with PCOS ($P = .8$). Serum cortisol (nmol/L) was significantly lower in PCOS [298.9 (237.1, 348.8)] than in FHA [374.1 (295.1, 435.4),

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

$P = .0099$], or healthy controls [389.5 (281.9, 470.2), $P = .0079$]. Cortisol trended lower in women with PCOS and obesity compared to those without, but did not reach statistical significance ($P = .13$). ACTH did not differ between the groups ($P > .8$).

Conclusions: In contrast to the expected association of FHA with stress, PSS scores and cortisol concentrations were not higher in FHA than in healthy women. Although women with PCOS had higher PSS scores, cortisol concentrations were lower than in healthy women or women with FHA. Cortisol concentrations are known to be reduced with obesity; however, we did not observe a significant reduction in cortisol concentrations with obesity in women with PCOS. Our data highlight the challenge in accurately distinguishing these two common causes of menstrual disturbance and that increased stress scores do not necessarily implicate FHA as the underlying aetiology.

P352 - ECE_2645 - Characterisation of pro-inflammatory cytokine profile across different BMI thresholds in women with Polycystic Ovary Syndrome

Martina Curcio[1,2], Fannie Lajeunesse-Trempe[3,4], Georgios K. Dimitriadis[1,5,6] and Royce Vincent[1,5]
[1]*King's College Hospital NHS Foundation Trust, London, United Kingdom;* [2]*Università Cattolica del Sacro Cuore, UCSC, Rome, Italy;* [3]*Quebec Heart and Lung Institute, Laval University, Quebec, Canada;* [4]*Nutrition Faculty, Laval University, Quebec, Canada;* [5]*Faculty of Life Sciences and Medicine, King's College, London, United Kingdom;* [6]*Eli Lilly and Company, Indianapolis, United States*

Background: Polycystic Ovarian Syndrome (PCOS) is an endocrine disorder affecting women of reproductive age, characterised by hyperandrogenism, menstrual irregularities, and the presence of polycystic ovaries. Pro-inflammatory cytokines, including interleukins (IL) and tumour necrosis factor (TNF), are elevated in both PCOS and in those with obesity, driving cardiovascular risk. Our aim was to characterise cytokine profiles across a wide range of body mass index (BMI) categories in women with and without PCOS.

Methods: Serum cytokine (IL-6, IL-1β, IL-8, TNF-α) levels from patients with and without PCOS presenting to a London teaching hospital were retrospectively analysed. Patients were classified into three groups, healthy-weight PCOS (BMI 18.5-24.9 kg/m^2; $n = 18$), PCOS with obesity (BMI ≥ 30 kg/m^2; $n = 29$), and with obesity but without PCOS ($n = 72$). Age was matched and BMI was adjusted to minimize confounding. Python (v3.14) was used for statistical analysis. Between-group comparisons were performed using one-way ANOVA, preceded by Levene's test for equality of variances. For localization of differences, Mann–Whitney U tests with Bonferroni correction were applied. Data are reported as median (IQR), and a $P < .05$ was considered statistically significant.

Results: Healthy-weight PCOS women exhibited higher TNF-α [14.6 (9.9-24.1) ng/L] than PCOS with obesity [9.7 (8.9-12.0) ng/L] and with obesity but without PCOS [11.9 (9.7-15.7) ng/L]. IL-1β showed a trend toward increased concentrations in healthy-weight PCOS women, compared with the other groups, but did not reach statistical significance. IL-6 and IL-8 were comparable between groups. No significant correlations were observed between cytokines and BMI in either the PCOS or non-PCOS groups. In PCOS women, TNF-α and IL-1β displayed a mild inverse trend with BMI ($r = -0.14$ and -0.09, respectively).

Conclusions: Healthy-weight PCOS women show a notable elevation of TNF-α, consistent with a BMI-independent inflammatory activation, possibly linked to intrinsic androgen or metabolic dysregulation. A limitation of these data is not assessing central adiposity or weight-to-height ratio. Larger studies are needed to better understand the higher inflammatory burden in women with PCOS and healthy weight.

P353 - ECE_3559 - Genetic variation in the gonadotropin signaling pathway and its role in PCOS pathogenesis

Giangela Stokes[1], Chloe Parker[1], Margrit Ubranek[1], Richard Legro[2] and Corrine Welt[3]
[1]*Northwestern University, Chicago, United States;* [2]*Penn State, Hershey, United States;* [3]*University of Utah, Salt Lake City, United States*

Background: Polycystic ovary syndrome (PCOS) is a common, complex endocrinopathy affecting 6-20% of reproductive age women. It is defined by elevated androgens, irregular or absent periods, and polycystic ovarian morphology. Physiological conditions contributing to PCOS pathogenesis include insulin resistance, and ovulatory and gonadotropin signaling dysfunction. Twin and family studies have shown PCOS to be highly heritable, and genome-wide association studies (GWAS) implicate several PCOS susceptibility loci near genes involved in gonadotropin and hypothalamic-pituitary secretion. The gonadotropin hormones, follicle stimulating hormone (FSH) and luteinizing hormone (LH), are neuroendocrine hormones that direct follicle development and overall ovarian health. Reproductive neuroendocrine dysfunction is a major pathophysiological component of PCOS. Women with PCOS have elevated LH levels contributing to hyperandrogenism and oligo/anovulation— two cardinal characteristics of PCOS.

Objective: Determine the impact of pathogenic variants in the gonadotropin signaling pathway on PCOS pathogenesis and elucidate the molecular mechanisms of impaired gonadotropin signaling.

Methods: To determine how disease-causing gonadotropin signaling variants contribute to PCOS pathogenesis, we sequenced the gonadotropin genes *FSHR, FSHB, LHCGR,* and *LHB* in two independent cohorts of women with PCOS. To elucidate the molecular mechanisms of gonadotropin signaling dysfunction, we used a cAMP assay to screen *FSHR* variants for impaired function.

Results: We found significant and reproducible evidence for association between variants in *FSHR* and *LHCGR* and PCOS ($P < 1e\text{-}15$) in two independent cohorts. We found that variation in *FSHB* is significantly associated with PCOS in our discovery cohort ($P < 1e\text{-}5$) and nominally associated in our replication cohort ($P = .02$). We identified 27 potentially pathogenic variants (PPVs) across the four gonadotropin genes in two independent cohorts.

Conclusions: *FSHR* variants have been identified in reproductive disorders such as hypogonadotropic hypogonadism (HH) or primary ovarian insufficiency (POI), but no pathogenic *FSHR*

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

variants have identified in PCOS. We identified 26 PPVs in *FSHR* in two independent cohorts of women with PCOS. These studies demonstrate that rare variation in the gonadotropin signaling pathway is significantly enriched in PCOS, providing substantial evidence for their role in PCOS pathogenesis. Identifying and understanding genetic contributions to complex endocrinopathies like PCOS can increase our ability to find causal variants and improve treatment efficacy.

Abstract citation ID: lvag096.497

P354 - ECE_3594 - Triiodothyronine (T3) as a regulator of insulin receptor (INSR) expression in epithelial ovarian cancer

Aleksandra Sirek, Anna Ptak and Justyna Gogola-Mruk
Laboratory of Physiology and Toxicology of Reproduction, Jagiellonian University, Institute of Zoology and Biomedical Research, Kraków, Poland

Epidemiological and clinical data link thyroid dysfunction with ovarian cancer (OC) risk, progression, and prognosis, yet underlying molecular mechanisms remain unclear. Increasing evidence suggests that thyroid hormones, particularly triiodothyronine (T_3), may modulate processes in OC not only through classical genomic mechanisms mediated by nuclear thyroid hormone receptors (TRα, TRβ), whose expression has been demonstrated in ovarian tissue, but also indirectly by regulating the expression and secretion of other metabolic hormones. A key component of these pathways is the insulin receptor (INSR), which regulates cellular metabolism and proliferation.

The aim of this study was to assess the expression and prognostic significance of *INSR*, in OC and to investigate the dose-dependent effect of T_3 on INSR mRNA expression level in epithelial ovarian cancer (EOC).

SKOV-3 and COV318 cell lines, representing EOC, were cultured as 3D spheroids and treated with T_3 at concentrations reflecting physiological (1 nM), hypothyroid (0.1 nM), and hyperthyroid (10 nM) conditions. Basal expression of *TRα*, *TRβ*, and *INSR* as well, as changes in *INSR* expression following T_3 exposure in SKOV-3 and COV318 cells were quantified by RT-qPCR. Gene expression (mRNA level) in OC tissues was analyzed using GEPIA (http://gepia.cancer-pku.cn). Moreover, the association between INSR expression levels and the survival of OC patients was analyzed using the Kaplan–Meier plotter (https://kmplot.com/analysis).

Basal expression analysis revealed expression of *TRα* and *TRβ* and INSR in both analyzed EOC cell lines. Higher levels of *TRα* and *TRβ* in SKOV-3 compared to COV318 was observed. *INSR* expression level was similar in both EOC lines. Additionally, bioinformatic analysis confirmed that *INSR* mRNA expression was significantly downregulated in OC tissue ($n = 426$) compared to normal tissue ($n = 88$; $P < .05$). However, survival analysis showed that high *INSR* expression was not significantly associated with overall survival (OS) or progression-free survival (PFS), although a protective trend was observed (HR < 1). Interestingly, exposure to T_3 resulted in a reduction of INSR expression in both SKOV-3 and COV318 cell lines at concentrations of 1 nM and 10 nM, whereas at 0.1 nM only a non-significant downward trend was observed.

To sum up, thyroid hormone signaling, particularly via T_3, may influence on progression of EOC that express *TRα* and *TRβ* gene through modulation of *INSR* expression. T_3 mediated regulation of *INSR* suggests involvement of metabolic signaling pathways, with potential prognostic and therapeutic implications.

P355 - ECE_2205 - Menstrual disorders' risk factors in young women

Alla Shepelkevich, Eleonora Kislach and Diana Baalbaki
Endocrinology, Belarusian State Medical University, Minsk, Belarus

Background: Menstrual disorders are a spectrum of conditions that pose a prevalent challenge among young women. They can adversely impact the quality of life by significantly raising the risk of reproductive and long-term complications (metabolic and cardiovascular diseases), as well as an increased likelihood of premature mortality. Establishing diagnosis requires thorough medical investigation; for instance, secondary amenorrhea where evaluation of factors, like chronic stress, energy deficiency, excessive exercise, and sleep disturbances, is crucial for timely intervention.

Objectives: To assess menstrual disorders and secondary amenorrhea frequency in young women, and evaluate their behavioral and clinical risk factors.

Methods: A cross-sectional survey was conducted using questionnaires on general demographic and anthropometric data, menstrual cycle characteristics (regularity, menarche age, history of amenorrhea, chronic conditions and medication anamnesis), eating behavior (based on the Dutch Eating Behavior Questionnaire—DEBQ), stress level (Reeder Stress Inventory—RSI), physical activity (International Physical Activity Questionnaire—IPAQ), and assessment of sleep quality.

Results: Of the 940 participants (age 18-30), 750 (79.8%) had a regular menstrual cycle (21-35 days), while 190 (20.2%) had an irregular cycle; the latter's median age was 21 years with menarche age—13 years. Secondary amenorrhea was found in 48 participants (5.1%). Polycystic ovary syndrome was detected in 16.84% of participants with menstrual irregularities, hypothyroidism—4.74%, and hyperprolactinemia—3.16%. BMI was within the normal range in 67.9% of participants, whereas 17.9% were underweight and 14.2% were overweight or obese. Psychotropic (11.1%) medications were the most commonly reported. According to DEBQ, eating disorders were identified in 90.5% of women with irregular menstrual cycles: external type was observed in 83.1%, emotional—70.9%, and restrictive—57%. Using RSI, stress levels were high in 20.5%, moderate—57.9%, and low—21.6%. Based on IPAQ, our participants were mostly physically inactive—52.1%, insufficiently active—34.2%, and only 13.7% had optimal activity. Poor sleep quality was reported by 73.7% of participants with menstrual irregularities.

Conclusions: Menstrual disorders are observed in a significant number of young women—20.2% (secondary amenorrhea—5.1%). They were more likely to experience eating disorders, insufficient physical activity, high and moderate stress levels, and sleep problems. This highlights the importance of an in-depth assessment of behavioral and clinical factors of menstrual

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

health for early prevention of reproductive and metabolic complications.

P356 - ECE_2765 - Primary hypogonadism following open abdominal aortic aneurysm repair: an under-recognised complication?

Hafiz Awais Javed, Daisy Beard and Joohi Majeed
Endocrinology, Bury St Edmunds, West Suffolk Hospital, United Kingdom

Abdominal aortic aneurysm (AAA) is a major health concern with curative surgery requiring open or endovascular aortic repair (EVAR). Transient secondary (hypogonadotrophic) hypogonadism post-operatively is relatively common due to surgical stress or opioid analgesia. Primary (hypergonadotropic) hypogonadism is rare and usually permanent. Mechanisms include compromised gonadal blood supply through cross-clamping (open repair), inadvertent vessel ligation, thrombosis or microembolisation. We describe a case of de novo primary hypogonadism following open AAA repair.

A 67-year-old man underwent elective open repair of a 5.5 cm infrarenal AAA in December 2024. His peri-operative course was uncomplicated. He had no prior history of orchitis, testicular trauma, chemotherapy or radiotherapy. He had fathered two children and reported normal sexual function and secondary sexual characteristics prior to surgery. A few months post-operatively, he developed episodic sweating and hot flushes. His body hair, shaved pre-operatively, had failed to regrow over the axillae, torso, and pubic region and facial shaving was reduced to alternate days from daily. He had gained a stone in weight, attributed to smoking cessation pre-operatively. He also reported loss of spontaneous erections and reduced libido. There had not been any testicular pain.

On examination, he appeared hypogonadal, with loss of secondary sexual characteristics and small, soft, non-tender testes.

Testing in primary care in April 2025 had demonstrated undetectable 09:00 hrs testosterone (<0.09 nmol/L), mildly elevated prolactin (824 mIU/L), normal TSH (1.03 mIU/L) and low cortisol (115 nmol/L). Endocrine evaluation in May 2025 confirmed severe **primary hypogonadism** with low 09:00 hrs testosterone (1.82 nmol/L) and elevated gonadotropins (FSH 22.4 IU/L, LH 12 IU/L). Prolactin (290 mIU/L), thyroid function and cortisol (449 nmol/L) were normal. Testicular ultrasound doppler in December 2025 confirmed testicular atrophy, with bilateral small testes measuring 2.5 cm, showing uniform echotexture and preserved, albeit reduced, vascular flow.

Following testosterone replacement, his sweats settled, spontaneous erections returned and body hair regrowth resumed.

The temporal relationship of the presentation of primary hypogonadism to AAA repair strongly suggests a link and the ultrasound findings suggest it is permanent. This is theoretically more likely after open repair due to the increased and prolonged insult, including aortic cross-clamping. However, while there are reported cases of primary hypogonadism occuring after EVAR, we believe this is the first reported case occuring after open repair. Clinicians may need to consider androgen deficiency in men presenting with persistent non-specific symptoms post-AAA repair, including weight gain, loss of energy and libido.

P357 - ECE_2016 - Adiposity and male reproductive function in young men

Wiwat Rodprasert[1,2], Jorma Toppari[1,3,4], Heidi Elamo[1], Kreeta Viitala[1], Helena Ollila[5], Niels Erik Skakkebæk[6,7], Niels Joergensen[6,7], Katharina M. Main[7] and Helena Virtanen[1,4]
[1]*University of Turku, Research Centre for Integrative Physiology and Pharmacology, Institute of Biomedicine, Turku, Finland;* [2]*Division of Endocrinology and Metabolism, Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand;* [3]*Department of Pediatrics, Turku University Hospital, Turku, Finland;* [4]*Centre for Population Health Research, University of Turku and Turku University Hospital, Turku, Finland;* [5]*Department of Biostatistics, University of Turku and Turku University Hospital, Turku, Finland;* [6]*Department of Growth and Reproduction, Copenhagen University Hospital—Rigshospitalet, Copenhagen, Denmark;* [7]*Copenhagen University Hospital—Rigshospitalet and University of Copenhagen, International Centre for Research and Research Training in Endocrine Disruption of Male Reproduction and Child Health (EDMaRC), Copenhagen, Denmark*

Background: Adiposity has been associated with reduced total testosterone (TT) levels, while findings on free testosterone (FT) and semen quality are inconsistent. The roles of different fat regions in reproductive health remain unclear. This study investigated the relationship of adiposity with hypothalamic–pituitary–gonadal axis hormones and semen quality in Finnish men.

Methods: This cross-sectional study included men aged 18-23 years (mean 20.8, SD 0.98) from Turku, Finland. Participants completed questionnaires, underwent andrological examination and dual-energy X-ray absorptiometry (DXA), and provided blood and semen samples. DXA-derived fat mass index (FMI; fat mass [kg]/height^2 [m^2]) was categorized into quartiles. Serum hormone levels were measured at Rigshospitalet, Copenhagen, Denmark, and semen analysis followed the 5th WHO manual. FT level was calculated using Vermeulen's formula, and FT percentage was calculated as FT/TT × 100). Multivariable linear regression compared hormone and semen variables across FMI quartiles, adjusting for age, smoking, cryptorchidism, and andrological diseases. Separate regression analyses assessed associations between total, visceral, and leg fat mass and hormone levels.

Results: A total of 286 Finnish men provided semen samples and underwent DXA scanning; hormone levels were available in 179 men. Higher FMI quartiles were associated with lower adjusted TT and SHBG levels and higher FT percentage compared with lower quartiles (all $P < .001$). Inhibin B levels were lower in the highest versus the lowest FMI quartile ($P = .011$), and LH levels were lower in the highest versus the 3rd quartile ($P = .04$). However, calculated FT, FSH, estradiol levels, sperm concentration, total sperm count, total motility, and percentage of sperm with normal morphology did not differ across FMI quartiles. Adjusted semen volume was lower in the highest compared with the 3rd FMI quartile ($P < .001$). Standardized regression analyses demonstrated inverse associations between TT and total body fat ($\beta = -.376$; 95% CI [−2.705, −1.277]), visceral fat ($\beta = -.306$; 95% CI [−2.324, −0.876]), and leg fat ($\beta = -.319$; 95% CI [−2.439, −0.960]). Associations of total, visceral, and peripheral fat mass with all testosterone variables were similar.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Conclusions: In young men, higher adiposity was associated with lower TT, mainly due to lower SHBG levels, whereas FT and semen quality were generally unaffected. Inhibin B levels were reduced only in men with the highest adiposity. Visceral and peripheral fat mass had a similar association with TT. These findings are in line with earlier BMI- and weight-based studies.

P358 - ECE_3215 - Diffusion-generated synthetic testicular ultrasound images for AI development in male infertility assessment

Daniele Renda Livraghi[1,2], Giorgia Spaggiari[1,2,3], Antonio Granata[1,3], Carlotta Pozza[4], Marta Tenuta[4], Andrea Isidori[4], Manuela Simoni[1,2], Nicola Morelli[5], Kevin Marchesini[5], Federico Bolelli[5], Costantino Grana[5] and Daniele Santi[1,2,3]

[1]Unit of Endocrinology, Department of Medical Specialties, Azienda Ospedaliero-Universitaria of Modena, Modena, Italy; [2]Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; [3]Bentivoglio (Bologna), Italy; [4]Section of Medical Pathophysiology and Endocrinology, Department of Experimental Medicine, Sapienza University of Rome, Rome, Italy; [5]Enzo Ferrari Department of Engineering, University of Modena and Reggio Emilia, Modena, Italy

Background: Testicular ultrasound is a cornerstone of male infertility assessment, particularly considering testicular volume and parenchymal inhomogeneity as key parameters associated with spermatogenic function. However, testicular parenchymal echogenicity assessment suffers from substantial operator dependency, limiting reproducibility and standardization. Artificial intelligence (AI) approaches offer transformative potential to convert subjective ultrasound features into objective, quantitative biomarkers. Nevertheless, the development of robust AI models is severely constrained by limited availability of large, shareable testicular ultrasound datasets due to privacy regulations and data scarcity. Denoising Diffusion Probabilistic Models (DDPMs) have demonstrated remarkable success in generating high-quality synthetic medical images across multiple modalities, yet their application to testicular ultrasound remains unexplored.

Aim of the Study: To investigate DDPMs to synthesize realistic B-mode testicular ultrasound images as privacy-preserving surrogates for AI model development and validation.

Methods: Synthetic image quality was rigorously evaluated through quantitative distribution-level metrics and a clinician-driven Visual Turing Test involving endocrinologists with varying expertise levels from two clinical centres (Modena and Rome). A two-stage filtering pipeline ensured feature-space consistency and anatomical plausibility. Images utility was assessed through two downstream tasks: (i) self-supervised pretraining for binary classification of testicular parenchymal homogeneity versus inhomogeneity and (ii) training of segmentation models for testicular region delineation, with synthetic data fully replacing real images during training.

Results: Twenty-two endocrinologists were involved and all of them, irrespective to their clinical expertise, evaluated 200 testicular images. All subjects were unable to reliably distinguish synthetic from real ultrasound images (accuracy:0.493 ± 0.092, sensitivity:0.473 ± 0.127, specificity:0.511 ± 0.154, d-prime -0.037), confirming visual realism. In downstream classification tasks, self-supervised pretraining on synthetic testicular images significantly improved performance compared to training from scratch and achieved results comparable to pretraining on real ultrasound data. Segmentation models trained exclusively on synthetic images achieved Dice similarity coefficients on real test images nearly equivalent to those obtained when training on real datasets, demonstrating effective substitutability. Application of the two-stage filtering pipeline further enhanced downstream task performance, validating the importance of quality control in synthetic data generation.

Conclusions: This study provides the first evidence that diffusion-generated synthetic testicular ultrasound images are visually realistic and useful for AI model development in male reproductive medicine. Our findings demonstrate that generative AI can provide privacy-preserving, scalable surrogate datasets that enable robust development of AI tools for objective assessment of testicular parenchymal characteristics. This approach has significant implications for advancing AI-assisted reproductive endocrinology while maintaining patient privacy and overcoming data scarcity limitations inherent to specialized medical imaging domains.

Background: Emerging data have shown that the shape of the glucose response curve during oral glucose tolerance test (OGTT) provides useful insights into insulin dynamics. A monophasic shape is defined as a simple increase to a peak with a subsequent decrease, whereas the biphasic shape was defined as a rise followed by a decrease and a subsequent increase ≥4.5 mg/

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

dL after the decline in glucose. However, the impact of these patterns, if any, on the pathophysiology of PCOS has not been fully elucidated yet.

Aim of the Study: To assess the association of OGTT shape with metabolic—hormonal profile in PCOS.

Methods: Data from 1328 women with PCOS with a mean age of 27.0 and BMI 26.7 kg/m^2 were analyzed and findings are presented before and after adjustment for age, BMI and area under the curve for glycemia (AUC).

Results: 461 subjects (34.7%) demonstrated a biphasic glucose response. The prevalence of impaired glucose tolerance (IGT) was higher in the biphasic group (20% vs 15%, *P*:.015), as well as testosterone levels (2.70 vs 2.58 mmol/L, *P*:.01) while HOMA-IR values, hormonal and lipid parameters were comparable among subgroups. Biphasic group was characterized by substantially lower glucose concentrations at 30-90′ and higher 120′ glucose levels, resulting in lower total glucose exposure (AUC_{0-120}) and markedly different late-phase slopes (ΔGLU60–90 and ΔGLU90–120), after adjustment for age and BMI. After adjustment for age and BMI the biphasic OGTT pattern remained strongly associated glucose values (30-90 min) and lower AUC_{0-120}, while exhibiting higher 120-minute glucose and it was also associated with higher odds of IGT. The favorable association of a biphasic response with lower glycemia was stronger at younger ages and progressively attenuated with increasing age (*P*: .0026). Also, an inverse relationship between AUC with increasing BMI was observed. Significant association between biphasic OGTT and testosterone (*P*:.002), FAI (*P*:.036) and DHEAS (*P*:.047) levels were disclosed after adjustment for age, BMI and AUC.

Conclusions: In our cohort those with biphasic OGTT exhibited lower early and mid-phase glucose values and lower total glucose exposure, and higher prevalence of IGT. However, younger age and normal weight are associated with less glycemic load. Furthermore, biphasic OGTT even after adjustment for age, BMI, and total glucose exposure was independently associated with higher androgen bioavailability. This finding suggests a potential link between OGTT glucose dynamics and steroidogenic regulation in PCOS.

P361 - ECE_3974 - Efficacy and safety of a therapeutic humanized FSH–blocking antibody in obesity and Alzheimer's disease models

Anusha Pallapati, Funda Korkmaz, Satish Rojekar, Steven Sims, Judit Gimenez-Roig, Anisa Gumerova, Uliana Cheliadinova, Anne McDonald, Vitaly Ryu, Ofer Moldavski, Tal Frolinger, Tony Yuen and Mone Zaidi
New York, United States

There is growing evidence for direct actions of follicle–stimulating hormone (FSH) on tissues other than the ovaries and testes. Blocking FSH action, either genetically or pharmacologically, protects against bone loss, fat gain, and memory loss in mice. We thus developed a humanized FSH–blocking antibody—MS-Hu6—as a lead therapeutic for three diseases of public health magnitude—osteoporosis, obesity and Alzheimer's disease (AD) that track together in post–menopausal women. Here, we report the crystal structure of MS-Hu6 and its interaction with FSH in atomistic detail. Using our Good Laboratory Practice (GLP) platform (21CFR58), we formulated MS-Hu6 and the murine equivalent Hf2 at an ultra–high concentration; both formulated antibodies displayed enhanced thermal and colloidal stability. A single injection of ^{89}Zr–labelled MS-Hu6 revealed a β–phase $t_{½}$ of 89 and 131 hours for female and male mice, respectively, with retention in regions of interest. Female mice injected subcutaneously with Hf2 displayed a dose–dependent reduction in body weight and body fat, in the face of reduced free (bioavailable) FSH and unperturbed estrogen levels. Hf2 also rescued recognition memory and spatial learning loss in a context– and time–dependent manner in AD–prone *3xTg* and *APP/PS1* mice. MS-Hu6 injected into African green monkeys (8 mg/kg) intravenously, and then subcutaneously at monthly intervals, was safe, and without effects on vitals, blood chemistries or blood counts. There was a notable ~4% weight loss in all four monkeys after the first injection, which continued in two of four monkeys. We thus provide IND–enabling data towards an upcoming first–in–human study.

P363 - ECE_1283 - The effect of submaximal doses of semaglutide with metformin on fertility outcomes in obese PCOS patients: a prospective observational study

Tomáš Bolek[1], Ivana Ságová[2], Matej Samoš[2], Peter Tudik[2] and Marian Mokan[3]
[1]*Jessenius faculty of medicine in Martin, Commenius University in Bratislava, Martin—Jahodníky;* [2]*Department of internal medicine 1st, Martin, Slovakia;* [3]*Department of internal medicine 1st, Martin—Jahodníky, Slovakia*

Background: Obesity-associated polycystic ovary syndrome (PCOS) is strongly linked to anovulation, subfertility, and adverse metabolic and pregnancy outcomes. While lifestyle modification and metformin alone often yield limited benefits, GLP-1 receptor agonists have shown promising metabolic and endocrine effects. Evidence on fertility outcomes using submaximal doses of semaglutide in combination with metformin remains scarce.

Aim: To assess menstrual and fertility outcomes following treatment with submaximal doses of semaglutide plus metformin in obese PCOS patients with secondary amenorrhea.

Methods: This prospective observational study included 20 obese PCOS patients (age 23-42; BMI 34.8 ± 4.3 kg/m^2) with amenorrhea. Patients were treated with metformin 1000 mg/day and semaglutide at submaximal doses (0.25-0.5-1.0 mg weekly), combined with standardized lifestyle counseling. Semaglutide was discontinued 30-60 days prior to planned conception. Follow-up lasted 6-8 months. Primary outcomes were menstrual normalization and pregnancy rate. Secondary outcomes included body composition changes and gestational outcomes.

Results: Normalization of menstrual cycles occurred in all participants within 3 months. Pregnancy was achieved in 12/20 patients (60%), all spontaneous. No gestational diabetes was observed on OGTT. Mean delivery occurred at 38 ± 2 weeks. Neonatal mean birthweight was 3400 ± 600 g (all eutrophic).

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Significant improvements were observed in fat mass reduction and lean mass increase after 3 months of therapy.

Conclusions: Treatment with submaximal-dose semaglutide combined with low-dose metformin resulted in substantial menstrual recovery and a high rate of spontaneous conception in obese PCOS patients with prediabetes. Favorable pregnancy outcomes were observed despite discontinuation of therapy before conception. These findings highlight the potential of lower-dose GLP-1RA/metformin combination therapy as an effective preconception strategy in PCOS. Randomized controlled trials are needed to confirm these results.

P364 - ECE_3399 - Assessment of the performance of a routine progesterone assay using a novel high sensitivity LC-MS/MS method

Jonathan S Atkins and Brian Keevil
Department of Clinical Biochemistry, Manchester University NHS Foundation Trust, Manchester, United Kingdom

Introduction: Measurement of luteal phase serum progesterone is indicated to assess ovulatory function in female patients presenting with possible infertility. Progesterone concentrations peak 7 days following ovulation and can be measured to confirm occurrence of ovulation in patients with regular menstrual cycles. The predominant method of measuring progesterone in the UK is immunoassay. These are known to have variable performance when measuring steroid hormones due to non-specific binding of structurally similar steroids and issues liberating steroids from binding proteins for analysis to occur. Here, we aimed to develop an LC-MS/MS method to measure progesterone in serum and apply it to assess the performance of a routine immunoassay.

Methods: The method was developed on a Waters TQ-XS mass spectrometer. Calibrators and quality controls were gravimetrically prepared from separate stocks of certified reference material. The method utilised a 96-well plate format, with a progesterone-2,3,4-$^{13}C_3$ internal standard. Extraction was performed using supported liquid extraction with MTBE. Male samples ($n = 74$), were spiked with a methanolic progesterone standard to concentrations spanning the analytical range. These were analysed using the Roche Elecsys Progesterone III electrochemiluminescence immunoassay and results were compared to those produced using LC-MS/MS.

Results: Progesterone and its internal standard eluted with a symmetrical peak at 3.3 minutes. Concentrations ranging from 0.025 to 54 nmol/L could be quantitated, with concentrations up to 800 nmol/L reliably measured on dilution. The method demonstrated good recovery and minimal matrix effects. Spiked samples had concentrations ranging from 0.57 to 46.2 nmol/L. The Roche immunoassay compared well to LC-MS/MS with a slight positive bias. The Passing-Bablok fit was $y = 0.48 + 1.03x$ and Bland-Altman analysis showed a mean bias of 1 nmol/L (7.5%).

Conclusions: We present a robust and sensitive LC-MS/MS method to measure serum progesterone and its application to verify the performance of a routine progesterone immunoassay. These results suggest the Roche immunoassay performs sufficiently for assessment of ovulation in a routine setting. Our LC-MS/MS method may be applied for assessment of further routine immunoassay methods.

P365 - ECE_2464 - Pregnancy outcomes following assisted reproduction in 17-Hydroxylase/17,20-Lyase Deficiency: a micro-cohort study and pooled analysis

Haining Wang[1], Ye Liu[1], Aihua Liu[1], Rui Yang[2], Ying Wang[2] and Tianpei Hong[1]
[1]*Department of Endocrinology and Metabolism, Peking University Third Hospital, Beijing, China;* [2]*The Center for Reproductive Medicine, Peking University Third Hospital, Beijing, China*

Background: 17α-Hydroxylase deficiency (17OHD), a rare congenital adrenal hyperplasia (CAH) subtype caused by CYP17A1 pathogenic variants, impairs sex hormone and glucocorticoid synthesis in females, with concurrent mineralocorticoid excess, This leads to hypertension, hypokalemia, infertility, and other manifestations. While assisted reproductive technology (ART) enables live births in these patients, data on optimal pregnancy management, obstetric outcomes, and long-term reproductive health remain limited and fragmented.

Methods: This study combined retrospective micro-cohort analysis and systematic literature review. Eligible 17OHD patients (46,XX karyotype, confirmed diagnosis, fertility desire, clinical pregnancy, ≥1 year postpartum follow-up) received multidisciplinary treatment at our center from 2009 to 2025). A systematic literature search (updated to May 2025) identified previously reported 17OHD-associated pregnancies. Demographic, clinical, ART protocol, obstetric, neonatal, and long-term reproductive data were extracted and synthesized.

Results: Among 18 females with 17OHD followed at our center, 3 met the inclusion criteria and achieved singleton pregnancies via ART. Combined with 17 literature-retrieved cases, 20 females (median conception age: 29 years) and 23 live births were analyzed. Most (14/20) had spontaneous menarche (median age: 14 years). Key features included small uterine volume (6/11 evaluable), ovarian cysts (12/16 evaluable), and elevated follicular-phase progesterone. All pregnancies relied on IVF: 11 with long-acting GnRHa downregulation, 6 with PPOS protocol. All used frozen embryo transfer (FET), 90% (18/20) receiving pre-transfer glucocorticoids for progesterone suppression. Among 13 cases with complications, 46.2% (6/13) had gestational hypertension, diabetes, or preeclampsia. Only 25% (5/20) had term vaginal deliveries; others involved preterm birth or cesarean section. Four children with ≥1 year follow-up showed normal physical and neurodevelopment. Postpartum, menstrual irregularity and recurrent ovarian cysts persisted.

Conclusions: Females with 17OHD face notable reproductive challenges, with high obstetric complications and long-term morbidity. ART combining glucocorticoid-mediated progesterone suppression, ovarian downregulation, and FET effectively achieves live births. Meticulous multidisciplinary prenatal care is needed to reduce gestational hypertension, preeclampsia, and preterm birth risks. Long-term surveillance of menstrual and ovarian issues is crucial. Larger prospective studies are

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

required to refine guidelines and improve lifelong reproductive care.

P366 - ECE_3280 - Effect of genetic variability and plasma concentration of osteocalcin and its relationship with serum testosterone levels in men

Mariana António[1], Joana Ferreira[2,3], Mário Rui Mascarenhas[4], Manuel Bicho[2,3] and Ana Paula Barbosa[5]
[1]*Faculty of Medicine, Lisbon University, Lisbpn, Portugal;* [2]*Environmental Health Institute (ISAMB), Faculty of Medicine, University of Lisbon, Lisbon, Portugal;* [3]*Institute for Scientific Research Bento da Rocha Cabral, Lisbon, Portugal;* [4]*CEDML-Endocrinology Diabetes and Metabolism Clinic of Lisbon, Lisbon, Portugal;* [5]*Endocrinology University Clinic, Faculty of Medicine, Lisbon, Portugal*

Introduction: Bone is recognised as an endocrine organ, playing an active role in the regulation of energy metabolism and male reproductive function. Osteocalcin (OC), secreted by osteoblasts, stimulates testicular steroidogenesis through the bone–testis axis via the GPRC6A receptor in the Leydig cells. Despite evidence of this OC actions from animal models, human studies remain scarce. This study aimed to evaluate the association between serum testosterone (T) levels, metabolic and bone parameters, and the genetic variability of osteocalcin (*BGLAP*, rs1800247) and its receptor (*GPRC6A*, rs2274911) in men.

Materials and Methods: A retrospective cross-sectional study was conducted in adult men stratified into four groups according to total serum testosterone: ≤2.5; >2.5–≤3.2; >3.2–<4 and ≥4 ng/mL. Anthropometric, biochemical, hormonal and DXA bone mineral density data (QDR Discovery, Hologic) were collected. Genotyping of rs1800247 and rs2274911 was performed using endpoint genotyping. Statistical analysis included parametric and non-parametric tests, ANOVA, genetic association tests, and Pearson/Spearman correlations, with $P < .05$ considered significant.

Results: A group of 123 men, with a mean age of 57.2 years, a median weight ranging from 79.1 to 91.3 kg, and a mean height of 1.7, was studied. Statistically significant differences were observed between testosterone groups for several key parameters. The group with T ≥4 ng/mL presented higher levels of vitamin D ($P = .026$), bone alkaline phosphatase ($P = .027$), SHBG ($P = .001$), and estradiol ($P = .003$) compared to groups with lower testosterone concentrations. Conversely, groups with lower T levels showed an unfavourable metabolic profile, characterised by significantly higher total cholesterol ($P = .014$) and LDL-cholesterol ($P = .030$). Additionally, significant differences in bone densitometric parameters were observed between testosterone groups, with more favourable values in individuals with higher T concentrations ($P < .05$). Regarding genetics, no statistically significant differences were found in the distribution of rs1800247 and rs2274911 genotypes among the four testosterone groups ($P > .05$). However, relevant metabolic trends were identified: carriers of the CC genotype (rs1800247) presented lower osteocalcin levels and higher HOMA-IR values, while the GG genotype (rs2274911) was associated with higher LH and estradiol levels, suggesting compensatory mechanisms within the gonadal axis.

Conclusion: This study suggests that higher testosterone levels are associated with more favourable bone and metabolic profiles. Although osteocalcin and GPRC6A polymorphisms do not directly determine serum testosterone concentrations, the observed trends, particularly the relationship between osteocalcin and insulin resistance, reinforce the relevance of the interaction between bone metabolism, energy homeostasis, and male reproductive function.

P367 - ECE_3602 - Impact of insulin delivery modality on gonadal axis hormonal profiles in men with type 1 diabetes mellitus

Paola Girardi[1], Edoardo Vergani[1], Alessandro Oliva[1], Linda Tartaglione[1], Alessandro Rizzi[2], Dario Pitocco[1], Domenico Milardi[1], Antonio Mancini[1] and Alfredo Pontecorvi[1]
[1]*UOC Medicina Interna, Endocrinologia e Diabetologia, Fondazione Policlinico A. Gemelli, IRCCS, Rome, Italy;* [2]*Rome, Italy*

Background: In men with type 1 diabetes mellitus (T1DM), multiple daily insulin injections (MDI) generally ensure satisfactory glycaemic control; however, continuous subcutaneous insulin infusion (CSII) is required in selected patients to achieve optimal metabolic stability. Although insulin plays a key role in hepatic sex hormone-binding globulin (SHBG) regulation and androgen bioavailability, evidence regarding gonadal axis alterations in men with T1DM under different insulin delivery modalities remains scarce and inconclusive.

Objective: To assess the impact of different insulin administration strategies on the gonadal axis in male patients with T1DM.

Methods: Between 2023 and 2025, 108 male subjects aged 18-69 years were enrolled and allocated into three groups:

- patients with T1DM treated with CSII (Group A, $n = 36$);
- patients with T1DM treated with MDI (Group B, $n = 36$);
- age-matched healthy controls (Group C, $n = 36$).

Serum concentrations of SHBG, total testosterone (TT), calculated free testosterone (cFT), estradiol, luteinizing hormone (LH), and follicle-stimulating hormone (FSH) were measured.

An age-stratified analysis was performed to evaluate hormonal variations across age groups.

Results: Mean SHBG concentrations were significantly higher in the CSII group compared with both the MDI group (57.22 ± 3.16 vs 46.69 ± 2.69 nmol/L) and healthy controls (57.22 ± 3.16 vs 38.78 ± 1.98 nmol/L), although values remained within the reference range. cFT levels were comparable among the three groups, while TT and LH exhibited a non-significant trend toward higher levels in CSII-treated patients. Estradiol concentrations were significantly lower in healthy controls compared with both T1DM groups. Age-stratified analysis demonstrated a more pronounced decline in cFT among patients with T1DM, regardless of insulin delivery modality, compared with controls.

Conclusions: In men with T1DM, insulin delivery strategy is associated with distinct differences in gonadal hormonal profiles,

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

particularly SHBG concentrations. Moreover, T1DM appears to be associated with an accentuated age-related decline in free testosterone, independent of insulin administration modality. These findings suggest a complex interplay between insulin therapy, hepatic SHBG regulation, and androgen availability in T1DM.

P369 - ECE_1256 - "Risk factors for endocrine complications in sickle cell disease: a 25-year review of the impact of age, iron burden, puberty, genetics, and nutrition"

Ashraf Soliman[1], Shayma Ahmed[1], Nada Alaaraj[1], Mohamed Yassin[2], Noor Hamed[1], Fawziya Alyafei[1] and Noora Alhemaidi[1]
[1]*Hamad Medical Center, Pediatric Endocrinology, DOHA, Qatar;* [2]*Hamad Medical Center, Hematology Oncology, DOHA, Qatar*

Background: Sickle cell disease (SCD) is a chronic hemoglobinopathy with increasing survival into adulthood, revealing a substantial burden of endocrine complications. These include growth failure, delayed puberty, hypogonadism, thyroid and adrenal dysfunction, glucose abnormalities, and poor bone health. The underlying mechanisms are multifactorial and reflect the combined effects of chronic hemolysis, recurrent vaso-occlusion, inflammation, iron overload, undernutrition, and genetic heterogeneity.

Objective: To review the prevalence, patterns, and determinants of endocrine complications in SCD and assess the contribution of major risk factors including age, genotype, pubertal development, iron overload, chelation adherence, sickling frequency, and nutritional status.

Methods: A structured review of studies published between 1999 and 2024 was undertaken using PubMed and major hematology–endocrinology sources. Included studies examined endocrine outcomes in pediatric and adult SCD populations. Data on anthropometry, endocrine profiles, iron parameters, and associated risk factors were synthesized into comparative impact estimates.

Results: Endocrine complications were highly prevalent and displayed clear risk factor dependency. **Age** was a major determinant: older adolescents and adults demonstrated higher frequencies of hypogonadism, osteopenia/osteoporosis, and disordered glucose metabolism (≈40% impact). **Genotype** contributed substantially, with HbSS patients experiencing more severe and frequent endocrine abnormalities than HbSC (≈25% impact). **Pubertal delay** affected up to 45% of adolescents, with associated short stature and reduced IGF-1 levels.

Iron overload emerged as the strongest modifiable risk factor (≈50% impact). Elevated ferritin or hepatic iron concentration correlated with hypogonadism, impaired glucose tolerance, hypothyroidism, and reduced IGF-1, while **regular chelation therapy** was associated with lower rates of endocrinopathy (≈30% protective effect). **Sickling frequency**—reflected in pain crises and hospitalization rate—was linked to growth failure, adrenal insufficiency, and elevated cortisol turnover (≈35% impact).

Nutritional deficiencies, particularly vitamin D deficiency (70-85% prevalence), contributed to low bone mineral density, poor linear growth, and increased fracture risk (≈40% impact). Across studies, children with SCD consistently exhibited lower BMI, reduced lean mass, and compromised GH–IGF-1 axis activity, reflecting chronic undernutrition and systemic disease stress.

Conclusions: Endocrine complications in SCD are common, multifactorial, and strongly influenced by iron burden, pubertal status, genotype, disease severity, and nutrition. Early endocrine monitoring—especially of growth, puberty, bone health, adrenal function, and glucose metabolism—combined with optimized chelation and nutritional therapy is essential to improve long-term outcomes and quality of life.

P371 - ECE_1289 - Intergenerational effects of maternal testosterone levels and polycystic ovary syndrome on sleep duration and timing in seven-year-old children. Odense child cohort

Anne Kjær[1], Dorte Glintborg[1], Camilla Viola Palm[2], Henrik Christesen[3], Hajir Al-Jorani[1], Anders Grøntved[4] and Marianne Andersen[1]
[1]*Department of Endocrinology and Metabolism, Odense University Hospital, Odense, Denmark;* [2]*Department of Gynecology and Obstetrics, Odense University Hospital, Odense, Denmark;* [3]*Odense University Hospital, Hans Christian Andersen Children's Hospital, Odense C, Denmark;* [4]*University of Southern Denmark, Department of Sports Science and Clinical Biomechanics, Research Unit for Exercise Epidemiology, Odense, Denmark*

Background: Sleep is essential for child health and development. Prenatal testosterone exposure decreased sleep in female rodents, but not in males, suggesting sex-specific developmental sensitivity. Human studies on whether prenatal maternal testosterone or PCOS diagnosis influence sleep in offspring are lacking.

Aim: To examine whether maternal third-trimester testosterone or PCOS diagnosis, were associated with sleep outcomes in 7-year-old children.

Materials and Methods: We included 737 mother-child dyads (363 girls and 374 boys) from the Odense Child Cohort. Exposures were maternal third trimester total testosterone (TT) and free testosterone (FT), and PCOS diagnosis ($n = 81$). Sleep was assessed by 24h/7days accelerometry. Outcomes included bedtime, chronotype (midsleep time on free days), sleep period time (SPT), total sleep time (TST), and waketime. Linear regression models were adjusted for maternal age, parity, and educational level.

Results: In all children, 1 nmol/L increase in maternal TT was associated with earlier weekend bedtime, $\beta = -.06$ h, (95%CI: −0.12; −0.02), $P = .01$. In girls, 1 nmol/L increase in maternal TT was associated with earlier weekend bedtime, $\beta = -.11$ h, (95% CI: −0.19; −0.04), $P = .01$ and 0.1 nmol/L increase in FT may be associated with earlier weekend bedtime, $\beta = -3.7$ h (95% CI: −6.78; 0.69), $P = .02$. In girls, 1 nmol/L increase in TT was associated with earlier chronotype, $\beta = -.10$ h (95% CI: −0.18; −0.01), $P = .02$. In boys, no significant associations were seen. In all children, maternal PCOS was associated with earlier weekday bedtime, $\beta = -.19$ h (95% CI: −0.36; −0.02), $P = .03$ and longer SPT and TST, $\beta = .19$ h (95% CI: 0.03; 0.36), $P = .02$ and $\beta = .18$ h (95% CI: 0.03; 0.34), $P = .02$, respectively.

Conclusions: In all children, maternal TT and PCOS showed subtle associations with sleep at 7 years of age. Associations with

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

maternal testosterone exposure were more evident in girls than in boys. Future follow-up in the Odense Child Cohort may help clarify whether these early differences in sleep duration and timing persist later in childhood.

P372 - ECE_1802 - Characterization of a dihydrotestosterone-induced mouse model of polycystic ovary syndrome (PCOS) using whole-ovary 3D imaging and metabolic profiling

Line Zachariassen, Annika Runegaard Thomsen, Malene Lundgaard Riis, Susanne Pors, Marie Biviano Rosenkilde, David Ari Ostenfeldt, Jacob Lercke Skytte and Allison Butt
Gubra A/S, Hørsholm, Denmark

Background and Aim: Polycystic ovary syndrome (PCOS) affects approximately 10-15% of women of reproductive age and is a leading cause of anovulation and infertility. PCOS is frequently accompanied by hyperandrogenism, insulin resistance, and altered body composition. Androgen-induced mouse models reproduce key reproductive and metabolic features of PCOS and are widely used in translational research. However, conventional ovarian histology relies on sectional sampling and semi-quantitative estimates of follicle number and size, limiting accurate assessment of especially antral follicular dynamics. This study aimed to characterize a dihydrotestosterone (DHT)-induced mouse model of PCOS using reproductive and metabolic endpoints, using whole-ovary 3D imaging as a fully quantitative method to assess ovarian morphology.

Methods: Female C57BL/6JRj mice were implanted subcutaneously at four weeks of age with slow-releasing DHT pellets (40 µg/day) or empty implants and maintained on a Western diet. After eight weeks of androgen exposure, mice received vehicle daily injections for four weeks prior to termination to mimic pharmacotherapy. Endpoints included body weight, body composition, anogenital distance, estrous cycle monitoring, and metabolic and endocrine plasma biomarkers. At termination, ovaries were imaged ex vivo using whole-ovary 3D light sheet fluorescence microscopy (LSFM) imaging, enabling complete volumetric reconstruction. From the volumes, follicle populations were detected and quantified using deep learning-based image analysis.

Results: DHT-treated mice exhibited a rapid and sustained increase in body weight, fat and lean tissue mass and anogenital distance, confirming androgenization. Estrous cyclicity was completely disrupted, with no animals entering estrus during the monitoring period. DHT-treated mice showed impaired glycemic control with elevated fasting glucose and insulin levels. Whole-ovary 3D imaging confirmed anovulation by the absence of corpora lutea and enabled unbiased quantification of follicular populations. DHT-PCOS mice displayed a marked increase in the number of large antral follicles and thinning of the granulosa cell layer compared with controls which confirm PCOS-like ovarian morphology.

Conclusions: The DHT-induced PCOS mouse model recapitulates key reproductive, metabolic, and androgenic features of PCOS. Whole-ovary 3D LSFM imaging provides a robust, fully quantitative assessment of ovarian morphology and represents a powerful translational tool for evaluating therapeutic interventions targeting PCOS.

P373 - ECE_2421 - Lobectomy versus total thyroidectomy in intermediate-risk papillary thyroid carcinoma: rethinking surgical extent

Jungah Lim[1], Min Joo Kim[2], Seung Eun Yoo[2], Jae Hoon Moon[2], Woo-Jin Jeong[2], Wonjae Cha[2], Jeong-Yeon Ji[2], Hunjong Lim[2], Sang Il Choi[2], Hee Young Na[2], So Yeon Park[2], Ja Kyung Lee[2], Hyeong Won Yu[2], June Young Choi[2] and Ka Hee Yi[3]
[1]Department of Internal Medicine, National Medical Center, Seoul, South Korea; [2]Seoul National University Bundang Hospital, Seongnam, South Korea; [3]Seoul, South Korea

Background: Thyroid lobectomy is increasingly being performed on patients with low-risk papillary thyroid carcinoma (PTC) following the expanded guideline recommendations. However, the oncological safety of lobectomy for patients with intermediate-risk PTC remains uncertain. The present study aimed to compare recurrence-free survival (RFS) between lobectomy and total thyroidectomy in a large cohort of patients with intermediate-risk PTC.

Materials and Methods: We retrospectively reviewed patients with intermediate-risk PTC who underwent surgery at a tertiary referral center between 2016 and 2020. Propensity score matching (PSM) was performed in a 1:1 ratio based on age, sex, preoperative lymph node status, and tumor size. RFS was compared using Kaplan–Meier curves and Cox proportional hazards regression.

Results: A total of 848 matched patients were analyzed, with 424 in each group. During a mean follow-up period of 63.5 months, recurrence occurred in 2.1% of the lobectomy group and 3.8% of the total thyroidectomy group ($P = .223$). Cox proportional hazards regression analysis showed that surgical extent was not significantly associated with RFS (HR 0.75, 95% CI 0.26-2.16, $P = .594$).

Conclusions: In this large cohort study of patients with intermediate-risk PTC, lobectomy showed no significant difference in recurrence rates compared to total thyroidectomy. These results suggest that for appropriately selected intermediate-risk PTC patients, lobectomy is a safe and feasible surgical option, offering reduced surgical morbidity and preserved thyroid function without compromising oncologic outcomes.

Objective: Papillary thyroid carcinoma (PTC) is the most common subtype of thyroid cancer, with a substantial proportion being microcarcinomas (uPTCs). Currently, there is no clear strategy for their treatment. This study focused on the most frequent pathogenic variant, V600E, of the *BRAF* gene. The aim was to correlate tumor size with clinicopathological characteristics and subsequent response to treatment.

Methods: A total of 969 fresh-frozen tissue samples from primary PTC tumors were analyzed for the presence of the most prevalent genetic alterations in PTC, including *BRAF, TERT, RAS*, and 23 fusion genes (*ALK, BRAF, GLIS3, NTRK1, NTRK3, PPARG*, and *RET*). Of the total PTC cohort, 253 (26.1%) cases were uPTCs. For the correlation between tumor size and aggressiveness, only PTCs harboring the *BRAF* V600E mutation were included. Multifocal PTCs were classified as carcinomas or microcarcinomas based on the largest lesion and included in the statistical analysis accordingly. If a clinicopathological feature was present in only one lesion, it was considered valid. Samples were excluded if a genetic alteration other than *BRAF* V600E was detected even in another lesion.

Results: In uPTCs, the risks of lymph node or distant metastasis, angioinvasion, invasiveness, and extrathyroidal extension were 19.8%, 6.3%, 23.3%, and 13.4%, respectively. In PTCs larger than 10 mm (*PTCs) and uPTCs, respectively, *BRAF* mutations were detected in 439 and 148 patients, *RAS* mutations in 61 and 18 patients, *TERT* mutations in 58 and 6 patients, and fusion genes in 156 and 43 patients. Of the 515 PTCs harboring only the *BRAF* V600E mutation, 138 (26.8%) were uPTCs. The only statistically significant differences ($P \leq .05$) between *PTCs and uPTCs were angioinvasion and tumor invasiveness with higher incidence in *PTCs. No statistically significant differences were observed in tumor metastasis or extrathyroidal extension. A 24-month follow-up was available for 196 (52.0%) *PTC patients and 64 (46.4%) uPTC patients. An excellent, indeterminate, structural incomplete, and biochemical incomplete response to treatment was observed in 62.8%, 23.0%, 8.2%, and 6.1% of *PTC patients and in 71.9%, 25.0%, 1.6%, and 1.6% of uPTC patients, respectively.

Conclusions: The risk of aggressive behavior in uPTCs harboring the *BRAF* V600E mutation is not negligible. Therefore, uPTCs should be managed cautiously, and molecular testing should be incorporated into their diagnostic and therapeutic evaluation.

P376 - ECE_1960 - Enhanced formation of neutrophil extracellular traps in patients with hyperthyroidism but not in those with hypothyroidism: effects of thyroid hormone normalization

Kamila Undas[1], Joanna Natorska[2,3], Alicja Hubalewska-Dydejczyk[4] and Anetta Undas[2,3]
[1]Jagiellonian University Medical College, Kraków, Poland; [2]Department of Thromboembolic Disorders, Jagiellonian University Medical College, Institute of Cardiology, Kraków, Poland; [3]St. John Paul II Hospital, Krakow Centre for Medical Research and Technologies, Kraków, Poland; [4]Department of Endocrinology, Jagiellonian University Medical College, Kraków, Poland

Formation of neutrophil extracellular traps (NETs; so-called NETosis), released by activated neutrophils and containing DNA, histones and antimicrobial proteins, has been shown in multiple infectious, inflammatory, and prothrombic diseases. Associations of increased NETs with arterial and venous thromboembolism have been reported mainly in cardiovascular and autoimmune disorders. A well-established marker of severity of NETosis is the circulating citrullinated histone 3 (citH3). To our knowledge, formation of NETs has not been explored in thyroid disorders yet.

The aim of this study was to investigate plasma citH3 in hyper- and hypothyroid individuals before and after therapy leading to euthyroidism. Moreover, we evaluated associations of citH3 with several prothrombotic markers including plasma fibrin clot parameters.

We enrolled 31 patients with hyperthyroidism and 29 with hypothyroidism at similar age (44.80 ± 16.19 years) along with 29 sex- and age-matched controls. Apart from citH3, we evaluated thyroid-stimulating hormone (TSH), free thyroxine (FT4) and triiodothyronine (FT3) concentrations as well as fibrin clot parameters (including clot lysis time), fibrinolysis proteins, thrombin generation, and platelet activation markers, all before and after 3-month therapy leading to thyroid hormone normalization. The study protocol was approved by the Jagiellonian University Ethical Committee. Informed written consent was acquired from study participants.

Pre-treatment citH3 concentrations were higher among hyperthyroid individuals by 88% and 106% in comparison to the hypothyroid group and controls, respectively (both $P < .001$) without any difference between the latter groups. Pre-treatment citH3 concentrations were positively correlated with FT4 and FT3 ($R = 0.870$, $P < .001$ and $R = 0.709$, $P < .001$, respectively) only in the hyperthyroid group. Plasminogen activator inhibitor-1 (PAI-1) antigen was also strongly positively correlated with citH3 in the hyperthyroid group ($R = 0.538$, $P = .002$), without any associations of any prothrombotic markers, including lysis time. There were no associations of pre-treatment citH3 with any demographic, clinical, and routine laboratory investigations including inflammatory markers. A decrease in citH3 concentrations of 43% was observed following treatment among hyperthyroid patients but not in hypothyroid

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

ones ($P < .001$). No associations of citH3 with on-treatment thyroid hormones or any prothrombotic markers were found.

This study is the first to show enhanced NETs formation in hyperthyroid patients, but not hypothyroid individuals, as reflected by increased citH3 concentrations, with a significant reduction after hormone normalization. Our report suggests that NETs-related prothrombotic mechanisms could be involved in thrombotic manifestations in hyperthyroid patients. These findings increase our knowledge on the impact of hyperthyroidism on blood coagulation, in particular on PAI-1-related fibrinolysis in relation to NETosis.

P377 - ECE_2478 - Thyroid antibody testing in practice: an audit on TPO measurement requests in a tertiary hospital

Kevin Veerasamy, Laura Ryan, Erum Rasheed and Anne Marie Hannon
University Hospital Limerick, Limerick, Ireland

Thyroid peroxidase (TPO) antibodies are commonly present in individuals with Hashimoto's thyroiditis and, less frequently, in those with Graves' disease. The National Institute for Health and Care Excellence (NICE) recommends measuring TPO antibodies once in adults with elevated thyroid-stimulating hormone (TSH) levels and advises against repeat testing due to their limited diagnostic value. This audit was undertaken to evaluate TPO antibody testing practices in the Midwest region and assess compliance with established guidelines.

A retrospective review was conducted of all TPO antibody tests performed in 2023 and 2024, including corresponding thyroid function tests. Individuals under 18 years were excluded. Laboratory-specific reference ranges were used to define normal TSH and TPO values. A total of 9960 TPO antibody tests were performed on 7425 individuals with 1279 (17.2%) having repeat TPO testing. On average, TPO testing was repeated 2.6 times, with the frequency of duplicates ranging between 2 to 11 times. The majority (77%) were female, with a median age of 47 years. Most requests originated from primary care (76.3%), followed by obstetrics and gynaecology (13.8%) and secondary care (3.1%). Only 10% ($n = 1032$) of tests were associated with a TSH above 4.2 mU/L, the threshold that justifies testing. Among these, 866 had subclinical hypothyroidism and 166 had overt hypothyroidism. While appropriate TPO testing can support the diagnosis of autoimmune thyroid disease, this audit highlights a high volume of potentially unnecessary testing. These findings support the need for improved adherence to clinical guidelines to ensure appropriate and cost-effective use of thyroid antibody testing.

P378 - ECE_2680 - Association of TSH and FT4 levels with incident dementia: a population-based cohort study

Gloria Hoi-Yee Li[1], Jiawen Lu[1], Elaine Yun-Ning Cheung[2], Kathryn Choon-Beng Tan[3], Wai-Chi Chan[4] and Ching-Lung Cheung[5]
[1]*Department of Health Technology and Informatics, The Hong Kong Polytechnic University, Hung Hom, Hong Kong;* [2]*Department of Medicine and Therapeutics, The Chinese University of Hong Kong, CUHK Medical Centre, Sha Tin, Hong Kong;* [3]*Department of Medicine, The University of Hong Kong, Queen Mary Hospital, Pok Fu Lam, Hong Kong;* [4]*Department of Psychiatry, The University of Hong Kong, Queen Mary Hospital, Pokfulam, Hong Kong;* [5]*Department of Pharmacology and Pharmacy, The University of Hong Kong, Pokfulam, Hong Kong*

Introduction: Contradictory findings were reported on the relationship of thyroid-stimulating hormone (TSH) and free thyroxine (FT4) levels with risk of dementia in cross-sectional studies, or prospective studies of limited sample size or short follow-up. In this study, we aimed to evaluate the association of TSH and FT4 levels, both across the full and normal reference ranges, with risk of dementia.

Methods: We used a population-based electronic health record database from Hong Kong to identify individuals aged ≥55 with valid TSH and/or FT4 measurements between 2006 and 2009. They were followed from the date of TSH/FT4 measurement (index date) until the first diagnosis of dementia, first prescription of anti-dementia medication, death, or study end on 31 December 2019, whichever earlier. Individuals who received any thyroid-related treatment after the index date were censored. The Fine-Gray competing risk model, with death as a competing event, was used to estimate the subdistribution hazard ratio (SHR) of incident dementia per unit increase in TSH/FT4, both in full and normal reference ranges.

Results: A total of 366 300 individuals had valid TSH records (median follow-up: 7.22 years) and 135 906 had valid FT4 (median follow-up: 3.53 years) records from 2006 to 2009. TSH, as a continuous trait, was inversely associated with incident dementia in both the full (SHR = 0.946; 95% confidence interval [CI]: 0.937-0.954; $P < .001$) and normal reference ranges (SHR = 0.937; 95% CI: 0.925-0.95; $P < .001$). Compared to the 3rd quintile, individuals in the 4th and 5th quintiles of TSH had a reduced risk of dementia in both the full (4th quintile: SHR = 0.965; 95% CI: 0.933-0.998; $P = .036$; 5th quintile: 0.838; 95% CI: 0.808-0.869; $P < .001$) and normal reference range (4th quintile: SHR = 0.963; 95% CI: 0.929-0.998; $P = .036$; 5th quintile: SHR = 0.884; 95% CI: 0.852-0.917; $P < .001$). As a continuous trait, FT4 in full range was positively associated with risk of dementia (SHR = 1.007; 95% CI: 1.001-1.014; $P = .031$), but such association was not observed for FT4 within normal range. Individuals in the 1st quintile of FT4 had a lower risk of incident dementia when compared to the 3rd quintile (Full range: SHR = 0.845; 95% CI: 0.79-0.905; $P < .001$; Normal range: SHR = 0.926; 95% CI: 0.866-0.991; $P = .027$). Sensitivity analysis excluding individuals with prior thyroid-related treatment (TSH cohort: $n = 339\,916$; FT4 cohort: $n = 112\,127$) yielded similar results.

Conclusions: TSH level, even within normal reference range, was inversely associated with risk of dementia. These findings support the need to define optimal thyroid function ranges based on risk of adverse health outcomes.

P379 - ECE_2673 - Genotype–phenotype correlation of biallelic DUOX2 mutations in transient and permanent congenital hypothyroidism

Dau-Ming Niu[1,2], Yung-Hsiu Lu[1], Sheng-Bin Liang[1], Chih-Ya Cheng[1], Yun-Ru Chen[1], Yann-Jang Chen[1,2] and Chia-Feng Yang[1,2]

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

[1]Department of Pediatrics, Taipei Veterans General Hospital, Taipei Veterans General Hospital, Taipei, Taiwan; [2]National Yang Ming Chiao Tung University Yangming Campus, Beitou District, Taiwan

Background: Congenital hypothyroidism (CH) due to biallelic DUOX2 mutations shows marked clinical heterogeneity. While some patients recover thyroid function during early childhood, others require long-term levothyroxine (LT4) therapy. Predictors of thyroid function recovery remain uncertain.

Aim: To investigate whether baseline biochemical severity, thyroid morphology, bone maturation, and biallelic DUOX2 variant severity are associated with thyroid function recovery in DUOX2-related CH.

Methods: We retrospectively analyzed 71 patients with CH carrying biallelic pathogenic DUOX2 variants. Patients were categorized into three outcome groups: LT4 discontinued by age 4 years ($n = 19$), LT4 discontinued after age 4 years ($n = 25$), and continued LT4 with biochemical worsening requiring dose escalation ($n = 27$). Baseline thyroid function tests (TSH, T3, T4, free T4, thyroglobulin), thyroid volume, and bone maturation were compared across groups. Bone maturation was assessed by distal femoral epiphyseal area (DFEA) and classified as normal (DFEA ≥ 0.22 cm^2) or delayed. Genotype–phenotype relationships were examined, including clinical variability among patients with identical biallelic genotypes. Putative severe alleles were evaluated to assess variant severity.

Results: Baseline thyroid function tests did not differ significantly among outcome groups (TSH $P = .222$; T3 $P = .314$; T4 $P = .422$; free T4 $P = .505$; thyroglobulin $P = .363$). Thyroid volume ($P = .246$) and bone maturation status ($P = .238$) were also not significantly different. The distribution of putative severe DUOX2 alleles was comparable across groups ($P = .862$). Patients with identical biallelic DUOX2 genotypes were observed in different outcome categories, demonstrating divergent clinical courses including both thyroid function recovery and persistent hypothyroidism requiring ongoing LT4 therapy.

Conclusions: Baseline biochemical severity, thyroid volume, bone maturation, and inferred DUOX2 variant severity do not reliably predict thyroid function recovery in DUOX2-related CH. Substantial within-genotype heterogeneity suggests the influence of compensatory H_2O_2-generating pathways and/or additional modifying genetic or environmental factors. Further studies are needed to identify biomarkers that can guide individualized long-term management.

P381 - ECE_3918 - Clinical utility of whole-exome sequencing in the etiological diagnosis of congenital hypothyroidism and thyroid axis disorders

Josef Vcelak and Karolina Hrckulakova
Department of Molecular Endocrinology, Institute of Endocrinology, Prague, Czech Republic

Background: Neonatal screening for congenital hypothyroidism (CH) is well established across Europe and enables early initiation of treatment. However, determination of the underlying etiology remains challenging in a substantial proportion of patients. Genetic testing is crucial for precise etiological classification, differentiation between transient and permanent CH, and optimization of long-term management. Whole exome sequencing (WES) allows comprehensive analysis of coding regions of the genome and enables simultaneous detection of causative variants and additional genetic comorbidities.

Methods: WES was performed in 40 pediatric probands diagnosed with congenital hypothyroidism and associated abnormalities of the thyroid axis. Genomic DNA was extracted from peripheral blood leukocytes. In cases suggestive of autosomal recessive inheritance with potential compound heterozygosity, parental testing was conducted using trio-based analysis. All families received genetic counseling, including the option of targeted testing of siblings and first-degree relatives.

Results: A definitive or likely genetic cause of disease was identified in 16 of 40 probands, yielding a diagnostic rate of 40%. Pathogenic and likely pathogenic variants were most frequently detected in genes associated with thyroid dysgenesis (*TSHR, PAX8, NKX2-1*), thyroid dyshormonogenesis (*SLC5A5, TG, TPO, DUOX2, DUOXA2*), and thyroid hormone resistance (*THRB, THRA*). Variants in genes linked to broader endocrine or syndromic disorders were also identified (*KDM6A, POU1F1, ALB*). Genetic findings led to refinement of diagnosis, improved prognostic stratification, and informed long-term clinical management in a substantial proportion of patients.

Conclusions: Whole exome sequencing represents a highly effective diagnostic tool for elucidating the genetic basis of congenital hypothyroidism and related thyroid axis disorders. Genetic diagnosis directly informs clinical decision-making, supports individualized thyroid hormone replacement strategies, and facilitates distinction between transient and permanent forms of disease. Our data challenge the outdated perception of genetic testing as inaccessible or impractical and support its integration into routine diagnostic algorithms. Incorporation of WES into clinical guidelines for congenital hypothyroidism and other hereditary endocrinopathies has the potential to significantly improve patient care and long-term outcomes.

P382 - ECE_3010 - Total thyroidectomy in Graves' orbitopathy: impact on TRAB levels and clinical activity score—a paired cohort analysis

Gratiela Bratu[1,2], Vlad Radulescu[1,2], Medeea Moraru[1], Daniela Alexandrescu[3], Romeo Smarandache[1], Cristina Stancu[1,4], Monica Livia Gheorghiu[1,2] and Corin Badiu[1,2]
[1]National Institute of Endocrinology CI Parhon, Bucharest, Romania; [2]University of Medicine and Pharmacy Carol Davila, Bucharest, Romania; [3]Bucharest, Romania; [4]Endocrinology, National Institute of Endocrinology "C.I. Parhon", Bucharest, Romania

Introduction: Graves' ophthalmopathy (GO), a sight-threatening extrathyroidal manifestation of Graves' disease (GD), poses significant challenges in management. Apart antithyroid drugs, thyroidectomy and radioiodine represent radical treatment methods for GD. While GO is clearly worsened after radioiodine,

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

its progression following total thyroidectomy (TT) is still debated.

Patients and Methods: Review of the patient's records from a tertiary endocrine center admitted between 2015-2025 with GD, aged 18-80 years at diagnosis, who underwent TT. Inclusion criteria encompassed euthyroid status preoperatively, thyroid-stimulating hormone receptor autoantibodies (TRAb) positivity (>1.75 IU/L), and minimum 12-month follow-up. Patients with GO and steroid pulse therapy were included. This retrospective cohort study evaluates the evolution of GO post-TT in 54 GD patients, incorporating TRAb levels and standardized GO classification before and after surgery, using the European Group on Graves' Ophthalmopathy (EUGOGO) severity criteria (mild, moderate-to-severe, sight-threatening) and Clinical Activity Score (CAS). Patients with GD without GO, submitted to TT were in control group ($n = 14$).

Results: Preoperatively, 31.5%(17/54) of patients presented with mild GO (EUGOGO), 57.4% (31/54) moderate-to-severe, and 11.1% (6/54) sight-threatening, alongside elevated median TRAb levels (19.27 IU/L, range 1.0-47). CAS scores averaged 3.33 ± 1.26 (preoperative). No significant TRAB-CAS correlation existed at baseline (Spearman $r = -0.044$, $P = .751$), although some studies linked TSH receptor antibodies to orbital fibroblast activation and glycosaminoglycan synthesis. TT aimed to ablate thyroid antigen source, potentially mitigating cross-reaction autoimmunity.

Post-TT outcomes revealed GO improvement: mild 55.6% (30/54); moderate-to-severe 35.2%(19/54) and severe 9.3%(5/54). TRAB decreased at median of 5.85 IU/L ($P = .004$, 95%CI 1.93-9.77) and CAS improved 0.44 points ($P < .001$, 95%CI 0.22-0.67). Persistent TRAB predicted residual activity (TRAB_POST-CAS_POST $r = 0.369$, $P = .006$). Thyroidectomy achieves significant autoimmune and inflammatory reduction but requires TRAB-guided monitoring for progressive orbital fibrosis.

In controls ($n = 14$), TRAB levels decreased significantly from mean 17.17 ± 13.66 IU/L preoperatively to 4.51 ± 4.75 IU/L postoperatively, demonstrating a role of TT in autoimmune resolution process in GD.

Conclusions: According to our study, we demonstrated statistically significant reductions in TRAb levels and CAS scores between baseline and follow-up assessments. Limitations include retrospective design and lack of randomization. These findings indicate a meaningful improvement in disease activity and orbital inflammatory status, supporting the therapeutic efficacy of the intervention. Further studies with controlled designs and longer follow-up periods are warranted to confirm these results and assess long-term clinical outcomes.

P383 - ECE_3656 - Slightly elevated calcitonin values in unselected thyroid nodules can be safely managed over time

Giulia Lisi[1], Carla Gambale[1], Alessio Faranda[1], Alessandro Prete[1], Elisa Minaldi[1], Eleonora Molinaro[1], Gabriele Materazzi[2], Liborio Torregrossa[3], Rossella Elisei[1] and Antonio Matrone[1]

[1]*Unit of Endocrinology, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy;* [2]*Endocrine Surgery Unit, Department of Surgical, Medical and Molecular Pathology and Critical Area, University of Pisa, Pisa, Italy;* [3]*Department of Surgical, Medical, Molecular Pathology and Critical Area, University of Pisa, Pisa, Italy*

Background: Calcitonin (CTN) is the most sensitive biomarker for pre-operative diagnosis of medullary thyroid cancer (MTC). However, one of the most criticisms in routinely using this marker is the interpretation of CTN values slightly above the upper limit of the normal ranges not necessarily diagnostic of MTC. We aimed to evaluate the prevalence and the clinical meaning of cases with these CTN values.

Methods: We evaluated 13 315 consecutive patients (2017-2024) who underwent their first clinical evaluation, neck US, and CTN measurement at the Unit of Endocrinology of the University of Pisa for thyroid nodule(s). CTN was measured with CLIA assay (normal range <11.5 and 18.2 ng/L in females and males, respectively)

Results: CTN values slightly above the normal range (median 20.8 ng/L—IQR 14.7-25.5) was found in 116/13 315 (0.87%) patients. Because the CTN values would have been the only reason for surgery, we decided to monitor the trend of CTN values and keep these patients under surveillance.

In 24/116(20.7%) patients (median CTN 21.1ng/L–IQR 14.43-23.6), we did not have follow-up data and were excluded from this analysis. In the remaining 92(79.3%) patients, the median CTN value at the first evaluation was 20.8ng/L (IQR 14.7-25.5) with a median follow-up time of 15.9 months (IQR 4.7-38.8). In 48 of these 92 (52.2%) patients (group1), whose CTN median values at first examination was 17.8 ng/L (IQR 13.3-22), CTN values returned to normal values in a median follow-up of 13.6 months (IQR 2.8-28.2). Ten of these 48 (20.83%) patients showed a new slightly increase of CTN during follow-up with CTN values no different from those of the first examination.

In 44/92(47.8%) patients (group2), whose CTN median values at first examination was 23.7 ng/L (IQR 19.8-32.5), CTN persisted slightly elevated during a median follow-up of 19.4 months (IQR 6.5-7.1) Median CTN values significantly decreased during follow-up (from 23.7 to 20.25ng/L; $P = .007$), and patients were kept under surveillance. A statistically significant difference was found between patients of group1 and group2 regarding the CTN values at first examination ($P < .0001$).

Conclusions: In our series of consecutive patients with thyroid nodules, the prevalence of slightly elevated CTN was very low (0.87%) and most of these patients are still under surveillance after about two years from initial observation. Indeed, in many cases CTN spontaneously normalized or showed stable values. These findings support a relaxed approach, reserving surgery for patients with significantly higher or progressively increasing CTN levels.

Institutet, Solna, Stockholm, Sweden; [3]Department of Endocrinology, Metabolism and Diabetes, Karolinska University Hospital, Stockholm, Sweden; [4]Region Värmland, Center for Clinical Research, Karlstad, Sweden

Background: Autoimmune diseases (ADs) often co-occur within individuals and families, suggesting shared genetic risk factors. However, the extent to which genetic contributions overlap across the autoimmune spectrum remains unclear.

Methods: This register-based nationwide sibling study included all Swedish individuals born between 1932 and 1983. Participants were identified through the Swedish Total Population Register, with the Multi-Generation Register used to identify full sibling pairs. The occurrence of 22 ADs was determined using diagnostic records in the National Patient Register and prescription data in the Prescribed Drug Register from 1969 to 2013. Pairwise genetic correlations of ADs were estimated based on sibling recurrence patterns. Network analysis and principal component analysis were used to explore the genetic interconnections of ADs.

Results: A total of 3 839 400 full-sibling pairs were identified in a cohort of 6 336 615 individuals, of whom 706 107 (11.1%) had at least one AD. In all, 802 335 AD-cases were recorded. The studied ADs formed a network of significant genetic correlations (mean $r_g = 0.23$) with clusters of more closely related ADs ($r_g \geq 0.3$). We found no evidence of a universal factor predisposing to autoimmunity.

Conclusions: This study demonstrates that ADs share substantial cluster-specific genetic overlap that largely aligns with affected tissue types, leading to distinct groupings of connective tissue diseases, gastrointestinal disorders, and endocrinopathies. This suggests that shared biological mechanisms may drive coaggregation within disease groups. Clinically, these insights highlight the importance of monitoring patients and their relatives for related autoimmune disorders.

P385 - ECE_2762 - Evaluation of the management of incidentally detected thyroid nodules prior to solid organ transplantation

Deniz Türküm Atikcan, Ekin Reyhan, Nihan Bakirtas, Uygar Ozkan, Hazım Cankaya, Parham Piltan, Shaheer Maaz, Ozlem Turhan Iyidir and Neslihan Başçıl Tütüncü
Istanbul, Türkiye

Introduction: The increasing use of cross-sectional imaging has led to more frequent incidental detection of thyroid nodules, particularly among solid organ transplant candidates undergoing extensive pre-transplant evaluation. In this population, the presence of a thyroid nodule may raise concerns regarding malignancy and potentially influence transplant eligibility or timing. However, current thyroid nodule management guidelines are based on the general population and do not offer transplant-specific recommendations. As a result, transplant candidates may be subjected to lower biopsy thresholds and more aggressive diagnostic approaches, increasing the risk of unnecessary procedures and delays in transplantation. Determining whether incidentally detected thyroid nodules in transplant candidates differ in ultrasonographic features, cytological findings, or malignancy risk compared with non-transplant patients is therefore essential to support appropriate and evidence-based clinical management.

Materials and Methods: This retrospective cohort study included 116 adult solid organ transplant candidates with incidentally detected thyroid nodules identified during routine pre-transplant imaging between January 2020 and December 2024. A control group of 135 age- and sex-matched patients with incidentally detected thyroid nodules unrelated to transplantation was also analyzed. Thyroid ultrasound examinations were reviewed for nodule size, echogenicity, margins, calcifications, vascularity patterns, and TI-RADS categories. FNAB indications followed standard ultrasonographic and clinical criteria. Cytological results were classified according to the Bethesda system, and histopathological findings were recorded for patients who underwent thyroid surgery.

Results: A total of 350 thyroid nodules were evaluated, including 172 nodules in transplant candidates and 178 nodules in the control group. Median nodule size was significantly smaller in transplant candidates compared with controls (10 mm vs 15 mm, $P < .001$). Vascularity patterns differed significantly between groups ($P = .003$), whereas echogenicity, margins, calcifications, and TI-RADS categories were similar. FNAB cytology distributions did not differ significantly between groups. Malignant or suspicious cytology was observed in 4.7% of nodules in transplant candidates and 7.3% in controls (Table 1). Rates of thyroidectomy and final histopathological malignancy were comparable.

Conclusions: Incidentally detected thyroid nodules in solid organ transplant candidates demonstrate ultrasonographic, cytological, and histopathological characteristics similar to those observed in non-transplant patients. These findings support the use of standard FNAB criteria for risk stratification in transplant candidates and highlight the need to avoid unnecessary invasive procedures that may delay transplantation.

P388 - ECE_3395 - The cytology of focal thyoid lesion classified as atypia of undetermined significance in fine-needle aspiration biopsy

Magdalena Turowska[1,2], Maria Szmigielska[1,2], Bernadetta Kałuża[1,2], Małgorzata Kołos[3] and Edward Franek[1,2,4]
[1]Warsaw, Poland; [2]Department of Internal Medicine, Endocrinology and Diabetology, National Medical Institute of the Ministry of the Interior and Administration in Warsaw, Warsaw, Poland; [3]Pathomorphology Centre, National Medical Institute of the Ministry of the Interior and Administration in Warsaw, Warsaw, Poland; [4]Department of Human Epigenetics, National Medical Institute of the Ministry of the Interior and Administration in Warsaw, Warsaw, Poland

Background: The Bethesda system is used to categorize fine-needle aspiration biopsy (FNAB) results of focal thyroid lesions. Bethesda category III comprises a heterogeneous group of lesions, including such subcategories as atypia of undetermined significance (AUS), follicular lesion of

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

undetermined significance (FLUS), cellular and architectural atypia (AUS/FLUS), Hurthle cell atypia (AUS and/or FLUS), and indeterminate atypia. The aim of this study was to characterize the focal lesions of the thyroid sampled via ultrasound-guided FNAB and classified as AUS.

Materials and Methods: For the purpose of this study, we reviewed the hospital database from the years 2023-2025 and, out of all ultrasound-guided FNAB, selected Bethesda category III samples ($n = 107$), and divided them into two groups: FLUS ($n = 65$) and AUS ($n = 42$).

Results: The compared groups differed in terms of the following parameters: groups of normal thyrocytes (78.46 vs 50.00%, $P = .002$), sheets of normal-type thyrocytes (50.77 vs 30.95%, $P = .04$), scattered thyrocytes (55.38 vs 30.95%, $P = .01$), small follicular structures (56.92 vs 2.38%, $P = .001$), microfollicular structures (30.77 vs 4.76%, $P = .001$), colloid (84.62 vs 47.62%, $P = .001$), oxyphilic metaplasia (27.69 vs 57.14%, $P = .002$), nuclear grooves (1.5 vs 11.9%, $P = .02$), anisocytosis (15.38 vs 50.0%, $P = .0001$), anisonucleosis (10.77 vs 40.48%, $P = .001$); however, they did not differ in terms of such parameters as macrofollicular structures (4.62 vs 0%, $P = .16$), nuclear enlargement (12.31 vs 4.76%, $P = .19$), hyperplasia (32.31 vs 23.81%, $P = .34$), nucleolar prominence (9.23 vs 11.9%, $P = .66$). Univariate logistic regression analysis indicated that the factors increasing the risk of AUS development include oxyphilic metaplasia (OR 3.481 [1.537-7.887], $P = .003$), anisocytosis (OR 5.5 [2.224-13.602], $P = .001$), and anisonucleosis (OR 5.634 [2.078-15.275], $P = .001$), whereas the factors increasing the risk of FLUS were normal-thyrocyte groups (OR 3.643 [1.563-8.488], $P = .003$) or sheets (OR 2.3 [1.018-5.198], $P = .045$), normal-type thyrocytes, and scattered normal thyrocytes (OR 2.769 [1.224-6.267], $P = .015$), small-follicular (OR 54.179 [7.019-418.171], $P = .0001$) and microfollicular structures (OR 8.889 [1.954-40.427], $P = .005$), and colloid (OR 6.05 [2.445-14.969], $P = .0001$).

Conclusions: Bethesda category III in ultrasound-guided FNAB of the thyroid is heterogenous, with numerous features, among which oxyphilic metaplasia, anisocytosis, and anisonucleosis best characterize the AUS subtype.

P389 - ECE_3639 - Associations between kallistatin and lipid parameters in Hashimoto's thyroiditis

Sára Bak-Csiha[1,2,3], István Molnár[2,3], Hajnalka Lőrincz[4], Anna Somogyi[2,3], Mónika Katkó[1], Mariann Harangi[3,4], Gyorgy Paragh[4], Endre Nagy[1], Miklos Bodor[1,2] and Eszter Berta[2,4]

[1]Division of Endocrinology, Department of Medicine, Faculty of Medicine, University of Debrecen, Debrecen, Hungary; [2]Department of Clinical Basics, Faculty of Pharmacy, University of Debrecen, Debrecen, Hungary; [3]University of Debrecen, Doctoral School of Health Sciences, Debrecen, Hungary; [4]Faculty of Medicine, Division of Metabolism, Department of Medicine, University of Debrecen, Debrecen, Hungary

Chronic lymphocytic thyroiditis, also called Hashimoto's thyroiditis, is a form of autoimmune thyroid disease with hypothyroidism. Hypothyroidism is known to induce atherogenic alterations in lipid metabolism; however, the effects of autoimmune inflammatory processes on atherosclerosis are not fully understood.

Kallistatin belongs to the superfamily of endogenous serine protease inhibitors and has multiple biological functions, including antioxidant, anti-inflammatory, and anti-atherosclerotic effects. Although disturbances in thyroid function are known to increase cardiovascular risk, the potential role of kallistatin in this process, has not yet been investigated.

We examined the associations between serum kallistatin levels, thyroid function, and lipid parameters in HT patients [$n = 88$; 82 women and 6 men; age: 45 ± 14 years; BMI: 25.4 (23.6-31.6)] recruited from the Endocrinology Outpatient Clinic of the Internal Medicine Clinic, University of Debrecen, and in healthy controls [$n = 86$; 80 women and 6 men; age: 46 ± 14 years; BMI: 26.3 (22.3-30)].

Kallistatin levels were significantly higher in the patient group compared to controls (7495 vs 6140 ng/mL; $P < .0001$). Furthermore, patients exhibited higher median TSH and fT4 levels (2.81 vs 1.82 mU/L;$P < .005$ and 17.6 vs 15.4 pmol/L;$P < .0001$), while their fT3 levels were lower (4.6 vs 5.0 pmol/L;$P < .0001$) compared with controls.

In the patient cohort, disease duration also showed a significant negative correlation with kallistatin levels ($r = -0.2908$; $P = .0255$). Additionally, positive correlations were detected between kallistatin and non-HDL-C ($r = 0.2724$; $P = .0107$), ApoB ($r = 0.3209$; $P = .0027$), log PAI-1 ($r = 0.2606$; $P = .0142$), and the FGF21/adiponectin ratio ($r = 0.2302$; $P = .0310$).

Our findings suggest that kallistatin is closely associated with lipid metabolism and levels of atherogenic lipids. Based on these results, kallistatin may play a role in modulating the lipid profile, and its levels could potentially serve as a biomarker for evaluating cardiometabolic risk in patients with Hashimoto's thyroiditis.

P390 - ECE_1526 - Predictors of malignancy and false-negative risk in large (≥3 cm) thyroid nodules: insights from a single-center cohort

Ömer Komaç, Elif Bilgili, Merve Yetişken, Deniz Çetin, Nesibe Kahraman Çetin, Ogün Aydoğan, Göksel Tuzcu, İmran Kurt Ömürlü, Mustafa Unubol, Mustafa Gökhan Ünsal and Engin Güney

Kocaeli, Türkiye

Background: In everyday clinical practice—particularly along non-tertiary referral pathways—large thyroid nodules are frequently perceived as inherently "high risk," often prompting early surgical referral before structured ultrasound-based risk assessment or fine-needle aspiration biopsy (FNAB). This size-driven perception persists despite guideline recommendations and may lead to avoidable surgery. We aimed to clarify how often malignancy is actually present in nodules ≥3 cm, which features meaningfully stratify risk beyond size, when benign cytology is sufficiently reassuring, and whether tumour behaviour changes as nodules enlarge.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Methods: We retrospectively analyzed 285 consecutive thyroidectomy patients (2018-2024) with a dominant thyroid nodule ≥3 cm (one patient = one analytic unit). EU-TIRADS category and suspicious cervical lymphadenopathy (LAP) were recorded from preoperative ultrasound when available ($n = 261$). FNAB was recoded by Bethesda. Primary outcomes were dominant-nodule malignancy and false-negative (FN) benign cytology (malignancy on final histology despite Bethesda II in the sampled dominant nodule; incidental microcarcinomas in non-dominant foci were excluded). Multivariable logistic regression identified independent predictors.

Results: Dominant-nodule malignancy was 13.3% (38/285), predominantly papillary thyroid carcinoma, indicating that large size alone does not confer a high cancer probability. Malignancy demonstrated a marked ultrasound risk gradient (EU-TIRADS TR3 3.6%, TR4 25.3%, TR5 64.3%). Independent predictors were TR4–5 (OR 7.59) and suspicious LAP (OR 5.97), with additional effects of solid composition (OR 3.34) and size ≥4 cm (OR 2.62). Thus, size contributed to risk only in conjunction with adverse imaging features.

Among 111 Bethesda II nodules, the overall FN rate was 4.5% (5/111); importantly, all FN events occurred in nodules ≥4 cm (7.5% vs 0% in 3-4 cm; $P = .023$). FN cases frequently showed cystic or infiltrative patterns, consistent with sampling limitations in heterogeneous large nodules. With increasing nodule size, we also observed a broader malignant histologic spectrum, including a notable proportion of aggressive thyroid cancers (~21% of malignancies; lymphomas excluded), suggesting that tumour behaviour—not only prevalence—may shift as nodules enlarge.

Conclusions: Large size alone should not mandate surgery. In nodules ≥3 cm, malignancy risk is best defined by EU-TIRADS category, nodal status, and internal composition rather than diameter in isolation. A benign FNAB is generally reassuring in 3-4 cm nodules, whereas ≥4 cm nodules—particularly those with TR4–5 patterns, solid structure, or suspicious LAP—require careful risk stratification, repeat or targeted FNAB, core biopsy, and avoidance of purely size-driven surgical decisions.

Baggiovara Hospital, Department of Biomedical, Metabolic and Neural Sciences, Modena, Italy*

Human chorionic gonadotropin (hCG) has high structural identity with thyrotropin (TSH), and may cross-activate TSH receptor (TSHR), sustaining thyroid hormone production during pregnancy. hCG shares the same receptor (LHCGR) of the luteinizing hormone (LH), which mediates gametogenesis although it is unclear if it may bind TSHR as well. Therefore, we compared the effects of hCG and LH on TSHR-mediated pathways.

Transfected COS7 cells overexpressing human TSHR were exposed to increasing (nM-μM range) LH and hCG concentrations *in vitro*, before to explore the activation of Gs and Gq protein-related pathways. Intracellular cyclic adenosine monophosphate (cAMP) and inositol monophosphate (IP1) levels were measured by homogeneous time-resolved fluorescence (HTRF). cAMP response element (*CRE*)-dependent transcriptional activity was assessed using a luciferase reporter assay. Cells treated with 300 nM TSH served as a positive control, while human thyroid organoids were used to confirm the effects of hCG on native tissues. All experiments were run in quadruplicate ($n = 4$) and statistical analyses were performed by Kruskal-Wallis test and Dunn's post hoc comparisons ($P < .05$).

1 μM hCG induced significant increase of intracellular cAMP levels, confirmed by the activation of *CRE*-dependent activity. These data are consistent with hCG-dependent activation of the TSHR/Gs pathway. Surprisingly, sub-μM LH doses did not induce cAMP accumulation and *CRE* activation, which were even inhibited by 1 μM LH. Neither hCG nor LH increased intracellular IP1 levels, although 1 μM LH (but not hCG) resulted in the reduction of TSH-induced IP1 accumulation when the two hormones were co-administered to cells. These results indicated LH-dependent inhibitory activity of TSHR-mediated Gq pathway. hCG-specific effects were confirmed in thyroid organoids, where the hCG supported sample viability and preserved its cAMP responsiveness to TSH. These findings demonstrate that hCG selectively cross-activates TSHR-dependent cAMP/*CRE* signals and thyroid tissue responsiveness, consistent with its role in gestation. LH behaves as a TSHR antagonist, negatively modulating both Gs and Gq pathways.

Previous studies demonstrated that LH and hCG elicit different LHCGR-mediated signaling pathways. Therefore, this study strengthens the concept of different LH vs hCG signaling and proposes TSHR as a new partner receptor for gonadotropins, opening to new mechanisms regulating thyroid pathophysiology.

Background: Medullary thyroid carcinoma (MTC) is a malignancy originating from parafollicular-C cells and characterized by

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

calcitonin (CT) secretion. Although basal calcitonin(bCT) levels have high sensitivity, mildly elevated CT levels may lead to diagnostic uncertainty. Since CT secreted by C cells is expected to rise in response to calcium stimulation, we aimed to assess the diagnostic value of the calcium stimulation test in patients with mildly CT levels who underwent surgery.

Methods: Forty-two patients with nodular thyroid disease and mildly elevated serum CT levels who underwent thyroidectomy were included in this study. None of the patients had any chronic disease known to cause elevated calcitonin. bCT and calcium-stimulated CT(casCT) levels were measured preoperative in all patients. CT reference values were considered positive at >6.4pg/mL for women and >9.5pg/mL for men. Given the known sex-releated differences in CT reference values, bCT and casCT levels were normalized by calculating the fold increase compared to the upper limit of normal(ULN). bCT and casCT levels were evaluated in relation to postoperative pathology for assessing diagnostic value.

Results: Among the 42 patients (19F/23M) with a mean age of 48 ± 12 years included in the study, MTC was diagnosed in 23.8% (6F/4M), while 76.2% (13F/19M) had non-MTC pathology. There were no significant differences between the groups in terms of age, sex, autoimmune thyroid disease, smoking or ppı use($P > .05$). Median bCT levels were significantly higher in the MTC group (20pg/mL;range 11-98) than non-MTC group (13pg/mL; range 9-57)($P = .048$). Similarly, the fold increase in bCT relative to the reference value was significantly higher in patients with MTC(2.75-fold;range 1.19-15.31) compared with the non-MTC group (1.57-fold;range 1.05-8.91)($P = .045$). Median casCT levels were significantly higher in the MTC group (631.5pg/mL;range 164-1820) than non-MTC group(213pg/mL;range 31-855)($P = .020$). The fold increase in casCT relative to the reference value was also significantly higher in patients with MTC (66.33-fold;range 25.63-284.38)compared with the non-MTC group(29.24-fold;range 4.84-97.66)($P = .017$). ROC analysis showed that casCT cut-off of 37.4×ULN provided 70% sensitivity and 66% specificity for MTC diagnosis (AUC = 0.748, 95% Cl:0.582-0.915;$P = .019$).

Conclusions: Both bCT and casCT levels, as well as their fold increases relative to reference values, are significantly higher in patients with MTC. CasCT, particularly when expressed as multiples of the ULN, provides additional diagnostic value in patients with mildly elevated CT levels. A casCT cutoff of 37.4×ULN offers an acceptable balance between sensitivity and specificity for identifying MTC, although validation in larger prospective studies is warranted.

P395 - ECE_1206 - Impact of subclinical hypothyroidism on renal outcomes: a systematic review and meta-analysis

Paolo Augusto Romero Merino[1], Carlos Valladares[2], Stefanni Vivanco[3], Jenny Zablah[4], Brigida Tueros[5], Rommel Portilla[6], Sebastian Vega[7] and Jia Chia[8]

[1]*Hospital Clinico Universitario of Valladolid, Valladolid, Spain;* [2]*University of Miami Miller School of Medicine, Miami, United States;* [3]*Universidad de San Martin de Porres, Lima, Peru;* [4]*Universidad Tecnológica Centroamericana, Tegucigalpa, Honduras;* [5]*Universidad Nacional Federico Villareal, Lima, Peru;* [6]*Universidad de las Américas, Quito, Ecuador;* [7]*Universidad Peruana Cayetano Heredia, Lima, Peru;* [8]*Texas Tech University Health Science Center, El paso, Texas, United States*

Background: Subclinical hypothyroidism (SCH), characterized by elevated serum TSH with preserved free thyroxine levels, is frequently identified in adult populations and has been suggested as a potential contributor to impaired renal function. Nevertheless, the strength and consistency of the association between SCH and the development of chronic kidney disease (CKD) remain unclear.

Methods: We carried out a systematic review and meta-analysis following PRISMA 2020 recommendations. A comprehensive search of major electronic databases identified observational studies that reported incident CKD among individuals with SCH. Five studies fulfilled the inclusion criteria, collectively encompassing more than 4 million participants. Random-effects models were used to estimate pooled risk ratios (RR). The quality and risk of bias of the included studies were assessed using the ROBINS-I tool.

Results: Across the pooled analysis, SCH was associated with a higher likelihood of developing CKD (RR 1.19; 95% CI 1.10-1.29). Heterogeneity across studies was moderate ($I^2 = 48.9\%$). Multiple sensitivity analyses, including exclusion of high-risk studies and alternative SCH definitions, showed consistent results, reinforcing the stability of the observed association. Evaluation of funnel plot symmetry did not reveal meaningful publication bias.

Conclusions: Individuals with SCH exhibit a modest but significant increase in the risk of incident CKD. These findings support the relevance of thyroid function abnormalities in renal risk profiling and raise the possibility that earlier recognition or intervention in SCH could influence long-term kidney outcomes. Future prospective studies and interventional trials are needed to clarify whether managing SCH may prevent or delay CKD progression.

P396 - ECE_1610 - Batoclimab induces very rapid and sustained post-treatment euthyroidism in Graves' disease

George Kahaly[1], Jan Wolf[1], Anna-Lena Ganz[1], Maximilian Luffy[1], Katherine Albert[2], Farah Ali[2], E Lin[2] and William Maclas[2]

[1]*Department of Medicine I, Johannes Gutenberg University Medical Center, Mainz, Germany;* [2]*Immunovant, Inc., New York, NY, United States*

Objective: To report post-treatment outcomes among hyperthyroid patients with Graves' disease (GD) who received batoclimab, a neonatal fragment crystallizable receptor blocker, in a phase 2a, proof-of-concept open-label study.

Methods: Overtly hyperthyroid GD participants with elevated thyrotropin receptor autoantibodies (TRAb) despite ≥12 weeks on moderate-to-high dose antithyroid drugs (ATD) received weekly subcutaneous injections of batoclimab for 24 weeks (Weeks 0-11,

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

680 mg; Weeks 12-23, 340 mg). At Week 24, participants with FT3/FT4 at or below the upper limit of normal (ULN) entered a 24-week treatment-free follow-up period (Weeks 24-48).

Results: By Week 2, 15/25 (60%) patients achieved FT3/FT4 levels at or below ULN without increasing their ATD dose; this increased to 20/25 (80%) patients at Week 12 or end of high-dose treatment, including 15 (60%) who were off ATD. At Week 24 or end of treatment (EOT), 18 (72%) patients had FT3/FT4 ≤ULN without increasing their ATD dose, including 10 (40%) who were off ATD. Six months following EOT, 17/25 (68%) patients had FT3/FT4 ≤ULN; of these, 8 were off ATD and 5 were on ≤2.5 mg ATD/day only. Mean (SD) TSH increased from 0.01 (0.01) mIU/L at baseline to 0.32 (0.61) mIU/L and 0.77 (0.85) mIU/L at Weeks 24 and 48, respectively. Patients who were off ATD 24 weeks after EOT had a mean (SD) TSH of 0.55 (0.47) mIU/L and low TRAb (<2xULN) at EOT/Week 24. Mean (SD) TRAb levels rapidly decreased from 17.96 (12.12) IU/L at baseline to 8.13 (8.82) IU/L, 6.16 (8.85) IU/L, and 9.94 (12.03) IU/L at Weeks 2, 24, and 48, respectively ($P < .0001$ vs baseline for all). Total IgG rebounded after treatment stopped, with a mean (SD) level of 11.72 (2.64) g/L at baseline compared with 4.10 (1.76) g/L at Week 24 ($P < .001$) and 11.14 (2.78) g/L at Week 48 ($P = .42$). In patients with eye signs/symptoms at baseline (20/25), EOT improvements in proptosis and Clinical Activity Score were sustained at Week 48. Batoclimab was well tolerated with no new safety signals observed.

Conclusions: Batoclimab resulted in very rapid and sustained normalization of FT3/FT4. Six months after stopping treatment, 52% of patients remained euthyroid either off ATD or on ≤2.5 mg ATD/day.

P397 - ECE_2810 - The impact of severe overt primary hypothyroidism on outcomes of hospitalized patients with bacteremia

Dor Eldar[1], Naftali Gross[2], Meir Frankel[1], Eli Ben-Chetrit[3], Noa Sylvetsky[1], Gavriel Lichewitz[3], Michal Manovich[1] and Gabriel Munter[1]

[1]*Shaare Zedek Medical Center, Hebrew University School of Medicine, Endocrinology, Diabetes & Metabolism Unit, Jerusalem, Israel;* [2]*Jerusalem, Israel;* [3]*Shaare Zedek Medical Center, Hebrew University School of Medicine, Endocrinology, Diabetes & Metabolism Unit, Jerusalem, Israel*

Background: Thyroid dysfunction is common among hospitalized patients and may adversely influence clinical outcomes during acute illness. This study evaluated whether severe overt primary hypothyroidism at admission is associated with worse outcomes among inpatients with blood culture proven bacteremia.

Methods: A retrospective cohort study was conducted at Shaare Zedek Medical Center (Jerusalem, Israel) between the years 2000 and 2024. Adult inpatients (≥18 years) with a history of hypothyroidism or levothyroxine use, and available thyroid function tests (TFTs) at admission were included. At our center, TSH is routinely measured for all hospitalized patients on admission. Hypothyroidism was defined by documented diagnosis, chronic levothyroxine use, or TSH > 20 mU/L. Uncontrolled hypothyroidism was defined as TSH > 10 mU/L. Primary outcomes included, among others, in-hospital mortality, and length of stay (LOS)

Results: Among 1756 patients (mean age 82.4 ± 11.8 years; 72.4% female), in-hospital mortality increased progressively with higher TSH levels: 14% for TSH 0.35-5 mU/L, 19.3% for TSH 5-10 mU/L, 22.9% for TSH 10-20 mU/L, and 32.7% for TSH > 20 mU/L. Adjusted Cox regression demonstrated that TSH > 20 mU/L was independently associated with mortality (HR 1.89, 95% CI 1.28-2.79, $P = .001$). A continuous TSH model confirmed an incremental risk (HR 1.02 per 1 mU/L TSH increase, $P < .001$). Additional independent correlates of mortality included older age (HR 1.05, $P < .001$), female sex (HR 1.35, $P = .037$), and vasopressor use (HR 1.77, $P < .001$), whereas higher albumin levels were significantly protective (HR 0.54, $P < .001$). Median LOS also increased with higher TSH: 8.0 days (IQR 5.0-16.0) for TSH 0.35-5 mU/L, 8.5 days (IQR 6.0-17.0) for TSH 5-10 mU/L, 11.0 days (IQR 6.0-26.0) for TSH 10-20 mU/L, and 13.0 days (IQR 7.0-21.25) for TSH > 20 mU/L.

Conclusions: Uncontrolled hypothyroidism, particularly TSH > 20 mU/L, is an independent predictor of higher in-hospital mortality and is associated with prolonged hospitalization among patients with bacteremia. These findings suggest that thyroid status serves as a significant prognostic marker in this high-risk population and warrant further prospective studies to evaluate targeted management strategies.

P400 - ECE_3966 - Treatment with intramuscular levothyroxine in refractory hypothyroidism: a case report

Ana Luísa Barbosa, Mafalda Canudas Costa, Marta Borges Canha, Sandra Belo and Joana Queirós

Department of Endocrinology, Diabetes and Metabolism, São João Local Health Unit, Porto, Portugal

Background: Oral levothyroxine is the standard treatment for hypothyroidism, with most patients achieving stable hormone levels. When standard therapy is ineffective and doses exceeding 1.9 μg/kg/day are required, the differential diagnosis includes levothyroxine malabsorption and pseudomalabsorption (nonadherence to therapy), and alternative approaches, including injectable levothyroxine, can be considered.

Case Report: We present a 66-year-old woman with a history of hypothyroidism following total thyroidectomy eleven years earlier for a follicular neoplasm, on oral levothyroxine therapy. Due to persistent hypothyroidism despite escalating doses of oral levothyroxine (up to 2.6μg/kg/day), she was referred to the Endocrinology clinic. Laboratory evaluation did not reveal signs of malabsorption, with normal haemoglobin, albumin, ferritin, vitamin B12 and folic acid, negative antibodies for celiac disease and autoimmune gastritis and a negative urea breath test for Helicobacter pylori infection. Due to suspected nonadherence, she was treated with oral levothyroxine twice weekly under supervision at her local health centre, with the dose escalated up to 4000μg/week. Nevertheless, hypothyroidism persisted with worsening biochemical parameters (thyroid-stimulating hormone [TSH] >100 [0.35-4.94] μUI/mL, low free thyroxine [FT4] 0.42 [0.70-1.48] ng/dL) and clinical manifestations including fatigue, brain fog, hair loss and peripheral and periorbital edema. She was admitted to the Endocrinology ward and treated with intravenous levothyroxine (100-150μg/day) for fourteen days,

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

resulting in normalization of thyroid function. Subsequently, a levothyroxine absorption test performed after an overnight fast, with supervised intake of 1600μg of levothyroxine, showed peak elevation of FT4 two hours after ingestion (from 1.01 ng/dL to 1.72ng/dL, representing an increase of more than 0.4ng/dL), with a concomitant decrease in TSH (from 7.13μUI/mL to 3.07μUI/mL), thereby ruling out levothyroxine malabsorption. The patient was discharged on 1800μg of oral levothyroxine twice weekly under supervision at her local health centre. Laboratory evaluation performed four months later showed TSH 53μUI/mL and FT4 0.64ng/dL. Treatment with weekly intramuscular levothyroxine (800μg), administered at her local health centre, was initiated, resulting in normalization of thyroid function after one month (TSH 2.99μUI/mL, FT4 1.36ng/dL).

Discussion: This case illustrates the challenges in managing refractory hypothyroidism and demonstrates that intramuscular levothyroxine can be an effective alternative in such situations. It highlights the importance of an individualized approach, considering all therapeutic options to achieve adequate thyroid hormone control and prevent progression to severe disease.

P401 - ECE_1443 - Refining ACR TI-RADS risk stratification with strain elastography: reducing unnecessary fine-needle aspirations in thyroid nodules

Nicholas Angelopoulos[1], Dimitrios Goulis[1], Ioannis Chrisogonidis[1], Ioannis Iakovou[1] and Fraklin Tessler[2]
[1]*Aristotle University of Thessaloniki, AHEPA Hospital, Nuclear Medicine, Thessaloniki, Greece;* [2]*Department of Radiology, University of Alabama at Birmingham, Birmingham, United States*

Background: The American College of Radiology Thyroid Imaging Reporting and Data System (ACR TI-RADS) relies exclusively on grayscale ultrasonography (US) for malignancy risk stratification, without incorporating clinical variables or adjunctive imaging modalities. Despite its effectiveness, a substantial number of benign thyroid nodules still undergo unnecessary fine-needle aspiration (FNA), particularly in low- and intermediate-risk categories.

Objective: To evaluate whether the integration of strain elastography, color Doppler ultrasonography (CDUS), and selected clinical parameters improves malignancy risk stratification and optimizes FNA utilization beyond current ACR TI-RADS recommendations.

Methods: In this prospective study, 556 adults with thyroid nodules ≥10 mm who met ACR TI-RADS criteria for FNA were enrolled between May 2023 and April 2025. All nodules underwent standardized B-mode US, CDUS, and strain elastography. A semi-quantitative elastography ratio (ER) was calculated as the ratio of nodule stiffness to the adjacent sternocleidomastoid muscle. Cytological results were classified using the Bethesda System, with histopathology serving as the reference standard when surgery was performed. Receiver operating characteristic (ROC) analyses were conducted to determine optimal ER thresholds overall and within each ACR TI-RADS category.

Results: Among the 556 nodules evaluated, 55 papillary thyroid carcinomas were identified. Overall, elastography demonstrated good diagnostic performance for malignancy prediction (AUC 0.886). When analyzed by ACR TI-RADS category, ER showed excellent discriminatory ability in TI-RADS 3 nodules (AUC 0.994), with an optimal threshold of ER >1.60 achieving 100% sensitivity and 99.4% specificity. Category-specific ER thresholds (>1.60 for TI-RADS 3, >0.44 for TI-RADS 4, and >0.54 for TI-RADS 5) allowed a reduction in FNAs from 501 to 260 (48%) without missing any malignant cases. Elastography provided the greatest additive value in low-risk nodules, where unnecessary biopsies are most frequent.

Conclusions: The integration of strain elastography into the ACR TI-RADS framework substantially improves risk stratification and safely reduces unnecessary FNAs, particularly in low- and intermediate-risk thyroid nodules. These findings support the incorporation of elastography-derived thresholds into future revisions of thyroid nodule risk stratification systems.

Introduction and Objectives: Bethesda III (atypia of undetermined significance) remains a major management challenge, and there is a need for simple malignancy risk-stratification tools to guide decision-making. This study aimed to identify clinical, ultrasonographic and cytological predictors of malignancy in Bethesda III thyroid nodules and to develop an easy-to-use score to estimate individual malignancy risk in histologically confirmed cases.

Methods: We conducted an observational, retrospective, multicentre study (2019-2024) including patients with a Bethesda III cytological diagnosis who subsequently underwent thyroid surgery. Clinical, ultrasonographic and cytological features of benign and malignant nodules were systematically compared. Univariate and multivariate logistic regression analyses were used to identify independent predictors of malignancy. Based on the final beta-coefficients, we constructed a 0-12 point risk score and defined three risk categories with suggested management strategies.

Results: Eighty-five Bethesda III nodules were analysed; 65 (76.5%) were benign and 20 (23.5%) malignant. Independent predictors of malignancy were: high-risk ACR-TIRADS category 4-5 (OR 6.15; 95% CI 1.17-32.37; $P = .032$), lymphocytic thyroiditis (OR 3.81; 95% CI 1.06-13.73; $P = .041$) and nuclear atypia (OR 5.23; 95% CI

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

1.53-17.90; $P = .008$). A cut-off of ≥8 points maximised Youden's index (0.54), with 75% sensitivity, 79% specificity, PPV 54% and NPV 91%.

Three risk strata were defined:- SCORE ≥8 (high/very high risk): recommendation for surgery.

- SCORE 5-7 (intermediate risk): consider repeat FNA and/or molecular testing.

- SCORE ≤4 (low risk): ultrasound follow-up.

Malignancy rates increased across categories, from low in the SCORE ≤4 group to approximately one in two nodules in the SCORE ≥8 group.

The model's discriminative capacity was high, with an area under the curve (AUC) of 0.83, indicating very good performance in differentiating benign from malignant nodules in the Bethesda III category. Limitations include retrospective design and modest sample; prospective validation planned.

Conclusions: In Bethesda III thyroid nodules, malignancy was independently associated with high-risk ACR-TIRADS categories, lymphocytic thyroiditis and nuclear atypia. The proposed 0-12 point score provides practical and individualised malignancy risk stratification and may help optimise the indication for surgery, repeat FNA or molecular testing in this uncertain diagnostic category.

P403 - ECE_1776 - Identification of a senescent-like cell population with a low differentiation state in BRAFV600E-mutated follicular cell-derived thyroid carcinoma

Alexandra Monnot[1,2], Myriam Decaussin-Petrucci[2,3], Marie Chanal[2], Flore Deroux[2], Gabriela Makunyte[2], Francoise Borson-Chazot[1], Lifante Jean-Christophe[4], David Bernard[2], Lasolle Hélène[1,2] and Philippe Bertolino[2]

[1]Endocrinology Department, Hospices Civils de Lyon, Hôpital Louis-Pradel, Bron, France; [2]Inserm U1052, CNRS UMR5286, Cancer Research Center of Lyon, Lyon 1 University, Lyon, France; [3]Hospices Civils de Lyon, Groupement Hospitalier Sud, Pathology Department, Pierre Bénite, France; [4]Centre Hospitalier Lyon Sud, Hospices Civils de Lyon, Endocrine Surgery Department, Pierre Bénite, France

Introduction: The role of senescence in follicular cell-derived thyroid carcinoma (FCDTC) has been confirmed *in vitro* and *in vivo*. While senescence markers, including SA-β-gal activity, p16, and p21 expression, vary across tumor contexts and thyroid cancer progression, the role of thyroid senescent tumor cells and their secretome has been confirmed at the invasive front where these cells contribute to collective migration and invasion. Here we explore the spatial heterogeneity and relationship between senescent markers and tumor differentiation to refine the characterization of senescent cells in BRAFV600E FCDTC.

Methods: Published single-cell transcriptomic datasets and Xenium spatial sequencing data from BRAFV600E FCDTC were analyzed. Thyroid Differentiation Score (TDS) and senescence signatures (Fridman_up, SenMayo) were assessed in clustered and spatially sequenced tumors. Differential gene expression analyses were conducted to identify novel markers of senescent tumor cells. Immunohistological validations were performed on differentiated and high-grade FCDTC to further assess senescence markers (SA-β-gal, p16, and p21) and validate a candidate marker (LAMC2, a known senescence-associated candidate gene).

Results: Single-cell transcriptomic analysis of 109956 cells integrated from 18 samples identified a FCDTC cell population with a lower Thyroid Differentiation Score that was enriched for *CDKN2A* expression and senescence signatures. Histological stainings demonstrated a tumor-specific, yet spatially heterogeneous expression of P16 in tumor tissues compared to normal thyroid controls, while expression of P21 was more homogeneous between tumor and control tissues. Spatial transcriptomic analysis of 2 BRAFV600E-FCDTC (DTC and HGFCDTC) identified two tumor cell clusters with distinct TDS profiles. Senescence markers were enriched in TDS-Low cells, which were frequently observed at the invasive front and displayed a mutually exclusive spatial distribution compared to TDS-High clustered cells. Thyroglobulin (TG) immunohistochemistry confirmed the exclusive spatial distribution between P16 and TG-expressing cells. Differential gene expression identified 74 candidate marker genes in TDS-Low senescent tumor cells. Histological expression and spatial distribution of LAMC2, an identified candidate marker, was confirmed in TDS-low tumor regions.

Conclusions: Integrated analysis of single-cell, spatial transcriptomic and histological staining supports that senescence markers are enriched in a tumor cell population that is located at the invasive front of BRAFV600E FCDTC. Our results further support that these cells exhibit a reduced expression of thyroid differentiation markers. The identification of a gene signature associated with these TDS-Low senescent cells refines the biological characterization of intratumoral FCDTC heterogeneity. It further provides a foundation for exploring the prognostic value of TDS-Low senescent cells and their potential therapeutic interest in thyroid cancer.

P405 - ECE_3240 - Risk of Parkinson's disease in long-term survivors of thyroid cancer: a nationwide population-based cohort study

Se Hee Park, Min Heui Yu, Jung Ho Kim and Namki Hong

Seoul, South Korea

Background: As the survival of patients with thyroid cancer (TC) increases, understanding long-term treatment-related complications has become essential. While thyroid hormone levels are known to influence neurodegenerative processes, the association between postoperative levothyroxine therapy and the risk of Parkinson's disease (PD) remains unclear. This study aimed to investigate the risk of PD in patients who underwent thyroidectomy for TC using a large-scale nationwide database.

Methods: We conducted a retrospective cohort study using data from the Korean National Health Insurance Service (2004-2019). A total of 269 963 patients aged 40 years or older who underwent thyroidectomy for TC were matched 1:1 by age and sex with controls without a history of cancer or PD. The primary outcome was the risk of developing PD, estimated using multivariable Cox proportional hazards models adjusted for age, sex, income level, and Charlson Comorbidity Index. Sub-analyses further evaluated the impact of thyroidectomy extent, radioactive iodine (RAI) therapy, and levothyroxine dose categories on PD risk.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Results: During the follow-up period, PD incidence rates were 8.86 vs 8.36 per 10 000 person-years in the TC and control groups, respectively. The overall risk of PD in TC patients was not significantly higher after adjusting for multiple comorbidities (adjusted hazard ratio (aHR) 1.02, 95% confidence interval (CI) 0.95-1.08, $P = .611$). However, a significant dose-response relationship was observed regarding the average postoperative levothyroxine dose. Compared to the control group, patients receiving high-doses of levothyroxine exhibited a significantly increased risk of PD: aHR 1.15 (95% CI, 1.01-1.31; $P = .041$) for 125-149 μg/day and aHR 2.28 (95% CI, 2.04-2.56; $P < .0001$) for ≥150 μg/day. In the subgroup analysis of levothyroxine ≥150 μg/day group, the risk was significantly more pronounced in females (aHR 1.62; 95% CI, 1.27-2.06) than in males (aHR 1.05; 95% CI, 0.72-1.55; P-interaction = .033). PD incidence did not differ significantly based on the extent of surgery or the use of RAI therapy.

Conclusions: While the overall risk of PD in thyroid cancer survivors is comparable to that of the general population, high-dose levothyroxine therapy is associated with a markedly increased risk of PD, especially at doses ≥150 μg/day. These findings suggest that the intensity of long-term TSH suppression therapy should be carefully balanced against potential neurodegenerative risks.

Abstract citation ID: lvag096.536

P406 - ECE_1051 - Thyroid hormone resistance or TSH-secreting pituitary adenoma: a diagnostic dilemna

Kevin Kwek[1] and Aaron Ng[2]
[1]Endocrinology, Khoo Teck Puat Hospital, Singapore; [2]Tan Tock Seng Hospital, Singapore

While interpretation of thyroid testing is generally straightforward, hyperthyroxinemia with inappropriately raised TSH presents a diagnostic challenge for Endocrinologists. Careful clinical, biochemical, radiological and genetic investigation are required to clinch an accurate diagnosis.

A 54-year-old gentleman with notable history of hypertension and pre-diabetes diagnosed 5 years prior was evaluated at our clinic for a screening thyroid function test (Roche Cobas E801 assay) showing free thyroxine (fT4) of 34.2 pmol/L (RR 12-22) and of TSH 1.74 mIU/L (RR 0.27-4.2). Of note, a previous thyroid function test at our institution 4 years prior showed a similarly elevated fT4 of 32.3 pmol/L with TSH of 1.84 mIU/L.

On clinical evaluation, he volunteered history of intermittent palpitations and tremors since childhood. Resting tachycardia (HR 110-120bpm) was observed. Thyroid eye disease, pretibial myxedema or palpable goitre were not observed. He had no family history of hyperthyroidism, pituitary tumour or other endocrinopathies. He was not consuming any potential interfering drugs or biotin-containing supplements.

Table 1 Repeat biochemistry

Test	Result	Reference Range
fT4 (Roche Cobas)	34.8 pmol/L	12-22
TSH (Roche Cobas)	1.75 mIU/L	0.27-4.2
Free triiodothyronine (Roche cobas)	7.8 pmol/L	3.1-6.8
fT4 (Abbott Alinity)	24 pmol/L	9-19.1
TSH (Abbott Alinity)	1.35 mIU/L	0.35-4.94
Total thyroxine (Abbott Alinity)	207 nmol/L	63-151

Concordant results (Table 1) obtained with the Abbott Alinity assay suggest against assay interference. Testing for thyrotropin receptor and anti-thyroid peroxidase antibodies was negative. Thus, we performed further evaluation to distinguish between TSH-producing pituitary adenoma (TSHoma) and resistance to thyroid hormone (RTH).

Table 2 Further testing

Test	Result	Reference Range
Alpha-subunit	0.1ng/ml	<0.5
TSH	1.57 mIU/L	0.27-4.2
Ferritin	136ng/ml	30-400
Sex hormone binding globulin (SHBG)	47 nmol/L	17-78

The normal alpha-subunit:TSH molar ratio (0.63) and normal tissue markers of thyroid hormone action suggest RTH over TSHoma. A TRH stimulation test demonstrated brisk response of TSH (1.75 mIU/L > 13.3 mIU/L (30min) > 7.84 mIU/L (60mins)) consistent with RTH. T3 suppression testing was contraindicated due to resting tachycardia. Thus, we performed genetic screening (Blueprint genetics thyroid hormone resistance panel), which unexepectedly did not detect any known disease-causing variants.

We performed pituitary magnetic resonance imaging to re-evaluate the diagnosis, which revealed 3x2x3mm pituitary tumour. As this may represent an incidental non-functioning microadenoma or a TSHoma, octreotide suppression testing was offered. At present, he is responding well to symptomatic therapy with beta blockade.

This diagnostic dilemma demonstrates the limitations of existing diagnostic algorithms in differentiating TSHoma and RTH. We await further advances, especially in genetic testing, which may shed further light on this case.

P407 - ECE_1277 - Preclinical evaluation of calcitriol in Graves' disease under varying vitamin D status

Daham Kim, Yaru Bao, So Jeong Lee, Se Hee Park and Eun Jig Lee
Yonsei University College of Medicine, Seoul, South Korea

Graves' disease (GD) is an autoimmune thyroid disorder driven by immune dysregulation. Vitamin D has immunomodulatory effects, but its activation is tightly controlled by rate-limiting hydroxylation steps. While supplementation offers limited benefit

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

in vitamin D-replete individuals, the active form of vitamin D (calcitriol) bypasses these steps and may provide stronger immune regulation. This study evaluated the effects of calcitriol in a preclinical GD model under vitamin D-sufficient and vitamin D-deficient conditions.

Rosa26_hTSHRa (Balb/c) mice were maintained on either a standard diet or a vitamin D-deficient diet initiated four weeks before the experimental schedule. Within each dietary condition, mice were assigned to three groups: Control, GD, and GD+calcitriol. The GD and GD+calcitriol groups received 250 U of TAT-Cre by intramuscular injection into one thigh at 8 weeks of age, followed by an injection into the contralateral thigh three weeks later. The GD+calcitriol group was treated with calcitriol (5 μg/kg, subcutaneously, three times weekly) beginning at week 7. Serum T4 and TSHR antibody levels were measured at weeks 6 and 13 using ELISA.

At week 6, both dietary conditions showed a significant elevation of TSHR antibodies in the GD and GD+calcitriol groups compared with the control group, with similar titers between the two groups. This increase was numerically greater in the vitamin D-deficient diet experiment. Serum T4 levels also began to rise, and in the standard diet experiment, a significant difference from the control group appeared earlier.

At week 13, although the difference between the GD and GD +calcitriol groups did not reach statistical significance, the vitamin D-deficient diet experiment demonstrated a greater reduction in TSHR antibodies in the GD+calcitriol group compared with the GD group. In the standard diet experiment, T4 levels tended to be higher in the GD group but no significant differences were observed between groups; however, the GD+calcitriol group showed a significant decrease in T4 levels relative to its week-6 level. In the vitamin D-deficient diet experiment, the GD group exhibited a significant increase in T4 compared with the control group, whereas the GD+calcitriol group maintained T4 levels comparable to those of the control group.

These findings suggest that calcitriol exerts a protective effect against GD-associated thyroid dysfunction, particularly under vitamin D-deficient conditions, by attenuating T4 elevation and promoting a reduction in TSHR antibody levels. Calcitriol may therefore serve as a potential adjunctive therapeutic strategy for GD, especially in individuals with inadequate vitamin D status.

P409 - ECE_2414 - Association of hashimoto thyroiditis with tumor characteristics and recurrence in papillary thyroid carcinoma

Solji An, Joonseon Park, Kwangsoon Kim and Ja Seong Bae
Seoul, South Korea

Background: The relationship between Hashimoto thyroiditis (HT) and papillary thyroid carcinoma (PTC) remains controversial. This study aimed to evaluate the clinicopathologic characteristics and prognostic impact of coexisting HT in patients with PTC.

Methods: A total of 6581 patients who underwent surgery for PTC were retrospectively analyzed. Patients were classified into control ($n = 5396$) and HT ($n = 1185$) groups based on histopathologic diagnosis. Clinicopathologic features, molecular profiles, surgical extent, and recurrence-free survival (RFS) were compared. Multivariate logistic regression analysis was performed to identify factors associated with coexisting HT. RFS was analyzed using the Kaplan–Meier method.

Results: Patients with HT were more likely to be female and younger (both $P < .001$). Total thyroidectomy and central lymph node dissection were more frequently performed in the HT group ($P = .005$ and $P = .003$, respectively). HT was associated with higher rates of multifocality ($P < .001$) but showed no significant differences in tumor size, vascular invasion, lymphatic invasion, extrathyroidal extension, or lateral lymph node metastasis. The HT group demonstrated a lower prevalence of BRAF mutation (72.2% vs 84.7%, $P < .001$), while TERT mutation rates were comparable. Preoperative TSH, thyroglobulin, and anti-thyroglobulin antibody levels were significantly higher in patients with HT (all $P < .001$). On multivariate analysis, female sex, younger age, multifocal disease, absence of extrathyroidal extension, absence of BRAF mutation, and higher preoperative anti-thyroglobulin antibody levels were independently associated with coexisting HT. During follow-up, recurrence rates did not differ significantly between groups (3.2% vs 3.4%, $P = .726$), and Kaplan–Meier analysis showed no significant difference in RFS ($P = .73$).

Conclusions: Coexisting Hashimoto thyroiditis in PTC is associated with distinct clinicopathologic and molecular characteristics, including female predominance, multifocality, and lower BRAF mutation rates. However, HT does not appear to influence recurrence-free survival. These findings suggest that while HT affects tumor presentation, it has limited prognostic impact on long-term outcomes in PTC.

Abstract citation ID: lvag096.539

P410 - ECE_2915 - Surgical extent, tumor size, and calcitonin levels in medullary thyroid carcinoma: impact on oncologic outcomes in a retrospective cohort study

Ekin Yiğit Köroğlu[1], Berna Evranos Ogmen[2], Muzaffer Serdar Deniz[1], Barış Saylam[3], Hilal Ahsen[4], Cevdet Aydin[2], Oya Topaloglu[2], Reyhan Ersoy[2] and Bekir Cakir[2]
[1]Endocrinology and Metabolism Diseases, Ankara Bilkent City Hospital, Ankara, Türkiye; [2]Endocrinology and Metabolism Diseases, Ankara Yıldırım Beyazıt University, Ankara, Türkiye; [3]Breast and Endocrine Surgery, General Surgery, Ankara Bilkent City Hospital, Ankara, Türkiye; [4]Medical Pathology, Ankara Bilkent City Hospital, Ankara, Türkiye

Background: Medullary thyroid carcinoma (MTC) treatment guidelines recommend surgical extent based primarily on calcitonin levels, yet the oncologic impact of deviating from these protocols remains incompletely characterized. This study evaluates whether individualized treatment approaches based on comprehensive tumor characterization compromise disease outcomes compared to guideline-adherent management, and examines the relative importance of tumor size, calcitonin levels, and surgical extent in predicting persistent disease.

Methods: This retrospective cohort study included 91 patients with histologically confirmed MTC followed at a tertiary center from January 2019 to March 2025. Surgical procedures were

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

compared against ATA-2015, ESMO-2019, and NCCN-2025 guideline recommendations and classified as concordant, less extensive, or more extensive. Primary outcomes included persistent disease (biochemical or structural incomplete response ≥6 months), reoperation rates, and postoperative complications. Associations between preoperative calcitonin levels and lymph node (LN) metastasis patterns were analyzed. Multivariable logistic regression identified independent predictors of persistent disease.

Results: Surgical procedures deviated from guidelines in 32.3% (ATA), 70.8% (ESMO), and 40.0% (NCCN) of cases. Deviation from guideline-recommended extent did not significantly impact persistent disease rates, reoperation requirements, or complication rates. Overall, 23.1% of patients had persistent disease at final follow-up. On multivariable analysis, independent predictors of persistent disease were higher preoperative calcitonin levels (OR 1.02 per 100 pg/mL increase, 95% CI 1.00-1.04, $P = .042$) and presence of LN metastasis (OR 4.52, 95% CI 1.01-20.24, $P = .049$), but not surgical extent classification. Primary tumor size correlated with metastatic involvement across all cervical compartments, while preoperative calcitonin levels predicted only ipsilateral lateral LN metastasis. A calcitonin threshold of 189.5 pg/mL predicted ipsilateral lateral metastasis with 92.3% sensitivity and 61.8% specificity.

Conclusions: Individualized surgical approaches based on comprehensive preoperative assessment do not compromise oncologic outcomes when compared to guideline-adherent protocols. Disease persistence is determined by tumor biology rather than adherence to standardized surgical algorithms. Integration of tumor size with calcitonin measurements may improve risk stratification and enable treatment personalization while maintaining disease control.

P411 - ECE_3079 - Diagnostic Value of Contrast-Enhanced Ultrasound in the Multimodal Assessment of Bethesda III and IV Thyroid Nodules

Agnieszka Żyłka[1], Katarzyna Dobruch-Sobczak[2], Jacek Gałczyński[1], Piotr Góralski[1], Elwira Bakuła-Zalewska[3] and Marek Dedecjus[1]

[1]Department of Endocrine Oncology and Nuclear Medicine, Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw, Poland; [2]Radiology Department II, Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw, Poland; [3]Department of Pathology, Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw, Poland

Background: Indeterminate thyroid nodules classified as Bethesda category III and IV remain a major diagnostic challenge and frequently result in potentially unnecessary surgery. Conventional B-mode ultrasound provides limited diagnostic accuracy in this subgroup. Contrast-enhanced ultrasound (CEUS) has been proposed as an adjunct imaging modality, but its role in risk stratification remains unclear.

Methods: This single-centre imaging study included 63 patients (51 women, 12 men) with Bethesda III ($n = 19$) or IV ($n = 44$) thyroid nodules scheduled for surgery. All nodules underwent standardized B-mode ultrasound evaluation, including EU-TIRADS and strain elastography (Asteria score), followed by CEUS prior to surgery. CEUS assessment included enhancement intensity, homogeneity, wash-out pattern, and enhancement type after intravenous administration of 1.5 mL of contrast agent and was independently evaluated by two observers blinded to final histopathological diagnosis. Histopathology served as the reference standard. Diagnostic performance was assessed using ROC analysis with AUC calculation. Associations with malignancy were explored using univariate and confirmatory multivariate logistic regression.

Results: Malignancy was confirmed in 39.7% of nodules ($n = 25$), with papillary thyroid carcinoma (PTC) as the predominant histological subtype ($n = 11$, 40%). In the benign group, follicular adenoma was the dominant pathology ($n = 22$, 57.9%). Age, sex, and nodule size did not differ between malignant and benign nodules. In univariate analysis, several B-mode ultrasound features were significantly associated with malignancy, including hypoechogenicity (OR 8.57, $P = .048$), Asteria score 4 (OR 7.66, $P = .018$), and non-smooth margins (OR 3.26, $P = .029$), all demonstrating modest diagnostic performance (AUC range 0.612-0.643). Selected combinations of B-mode and CEUS features showed stronger associations with malignancy in univariate analysis, particularly non-smooth margins combined with hypoenhancement (OR 14.39, 95% CI 2.32-279.84; $P = .016$), as well as combinations of non-smooth margins with heterogeneous enhancement or fast wash-out, and hypoechogenicity combined with heterogeneous enhancement (OR range 2.92-3.71; all $P < .05$). Among these, the combination of non-smooth margins and CEUS hypoenhancement demonstrated the most robust diagnostic profile, with very high specificity (97%) and remained independently associated with malignancy in multivariate analysis (OR 10.46, 95% CI 1.53-210.66; $P = .040$).

Conclusions: In Bethesda III and IV thyroid nodules, conventional B-mode ultrasound remains fundamental for malignancy risk assessment, while contrast-enhanced ultrasound may provide incremental value when interpreted alongside standard ultrasound features. A multimodal ultrasound approach may improve diagnostic confidence and support clinical decision-making, although further validation in larger patient cohorts is required.

Abstract citation ID: lvag096.541

P412 - ECE_2422 - Serum selenium positively correlates with 25-hydroxyvitamin D in patients with Graves' disease

Cheng-Yu Tsai and Chia-Hung Lin

New Taipei City, Taiwan

Introduction: Serum selenium (Se) and 25-hydroxyvitamin D (25(OH)D) concentrations have been reported to differ between patients with and without Graves' disease (GD), yet the relationship between these two parameters remains unclear. Furthermore, whether GD status influences this relationship is also unknown. Thus, we aimed to investigate the association between serum Se and 25(OH)D and determine whether GD status modifies this relationship.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Methods: We analyzed data from a prospective cohort in a selenium-sufficient population at National Taiwan University Hospital. Participants with and without GD were enrolled, excluding those taking Se supplements. The association between serum Se and 25(OH)D was evaluated using Pearson's correlation and linear regression analyses stratified by GD status.

Results: A total of 116 subjects were enrolled, comprising 59 subjects with GD and 57 subjects without GD (non-GD). Serum Se levels were significantly higher in GD patients compared to non-GD controls (128.58 vs 119.32 μg/L, $P = .024$), while there was a trend toward lower 25(OH)D levels in GD patients (21.44 vs 24.05 ng/mL, $P = .071$). Serum Se levels were positively correlated with 25(OH)D (Pearson's correlation coefficient $r = 0.186$, $P = .045$). Correlation analysis stratified by GD status revealed a significant correlation between Se and 25(OH)D only in the GD group ($r = 0.287$, $P = .028$) but not in the non-GD group ($r = 0.153$, $P = .255$). Linear regression demonstrated a significant overall association between Se and 25(OH)D ($\beta = .299$, $P = .028$). Upon GD status stratification, a significant positive association was observed only in the GD group ($\beta = 0.568$, $P = .012$), whereas no such relationship was found in the non-GD group ($\beta = .135$, $P = .349$). After adjusting for age and fasting plasma glucose, the association between 25(OH)D and serum Se in the GD group still showed a trend toward statistical significance ($\beta = .376$, $P = .088$). In contrast, the association between serum Se and 25(OH)D remained non-significant in the non-GD group.

Conclusions: To our knowledge, this study is the first to investigate whether GD status modifies the association between serum Se and 25(OH)D levels in Taiwan, a selenium-sufficient country. We identified a distinct positive correlation between serum Se and 25(OH)D levels in subjects with GD, which was absent in subjects without GD. These findings imply a potential disease-specific link between selenium and vitamin D that warrants further investigation in larger cohorts and interventional studies.

P414 - ECE_3563 - Destructive thyroiditis due to metastatic thyroid infiltration in a patient with adenocarcinoma of unknown primary origin

Mafalda Canudas Costa[1], Juliana Gonçalves[1], Ana Rita Leite[1], Ines Pereira[1], Ana Luísa Barbosa[1], Ana Varela[1], João Neves[1], Luís Guimarães[2] and Joana Queirós[1]

[1]Department of Endocrinology, Diabetes and Metabolism, São João Local Health Unit, Porto, Portugal, Oporto, Portugal; [2]Department of Radiology, São João Local Health Unit, Porto, Portugal, Oporto, Portugal

Background: Metastases to the thyroid gland from nonthyroid neoplasms are uncommon and most patients remain euthyroid. Destructive thyroiditis in this context is an uncommon cause of thyrotoxicosis. Recognition of this entity is essential, as management differs from primary hyperthyroidism.

Case Presentation: We describe a 70-year-old male with stage IV tubular adenocarcinoma of unknown primary origin with loss of SMARCA4 expression, admitted for recurrent episodes of presyncope. He had a previous medical history of non-toxic multinodular goiter. He initially presented to the emergency department with palpitations and was found to have clinical thyrotoxicosis (TSH < 0.001 (0.35-4.94)μUI/mL, free T4 1.90 (0.70-1.48)ng/dL). He was discharged with methimazole and propranolol. He was subsequently admitted due to recurrent presyncope, at which point endocrinology consultation was requested for persistent thyrotoxicosis. In the weeks preceding admission, he reported palpitations, nocturnal sweating and mild heat intolerance.

Thyroid hormone levels transiently worsened during hospitalization, with peak free T3 10.26 (1.71-3.71)pg/mL and free T4 3.33ng/dL. During the endocrine evaluation, TSH-receptor antibodies and anti-thyroid antibodies were negative. A cervical CT performed two months prior to the onset of thyrotoxicosis, showed a thyroid gland of normal size and morphology, without structural abnormalities apart from a suspicious left level IV cervical lymphadenopathy. He repeated cervical CT which demonstrated near complete replacement of the thyroid gland by neoplastic tissue. Thyroid ultrasound with Doppler, revealed a diffusely enlarged, heterogeneous, pseudonodular gland with marked hypovascularity, along with bilateral laterocervical adenopathies. These findings, supported the diagnosis of destructive thyroiditis secondary to neoplastic infiltration.

Systemic corticosteroid therapy, previously initiated during hospitalization by the oncology team, was maintained, and antithyroid therapy was discontinued. Pre-existing beta-blocker therapy with bisoprolol was optimized. Thyroid hormone levels progressively declined, with concomitant clinical improvement. After 4 days, free T4 had decreased to 2.27ng/dL and free T3 to 3.83pg/mL. At outpatient follow-up seven days later, further biochemical improvement was documented (free T4 1.69ng/dL, free T3 3.18pg/mL), allowing gradual tapering of corticosteroids. Three weeks later, thyroid function continued to improve (TSH 0.01μUI/mL, free T4 1.34ng/dL).

Conclusions: This case illustrates a rare cause of thyrotoxicoses due to destructive thyroiditis in the context of rapid and extensive neoplastic thyroid infiltration. Awareness of this entity is crucial in patients with disseminated malignancy to avoid unnecessary antithyroid therapy and to ensure appropriate multidisciplinary management.

P415 - ECE_3878 - Resistance to thyroid hormone due to a novel THRB variant and coexisting pituitary lesion: A case report

Georgios Kostopoulos[1], Evangelia Makri[1], Athina Ververi[2], Sokratis Katafigiotis[2], Thomais Stavridoi[3] and Foteini Adamidou[1]

[1]Endocrinology, Hippokration General Hospital, Thessaloniki, Greece; [2]Department of Genetics for Rare Diseases, Papageorgiou General Hospital, Thessaloniki, Greece; [3]Private Practice, Castoria, Greece

Background: Elevated free thyroid hormone levels with non-suppressed thyrotropin (TSH) represent a diagnostic challenge and require differentiation between resistance to thyroid hormone (RTH), TSH-secreting pituitary adenoma (TSHoma), and familial dysalbuminemic hyperthyroxinemia (FDH). Most cases of resistance to thyroid hormone beta (RTH) are caused by

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

heterozygous mutations in the thyroid hormone receptor beta gene (*THRB*) and follow an autosomal dominant inheritance pattern. The reported coexistence of RTHβ with pituitary incidentalomas further complicates the diagnostic approach.

Case Presentation: A 69-year-old male with a history of type 2 diabetes mellitus, chronic hepatitis B and solitary kidney was referred for persistently elevated free T4 and free T3, with high normal TSH levels on repeated routine testing. Clinically, the patient was asymptomatic, apart from sinus bradycardia. Mild cognitive impairment was noted. Thyroid antibodies were negative, sex hormone binding globulin was normal, and thyroid ultrasound revealed a multinodular goiter. Notably, the patient's mother had undergone total thyroidectomy for a benign multinodular goiter and required addition of T3 supplementation to thyroxine replacement to normalize her persistently elevated TSH. Extensive laboratory evaluation excluded assay interference and anterior pituitary dysfunction. Pituitary MRI revealed a 5x7 mm pituitary lesion. Dynamic endocrine testing, including TRH stimulation and T3 suppression test, favored the diagnosis of RTH over TSHoma.

Based on the biochemical profile and family history, the patient underwent Whole Exome Sequencing, which identified a novel heterozygous missense variant in the THRB gene, c.1054G>C (p.Ala352Pro). According to ACMG criteria, this variant was initially classified as a variant of uncertain significance (VUS). Subsequent familial testing demonstrated the presence of the same variant in the patient's mother. Segregation of the variant within the family supported its pathogenicity and was consistent with a diagnosis of resistance to thyroid hormone beta (RTHβ).

Conclusions: The differential diagnosis of apparently inappropriate TSH secretion as in RTH, calls for integrated clinical evaluation and family history, dynamic hormonal testing, thyroid and pituitary imaging and genetic testing to avoid unnecessary therapeutic interventions.

P416 - ECE_2108 - Perchlorate and thiocyanate environmental contaminants in mother-baby cohort in N.I

Doua S Ahmed[1], Paul McMullan[1], Jayne V Woodside[2], Elizabeth N. Pearce[3] and Karen Mullan[1]

[1]Regional Centre for Endocrinology and Diabetes, Belfast Health and Social Care Trust, Belfast, United Kingdom; [2]Centre for Public Health, Queen's University Belfast, Belfast, United Kingdom; [3]Boston University Chobanian & Avedisian School of Medicine, Boston, United States

Sufficient iodine supply is essential for thyroid hormone synthesis, which is crucial for foetal neurodevelopment. Perchlorate (ClO_4^-) and thiocyanate (SCN^-) are environmental pollutants that inhibit iodine uptake into thyroid cells. Contamination has been found in water, milk, and some food supplies and originates from products such as cigarettes, nitrogen fertilisers, and rocket fuel. These pollutants may potentially compound iodine deficiency and partly explain the significant rise in congenital hypothyroidism described in Northern Ireland (N.I), Ireland, and other Western countries over the last 40 years.

A prospective cohort of 241 mothers in N.I provided urine samples for storage during each trimester of pregnancy and postpartum, with a subset of 80 providing an offspring sample (6-24 weeks).

Mothers were iodine deficient throughout pregnancy and postpartum, while babies were iodine replete, as previously reported. Maternal median urinary iodine concentrations (mUIC) across the three trimesters and postpartum were 73 mcg/L, 94 mcg/L, 117 mcg/L, and 90 mcg/L, respectively. Infant mUIC was 40 µg/L. Perchlorate and thiocyanate were highly prevalent in maternal urine samples, detected in 95% and 100%, respectively, indicating ubiquitous exposure. Maternal median perchlorate levels across the three trimesters and postpartum were 3.6, 4.1, 3.3, and 3.8 mcg/L, respectively, and 1.9 mcg/L in offspring (detected in 65% of infants). Maternal median thiocyanate levels were 353, 709, 572, and 751 mcg/L, respectively, and 136 mcg/L in offspring (detected in 100% of infants). Smoking was associated with a four-fold increase in maternal thiocyanate levels in the second trimester compared with non-smokers (2970 vs 657 µg/L, $P < .001$). Formula feeding was associated with higher perchlorate levels in infants. Median urinary perchlorate concentrations were 0.9 mcg/L in breastfed infants and 1.8 mcg/L in formula-fed infants ($P = .011$). There was no significant ClO_4^- or SCN^- contamination detected in contemporaneous water samples from across the island of Ireland (median <0.05 and <0.5 µg/L, respectively). Only 2/29 locations had measurable, but low, levels.

To our knowledge, this is the first European cohort shown to have evidence of thyroid hormone synthesis blocker contamination in infants. Results are similar to a mother-infant cohort in Boston, USA. However, in the Boston cohort, mothers were iodine replete, which may provide some protection not afforded to Ireland and UK, which have no iodine fortification programmes. These findings highlight the need for public health strategies to optimise iodine nutrition in Northern Ireland and raise concerns regarding concurrent exposure to environmental thyroid disruptors.

P417 - ECE_1959 - Thyroid hormone receptor β1 as a key regulator of hepatic gene expression and bile secretion

Liudmyla Kaminska[1,2] and John Blacked[1]

[1]NIHR Liverpool Clinical Research Facility, Liverpool, United Kingdom; [2]University of Liverpool, Biosciences, Liverpool, United Kingdom

Background: The ATP-binding cassette transporter ABCB4 (MDR3) is essential for the excretion of phosphatidylcholine (PC) into bile, a critical process for maintaining hepatobiliary lipid homeostasis. Impaired ABCB4 expression or function leads to cholestatic liver disease and bile duct injury. Thyroid hormones are key regulators of hepatic lipid metabolism; however, the role of thyroid hormone receptor β1 (THRβ1), the predominant hepatic isoform, in modulating ABCB4 expression remains unclear.

Methods: Human hepatocyte models were treated with triiodothyronine (T3) to assess dose- and time-dependent effects on ABCB4 transcription. THRβ1-selective agonists, including GC-1 and KB-141, were used to evaluate isoform-specific regulation.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

In vivo studies in mice examined the impact of THRβ1 activation on hepatic ABCB4 expression and biliary PC secretion. Conserved THR response elements upstream of the ABCB4 gene were identified using genomic analyses.

Results: T3 stimulation induced robust, dose- and time-dependent upregulation of ABCB4 mRNA in human hepatocytes. THRβ1-selective agonists elicited greater transcriptional activation than native T3, confirming isoform-specific regulation. In mice, KB-141 treatment increased hepatic ABCB4 expression and significantly enhanced biliary PC secretion. Conserved THR response elements located ~6 kb upstream of the ABCB4 locus were identified in both human and murine genomes, providing direct mechanistic evidence for THRβ1-mediated transcriptional control.

Conclusions: THRβ1 functions as a novel transcriptional activator of ABCB4, promoting increased canalicular transporter levels and facilitating phosphatidylcholine secretion into bile. These findings establish a direct link between thyroid hormone signaling and hepatobiliary lipid metabolism, highlighting THRβ1 as a key modulator of bile duct homeostasis. Furthermore, selective THRβ1 agonists may represent a promising therapeutic strategy for enhancing ABCB4-mediated biliary lipid excretion and improving liver function in cholestatic disorders.

Objective: *CCDC6/RET* (also known as *RET/PTC1*) and *ETV6/NTRK3* gene fusions represent recurrent oncogenic drivers in papillary thyroid carcinoma (PTC), particularly in radiation-associated and pediatric cases, but are also detected in adult sporadic tumors. Although these fusions are generally associated with favorable outcomes, increasing evidence suggests substantial heterogeneity in clinical behavior, ranging from indolent tumors to aggressive disease with locoregional invasion or distant metastases. MicroRNAs (miRNAs) are key post-transcriptional regulators involved in thyroid tumorigenesis and may contribute to differences in tumor aggressiveness. The aim of this study was to characterize miRNA expression profiles associated with aggressive versus indolent clinical behavior in *CCDC6/RET*- and *ETV6/NTRK3*-positive PTC.

Methods: A total of 60 PTC samples were analyzed, including 30 tumors harboring the *CCDC6/RET* fusion and 30 tumors positive for the *ETV6/NTRK3* fusion. *CCDC6/RET*-positive PTCs comprised 15 indolent and 15 aggressive tumors, while the *ETV6/NTRK3*-positive cohort included 16 indolent and 14 aggressive PTCs. Tumors were classified as aggressive based on advanced local disease, lymph node involvement, angioinvasion, or presence of distant metastases, whereas indolent tumors were defined as T1–T2, N0, M0 with excellent response to therapy. Total RNA was isolated from fresh-frozen thyroid tissues, and miRNA libraries for next-generation sequencing were prepared using the QIAseq miRNA Library Kit (Qiagen). Differential miRNA expression analysis was performed using the miRge3.0 pipeline and the DESeq2 package in R, with comparisons focused on aggressive versus indolent tumors within each fusion-positive group.

Results: In *CCDC6/RET*-positive PTCs, aggressive tumors showed significantly altered expression of 12 miRNAs compared with indolent tumors, including 10 upregulated and two downregulated miRNAs. The most statistically significant upregulated miRNAs were hsa-miR-224-5p, hsa-miR-193a-5p, and hsa-miR-12136, while hsa-miR-3065-3p and hsa-miR-3065-5p were the most significantly downregulated. In *ETV6/NTRK3*-positive PTCs, aggressive tumors exhibited upregulation of 6 miRNAs compared with indolent tumors, with no miRNAs showing significant downregulation. The most significantly upregulated miRNAs included hsa-miR-1248, hsa-miR-27a-5p, and hsa-miR-323a-3p.

Conclusions: Our results demonstrate distinct miRNA expression patterns associated with aggressive clinical behavior in *CCDC6/RET*- and *ETV6/NTRK3*-positive PTC. These findings suggest that miRNA profiling may contribute to improved risk stratification and help identify fusion-positive PTC patients with a higher likelihood of aggressive disease, potentially supporting more personalized clinical management.

P422 - ECE_1738 - Endocrine immune-related adverse events and survival in cancer immunotherapy: a bias-corrected meta-analysis

Lavanya Mangla

Maulana Azad Medical College, Delhi, India

Background: Endocrine immune-related adverse events (e-irAEs) are common during immune checkpoint inhibitor (ICI) therapy and have been associated with improved survival in observational studies. However, most prior analyses are vulnerable

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

to immortal time bias—whereby patients must survive long enough to develop endocrine toxicity, artificially inflating survival estimates—limiting causal interpretation from an endocrine standpoint. Clarifying whether endocrine toxicity reflects true immune activation or methodological artefact is clinically relevant for endocrinologists managing these patients, particularly with respect to surveillance intensity and prognostic counselling.

Methods: We conducted a systematic review and meta-analysis following PRISMA guidelines, identifying studies published between 2019 and 2025 that evaluated survival outcomes in patients developing endocrine irAEs during ICI therapy. Primary analyses were restricted to studies employing landmark-adjusted or time-dependent Cox models, excluding naïve time-to-event analyses. Overall survival (OS) was analysed using a random-effects Bayesian framework. Meta-regression explored differences by endocrine organ, cancer type, and ICI regimen. Trial Sequential Analysis (TSA) assessed evidence sufficiency, and sensitivity analyses evaluated robustness.

Results: Four studies employing bias-corrected methods were included. Development of endocrine irAEs was associated with improved OS (posterior hazard ratio [HR] 0.68, 95% credible interval [CrI] 0.49-0.93; $I^2 = 2\%$), indicating a high posterior probability of survival benefit. Thyroid irAEs showed a trend toward improved survival (posterior HR 0.67, 95% CrI 0.41-1.11, crossing unity), reflecting substantial uncertainty, while pituitary and adrenal toxicities showed insufficient evidence to determine an association**.** Despite the small number of studies, TSA demonstrated that the cumulative Z-curve crossed the monitoring boundary in favour of benefit after the second study, indicating a low probability that the overall association is due to chance. Sensitivity analyses confirmed robustness of the primary finding.

Conclusions: After correction for immortal time bias, endocrine immune-related adverse events are associated with improved overall survival during cancer immunotherapy. These findings support endocrine toxicity as a prognostic correlate of systemic immune activation, rather than definitive evidence of a clinically actionable biomarker. Whether endocrine irAEs can be used for risk stratification or treatment decision-making—for example, in selecting patients for treatment intensification or de-escalation—requires prospective endocrine-focused validation.

P423 - ECE_1702 - Management of refractory thyrotoxicosis to facilitate salvage multivisceral transplantation in a critically ill patient

Sarishka Singh, Zin Tun, Saira Yousaf, Shafiq Yusuff and Hassan Ibrahim
Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom

Introduction: Distinguishing between severe non thyroidal illness and primary hyperthyroidism in the intensive care unit is challenging. In the context of salvage multivisceral transplantation (MVT) achieving biochemical stability is vital for perioperative safety. We describe a case of severe thyrotoxicosis refractory to high dose therapy necessitating complex perioperative planning and multidisciplinary collaboration.

Case Presentation: A 38 year old female was transferred from Ireland for MVT assessment following mesenteric ischaemia and septic shock. History included portal vein thrombosis, ascites, and spontaneous bacterial peritonitis. Her course required intensive care, haemofiltration, and surgeries resulting in short bowel syndrome.

Thyroid function progressed through three distinct stages. Local reference ranges were TSH (0.35-5.50 mU/L), Free T3 (3.50-6.5 pmol/L), and Free T4 (11.5-22.7 pmol/L). Initial tests on admission (TSH 0.59 mU/L, FT3 2.4 pmol/L, FT4 8.5 pmol/L) suggested non-thyroidal illness. Four months later, she demonstrated T3 thyrotoxicosis (TSH <0.03 mU/L, FT3 7.3 pmol/L, FT4 19.7 pmol/L), progressing by nine months to overt thyrotoxicosis (TSH <0.03 mU/L, FT4 12.9 pmol/L, FT3 53.6 pmol/L) associated with tachycardia and high stoma output.

Work up excluded assay interference and heparin effect. TSI and TPO antibodies were negative. Thyroid ultrasound showed benign nodules (<1cm, BTA U2) without increased vascularity. Thyroid uptake was markedly reduced at 0.2%, consistent with thyroiditis. While multiple contrast exposures contributed, the deterioration in thyroid function observed four months after the last exposure might suggest a cumulative staggering effect rather than a purely contrast-driven aetiology.

To facilitate MVT, carbimazole was titrated to 60 mg daily but the response was refractory possibly due to malabsorption from short bowel syndrome. A contingency plan involved iopanoic acid to inhibit 5′-deiodinase and reduce peripheral conversion of T4 to T3.

Pre-operatively, her tests demonstrated TSH <0.03 mU/L; FT3 9.4 pmol/L; FT4 33.3 pmol/L. Following MVT, thyroid function corrected rapidly. Five days post-surgery, FT3 was 2.8 pmol/L and FT4 12.5 pmol/L. Improvement could possibly be related to iodine washout during intraoperative and early post-operative haemofiltration and resolution of illness. Subsequent autoantibody screens remained negative, suggesting transient thyroiditis evolving into non-thyroidal illness.

Conclusions: This case illustrates the complexities of managing thyrotoxicosis in surgical intensive care. It highlights the impact of gastrointestinal failure on oral medication efficacy and the utility of alternative strategies for perioperative stabilisation. Furthermore, it demonstrates that clinical features suggesting hyperthyroidism may ultimately represent non-thyroidal illness or transient thyroiditis.

P424 - ECE_1949 - Cytokine signatures predicting thyroid toxicity during immune checkpoint therapy

Ketevan Lomidze[1], Nino Kikodze[2] and Marine Gordeladze[3]
[1]*Tbilisi State Medical University, Tbilisi, Georgia;* [2]*Immunology, Tbilisi State Medical University, Tbilisi, Georgia;* [3]*Endocrinology, Tbilisi State Medical University, Tbilisi, Georgia*

Background: Hypothyroidism is one of the most common endocrine immune-related adverse events associated with immune checkpoint inhibitor (ICI) therapy. Current guideline-recommended monitoring strategies rely on uniform biochemical surveillance and do not incorporate individual immunological risk profiles. Identification of clinically applicable

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

biomarkers may enable more precise prediction and management of ICI-associated thyroid dysfunction.

Methods: We conducted a prospective observational study including 35 patients with advanced solid tumours treated with PD-1 or combined PD-1/CTLA-4 inhibitors. Serum levels of interleukin-6 (IL-6), interleukin-10 (IL-10), and interferon-gamma (IFN-γ) were measured at baseline and during early treatment. Cytokine concentrations were compared between patients who developed hypothyroidism and those who remained euthyroid using non-parametric testing. Predictive performance was evaluated using receiver operating characteristic (ROC) analysis, with optimal thresholds determined by Youden's index.

Results: Patients who developed hypothyroidism exhibited significantly lower circulating levels of IL-10 and IL-6 compared with disease-free individuals ($P < .01$), whereas IFN-γ showed no statistically significant difference. ROC analysis demonstrated strong predictive performance for IL-10 (AUC 0.93) and IL-6 (AUC 0.82), while IFN-γ showed moderate discriminative ability (AUC 0.72). Power analysis confirmed adequate statistical power for IL-10 and IL-6. Substantial overlap in IFN-γ levels limited its utility as a standalone systemic biomarker.

Conclusions: Reduced IL-10 and IL-6 levels define a cytokine profile associated with increased susceptibility to ICI-induced hypothyroidism. Cytokine-based biomarkers represent a feasible and biologically grounded approach to precision clinical medicine, enabling biomarker-driven risk stratification and individualized monitoring strategies for immune-related endocrine toxicity.

P425 - ECE_3457 - The epidemiology of focal thyroid lesions classified as category iv lesions in fine-needle aspiration biopsy

Maria Szmigielska[1,2], Magdalena Turowska[1,2], Bernadetta Kałuża[1,2], Małgorzata Kołos[3] and Edward Franek[1,2,4]

[1]*Department of Internal Medicine, Endocrinology and Diabetology, National Medical Institute of the Ministry of the Interior and Administration in Warsaw, Warsaw, Poland;* [2]*Warsaw, Poland;* [3]*Pathomorphology Centre, National Medical Institute of the Ministry of the Interior and Administration in Warsaw, Warsaw, Poland;* [4]*Department of Human Epigenetics, Mossakowski Medical Research Centre Polish Academy of Sciences, Warsaw, Poland*

Background: Bethesda system category IV determined via fine-needle aspiration biopsy (FNAB) of the thyroid is consistent with suspected follicular neoplasm; with the postoperative pathology report possibly indicating follicular adenoma, a highly cellular hyperplastic nodule, noninvasive follicular thyroid neoplasm with papillary-like nuclear features (NIFTP), lymphocytic thyroiditis, and follicular carcinoma, Hurthle-cell carcinoma, and follicular and oxyphilic variant of papillary thyroid carcinoma. The purpose of this study was to determine the incidence of heterogenous lesions from the Bethesda category IV in thyroid ultrasound-guided FNAB.

Material and Methods: We searched the hospital database for the period 2023-2025 and, out of all ultrasound-guided FNAB reports, we culled Bethesda category IV results.

Results: Out of the 1671 ultrasound-guided FNAB, category IV was observed in 0.59% of cases ($n = 10$). Bethesda category IV was observed in 6 patients (16.7% male [$n = 1$] and 83.3% female [$n = 5$], aged 59 ± 17.92 years [37-83]). Eighty percent of the aspirated lesions ($n = 8$) were focal hypoechoic lesions, and 20% ($n = 2$) were focal normoechoic lesions; the lesion diameter was 12.4 ± 3.29 mm (10-50 mm). Thyrocytes of oxyphilic cell morphology were found in 40% of cases ($n = 4$), small follicular structures were found in 20% of cases ($n = 2$), microfollicular in 20% of cases ($n = 2$), and colloid in 30% of cases ($n = 3$).

Conclusions: Suspected follicular thyroid neoplasm is a relatively rare cytological diagnosis and is characterized by relatively high heterogenicity.

P426 - ECE_3821 - Epigenetic silencing of RASSF1A, MGMT and NALCN in plasma cfDNA of sporadic medullary thyroid carcinoma patients

George Simeakis[1], Konstantina Tekou[2], Elina Lagopodi[2], Maria Boudina[3], Georgios Christantoniou[3], Alexandra Chrisoulidou[3], Pantelis Constantoulakis[4], Konstantinos Chanopoulos[1], Maria Alevizaki[5], Kyriakos Vamvakidis[6], Athina Markou[2] and Evi Lianidou[2]

[1]*Thyroid Cancer Outpatient's Clinic, Endocrine Dept., 401 General Military Hospital of Athens, Athens, Greece;* [2]*Analysis of Circulating Tumor Cells (ACTC) Lab, Dept of Chemistry, National and Kapodistrian University of Athens, Athens, Greece;* [3]*Endocrine Dept., Theagenio Cancer Hospital, Thessaloniki, Greece;* [4]*Genotypos S.A, Athens, Greece;* [5]*National and Kapodistrian University of Athens, Athens, Greece;* [6]*Dept of Endocrine Surgery, Henry Dunant Hospital Center, Athens, Greece*

Objectives: Distant metastases (DM) and/or biochemical persistent disease (BPD) in MTC, adversely affect disease prognosis, with calcitonin and CEA doubling-times serving as the main prognostic indicators. The role of epigenetic modifications in thyroid cancer is under investigation. Liquid-biopsy, particularly through cell-free DNA (cfDNA) analysis, is a non-invasive tool providing real-time monitoring of disease progression and information on tumor biology. We aimed to evaluate whether DNA methylation of selected tumor suppressor genes in plasma-cfDNA provides prognostic information in sporadic medullary thyroid carcinoma (spMTC) patients.

Methods: The methylation status of three selected gene promoters (*RASSF1A, MGMT* and *NALCN*) was examined by highly specific and sensitive real-time methylation specific PCR assays in: (a) 60 peripheral blood (PB) samples of 24 spMTC patients with DM and/or BPD, collected at different time-points every 3-6 months, depending on disease progression, (b) 14 healthy donor (HD) samples. PB samples were processed for cfDNA extraction using the Qiagen Circulating Nucleic Acid Kit. Sodium-Bisulfite conversion of cfDNA was performed using the EZ DNA-Methylation-Kit. Methylation-Specific PCR was further performed using gene-specific primers that selectively amplified methylated sequences.

Results: In the 60 spMTC plasma-cfDNA samples DNA promoter was highly methylated in 11/60 (18.3%) for *RASSF1A*, 6/60

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

(10.0%) for *MGMT* and 3/60 (5.0%) for *NALCN*. In the 24 patients studied, DNA promoter was highly methylated in 14/24 (58.3%) for *RASSF1A*, 5/24 (20.8%) for *MGMT* and 3/24 (12.5%) for *NALCN*. When we analyzed patients with **DM ($n = 14$) vs BPD ($n = 10$)**, DNA promoter was highly methylated in 8/14 (57.1%) vs 3/10 (30.0%) for *RASSF1A*, 4/14 (28.6%) vs 1/10 (10.0%) for *MGMT* and 3/14 (21.4%) vs 0/10 (0.0%) for *NALCN*. Comparing methylation status of the three selected tumor suppressor genes in patients with **DM vs BPD**, we found that 10/14 (71.4%) DM vs 3/10 (30.0%) BPD patients, $P < .05$, were characterized by significantly higher percentage of DNA methylation in at least one of the tumor suppressor genes studied. Notably, in 5/14 (35.7%) DM vs 1/10 (10.0%) BPD patients, DNA promoter methylation was detected concomitantly in two tumor suppressor genes. No methylation for any of the three genes was detected in all 14 HD samples.

Conclusions: DNA methylation status was significantly higher in spMTC patients with DM vs BPD possibly implicating a role of DNA methylation of tumor suppressor genes in the progression and metastatic potential of spMTC. Larger patients' series and comparison with the methylation status of the primary tumor are required to validate these results.

Abstract citation ID: lvag096.552

P427 - ECE_3323 - Thyroid Eye Disease Following Immunomodulatory Therapy for Multiple Sclerosis: A Case Series

Sandhi Nyunt[1,2], Mohammud Musleh[3,4], Claire Feeny[2], Ahmad Aziz[3,4], Vassiliki Bravis[2], Richard Nicholas[5], Karim Meeran[1,2] and Vickie Lee[3,4]

[1]Department of Metabolism, Digestion and Reproduction, Imperial College London, London, United Kingdom; [2]Department of Endocrinology, Imperial College Healthcare NHS Trust, London, United Kingdom; [3]Oculoplastic and Adnexal Service, Western Eye Hospital, Imperial College NHS Foundation Trust, London, United Kingdom; [4]Imperial College Ophthalmology Research Group (ICORG), London, United Kingdom; [5]Department of Neurology, Imperial College Healthcare NHS Trust, London, United Kingdom

Background: Immunomodulatory therapies for multiple sclerosis (MS), particularly immune reconstitution therapy, are associated with secondary autoimmune diseases, including autoimmune thyroid disease such as Graves' disease. However, the development of clinically significant thyroid eye disease (TED) following these therapies remains under-reported and poorly characterised. Alemtuzumab-induced immune reconstitution can trigger thyroid autoantibodies and orbital autoimmunity, providing a mechanistic basis for therapy-associated TED.

Methods: We conducted a retrospective case series of patients with MS who developed TED following exposure to immunomodulatory therapy. Patients were identified from a specialist thyroid eye disease multidisciplinary clinic at Imperial College Healthcare NHS Trust. Clinical data collected included patient demographics, thyroid and TED status with relevant investigations and management strategies and MS-related clinical features and treatments.

Results: Six patients with MS who developed TED following immunomodulatory therapy were identified: alemtuzumab ($n = 4$), natalizumab ($n = 1$) and interferon-based therapy with intravenous methylprednisolone and cyclophosphamide ($n = 1$). All patients were euthyroid with no prior history of Graves' disease or TED before initiation of immunotherapy. Smoking status was available for all patients; one was a current smoker, two were ex-smokers and the remainder were never-smokers.

TED developed after treatment exposure in all cases. Among alemtuzumab-treated patients, TED occurred at a median of 36 months following therapy (range 24-48 months). All patients were diagnosed with Graves' disease with positive thyrotropin receptor antibodies; four had suppressed TSH levels (<0.001 mU/L) at TED diagnosis.

At presentation, TED severity according to EUGOGO criteria ranged from mild to severe, with one patient classified as mild, four as moderate and one as severe. During follow-up, disease progression was observed, with peak EUGOGO severity reaching severe disease in four patients while one patient remained moderate and one mild. TED-directed immunosuppression included intravenous methylprednisolone ($n = 2$) and local triamcinolone ($n = 1$). Three patients underwent rehabilitative interventions, including extraocular muscle botulinum toxin injection, strabismus surgery, orbital decompression or eyelid surgery. Thyroid management included antithyroid drugs ($n = 3$) or thyroidectomy ($n = 3$).

Conclusions: This case series highlights that patients treated with immunomodulatory therapies for MS, particularly immune reconstitution therapy with alemtuzumab, may be predisposed to clinically significant TED in addition to secondary thyroid autoimmunity. From an endocrinology perspective, these findings support the need for prolonged thyroid and ocular surveillance for at least 3-5 years following treatment, with prompt assessment of ocular symptoms and timely referral to specialist multidisciplinary centres.

P428 - ECE_2815 - Clustering and response prediction in differentiated thyroid cancer: insights from the Hungarian thyroid cancer register

Celia Blasszauer[1] and Emese Mezosi[2,3]

[1]Budapest, Hungary; [2]PTE AOK, Pécs, Hungary; [3]Ist Department of Internal Medicine, University of Pecs, Pecs, Hungary

Differentiated thyroid cancer (DTC) is the most common endocrine malignancy, showing generally favorable prognoses but variable clinical presentations.

We analyzed anonymized data from the Hungarian Thyroid Cancer Register collected over 2023-2024. The cohort included 833 patients diagnosed with DTC. To uncover patient subgroups, unsupervised K-means clustering was implemented in Python, comparing predicted outcomes with recorded clinical responses. Results revealed four distinct clusters corresponding to varied outcome profiles.

Cluster 1 comprises younger patients with predominantly structural thyroid disease, characterized by nodular goiter and low systemic comorbidity burden. **Cluster 2** represented the lowest-risk phenotype, consisting of middle-aged patients with minimal symptom burden and the lowest prevalence of metabolic and cardiovascular comorbidities. **Cluster 3** reflected an older, metabolically burdened phenotype with high rates of diabetes, hyperlipidemia, and cardiovascular disease but without

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

enrichment for aggressive tumor features. In contrast, **Cluster 4** represented a small but clinically severe subgroup, characterized by advanced age, high comorbidity burden, increased lymph-node–related symptoms, and enrichment for advanced stage and metastatic disease.

Clinical stage distribution differed markedly across clusters, with Clusters 1 and 2 predominantly composed of early-stage disease, Cluster 3 showing intermediate stage distribution, and Cluster 4 enriched for advanced clinical stages. Treatment response also varied by cluster, with Clusters 1 and 2 demonstrating the highest rates of favorable response, Cluster 3 showing generally preserved response despite higher comorbidity burden, and Cluster 4 exhibiting the poorest response profile.

This study underscores the value of merging real-world registry data with machine learning for personalized DTC management. By associating demographics, clinical features, morphology, and comorbidities with treatment responses, this dual-layer analysis advances segment-level risk stratification and supports tailored clinical decision-making.

P429 - ECE_2074 - Efficacy and safety of RFA therapy in patients with benign thyroid nodules compared to other modalities

Roni Mechorish[1], Moshe Yehuda[1,2], Gideon Bachar[1,2], Ilan Shimon[1,3], Eyal Robenshtok[1,3] and Hadar Duskin-Bitan[1,3]

[1]*Gray Faculty of Medicine, Tel Aviv University, Petah Tiqva, Israel;* [2]*Department of Otolaryngology, Head and Neck Surgery, Rabin Medical Center, Petah Tiqva, Israel;* [3]*Rabin Medical Center, Endocrinology & Metabolism Institute, Petah Tiqva, Israel*

Background: Lobectomy had been a standard treatment for large and/or functioning thyroid nodules for many years, but may lead to postoperative hypothyroidism and visible scarring. Radiofrequency ablation (RFA) offers a minimally invasive alternative with preserving normal of thyroid tissue. Comparative outcome data from Israel remain limited.

Methods: A retrospective cohort study was conducted at Rabin Medical Center (2020-2025) including 206 adults with benign thyroid nodules: 116 treated with RFA and 90 with lobectomy. Demographic variables, thyroid function (TSH, FT4, FT3), need for chronic LT4 or antithyroid therapy, nodule volume change, and adverse events were assessed. The primary outcome was maintenance of euthyroidism; secondary outcomes included volume reduction and safety.

Results: Patients treated with RFA were younger (mean 48.8 vs 57.9 years) and predominantly female (106/116 vs 67/90). RFA preserved thyroid function in almost all cases, with 0/116 requiring chronic levothyroxine, compared to 15/90 (17%) after lobectomy. RFA achieved a mean nodule volume reduction of $66 \pm 7\%$, while no comparable data was available after lobectomy due to complete lobe excision. Early voice-related symptoms occurred in 14/90 (15.6%) after lobectomy vs 8/116 (6.9%) after RFA, and permanent vocal cord paralysis in two lobectomy patients (2.2%) and one RFA patient (0.9%). Postoperative swallowing discomfort was reported in 5/90 (5.6%) vs 4/116 (3.4%), respectively. RFA did not create a scar.

Conclusions: In this cohort, RFA provided a practical and safe alternative to lobectomy, maintaining euthyroidism, achieving substantial volume reduction, and resulting in fewer long-term hormone requirements and fewer local complications, without surgical scarring. These findings support the integration of RFA into routine practice for selected patients with benign thyroid nodules.

P431 - ECE_2913 - Hashimoto's Thyroiditis natural history—a single centre prospective study

Arianna Benedetti[1], Giulia Di Dalmazi[2], Tommaso Luciano[1], Noemi Mariello[1], Giorgia Rapagnetta[1], Ines Bucci[3] and Giorgio Napolitano[1]

[1]*Università "G. D'Annunzio" Chieti-Pescara, Chieti, Italy;* [2]*UOC Endocrinologia e Malattie Metaboliche, ASL Pescara, Pescara, Italy;* [3]*Chieti, Italy*

Background: Hashimoto's Thyroiditis (HT) is a common autoimmune disease characterized by lymphocytic infiltration of the thyroid gland, presence of thyroid-specific circulating autoantibodies (anti-Tg and anti-TPO) and varying degrees of thyroid dysfunction. Most patients present a normal thyroid function at diagnosis, and not all of them will progress to hypothyroidism: most studies reveal a progression rate to hypothyroidism of 5-15% within 5-10 years since diagnosis. We aimed to establish the prevalence of thyroid disfunction in patients with HT at diagnosis and during follow-up, defining the mean time to its onset, possible prognostic factors and impact on quality of life (QoL).

Methods: We designed a single centre prospective study including 178 adult patients who referred to our Endocrinology unit with a new diagnosis of HT, followed every 6 months. For each visit, we collected information about their anamnesis and QoL evaluated with the ThyPRO-39it questionnaire and performed thyroid gland ultrasound and blood tests regarding thyroid function. Median follow-up duration was 4.9 years (2020-2025).

Results: At diagnosis, 123 patients (69.1%) were euthyroid, 4 (2.3%) were hyperthyroid and 51 (28.6%) were hypothyroid. 16 of 123 (13%) initially euthyroid patients developed hypothyroidism during the study follow-up, with a mean time to progression of 19 ($\pm$21) months and a high interindividual variability. Patients who progressed to hypothyroidism showed significantly higher baseline TSH levels compared with those without progression (2.98 ± 0.86 vs 2.02 ± 1.06 respectively, *P*-value <.001). No significant differences were observed between groups with respect to age, sex, familial history of autoimmune thyroid disease, presence of other autoimmune disorders, FT4 levels, anti-thyroid antibodies, thyroid volume, the presence of thyroid nodules, or the ultrasound pattern of thyroid. A multivariate analysis with Cox regression model revealed that TSH was the only independent prognostic factor of progression to hypothyroidism (HR 1.99, *P*-value <.001). QoL, evaluated at 6 and 36 months since HT diagnosis, resulted compromised in all patients affected by HT irrespective of thyroid function, with the only exception of cosmetic complaints scale, significantly more compromised in patients with hyperthyroidism at the 6-month evaluation (*P*-value .01).

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Conclusions: HT is a common autoimmune disorder with important implications in QoL and a heterogeneous clinical course, with different possible effects on thyroid function. In our study, consistent with current literature, baseline TSH levels emerged as the only independent prognostic factor the development of hypothyroidism, potentially representing a discriminant to personalize follow-up timing in patients with HT.

P432 - ECE_2246 - Investigating the effects of maternal thyroid hormones on offspring cardiometabolic risk factors in adulthood: an intergenerational Mendelian randomization study

Marion Denos[1], Laxmi Bhatta[1], Marco Medici[2], Alexander Teumer[3], Ben Brumpton[1] and Bjørn Olav Åsvold[1]
[1]Trondheim, Norway; [2]Radboud University Medical Center, Nijmegen, The Netherlands; [3]University Medicine Greifswald, Greifswald, Germany

Background: Epidemiological studies reported that maternal thyroid function in pregnancy may have lasting effects on the offspring. However, only a very few studies investigated these lasting effects on cardiometabolic outcomes in offspring.

Objectives: This study used an instrumental variable framework as an alternative approach to investigate the effects of maternal thyroid hormones on offspring cardiometabolic risk factors related to body composition, blood pressure, glucose and lipid levels in adulthood.

Methods: We performed a two-sample intergenerational Mendelian randomization (MR) using genetic instruments selected from recent genome-wide association studies (GWAS) of thyroid hormones in up to 271 040 individuals of European ancestry, including thyrotropin (TSH) (259 single nucleotide polymorphisms (SNPs)), free thyroxine (FT4) (85 SNPs) and triiodothyronine (T3) (62 SNPs). SNP-outcome associations were obtained from adjusted GWAS (parental genotype adjusted for offspring genotype) of adult cardiovascular outcomes in three European cohorts (n = up to 564 765). Outcomes in this MR analysis were offspring body mass index, waist-to-hip ratio, systolic and diastolic blood pressure, blood glucose, HbA1c, C-reactive protein, total cholesterol, low- and high-density lipoprotein cholesterol, and triglycerides, measured at 24-62 years of age.

Results: We found no strong evidence of an effect of genetically predicted variation in maternal thyroid function on offspring cardiometabolic outcomes. In adjusted MR analyses, higher maternal TSH levels were associated with lower levels of triglycerides and diastolic and systolic blood pressure in adult offspring (mean differences in standard deviation (SD) units per one SD higher maternal TSH: triglycerides −0.05, 95% CI −0.09 to −0.01; diastolic blood pressure −0.05, 95% CI −0.09 to −0.01; systolic blood pressure −0.04, 95% CI −0.07 to 0.00), but these results were not robust to adjustment for multiple testing and not consistently supported by sensitivity analyses. Moreover, genetically predicted maternal FT4 and FT3 levels were not related to cardiometabolic outcomes in offspring.

Conclusions: Overall, our findings using available genetic instruments suggest that maternal thyroid hormones levels have little influence on offspring cardiometabolic risk factors in adulthood.

P434 - ECE_1052 - Thyroid storm—a rare presentation of subacute thyroiditis

Kevin Kwek, Hui Chia Wee and Htoo Htoo Mar
Endocrinology, Khoo Teck Puat Hospital, Singapore

Thyroid storm is a severe multi-system presentation of thyrotoxicosis, most common in patients with Graves disease. Severe subacute thyroiditis typically causes a self-limited short duration of hyperthyroidism and significant morbidity is typically rare. We present an unusual case of subacute thyroiditis presenting as thyroid storm.

A 66-year-old female was admitted via the Emergency Department to our institution after a pair of mechanical falls precipitated by generalized weakness without focal neurological symptoms. She had significant history of Type 2 Diabetes Mellitus, Hypertension, Dyslipidemia and Non-alcoholic Fatty Liver Disease. She had been suffering from fever, diarrhea and coryzal symptoms for several days prior to admission. On initial evaluation, she was severely dehydrated, pyrexic and lethargic. Evaluation of vital signs revealed sinus tachycardic (heart rate 120-140bpm) without hypotension. A thyroid function test performed for evaluation of tachycardia revealed severe primary hypothyroidism with free thyroxine (fT4) 96.6 pmol/L (RR 12-22) and TSH 0.015 mIU/L (RR 0.27-4.2).

As the calculated Burch-Warforsky Point Scale (BWPS) was 80pts, we made a diagnosis of thyroid storm. She was treated emergently with carbimazole 30mg twice daily, Lugol's iodine at 10 drops (65mg of inorganic iodine) thrice daily and intravenous hydrocortisone at 100mg thrice daily. The likely precipitant was a urinary tract infection, for which she received intravenous antibiotics.

Table 1 Further biochemistry

Test	Result	Reference range
fT4	97.6 pmol/L	12-22
TSH	0.015 pmol/L	0.27-4.2
Free triiodothyronine (fT3)	5.5 pmol/L	3.1-6.8
Thyrotropin receptor antibody	negative	
Thyroid stimulating immunoglobulin	negative	
Anti-thyroid peroxidase antibody	negative	
Anti-thyroglobulin antibody	negative	

The negative antibody screen and absence of thyroid eye disease, goitre and pretibial myxedema led us to question the presumptive diagnosis of Graves disease. In addition, the markedly raised fT4:fT3 ratio of 17.75 favoured thyroiditis, though non-thyroidal illness from infection would confound this interpretation. Thyroid ultrasonography demonstrated heterogenous echogenicity without increased internal vascularity and small subcentimetre nodules, which favoured thyroiditis.

Due to the severity of the initial presentation, carbimazole therapy was continued for 1 week. However, despite clinical

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

improvement, fT4 levels remained persistently elevated at 39.4 pmol/L. A radioiodine uptake scan was performed and demonstrated diffusely reduced tracer uptake in both thyroid lobes, confirming the diagnosis of thyroiditis. Thus, Carbimazole was ceased and her fT4 levels subsequently normalized without treatment.

This case highlights that subacute thyroiditis, while typically biochemically mild, can present explosively and cause significant morbidity. While subacute thyroiditis remains a rare cause, it should be considered when the clinical picture is inconsistent with Graves disease.

P435 - ECE_1997 - Multimodal management of ectopic lingual thyroid: surgical excision and radioactive iodine ablation

Praneet Bolusani[1], Aled Rees[2], David Scott-Coombes[2], John Rees[2] and Fizzah Iqbal[2]
[1]*Gloucestershire Hospitals NHS Trust, Gloucester, United Kingdom;* [2]*University Hospital of Wales, Cardiff, United Kingdom*

Introduction: Lingual thyroid represents the most common form of ectopic thyroid tissue and results from abnormal embryological migration of the thyroid gland. It can present in adulthood secondary to compressive symptoms or hypothyroidism, in the absence of normally located thyroid tissue. We present a case of dual ectopic thyroid tissue causing significant compressive symptoms, requiring multidisciplinary management with combination of surgical excision and radioactive iodine ablation.

Case: 52-year-old female presented with a 1-year history of dry cough associated with eating and drinking, with a globus sensation. She also reported several months of inability using her voice over prolonged periods. Past medical history included bilateral sensorineural hearing loss. Her work as an aviation safety trainer was affected, prompting investigation. Ultrasound scan of the neck demonstrated absence of thyroid tissue in the normal anatomical location. Subsequent MRI neck and thyroid uptake scan confirmed absence of normal functioning thyroid tissue, with two adjacent rounded masses seen at the tongue base. A 35mm anterior nodule towards the floor of mouth was mildly iodine-avid while a smaller 22mm posterior nodule was intensely avid. TSH was normal at 3.52 with a FT4 of 15.7. Following multidisciplinary discussion, surgical resection of the larger nodule, felt to be the main contributor to her compressive symptoms, was performed. Histopathology showed a multinodular goitre. CT-neck with contrast at 6 months demonstrated residual nodule at the tongue base. After discussion with the patient, radioactive iodine (RAI) treatment was undertaken. A 1-year post-RAI ultrasound neck showed size reduction from 22x20x23mm to 11x11x18mm. The patient reported full resolution of her symptoms and is now maintained on replacement dose levothyroxine.

Conclusion/Discussion: Lingual thyroid is a rare oropharyngeal entity resulting from failure of thyroid descent to its normal position during embryogenesis. It is more common in females and frequently associated with hypothyroidism. Patients may present with compressive symptoms including dysphagia, dysphonia, and upper airway obstruction. Management is individualised and based on symptom burden, size and thyroid function. While asymptomatic patients may be managed conservatively, the presence of compressive/voice-related symptoms warrants intervention. I-123 uptake scanning is a valuable diagnostic tool for confirming ectopic functioning thyroid tissue and guiding management.

This case highlights the complexity of dual ectopic lingual thyroid tissue and demonstrates the effectiveness of a multidisciplinary-guided combined surgical and RAI approach. Initial surgical resection relieved compressive symptoms, while subsequent RAI successfully reduced residual disease and avoided further invasive surgery, achieving symptom resolution and disease control.

P436 - ECE_2418 - When radioiodine uptake misleads: severe thyrotoxicosis from a long-standing multinodular goiter

Humera Tabassum[1,2,3], Evelyn Morales[1,2,3], Sathya Jyothinagaram[1,2] and Karyne Vinales[1,2]
[1]*Endocrinology, University of Arizona College of Medicine, Phoenix, United States;* [2]*Phoenix VA Healthcare System, Phoenix, United States;* [3]*Banner—University Medical Center Phoenix, Endocrinology, Medicine, Phoenix, United States*

Introduction: Subclinical hyperthyroidism due to multinodular goiter is often indolent and may remain untreated for years. Progression to severe thyrotoxicosis with neurological manifestations and delayed biochemical response to antithyroid therapy is rare, particularly with persistently negative radioiodine uptake.

Case Presentation: A 72-year-old male with a long-standing multinodular goiter incidentally identified on computed tomography in 2012 and a 10-year history of untreated subclinical hyperthyroidism was followed conservatively, as he remained asymptomatic and declined treatment. Thyroid radioiodine uptake scans performed in 2012, 2017, 2019, and 2024 consistently demonstrated absent uptake. Due to the markedly enlarged thyroid, pulmonary function testing revealed a moderately severe obstructive ventilatory defect, with diminished mid–lung volume expiratory flows, inspiratory limb flattening on flow-volume loops, and forced expiratory volume in one second (FEV1) of 57% predicted.

The patient later presented to the emergency department with acute encephalopathy. Laboratory evaluation revealed undetectable thyroid-stimulating hormone with elevated free triiodothyronine (5.8 pg/mL) and free thyroxine (3.56 ng/dL). Thyroid-stimulating immunoglobulin, TSH receptor antibodies, and thyroid peroxidase antibodies were negative, consistent with prior testing. Extensive evaluation for infectious, metabolic, and structural causes of encephalopathy was unrevealing.

The patient was initiated on methimazole 20 mg three times daily for four weeks without clinical or biochemical improvement and was subsequently transitioned to propylthiouracil 400 mg every eight hours, again without early response. Despite continuous inpatient therapy, thyroid hormone levels remained elevated, with free thyroxine measuring 2.32 ng/dL after nearly eight weeks. Biochemical euthyroidism was achieved only after more than ten weeks of antithyroid therapy, coinciding with complete resolution of encephalopathy. The patient is planned for definitive treatment with radioactive iodine.

Discussion: This case represents Jod-Basedow–independent decompensation of a long-standing autonomous multinodular goiter. Chronic autonomy and prolonged TSH suppression lead to reduced sodium-iodide symporter expression and inefficient

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

iodine trapping, explaining persistently negative radioiodine uptake despite large intrathyroidal hormone stores. Acute physiologic stress likely precipitated excessive hormone release, resulting in severe thyrotoxicosis and encephalopathy. Apparent resistance to antithyroid drugs reflects continued release of preformed hormone rather than increased synthesis.

Conclusions: This case highlights a rare but important mechanism of thyrotoxicosis in which long-standing autonomous multinodular goiter produces severe hormone excess despite absent radioiodine uptake. Recognizing this dissociation between iodine trapping and hormone output is critical to avoid misdiagnosis and delayed definitive therapy.

P437 - ECE_1239 - Preoperative use of potassium iodide (KI) in poorly controlled thyrotoxicosis: an audit of safety and efficacy

Helen Loo, Christine May and Helen Turner
Oxford University Hospital, Endocrinology, Oxford Centre for Diabetes, Endocrinology and Metabolism, Oxford, United Kingdom

Background: The use of KI or Lugol's iodine solution as a preoperative treatment for patients with poorly controlled thyrotoxicosis who are intolerant or unresponsive to antithyroid drugs (ATDs) is well-documented but rarely systematically evaluated. This audit assesses the implementation and outcomes of outpatient KI therapy in patients at Oxford University Hospitals (OUH) requiring thyroidectomy due to inability to tolerate or poorly controlled thyrotoxicosis with ATD therapy.

Methods: Following registration as an audit, and patient selection from the endocrinology database, a 6-year retrospective data collection included: indication for KI treatment, thyroid biochemical changes with KI, patient outcomes, and tolerability.

Results: $N = 18$ patients (14/18 female 77.8%), mean age 48 years (31-72), $n = 3$ smokers, received iodine therapy before thyroidectomy. Graves' disease was the diagnosis for 100%; 5/18 (27.8%) had Thyroid eye disease. Indications for treatment were intolerance $n = 7$ (39%), LFT abnormality $n = 2$, neutropenia $n = 7$ (39%), cardiac indication $n = 2$

Thirteen patients received potassium iodide (65mg TDS), 4 received Potassium iodide (60mg TDS) (doses varying due to drug availability) and 1 patient was treated with Lugol's solution due to lactose intolerance. The treatment was well tolerated. 1 patient had delayed surgery due to contracting COVID post commencement of KI, with no rebound thyrotoxicosis after 7 pre-surgery days. 17 patients had KI for 10 days pre surgery, and 1 patient with fT3 < 8.4 pmol/L only required 7 days of KI therapy. Pre-treatment fT4 mean 31.8 pmol/L (range 23.2-58.3, (upper limit of normal 19 pmol/L)) and fT3 mean 17.38 pmol/L (range 8.4- 30.72, (upper limit of normal 5.4 pmol/L)). Thyroid function was monitored at 2-4-day intervals to ensure improvement. Thyroid function one day prior to surgery had fallen to fT4 mean 18.4 pmol/L (range 14.4-24.4) and fT3 mean 6.5 pmol/L (range 4.3-11). There were no perioperative complications eg thyroid storm, excess bleeding, or arrythmia, and KI was well tolerated by all.

Conclusions: This audit supports the efficacy and safety of preoperative outpatient iodine therapy in patients with uncontrolled thyrotoxicosis with appropriate monitoring. Patients with milder fT3 and fT4 elevation could be considered for a shorter treatment course. Logistical planning regarding date of planned surgery between medical and surgical teams is vital.

P440 - LBA_ECE_1022 - Evaluation of muscle quality and strength in type 2 diabetes using handgrip strength and triceps muscle ultrasound

Sabri Engin Altıntop[1], Irem Sonmezoglu Kutuk[1], Refika Yorulmaz Kaya[1], Mahinur Cerit[2], Mehmet Muhittin Yalcin[1], Altinova Alev[1], Mujde Akturk[1], Fusun Toruner[1], Ayhan Karakoc[1] and Ethem Turgay Cerit[1]
[1]Department of Endocrinology and Metabolism, Gazi University Faculty of Medicine, Ankara, Türkiye; [2]Department of Radiology, Gazi University Faculty of Medicine, Ankara, Türkiye

Background: Type 2 diabetes mellitus (T2DM) is associated with reduced skeletal muscle mass and function, a condition increasingly referred to as diabetic sarcopenia. These alterations highlight the importance of early assessment of muscle strength and quality in individuals with diabetes. This study aimed to evaluate handgrip strength and ultrasonographic characteristics of the triceps muscle in individuals with T2DM and to examine their associations with anthropometric parameters, body composition, and physical activity.

Methods: This cross-sectional study included 120 participants aged 18-65 years, comprising 60 individuals with T2DM and 60 healthy controls matched for age, sex, and body mass index (BMI). Body composition was assessed using a Tanita bioelectrical impedance analysis device, and physical activity was evaluated using the Rapid Assessment of Physical Activity (RAPA) questionnaire. Handgrip strength was measured from the dominant hand using a digital dynamometer. The triceps muscle of the dominant arm was evaluated by ultrasonography, and muscle thickness, subcutaneous fat thickness, muscle-to-fat ratio, and muscle echogenicity (an indirect indicator of muscle quality) were recorded.

Results: The median age was 55 years, and each group included 36 women and 24 men. Triceps muscle thickness correlated with arm muscle mass measured by bioelectrical impedance analysis ($P < .001$). Handgrip strength was lower in individuals with T2DM than in healthy controls (24.47 [13.56] kg vs 27.40 [10.60] kg; $P = .019$), whereas triceps muscle echogenicity was higher in the T2DM group ($P = .003$). Triceps muscle thickness and muscle-to-fat ratio did not differ between groups ($P > .05$). In sex-specific analyses, women with T2DM had lower handgrip strength (20.60 [5.88] kg vs 24.95 [4.05] kg; $P < .001$) and higher triceps muscle echogenicity ($P = .019$) than healthy women. In men, handgrip strength was similar between groups ($P = .797$), whereas triceps muscle echogenicity was higher in those with T2DM ($P = .044$). Treatment with SGLT2 inhibitors was

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

associated with lower handgrip strength ($P = .034$) and higher triceps muscle echogenicity ($P = .003$). ROC analysis showed that diabetes duration predicted low handgrip strength (AUC = 0.75), with a cut-off of 7.5 years.

Conclusions: Our findings indicate that individuals with T2DM exhibit impairments in muscle quality (increased echogenicity) and muscle function (reduced handgrip strength) even without loss of muscle mass, with these alterations being more pronounced in women. These findings suggest that assessing diabetic sarcopenia should include muscle quality and function, not muscle mass alone.

P442 - LBA_ECE_1217 - Thyroid hormone alterations reshape gut microbial ecosystems in a rat model

Alara Ataacar Aydınoğlu[1], Akif Enes Arikan[2], Osman Ugur Sezerman[3], Tayyip Karaman[3], Samed Ozer[4] and İnan Anaforoglu[5]

[1]Acibadem Mehmet Ali Aydinlar University, Internal Medicine, Istanbul, Türkiye; [2]Acibadem Mehmet Ali Aydinlar University, General Surgery, Istanbul, Türkiye; [3]Department of Biostatistics and Medical Informatics, Acibadem Mehmet Ali Aydinlar University, Istanbul, Türkiye; [4]Acibadem Mehmet Ali Aydinlar University, Laboratory Animal Application and Research Center, Physiology, Istanbul, Türkiye; [5]Endocrinology and Metabolism, Internal Medicine, Acibadem Mehmet Ali Aydinlar University, Istanbul, Türkiye

Introduction: Thyroid dysfunctions profoundly affect multiple physiological systems. Growing evidence highlights a bidirectional interaction between gut microbiota and thyroid function, conceptualized as the "gut–thyroid axis." Dysbiosis may influence hormonal homeostasis through increased intestinal permeability and altered immune regulation while thyroid hormones themselves may reshape microbial communities. Yet, the mechanisms underlying this interaction remain unclear. A subset of patients with thyroid disorders continues to experience persistent symptoms such as fatigue, weight gain and impaired quality of life despite achieving biochemical euthyroidism. This clinical discordance raises the possibility that factors beyond circulating thyroid hormone levels, including alterations in gut microbiota, may contribute to the persistence of these symptoms.

Objective: This study aimed to investigate the effects of thyroid dysfunction, induced either chemically (levothyroxine, methimazole) or surgically (subtotal thyroidectomy), on gut microbiota composition in a rat model.

Methods: Twenty-five male Wistar Albino rats were allocated into control, hyperthyroidism (HE), hypothyroidism (HO), sham-operated (SHAM) and thyroidectomy (SHO) groups. Fecal samples were collected at baseline, weeks 4 and 7. Serum TSH and free T4 levels were measured at weeks 4 and 7. Microbial composition and diversity were assessed using 16S rRNA sequencing and bioinformatics analysis.

Results: Thyroid dysfunction induced significant alterations in microbial composition. HE rats exhibited increased *Oscillospiracea* and *Spirochaetaceae*, along with depletion of *Lactobacillus*. HO groups showed enrichment of anaerobic taxa such as *Desulfobacterota* and *Spirochaetota* (Table 1), whereas SHO groups were characterized by increased abundance of *Muribaculaceae* and *Desulfovibrionaceae* (Table 2). Alpha diversity increased over time, suggesting adaptive restructuring of the microbial ecosystem, while beta diversity analyses revealed temporal shifts in community composition. These microbial alterations occurred in parallel with changes in thyroid hormone levels and body weight dynamics, indicating a coordinated interaction between endocrine status and microbial ecology.

Conclusions: Specific taxa including *Lactobacillus*, *Campylobacterota* and *Desulfobacterota* may represent microbial signatures of thyroid dysfunction. These findings provide experimental support for the gut–thyroid axis and suggest that thyroid hormones may act as key ecological regulators of the intestinal microbiome. Importantly, the observed microbial shifts may offer a potential biological explanation for persistent metabolic symptoms and impaired quality of life reported in some patients despite achieving biochemical euthyroidism. These results highlight the need to consider microbiota-targeted approaches as potential adjunctive strategies in the management of thyroid disorders.

P443 - LBA_ECE_1020 - Causal analysis of traditional and environmental risk factors for long-term development of type 2 diabetes using a conditional survival Bayesian network

Jiyoung Choi and Mansuk Oh
Ewha Womans University, Statistics, Seoul, South Korea

Background: Traditional metabolic and lifestyle factors and ambient air pollutants are established contributors to type 2 diabetes (T2D), yet their joint causal structure and individual versus interacting interventional effects remain poorly characterized in long-term population studies.

Methods: We analyzed 11-year follow-up data from 2102 adults free of T2D at baseline in the Ansan cohort of the Korean Genome and Epidemiology Study (KoGES). A Conditional Survival Bayesian Network (CSBN)—integrating survival analysis with Bayesian network modeling—was applied to accommodate censored data, reconstruct the causal structure among demographic, lifestyle, metabolic, and air pollution variables, and quantify individual and joint interventional effects on T2D incidence.

Results: The CSBN revealed a holistic causal network distinguishing direct and indirect pathways from likely confounding associations. Obesity exerted the largest individual causal effect, approximately doubling 11-year T2D risk relative to normal weight. Elevated alanine aminotransferase (ALT) and older age increased risk by 40-50%, while family history of T2D, dyslipidemia, overweight, $PM_{2.5}$ and gaseous pollutants showed intermediate effects. Synergistic interactions were identified predominantly among metabolic factors: ALT combined with family history, dyslipidemia, or obesity displayed strong additive interactions. Air pollutants, by contrast, influenced T2D risk independently rather than through interactions with metabolic variables.

Conclusions: These findings support integrated public health strategies addressing multiple risk factors simultaneously. The CSBN framework provides a powerful tool for explicitly modeling causal interactions, informing targeted preventive interventions and efficient resource allocation for T2D prevention.

P444 - LBA_ECE_1458 - Toward risk-adapted management of testicular lesions: a data-driven imaging framework derived from 20 years of clinical practice

Marta Tenuta[1,2], Francesco Carlomagno[1], Franz Sesti[1], Francesco Angelini[1], Giulia Pellegrini[1], Daniele Apostoli[1], Gabriele Savarese[3], Giorgio Franco[3], Lucia Manganaro[4], Fabio Magliocca[4], Daniele Gianfrilli[1], Andrea Isidori[1] and Carlotta Pozza[1]
[1]*Sapienza University, Experimental Medicine, Roma, Italy;* [2]*Department of Experimental Medicine, Sapienza University of Rome, Rome, Italy;* [3]*Maternal and Child Health and Urological Sciences, Sapienza University, Roma, Italy;* [4]*Radiological, Oncological and Pathological Sciences, Sapienza University, Roma, Italy*

Background: Intratesticular lesions represent a heterogeneous group of neoplastic and non-neoplastic conditions, increasingly detected due to widespread use of high-resolution ultrasound. While ultrasound is highly sensitive, lesion characterization remains challenging, often leading to uncertainty-driven management and potential overtreatment. This study aimed to describe real-world management and develop an imaging-based, risk-adapted diagnostic framework for intratesticular lesions.

Methods: We conducted a single-center observational cohort study including 750 consecutive patients with intratesticular lesions evaluated between January 2005 and December 2025. Clinical, imaging, and follow-up data were prospectively collected. Management strategies included active surveillance (AS), testis-sparing surgery (TSS), or total orchiectomy (TO). Histopathology or ≥18 months of imaging stability served as reference standards. A stepwise diagnostic framework was derived a posteriori, integrating lesion size, ultrasound features, and second-level imaging such as contrast-enhanced ultrasound (CEUS) and MRI. Logistic regression, ROC analysis, and bootstrap validation were used for model development and performance assessment.

Results: Among 750 lesions, 415 (55.3%) were malignant. TO was performed in 57.6% of cases, TSS in 12.4%, and AS in 30%. Malignancy was confirmed in 94.7% of TO specimens. All malignant lesions under AS showed interval growth, whereas benign lesions remained stable or regressed.

Lesion size demonstrated excellent discrimination for malignancy (AUC 0.92), with <0.5 cm identifying a low-risk group (malignancy 5.2%) and ≥1.8 cm a high-risk group (PPV 94.6%). Intermediate-size lesions (0.5-1.8 cm, malignancy 45.3%) were further stratified using a five-feature ultrasound-based score (T-Les-SCORE), incorporating vascularization, calcifications, margins, echogenicity, and multifocality. The combined score (0-9) achieved good discrimination (AUC 0.902) and defined low- (≤3), intermediate- (4-5), and high-risk (≥6) categories.

Clinical modifiers such as prior germ cell tumor and testicular microlithiasis improved model performance (AUC 0.929), while positive tumor markers acted as an absolute indication for surgery.

In intermediate-risk lesions, CEUS showed good diagnostic performance (AUC 0.789), capturing most residual diagnostic information. MRI demonstrated similar performance (AUC 0.793) and provided additional reassurance in selected cases with non-suspicious CEUS, although findings were exploratory. Sequential imaging reduced malignancy prevalence from 55.3% overall to 0% in lesions with both negative CEUS and MRI.

Conclusions: This study proposes a pragmatic, stepwise imaging framework integrating lesion size, structured ultrasound assessment, and selective second-level imaging. The model enables risk-adapted management, potentially reducing unnecessary orchiectomy while maintaining oncological safety.

Background: Chronic hypoparathyroidism is a rare endocrine disorder associated with biochemical instability, renal complications, and impaired quality of life. Real-world evidence describing disease burden and management patterns outside centralized registries remains limited. We aimed to characterize clinical features, biochemical control, monitoring practices, and treatment gaps in a nationwide multicentre cohort.

Methods: The OPA study is a retrospective multicentre registry conducted across 41 endocrinology clinics in Greece. Adult patients with chronic hypoparathyroidism (>12 months disease duration) were identified through combined ICD-10 diagnostic codes and active vitamin D prescription records, followed by manual chart verification. Demographic, biochemical, treatment, and complication data were extracted from medical records. Multivariable logistic regression analyses were performed to identify predictors of suboptimal biochemical control, care gaps, and renal impairment.

Results: A total of 522 patients were included; 83.1% were female and median disease duration was 8.0 years (IQR 5.0-15.0). Post-surgical disease accounted for 95% of cases. Optimal biochemical disease control was achieved in 54.8% of patients with complete datasets, while 45.2% had suboptimal control and 6.7% had persistent hypocalcaemia. Hypercalciuria occurred in 37.0% of assessed patients, and nephrolithiasis and nephrocalcinosis were observed in 17.0% and 5.2%, respectively. Overall, 80.8% of patients exhibited at least one predefined care gap related to biochemical targets, monitoring practices, or treatment optimization. Although 45.8% of patients met predefined eligibility criteria for PTH replacement therapy, only 8.2% were receiving PTH treatment. In multivariable analyses, younger age was associated with suboptimal biochemical control, longer disease duration predicted care gaps, and renal impairment was associated with older age and cumulative disease duration.

Conclusions: In this large real-world multicentre cohort, chronic hypoparathyroidism remained associated with substantial biochemical instability, renal complications, and gaps in recommended monitoring despite specialist care. The low utilization of PTH replacement therapy among eligible patients highlights potential barriers to implementation of guideline-recommended management.

P447 - LBA_ECE_1469 - From valve to algorithm: first report of advanced hybrid closed-loop insulin delivery during major cardiac surgery

Martha Scherer[1], Michael Uth[1], Serghei Cebotari[1] and Maria Tichomirowa[2]

[1]Institut national de chirurgie cardiaque et de cardiologie interventionnelle, Luxembourg; [2]Endocrinology, Centre Hospitalier du Nord, Ettelbrück, Luxembourg

Background: Management of glycemia during major cardiac surgery remains challenging, particularly in elderly patients with long-standing type 2 diabetes and high glycemic variability. While intravenous insulin infusion is standard, the intraoperative use of advanced hybrid closed-loop (AHCL) systems has not been reported in this setting.

Case Presentation: We report the first use of an AHCL system during major cardiac surgery in a 79-year-old woman with type 2 diabetes and acute heart failure following unsuccessful MitraClip therapy. Due to intolerance to injectable GLP-1 receptor agonists and suboptimal glycemic control, she was initiated on an AHCL system (MiniMed™ 780G with Simplera Sync sensor).

The patient underwent elective mitral valve replacement. Total anesthesia time was 5 h 30 min, including 4 h 30 min of surgery and 2 h 10 min of cardiopulmonary bypass. During the entire procedure, the patient received continuous norepinephrine for hemodynamic support. The AHCL system was maintained in SmartGuard™ mode throughout.

Results: Intraoperative glycemic control was excellent, with time in range (70-180 mg/dL) of 90% and no time below range. Simplera sensor values showed strong concordance with arterial blood glucose measurements (Mean arterial glucose was 158.7 ± 7.6 mg/dL). While a parallel FreeStyle Libre 3 Plus sensor displayed signal disturbances during electrocautery use, the Simplera sensor remained stable and unaffected.

Conclusions: This case demonstrates the feasibility, safety, and robustness of AHCL systems during prolonged cardiac surgery, even under cardiopulmonary bypass and continuous inotropic support with levosimendan. AHCL may represent a promising alternative to conventional insulin protocols in complex perioperative settings.

P448 - LBA_ECE_1352 - Lean Young-Onset Diabetes in Bangladesh: Distinct Clinical and Metabolic Features Beyond Classical Type 2 Diabetes

Nusrat Sultana, Mashfiqul Hasan, Kishore Shil, Sayad Abdus-Salam, Koushik Ashraf, Abdullah Bhuiyan and Muhammad Hasanat
Department of Endocrinology, Bangladesh Medical University, Dhaka, Bangladesh

Background: Young-onset diabetes in South Asians manifests frequently in lean individuals. However, the metabolic triggers of this phenotype remain poorly characterized.

Objective: This study aimed to evaluate the metabolic profiles in lean, non-autoimmune young-onset diabetes mellitus (DM) in a Bangladeshi cohort.

Methods: This cross-sectional study enrolled 373 participants, aged 18 to 34 years, from the Young Diabetes Clinic of the Department of Endocrinology at Bangladesh Medical University, Dhaka, Bangladesh, during the period of 2023 and 2024. Before enrollment, those with positive islet autoantibodies, low C-peptide, pancreatic pathology, and monogenic variants were excluded. β-cell function (HOMA2-B) and insulin resistance (HOMA2-IR) were quantified using the HOMA2 C-peptide calculator. Participants were categorized into four groups based on glycemic status and body mass index (BMI): lean DM ($n = 53$), obese DM ($n = 125$), lean non-DM ($n = 78$), and obese non-DM ($n = 117$).

Results: Lean DM participants were comparable to other groups in age, sex, and family history, though smoking was more prevalent than in lean controls ($P < .05$). Prevalence of central obesity and blood pressure levels of lean DM were similar to those of lean controls, but the lipid profile was comparable to that of obese DM. The median HbA1c was higher in lean DM than in obese DM (11.6% vs 8.5%; $P < .001$), while their median HOMA2-B was lowest across all other groups ($P < .01$). The HOMA2−IR in lean DM was lower than in obese DM but significantly higher than in lean controls and mirrored the resistance seen in the obese non-DM group ($P < .001$).

Conclusions: Lean young-onset diabetes in Bangladesh seems to represent a distinct phenotype with disproportionate insulin secretory defect and only modest insulin resistance and metabolic dysfunction. These features do not align well with the classic type 2 diabetes spectrum, suggesting the need for more tailored screening approaches and a reconsideration of its classification to support more appropriate management.

P449 - LBA_ECE_1231 - Does the use of reflex testing for thyroid function tests (TFTs) –only testing FT4 when TSH is out of range—effect the prescribing of levothyroxine (LT4)? an England wide investigation

Adrian Heald[1], Mike Stedman[2], Peter Taylor[3], Suhani Bahl[3], Anish Patil[1], Nadia Chaudhury[4], Robert Kemp[1], Rajshekhar Mudaliar[1], Rupinder Kochhar[1], Lakdasa Premawardhana[3], David Halsall[5], Ian Halsall[5], David Holland[6], Antonio Bianco[7], Onyebuchi Okosieme[3] and Colin Dayan[8]
[1]Endocrinology, Salford Royal Hospital, Salford, United Kingdom; [2]Res Consortium, Andover, United Kingdom; [3]University of Cardiff, Cardiff, United Kingdom; [4]University of Oxford, Oxford, United Kingdom; [5]Addenbrookes Hospital, Cambridge, United Kingdom; [6]The Benchmarking Partnership, Keele, United Kingdom; [7]University of Texas, Galveston, United States; [8]University of Birmingham, Birmingham, United Kingdom

Objective: There has been a significant growth in LT4 prescribing over the last 20 years, most of which has been of lower dose tablets. Most decisions about initiation and dosing are based levels of TSH and FT4 measured in requested TFTs. We report here an exploratory exercise to determine if there is any difference at general-practice level in the way that the amount of TFT data being presented affects the amount/doses of LT4 prescribed

Methods: Data for total number of TSH (1.179million) and FT4 (0.680million) tests in each of 763 GP practices was made available. The number of total FT4 as %total TSH was taken as amount reflex testing. Practices were split into 3-reflex classes by FT4 as % of TSH results in each practice, with High Reflex (<20%FT4+TSH), Moderate (20%-79%) and Low (90+%). The actual monthly amount of LT4 prescribed was extracted from publicly reported annual prescribing data. Data in 300 of the 763 GP practices where both prescribed patient demographic and prescribing data were available were applied to each practice population split by age group/sex to calculate the expected number of prescriptions/total mcg/ total number of tablets for LT4, % of actual vs expected standardised for the practice population size/sex/age mix.

Results: The laboratory number of TFT tests carried out in 2023 was used for 731-general practices with over 2000-registered patients each. The table below reflects the levels of prescribing relative to expected for those practices with different levels of reflex testing. Total number of prescriptions analysed was 3.51million.

Reflex level of FT4% TSH	Number of practices (% total)	TFT ratio FT4/ TSH	LT4 prescriptions actual/ expected	LT4 mcg actual/ expected
High reflex (<20%)	274 (37.5%)	13.7%	90.9%	106.2%
Moderate reflex (20%-89%)	224 (30.6%)	47.3%	96.7%	99.9%
Low reflex (≥90%)	233 (31.9%)	98.3%	98.4%	94.1%

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

This shows that when reflex testing is high ie often TSH alone, fewer prescriptions are being written, but the total mcg LT4 are higher, so on average each prescription is for a higher dose.

Conclusions: Our findings suggest that general practices that are provided with less data (high reflex: TSH alone) are prescribing more LT4 to fewer patients than general practices that receive both FT4+TSH values. Thus, the level of information being provided might be being reflected into their prescribing decisions. We suggest that consideration be given to providing both TSH and FT4 levels to clinicians to enable the most appropriate initiation/adjustment of LT4 dose.

P450 - LBA_ECE_1110 - Evaluation of a nutraceutical based on white mulberry leaves, fenugreek, niacin, chrome, zinc and a probiotic for reducing insulin resistance in patients with prediabetes: the NoDiab study

Francisco Javier Martinez-Martin[1,2], Sara Andrada-Diaz[3], Agnieszka Kuzior[2], Ana Maria Sanchez Garcia[2], Juan Fernandez-Jimenez[2], Irene Hernandez-Hernandez[1,2], Facundo Marcelo Guerrero-Kesselman[2], Borja Santana-Ojeda[1], Inmaculada Molinero-Marcos[1] and Claudia Arnas-Leon[1,2]

[1]Endocrinology & Nutrition, Hospital Universitario de Gran Canaria Doctor Negrin, Las Palmas de Gran Canaria, Spain; [2]Endocrinology & Nutrition, Hospitales Universitarios San Roque, Las Palmas de Gran Canaria, Spain; [3]Bioksan Naturalmente Juntos, Medical Advisory, Las Palmas de Gran Canaria, Spain

Introduction and Objectives: In the adult Spanish population the prevalence of prediabetes has been estimated at 15%, with an annual diabetes incidence of 1.16% (approximately 386 000 individuals). While metformin, glitazones, GLP-1RAs and SGLT2is may reduce this risk, none is currently approved for this indication. Acarbose, an α-glucosidase inhibitor, reduces the risk of progression to T2DM (STOP-NIDDM trial). White mulberry (Morus Alba) leaves contain 1-deoxynojirimycin, a potent α-glucosidase inhibitor. A nutraceutical based on a standardized white mulberry leaf extract, also containing fenugreek, inulin, *Lactiplantibacillus plantarum* A14, chromium, zinc and niacin has been developed for the treatment of prediabetes. We conducted an open-label trial (NoDiab) to evaluate the tolerability and efficacy of this nutraceutical, using the HOMA2-IR index (a validated predictor of T2DM development) as the primary outcome.

Methods: Adult subjects with prediabetes were recruited, excluding those with morbid obesity, serious concomitant diseases, alcoholism, substance abuse, and current or planned pregnancy. After informed consent, baseline anthropometry and laboratory tests, they were instructed to take one pill of the nutraceutical daily before lunch with a glass of water. Follow- up visits are scheduled at 3-4 and 6-7 months. In addition to changes in the HOMA2-IR, secondary endpoints were HOMA2-β, 10-year cardiovascular risk (SCORE2), lipid profile, systolic BP, BMI, fasting glucose and insulin, HbA1c, albuminuria, liver fibrosis risk (FIB-4 index) and tolerability (questionnaire).

Results: In 113 subjects (71 women, age 56.4 ± 6.7 years), HOMA2-IR decreased from 1.659 ± 0.721 to 1.269 ± 0.581 ($P < .001$) while HOMA2-β remained unchanged; SCORE2 decreased from to 4.23 ± 1.98 to 3.58 ± 1.76% ($P < .001$); non-HDLc from 161.5 ± 31.2 to 145.1 ± 20.9 mg/dL ($P < .001$); systolic BP from 138.8 ± 13.6 to 133.1 ± 11.2 mmHg ($P < .001$); fasting glucose from 107.5 ± 10.8 to 98.5 ± 8.9 mg/dL ($P < .001$); fasting insulin from 12.6 ± 6.1 to 9.7 ± 4.4 μU/ml ($P < .001$); HbA1c from 6.06 ± 0.24 to 5.83 ± 0.18% ($P < .001$); albuminuria from 28.4 ± 15.2 to 21.5 ± 14.3 mg/g Cr ($P = .035$); C-reactive protein from 3.66 ± 1.97 to 2.89 ± 1.27 mg/dL ($P < .001$); FIB-4 index from 1.42 ± 0.25 to 1.22 ± 0.24 ($P = .003$). Weight reduction was non-significant. No serious tolerability issues were reported, and no patient withdrew from the study due to adverse effects.

Conclusions: In the open-label NoDiab study, this nutraceutical produced a significant reduction in insulin resistance (−22.5%), along with improvements in the cardiovascular risk profile of prediabetic subjects (15.4% reduction in SCORE2, 9.9% in non-HDL cholesterol and 5.7 mmHg in systolic BP), with excellent tolerability. Prediabetes is primarily managed through lifestyle modifications, but their effectiveness is limited and no pharmacological options are currently approved; this nutraceutical may help fill this therapeutic gap.

Abstract citation ID: lvag096.570

P451 - LBA_ECE_1255 - Assessment of adrenal vein sampling selectivity by plasma metanephrine in primary aldosteronism with and without mild autonomous cortisol secretion

Tatiana Kokorina, Nadezhda Platonova, Ivan Sitkin, Vitalii Ioutsi, Khamzat Magomedov, Kseniya Komshilova, Ekaterina Troshina, Galina Melnichenko and Natalia Mokrysheva

Endocrinology Research Centre, Moscow, Russia

Introduction: Adrenal vein sampling (AVS) is the gold standard for subtype diagnosis in primary aldosteronism (PA). However, cortisol-based assessment of selectivity may be unreliable in patients with mild autonomous cortisol secretion (MACS), potentially leading to misinterpretation of AVS results. Plasma metanephrine has been proposed as a more stable marker of adrenal vein cannulation.

Aim: To evaluate cortisol-based selectivity and the additional value of metanephrine during unstimulated AVS in patients with PA, both with and without MACS.

Methods: We retrospectively analysed 90 sequential unstimulated AVS procedures performed by a single operator in 83 patients with confirmed PA in a tertiary referral centre between October 2024 and March 2026. All patients underwent systematic screening for MACS with 1-mg overnight dexamethasone suppression (DST). MACS was defined as post-dexamethasone serum cortisol >50 nmol/L. Cannulation success was defined as a cortisol selectivity index >3 and a metanephrine selectivity index >12.

Results: Forty patients (48.2%) were classified as MACS. The cannulation success rate defined by cortisol was lower in patients with MACS than in those without MACS (56% vs 73%). Application of a metanephrine-based selectivity index >12

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

increased the overall cannulation success rate to 92.2%. High success rates were observed both in patients with MACS (91.1%) and without MACS (93.3%), corresponding to absolute increases of 35% and 20%, respectively.

Table 1 Patient characteristics

Variable	MACS ($n = 40$)	No MACS ($n = 43$)	*P*-value
Age, years	56.5 [48; 63.5]	48 [43; 54]	.002
BMI, kg/m^2	29.5 [25.7; 34.1]	28.3 [24.4; 34.4]	.845
Aldosterone, pmol/L	1022.5 [634; 2144.9]	1000 [614; 2080]	.743
Renin, mU/L	0.84 [0.5; 4.35]	0.8 [0.5; 1.6]	.321
Serum potassium, mmol/L	4.2 [3.58; 4.62]	3.96 [3.67; 4.35]	.346
Serum creatinine, µmol/L	84.6 [65.6; 113.1]	69.2 [64.7; 81.7]	.102
SBP, mmHg	157 [145; 175]	158 [140; 170]	.599
DBP, mmHg	90 [84; 102.5]	100 [85; 107]	.671
Antihypertensive drugs, *n*	3 [2; 4]	3 [2; 4]	.134

Conclusions: Cortisol-based assessment of AVS selectivity appears less effective in patients with PA and MACS, likely due to cortisol co-secretion. Metanephrine may be a more suitable marker for evaluating AVS selectivity in patients with PA and concomitant cortisol secretion.

Background: Arterial hypertension can be considered a global epidemic, and despite increased disease awareness and the availability of effective treatment options, global control rates remain unsatisfactory. Early identification of endocrine hypertension (EHT), including primary aldosteronism (PA), pheochromocytoma/paraganglioma (PPGL), and Cushing syndrome (CS), is essential for patient-tailored management, as these conditions are potentially curable and require disease-specific treatment strategies. However, current diagnostic pathways are complex and resource-intensive. We previously demonstrated promising results using targeted metabolomics (TM) to distinguish primary hypertension (PHT) from EHT in a retrospective cohort. The aim of this prospective multicenter study was to further examine the diagnostic performance and reproducibility of our previous findings.

Methods: In this prospective study, patients with PHT and EHT were recruited from seven European centers within the ENSAT-HT consortium. Targeted metabolomics profiling was performed on plasma samples using liquid chromatography–mass spectrometry. Discriminatory metabolites were identified using two complementary analytical strategies: a conventional statistical approach based on sequential univariate and multivariate analyses and a machine learning approach using random forest models.

Results: From July 2016 till March 2020 a total of 1050 patients were recruited (474 PHT: mean age 49 years, 46.2% female; 576 EHT: mean age 50 years, 41.4% female), including 495 PA, 38 PPGL, and 43 CS patients. Among 155 metabolites and 22 metabolic indices analyzed, the conventional statistical approach identified 66 discriminatory metabolites (14 of 31 previously identified) and 14 metabolic indices (4 of 7 previously identified). The machine learning approach identified 19 discriminatory

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

metabolites (4 of 15 previously identified) and 9 metabolic indices (3 of 8 previously identified). The discriminative performance of the top 15 metabolites (C10, C12, C14:1, C18:2, C2, lysoPCaC17:0, PCaaC32:2, PCaaC34:1, PCaaC34:2, PCaaC34:3, PCaaC36:1, PCaaC36:2, PCaaC36:3, Serotonin, Taurine) identified by the conventional approach (AUC 0.764) and the 19 metabolites (Ac-Orn, C10, C12, C14:1, C18:1, C18:2, C2, Glu, lysoPCaC17:0, PCaa32:2, PCaa34:1, PCaa34:2, PCaaC34:3, PCaaC36:1, PCaaC36:2, PCaaC36:3, PCaeC36:3, Serotonine, Taurine) identified by the machine learning approach (AUC 0.72) was comparable between methods but lower than observed in the previous retrospective study (AUC 0.86 and 0.83, respectively).

Conclusions: Targeted metabolomics demonstrated moderate discriminatory performance in this large prospective multicenter cohort of hypertensive patients. However, only a subset of previously identified metabolites and metabolic indices was reproducibly confirmed. Understanding the sources of these differences will be essential before targeted metabolomics can be implemented in routine clinical practice.

P453 - LBA_ECE_1004 - Multi-Omics identifies STK11-Driven Signalling Shift in sparsely granulated somatotropinomas

Pinaki Dutta[1], Vaishali Kaur[1], Debajyoti Chatterjee[2], Apinderpreet Singh[3], Maryada Sharma[4] and Ashutosh Rai[5]
[1]Postgraduate Institute Of Medical Education And Research Chandigarh, Endocrinology, Chandīgarh, India; [2]Postgraduate Institute Of Medical Education And Research Chandigarh, Histopathology, Chandīgarh, India; [3]Postgraduate Institute Of Medical Education And Research Chandigarh, Neurosurgery, Chandīgarh, India; [4]Postgraduate Institute Of Medical Education And Research Chandigarh, ENT, Chandīgarh, India; [5]Panjab University, Biochemistry, Chandīgarh, India

Background: Somatotropinomas are divided into sparsely (SG) and densely granulated (DG) based on granularity. SG exhibits aggressive clinical behaviour (presentation at younger age, high proportion of invasiveness, resistance to treatments and recurrence compared to DG). We hypothesized that proteomic and phosphoproteomic differences underpin this heterogeneity.

Methods: High-throughput mass spectrometry-based proteomics and phosphoproteomics analysis was performed on SG ($n = 4$) and DG ($n = 4$) tumours. Gene ontology and pathway enrichment done using Fun Rich. Candidates (AMPKβ S108, mTOR, ULK1 S638, MAPT T548, and TSC1 S1080) of significantly enriched STK11 pathway (cut-off = 1.5-fold-change) were considered for validation by immunohistochemistry (IHC) ($n = 33$; SG = 25, DG = 8) on tissue microarray in an independent cohort. Functional assays on GH3 cell lines and primary culture ($n = 9$) treated with selective inhibitors included proliferation, apoptosis, and phosphorylation of downstream substrates. Public transcriptomic datasets were re-analysed for independent validation.

Results: We identified 788 proteins and 5081 phosphopeptides differentially regulated between SG and DG tumours (FDR < 0.05). Phosphoproteomic shifts enriched for metabolic regulation indicated increased activity of the STK11 pathway (90 proteins over-phosphorylated) in SG tumours ($P < .0001$). There was increased expression of STK11 ($P = .007$) in SG compared to DG tumours, along with enhanced expression of its regulatory adaptor STRAD ($P = .003$). Mass spectrometry showed significantly higher phosphorylation of AMPKβ S108, ULK1 S638, TSC1 S1080, and MAPT (Tau) T548 in SG tumours. Validation by IHC showed strong cytoplasmic and nuclear staining of TSC1 S1080 ($P = .009$), ULK1 S638 ($P = .006$), AMPKβ S108 ($P = .0005$), and MAPT (Tau) T548 ($P = .01$) predominantly in SG tumours compared to DG. Functional relevance of STK11/AMPK signalling was assessed using GH3 cell lines and primary somatotropinoma cultures treated with selective inhibitors. Treatment with Rapamycin, HY-16966 and Dorsomorphin resulted in significant decrease in cell viability in SG tumours ($P < .0001$) and GH3 cells ($P < .0001$). No haemolysis was observed at 1 μM of these inhibitors suggesting safety for normal cells. We observed significant decrease in GH levels ($P < .05$) at 1 μM concentration of these inhibitors. Inhibitor treatment reduced downstream phosphorylation of TSC S1080 ($P = .003$), ULK1 S638 ($P = .004$), and AMPKβ S108 ($P = .01$), supporting a functional role for STK11 signalling in tumour cell survival and growth. Our in-house proteomics data and publicly available transcriptomic datasets showed decreased expression of STK11 pathway proteins (MEF2C, FGFR3, TBC1D4, SPP1, SORBS1, mTOR, MAPT).

Conclusions: Multi-omics analysis reveals distinct STK11-driven signalling in sparsely-granulated somatotropinomas, with consistent validation by orthogonal methods. AMPK, mTOR, and ULK1 emerge as candidate therapeutic targets for subtype-directed tumour management.

P454 - LBA_ECE_1115 - Follicular fluid steroidomic signatures as predictors of oocyte competence and IVF outcomes

Tinatin Kutchukhidze
University of Oxford, Oxford, United Kingdom

Background: Oocyte competence is a key determinant of IVF. Accurate prediction of oocyte competence remains a major challenge in IVF, with 40-50% of morphologically normal oocytes failing to produce high-quality embryos. Follicular fluid steroidomics offers a window into the oocyte microenvironment. Follicular fluid, as the oocyte's immediate microinvironment, contains steroid hormones, growth factors, and metabolites that directly influence maturation and embryonic potential. Steroidal hormones such as estradiol, progesterone, testosterone, androstenediole, and cortisol have been linked to follicle size, oocyte maturation, and fertilization in small-scale studies (<50 00cyte). Advances in LC-MS/MS-based steriodiomics now allow simultaneous high-sensitivity quantification of multiple steroid metabolites, offering the potential to define predictive

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

hormonal signatures. A large-scale, systematic evaluation is needed to translate these laboratory findings into clinical IVF practice.

Objectives: Map the steroidomic profile of follicular fluid in a large IVF cohort and identify predictive hormonal signatures for oocyte competence and IVF outcomes.

Methods: In this prospective observational study, 120 women undergoing IVF/ICSI at a tertiary reproductive center contributed follicular fluid from 842 dominant follicles (>18 mm). LC-MS/MC quantified 15 steroid hormones and metabolites, including estradiol, progesterone, testosterone, androstenedione, DHEA, and cortisol. Oocyte competence was defined as mature (MII vs MI/GV), fertilization(2PN formation), and embryo quality(blastocyte grading on day 5). Clinical endpoints included implantation and clinical pregnancy rates. Multivariate logistic regression identified independent steroidomic predictors, while ROC curves evaluated predictive performance. Subgroup analyses examined ratios such as estradiol-totestosterone, reflecting the estrogen/androgen balance within the follicular microenvironment.

Results: Higher estradiol and progesterone levels were strongly associated with MII oocyte ($P < .001$). elevated androstenedione and testosterone correlated negatively with fertilization ($P = .003$). a distinct steroidomic signature, featuring a high estradiol-to testosterone ratio and optimal progesterone, predicted high-quality blastocyst formation (AUC = .81). Cortisol elevation was linked to poorer embryo quality and lower implantation rates ($P < .01$). In multivariate models, estradiol/testosterone ratio and progesterone remained independent predictors of oocyte competence and clinical pregnancy(adjusted OR 2.4,95% CL 1.6-3.8)

Conclusions: follicular fluid steroidomic profiling provides a robust, biologically meaningful predictor of oocyte competence and IVF outcomes. The intrafollicular balance between estrogens and androgens emerges as a key determinant of developmental potential. Applying biomarkers in embryology practice could enhance oocyte selection, optimize stimulation protocols, personalize IVF strategies, and make a transformative step in precision reproductive endocrinology.

P455 - LBA_ECE_1092 - Metyrapone treatment improves the pro-inflammatory profile in patients with mild autonomous cortisol secretion

Anna Tosin[1], Sebastian Wrighton[2], Helena Niziolek[1], Clemens Baumgartner[1], Paul Fellinger[1], Luise Bellach[1], Alexandra Kautzky-Willer[1], Michael Krebs[1], Michael Leutner[1], Winfried Pickl[2] and Peter Wolf[1]

[1]Division of Endocrinology and Metabolism, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria; [2]Center for Pathophysiology, Infectiology and Immunology, Medical University of Vienna, Institute of Immunology, Vienna, Austria

Research Question: Hypercortisolism is associated with a low-grade inflammatory state; however, evidence in patients with mild autonomous cortisol secretion (MACS) remains limited. This study aims to compare disease-specific shifts of inflammatory cytokine profiles between patients with MACS to patients with non-functional adrenal adenoma (NFA) and to investigate the effects of medical treatment with metyrapone.

Methods and Material: Patients with MACS ($n = 25$, 21 females) were compared to patients with NFA ($n = 25$, 21 females) of comparable age (63 (55-67) vs 61 (54-68) years) and BMI (27 (24.2-30.5) vs 28.5 (27.5-32.2) kg/m^2). A sub-cohort of 14 MACS patients was prospectively re-evaluated following 12 weeks of treatment with evening doses of metyrapone (500 mg at 6 PM & 250 mg at 10 PM) as part of an exploratory secondary analysis of the AdrenalCLOCK study. Leukocytes, lymphocytes, and neutrophils were assessed and individual ratios were calculated. Cytokine levels were measured using a 37-plex Luminex bead-based assay. Mann-Whitney U tests were applied for intergroup cross-sectional analysis. Wilcoxon signed-rank tests were performed for outcome comparison after medical treatment in MACS patients.

Results: Treatment with metyrapone led to a significant improvement in the neutrophil-to-lymphocyte ratio (2.22(1.67-2.77) vs 2.14 (1.37-2.60) $P < .001$), accompanied by significant alterations in 15 cytokines, including CD40L, EGF, FLT-3L, G-CSF, GROa, IFNg, IL 1RA, IL-4, IL-9, IL-12p40, IL-17A, TGFa and TNFb. Statistically, follow-up examination after metyrapone treatment revealed the most pronounced decreases in IL-15 ($P = .0009$) and IL-18 ($P = .001$), cytokines that play key roles in NK-cell homeostasis and activation, respectively. Comparison between patients with MACS and NFA revealed no significant differences between groups.

Conclusions: Treatment with evening doses of metyrapone attenuates the pro-inflammatory immune profile in MACS. Whether this immune modulation contributes to improvement of the adverse cardiometabolic risk profile observed in these patients will require further investigation.

P457 - LBA_ECE_1018 - Telomere length in untreated congenital isolated growth hormone deficiency

Angela Leal[1], Júnia Ribeiro De Oliveira Longo Schweizer[2], Rodrigo Calado[3], Martin Bidlingmaier[2], Roberto Salvatori[4], Barbara Santana[3], Jan Frystyk[5], Fabricia Alvisi[1], Viviane Almeida[1], Elenilde G. Santos[1], Keila R. Villar-Gouy[1], Enaldo Melo[1], Nathalie Santana[1], Francisco Pereira[1], Carla R. P. Oliveira[1], Luciana Pedral S. D. Leite[1], Francisco de Paula[3], Angela Silva[1], Margaret Castro[3] and Manuel H. Aguiar Oliveira[1]

[1]Hospital Universitário, Endocrinology, Medicine, Aracaju, Brazil; [2]Department of Medicine IV, Ludwig Maximilian University of Munich, Munich, Germany; [3]University of Sao Paulo Ribeirao Preto Medical School, Ribeirao Preto, Brazil; [4]Johns Hopkins, Endocrinology, Baltimore, United States; [5]University of Southern Denmark, Odense, Denmark

Background: Accelerated telomere shortening has been associated with biological aging and influence of the GH-IGF-I axis has

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

been implicated in this process. The Itabaianinha cohort in Brazil presents with severe isolated congenital GH deficiency (IGHD) due to a homozygous mutation in the GHRH receptor gene (*GHRHR*). Affected individuals exhibit severe short stature, central obesity, and hypercholesterolemia, but do not show premature atherosclerosis and maintain a normal life expectancy, with brain aging consistent with chronological age. The objective of this study was to evaluate the leukocyte telomere length (LTL) in these IGHD individuals.

Methods: We assessed LTL in 36 IGHD subjects with homozygous *GHRHR* c.57+1G→A mutation, and 36 controls homozygous for the wild type allele. Serum IGF-I, IGF-II, and biochemical parameters were measured. LTL was measured by quantitative polymerase chain reaction using telomere-to-single copy gene (T/S) ratio.

Results: IGHD individuals had markedly reduced height and body weight compared with controls (height: 1.3 (0.1) vs 1.7 (0.1) m; weight: 43.1 (7.3) vs 70.8 (11.2) kg; $P < .0001$ for both), while BMI was similar (27.2 (7.0) vs 27.1 (4.8) kg/m^2; $P = .942$). IGF-I (ng/mL) and IGF-II (ng/mL) were profoundly reduced in IGHD (IGF-I: 11.0 (5.5) vs 144.5 (70.5); IGF-II: 327.0 (122.5) vs 896.5 (363.0), respectively; $P < 0.0001$ for both). IGHD subjects exhibited undetectable or extremely low IGF-I concentrations, while IGF-II levels were approximately 2.5-fold lower than in controls. The T/S ratio did not differ significantly between IGHD and controls (0.8 (0.6) vs 0.9 (0.4); $P = .593$). A modest positive correlation was found between the T/S ratio and IGF-II ($r = 0.376$; $P = .045$), whereas no significant correlations were observed between the T/S ratio and IGF-I or HOMA-IR.

Conclusion: Lifelong untreated IGHD is not associated with alterations in leukocyte telomere length. These findings are consistent with the normal longevity and normal brain aging observed in this IGHD cohort.

[1]Diabetes, Endocrinology and Nutrition, Rennes University Hospital, Rennes, France; [2]Endocrinology, Diabetes and Nutrition, Grenoble University Hospital, Grenoble, France; [3]Endocrinology and Diabetes, Saint-Joseph Hospital, Paris, France; [4]Endocrinology—CARDEO Department, Boulogne-sur-mer Hospital, Boulogne-sur-mer, France; [5]Toulouse University Hospital, Diabetes, Toulouse, France; [6]Diabetes and Endocrinology, Limoges University Hospital, Limoges, France; [7]Endocrinology and Diabetes, Lariboisière Hospital, Paris, France; [8]Endocrinology, Diabetes and Nutrition, Avicenne—Bobigny University Hospital, Bobigny, France; [9]Department of Precision Health, Luxembourg Institute of Health, Luxembourg, Luxembourg

Background and aims: Type 1 diabetes (T1D) is increasingly associated with features of insulin resistance and obesity, a phenotype known as "double diabetes". This study aimed to evaluate the prevalence of metabolic syndrome (MetS) features and its associated vascular complications, while assessing the utilization patterns of non-insulin adjunct therapies in a large real-world cohort.

Methods: We conducted a retrospective observational study of 2043 adult patients with T1D (pwT1D) from the French SFDT1 national cohort. MetS was defined according to IDF/AHA criteria. Dyslipidemia and hypertension were assessed using ESC/EAS 2023 guidelines. Logistic regression models were used to identify factors associated with chronic complications and the prescription of adjunct therapies.

Results: In the whole population, the median age and duration of T1D were 38 years [28-51 years] and 21 years [12-32 years], respectively. MetS, MASLD (FLI>60) and insulin resistance (eGDR<7.5 mg/kg/min) affected 32%, 18.9% and 32% of the population, respectively. Dyslipidemia, hypertension, and obesity were present in 50.7%, 20.3%, and 19.2% of the participants, respectively. Suboptimal management was frequent: 81.4% had inadequately treated dyslipidemia and 11.7% had inadequately managed or undiagnosed hypertension. Longer diabetes duration (OR = 1.05; $P < .01$), retinopathy (OR = 1.85; $P = .0017$), and nephropathy (OR = 1.77; $P = .0158$) were linked to higher risks of untreated dyslipidemia. Complications rates were: 37.2% of retinopathy, 15% of nephropathy, and 4.7% of major adverse cardiovascular events. Patients accumulating both hypertension and dyslipidemia exhibited critical complication rates (71.4% of retinopathy and 45.3% of nephropathy). Adjunct non-insulin therapies were prescribed, off-label, to 5.6% of patients (Metformin:3.7%; GLP-1R agonists:2.5%; SGLT2 inhibitors:0.1%). Multivariable analyses revealed that prescription of these therapies was significantly associated with a 42% reduction in the risk of uncontrolled hypertension (OR = 0.58; $P = .0464$). Conversely, longer diabetes duration (years) (OR = 1.05; $P < .01$), retinopathy (OR = 1.85; $P = .0017$), and nephropathy (OR = 1.77; $P = .0158$) were linked to higher risks of untreated dyslipidemia. Prescription of these agents was primarily driven by BMI (kg/m^2) (OR = 1.20) and the presence of hypertension (OR = 2.34) rather than glycemic levels. Eating disorders (SCOFF score ≥ 2) were reported in 31.9% of participants, with no significant association with adjunct therapy use.

Conclusion: Double diabetes affects one-third of the T1D population and is a major driver of micro/macrovascular complications. Despite a high prevalence of metabolic risk in our cohort of pwT1D, we observed a marginal use of currently off-label adjunct non-insulin therapies. These findings underscore the need for efficacy and safety trials, as well as updated clinical guidelines to integrate metabolic management beyond insulin therapy in T1D.

P459 - LBA_ECE_1387 - Liver fibrosis enhances risk stratification beyond cardiovascular–kidney–metabolic staging

Weinan Xie[1,2], Zhujun Sheng[3] and Xiyan Zhao[3]

[1]Beijing, China; [2]Beijing University of Chinese Medicine, Beijing, China; [3]Guang'anmen Hospital, China Academy of Chinese Medical Sciences, Beijing, China

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Background: The cardiovascular–kidney–metabolic (CKM) framework has recently been proposed to improve integrated risk stratification across metabolic, renal, and cardiovascular domains. However, liver fibrosis, a key manifestation of systemic metabolic dysfunction, is not incorporated into current CKM staging. Its potential incremental value in risk prediction remains unclear.

Methods: We conducted a population-based analysis using data from the National Health and Nutrition Examination Survey (NHANES) 2017-2018 cycle, including participants with available vibration-controlled transient elastography data. Liver fibrosis was assessed using liver stiffness measurement (LSM). CKM stages were defined based on metabolic risk factors, diabetes, chronic kidney disease, and cardiovascular disease. All-cause mortality was ascertained through linkage with the National Death Index. Cox proportional hazards models were used to evaluate the association between liver fibrosis and mortality. The incremental predictive value of liver fibrosis beyond CKM staging was assessed using discrimination and reclassification metrics, including C-statistics, net reclassification improvement (NRI), and integrated discrimination improvement (IDI).

Results: Liver fibrosis was associated with increased risk of all-cause mortality independent of CKM stage and conventional risk factors. Incorporation of liver fibrosis into the CKM framework improved risk discrimination and reclassification performance compared with CKM staging alone. These associations were consistent across different CKM strata.

Conclusions: Liver fibrosis may provide additional prognostic information beyond the current CKM framework. Integrating hepatic fibrosis into cardiometabolic risk stratification models may enhance identification of individuals at high risk of adverse outcomes.

P460 - LBA_ECE_1332 - Preserved muscle mass does not reflect functional status in patients with acromegaly in remission: the role of muscle quality

Ayşe Merve Ok Kurt[1,2], Ümmü Mutlu[1], Fatih Bektaş[1,3], Hulya Hacisahinogullari[1], Gulsah Yenidunya Yalin[1], Tuğba Erdoğan[4], Gulistan Bahat[4], Nurdan Gul[1], Ayse Kubat Uzum[1] and Ozlem Soyluk Selcukbiricik[1]

[1]Endocrinology and Metabolism, Istanbul University Istanbul Faculty of Medicine, Istanbul, Türkiye; [2]Endocrinology and Metabolism, Kocaeli City Hospital, Kocaeli, Türkiye; [3]Endocrinology and Metabolism, Bağcılar Training and Research Hospital, İstanbul, Türkiye; [4]Geriatrics, Internal Medicine, Istanbul University Istanbul Faculty of Medicine, İstanbul, Türkiye

Background: Acromegaly is characterized by excess growth hormone (GH), leading to significant alterations in body composition, including increases in body size, skeletal muscle and fat mass. Despite increased muscle mass, muscle strength and quality may not be preserved, and data on their clinical impact remain limited. It is unclear whether these alterations persist and affect physical performance after biochemical remission.

Objective: To evaluate alterations in body composition and their impact on muscle mass, muscle strength, and muscle quality, and to identify impaired physical performance in patients with acromegaly in remission.

Methods: This cross-sectional study included 81 patients with acromegaly in remission (41 women, 40 men). Body composition and muscle mass parameters, including skeletal muscle mass (SMM) and SMM indices adjusted for body mass index, weight, and height^2 [SMMI (BMI), SMMI (weight), SMMI (height^2)], and muscle quality indices (MQI), were assessed with BIA. MQIs were calculated as handgrip strength divided by SMM and SMMI parameters. Muscle strength was evaluated using handgrip dynamometry, with low muscle strength defined as <20 kg in women and <35 kg in men. Parameters were classified according to sex-specific cut-off values derived from the Turkish population (Bahat et al.). Physical performance impairment was defined as reduced performance in either the chair stand test or 4-meter walking speed test. ROC curve analysis was performed.

Results: The study population had a mean age of 49.2 ± 10.9 years, with a median follow-up of 109 (73-157) months. Impaired physical performance was identified in 6 patients (7.4%).

Handgrip strength was lower in patients with impaired physical performance (26.3 ± 3.6 vs 42.4 ± 12.6 kg, $P < .001$); however, low handgrip strength was observed in only three patients, none of whom were in the impaired group. SMM and SMMI (height^2) did not differ ($P = .185$; $P = .878$), SMMI (BMI) (0.83 ± 0.18 vs 1.18 ± 0.28, $P < .001$) and SMMI (weight) (35.2 [29.4-37.9] vs 40.6 [36.7-43.9], $P = .014$) were lower in patients with impaired performance.

MQI-SMM and MQI-SMMI (height^2) were lower in patients with impaired performance (0.88 ± 0.13 vs 1.22 ± 0.21; 2.19 ± 0.26 vs 3.6 ± 0.89, respectively; both $P < .001$). In contrast, MQI-SMMI (BMI) and MQI-SMMI (weight) did not differ ($P = .513$; $P = .138$).

MQI-SMMI (height^2) showed the highest discriminative performance (AUC: 0.973), followed by MQI-SMM (0.940) and handgrip strength (0.920).

Conclusions: Even in remission, acromegaly may remain associated with impaired physical performance. Despite increased muscle mass, functional impairment may persist and be masked. Therefore, patients with acromegaly should be evaluated for muscle function and quality during follow-up.

Tampa, Florida, United States; [8]Endocrine Unit, Department of Clinical Therapeutics, National and Kapodistrian University, Athens, Greece

Background: Thyroid paragangliomas (TPGLs) are exceptionally rare (<0.1% of thyroid neoplasms, ~0.5% of all paragangliomas) and frequently occur within hereditary head and neck paraganglioma syndromes. While hereditary paragangliomas are frequently linked to *SDHD* germline variants, intronic splice-site alterations are scarcely reported in TPGLs. We describe the clinical and functional characterization of a TPGL associated with a novel intronic *SDHD* variant.

Methods: We investigated a family of a 36-year-old woman with intrathyroidal TPGL and bilateral carotid body paragangliomas in her father and brother, all carrying a heterozygous intronic *SDHD* variant, c.314+4A > G (NM_003002.5). Germline testing was performed by next-generation sequencing, followed by in-depth RNA sequencing on whole blood to assess splicing and allele-specific expression. RNA-seq libraries were prepared with a directional protocol and sequenced on an Illumina NextSeq 2000 (~80 M 150-bp paired-end reads/sample), aligned with HISAT2, quantified with HTSeq, and analyzed with DESeq2; splice junctions were visualized by sashimi plots in IGV.

Results: The *SDHD* c.314+4A > G variant lies within the intron 3 donor site and is absent from gnomAD and the Leiden University Medical Center SDHD gene variant database; SpliceAI predicts splice disruption (Δ score 0.81). RNA-seq demonstrated two competing exon 3→4 junctions in both carriers: a canonical junction from the wild-type allele and a cryptic junction 4 bp downstream, attributable to the mutant allele. In the proband and her brother, aberrant junctions accounted for approximately half of all exon 3→4 splice events, consistent with a "leaky" splice-site defect and predicted frameshift with premature termination. Despite sharing the same variant, overall *SDHD* expression was lower in the proband than in her brother, consistent with allele-specific transcript imbalance and possible haploinsufficiency. Co-segregation of c.314+4A > G with thyroid and bilateral carotid body paragangliomas across three paternally related relatives supports its role in a hereditary SDHD-associated paraganglioma syndrome.

Conclusions: This study provides direct RNA-level evidence that the intronic *SDHD* c.314+4A > G variant causes aberrant splicing and supports reclassification from VUS to likely pathogenic under ACMG/AMP criteria (PS3, PM2, PP3, segregation). These findings expand the spectrum of splice-disrupting *SDHD* c.314 variants implicated in hereditary head and neck paragangliomas, highlight TPGL as part of this spectrum, and underscore the value of RNA-based assays in interpreting non-canonical splice-site changes.

P462 - LBA_ECE_1305 - Combined Effect of Osilodrostat and Mitotane in Adrenocortical Carcinoma 3D models

Fabiola Vaglica[1], Laura Tomasello[1], Mattia Biondo[2], Giuseppe Siragusa[2], Giorgio Arnaldi[1], Giuseppe Pizzolanti[1,3] and Valentina Guarnotta[1]

[1]Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties (PROMISE), University of Palermo, Palermo, Italy; [2]Department of Biological, Chemical and Pharmaceutical Sciences and Technologies (STEBICEF), University of Palermo, Palermo, Italy; [3]ATeN Center, Palermo, Italy

Systemic treatment of adrenocortical carcinoma (ACC) relies on mitotane. Osilodrostat, an 11β-hydroxylase inhibitor used to treat Cushing's syndrome, is also used to manage the ACC-associated hypercortisolism. Currently, the combination of osilodrostat and mitotane remains poorly investigated, even though it represents a treatment strategy in ACC with combined hypercortisolism. We assessed the effects of osilodrostat and mitotane, both individually and in combination, using the NCI-H295R cell line in two-dimensional (2D) cultures and three-dimensional (3D) spheroid models, which more closely recapitulate the *in vivo* tumour microenvironment. Osilodrostat showed no significant cytotoxicity in either the 2D or 3D models (IC_{50} > 100 μM). By contrast, mitotane reduced cell viability in a dose-dependent way, with IC_{50} values of 25.92 μM in 2D and 44.98 μM in 3D, indicating lower sensitivity in the 3D context. Drug interaction was studied using a dose-dose matrix and the Highest Single Agent (HSA) model. In 3D models, the drug combination produced greater inhibition of cell viability than mitotane alone; at 50 μM mitotane, inhibition increased from 21.84% (alone) to 42.89% (combined with 100 μM osilodrostat). The HSA analysis showed a mean synergy score of 5.97 ($P = 1.35 \times 10^{-6}$), reaching a maximum score of 18.12 for the combination of 50 μM mitotane and 100 μM osilodrostat. Morphological analysis also showed a significant reduction in spheroid area after the administration of the drug combination compared to mitotane alone at 50 μM (−45.6% vs −21.2%; $P = .0076$). Moreover, calcein AM/DAPI fluorescent staining revealed a significant increase in the ratio of non-viable to viable cells (MFIb/g from 0.84 with the combination to 1.79 with 50 μM of mitotane; $P < .0001$). Cell counting confirmed a 72% reduction in viability with the combination, compared with a 46% reduction observed with 50 μM mitotane alone. Docking analysis of CYP11B1 identified a primary catalytic site (C1) for both compounds. However, they displayed distinct orientations and steric incompatibilities that precluded simultaneous binding to the same site. Sequential docking revealed an alternative, lower-affinity cavity (C4) for mitotane when osilodrostat occupied C1, suggesting a potential concentration-dependent multi-site effect. Overall, osilodrostat does not exert a direct cytotoxic effect but significantly enhances mitotane's adrenolytic activity in 3D ACC models. These findings provide a preclinical rationale for combination strategies and support further translational and clinical studies integrating steroidogenesis inhibition with adrenolytic therapy in ACC.

Pharmacy, ANKARA, Türkiye; [5]Division of Endocrinology and Metabolism, Hacettepe University School of Medicine, Division of Endocrinology and Metabolism, ANKARA, Türkiye

Background: Polycystic ovary syndrome (PCOS) is a heterogeneous endocrine disorder with metabolic alterations not fully explained by obesity or androgen excess.

Objective: To define a plasma metabolomic signature of PCOS independent of BMI and to evaluate associations with measures of androgen excess.

Methods: Forty women with PCOS (mean age: 22.9 ± 2.7 years; mean BMI: 23.4 ± 4.6 kg/m^2) and 40 age- and BMI-matched healthy controls underwent standardized clinical, biochemical, and hormonal assessment. Plasma metabolomic profiling was performed using integrated GC–MS and LC–MS platforms. Data were analyzed using principal component analysis (PCA), partial least squares–discriminant analysis (PLS-DA) with cross-validation and permutation testing, false discovery rate (FDR)-adjusted univariate analysis, receiver operating characteristic (ROC) analysis, pathway enrichment (MetaboAnalyst), and Spearman correlations with clinical parameters.

Results: PCA and PLS-DA demonstrated clear separation of PCOS and control groups. PLS-DA achieved high discrimination (accuracy = 0.95, $R^2 = 0.92$, $Q^2 = 0.78$) and was validated by permutation testing ($P = .002$). Thirty-one metabolites were significantly altered after FDR correction.

Threitol, a four-carbon sugar alcohol, emerged as the top discriminatory metabolite (fold change = 5.86, FDR = 3.59×10^{-14}), achieving near-perfect discrimination between PCOS and controls (multivariate ROC AUC = 0.993; 95% CI: 0.962-1.000), highlighting its potential as a novel metabolic marker.

Pathway analysis revealed significant perturbations in branched-chain amino acid (BCAA: valine, leucine, isoleucine)) biosynthesis ($P = 5.49\times10^{-5}$, FDR = 0.004), alanine–aspartate–glutamate metabolism (a central amino acid–energy pathway) ($P = 1.56\times10^{-4}$, FDR = 0.006), and the citrate cycle ($P = .00103$, FDR = 0.028), indicating disrupted core energy metabolism.

Threitol correlated inversely with total testosterone (r = −0.46), free androgen index (r = −0.56), and anti-Müllerian hormone (AMH) (all $P < .001$). Palmitoylcarnitine correlated positively with total testosterone (r = 0.35, $P = .001$). Other key metabolites, including BCAA and energy metabolites, showed no significant association with androgen or insulin resistance measures.

Conclusions: High-resolution metabolomics identifies a robust, BMI-independent metabolic signature in PCOS characterized by BCAA and energy metabolism alterations. Selected metabolites show targeted associations with androgen levels, supporting refined metabolic phenotyping in PCOS.

P464 - LBA_ECE_1425 - Prognostic value of site-specific methylation of G0S2 gene in low-risk patients with adrenocortical carcinoma

Arianna Propato[1], Anna Aurora Dedonno[1], Giulia Cantini[1], Julia Penitenti[1], Chiara Lepri[1,2], Tonino Ercolino[1], Guido Di Dalmazi[3], Antonio De Leo[3], Lorenzo Zanatta[1], Gabriella Nesi[4], Letizia Canu[1] and Michaela Luconi[1,5]

[1]Florence, Italy; [2]Department of Experimental and Clinical Biomedical Sciences "Mario Serio", University of Florence, Florence, Italy; [3]Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy; [4]University of Florence, Health Sciences, Florence, Italy; [5]University of Florence, Experimental and Clinical Biomedical Sciences, Florence, Italy

Adrenocortical cancer is a rare malignancy, characterized by a high heterogeneity of the tumor mass and aggressiveness in the advanced infiltrating and metastatic stages (ENSAT stage III and IV). However, even cancers with the low staging (ENSAT I and II) characterized by low risk of recurrence can display poor prognosis. Therefore, there is a pressing need for novel markers to improve patients' molecular characterization in view of applying personalized and precision medicine approaches to the disease.

In this small pilot study, we developed a novel method to quantify the percentage of specific CpG methylation in the promoter of G0S2 gene (Met-G0S2), previously identified as a good marker of gene hypermethylation signature (CIMP high) associated with ACC poor outcome. Met-G0S2 levels were significantly higher and more heterogenous in the tumor samples from 35 patients with diagnosis of ACC compared with the 10 normal adrenals analyzed ($P < .01$). MetG0S2 did not correlate with ENSAT tumor stages. When focusing on ACCs classified at low ENSAT stage I and II, high MetG0S2 percentage (cut-off corresponding to the 80th percentile of MetG0S2 percentage distribution in ACC) was able to identify those patients characterized by a significantly lower overall and progression free survival (Kaplan-Meier survival curve log-rank = 0.013 and 0.038, respectively). In a Cox regression multivariable survival-risk analysis adjusted for tumor resection margin status and cortisol secretion as confounding factors, only Met-G0S2 percentage maintained statistical significance of the risk of tumor progression (Hazard Ratio[95%CI] = 21.4[1.5-310.0], $P = .025$, $n = 20$). Finally, ACCs stratification according to Met-G0S2 showed a statistically significant difference in G0S2 expression evaluated by qRT-PCR ($P = .036$) and in Ki67% ($P = .024$), respectively lower and higher in high Met-G0S2 tumors.

In conclusion, these preliminary data suggest MetG0S2 as a potential molecular marker able to identify a subgroup of patients with poor prognosis among ACC patients classified at poor risk on the base of stage I/II, enabling a more refined profiling of the tumors and improvement of patients' clinical management.

P465 - LBA_ECE_1235 - Skeletal and renal complications in patients with X-linked rickets: patterns related to age at diagnosis and treatment exposure

Anna Skowrońska-Szcześniak[1] and Michal Popow[2]

[1]Department of Internal Medicine and Endocrinology, Medical University of Warsaw, Warsaw, Poland; [2]Warsaw, Poland

Background: X–linked hypophosphataemic rickets (XLH) is a hereditary disorder characterized by FGF23–mediated renal phosphate wasting and impaired bone mineralization. Despite treatment, long–term skeletal and renal complications remain a significant clinical concern.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Aim: To evaluate the prevalence of skeletal and renal complications in adulth patients with XLH and explore their relationship with age at diagnosis and treatment exposure.

Methods: We conducted a retrospective single–centre analysis of 26 patients with XLH. Clinical data included age at diagnosis, treatment duration, and the presence of fractures and renal complications (nephrocalcinosis and/or nephrolithiasis). Patients were stratified according to age at diagnosis (≤4 years vs >4 years).

Results: The median age at diagnosis was 3 years, with most patients diagnosed in early childhood, although delayed diagnosis was observed in a subset. Fractures were present in 46% of patients, while renal complications were observed in 85%. Patients diagnosed after the age of 4 years tended to have a higher prevalence of fractures (50% vs 37.5%). In contrast, renal complications were highly prevalent regardless of age at diagnosis (100% vs 75%). No clear association was observed between treatment duration and the presence of renal complications. Male patients tended to have a higher rate of skeletal complications, although this finding should be interpreted with caution due to the small sample size.

Conclusions: In our centre, skeletal and renal complications are highly prevalent in adult patients with XLH and may reflect different underlying mechanisms. While skeletal complications appear to be associated with delayed diagnosis, renal complications are common and are not clearly explained by treatment duration alone, suggesting a potential contribution of disease-related factors. These findings highlight the complexity of disease burden in XLH and the need for optimized management strategies.

P466 - LBA_ECE_1294 - Artificial intelligence on opportunistic Pet/CT scans for predicting vertebral fracture risk in men undergoing androgen deprivation therapy for prostate cancer

Maria Francesca Birtolo[1,2], Riccardo Levi[1,3], Cristina Garibbo[1], Tommaso Lania[1], Andrea Lania[1,2], Letterio Politi[1,3] and Gherardo Mazziotti[1,2]
[1]*Department of Biomedical Sciences, Humanitas University, Pieve-Emanuele (Milan), Italy;* [2]*Endocrinology, Diabetology and Andrology Unit, Metabolic Bone Diseases and Osteoporosis Section, Humanitas Research Hospital, Rozzano (Milan), Italy;* [3]*Neuroradiology Unit, Humanitas Research Hospital, Rozzano, Italy*

Purpose: Predicting fracture risk in men undergoing androgen deprivation therapy (ADT) for prostate cancer is challenging, as bone mineral density may not be a reliable tool in this context. We recently demonstrated the high potential of a radiomics-based machine learning model for identifying women at high fracture risk during hormone deprivation therapy for breast cancer. This study aims to test the same approach in men undergoing ADT.

Methods: one hundred and ninety-nine men (median age 79 years; IQR 73-84) who were exposed to ADT (median duration: 24 months, IQR 11-48) for prostate cancer were included. Radiomics analyses were performed on CT images co-registered with PSMA PET scans, which were performed for tumour staging. Non-fractured and non-metastatic vertebrae (C1–L5) were automatically segmented using a convolutional neural network to extract radiomics features (RFs). Each feature was tested for its ability to predict vertebral fractures (VFs), as assessed by a longitudinal morphometric approach during ADT. Predictive models were built using a machine learning pipeline based on Random Forest classifier model, including automatic feature selection on training sets. These models were then tested using cross-validation to assess their ability to predict VFs.

Results: During ADT, new VFs were diagnosed in 28 men (14.1%) in association with lower L1-L4 T-score ($P = .0158$), and higher FRAX score for hip and major fractures ($P < .001$ and $P = .006$, respectively). In the univariate analysis, 50 out of 107 feature values calculated from unfractured vertebrae were found to be significantly associated with VFs. Significant differences were found between men with and without VFs in terms of first, second and shape-based features. Fifteen RFs were selected as the most important for developing the machine learning model. In the clinical model, the two most important features for predicting VFs in the Random forest model were age and the duration of ADT exposure. The ML model based on RFs showed a high ability to predict VFs (accuracy 0.783, ROC 0.735, sensitivity 0.519, specificty 0.827), outperforming that based on clinical features (accuracy 0.672, ROC 0.650, sensitivity 0.519, specifity 0.698). The RF "first order 10 Percentile" was the most relevant feature in the model, suggesting that a reduction in the lower bound of intensity values is positively associated with the development of VFs ($P = .0023$).

Conclusions: The radiomics-based ML model showed high potential in identifying men at high fracture risk during ADT for prostate cancer.

P467 - LBA_ECE_1195 - Improved detection of advanced fibrosis using a metabolically informed model in the MASLD era: comparison with FIB-4

Meliha Melin Uygur[1], Volkan Yazman[1], Ayse Nur Gul[1], Ismail Keskin[1], Özgür Uygur[2] and Caglayan Keklikkiran[3]
[1]*Department of Endocrinology and Metabolism, Faculty of Medicine, Recep Tayyip Erdoğan University, Rize Merkez, Türkiye;* [2]*Department of Geomatic Engineering, Faculty of Civil Engineering, Yildiz Teknik Universitesi, İstanbul, Türkiye;* [3]*Faculty of Medicine, Department of Radiology, Recep Tayyip Erdoğan University, Rize, Türkiye*

Background: The transition from nonalcoholic fatty liver disease (NAFLD) to metabolic dysfunction–associated steatotic liver disease (MASLD) reflects a paradigm shift emphasizing the central role of metabolic dysfunction in liver disease progression. While non-invasive scores such as FIB-4 are widely used for risk stratification, their performance may be suboptimal in metabolically high-risk populations. We aimed to develop and evaluate a

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

metabolically informed model for predicting advanced fibrosis and to compare its performance with FIB-4.

Methods: In this cross-sectional study, we included 346 adults with body mass index (BMI) ≥25 kg/m^2 who underwent liver stiffness assessment using transient elastography. Advanced fibrosis was defined according to established liver stiffness measurement thresholds. Multivariable logistic regression analysis was performed to identify independent predictors of advanced fibrosis, including liver enzymes, fasting glucose, and prediabetes/diabetes status. Model performance was assessed using receiver operating characteristic (ROC) analysis and compared with FIB-4. Risk stratification performance was evaluated across predefined low-, intermediate-, and high-risk categories.

Results: Advanced fibrosis was identified in a subset of patients characterized by a high metabolic burden. In multivariable analysis, prediabetes/diabetes emerged as the strongest independent predictor of advanced fibrosis (OR 4.18, 95% CI 1.87-9.36, $P < .001$). Additional independent predictors included AST (OR 1.09), GGT (OR 1.01), and fasting glucose (OR 1.01), while ALT showed an inverse association (OR 0.96). Notably, BMI was not associated with advanced fibrosis ($P = .355$). The proposed model demonstrated superior discriminative ability compared to FIB-4 (AUC 0.816 vs 0.711). Furthermore, the model improved risk stratification, with a lower prevalence of advanced fibrosis in the low-risk group (3.8% vs 15.3%) and better separation across intermediate and high-risk categories.

Conclusions: In patients with overweight or obesity, advanced fibrosis is primarily driven by metabolic dysfunction rather than adiposity itself. A metabolically informed model incorporating glycemic status and liver enzymes outperforms FIB-4 in both discrimination and risk stratification. These findings support the conceptual shift from NAFLD to MASLD and highlight the importance of integrating metabolic parameters into fibrosis risk assessment.

Figure 1

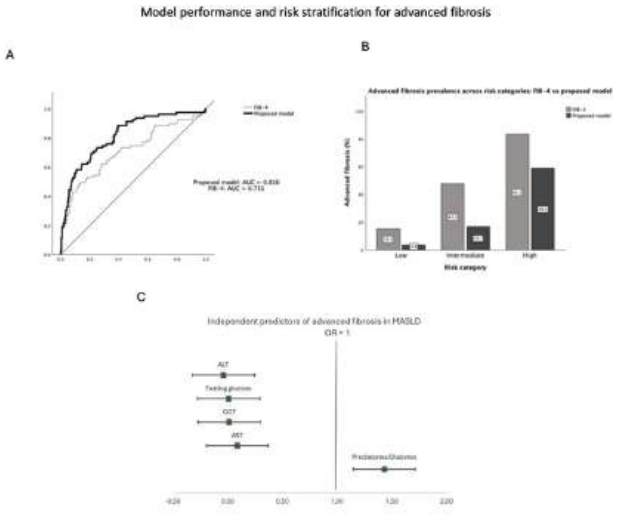

Figure 1. Model performance and predictors of advanced fibrosis in MASLD.
(A) ROC curve comparison showing improved discrimination of the proposed model compared to FIB-4
(B) Prevalence of advanced fibrosis across risk categories demonstrating improved stratification by the proposed model.
(C) Forest plot of multivariable logistic regression identifying independent predictors of advanced fibrosis.

P468 - LBA_ECE_1424 - Peptides mimicking transmembrane helices modulate Follicle-stimulating hormone receptor oligomerisation, signalling, and follicle growth

Ruijuan Xu[1], Thomas Hopkins[1], Chrisel D'souza[1], Peter McCormick[2] and Kim Jonas[1]
[1]King's College London, London, United Kingdom; [2]University of Liverpool, Liverpool, United Kingdom

Introduction: Follicle-stimulating hormone receptor (FSHR) is a G protein-coupled receptor (GPCR) expressed in ovarian granulosa cells, where it regulates follicle growth, development and oestradiol production[1]. While the physiological importance of FSHR is clear, the mechanisms specifying its pleiotropic signalling outcomes remain elusive. FSHR has been shown to form oligomers, a structural arrangement known to govern the trafficking and signalling profiles of GPCRs[2]. Transmembrane (TM) mimicking peptides can insert into the lipid bilayer and interfere with these TM–TM interactions[3]. Therefore, targeting FSHR oligomerisation represents a novel pharmacological strategy distinct from conventional agonism or antagonism.

Aim: To design FSHR targeting transmembrane (TM) mimetic peptides and assess their effects on FSH/FSHR-dependent signalling, oligomerisation, and follicle growth.

Methods: FSHR TM peptides were designed and synthesised based on TM regions: TM1, TM3, TM4, TM6, and TM7. To test their ability to impact FSH/FSHR functions, HEK293 cells expressing mFSHR were used impact on FSHR signalling as follows: cAMP via Glosensor™ live kinetic assay, Western blotting for phospho-ERK/AKT/CREB, HTRF for IP1 generation. FSHR oligomerisation was assessed by NanoBiT® complementation. The effect of TM peptides on FSH/FSHR-dependent follicle growth was assessed in isolated murine pre-antral follicles.

Results and Discussion: Individual FSHR-targeting peptides had no effect on FSH-dependent signalling. However, combinations of TM peptides produced distinct modulatory effects. TM1,7 and TM1,3,4,6,7 reduced FSH-dependent cAMP production, whereas TM1,3 selectively decreased FSH-dependent ERK phosphorylation, and TM1,7 enhanced IP1 production. NanoBiT complementation assays showed that TM1,3 and TM1,3,4,6,7 increased FSHR oligomerisation. In isolated murine follicle cultures, TM1,7 attenuated FSH-dependent follicle growth, consistent with its inhibitory effect on cAMP signalling. Taken together, these findings suggest that distinct FSHR oligomeric complexes mediate different aspects of FSH signalling and function. Targeting specific FSHR oligomers with TM-mimetic peptides may therefore represent a novel strategy for selective ovarian FSHR modulation.

P469 - LBA_ECE_1347 - Low-dose atomoxetine improves brain fatigue syndrome in women with Hashimoto's thyroiditis: a pilot study

Rana Almudhammed[1,2]
[1]*department of Biochemistry and Internal Medicine, Diyala College of Medicine, private Clinic, BAGHDAD, Iraq;* [2]*department of Biochemistry and Internal Medicine, Diyala College of Medicine, Diyala, Iraq*

Background: A subset of young women with Hashimoto's Thyroiditis (HT) report persistent brain fatigue and cognitive slowing despite achieving biochemical euthyroidism (TSH < 4 mIU/L) on levothyroxine. Symptoms including cognitive slowing, emotional lability, sensory and emotional sensitivity, drained mental energy, brain fog, inability to maintain focus, and a long recovery time after mental effort are extremely common among women with hypothyroidism despite achieving biochemical euthyroidism. We hypothesize this is driven by autoimmune-related microglial neuroinflammation rather than residual hypothyroidism. This study evaluates the use of low-dose atomoxetine (10 mg) in addressing brain fatigue syndrome.

Methods: We evaluated 50 women (aged 25-35) with HT who reported persistent mental fatigue, impaired attention, and prolonged cognitive recovery times. To isolate autoimmune-related fatigue, we applied strict exclusion criteria: BMI > 27, prediabetes/diabetes (HbA1c > 5.7%, fasting glucose > 100 mg/dL), premature ovarian insufficiency, iron or B12 deficiency, and psychiatric comorbidities (anxiety/depression). Patients over 35 were excluded to rule out perimenopausal symptom overlap. Baseline and 12-week fatigue levels were measured using the Mental Fatigue Scale (MFS). Patients received atomoxetine 10 mg daily alongside their standard levothyroxine. Atomoxetine increases norepinephrine in the prefrontal cortex. Recent research suggests that norepinephrine isn't just a neurotransmitter; it is a potent immunosuppressor within the Central Nervous System (CNS). Norepinephrine acts on beta-adrenoceptors on microglial cells and astrocytes. High levels of norepinephrine suppress the production of pro-inflammatory cytokines.

Results: At baseline, the cohort exhibited clinically significant mental fatigue with a mean MFS score of 22.8 (SD ± 4.1). After 12 weeks of the combined intervention, the mean MFS score decreased to 16.4 (SD ± 4.5). This reduction achieved statistical significance ($P = .014$). Patients reported noticeable clinical improvements, primarily in attention span and recovery time after cognitive exertion. The intervention was well tolerated, with few patients discontinuing the trial due to adverse effects, and thyroid function tests remained stable.

Conclusions: The combination of low-dose atomoxetine and levothyroxine provides a clinically meaningful reduction in persistent mental fatigue for euthyroid women with HT. These preliminary findings support the theory that targeted neuro-inflammatory modulation may benefit patients whose cognitive symptoms do not respond to standard thyroxine replacement.

P470 - LBA_ECE_1453 - Is preoperative alpha-blockade still necessary? initial experience from a newly established adrenal center

Dmitrii Buzanakov[1], Pier Alesina[2], Anke Meyer[1], Serge Tahl[3], Peter Goretzki[1] and Polina Knyazeva[1]
[1]*Helios University Hospital Wuppertal, Department of Endocrine Surgery, Wuppertal, Germany;* [2]*Evang. Kliniken Essen-Mitte, University of Duisburg-Essen, Essen, Germany;* [3]*Department of Anesthesiology, Helios University Hospital Wuppertal, Wuppertal, Germany*

Introduction: Catecholamine-secreting tumors have traditionally been managed with preoperative alpha-adrenergic blockade. Recently, the necessity of this standard approach has been increasingly debated. In this study, we present our initial experience demonstrating the feasibility of performing surgery for such tumors without preoperative alpha-blockade.

Materials and Methods: From May 2022 to September 2025, 17 patients (13 female, 4 male; mean age 58 ± 15 years) with catecholamine-producing tumors (14 pheochromocytomas and 3 paragangliomas) underwent surgery at a center without previous specialization in adrenal surgery. Standard anesthesiological management included general anesthesia, insertion of a central venous catheter, and placement of an arterial line, with Urapidil used as the main antihypertensive agent. Preoperative alpha-blockade was not applied, except in one case where it had been initiated prior to referral.

Results: Most patients were symptomatic: 14 patients had arterial hypertension, and 3 patients had diabetes mellitus. The median duration of surgery was 40 minutes (range: 20-240 minutes). One patient with a 10 cm paraganglioma underwent primary open surgery. In one additional case, conversion from laparoscopic to open surgery was required due to strong tumor adherence to the liver and a tumor size of 13 cm. The remaining 14 procedures were performed using minimally invasive techniques, including one laparoscopic adrenalectomy (combined with distal pancreatectomy) and 13 retroperitoneoscopic operations. Partial adrenalectomy was performed in 6 patients. The mean tumor size was 5.1 ± 3.4 cm (median 4 cm; range 2-13 cm). The median maximal systolic arterial pressure was 190 mmHg (range: 130-210 mmHg). Two patients developed atrial fibrillation, which resolved spontaneously. Two patients who underwent open surgery were admitted to the intensive care unit for 1 day. The median postoperative hospital stay was 2 days (range: 2-8 days). No major complications or mortality were observed.

Conclusions: Our preliminary findings suggest that omitting preoperative alpha-blockade in surgery for catecholamine-secreting tumors is feasible and safe. Targeted training of the anesthesiology team, standardized perioperative management, and close interdisciplinary coordination are essential for achieving favorable outcomes.

P471 - LBA_ECE_1019 - Quantitative proteomic profiling of adrenal tumors identifies key drivers of malignancy

Anna Angelousi[1], Georgia Rouni[2], Martha Nikopaschou[2], Gregory Kaltsas[3], Georgios Kyriakopoulos[4], Athina Markou[5], Nicolas Nicolaides[6] and Martina Samiotaki[2]

[1]First Departmenet of Internal Medicine, Unit of Endcorinology, National and Kapodistrian University of Athens, Laikon General Hospital, Athens, Greece; [2]BSRC Alexander Fleming, Athens, Greece; [3]First Propaideutic Departement of Internal Medicine, National and Kapodistrian University of Athens, Athens, Greece; [4]Evaggelismos Hospital, Athens, Greece; [5]Department of Endocrinology, Genennimatas General Hospital, Athens, Greece; [6]University of Cyprus, Nicosia, Greece

Background: Adrenocortical carcinoma (ACC) is a rare but aggressive neoplasm, for which early diagnosis and differentiation from adrenocortical adenoma (ACA) is crucial for subsequent treatment and prognosis.The aim of the study was to identify proteomic markers that differentiate ACC, ACA, and normal adrenal tissue based on analysis of archival adrenal tissue sections preserved as formalin-fixed paraffin-embedded (FFPE) samples.

Methods: A total of 24 FFPE tissues were included from 9 patients with ACC (median age of 55.5 years), 9 patients with ACA (median age of 60.5 years), and 6 patients with normal adrenal glands (controls), based on histological evaluation. All ACA cases ($n = 9$), as well as 4/9 ACC tumors, were secretory. The majority of ACC cases ($n = 7/9$) were stage III/IV according to ENSAT, with a median Ki-67 proliferation index of 29%, and were metastatic. Tissue was collected by scraping from microscope slides, and proteins were extracted using repeated cycles of heating and sonication in a 4% SDS lysis buffer. Digestion was performed using the SP3 method, and quantification was carried out by LC–MS/MS using Data-Independent Acquisition. Data processing was performed using DIA-NN (library-free), followed by statistical analysis and pathway enrichment.

Results: More than 6000 proteins were quantified from FFPE material. ACC samples showed increased signaling of insulin-like growth factor 2 (IGF2) along with reduced expression of the following mitochondrial membrane and steroidogenesis-related proteins: Ferredoxin Reductase (FDXR), 11-beta-hydroxylase (CYP11B1), and Glycosylphosphatidylinositol Specific Phospholipase D1 (GPLD1). Secretogranin-1 and Chromogranin-A, proteins associated with hormone storage and secretion, were decreased in ACC. In addition, enrichment of the Nucleotide Excision Repair pathway was observed, consistent with increased cellular proliferation.

Conclusions: DIA-based proteomic analysis of FFPE tissues reveals distinct molecular signatures that differentiate ACC from ACA and normal adrenal tissue. Alterations in the IGF2 axis, steroidogenesis, and DNA repair mechanisms may serve as useful diagnostic and biological markers for understanding adrenal tumorigenesis

P473 - LBA_ECE_1355 - Gestational diabetes and adverse neonatal outcomes: evidence from a prospective cohort study

Tania Tofail, Nusrat Sultana, Prodipta Chowdhury, Tahmina Ferdousi, Nazia Akter, Solaiman Hossain and Muhammad Hasanat

Department of Endocrinology, Bangladesh Medical University, Dhaka, Bangladesh

Background: Gestational diabetes mellitus (GDM) is a major contributor to adverse perinatal outcomes, yet evidence from South Asian populations using contemporary diagnostic criteria remains limited. This study evaluated maternal and neonatal outcomes among women with GDM compared with those with normal glucose tolerance (NGT) in a tertiary care setting in Bangladesh.

Methods: A prospective cohort study was conducted among pregnant women attending the antenatal clinic of Bangladesh Medical University between May 2022 and January 2025. GDM was diagnosed using the International Association of Diabetes and Pregnancy Study Groups (IADPSG) criteria. Women with singleton pregnancies were followed until delivery. Maternal and neonatal outcomes were assessed, and multivariable logistic regression was performed to evaluate the independent association between GDM and neonatal outcomes.

Results: Among 325 participants, women with GDM ($n = 178$) were older and had higher BMI, a greater family history of diabetes, and a higher prevalence of previous GDM than women with NGT (all $P < .01$). Hypothyroidism was more frequent in the GDM group (25.8% vs 15.0%; $P = .016$), while other maternal complications were similar. Neonates born to mothers with GDM had significantly higher rates of macrosomia (13.0% vs 1.4%; $P < .001$), jaundice (24.2% vs 11.6%; $P = .004$), fetal distress (14.0% vs 5.4%; $P = .011$), and hypoglycemia (9.0% vs 0.7%; $P < .001$). In multivariable logistic regression analysis, GDM remained independently associated with macrosomia (aOR 10.28, 95% CI 2.21-47.75), neonatal hypoglycemia (aOR 9.83, 95% CI 1.23-78.21) and neonatal jaundice (aOR 2.94, 95% CI 1.31-6.61).

Conclusions: GDM diagnosed using IADPSG criteria was independently associated with increased risks of macrosomia, neonatal hypoglycemia, jaundice, and fetal distress. These findings highlight the importance of early detection and optimal management of GDM to reduce preventable neonatal complications.

Keywords GDM, macrosomia, neonatal hypoglycemia, perinatal outcome

P475 - LBA_ECE_1057 - Clinical outcome and safety profile of combination therapy with low-dose semaglutide and metformin vs metformin alone in polycystic ovary syndrome with obesity

Hurjahan Banu[1] and Rafayel Islam[2]

[1]Endocrinology, Bangladesh Medical university, Dhaka, Bangladesh; [2]Endocrinology, Bangabandhu Sheikh Mujib Medical University, Dhaka, Bangladesh

Background: Polycystic ovary syndrome (PCOS) is a common endocrine disorder where obesity exacerbates metabolic and androgenic features. The combination of low-dose semaglutide and metformin in South Asian women with PCOS and obesity may be an effective and safe treatment modality.

Objectives: To compare the effectiveness and safety of a combined low-dose semaglutide and metformin with metformin alone in women with PCOS and obesity.

Materials and Methods: This Phase II randomized controlled trial was conducted at the Department of Endocrinology at

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Bangladesh Medical University from January 11 to October 16, 2025. A total of 31 reproductive-aged Bangladeshi women with PCOS and obesity (BMI $\geq$ 27.5 kg/m^2) were randomly assigned to two groups. The metformin group ($n = 16$) received 1000 mg of metformin daily. The combination group ($n = 15$) received the same metformin dose plus subcutaneous semaglutide, starting at 0.25 mg weekly for 4 weeks, then increasing to 0.5 mg weekly for 12 weeks. Both groups received similar standardized lifestyle modifications. Clinical and metabolic data were collected at baseline and after 16 weeks, with interim evaluations at weeks 4, 8, and 12. Data analysis used paired and independent t-tests, Mann-Whitney U test, Chi-square test, and Fisher's Exact test, with a significance level set at $P < .05$.

Results: The combination therapy group achieved greater reduction in body weight (mean difference, MD = −4.6%, $P = .001$), waist circumference (MD = −5.7%, $P < .001$), hip circumference (MD = −3.2%, $P < .001$), waist-to-hip ratio (MD = −2.9%, $P = .028$) and diastolic blood pressure (MD = −6.8%, $P = .023$) compared to the metformin group. Changes in the modified Ferriman–Gallwey score and systolic blood pressure did not differ significantly between groups. Notably, 93.3% of combination-treated participants achieved clinically meaningful weight loss (≥5% from baseline), compared with only 43.8% receiving monotherapy ($P = .006$). Adverse events were primarily gastrointestinal, predominantly in the initial treatment weeks, and resolved completely.

Conclusions: Combining low-dose semaglutide with metformin substantially outperforms metformin monotherapy in managing obesity and associated clinical metabolic derangements in women with PCOS and obesity. The superior weight loss, enhanced mobilization of abdominal fat, and reduced diastolic blood pressure, combined with a favorable safety profile, establish this combination as a valuable therapeutic option for PCOS cases with obesity in Bangladesh.

P478 - LBA_ECE_1368 - Remodelling of GPCR expression in endometrial cancer highlights KISS1R as a candidate receptor

Ece Akgun, Niamh Sayers and Aylin Hanyaloglu
London, United Kingdom

Background: G protein-coupled receptors (GPCRs) are the largest family of cell-surface receptors and play central roles in mediating extracellular signaling, including hormonal, metabolic, and microenvironmental cues. Increasing evidence indicates that aberrant GPCR expression contributes to cancer-associated processes such as proliferation, invasion, immune modulation, and metabolic adaptation. Moreover, recent pan-cancer studies suggest that this is highly tissue-specific and may reveal clinically relevant signaling signatures. Endometrial cancer is characterised by strong hormonal regulation and a dynamic tumour microenvironment, both of which are likely to influence GPCR-mediated signalling. However, the global GPCR expression profile in endometrial cancer remains poorly defined, limiting our understanding of this disease.

Objective: The objective of this study is to define the differential expression profile of GPCRs in endometrial cancer based upon data generated by the TCGA Research Network.

Methods: In this study, we performed a comprehensive bioinformatic analysis of GPCR expression in endometrial cancer using publicly available RNA-sequencing data from The Cancer Genome Atlas Uterine Corpus Endometrial Carcinoma (TCGA-UCEC). All analyses were performed using R Statistical Software (v4.5.2.). A paired analysis was conducted on 23 primary endometrial adenocarcinoma tumors and matched adjacent healthy endometrium tissues. Raw count data were processed using edgeR package (v4.0) with TMM normalization and logCPM transformation, followed by differential expression analysis with Benjamini–Hochberg false discovery rate (FDR) correction. Guide to Pharmacology GPCR list (v2025.3) excluding olfactory receptors was used to curate the GPCR list.

Results: After filtering, 17432 genes were retained, of which 10224 were significantly differentially expressed (FDR < 0.05). Among 402 genes from the curated GPCR list, 149 GPCRs were significantly differentially expressed in the paired analysis (FDR < 0.05). Notably, the majority of differentially expressed GPCRs exhibited strong down-regulation with large effect sizes, whereas a smaller subset of receptors showed consistent up-regulation across patients. Among the most significantly upregulated receptors, KISS1R emerged as a top candidate (logFC ≈ 4.06, FDR ≈ 2.3×10^{-7}), alongside other GPCRs linked to diverse signaling pathways. Exploratory analysis stratified by tumour grade indicated a tendency for increased expression of selected GPCRs, including KISS1R, in higher-grade tumours, although this observation requires further validation.

Conclusions: Overall, these findings reveal a pronounced remodeling of the GPCR expression landscape in endometrial cancer, characterized by widespread receptor down-regulation and selective up-regulation of specific GPCRs. This study provides a systematic framework for understanding GPCR dysregulation and highlights candidate GPCRs for future functional and translational investigation.

P479 - LBA_ECE_1402 - Urinary aldosterone and related metabolites by LC-MS/MS for the screening and subtyping of primary aldosteronism

Alice Stephenson[1], Brian Keevil[1], David Marshall[1] and Emily Goodchild[2]
[1]*Manchester University NHS Foundation Trust, Manchester, United Kingdom;* [2]*St Bartholomew's Hospital, London, United Kingdom*

Introduction: Primary Aldosteronism (PA) is the most common cause of secondary hypertension and is associated with increased risk of morbidity and mortality when compared to primary hypertension. We have developed a LC-MS/MS method for the measurement of aldosterone, cortisol and related metabolites in early morning urine samples, with the aim of providing an alternative screening test for PA. This aims to streamline identification and subtyping of PA. This would be of particular value in patients with KCNJ5 mutations, allowing faster referrals for adrenalectomy and improved patient outcomes.

Method: Analysis of 18-hydroxycortisol (18-OHF), 18-oxocortisol (18-OXOF), aldosterone, cortisol, 18-hydroxycortisosterone and tetrahydroaldosterone was performed in a single LC-MS/MS method, following liquid-liquid extraction with ethyl acetate.

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Correlation of urinary steroids was evaluated. Correlation of the hybrid steroids 18-OHF and 18-OXOF was compared between matched urine and serum samples from patients with PA ($n = 57$).

Results: Validation parameters were acceptable, with the method demonstrating good recovery and minimal matrix effects. Urinary tetrahydroaldosterone and aldosterone showed agreement in numerical values ($r = 0.7212$). A clear numerical correlation was observed between 18-OXOF concentrations in serum and urine ($r = 0.7765$). A correlation was also observed between serum 18-OXOF and 18-OHF and urine 18OHF:cortisol ratios ($r = 0.6023, 0.6715$).

Conclusions: We have developed an LC-MS/MS assay to measure aldosterone and related metabolites in early morning urine samples. This has clinical applications at providing a streamlined screening test for PA, which could allow for early identification of PA subtypes. We hope to develop our in-house method further and aim to implement this approach in the future diagnostic work-up of PA patients. The results of this investigation will be matched with patient genotypes in future.

P480 - LBA_ECE_1416 - Right molecule, wrong moment: timing-dependent consequences of calcitriol on follicular dynamics and oocyte maturation

Ali Zeyghami[1,2,3], Hamid Ahmadi[1], Timea Judith Csabai-Tanics[1,2,3] and Zoltan Bognar[1,2,3]

[1]Department of Medical Biology, University of pecs Medical School, Pécs, Hungary; [2]National Laboratory of Human Reproduction, University of Pécs, Pecs, Hungary; [3]Szentágothai Research Centre, Universsity of Pecs, Pécs, Hungary

Introduction: The ovarian follicle is a precisely regulated endocrine microenvironment in which granulosa cells coordinate hormonal signalling and oocyte development. Among its modulators, calcitriol (1,25-dihydroxyvitamin D_3)—the biologically active form of vitamin D—has emerged as a significant regulator of reproductive function, acting through the nuclear vitamin D receptor (VDR) expressed in granulosa cells and follicular tissue. VDR activation influences anti-Müllerian hormone (AMH), a glycoprotein governing primordial follicle recruitment and ovarian reserve. Equally central is the steroidogenic enzyme aromatase (CYP19A1), which drives androgen to estradiol conversion within granulosa cells—a process integral to oocyte quality. While the roles of these mediators in folliculogenesis are increasingly recognized, how the timing of calcitriol exposure relative to FSH stimulation shapes their downstream regulation remains an underexplored question in reproductive endocrinology.

Methods: Adult female CD-1 mice (8-12 weeks) underwent controlled ovarian stimulation with exogenous FSH, followed by hCG to trigger ovulation. A supra-physiological dose of calcitriol (100 ng, i.p.) was administered at one of three time points: two days prior to gonadotropin stimulation (Vit D −2), concurrently with FSH, or two days thereafter. A vehicle-treated cohort served as the reference control. Cumulus–oocyte complexes (COCs) were retrieved sixteen hours post-hCG and assessed for meiotic maturation. Ovarian tissue was processed for immunohistochemical localization of AMH and aromatase (CYP19A1) and protein extraction for quantitative expression analyses.

Results: Immunohistochemical assessment revealed differential AMH and aromatase (CYP19A1) expression patterns across experimental groups. The Vit D −2 group exhibited elevated AMH localization alongside reduced aromatase (CYP19A1) expression compared to other groups, while an opposing pattern—characterized by diminished AMH and enhanced aromatase localization—was observed in the Vit D +2 group. Western blot analysis provided quantitative corroboration of these findings, indicating that calcitriol exerts a timing-dependent influence on the endocrine profile of granulosa cells. Follicular distribution analysis in the Vit D −2 group further demonstrated a decline in primary follicle proportion alongside a relative expansion of the antral follicle pool.

Conclusions: These findings underscore calcitriol timing as a critical modulator of granulosa cell endocrine function, follicular dynamics, and meiotic competence. The bidirectional, timing-dependent shifts in AMH and aromatase expression—corroborated by Western blot—highlight a context-dependent mechanism of vitamin D signaling with meaningful implications for its precise use in assisted reproductive protocols.

Keywords anti-Müllerian hormone (AMH), aromatase, folliculogenesis, vitamin D (calcitriol)

P484 - LBA_ECE_1385 - Acromegaly-associated diabetes and cardiovascular risk: evidence from a Swedish nationwide matched-cohort study

Angelo Milioto[1,2], Oskar Ragnarsson[1,2], Annika Rosengren[3,4], Martin Adiels[5], Diego Ferone[6,7], Gudmundur Johannsson[1,2] and Daniela Esposito[1,2]

[1]Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; [2]Department of Endocrinology, Sahlgrenska University Hospital, Gothenburg, Sweden; [3]Department of Molecular and Clinical Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; [4]Department of Medicine, Geriatrics and Emergency Medicine, Sahlgrenska University Hospital/Östra, Gothenburg, Sweden; [5]University of Gothenburg, 5School of Public Health and Community Medicine, Institute of Medicine, Gothenburg, Sweden; [6]Endocrinology Unit, Department of Internal Medicine and Medical Specialties (DIMI), University of Genova, Centre of Excellence for Biomedical Research (CEBR), Genova, Italy; [7]Endocrinology Unit, IRCCS Ospedale Policlinico San Martino, Genova, Italy

Introduction: While type 2 diabetes (T2DM) is typically linked to obesity, acromegaly-associated diabetes mellitus (ACRO-DM) develops in patients with relatively lean phenotype due to their excess growth hormone exposure. The clinical impact of this distinct metabolic profile is not fully understood. This study aims to primarily investigate the burden of cardiovascular morbidity, alongside survival outcomes, in individuals with ACRO-DM compared to those with T2DM.

Methods: This population-based, matched-cohort study utilized Swedish national health registries. The study cohort consisted of patients with acromegaly identified in the National Patient

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Register (PNR) who had concurrent diabetes recorded in the National Diabetes Register (NDR) or were treated with an antidiabetic drug recorded in the National Drug Register. A T2DM reference group was extracted from the National Diabetes Register and matched 10:1 to the ACRO-DM subjects based on gender, age, calendar year and duration of diabetes. Data on cardiovascular diseases were extracted from PNR. The baseline was defined as the date of the first NDR entry or the initial prescription of an antidiabetic drug, whichever occurred first. Hazard ratios (HRs) have been adjusted for smoking, income and education.

Results: The study included 348 ACRO-DM patients and 3480 matched T2DM controls. Both cohorts had comparable baseline characteristics, including mean age (~60 years), glycemic control (HbA1c ~55 mmol/mol), diabetes duration (~3 years) and follow-up period (~9.3 years). At baseline, cardiovascular disease was more frequent in the ACRO-DM cohort compared to the T2DM controls (61.2% vs 43.2%), specifically for stroke, hypertension, heart failure and arrhythmia. During follow-up, longitudinal analyses showed that patients with ACRO-DM had higher risk of cardiovascular events than T2DM controls (HR 1.55; 95% CI, 1.24-1.94), pulmonary embolism (HR 3.26; 95% CI, 1.94-5.95), venous embolism (HR 2.27; 95% CI, 1.29-4.00) and arrhythmias (HR 1.48; 95% CI, 1.11-1.98). A sensitivity analysis showed that hydrocortisone replacement did not affect the risk of pulmonary or venous embolism in patients with ACRO-DM. Mortality did not significantly differ among the two groups, cardiovascular mortality (HR 1.12; 95% CI, 0.78-1.60) and all-cause mortality (HR 1.18; 95% CI, 0.96-1.46).

Conclusions: ACRO-DM is characterized by a higher cardiovascular disease burden than standard T2DM. Despite this increased cardiovascular morbidity, overall and cardiovascular mortality rates remain comparable between the two conditions.

P485 - LBA_ECE_1392 - The impact of pegvisomant on lipid metabolism in acromegaly: a systematic review and meta-analysis

Angelo Milioto[1,2], Federico Gatto[3,4], Christian Basile[5,6], Eva Hessman[7], Diego Ferone[3,4], Oskar Ragnarsson[1,2], Gudmundur Johannsson[1,2] and Daniela Esposito[1,2]
[1]*Department of Internal Medicine and Clinical Nutrition, University of Gothenburg, Institute of Medicine, Sahlgrenska Academy, Gothenburg, Sweden;* [2]*Department of Endocrinology, Sahlgrenska University Hospital, Gothenburg, Sweden;* [3]*Department of Internal Medicine and Medical Specialties (DIMI), University of Genova, Endocrinology Unit, School of Medical and Pharmaceutical Sciences, Genova, Italy;* [4]*Endocrinology Unit, IRCCS Ospedale Policlinico San Martino, Genova, Italy;* [5]*Department of Clinical Science and Education, Karolinska Institutet, Södersjukhuset, Stockholm, Sweden;* [6]*Heart Care Foundation, ANMCO Research Center, Florence, Italy;* [7]*University of Gothenburg, Biomedical Library, Gothenburg University Library, Gothenburg, Sweden*

Introduction: Acromegaly is characterized by altered lipid profile due to the effect that growth hormone (GH) has on lipid metabolism. Pegvisomant is a GH-receptor antagonist approved for the treatment of acromegaly that has demonstrated a favorable impact on glucose metabolism; however, data on its effect on lipid metabolism are limited. The aim of this study is to synthesize available evidence on the impact of pegvisomant on total cholesterol (TC), low density lipoprotein (LDL), high density lipoprotein (HDL) and triglycerides (TGL) in patients with acromegaly.

Methods: A database search of PubMed, Cochrane Central and Embase was conducted for studies on pegvisomant in acromegaly in May 2025 and updated in March 2026. Two reviewers performed an initial screening of titles and abstracts and examined the full texts of the selected articles. Retrospective and prospective studies assessing lipid metabolism in patients with acromegaly before and after treatment with pegvisomant were included. Extracted data were systematically synthesized. Study quality was independently assessed by two reviewers using the NHLBI Quality Assessment Tool. The protocol for this systematic review adheres to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines and was registered in PROSPERO (CRD420261344770). Results are reported as mean difference (MD) and 95% confidence interval (CI).

Results: In total, 2239 articles were identified. After title and abstract screening, 147 articles involving 343 patients were reviewed in full text and ten were included in the systematic review. In most cases, TC, LDL, HDL and TGL remained unchanged after treatment with pegvisomant. Six studies were included in the meta-analyses as 4 were excluded due to overlapping populations. Following pegvisomant treatment, pooled analysis of 5 studies (involving 248 patients) revealed that TC remained unchanged after treatment with pegvisomant (MD 0.03 mg/dL; 95% CI: −0.17 to 0.23). Likewise, LDL showed no significant change in pooled analysis of 4 studies involving 163 patients (MD 0.05 mg/dL; 95% CI: −0.29 to 0.39). Similarly, pooled analysis of 3 studies involving 141 patients demonstrated no significant change in HDL (MD −0.02 mg/dL; 95% CI: −0.06 to 0.03). In contrast, TGL increased after treatment with pegvisomant with an MD of 0.22 mg/dL (95% CI: 0.08 to 0.36), based on 3 studies involving 96 patients.

Conclusions: This is the first systematic review and meta-analysis evaluating the impact of pegvisomant on lipid metabolism. Meta-analysis demonstrated a significant increase in TGL, while TC, LDL, and HDL remained unchanged after pegvisomant treatment.

Sciences, Kartal Dr. Lütfi Kırdar City Hospital, istanbul, Türkiye; [5]Department of Endocrinology and Metabolism, Endocrinology and metabolism, University of Health Sciences, Kartal Dr. Lütfi Kırdar City Hospital, İstanbul, Türkiye; [6]İstanbul, Türkiye

Background: Primary hyperparathyroidism (PHPT) is characterized by predominant cortical bone loss. Although bone mineral density (BMD) is expected to improve after parathyroidectomy, early postoperative changes and their relationship with baseline BMD and metabolic parameters remain unclear. This study aimed to evaluate the association between baseline regional BMD and early postoperative changes in BMD (ΔBMD) as the primary outcome, and to explore correlations with metabolic parameters as the secondary outcome in a real-world cohort.

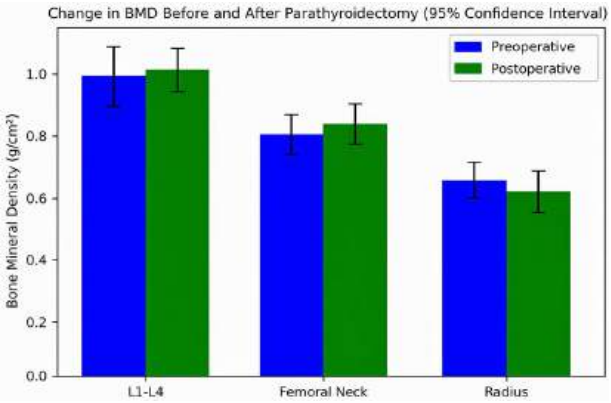
Methods: This retrospective study included patients who underwent parathyroidectomy for PHPT between 2014 and 2024. Patients with chronic kidney disease or multiglandular disease were excluded. Preoperative and first-year postoperative BMD (lumbar spine, femoral neck, distal radius) and biochemical parameters were analyzed. Changes in BMD (ΔBMD) and their associations were assessed using Spearman correlation analysis. A *P*-value <.05 was considered statistically significant.

Results: A total of 39 patients were included in the study. Preoperative PTH levels were 181.6 ± 114.6 pg/mL, serum calcium levels were 11.29 ± 0.64 mg/dL, and phosphorus levels were 2.66 ± 0.54 mg/dL. Preoperative BMD was 0.997 ± 0.24 g/cm^2 at the L1–L4 lumbar spine, 0.808 ± 0.15 g/cm^2 at the femoral neck, and 0.652 ± 0.11 g/cm^2 at the distal one-third radius. Parathyroidectomy resulted in significant increases in lumbar spine and femoral neck BMD ($P = .003$ and $P = .002$, respectively), whereas no significant change was observed at the distal radius ($P = .612$).

No significant association was found between baseline BMD and ΔBMD at any skeletal site (lumbar: r = −0.360, $P = .055$; femoral neck: r = −0.165, $P = .393$). Changes in PTH were also not associated with ΔBMD. In contrast, Δlumbar and Δfemoral neck BMD showed a moderate positive correlation (r = 0.394, $P = .034$).

Metabolic analysis revealed a significant negative correlation between insulin resistance and serum phosphorus levels (HOMA-IR: r = −0.490, $P = .004$).

Figure



Conclusions: In this cohort, early postoperative BMD improvement following parathyroidectomy occurred independently of baseline BMD, suggesting that initial skeletal status does not predict short-term bone recovery. These findings support a multifactorial regulation of early skeletal response beyond baseline bone mass. The lack of improvement at cortical sites is consistent with slower cortical bone remodeling. This may have implications for postoperative monitoring and risk stratification in PHPT patients.

Abstract citation ID: lvag096.598

P487 - LBA_ECE_1248 - Real-world efficacy and safety of mitotane monotherapy in the management of severe Cushing syndrome at a tertiary referral center

Xiang Zhou, Wan Su, Lian Duan, Huijuan Zhu and Lin Lu
Peking Union Medical College Hospital, Beijing, China

Objective: Mitotane is a potent steroidogenesis inhibitor; however, its use in severe Cushing syndrome (CS) is often limited by the delayed onset of action and side effects. This study was aimed to evaluate the real-world efficacy and safety of mitotane monotherapy in patients with challenging severe CS.

Design: Retrospective, single-center study.

Methods: We analyzed patients with severe CS treated with mitotane at Peking Union Medical College Hospital between January 2024 and January 2026. Mitotane was initiated at 500 mg twice daily and titrated based on tolerance and therapeutic response. Remission was defined as the normalization of 24-hour urinary free cortisol (24h-UFC). Clinical characteristics, treatment outcomes as well as frequency and severity of adverse events (AEs) were assessed.

Results: As of the data cut-off (4 March 2026), eighteen patients were included, with median baseline 24h-UFC 69-fold (IQR 18-115; range 5.5-303.4) the upper limit of normal (ULN). One patient died from cardiac arrest three days after initiation of mitotane and was excluded from efficacy analysis. Remission was achieved in twelve (70.6%) patients, after a median time of 42 d (IQR 24-96), with a mean mitotane dose of 1.56 ± 0.52 g/d. In the five patients who didn't achieve remission, their 24h-UFC decreased by 95.3% (IQR 85.5%-95.3%), dropping from 100.4-fold (IQR 87.6-140.5) to 4.8-fold (IQR 3.2-12.1) ULN, at a median mitotane dose of 1.25 g/d (IQR 0.8-2.0). Baseline lymphocyte percentage, CD 4+ lymphocyte count and potassium levels were significantly higher in the remission group compared to the non-remission group ($P < .05$). Common AEs included: liver enzyme abnormality (grade 1-2, $n = 9$; grade 3-4, $n = 7$), hyperlipidemia (grade 1-2, $n = 10$; grade 3-4, $n = 4$), gastrointestinal syndromes (grade 1-2, $n = 10$) and adrenal insufficiency (grade 1-2, $n = 6$). Notably, among seven patients with grade 3-4 liver enzyme abnormality, four exhibited isolated gamma-glutamyl transferase elevation while alanine aminotransferase, aspartate aminotransferase, and bilirubin levels were normal. Treatment discontinuation occurred in two patients due to severe hepatotoxicity.

Conclusions: Monotherapy of mitotane demonstrated substantial efficacy in controlling severe hypercortisolism with good tolerance, and the time to remission was comparable

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

to other oral steroidogenesis inhibitors. This suggested the potential role of mitotane as a viable option for severe CS, particularly in regions where alternative steroidogenesis inhibitors are inaccessible.

Abstract citation ID: lvag096.599

P489 - LBA_ECE_1144 - Autoimmunity following subacute thyroiditis: thyroid autoantibody development and associated clinical factors

Murat Calapkulu, Murat Görgülü, İlknur Ozturk Unsal and Erman Cakal
Endocrinology and Metabolism, Ankara Etlik City Hospital, Ankara Etlik City Hospital, Ankara, Türkiye

Background: Subacute thyroiditis is a self-limited inflammatory thyroid disorder, most commonly following viral infections. Although thyroid function typically recovers, follicular destruction may trigger thyroid autoimmunity through antigen release. The development of thyroid autoantibodies and, in some cases, progression to chronic autoimmune thyroid disease have been reported; however, data on long-term autoantibody development and its determinants remain limited. This study aimed to investigate the incidence and predictors of thyroid autoantibody development during long-term follow-up in patients with subacute thyroiditis.

Methods: This study was designed as a retrospective cohort analysis. Medical records of 734 patients diagnosed with subacute thyroiditis at our center were retrospectively reviewed.. Patients with at least one year of follow-up and negative thyroid autoantibodies at diagnosis were included. Patients with positive thyroid autoantibodies at baseline or a prior diagnosis of hypothyroidism were excluded. A total of 73 patients met the inclusion criteria. Patients were divided into two groups based on the development of thyroid autoantibody positivity during follow-up, and demographic, laboratory, and treatment-related data were compared between groups.

Results: During follow-up, thyroid autoantibody positivity developed in 12 patients (16.4%). Anti–thyroid peroxidase antibody positivity was observed in 4 of 73 patients (5.5%), anti-thyroglobulin antibody positivity in 9 of 73 patients (12.3%), and TSH receptor antibody positivity in 3 of 61 patients (4.9%). The majority of patients remained autoantibody-negative throughout follow-up. Patients were divided into two groups based on the development of thyroid autoantibody positivity during follow-up. There were no significant differences between the groups in terms of age, gender, white blood cell count, neutrophil count, lymphocyte count, erythrocyte sedimentation rate, C-reactive protein levels, TSH, free T4, or free T3 levels. However, total thyroid volume was significantly higher in patients who developed thyroid autoantibody positivity compared with those who did not. No significant associations were observed between thyroid autoantibody development and thyroid functional status at diagnosis, ultrasonographic involvement pattern (unilateral or bilateral involvement), recurrence status, number of recurrences, or treatment modality, including nonsteroidal anti-inflammatory drugs and corticosteroid therapy.

Conclusions: Thyroid autoimmunity may develop in a considerable proportion of patients following subacute thyroiditis. While most demographic, biochemical, and clinical parameters were not associated with autoantibody development, increased thyroid volume emerged as a potential risk factor. These findings suggest that structural thyroid changes during the acute phase of subacute thyroiditis may contribute to subsequent autoimmune activation, highlighting the importance of long-term follow-up in patients with marked thyroid enlargement.

Keywords subacute thyroiditis, autoimmunity

P490 - LBA_ECE_1448 - Patterns of polyautoimmunity in patients with autoimmune thyroid diseases

Reti Zsuzsanna[1,2], Boglarka Kiss[3,4] and Alpar Kiss[5]
[1]*George Emil Palade University of Medicine, Pharmacy, Science, and Technology of Targu Mures, Endocrinology, Targu Mures, Romania;* [2]*Endocrinology, Mures County Hospital, Târgu Mureș, Romania;* [3]*University of Pecs, Pecs, Hungary;* [4]*University of Pecs, Oncology, Pecs, Hungary;* [5]*Codespring, Odorheiu Secuiesc, Romania*

Introduction: Autoimmune thyroid diseases (ATDs), Hashimoto's thyroiditis (HT) and Graves' disease (GD), often coexist with other autoimmune disorders. This study aimed to assess the frequency of these associations and to analyze their patterns in relation to the timing of disease onset.

Materials and Methods: In this retrospective study, we analyzed data from patients with ATD registered during a 10-month interval in our Endocrinology Department. The sole inclusion criteria were the presence of at least one additional confirmed autoimmune disease beside thyroid autoimmune disease. Data were analysed using network analysis in Python, and statistical evaluation was conducted using a binomial test. Triple associations were included in a weighted manner.

Results: A total of 780 patients were evaluated, of whom 130 met the inclusion criteria. Among these, 86.9% ($n = 113$) had HT and 13.1% ($n = 17$) had GD. Network analysis identified 28 autoimmune diseases, yielding 48 distinct combinations. In 84.6% of cases, two autoimmune conditions were present, while in 15.4% of cases, three or more conditions coexisted. Multiple associations involved 15 different conditions, most commonly vitiligo ($n = 7$) and type 1 diabetes (T1DM) ($n = 6$). T1DM was observed only with vitiligo and Addison's disease (AD), whereas vitiligo co-occurred with a different disorder in every case, showing the most diverse pattern. In multiple associations, systemic diseases other than vitiligo appeared only in the presence of other systemic diseases. When HT-associated comorbidities were categorized, binomial testing indicated that autoimmune conditions affecting the skin ($P = .00274$) and the nervous system ($P = .031$) were more likely to precede HT. In contrast, systemic ($P = .00015$) and gastrointestinal diseases ($P = .0059$) were more frequently observed following HT. These findings were also reflected in the most diverse multiple associations. In cases where HT and T1DM co-occurred ($n = 7$), neither condition showed temporal predominance. In contrast, among patients with concurrent AD and HT ($n = 13$), HT preceded AD in 7 cases, while both conditions were diagnosed simultaneously in the remaining 6 cases. All three conditions co-occurred in 4 cases. HT was most associated with rheumatoid arthritis ($n = 26$). GD was associated with 9 different diseases, most commonly psoriasis ($n = 5$), and appeared as a secondary

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

disease ($P = .007$).

Conclusions: HT demonstrated a relatively consistent temporal pattern depending on the associated comorbidity, whereas GD more frequently appeared as a secondary condition. Network analysis may help guide screening frequency in multisystem autoimmune disorders.

P491 - LBA_ECE_1191 - The influence of zinc administration on VEGF imunoexpression in lungs of diabetic rats

Cristina Gales[1], Carmen Lacramioara Zamfir[1], Gabriela Rusu-Zota[1], Mihai Nechifor[1] and Daniel Costel Gales[2]
[1]*Histology Department, University of Medicine and Pharmacy "Grigore T Popa" Iasi, Iasi, Romania;* [2]*Pedology Department, University of Life Sciences "Ion Ionescu de la Brad", Iasi, Romania*

Introduction: Diabetes mellitus is a systemic disorder associated with inflammation and oxidative stress, targeting kidney, lungs and the vascular system. Zinc is an essential microelement and an antioxidant which was found to be deficient in diabetes mellitus with poor glycemic control. Vascular endothelial growth factor (VEGF) plays a crucial role in angiogenesis and vascular homeostasis. The study investigates the influence of $ZnCl_2$ administration on lung diabetic lesions and VEGF expression.

Materials and Methods: The study was carried out on four groups of 6 adult male Wistar rats, for 8 weeks. The first group received only a 2 mL/kg/day saline solution daily. The second group received on the first day 65 mg/kg streptozotocin (STZ) i.p. in a single dose. The third group received $ZnCl_2$ 5 mg/kg/day i.p. daily. The fourth group received on the first day 60 mg/kg STZ i.p. in a single dose and $ZnCl_2$ 5 mg/kg/day daily. Diabetic rats had fasting blood glucose levels exceeding 250 mg/dL. After eight weeks all animals were anesthetized and were sacrificed. For each lung, 5 sections were stained with HE and Anti-VEGFA antibody (Abcam, 1:200 in PBST) and were examined using a Leica microscope. The extent of lung lesions (fibrosis and neutrophil infiltration) was evaluated semi-quantitative with the following score: 0 = none; 1 <0-25% of the lung (mild severity); 2 = 25-50% of the lung (moderate); 3 >50% of the lung (severe). We used IHC Profiler program for the automated scoring of the intensity and percentage of VEGF positive stained cells. The obtained data were statistically interpreted by ANOVA test.

Results: After 8 weeks the STZ group presented thickening of the alveolar and bronchiolar walls and septal, peribronchiolar and perivascular inflammatory infiltration; also a strong, positive VEGF cytoplasmic expression in the alveolar and bronchial epithelium. $ZnCl_2$ significantly reduced the extent of lung lesions score (2.27 ± 0.43 in the STZ group vs1.92 ± 0.28 in the STZ+ $ZnCl_2$ group, $P < .05$) and the percentage of moderate cytoplasmic stained cells (36.90 ± 4.81 in the STZ group, with a final positive staining score, vs 32.78 ± 3.14 in the STZ+ $ZnCl_2$ group, $P < .05$, with a final positive and low positive staining score).

Conclusions: The obtained results showed that $ZnCl_2$ significantly reduced diabetic lung inflammation and fibrosis and VEGF imunoexpression score. Zinc supplementation may be protective against lung lesions and VEGF-induced angiogenesis in diabetes.

P493 - LBA_ECE_1189 - Risk factors for post-transplant diabetes mellitus in heart transplant recipients: emphasis on postoperative glycemic control

Rui Zhang, Hongzhao You, Yingying Hu, Yanyan Chen, Jie Huang and Sheng Liu
National Center for Cardiovascular Diseases, Fuwai Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background and Aim: Post-transplant diabetes mellitus (PTDM) is a common metabolic complication after heart transplantation (HT), yet data on its risk factors, particularly the role of postoperative glycemic control, remain limited. This study aimed to identify predictors of PTDM in HT recipients, with a specific focus on postoperative mean blood glucose (MBG) levels.

Methods: This retrospective cohort study included 305 adult HT recipients without pre-existing diabetes who underwent transplantation at Fuwai Hospital (2015-2020). Patients were categorized by in-hospital MBG: strict (<7.8 mmol/L), moderate (7.8-10.0 mmol/L), or liberal (≥10.0 mmol/L) glycemic control. PTDM was diagnosed according to WHO/ADA criteria. Multivariable logistic regression and restricted cubic spline (RCS) analyses were used to evaluate associations.

Results: Over a 5-year follow-up, PTDM occurred in 130 patients (42.6%). Independent pre-transplant predictors included male sex (OR 2.77, 95% CI 1.34-5.71), higher preoperative HbA1c (OR 1.97, 95% CI 1.02-3.80), and elevated triglyceride levels (OR 2.36, 95% CI 1.26-4.40). RCS analysis showed a linear positive association between MBG and PTDM risk (P overall <.001). Higher MBG remained an independent predictor after multivariable adjustment (OR 1.55, 95% CI 1.16-2.06). Compared with moderate control, liberal glycemic control (MBG ≥10.0 mmol/L) was associated with a significantly increased PTDM risk (OR 2.30-3.39 across models, $P < .05$).

Conclusions: Male sex, adverse preoperative metabolic profiles, and poor postoperative glycemic control independently increase PTDM risk after HT. Liberal glycemic targets (≥10.0 mmol/L) should be avoided to reduce PTDM incidence in patients without pre-existing diabetes.

[3]German Center for Diabetes Research (DZD), München-Neuherberg, Germany; [4]Department of Human Nutrition, German Institute of Human Nutrition, Potsdam-Rehbruecke, Nuthetal, Germany; [5]Charité—Universitätsmedizin Berlin, Institute of Biometry and Clinical Epidemiology, Berlin, Germany; [6]Institute for Diabetes Research and Metabolic Diseases (IDM) of the Helmholtz Center Munich, Tübingen, Germany; [7]DZHK (German Centre for Cardiovascular Research), Berlin, Germany

Introduction: A reduced visceral and non-visceral adipose tissue (VAT, NVAT) content was reported after 12 months of an isocaloric diet high in proteins and unsaturated fatty acids within the randomized controlled trial NutriACT. This reduction was independent of body weight changes, primarily driven by higher dietary PUFA intake, and led to reduced LDL-cholesterol (LDL).

Objectives: We aimed to investigate whether reductions in VAT/NVAT and associated improvements in cardiometabolic risk markers can be sustained over 36 months and, if so, what factors contribute to this.

Methods: Participants in the intervention group (IG) followed a dietary pattern high in mono-/poly-UFA (15-20%E/10-15%E), plant protein (15-25%E) and fiber (≥30 g/day); the control group (CG) followed standard of care per the German Nutrition Society. MRI-based assessment of VAT/NVAT and metabolic phenotyping were performed at 0, 12 and 36 months. A subgroup of 320 subjects (50-79 years) with MRI data at baseline and at least one follow-up was analyzed. Linear mixed models assessed intervention effects on VAT and NVAT; mediation analyses identified contributing factors.

Results: Marked increases in protein and PUFA intake were achieved within 12 months and maintained through month 36. The intervention significantly affected VAT and NVAT over 3 years ($P = .038$, $P = .003$). In the IG, VAT decreased at 12 months ($P < .001$) but returned to near-baseline levels by 36 months (p t12–t36 = .004, t0–t36 = .919), while NVAT decreased at 12 months ($P = .009$) and remained below baseline at 36 months (p t0–t36 < .001). In the CG, VAT increased from 12 to 36 months ($P = .041$), and NVAT decreased at 12 months ($P < .001$) but stabilized thereafter. Protein and PUFA intake were inversely associated with both VAT and NVAT; fiber intake selectively affected VAT. Total and LDL-cholesterol improved significantly after 12 months in women in the IG but rebounded by 36 months. In men, both markers stabilized after an initial decrease without reaching significance versus baseline.

Conclusions: The intervention had a stronger, more sustained effect on NVAT than on VAT, with VAT returning to near-baseline levels by 36 months. Reductions in both depots were driven by protein and PUFA intake; fiber intake selectively affected VAT. Early cardiometabolic improvements were not maintained long-term, underscoring the need for longer dietary intervention trials to identify strategies for sustainable adipose tissue reduction.

P495 - LBA_ECE_1275 - ZIP9 links zinc homeostasis to neuroendocrine regulation of reproduction in zebrafish

Rui Wang[1], Ruijuan Xu[1], Rhiannon Boseley[2], Tina Geraki[2], Alexander Morrell[3], Alexander Griffiths[3], Robert Hindges[4], Kim Jonas[1] and Christer Hogstrand[5]

[1]Department of Women & Children's Health, King's College London, London, United Kingdom; [2]Diamond Light Source, Harwell Science and Innovation Campus, Didcot, United Kingdom; [3]London Metallomics Facility, King's College London, London, United Kingdom; [4]Centre for Developmental Neurobiology, King's College London, London, United Kingdom; [5]Department of Analytical, Environmental & Forensic Sciences, King's College London, London, United Kingdom

The zinc transporter ZIP9 has been proposed to function as a membrane androgen receptor; however, its role in endocrine regulation of reproduction remains unclear.

This study aimed to characterise the reproductive phenotype of ZIP9 deficiency in a vertebrate model and define the underlying endocrine and mechanistic basis.

A zebrafish *zip9* knockout line was generated using CRISPR/Cas9. Reproductive performance was assessed in incross and outcross mating pairs, and embryo development was monitored up to 24 hours post-fertilisation (hpf). Expression of key hypothalamic-pituitary-gonadal (HPG) axis genes was analysed by qPCR, and ovarian histology was performed. Metal distribution in larvae was analysed by laser ablation inductively coupled plasma time-of-flight mass spectrometry (LA-ICP-TOF-MS), followed by micro X-ray fluorescence (XRF) imaging and tomography of the head region.

Zip9 knockout zebrafish exhibited reduced growth. While courtship behaviour appeared normal, reproductive output was markedly impaired in females but not males. Crosses involving $zip9^{-/-}$ females showed significantly reduced spawning rates and egg numbers, irrespective of male genotype, whereas $zip9^{-/-}$ males reproduced normally. Female-specific infertility was further evidenced by 100% embryo mortality by 24 hpf, with embryos arrested at the 1-cell stage and reduced chorion size.

Histological analysis revealed ovarian disorganisation with accumulation of early-stage follicles, indicating disrupted folliculogenesis. qPCR analysis demonstrated pronounced, sex-specific dysregulation of HPG axis genes. Key neuroendocrine regulators (*kiss1, kiss2, gnrh2, gnrh3, fshb, lhb*) were suppressed in female brains but elevated in males, with downstream disruption of gonadal gene expression. In addition, hepatic expression of vitellogenin (*vtg*) and oestrogen receptor (*esr1*), essential for yolk formation, was reduced by more than 60%.

LA-ICP-TOF-MS revealed reduced zinc, copper and iron levels in *zip9*-deficient larvae. In wildtype larvae, zinc was enriched in a brain region corresponding to the hypothalamic-pituitary area; this localisation was absent in *zip9* mutants. XRF imaging and tomography confirmed the loss of this distinct zinc distribution, indicating disruption of zinc-dependent neuroendocrine signalling.

ZIP9 is a critical, female-specific regulator of reproductive function. Its loss disrupts ovarian development, impairs yolk formation, and results in complete embryo mortality. The associated sex-specific dysregulation of HPG axis genes, together with loss of zinc patterning in neuroendocrine regions, supports a model in which ZIP9 maintains hypothalamus-pituitary-gonad communication through regulation of zinc distribution, thereby enabling female fertility.

P497 - LBA_ECE_1171 - A pilot trial for phytosomal silymarin plus N-acetyl L-cystein, vitamin E and myo-inositol in prediabetic patients with preclinical liver disease. Focus: risk of liver fibrosis and insulin resistance

Francisco Javier Martinez-Martin[1,2], Sara Andrada-Diaz[3], Borja Santana-Ojeda[1], Inmaculada Molinero-Marcos[1], Claudia Arnas-Leon[1,2], Ricardo Jose de Leon-Durango[1], Alba Hernandez-Lazaro[4], Agnieszka Kuzior[2], Maria del Pino Perez-García[5] and Carmen Acosta-Calero[6]

[1]Endocrinology & Nutrition, Hospital Universitario de Gran Canaria Doctor Negrin, Las Palmas de Gran Canaria, Spain; [2]Endocrinology & Nutrition, Hospitales Universitarios San Roque, Las Palmas de Gran Canaria, Spain; [3]Bioksan Naturalmente Juntos, Medical Advisory, Las Palmas de Gran Canaria, Spain; [4]Servei d'Endocrinologia i Nutricio, Sabadell, Parc Taulí Hospital Universitari, Barcelona, Spain; [5]Centro de Salud San Gregorio, Family & Community Medicine, Telde, Las Palmas, Spain; [6]Hospital Universitario de Gran Canaria Doctor Negrin, Cardiology, Las Palmas de Gran Canaria, Spain

Introduction: Silymarin is an extract of the milk thistle (Sylibum marianum) seeds, containing a mixture of flavonolignans (silybinin, isosilybinin, silycristin, silydianin, and others), useful in the treatment of toxic liver damage and as adjunctive therapy in chronic hepatitis and cirrhosis. Recent studies have shown potential benefits of silymarin in the treatment of diabetes mellitus and metabolic liver disease. We conducted a study on the effect of silymarin on insulin sensitivity in prediabetic patients with preclinical liver disease.

Methods: For this open, uncontrolled trial, patients 40-75 years old of both sexes with prediabetes and moderately elevated transaminases or GGT (<3×ULN) were assigned for treatment twice a day for 3 months with a capsule containing SILIPHOS® 180 mg (standardized phytosomal silymarin) plus N-acetyl L-cystein 150 mg, alpha-tocopherol 116 mg (vitamin E) and myo-inositol 50 mg. The main endpoint was the change in the FIB-4 score for the risk of liver fibrosis. Secondary endpoints: change in the HOMA2-IR index (https://dtu.ox.ac.uk/homacalculator), fasting glucose, insulin, HbA1C, and the change of status from prediabetes to normoglycemia or diabetes mellitus. Tertiary endpoints: changes in AST, ALT and GGT. Additional endpoints: changes in BMI, lipid profile, blood pressure and heart rate. Security endpoints: Reported adverse effects and compliance (by questionnaire).

Results: 12 patients were recruited (67% women, age 51.6 ± 8.3 years, BMI 31.2 ± 5.6 kg/m^2). The FIB-4 score was significantly reduced from 1.58 ± 0.56 to 1.25 ± 0.48 ($P = .021$, paired t-test).The HOMA-2 index was significantly reduced from 3.51 ± 0.57 to 2.95 ± 0.46 ($P = .028$, paired t-test). Fasting insulin, but not fasting glucose or HbA1C, was also significantly reduced. 2 patients changed status to normoglycemia but none progressed to diabetes mellitus. AST, ALT and GGT were significantly reduced. BMI, lipid profile, blood pressure and heart rate did not change significantly, but there was a trend for reduced triglycerides and increased HDL-cholesterol. The mean reported compliance was 88% and no serious side effects were reported; no patient withdrew from the study.

Conclusions: The combination (extracts of Silybum marianum, plus N-acetyl L-cystein, alpha-tocopherol and myo-inositol) was well tolerated and able to ameliorate the FIB-4 index and the HOMA-2 IR index of prediabetic patients with preclinical liver damage. Their fasting insulin and the liver enzyme profile was also improved. This combination could be expected to reduce the long term risk of progression to clinical metabolic liver disease and type 2 diabetes in these patients. The limitations of this pilot trial are obvious, but a full-scale trial seems warranted.

P498 - LBA_ECE_1477 - Very low-dose cyproterone acetate (12.5 mg/day) is effective and well tolerated without increasing hypertension risk in young transgender women

Ricardo Jose de Leon-Durango[1], Inmaculada Molinero-Marcos[1], Borja Santana-Ojeda[1], Claudia Arnas-Leon[1,2], Agnieszka Kuzior[1,2], Irene Hernandez-Hernandez[1,2], Carmen Acosta-Calero[1,3], Alba Hernandez-Lazaro[1,4], Jennifer Maria Perez-Rivero[5] and Francisco Javier Martinez-Martin[1,2]

[1]Endocrinology & Nutrition, Hospital Universitario de Gran Canaria Doctor Negrin, Las Palmas de Gran Canaria, Spain; [2]Endocrinology & Nutrition, Hospitales Universitarios San Roque, Las Palmas de Gran Canaria, Spain; [3]Cardiology, Hospital Universitario de Gran Canaria Doctor Negrin, Las Palmas de Gran Canaria, Spain; [4]Servei d'Endocrinologia i Nutricio, Parc Taulí Hospital Universitari, Sabadell, Barcelona, Spain; [5]Centro de Salud de Escaleritas, Las Palmas, Spain

Background and Objective: Cyproterone acetate (CPA) is associated with significant adverse effects, including hyperprolactinemia, weight gain, depression, thromboembolic risk, hepatotoxicity, and meningioma, yet its optimal dose remains undefined. CPA has also been linked to an increased risk of hypertension, even at doses as low as 25 mg/day. We aimed to evaluate whether a very low dose of CPA (12.5 mg/day) is effective as an antiandrogen, assess its safety profile, and determine its association with hypertension.

Methods: Transgender women under 30 years of age without prior orchiectomy were offered CPA at 12.5 mg/day instead of the classical standard 50-100 mg/day, in combination with individually titrated estradiol. The CPA dose was increased to 25 mg/day (and up to 50 mg/day if needed) in cases of plasma testosterone >2 nmol/L or clinical hyperandrogenism.

Body weight, blood pressure, AST, ALT, GGT, prolactin, FSH, LH, estradiol, and testosterone were monitored. A historical control group treated with standard-dose CPA (50-100 mg/day) plus estradiol was used for comparison. Hypertension was defined according to current European Society of Hypertension guidelines. All participants provided informed consent.

Results: A total of 198 patients were enrolled, with a median follow-up of 4.9 years. 159 (80.3%) remained on CPA 12.5 mg/day, 15 (7.6%) required escalation to 25 mg/day, and 6 (3.0%) to 50 mg/day; 16 (8.1%) discontinued due to gender-affirming surgery and 2 (1.0%) were lost to follow-up. No serious adverse events or treatment discontinuations due to side effects were observed.

The historical control group included 100 patients with comparable baseline characteristics. Suppression of testosterone, LH, and FSH was effective and comparable between groups. A moderate increase in prolactin was observed (25.2 ± 12.5 to 39 ± 24.2 ng/mL, $P = .003$).

No significant changes in liver enzymes, blood pressure, or body weight were observed in the study group, whereas these

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

parameters increased significantly in the control group. The incidence of hypertension was significantly lower in the low-dose group (4 vs 18 patients, *P*-value = .000002, Odds-Ratio = 0.1032, 95% CI: 0.0357-0.2984).

Conclusions: Very low-dose CPA (12.5 mg/day) was effective and well tolerated as an antiandrogen in most young transgender women. While higher doses are associated with a dose-dependent increase in hypertension risk, this lower dose appears safer. Further studies are needed to confirm these findings.

P499 - LBA_ECE_1127 - Mopal-27 attenuates hepatic fibrosis through FGF-21–mediated endocrine signaling

Hye In An and Hyo-Jong Lee
Sungkyunkwan University, School of Pharmacy, Suwon-si, Gyeonggi-do, South Korea

Fibroblast growth factor-21 (FGF-21) is a liver-derived endocrine hormone that plays a central role in systemic metabolic stress adaptation and hepatic homeostasis. Increasing evidence indicates that FGF-21 exerts protective effects against chronic liver injury and fibrogenesis, key processes driving the progression of hepatic fibrosis. Hepatic fibrosis, characterized by excessive extracellular matrix deposition, represents a critical pathological stage leading to cirrhosis and liver failure. However, the antifibrotic potential of Mopal-27, a plant-derived alkaloid isolated from *Loganiaceae* seeds, and its relevance to endocrine-mediated metabolic regulation remain unclear.

In this study, Mopal-27 suppressed α-smooth muscle actin (α-SMA) expression in human hepatic stellate cells (LX-2), indicating inhibition of stellate cell activation. In a thioacetamide (TAA)-induced mouse model of hepatic fibrosis, Mopal-27 administration markedly attenuated fibrotic pathology, accompanied by reduced expression of fibrosis-associated markers including α-SMA, vimentin, and collagen type I. In parallel, inflammatory responses were diminished, as evidenced by decreased levels of IL-6 and TNF-α and reduced infiltration of F4/80-positive macrophages in liver tissue. Notably, Mopal-27 treatment induced a dose-dependent increase in hepatic FGF-21 expression.

Collectively, these findings suggest that Mopal-27 alleviates hepatic fibrosis by suppressing stellate cell activation and inflammatory responses, potentially through induction of FGF-21–mediated endocrine signaling pathways. These results highlight Mopal-27 as a promising therapeutic candidate targeting the metabolic–endocrine axis in fibrotic liver disease.

P500 - LBA_ECE_1111 - Evaluation of the association between metabolic and hepatic markers and diabetic retinopathy in patients with type 2 diabetes mellitus

Irem Sonmezoglu Kutuk[1], Sena Cetin[2], Benay Karabulut[3], Sabri Engin Altıntop[4], Huseyin Baran Ozdemir[3] and Altinova Alev[1]
[1]*Department of Internal Medicine, Division of Endocrinology and Metabolism, Gazi University Faculty of Medicine, Ankara, Türkiye;* [2]*Department of Internal Medicine, Gazi University Faculty of Medicine, Ankara, Türkiye;* [3]*Department of Ophthalmology, Gazi University Faculty of Medicine, Ankara, Türkiye;* [4]*Ankara, Türkiye*

Objective: In recent years, non-invasive hepatic injury markers associated with metabolic dysfunction-associated fatty liver disease (MAFLD) have been suggested to reflect systemic inflammation and metabolic burden, and therefore may have a role in predicting diabetic microvascular complications. In this study, we aimed to evaluate the relationship between hepatic injury and fibrosis markers as well as atherogenic lipid indices with the presence and severity of diabetic retinopathy in patients with type 2 diabetes mellitus.

Methods: A total of 209 patients with type 2 diabetes mellitus were included in the study. Diabetic retinopathy was classified based on ophthalmological evaluation as no retinopathy, non-proliferative diabetic retinopathy (NPDR), and proliferative diabetic retinopathy (PDR). Metabolic and hepatic markers evaluated included LDL/HDL cholesterol ratio, non-HDL cholesterol, atherogenic index of plasma (AIP), triglyceride-glucose (TyG) index, AST/ALT ratio, and FIB-4 score. Additionally, age, duration of diabetes, and HbA1c levels were recorded.

Results: Among the 209 patients, 95 (57.2%) had no diabetic retinopathy, while 39 (23.5%) had NPDR and 32 (19.3%) had PDR. Group comparisons demonstrated significant differences in LDL/HDL ratio ($P < .001$), non-HDL cholesterol ($P < .001$), AIP ($P = .003$), TyG index ($P = .010$), AST/ALT ratio ($P = .002$), and FIB-4 score ($P = .019$). Significant positive correlations were found between retinopathy presence and severity and age ($r = 0.429$, $P < .001$), diabetes duration ($r = 0.229$, $P < .001$), and HbA1c ($r = 0.219$, $P = .001$). Among metabolic indices, LDL/HDL ratio ($r = 0.346$, $P < .001$), non-HDL cholesterol ($r = 0.271$, $P < .001$), AIP ($r = 0.242$, $P < .001$), and TyG index ($r = 0.239$, $P = .001$) were found to be associated with retinopathy. AST/ALT ratio ($r = 0.238$, $P < .001$) and FIB-4 score ($r = 0.151$, $P = .029$) also showed significant associations with retinopathy.

Conclusions: FIB-4 score, AST/ALT ratio, and atherogenic lipid profile were found to be associated with diabetic retinopathy in patients with type 2 diabetes mellitus. In particular, the association of the LDL/HDL ratio with both the presence and severity of retinopathy suggests that metabolic dyslipidemia may play a role in the development and progression of diabetic retinopathy.

P501 - LBA_ECE_1260 - Androgen sensitivity and hypogonadotropic hypogonadism correlate differently and independently with cardiovascular risk in severe obesity

Biagio Cangiano[1,2,3], Alessandro Chilà[4], Ilaria Gentile[1], Gabriele Pogliaghi[5], Alice Casiraghi[4], Alessandro Amodeo[1], Nicoletta Del Duca[1], Alessandra Milesi[1], Stefania Mai[1], Ilinka Garavaglia[4], Valeria Vezzoli[1], Luca Persani[1,4], Massimo Scacchi[1] and Marco Bonomi[1,4]
[1]*Division of Endocrine and Metabolic Diseases, Istituto Auxologico Italiano IRCCS, Milan, Italy;* [2]*Department of Medical Biotechnology and Translational Medicine, University of Milan, Milan, Italy;* [3]*Department of Medical Biotechnology and Translational Medicine, University of Milan, Milan, Italy;* [4]*Seregno, Italy;* [5]*Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy*

Downloaded from academic.oup.com/ejendo/issue/195/Supplement_1 by guest on 05 September 2026

Background: Androgen activity has been variably associated with cardiovascular disease (CVD) in the literature. Obesity is known to be linked to both hypogonadism and an increased risk of CVD. However, evidence regarding the relationship between increased androgen sensitivity and CVD remains heterogeneous and inconclusive.

Objective: To evaluate, in a large cohort of patients with severe obesity: (I) the length of CAG repeats in the androgen receptor (AR) gene, as a marker of androgen sensitivity, as compared with the general population; and (II) the potential association between gonadal function and androgen sensitivity with CVD.

Methods: A total of 163 adult male patients (age >18 years) with severe obesity (BMI > 35 kg/m^2) were consecutively enrolled in a cross-sectional observational study. Clinical history was collected for each participant, and gonadal function was assessed by calculating free testosterone (cFT) and measuring gonadotropin levels.

Hypogonadism was defined as persistent cFT <225 pmol/L and classified as hypogonadotropic (HH) or hypergonadotropic based on LH levels (cut-off ≤9.4 IU/L). Androgen receptor sensitivity was evaluated by analyzing the length of CAG repeats in the AR gene, using PCR amplification followed by DNA fragment analysis. Androgen sensitivity was categorized as reduced (>24 CAG repeats), intermediate (21-24 repeats), or increased (<21 repeats).

Funded by the European Union—Next Generation EU—NRRP M6C2—Investment: 1.3.2, Sub-investment 1.3.2.3.3. CUP E43C25005270001

Results: Chi-square analysis assessing androgen sensitivity revealed a significantly higher frequency of AR gene CAG repeats <21 ($P < .0001$) in our cohort, indicating greater androgen sensitivity than the general population. Logistic regression analysis investigating the association between CVD with gonadal function and androgen sensitivity demonstrated an independent association with both a lower number of CAG repeats ($P = .037$) and the presence of HH ($P = .041$), after adjustment for age, BMI, arterial hypertension, type 2 diabetes mellitus, obstructive sleep apnea (OSA), and smoking history (pack-years).
