# Welcome

---

On behalf of the European College of Sport Science (ECSS) and the Free Universities of Brussels, we welcome you to Bruges for the 17th annual congress of the ECSS.

The two universities hosting ECSS 2012, Université Libre de Bruxelles and Vrije Universiteit Brussel, have for many years contributed to the development of sport science in Europe. This sustained commitment to sport-related research from Brussels, the site of the European Institutions, led us to choose **"Sport Science in the Heart of Europe"** as the theme of the 17th congress of the ECSS.

The Bruges congress comprises an outstanding scientific programme that emphasizes contemporary knowledge in sport science. The congress will feature 4 plenary sessions and 36 invited symposia on topical issues in the field, the vitality of which is underscored by the submission of close to 2000 abstracts from approximately 60 countries. After a thorough review and the withdrawal of some abstracts, ~85% of the submitted abstracts have been selected for the final programme. These free communications are distributed among 74 thematic oral and 115 e-poster sessions. A new feature this year is that all posters (1132 abstracts) will be presented in electronic format, which we anticipate will increase interactions among meeting participants.

Bruges was chosen as the host city for the congress due to its beauty and its historical role in the development of Europe. In these ancient times, Bruges was one of the European cities in which intellectual, artistic, and trading activities converged and then expanded into Europe and well beyond. This history captures the objective of the College to establish a strong foundation for sport science in Europe and into the world.

By combining the cultural heritage and beauty of Bruges with a high-quality scientific programme, we anticipate that the 17th annual congress of the ECSS will be an exceptional professional experience. On behalf of the ECSS and the local organisers, we wish you a productive and enjoyable stay in **Bruges**.

Prof. R. Meeusen (VUB)

Prof. J. Duchateau (ULB)

## Invited symposia

### IS-PM05 Exercise in Extreme Environments: From Space to Antarctica

#### 1. NEUROCOGNITIVE ENHANCEMENT THROUGH EXERCISE. CURRENT APPROACHES AND APPLICATIONS

Schneider, S.

*German Sport University Cologne*

The definition for health raised by the World Health Organization (WHO) includes physical and mental health. Today exercise science holds extensive knowledge about the adaptation of peripheral physiological systems to exercise (e.g. the hormonal, cardiovascular and musculoskeletal system). Although the impact of exercise on mental fitness, cognitive performance and overall well-being has been extensively described in the recent decade, comparatively little is known about the underlying neurophysiological processes. This is mainly due to missing imaging possibilities as standardized imaging procedures, as positron emission tomography (PET) or functional magnetic resonance imaging (fMRI) are hardly applicable to health-orientated exercise settings. Nevertheless a deeper insight in the underlying neurophysiological parameters of exercise and their implications for neurocognition and emotional well-being are of utter importance to a holistic understanding on how exercise promotes health. The aim of this lecture is three folded: (1) to give an overview of current theories concerning the relationship between exercise and neuro-cognitive function, (2) to display methodological approaches in the area of exercise neuroscience and (3) to verify this theoretical background with two current studies from extreme environments: Space and school.

#### MOVE TO SLEEP: HOW PHYSICAL ACTIVITY ENHANCES SLEEP EFFICIENCY DURING ANTARCTIC EXPEDITIONS

Pattyn, N.

*Royal Military Academy/Vrije Universiteit Brussel*

Introduction Sleep complaints are consistently cited as the most prominent problem in Arctic and Antarctic expeditions. Continuous bright light exposure in the summer, and continuous darkness in the winter suggest a fundamental disturbance of circadian sleep-wake regulation in this environment. The present investigation was conducted during two Antarctic summer expeditions, the BELARE (Belgian Antarctic Research Expedition) campaigns 2007-2008 and 2008-2009. We hypothesized that participants with a more intense physical activity would increase their homeostatic sleep pressure, and therefore suffer less from the possible circadian disruption due to the constant daylight conditions. Method 8 subjects were investigated in the first expedition. Actigraphy data were collected for 72 hrs every ten days. Sleep efficiency (sleep time/lying down time) as well as a sleep fragmentation were computed, and related to the magnitude of active energy expenditure. 21 subjects participated during the second campaign. Data were collected every 2 weeks for each subject. These included 48 hrs actigraphy, one night polysomnography, morning and evening Profile of Mood States and Karolinska Sleepiness Scale, morning Psychomotor Vigilance Test. Circadian rhythms profiles were determined with a 24 hrs cortisol and melatonin sampling. Results First year data showed poor sleep efficiency and high sleep fragmentation, in concordance with participants' subjective evaluations. Furthermore, there was a strong correlation between sleep efficiency and active energy expenditure (Pearson's  $r = 0,63$ ;  $p = 0,015$ ), as well as a strong relationship between active energy expenditure and sleep fractionation. Second year data results didn't confirm this relationship (Pearson's  $r = 0,21$ ;  $p = ns$ ). Discussion Results from the first campaign confirmed our hypotheses, namely the lower sleep quality (lower efficiency and higher fragmentation) during the expedition and the relationship between sleep quality and active energy expenditure. Data from the second campaign, despite what was expected to be a stronger methodological set-up, due to the larger sample size, failed to evidence the relationship between sleep efficiency and the intensity of physical activity. Considering the difference in set-up, and the frequent repeated measures on a small number of participants during the first campaign, this shows that the relationship between sleep efficiency and energy expenditure is valid at an intra-individual level, but fails to show at an interindividual level, especially in a population where a wide range of physical activity intensity is present. These findings are discussed in the framework of the existing literature on sleep and exercise, and the argument is being made for the use of exercise as a potential countermeasure in isolated and confined environments.

#### BRAIN FUNCTION, COGNITIVE PERFORMANCE AND PHYSICAL ACTIVITY: RECENT INSIGHTS INTO MECHANISMS AND COUNTERMEASURES FROM RESEARCH IN EXTREME ENVIRONMENTS.

Stahn, A.

*Center for Space Medicine Berlin, Charité University Medicine Berlin*

'Because running makes you free.' (Edison Pena, December 2010) In October 2010 the world held its breath like rarely before when Chilean miners were successfully rescued after being trapped 700 m underground for 69 days, setting a new world record for the longest time survived underground after a mining accident. When the freed miner Edison Pena was asked how he dealt with the stress of being trapped and the constant fear of death he said that he started exercising in the mine. During the last decade there has been an increasing interest in understanding the relationships between exercise, cognition and its neural correlates. In line with the Chilean example data from various extreme environmental conditions indicate that physical activity might play a dominant role in minimizing cognitive impairments. While meta-analytic findings indicate that exercise seems to be beneficial for brain function and cognition, its underlying mechanisms and potential moderators and mediators remain to be determined though. Some of these aspects could be pinpointed by studies under extreme environmental conditions, where human adaptations are accelerated to an extent that can typically only be seen in long-term observation studies or employing very unique experimental conditions. Accordingly, monitoring human performance in

extreme environments can pave innovative and unique ways in promoting research typically confined to conventional laboratory settings. Recent studies indicate that executive control and decision-making can be affected by long-term bedrest and overwintering in Antarctica, the former providing an excellent control for the impact of physical activity on cognition. Data from real and simulated spaceflight imply that the changes in cognitive function might be related to changes in the autonomic nervous system, and specifically heart rate variability, which might serve as a global indicator of prefrontal cortex excitability. Moreover, it is suggested that stimulation of mechanoreceptors in the feet might be important to reveal the true potential of physical activity on brain function and cognitive performance. Finally, in addition to a lack of physical activity both perceived loneliness as well as sensual deprivation have been shown to be independently related to cognitive function. It is therefore suggested that studying humans exposed to isolation, confinement and environmental conditions can lead to a better insight into some of the potential mechanisms underlying the interaction between physical activity and cognition and promote an integrative model. Such knowledge will help the full range of activity-related cognitive plasticity to be mapped and might be useful in designing future intervention studies for investigating the interaction between physical activity and cognition.

**15:00 - 16:30**

## Oral presentations

### OP-SH01 Sport Management

#### EUROPEAN GOVERNANCE, ANTI-DOPING AND THE RIGHT TO PRIVACY

MacGregor, O.

*Swansea University*

The European Convention on Human Rights is an international human rights document, ratification of which is a prerequisite for nation state membership in the Council of Europe. The Convention includes provisions for, among other things, the creation of an international court - the European Court of Human Rights in Strasbourg - to monitor compliance with the Convention in Council of Europe member states. The Court hears cases brought by individuals claiming a breach of their rights, as enunciated in the Convention, by a member state. (ECHR, sec II) Among the rights of the Convention, article 8.1 establishes a right of individuals to a 'private and family life'. This is understood as a qualified right, which can be defeated by any of a number of legitimately overriding social goods, including, as per article 8.2 of the same convention, the 'protection of public health or morals'. (ECHR, art 8) In elite sports, the whereabouts requirements of the World Anti-Doping Agency (WADA) stipulate that all elite athletes, regardless of their sport, must submit their whereabouts for every day of the year to their relevant anti-doping organization (WADA 2009a, ch 14.3; WADA 2009b, ch 11). Critics have argued, among other things, that the requirements infringe athlete rights to privacy (Møller 2011). WADA, however, views the requirements as a crucial element in the fight against doping in sport, and considers them justified in light of its goal - doping-free sport - and regardless of any further and potentially deleterious effects (Hanstad and Loland, 2009). In this paper, I argue that the contextual differences between various sports indicate that there are stronger justifying reasons to monitor out-of-competition doping rule compliance in certain sports (with higher risk of out-of-competition doping) than in others, and that in some it fails to be sufficiently strong to override athlete privacy rights. In the latter cases, therefore, the whereabouts requirements constitute a breach of an athlete right to privacy, as per the European Convention on Human Rights. This state of affairs recommends a redrafting of WADA's whereabouts requirements, to better reflect the broad heterogeneity of sports. #### A RESOURCE BASED EVALUATION OF COMPETITIVENESS IN ELITE ATHLETICS

TRUYENS, J.1, DE BOSSCHER, V.1, HEYNDELS, B.2

*Vrije Universiteit Brussel*

INTRODUCTION The increase in medal-winning capability of countries in international competition is explained by an increasing number of nations taking a more strategic approach to the development of medal-winning elites (De Bosscher, 2007; Green & Oakley, 2001; Houlihan & Green, 2008). Despite the extensive scientific focus on elite development systems, there is a lack of studies on elite sport development at sport specific level (Sotiriadou & Shillbury, 2009) that describe and measure specific practices at organisational level. Within economic research, the resource-based theory conceptualises competitiveness starting from the relationship between internal resources and dynamic capabilities of an industry and its performances (Barney, 2001). These internal resources and more especially, the policy dimensions in elite athletics are the focal point of attention. METHODS Based on a resource-based perspective, this paper measures and evaluates policy resources and capabilities leading to a competitive advantage in elite athletics of four different countries (BEL (Flanders and Wallonia), CAN, FIN and NED), based on an athletics policy inventory. This instrument is based on a model referring to 11 different policy areas/pillars in elite athletics development. The model is developed through an inductive-deductive analysis (Patton, 2002) of international literature, surveys (N=13) and in-depth interviews (N=21) with national high performance directors in athletics. Later on, 57 international coaches and high performance directors participated in a written survey to validate the model. RESULTS AND DISCUSSION A major contribution of this sport specific inventory of policy factors is its organisational scope: specific practices for national governing bodies in the elite development process are measured and evaluated in a functionalistic model for elite development. Although the NGBs lived through the same tendencies like the professionalization and formalisation of development programs, specific dimensions in the policy process strongly differ. While the development process of potential athletes (pillar 4A&B) is stronger developed in Flanders, coach education, career support and training facilities are more profound for elite development in the Finland, Canada and the Netherlands. ## PERCEIVED DIFFICULTY TO COMBINE THE SPORT AND ACADEMIC CAREER IN ELITE ATHLETES

López de Subijana, C.I, Conde, E.I, Barriopedro, M.I.I, Gallardo, L.2

1 Sport Sciences Faculty- Technical University of Madrid- Madrid-Spain; 2-Sport Sciences Faculty- Castilla-LaMancha University- Toledo-Spain

**Introduction** As the athletes improve in sport they expend the less time for other fields of life (Heinemann, 1998). The sport career development model showed how many areas of life are influenced when the athlete is playing the role of competing in high performance sport (Wylleman, Alferman & Lavalley, 2004). Spain, in a UE Policies comparison, follows the State Centric Regulation in the education services for elite athletes (Aquilina & Henry, 2010). The aim of this study was to measure the perceived difficulty to combine the sport and academic career in elite athletes. **Methods** A survey questionnaire was sent to the entire population of 2697 elite athletes in Spain. A Pearson's chi-square test was done to analyze the relation between variables. The significant level was set at  $p=0.05$ . The response rate was 27,8% in Olympic men, 37,3% in Olympic women, 9,3% in non-Olympic men and 11,9% in non-Olympic women. **Results and Discussion** 840 athletes (23.1  $\pm$  7.4 years-old), 513 men y 327 women answered the questionnaire. Most of the athletes were studying Higher Education (26,9 %), followed by Secondary School (19,3 %) and 18 % did not study any course. Most of the courses taken (74,6%) the athlete had to attend to class. Only some of them (46,5%) ask for help in combining the academic and the sport career. The athletes felt combining these two fields was difficult (41,7%) or moderate (44,8%). Out of all the athletes, 21,1% of them worked, being 48,3% full time and 41,1% part time. The perceived difficulty of studying and training was related with the number of days per week training ( $X^2(18) = 39,8, P=0.001$ ) and also with the type of studies (on-line, mandatory to attend...) ( $X^2(28) = 55,1, P=0.002$ ). The most frequent reasons for not studying were: "I don't have time, the academic timetables are not flexible, the price of the studies is high, I lose the rhythm of the courses, and my actual job situation does not allow me to do so". **Conclusions** In conclusion, more efforts should be done by National Government, Regional Governments, Sports Federations and Educational Institutions to guide the elite athletes the in their academic, social and economic affairs. **Acknowledge** This study was funded by the Spanish Sport Council (022/UPB10/11). **References** Aquilina, D., & Henry, I. ## ELITE SPORT CLIMATE, MEASUREMENT TWO

De Croock, S., De Bosscher, V.

*Vrije Universiteit Brussel*

**Introduction** Talent, ambition and commitment are the core to success but further investment in elite sports is a must in order to compete in the 'Global Sporting Arms Race'. Without a structured policy at different levels there is a risk to vanish between the Elite sport countries. Therefore, it's important to evaluate and compare the Elite sport policies. In 2003 the 0-measurement started with the aim to investigate how the elite sport policy in Flanders could be improved in an efficient and effective way. This year the two measurement started. **Methods** Just as in 2003 and 2007 elite athletes, coaches and federations were surveyed to assess the elite sport climate. Hereby, the climate is charted objectively in nine performance determining factors (De Bosscher et al., 2008). By interviewing various stakeholders, it is possible to obtain more insight in the developments and expectations of the stakeholders. **Results** 43% of coaches consider the elite sport climate in Flanders to be insufficient. Yet the policy efforts of recent years had its effect because only 7,9% of coaches considers that the elite sport climate has deteriorated compared to 2007. The stakeholders, that were surveyed, have the opinion that the financial input, the coach facilities/developments and the elite sport infrastructure are factors which have the biggest influence on international elite sports success. Also, these are the three factors that, according to the stakeholders, have most need for improvement in Flanders. The Flemish government resources increased continuously and even virtually tripled in the last five years. However, financial resources are no longer a guarantee for success. The elite sport policy has to invest in the various performance determinants. In terms of infrastructure, Flanders has a need for more top sports infrastructure with absolute priority rule for elite athletes. Half of the trainers consider that there are insufficient recognised trainers courses available for elite sport trainers. Also noteworthy is that only some federations have a system to transfer knowledge between coaches. The establishment of a centre of expertise can address this problem. The individual living circumstances of the coaches there is slightly improved compared to 2003 and 2007. **Conclusion** Despite the necessary adjustments of the elite policy, a lacuna still exist in the elite sport climate in Flanders. Certain deficiencies which were already identified in 2003 and 2007 are still a weakness. The efforts of the Flemish elite policy were mainly done to "catch-up" with things, but there's still need for extra efforts. **References** De Bosscher, V., De Knop P. & Van Bottenburg, M. (2008). Vlaanderen sport ook aan de top.

## THAT'S THE SPIRIT: THE DIFFERENCE BETWEEN ELITE AND NON-ELITE SPORT

Huybers, T., Mazanov, J., Connor, J.

*University of New South Wales - Canberra*

**Introduction** The moral basis for protecting the integrity of sport is defined by the 11 attributes in the World Anti-Doping Code's Spirit of Sport statement (Mazanov & Connor, 2010). There is no guidance on how the attributes are to be interpreted or whether the list reflects an intentional order. It is also unclear whether the attributes contained in the Spirit of Sport statement reflect the values of elite sport or non-elite sport. The aim of the study reported in this paper was to determine whether what is considered important to the Spirit of Sport varies by elite and non-elite contexts. **Methods** We used a Best-Worst Scaling (BWS) experiment (Marley and Louviere, 2005) to obtain ratio scores that provide estimates of the relative importance of the 11 attributes listed in the Spirit of Sport statement. Half of the responses of a sample of 154 Australians had been framed in the 'elite' context while the other half had received the 'non-elite' condition. **Results** The BWS scores for the aggregate data showed that "Ethics, fair play and honesty" and "Respect for self and other participants" were the most important attributes across contexts. The disaggregated data, divided into non-elite and elite contexts, revealed a low correlation between non-elite and elite scores ( $R^2=0.372$ ). In the non-elite context, the main differences in comparison with the aggregate model were the higher scores and relative ranking of "Fun and joy" and "Respect for self and other participants", while the main departure in the elite framing was the higher prioritisation of "Dedication and commitment" and "Excellence in performance" and the decline in relative importance of "Fun and joy". **Discussion** While "Ethics, fair play and honesty" was perceived to be a key characteristic of elite and non-elite sports, members of the Australian general population perceived other attributes differently in the two contexts. The non-elite sport importance of the role of "Fun and joy" may be due to non-elite sport participation being seen as an end in itself; i.e. being more a "game"

than "sport" (Suits, 1988). In the elite sport context, the process underlying elite sports production, characterised by attributes such as "Dedication and commitment" and "Respect for rules and laws", was deemed to be particularly important. The implication is that social research designed to inform sport policy or practice at one level of sport does not necessarily translate to other levels. This has implications for "pyramid" approaches to sports policy, where policy is focused at the top of the pyramid (elite sport) in the expectation of beneficial trickle effects (non-elite sport) (Hogan & Norton, 2000). ##### EFFECT OF KAYAK ERGOMETER LOADING ON UPPER LIMB RECRUITMENT AND KINEMATICS.

Fleming, N., Donne, B., Fletcher, D.

*Trinity College Dublin*

**Introduction** Altered upper limb muscle recruitment patterns were recently reported comparing on-ergometer and on-water kayaking (Fleming et al., 2010, 2012); however, precise mechanisms underlying EMG changes remain to be elucidated. This study assessed the effect of altered ergometer recoil force on upper limb recruitment patterns and kinematics during the kayak stroke via EMG and 3D kinematic analysis. **Methods** Male flat-water kayakers (n=10, mean  $\pm$  SD; age  $21\pm 3$ yr, height  $1.80\pm 0.06$ m, body mass  $74.6\pm 5.8$ kg) performed 4 by 1 min on-ergometer exercise bouts at a load equivalent to 85%VO<sub>2</sub>max at varying elastic recoil tensions ranging from 0% shortened (T1) up to 30% shortened (T4). Trials were randomised to eliminate possible effect of tension order on kinematics or EMG activity. During exercise, surface EMG data (Mega ME6000) were recorded from Anterior Deltoid (AD), Triceps Brachii (TB) and Latissimus Dorsi (LD). In addition, stroke force (instrumented paddle) and 3D kinematic (CODA) data were recorded. EMG data from 10 consecutive stroke cycles in the latter stages of each trial were amplitude processed via root mean squaring and normalised relative to pre-trial isometric MVC. Stroke force and 3D kinematic data recorded from wrist, elbow, shoulder and scapular markers were assessed over the same time frame. Data were analysed using repeated measures ANOVA and detected differences quantified using post-hoc Tukey tests (P<0.05). **Results** While stationary recoil forces significantly increased across investigated tensions ( $20\pm 4$  to  $45\pm 8$  N, P<0.001), no significant differences were detected in assessed stroke force variables. Increasing tension induced significantly higher normalised AD rmsEMG activity in the 70 to 90% stages of the stroke cycle (T4 vs. T1;  $18.1\pm 12.0$  vs.  $10.6\pm 5.3$  %, P<0.05;  $37.6\pm 16.2$  vs.  $22.7\pm 11.0$  %, P<0.001 and  $26.3\pm 10.1$  vs.  $15.6\pm 8.9$  %, P<0.001 at 70, 80 and 90 %, respectively). No significant differences were observed across tension in TB or LD. A detailed 3D kinematic analysis revealed that overhead arm movements accounted for  $58\pm 10\%$  of the cycle. At stroke cycle onset mean elbow angle was  $144\pm 10^\circ$  and maximal angle ( $151\pm 7^\circ$ ) occurred at  $78\pm 10$  % of stroke cycle. Overall upper arm kinematic markers moved horizontally forward as recoil tension increased. No significant change in wrist marker elevation was observed. Elbow and shoulder marker elevations significantly increased during the 70 and 80% intervals of the cycle (P<0.05). **Discussion** Data suggested that kayakers maintained normal hand position during the cycle via additional AD recruitment despite ergometer induced recoil forces being applied to the upper arm. **References** Fleming N, Donne B, Fletcher D (2010) 15th ECSS Congress, pp. 31 Fleming N, Donne B, Fletcher D, Mahony N (2012) *J Sports Sci Med* 11, in press

##### ARM COORDINATION IN SEMI-TETHERED SWIMMING

Dominguez, R., Morales, E., Arellano, R.

*University of Granada*

**ARM COORDINATION IN SEMI-TETHERED SWIMMING** Dominguez-Castells, R.1, Morales, E.1, Arellano, R.1 UGR (Granada, Spain) **Introduction** In swimming, stroke is composed of different phases: entry-catch, pull, push and recovery. Arm coordination is important and related with freestyle performance. Index of Coordination (IdC) allows precise quantification of lag time between start of propulsion by one arm and end of propulsion by the other. Recent studies have emphasized the close relationship between arm coordination and velocity, but only one has included resistance (Telles et al., 2011). Therefore, the aim of this study was to analyze the relationship between IdC and technical parameters, using semi-resisted swimming with different loads. **Methods** The test consisted on eleven 12.5m trials on semi-tethered swimming. Eighteen swimmers pulled a different load each trial, from 1.59 to 7.84kg. Swimmer's feet were tied together, keeping a pull-buoy between legs and isolating the upper limb action. No breathing was allowed. The test was recorded from a frontal and two lateral underwater cameras (50 Hz). IdC was assessed for each trial. Pearson's correlation coefficients were calculated between IdC and mean speed (v), stroke rate (SR), stroke length (SL) and stroke index (SI) (level of significance: p<0.05). **Results** Coordination mode used in free and semi-tethered swimming was superposition (IdC>0%). IdC was 6.6% when swimming free and it increased significantly with loads (p<0.05). It was, on average, 7.1% with 1.59kg and 14.8% with 7.84kg. Significant correlations (p<0.01) were found between IdC and load (r=0.91), v (r=-0.94), SL (r=-0.93) and SI (r=-0.95), but not between IdC and SR. **Discussion** Concerning arm coordination in swimming, IdC was higher when swimming with parachute (0.1%) than when swimming free (-2.3%) (Telles et al., 2011). Catch-up model was used for long and middle distance (3000 to 200m), while for sprints (100 and 50m) opposition or superposition were used (Chollet et al., 2000; Seifert et al., 2004). In the latter case, the relative duration of non-propulsive phases decreased, while the duration of propulsive phases increased. The same happened in semi-tethered swimming, where swimmers used superposition. IdC increased, v, SL and SI decreased and SR remained constant as loads increased. Some of these results are not in keeping with previous studies which, however, did not include loads (Alberly et al., 2005; Chollet et al., 2000). These differences may be due to the application of loads, which led to fatigue and, therefore, higher IdC (Alberly et al., 2005). Considering that resisted swimming is a widely applied training method, results suggest that load should be carefully controlled, as it modifies swimming coordination. **References** Alberly M, Sidney M, Huot-Marchand F, Hespel J, Pelayo P (2005). *Int J Sports Med*, 26, 471-475. ### 3D AUTOMATIC MOTION TRACKING IN WATER FOR MEASURING INTRA CYCLIC VELOCITY VARIATIONS IN BREAST-STROKE SWIMMING

Olstad, B.H.1, Zinner, C.2, Haakonsen, D.1, Cabri, J.1, Kjendlie, P.L.1,3

1: NSSS (Oslo, Norway), 2: GSU (Cologne, Germany), 3: VUC (Toensberg, Norway)

**Introduction** Until recently, 3D tracking of human swimming motion capture (mo-cap) from an image has been conducted using interactive tracking (IT). New technology within automatic tracking (AT) in water uses computer algorithms to identify and track small reflective markers attached to the swimmer. The purpose of this study was to show that 3D AT can be used for measuring kinematic variables in human swimming such as the intra-cyclic velocity variations (dv) within a stroke cycle in breaststroke. **Methods** Four swimmers (one male, world championship medalist and three females, one olympic medalist, one national medalist and one national finalist) performed one trial of 20m normal breaststroke at the speeds of 60, 70, 80, 90 and 100% of maximal effort. During each trial, the dv of the swimmers body were recorded at the left and right pelvic and left and right trochanter major (glued to the swimmers suit) with ten underwater mo-cap cameras (Oqus Underwater, Qualisys, Gothenburg, Sweden). The cameras recorded spherical markers (diameter of 19 mm) attached to the swimmers using cyan LED light. A 2.5(z)x1.5(y)x10(x) volume was calibrated using a moving wand method. For statistical analysis trochanter major was selected due to a tracking recording of 100%. The second and third stroke cycle was selected to avoid excess speed from the push-off. The stroke cycle started when the heels were fully pulled up, flexed and ready to kick backward. dv was calculated as the difference between the highest and lowest velocity peaks within the stroke cycle, relative to the average velocity. **Results** The highest and lowest velocity was on average recorded at 72.05% and 93.83% into the stroke cycle for the world class swimmers (WC) and at 63.03% and 96.36% for the national elite swimmers (NE). A t-test showed a significant difference among the groups for the highest dv  $p < 0.001$  and no differences for the lowest dv ( $p = 0.07$ ). R values of .959 for the WC and .859 for the NE showed strong correlations between average cycle velocity and the dv fluctuations. **Discussion** We found that the highest velocity during the breaststroke cycle corresponded to approximately the middle of the insweep phase. Subjects had no movement constraints, but had significant added drag from wearing 36 reflective markers (Kjendlie et al., 2012) and also wearing sEMG equipment described by (Olstad et al., 2011). The study successfully showed that 3D analysis can be performed in water using AT. Data analysis with AT is time effective, and open up new possibilities for conducting wide-scale studies investigating different kinematic variables in swimming. **References** Kjendlie, P. ### QUANTIFYING BILATERAL ASYMMETRY IN COMPETITIVE FRONT CRAWL SWIMMING

Barden, J.

University of Regina

**Introduction** Studies show that the different phases of the arm stroke cycle in front crawl swimming are bilaterally asymmetric [1,3], and that asymmetry is affected by speed, arm dominance and bilateral differences in body roll [4]. However, little is known about the effect of asymmetry on performance, and given its importance to propulsion mechanics, a simple method to quantify arm asymmetry in competitive front crawl swimming is needed. Therefore, the purpose of this study was to quantify bilateral asymmetry in a group of elite front crawl swimmers at two different speeds using two different stroke-related spatiotemporal parameters. **Methods** Eight swimmers (6 female, 2 male;  $17.9 \pm 0.86$  yrs) performed front crawl for 2 x 200 m repetitions in a 25 m pool at two different speeds: 1) 91% and 2) 110% of critical speed. Stroke frequency (SF) and stroke length (SL) were recorded independently for both arms for each length of each 200 m repetition. An asymmetry index (ASI), previously used to assess gait asymmetry [2], quantified individual asymmetries for SF and SL according to the following equation:  $ASI (\%) = [X_r - X_l] / 0.5(X_r + X_l)] \times 100$  where  $X_r$  and  $X_l$  are the values of the specific stroke variable (SF or SL) measured for the right and left arm, respectively. Group asymmetries were calculated using the absolute value of  $X_r - X_l$ . For the purpose of this study, a stroke (right or left) was defined as consisting of one half of a complete stroke cycle (synonymous with a step in walking). A paired Student's t-test compared mean absolute ASI values for SF and SL between the two 200's. **Results** A range of asymmetries were found (SF: -7.3 to 9.8%; SL: -10.0 to 10.8%), with some participants being more asymmetric than others. The group was divided equally in terms of right (4) vs. left (4) asymmetry. No significant differences in absolute ASI were found for either SF or SL between the two speeds. **Discussion** The findings show that arm asymmetries in front crawl swimming can be easily quantified by adopting existing gait asymmetry indices to the cyclic motion of swimming. Of particular interest was the finding that no ASI differences existed between the two speeds, and that positive SL asymmetries (right arm > left arm) were associated with negative SF asymmetries (right arm < left arm), and vice versa. This indicates that longer stroke times on one side are associated with longer stroke lengths on the same side (and vice versa), demonstrating the important bilateral relationship between stroke phase duration and distance per stroke. It is hoped that future studies will employ the method used here to investigate the effects of breathing, body roll and lateral dominance on bilateral asymmetry in competitive front crawl swimming. **References** 1. ### OP-PM01 Muscle signaling and adaptation

#### LOW PHYSICAL ACTIVITY INFLUENCES THE EXPRESSION OF MIRNAS IN HUMAN MUSCLE TISSUE

Kristensen, M.M.1, Bork-Jensen, J.2, Vaag, A.2, Dela, F.1

1: Center for Healthy Aging, University of Copenhagen, Denmark; 2: Rigshospitalet, University of Copenhagen, Denmark

**Introduction** MicroRNAs (miRNAs) are important cellular regulators of gene expression in both health and disease. Studies have found changes in miRNA levels in muscle (1) and blood (2) in response to training. Elucidating the roles of miRNAs in physically inactive humans is important to understand how sedentarism influences gene expression and potentially insulin resistance. We examined the influence of nine days of bed rest on miRNA expression profiles in human skeletal muscle tissue. **Methods** 20 healthy young males were studied before and after bed rest for nine days and after four weeks of retraining. Muscle biopsies (vastus lateralis) were used for RNA extraction and miRNA expression profiling was performed using LNA arrays (Exiqon, Denmark). Linear models for microarray analysis (limma) was used to identify differentially expressed miRNAs using Benjamini and Hochberg's false discovery rate (fdr) adjustment for multiple testing. In silico target predictions (Targetscan) were carried out to understand the biological implications further. **Results** Comparing microarray miRNA expression profiles before and after bed rest, we identified seven differentially expressed miRNAs (P(fdr) less than or equal 0.1) of which three were down-regulated (miR-486-3p, miR-24-2\*, and miR-126) and four were up-regulated (ebv-miR-BART2-5p, miR-1246, miR-21, and miR-1908) after bed rest. Interestingly, none of the miRNAs returned to pre-bed rest levels after the retraining period. Targetscan revealed multiple possible targets for each of the seven differentially expressed miRNAs. Among these were IRS-1 (insulin receptor substrate 1) being a target of miR-126 as well as PIK3R1 (phosphoinositide-3-kinase, regulatory subunit 1) being a target of miR-21. **Discussion** We identified seven miRNAs with altered expression levels in response to short term bed rest, and none of them returned to the pre-bed rest values even after four weeks of retraining. Predicted targets of the miRNAs relevant to understanding insulin resistance included IRS-1 and PIK3R1. Ongoing analyses should reinforce these findings and elucidate the relation between these miRNAs and their respective targets. **In conclusion**, nine days of inactivity induced changes in the expression of miRNAs with relevance to insulin resistance, which in turn were not reversed by four weeks of retraining. **References** 1. #### ACUTE HYPOXIA REDUCES MUSCLE PROTEIN TURNOVER IN HUMAN SKELETAL MUSCLE.

D'Hulst, G., Jamart, C., Van Thienen, R., Hespel, P., Francaux, M., Deldicque, L.

KU Leuven, Université catholique de Louvain

**Introduction:** Hypoxia is a state of reduced O<sub>2</sub> tension in tissue, including skeletal muscle. It elicits various responses in the cell leading to preserving O<sub>2</sub>. One of these responses is decreasing protein turnover, as stated by in vitro studies (Pettersen et al., 1986). On the other hand, in vivo studies are not that conclusive due to higher variability (Mizuno et al. 2008). Therefore, this study aims to get more detail on pathways involved in anabolic and catabolic signaling in human skeletal muscle as a response to acute hypoxia. **Methods:** According to a randomized cross-over study, 15 healthy men participated in 2 experimental sessions separated by a 4-week wash-out period. After a standardized breakfast, subjects were randomly assigned to a 4-h lasting seated experimental trial in normoxia (NOR) or hypoxia (11% O<sub>2</sub>, HYP). Three biopsies were taken at the start (T0), after 1-h (T60) and at the end of the trials (T240). Furthermore, arterial blood saturation (SpO<sub>2</sub>) and muscle tissue oxygenation (TOI) were measured by pulseoximetry and Near-infrared spectroscopy (NIRS). Western blot and qPCR were used to determine phosphorylation status or mRNA quantity of several components involved in the regulation of protein synthesis (i.e. protein kinase B and p70 ribosomal S6 kinase, Redd1), breakdown (i.e. 26s Proteasome β5) and hypoxic signaling (i.e. Hypoxia Inducible Factor-1α, VEGF-A). **Results:** Despite a large decrease in SpO<sub>2</sub> (HYP, 75.5 ± 2.02% vs NOR, 99.0 ± 0.18%, p<0.05), TOI was only slightly reduced (HYP, 65.8 ± 1.39% vs NOR, 68.5 ± 1.19%, p<0.05). Hypoxia delayed the return to basal state after feeding for both PKB and P70S6K phosphorylation (p<0.05), furthermore significant differences were found between NOR and HYP at T240 (p-PKB: NOR, 0.44±0.06 vs. HYP, 0.75±0.06 and p-P70S6K: NOR, 0.32±0.09 vs. HYP, 0.48±0.10, p<0.05). Redd1, increased ~2-fold at T240 in HYP compared to NOR at the same time (p<0.05). Activity of 26s proteasome β5 increased by 19 % in NOR at T240 compared to T0 (p<0.05). Conversely, no effect in time was present in HYP (p>0.05). HIF-1α mRNA was not changed throughout the experiment, whereas VEGF-A significantly increased in HYP compared to NOR at T240 (-1.5 fold, p<0.05). **Conclusion:** Our results provide evidence that acute hypoxia slows down the return to basal state of several components of protein synthesis and protein breakdown after feeding. This impairment in the regulation of protein turnover could participate to the decrease in muscle mass observed after long-term exposure to hypoxia.

#### A ROLE FOR FOCAL ADHESION KINASE IN CONTRACTION AND IGF-1 INDUCED SKELETAL MUSCLE CELL GROWTH

Crossland, H., Kazi, A., Smith, K., Szewczyk, N.J., Atherton, P.J.

University of Nottingham

Increasing evidence links the costamere-associated protein focal adhesion kinase (FAK) to the hypertrophic response to mechanical stress and growth factor stimulation in skeletal muscle, and its expression is reciprocal to loading patterns (i.e. downregulated in atrophy/upregulated in hypertrophy (1)). On this basis, we reasoned that reducing FAK expression by short hairpin (sh)RNA interference would restrict cell growth associated with insulin-like growth factor-1 (IGF-1) and contraction (mechanotransduction). Lentiviral transfection techniques were used to produce stably transfected C2C12 cells harbouring FAK targeted (pLKO.1-mFAK) or scrambled shRNA. Myotubes were contracted for 24 h (0.2 Hz, 5 V, 2 ms) using a C-pace system, before assay of total protein. In separate experiments, myotubes were incubated for 72 h with IGF-1 (10 ng.ml<sup>-1</sup>) for measurement of total protein. Immunoblotting was used to determine phosphorylation of 'hypertrophy' signalling targets (i.e. Akt-mammalian target of rapamycin (mTOR)) following 2 h contraction or IGF-1 incubation. Results were analysed by one-way ANOVA and Tukey's post-hoc testing with the level of significance set at P<0.05. Data are presented as mean percentage differences ± standard error. FAK depletion was confirmed at the protein level (-90%: FAK vs. scrambled shRNA; P<0.00001). Increases in total protein in scrambled shRNA cells following 24 h contraction (+57±9%; P<0.01) were absent in FAK shRNA cells (+7±11%

$P=0.65$ ). After 2 h contraction, levels of FAK phosphorylation were increased in scramble shRNA cells (Tyr397:  $+44\pm 6.6\%$ ;  $P<0.01$ ), and contraction-induced increases in phosphorylated Akt (Ser473;  $+87\pm 11\%$ ;  $P<0.01$ ) and p70 S6 kinase (Thr389;  $+170\pm 16\%$ ;  $P<0.001$ ) in scramble cells were significantly attenuated in FAK shRNA cells (both  $P<0.05$ ). IGF-1 treatment for 72 h elicited marked increases in total protein in scramble shRNA cells ( $+77\pm 10\%$ ;  $P<0.001$ ), and this was significantly blunted in FAK shRNA cells ( $+34\pm 14\%$ ;  $P=0.14$ ). Increases in p-Akt ( $+390\pm 49\%$ ;  $P<0.001$ ) and p-mTOR (Ser2448;  $+190\pm 31\%$ ;  $P<0.001$ ) following 2 h IGF-1 treatment in scramble shRNA cells were significantly attenuated in FAK shRNA cells (all  $P<0.05$  vs. IGF-1-treated scramble shRNA cells). The present findings indicate that FAK is required for growth factor (IGF-1) and contraction-induced muscle cell growth, and may act through an Akt/mTOR-dependent pathway. 1. ### IDENTIFICATION AND CHARACTERISATION OF A NOVEL, MULTI-POTENT SKELETAL MUSCLE-DERIVED STEM CELL WITH BROAD DEVELOPMENTAL PLASTICITY

Henning, B.J.1, Lewis, F.C.1, Sassoon, D.2, Marazzi, G.2, Nadal-Ginard, B.1, Ellison, G.M.1

1:Liverpool JMU, UK, 2:INSERM, Paris, France

**Introduction:** PW1+/Pax7- skeletal muscle-derived interstitial progenitor cells (PICs) are myogenic in vitro and efficiently contribute to skeletal muscle regeneration in vivo (Mitchell et al. 2010). Some stem cells are multipotent and exhibit broad developmental plasticity giving rise to cells and tissues from the 3 germ layers; endoderm, ectoderm and mesoderm. Here we have isolated and characterised a multi-potent PIC population from both mouse and porcine skeletal muscle, which could be used for a variety of regenerative medicine therapies. **Methods:** Satellite cells (PW1+/Pax7+) and PICs (PW1+/Pax7-) were identified and characterised on mouse and porcine skeletal muscle cross sections. Hindlimb skeletal muscle of mouse and porcine was minced and digested in a solution containing collagenase A (100mg/ml), Dispase II (3mg/ml) and DNase I (10mg/ml) for 2 hours at 37°C. The PICs were then purified from the population of small cells using MACS technology (Miltenyi) according to expression of the cell surface markers, Sca-1 and CD34. PICs were characterised for stem cell surface marker expression, clonogenicity, multipotency genes, and myogenic differentiation potential using flow cytometry, cell culture, immunocytochemistry and qRT-PCR. The developmental plasticity of the multi-potent PICs was determined through differentiation into endothelial, epithelial, skeletal muscle, cardiac, adipogenic, hepatic and neurogenic lineages. **Results:** We identified interstitial PW1+/Pax7- PICs as well as PW1+/Pax7+ satellite cells, located underneath the basal lamina of the muscle fibre, in mouse ( $53\pm 5\%$  of PW1+ cells were PICs) and porcine ( $45\pm 4\%$ ) skeletal muscle cross sections. Isolated Sca-1+/CD34+/PW1+/Pax7- PICs showed stem cell properties of clonogenicity (mouse  $48\pm 5\%$ , porcine  $50\pm 10\%$ ), expressed multipotency markers and myogenic differentiation potential in vitro. We purified a subset of PICs that expressed multi-potency markers Oct-4 (99%), Nanog (93%), and Sox-2 (92%). These multi-potent PICs showed a broad developmental plasticity, giving rise to all 3 germ layers. **Conclusion:** We have identified a novel, multi-potent skeletal muscle-derived stem cell which has broad developmental plasticity, and can be propagated and maintained in a primitive state in culture. These findings open new avenues for a variety of solid tissue engineering and regeneration utilising a single multi-potent stem cell type isolated from an easily accessible source such as skeletal muscle. **References** Mitchell KJ et al. Identification and characterisation of a non-satellite cell muscle resident progenitor during postnatal development. *Nature Cell Biology*, 2010;12:257-66.

### DEFECTIVE ADAPTATIONS TO ACUTE EXERCISE IN AGED HUMAN MUSCLE ARE PREVENTED BY LIFE-LONG EXERCISE TRAINING

Cobley, J.N., Waldron, S., Gregson, W., Cable, T., Burniston, J.G., Morton, J.P., Glose, G.L.

Liverpool John Moores University

Defective adaptations to acute exercise in aged human muscle are prevented by life-long exercise training. Cobley, J.N., Waldron, S., Gregson, W., Cable, N.T., Burniston, J.G., Morton, J.P., & Close, G.L. Liverpool John Moores University (Liverpool, UK) **Introduction** Animal models suggest that attenuated heat shock protein (HSP) expression and diminished signalling towards mitochondrial biogenesis following exercise in aged muscle may underlie age-related muscle frailty (Jackson & McArdle, 2011; Ljubicic et al., 2010) however this hypothesis has not been tested in humans. **Methods** Twenty-four subjects were recruited, 12 aged ( $+55$  yrs) and 12 young (18-25 yrs). These groups were further segregated into trained ( $n = 6$ ) and untrained ( $n = 6$ ) groups. Subjects completed a 20 minute high-intensity interval training session on a bicycle ergometer. Muscle biopsies were obtained pre, post and 3 days following exercise. Samples were analysed for HSP72, HSP27, Lon protease and cytochrome c oxidase IV (COXIV) protein content at baseline and 3 days post-exercise. Peroxisome proliferator activated receptor gamma co-activator one alpha (PGC-1 $\alpha$ ) protein content was determined at baseline. **Results** There was significantly greater PGC-1 $\alpha$  protein content at baseline in old trained subjects compared with old untrained ( $P=0.001$ ) and young untrained ( $P=0.002$ ) subjects. COXIV content was not different at baseline between groups ( $P=0.138$ ). COXIV protein content increased at 3 days ( $P=0.002$ ) but this increase was significantly attenuated in old untrained compared to young trained ( $P=0.008$ ) subjects. Irrespective of age, only trained subjects were able to significantly increase HSP72 protein content at 3 days post-exercise ( $P=0.028$ ). No group or time effects were observed for HSP27 and Lon at baseline or 3 days ( $P>0.05$ ). **Discussion** These data represent the first attempt to characterise both the adaptive cytoprotective and mitochondrial responses to exercise in aged trained and untrained human muscle. Life-long training up-regulates PGC-1 $\alpha$  protein content in aged muscle compared with untrained subjects and training is associated with a preserved ability to induct COXIV and HSP72 expression post-exercise. Conversely, untrained aged muscle exhibits decreased basal PGC-1 $\alpha$  expression and defective up-regulation of COXIV post-exercise. PGC-1 $\alpha$  over-expression attenuates age-related muscle wastage in animal models (Wenz et al., 2009) hence elevated expression in humans may help maintain muscle mass in old trained individuals. **In conclusion**, certain exercise adaptations fail in untrained aged individuals which may underlie muscle frailty. **References** Jackson, M.J. & McArdle, A. (2011). *J Physiol*. 589:2139-45 Ljubicic V, Joseph AM, Saleem A, Uguccioni G, Collu-Marchese M, Lai RY, Nguyen LM, Hood DA. ## INSULATIVE TROUSERS INCORPORATING ACTIVE HEATING REDUCE MUSCLE TEMPERATURE DECLINE FOLLOWING WARM UP AND IMPROVE SPRINT CYCLING PERFORMANCE

Faulkner, S.1, Ferguson, R.A.2, Gerrett, N.1, Hodder, S.G.1, Hupperets, M.3, Havenith, G.1

*Loughborough University*

**INTRODUCTION:** Elevations in muscle temperature ( $T_m$ ) have been shown to be important for enhancing maximal muscle power output during short duration, sprint based activities, hence the completion of a warm up prior to many exercise types. In many sporting competitions it is not uncommon for there to be delays between warm up completion and performance execution, during which time activity levels may be insufficient to maintain elevations in  $T_m$ . Excessive decline in  $T_m$  may lead to sub-optimal contractile conditions and impaired exercise performance. Therefore, the aim of the present study was to determine to what extent a delay between warm up and competition might influence  $T_m$  and performance and whether this may be attenuated using an insulated athletic trouser with optional heating. **METHODS:** On three separate occasions, 11 male cyclists ( $24 \pm 5$  yrs;  $182.4 \pm 7.6$  cm;  $77.4 \pm 10.0$  kg) completed a standardized 15 min intermittent sprint-based warm up on a cycle ergometer, followed by a 30 min passive recovery period before completing a 30 sec maximal sprint test.  $T_m$  of the vastus lateralis was measured at depths of 1, 2 and 3 cm prior to and following the warm up and immediately before the sprint test. Measures of absolute and relative peak power output were taken. During the recovery period subjects wore a tracksuit top and (in a balanced order) either i) a standard tracksuit ensemble (CONT), ii) a pair of insulated athletic trousers (INS) or iii) insulated athletic trouser with inbuilt electric heating elements around the thighs (HEAT). **RESULTS:** The warm up increased  $T_m$  at all depths by  $\sim 2.5^\circ\text{C}$ , with no differences between conditions. Following the recovery period  $T_m$  declined in both CONT (1cm  $36.3 \pm 0.4^\circ\text{C}$ ; 2cm  $36.6 \pm 0.3^\circ\text{C}$ ; 3cm  $36.9 \pm 0.2^\circ\text{C}$ ) and INS (1cm  $36.5 \pm 0.6^\circ\text{C}$ ; 2cm  $36.8 \pm 0.4^\circ\text{C}$ ; 3cm  $37.0 \pm 0.3^\circ\text{C}$ ), whereas  $T_m$  for HEAT remained elevated at all depths compared to both INS and CONT (1cm  $37.4 \pm 0.3^\circ\text{C}$ ; 2cm  $37.3 \pm 0.2^\circ\text{C}$ ; 3cm  $37.3 \pm 0.2^\circ\text{C}$ ;  $p < 0.01$ ). Peak power output was higher in HEAT ( $20.9 \pm 1.6$  W/kg) than both CONT ( $19.2 \pm 1.7$  W/kg; 9%,  $p < 0.05$ ) and INS ( $20.3 \pm 2.3$  W/kg; 3%,  $p < 0.05$ ). **DISCUSSION:** Though insulated trousers alone were not effective, the use of an insulated athletic trouser with the addition of electric heating elements around the thighs was able to reduce the decline in  $T_m$  that is associated with forced periods of inactivity between warm up completion and competition. Furthermore, the prevention of the decline in  $T_m$  improved subsequent sprint performance compared to when passive heating is not used.

### OP-PM02 Health and Lifestyle Interventions

#### DETERMINING THE OPTIMAL WEEKLY DOSAGE OF INTERMITTENT HYPOXIC EXPOSURE FOR HEALTH BENEFIT

Lizamore, C.1, Kathiravel, Y.2, Elliott, J.3, Hellemans, J.4, Hamlin, M.1

*1: Lincoln University (Christchurch), 2: Active Health (Christchurch), 3: University of Otago Christchurch (Christchurch), 4: National Triathlon Coach (Netherlands)*

**Introduction** Intermittent hypoxic exposure (IHE) is a technique used by athletes to simulate training at altitude. IHE has also been applied to improve cardiovascular health in a compromised population; however, optimal weekly dosages for health benefit are unknown. **Methods** Thirty untrained participants (13 male, 17 female; aged:  $55.9 \pm 5.0$ ; BMI:  $28.0 \pm 4.9$ , mean  $\pm$  SD) were randomly allocated into groups receiving IHE treatments 2-3 times per week (IHE3); IHE treatments 5 times per week (IHE5) or a control group receiving normoxic placebo 2-3 times per week (C). Pre- and post-intervention assessments included: supine heart rate variability (HRV), resting systolic blood pressure (SBP), and maximal oxygen consumption ( $\text{VO}_{2\text{max}}$ ). Highly sensitive C-Reactive Protein (hs-CRP) and Haemoglobin concentration (Hb) were also measured. Participants completed 5 weeks of treatment whereby IHE participants breathed hypoxic air to yield peripheral blood oxygen saturation levels ( $\text{SpO}_2$ ) as follows: week 1:  $\text{SpO}_2 > 95\%$ ; week 2:  $\text{SpO}_2 = 90\%$ ; week 3:  $\text{SpO}_2 = 85\%$ ; week 4-5:  $\text{SpO}_2 = 80\%$ . C participants breathed a normoxic placebo, week 1-5:  $\text{SpO}_2 > 95\%$ . Each session consisted of 5 min hypoxia/placebo:5 min ambient air intervals for 1 hour. Magnitude based inference was used to analyse the data for practical significance, using the mean change  $\pm$  90% confidence interval, and the % chances for harmful/trivial/beneficial outcomes based on Cohen's standardised units for smallest worthwhile change. Hopkins (2007)'s qualitative analysis of the outcome has also been included. **Results** After 5 weeks of treatment, compared to C, SBP (mmHg) decreased in IHE3 ( $10.1 \pm 7.7\%$ ; 0/5/95%; very likely beneficial); and IHE5 ( $6.5 \pm 7.9\%$ ; 1/25/74%; possibly beneficial); HRV (rMSSD) increased substantially in IHE5 ( $50.9 \pm 24.2\%$ ; 0/1/99%; very likely beneficial) but less so in IHE3 ( $15.1 \pm 59.4\%$ ; 18/24/57%; unclear); similarly, Hb (g/L) increased more in IHE5 ( $2.6 \pm 2.5\%$ ; 0/34/66%; possibly beneficial) than IHE3 ( $1.0 \pm 2.9\%$ ; 7/58/35%; unclear). There were no beneficial changes in hs-CRP or  $\text{VO}_{2\text{max}}$  in the IHE groups compared to C. **Discussion** Both IHE groups showed improvement in HRV (especially IHE5), and BP (especially IHE3), with a possible Hb increase in IHE5 only. These results suggest IHE 3-5 times per week is optimal for BP and HRV improvement in untrained subjects. As HRV (Kleiger et al., 2005) and BP (Wilson et al., 1998) are risk factors for heart disease, IHE warrants further investigation as a preventative therapy. **References** Hopkins W (2007). *SportSci*, 11, 16-20 Kleiger R, Stein P, Bigger T (2005). *A.N.E.* 10, 88-101 Wilson P, D'Agostino R, Levy D, Belanger A, Silbershatz H, Kannel W (1998). *Circ*, 97, 1837-1847

#### EFFECTS OF A SIX-MONTH ACTIVE PLAY PROGRAMME ON PRESCHOOL CHILDREN'S HABITUAL PHYSICAL ACTIVITY LEVELS.

O'Dwyer, M.V., Knowles, Z., Fairclough, S.J., Fowweather, L., Stratton, G.

*Liverpool John Moores University*

**BACKGROUND** Despite being the most active segment of the population, monitoring studies suggest that a high proportion of young children may not be sufficiently active for adequate development and health. Intervention during early childhood might be required to ensure health promoting behaviours are established. **AIM** To investigate the 6-month effect of an Active Play intervention on preschool children's moderate-to-vigorous physical activity (MVPA) levels. **METHOD** Participants ( $n=240$ ; 52% male,  $\text{Mage} = 4.4 \pm 0.6$  years) from 12

schools participated in the study. Intervention schools (n=6) received one Active Play session (~30 min) per week for 6-weeks from a trained deliverer. Six schools served as socioeconomic matched comparisons. Details of intervention are described elsewhere (O'Dwyer et al. 2011). Physical activity was quantified using accelerometry at baseline, post-intervention and 6 months. A three-level (time, pupil and school) multilevel analysis was used to determine the effects of the intervention across time on MVPA. RESULTS At six-months non-significant intervention effects were found for MVPA when confounding variables were added to the model. However, it was found that sex and the amount of hours children spent at school were significant predictors of MVPA. Boys engaged in more MVPA than girls ( $2.6 \pm 1.4$  mins). Children who spent a half-day at school engaged in more MVPA than their full-day counterparts ( $6.2 \pm 1.6$  mins). The child's BMI, ethnicity and maternal education were not significant predictors of MVPA. DISCUSSION The intervention did not significantly increase MVPA possibly because there may not have been an ample dose of activity. Additionally, socio-ecological theories propose that the active involvement of a parent during interventions may contribute to a more meaningful behaviour change. Future interventions should aim to incorporate the home environment and run over a longer period of time.

### PREPUBERTAL CHILDREN WITH SUITABLE FITNESS AND PHYSICAL ACTIVITY PRESENT REDUCED RISK OF OXIDATIVE STRESS

Llorente-Cantarero, F.J., Gil-Campos, M., Munoz-Villanueva, M.C., Pérez-Navero, J.L.

*University Hospital Reina Sofia*

**Introduction** Overproduction of oxygen free radicals can damage essential molecules in a process called oxidative stress (OS). Thus, OS is an important pathogenic ageing factor that has been associated with various disorders such as cardiovascular, metabolic and neurodegenerative diseases. To assess the impact of fitness status and physical activity on OS in prepubertal children, we measured selected biomarkers such as protein carbonyls (PC), lipid peroxidation products (LPO) and total nitrites, as well as on the antioxidant system: total glutathione (TG), oxidized glutathione (GSSG), reduced glutathione (GSH), superoxide dismutase activity, and glutathione peroxidase (GPx). **Methods** A total of 132 healthy children aged 7-12, at prepubertal stage were classified into two groups according to their fitness level: low fitness (LF) and high fitness (HF). This level was evaluated by a group of test took of Eurofit Battery and classified with the Olds et al. (2006) score. They were observed while engaged in an after-school exercise program, and a questionnaire was realized to obtain information on their physical activity or sedentary habits. Plasma and red blood cells were obtained to analyze biomarkers. **Results** Regarding oxidative stress markers, the LF group and the sedentary group showed higher levels of TG and GSSG and a lower GSH/GSSG ratio than the HF group and the children engaged in physical activity. A negative association was found between PC and GSSG and TG, and between TG and the GSH/GSSG ratio. Moreover, a negative correlation was found between GSSG and fitness, with a positive correlation with the GSH/GSSG ratio. **Discussion** In this study, the biomarkers TG, GSSG and GSH/GSSG ratio seem to be precocious and sensitive parameters for measuring changes in OS in prepubertal children, in relation to their CRF and PA. These results are in agreement with other associations described between CRF and OS. Antioxidant activity have been assessed in trained and untrained adults, suggesting lower OS in trained subjects [1,2]. This research contributes to recognize that an adequate level of fitness and recreational physical activity in childhood leads to better health and oxidative status. **References** Olds, T.; Tomkinson, G.; Léger, L.; Cazorla, G. *Sports Sci.* 24:1025-38;2006. 1. ### THE HYPOTENSIVE EFFECT OF HIGH AND LOW INTENSITY RESISTANCE EXERCISE IN YOUNG WOMEN

Terblanche, E.

*Stellenbosch University*

**Introduction** Post-exercise hypotension (PEH) following an acute bout of exercise is considered a possible mechanism for the reduction in cardiovascular disease and mortality associated with regular physical exercise. The effect of aerobic exercise on PEH is well-documented and evidence suggests that this mode of exercise lead to clinically significant reductions in blood pressure (BP) in both normotensive and hypertensive individuals. However, the evidence for resistance training is both limited and conflicting and the majority of studies only involves men. Thus the aims of this study were to determine (1) if resistance training causes PEH in normotensive young women and (2) whether the intensity of the exercise bout affects the magnitude of the BP response. **Methods** Eight healthy young women (age: 18 to 22 years), with previous experience in weight training, were evaluated during three randomized sessions. One repetition maximum (1RM) was determined for the bench press, leg press, biceps curl and overhead triceps extension. Participants then completed a high and low intensity session which consisted of three sets of ten repetitions of each exercise at 70% (HIT) and 30% (LIT) of 1RM, respectively. Subjects also completed a control session of passive rest. Systolic blood pressure (SBP) and diastolic blood pressure (DBP) were determined before and up to 60 minutes post-exercise using an ambulatory blood pressure monitor (Ergoline Ergoscan 2008, Germany). **Results** SBP was slightly more elevated directly after HIT compared to LIT ( $126 \pm 8$  vs  $114 \pm 12$  mmHg). Both the 60 minute post-exercise SBP and DBP was significantly more reduced after HIT compared to LIT and control [SBP:  $-5.7 \pm 2.0$  vs  $-0.5 \pm 3.5$  vs  $-2.5 \pm 1.5$  mmHg;  $p < 0.05$  and DBP:  $-7.4 \pm 2.5$  vs  $+3.0 \pm 1.5$  vs  $-0.5 \pm 1.5$  mmHg;  $p < 0.05$ ]. **Discussion** A single episode of high intensity resistance exercise caused small, but clinically significant reductions in BP that lasted for at least 60 minutes following exercise in young, normotensive women. This is in contrast to previous studies (Bermudes et al, 2004; Melo et al, 2006) which suggested that low intensity resistance exercise have a stronger hypotensive effect than high intensity exercise. However, these conflicting results could be explained by the differences in subject characteristics and exercise protocols. Importantly, this study confirms the hypotensive effects of resistance exercise and emphasizes the need to elucidate the optimal training load that is associated with the greatest PEH response in terms of magnitude and duration. **Bermudes AM, Vassallo DV, Vasquez EC, Lima EG. (2004). Arq Bras Cardiol, 82,65-71. Melo CM, Alencar AC, Tinucci T, Mion D, Forjaz CL. (2006). Blood Press Monit, 11,183-189.**

### STRENGTH, BODY COMPOSITION AND CARDIOVASCULAR EFFECTS OF HIGH-RESISTANCE CIRCUIT VS. TRADITIONAL STRENGTH TRAINING IN AN ELDERLY POPULATION

Romero-Arenas, S.1, Martínez-Pascual, M.2, Marín-Pagán, C.1, Blazevich, A.J.3, Luque, A.J.1, López-Román, F.J.1, Pérez-Gómez, J.4, Alcaraz, P.E.1

1: UCAM (Murcia, Spain), 2: HGUSL (Cartagena, Spain), 3: ECU (Perth, Australia), 4: UEX (Cáceres, Spain).

**INTRODUCTION** Circuit training is a time-efficient training modality that can elicit demonstrable improvements in health and physical fitness (Gettman et al., 2002). A significant drawback of standard circuit training programs, however, is that the loads lifted are typically low, so the stimulus for strength and muscle, and bone mass adaptations is minimal. Therefore, the aim of this study was determine the efficacy of a program of high-resistance circuit (HRC) training, and to compare the effects of high-resistance traditional (ST) and circuit strength training on muscle size and strength, body composition and cardiovascular fitness in healthy elderly. **METHODS** Thirty elderly (age  $62.3 \pm 5.9$  years, height  $1.55 \pm 0.07$  m and weight  $71.9 \pm 11.2$  kg) were randomly assigned to the TS group ( $n = 14$ , 6RM, 1-3 sets) or to the HRC group ( $n = 16$ , 6RM, 1-3 sets). Training consisted of weight lifting 2 times a week during 12 weeks. Prior to and at the end of the training program, maximum isokinetic torque ( $90^\circ \cdot s^{-1}$ ), body composition (DXA) and aerobic capacity were determined. Main and interaction effects resulting from the intervention were analyzed using single or multivariate analyses of variance (ANOVA) with repeated measures ( $p \leq 0.05$ ). **RESULTS** After training, total fat free mass (3.4% and 2.2%, HRC and TS, respectively) and bone mineral density (BMD) (1.2% and 1.1%, HRC and TS, respectively) was increased in both experimental groups. Only in the HRC group, the aerobic capacity was improved (10%) and the percentage of body fat was decreased (-4.4%), being established statistically significant differences between HRC and TS. A significant increase of isokinetic strength was observed in both experimental groups for the angular speed of  $90^\circ \cdot s^{-1}$  upper and lower limbs. **DISCUSSION** In this study, we observe the HRC training was as effective as TS for improving isokinetic torque, the lean mass and BMD. Only HRC training promoted decrease the fat mass and improvement the aerobic capacity. Modifications in lean-to-fat mass ratios and improved cardiovascular function have been closely linked with reductions in disease risk and all cause mortality (Sui et al., 2007). Thus, HRC training shows enormous promise as a health modification intervention. **REFERENCES** Gettman LR, Ward P, Hagan RD. (1982). *Med Sci Sports Exerc*, 14(3), 229-34. ### JUMPING PERFORMANCE DIFFERENCES AMONG COMPETING ELITE MALE HANDBALL

Setuain, I.

*Research, Studies and Sport Medicine Center, Government of Navarre, Spain*

Handball, is one of the most challenging sports for the knee joint. Although female handball players are one of the most exposed athletes to the ACL injury, the incidence of this injury on their male counterparts is not infrequent. Persisting strength and neuromuscular control deficits may be observed among the athletes who had suffered ACL injury, despite having complete the rehabilitation process due to inadequate or incomplete rehabilitation. This factor could be one of the explaining reasons for the ACL reinjury rates among this population. Measuring jumping performance variables such as stance phase contact time, flight time and mechanical power output during the rehabilitation process would help to minimize high-cost reinjury rate among handball elite athletes. **PURPOSE:** To describe jumping performance among a group of 13 male handball elite athletes using a previously validated jump test battery. Secondly, to identify possible differences between injured and uninjured extremities, in vertical and horizontal jump flight times, stance phase contact time, mechanical power, and reached distance obtained. We hypothesized that previously injured extremities would show deficits in jumping performance despite the injured athletes have completed their rehabilitation process and being competing at the maximum level. **METHODS:** 13 male elite athletes (6 previously injured and reconstructed and 7 uninjured control subjects) were evaluated performing a previously validated jump test battery that includes bilateral drop jump, unilateral drop jump, unilateral countermovement jump, unilateral triple jump for distance and the cross over hop for distance. Height (m), flight time (s), stance phase contact time (s), mechanical power ( $W \cdot kg^{-1}$ ) and distance (m) were obtained in each jump test performed. For the unilateral jump tests, comparison was made between reconstructed legs and the dominant ones of the uninjured subjects. For the bilateral drop jump test, comparison was made between reconstructed and uninjured subjects. **RESULTS:** Previously ACL reconstructed athletes demonstrated significantly lower mechanical power values during the unilateral drop jump ( $11,06$  vs.  $17,43$   $W \cdot kg^{-1}$ ;  $P < 0.05$ ) on their reconstructed leg compared with the healthy legs of the uninjured subjects. No significant differences were observed in the other variables recorded. **CONCLUSION:** Previously ACL reconstructed athletes may cope with some functional deficits once returning to competition, such as in lower mechanical power output ability in the injury limb, potentially increasing their reinjury risk. Restoration of these deficits would help to decrease the reinjury rates among this population. **REFERENCES:** 1. #### IS-SH10 A Cost-Benefit Analysis of Exercise for Health (\*)

#### COSTS OF PHYSICAL ACTIVITY AND SPORTS RELATED INJURIES: A DIFFERENT VIEW ON INJURY BURDEN

Verhagen, E.

*EMGO-Institute/VU University medical center*

Regular participation in physical activity and sports is beneficial for health. Thereby, safety in sports and PA is an important prerequisite for continuing participation in sports, as well as maintenance of a healthy physically active lifestyle. A variety of preventive, diagnostic, and therapeutic interventions are commonly used in sports medicine. In addition, an increasing number of randomised trials has evaluated the effectiveness of these interventions. Up till now the financial part of sports and physical related injuries and their prevention has

been mostly neglected in scientific literature. Nevertheless, sports injuries have a huge financial impact on society, because of the costs of the interventions and the costs associated with production loss due to work absenteeism and disablement as a result of sports injuries. In the Netherlands alone, in a population of about 7 million active sports participants, the annual estimated sports injury related costs are just over 3 billion euro's. Reliable descriptive cost data can aid policy makers and governmental agencies in determining 'problem' injuries and sports that require further investigation. In addition, it is important to obtain insight into the efficiency or cost-effectiveness of sports medicine interventions. Economic evaluations may help policy makers in their decision to include an intervention in the public health insurance system and they may help health professionals and patients to make decisions in clinical practice. A more efficient use of limited financial resources results in optimal care for more individuals. In short, financial analyses are a strong tool for agenda setting and implementation.

## **COSTS OF MAJOR BICYCLE ACCIDENTS IN FLANDERS**

de Geus, B.

*Vrije Universiteit Brussel*

**INTRODUCTION** Utilitarian cycling is recognized as an excellent way of being physically active on a regular basis and maintaining good health (Oja et al., 2011). Obesity prevention, reducing the physical inactivity burden, sickness absence reductions, increased productivity and the reduction of disease could result in cost savings. Unfortunately, some cyclists will be involved in accidents, will need medical care and may incur temporal or permanent physical injuries, which will induce costs to the cyclist and the society. In the Belgian SHAPES project, Aertsens et al. (2010) estimated the average total cost of minor bicycle accidents at 841 euro (95% CI: 579-1205) per accident or 0.125 euro per kilometre cycled. Overall, productivity loss is the most important component accounting for 48% of the total cost. The aim of this abstract is to provide more insight into the resulting costs of major bicycle accidents in Flanders. Major bicycle accidents are defined as accidents for which the cyclist had to be hospitalised for more than 24 hours. **MATERIALS AND METHODS** The data for this study were collected in a retrospective study design, using national statistics. In 2008, 2364 bicycle accidents that occurred in Flanders were registered by the National Trust for Accidents (FAO). From those 2364 invited participants, 289 returned the questionnaire and 28 were classified as a major accidents and used for the data analysis. Direct costs, including material damage as well as medical costs and productivity loss are calculated. For calculating the medical costs and productivity loss, a differentiation was made between a recovery phase and a permanent disability phase. **RESULTS** The average costs for the 28 accidents are composed by: a one time cost of 350 euro for material damage and a yearly cost of 1443 euro due to permanent disability resulting in productivity loss. The average medical costs during the recovery phase were composed by 1861 euro for doctor costs, 2680 euro for surgical interventions and 104 euro for medication. As a consequence of the accident, 17 (61%) participants did not fully recover. In the "permanent disability" phase, the average medical costs are 242 euro per year. **DISCUSSION** The calculations in this study does not take into account the indirect costs (productivity loss and leisure time loss) nor intangible costs of pain and psychological suffering. Based on Norwegian data, annual economic costs of bicycle injuries were estimated to approximately 300 million euro or 5804 euro per minor accident, compared to 7617 euro per major accident in Flanders. **CONCLUSION** Total annual bicycle injury costs are huge, but these costs must be balanced against the benefits of bicycling, related to health and environment. **REFERENCES** Aertsens et al, 2010, *Acc Anal Prev*, 42, 2149-2157 Oja et al, 2011, *Scan J Med Sci Sports*, 21, 496-509 Veisten et al, 2007, *Acc Anal Prev*, 39, 1162-1169

## **THE COST-BENEFIT AND COST-EFFECTIVENESS OF PHYSICAL ACTIVITY AND EXERCISE**

van Mechelen, W.

*VU University Medical Center*

**Speaker 1: Willem van Mechelen (NED)** The cost-effectiveness of workplace physical activity and exercise interventions **Running title: Workplace PA programmes** Physical inactivity is now according to WHO worldwide the 4th leading cause of mortality due to non-communicable chronic (i.e. lifestyle-related) disease. In addition, we are faced with demographic changes by which by 2025 in North-West Europe 1 out of 3 adults older than 18, will be older than 65 years. As a consequence of these epidemiologic and demographic trends there is a push for workplace-related physical activity and exercise programmes to counteract both trends of relevance for the vitality of the workforce. Purpose of this presentation is to provide evidence on the cost-benefit and cost-effectiveness of workplace physical activity and exercise interventions. For this purpose the results of a number of recent systematic reviews will be presented, as well as a number of recently conducted randomised controlled trials. From this evidence it can be concluded that workplace physical activity and exercise interventions hold a promise for the future, but also that more high quality studies are needed to be able to make a balanced judgement on the cost-benefit and cost-effectiveness of such interventions. **References** van Dongen JM, Proper KI, van Wier MF, van der Beek AJ, Bongers PM, van Mechelen W, van Tulder MW. **15:00 - 16:30****Invited symposia****IS-BN01 Importance of Feedback in Motor Control and Learning**

---

**AUGMENTED FEEDBACK: FROM BEHAVIORAL PRINCIPLES TO NEURAL MECHANISMS**

Swinnen, S.

*KU Leuven*

Processing sensory input and using this source of information to support action is critical for performance and learning of gross and fine motor skills, such as the control of balance, lifting an object, and coordinating the upper and/or lower limbs. Here, I will start with an overview of some general principles of feedback that have inspired research on human motor performance and learning during the past decades. I will particularly elaborate on how extrinsic feedback can be augmented to the feedback that is normally available through our sensory sources and whether this may have positive or negative consequences for performance, learning and retention. I will then elaborate on the neural correlates of movement performed in the presence or absence of augmented visual feedback in view of the distinction between internal versus external movement generation. Internally-generated movement is generally based on a medial (Basal Ganglia to Supplementary Motor Area) brain activation network and external generation on a parieto-premotor network. Finally, I will provide a neural basis for Schmidt's guidance hypothesis of information feedback, addressing the 'double edged sword' surrounding feedback. More specifically, I will discuss how augmented feedback can give a boost to performance, yet may hamper motor consolidation and retention. This has important implications for rehabilitation intervention because our general aim is to help patients to improve performance not only in the presence of various modes of augmented feedback but also in their local habitat where these sources of augmented feedback may no longer be present.

**ADAPTIVE FEEDFORWARD AND FEEDBACK STRATEGIES IN SENSORIMOTOR CONTROL**

Franklin, D.W.

*University of Cambridge*

The sensorimotor control system has exceptional abilities to perform skilful action despite ever changing conditions. I will discuss how this adaptability can result through intrinsic feedback mechanisms in two different ways: sensory feedback driving feedforward adaptation; and feedforward adaptation in turn adapting the feedback responses and tuning them to the environment. When we learn a new skill, sensory feedback from previous errors are incorporated into the feedforward motor command to gradually refine our movements. I will describe a model of motor learning based on the simultaneous optimization of stability, accuracy and efficiency. This model of motor learning offers new insights as to how the brain controls the complex musculoskeletal system and iteratively adjusts motor commands to improve motor skills with practice. However learning can also be used to adjust intrinsic feedback control. I will discuss new experiments in which we examine the control and modulation of involuntary visuomotor responses. These rapid visuomotor responses generate corrective arm movements to small positional changes in the visual feedback of the hand during movements. I will describe experiments demonstrating that these feedback responses can be precisely tuned by the sensorimotor control system to the environment.

**THE ROLE OF INTRINSIC AND EXTRINSIC FEEDBACK IN HUMAN MOTOR LEARNING**

Lundbye-Jensen, J.

*University of Copenhagen*

It is evident that the central nervous system has an impressive capability of forming and maintaining multiple long-term motor memories. The human capacity of learning new motor skills has a tremendous importance across the lifespan. The practice of movements is essential for the acquisition of new motor skills, and once we have acquired skills such as bicycling, ice skating or driving a car, these skills are often retained for a very long time. When we practice a motor task and acquire new skills, our movements are gradually refined over time. This gradual optimization of the feedforward motor command is to a large extent driven by errors in previous movements arising from a comparison between the predicted consequences of the movement and the actual outcome (perceived feedback from the body and the surrounding world). In my presentation, I will focus on motor behavior and the role of intrinsic and extrinsic feedback mechanisms in motor learning. I will present behavioral and electrophysiological results from recent experiments, which demonstrate that sensory feedback may provide strong error and learning signals for the central nervous system. Not only can sensory feedback update the feedforward motor command, learning is also accompanied by optimized feedback control. In this way, feedback is an essential part of learning.

**IS-PM01 JSPFSM Exchange Symposium: Physiological and environmental factors influencing sports performance****PERIPHERAL VISUAL PERCEPTION DURING EXERCISE: WHY WE CANNOT SEE**

Ando, S.

*Fukuoka University*

Vision is one of the most important sensory modalities in humans. The visual field is defined as the area perceived by the eyes while people fixate on a point, and is composed of the central and peripheral visual fields. Many sports require high-level visual perceptual skills under conditions of physiological stress. In sports such as football, players gather visual information from the periphery of the visual field to see other players and objects beyond the central visual field. Thus, peripheral visual perception may play an important role in sports performance. In recent years, increasing empirical evidence suggests that acute exercise affects peripheral visual perception. A behavioral study has shown that peripheral visual perception may be vulnerable to exercise as compared with central visual perception (Ando et al. 2008). The following study suggested that the detrimental effects of exercise on peripheral visual perception are not primarily ascribed to low visual resolution, but to the impaired top-down control of visual attention (Ando et al. 2012). During incremental exercise, peripheral visual perception was impaired when engaged at exercise at high workloads above the ventilatory threshold (Ando et al. 2005). Furthermore, high aerobic capacity attenuated the increase in peripheral visual reaction time during strenuous exercise, suggesting that oxygen availability play a role in peripheral visual perception (Ando et al. 2005). Peripheral visual perception was impaired to some extent during exercise under mild hypoxia relative to normoxia although the differences between normoxia and hypoxia failed to reach statistical significance (Ando et al. 2010). Further analysis demonstrated that decreases in cerebral oxygenation were closely associated with the impairment in peripheral visual perception during exercise (Ando et al. 2010). In contrast, peripheral visual perception was not impaired even during strenuous exercise under hyperoxia where oxygen availability was elevated (Ando et al. 2009). These findings suggest that a decrease in cerebral oxygenation is associated with impairment in peripheral visual perception during strenuous exercise. The decrease in cerebral oxygenation during exercise means that oxygen availability may be insufficient to meet metabolic demand. It is plausible that decreases in cerebral oxygenation have detrimental effects on visual perceptual performance during exercise. References Ando et al. (2008) *Int J Sport Med*, 29, 994-998. **ENDURANCE EXERCISE PERFORMANCE AND BODY TEMPERATURE UNDER VARIOUS HUMIDITY CONDITIONS IN THE HEAT**

Otani, H., Watson, P., Maughan, R.J.

*Himeji Dokkyo University*

Endurance exercise performance and body temperature under various humidity conditions in the heat Hidenori Otani 1,2, Phillip Watson 2, Ronald J. Maughan 2 1 Faculty of Health Care Sciences, Himeji Dokkyo University, Japan 2 School of Sport, Exercise and Health Sciences, Loughborough University, UK Introduction: It is well known that endurance exercise performance is impaired in the heat. Galloway and Maughan (1997) demonstrated a progressive reduction in endurance exercise capacity in the heat as the ambient temperature increased. However, although the importance of the relative humidity (RH) for effective thermoregulation and endurance exercise performance in the heat has been recognized, there have been no systematic studies to confirm and quantify this effect. The aim of this study was to examine the effect of RH on endurance exercise performance and body temperature in the heat. Methods: Eight healthy males completed four cycling trials at 70% of their maximum oxygen uptake until volitional exhaustion. Experimental trials were undertaken in a climatic chamber with the ambient temperature at 30°C and RH was maintained at either 24%, 40%, 60% or 80%. Rectal temperature, skin temperature (chest, upper arm, thigh and calf), heart rate, skin blood flow and blood pressure were recorded at rest and during exercise. Expired air was collected every 15 minutes during exercise. Blood samples were collected before exercise, at 15 and 30 minutes during exercise, and immediately after exhaustion. Results: Exercise time to exhaustion ( $\pm$  SD) was  $68 \pm 19$ ,  $60 \pm 17$ ,  $54 \pm 17$  and  $46 \pm 14$  minutes in the 24, 40, 60 and 80% trials, respectively; exercise time was less in the 60% ( $P = 0.013$ ) and 80% ( $P = 0.005$ ) trials than in the 24% trial. There was no difference in rectal temperature between the trials. Rectal temperature at exhaustion was  $39.0 \pm 0.3^\circ\text{C}$  in the 24, 40 and 60% trials and  $39.1 \pm 0.3^\circ\text{C}$  in the 80% trial. The rate of rise in rectal temperature during exercise was faster ( $P < 0.001$ ) in the 80% trial than in the 24% trial. Mean skin temperature at the point of exhaustion was higher ( $P < 0.001$ ) in the 80% trial than in the 24% trial. Heart rate, skin blood flow and cutaneous vascular conductance during exercise were not different between the trials. Total sweat loss was similar between the trials, but sweating rate was higher in the 60% ( $P = 0.002$ ) and 80% ( $P = 0.003$ ) trials than in the 24% trial. There were no differences in the calculated rates of fat and carbohydrate oxidation between the trials. Percentage changes in plasma volume, serum osmolality, serum sodium, serum potassium and blood glucose during exercise were not different between the trials. Conclusion: This study demonstrates a progressive reduction in endurance exercise performance in the heat as RH increases. Early fatigue in the higher humidity trials is accompanied by a faster rate of rise in core temperature and a higher skin temperature. Reference: Galloway SDR, Maughan RJ. *MSSE* 29, 1997.

**CEREBRAL BLOOD FLOW REGULATION IN INTERNAL CAROTID AND VERTEBRAL ARTERIES DURING ORTHOSTATIC STRESS**

Ogoh, S.1,4, Sato, K.1, Fisher, J.2, Seifert, T.3, Overgaard, M.3, Secher, N.3

*1 Japan Women's College of Physical Education, Japan; 2 University of Birmingham, UK; 3 University of Copenhagen, Denmark; 4 Toyo University, Japan*

Introduction: Global cerebral blood flow (CBF) is decreased during orthostatic stress (Alperin et al. 2005). However, the effect of orthostatic stress on the distribution of blood flow to carotid or vertebro-basilar systems remains unclear. Given its importance for the neural regula-

tion of the circulation, CBF regulation in the medulla oblongata (vertebra-basilar system) may be more important for orthostatic tolerance than in the cerebral cortex (carotid system) (Deegan et al. 2010). The purpose of the present study was to compare blood flow regulation in the carotid and vertebro-basilar circulations during orthostatic stress in healthy young subjects. Methods: Blood flow in the internal carotid artery (ICA) and vertebral artery (VA) at supine rest (Supine) and 60° head-up tilt (HUT) were measured using Doppler ultrasonography. Dynamic cerebral autoregulation (CA) was also determined during Supine and HUT conditions, from the rate of regulation (RoR) in cerebrovascular conductance of the ICA and VA during acute hypotension induced by the release of bilateral thigh cuffs. Results: HUT significantly decreased ICA blood flow by  $-9.4 \pm 1.7\%$  ( $P < 0.01$  vs. Supine), while ICA conductance was unchanged. In contrast, there was no significant difference in VA blood flow between Supine and HUT, while VA conductance significantly increased ( $3.9 \pm 0.6\%$ ;  $P < 0.05$ ). In addition, dynamic CA in both the ICA and VA was attenuated during HUT, however, the magnitude of the attenuation in dynamic CA to orthostatic stress was greater in the VA ( $0.25 \pm 0.03$  /s in Supine vs.  $0.16 \pm 0.02$  /s in HUT;  $P < 0.05$ ) compared with the ICA ( $0.23 \pm 0.02$  vs.  $0.20 \pm 0.03$ ). Discussion: Our findings indicate that there are notable regional differences in CBF regulation during orthostatic stress. The results of the present study suggest that although the preservation of VA blood flow would be beneficial for the vertebra-basilar system to regulate systemic circulation against orthostatic stress, the posterior cerebral circulation may be more vulnerable than the anterior (carotid) cerebral circulation to an acute change in perfusion pressure. ## SUBSTRATE METABOLISM DURING EXERCISE IN THE COLD

Helge, J.

*University of Copenhagen*

This talk will focus on the effect of prolonged exercise in a cold environment and substrate metabolism during exercise in the cold. During very prolonged exercise in cold conditions energy turnover is increased and under strenuous conditions energy balance may be compromised (1). Substrate metabolism during exercise in the cold is influenced by a number of factors; exercise intensity, temperature, duration of cold exposure, behavioural adaptation and training status. The literature is by no means clear cut, but overall a majority studies demonstrate higher carbohydrate utilization during exercise in the cold. Regular prolonged whole body moderate intensity exercise in cold conditions where large distances are traversed on cross country skis, lead to adaptations in skeletal muscle both arm and leg, but does not necessarily change maximal aerobic capacity (2). It is likely that dietary supply and composition as well as body composition may exert a major influence on the adaptive patterns observed through prolonged exposure to cold during exercise. In Inuit, that have been chronically exposed and adapted to cold conditions for generations, there are physiological differences both at the whole body and within the skeletal muscle. The capacity to perform upper body exercise at a markedly higher oxygen uptake than Caucasian in a similar training condition and enhanced muscle mitochondrial capacity are possible adaptive patterns in Inuit. ### OP-PM03 Neuromuscular Physiology 1

#### FATIGUE INDUCES A GREATER DECLINE IN EXPLOSIVE THAN MAXIMAL FORCE PRODUCTION WITH EVIDENCE FOR NEURAL AND CONTRACTILE MECHANISMS

Buckthorpe, M.W., Pain, M.T.G., Folland, J.P.

*Loughborough University*

**Introduction** The human capacity for explosive force (EF) production is considered functionally more important than maximal voluntary force (MVF) during explosive movements, such as sprinting, jumping or when restabilising the musculo-skeletal system following a loss of balance and thus in preventing injury (1). Fatigue is thought to increase injury risk (2), however, the effect of fatigue on EF and the mechanisms responsible (neural or contractile) have received little attention. This study assessed the neural and contractile contributions to fatigue during EF production. **Method** Eleven healthy untrained males ( $24 \pm 4$  yrs) completed 10 sets of voluntary maximal explosive isometric contractions of the knee extensors ( $5 \times 3$ -s duration, 2-s rest). Sets were separated by 5-s, during which twitch and octet (8 pulses at 300 Hz; evokes the muscle's maximal rate of force development [RFD]) contractions were electrically evoked via supramaximal stimulation of the femoral nerve. EF was measured over the initial 50 (Octet) and 150 ms (volitional) of contraction. Peak octet force (PF) and MVF were also assessed. Voluntary EF was reported in absolute and relative (%MVF) terms. Surface EMG RMS amplitude was recorded over the superficial agonists (VL, VM and RF) during the initial 150 ms of contraction and at MVF (500 ms epoch). EMG was normalised to  $M_{\text{max}}$  Area during the same set of contractions before being averaged across the agonists. To assess fatigue paired t-tests were used to i) compare measurements during the initial vs. final sets and ii) contrast the fatigue induced reduction in different parameters. Results Voluntary EF after 50-150 ms of contraction declined by 47-52% with a 42% reduction in MVF (All,  $P < 0.001$ ). Relative EF decreased by 12-18% ( $P \leq 0.038$ ). The decline in octet force at 50 ms (23%,  $P < 0.001$ ) and PF (28%,  $P < 0.001$ ) were less than the equivalent changes in voluntary force (All,  $P \leq 0.027$ ). Agonist EMG during the initial 150 ms of contraction and at MVF decreased by 15-28% (All,  $P \leq 0.010$ ). **Conclusion** EF exhibited a marked decline with fatigue, which was more pronounced than the decrease in MVF, as shown by the reduction in relative EF. This finding may help explain the greater incidence of injuries associated with fatigue (i.e., at the end of a football match). Contractile fatigue was demonstrated by declines in Octet EF after 50 ms and at PF, but these changes were smaller than volitional decrements. The decline in agonist EMG and the greater decrease in voluntary than Octet EF demonstrated a substantial central neural component to the reduction in volitional EF. (1) Aagaard et al. (2002). *J Appl Physiol* 93, 1318–1326. (2) Hawkins et al. (2001). *Br J Sports Med* 35, 43–47.

**PERIPHERAL FATIGUE INDUCED BY REPEATED TETANI EVOKED VIA ELECTROMYOSTIMULATION**

MATKOWSKI, B.1, PLACE, N.2, LEPERS, R.1, WESTERBLAD, H.3, MARTIN, A.1

1: *Université de Bourgogne (Dijon, France)*, 2: *Université de Genève (Genève, Switzerland)*, 3: *Karolinska Institutet (Stockholm, Sweden)*

**Introduction** The level of central fatigue is commonly quantified by the interpolated twitch technique (ITT). It has recently been shown with mouse intact single fibres that ITT takes into account peripheral properties of fatigue and thus may overestimate the extent of central fatigue measured after exercise (Place et al. 2008). In a first experiment on human muscle, we observed a progressive increase in the interpolated twitch amplitude, whereas the electromyostimulation (EMS)-induced tetanic torque and post tetanic twitch amplitude decreased. However, twitches were induced by supramaximal nerve stimulation, i.e. all motor units (MUs) were activated while during EMS only a fraction of total MUs were activated. Therefore, the present study was designed to monitor fatigue development in active MUs during repeated tetanic stimulation induced by EMS in human quadriceps muscle. **Methods** Experiments were performed on 9 healthy men. The quadriceps muscle was fatigued by a series of 15 EMS-induced contractions (6s on-6s off), whereas a twitch was evoked using the same current intensity 2s after each EMS contraction (post tetanic twitch). This protocol was performed in isometric condition with a knee angle of 90°. The intensity used for the EMS-induced contractions was set to 20% initial maximal voluntary contraction (MVC) and kept constant throughout the 15 contractions. MVC were performed before and after the EMS-induced contractions, and a set of 10 different frequencies (from 5 to 100Hz) were randomly evoked by EMS before and after the fatiguing contractions. **Results** The repeated tetanic contractions induced by EMS resulted in a decreased MVC torque ( $-21.3 \pm 7.7\%$ ;  $P < 0.001$ ). The EMS-induced tetanic torque and the potentiated peak twitch were significantly depressed ( $-59.0 \pm 17.5\%$  and  $-65.6 \pm 9.5\%$  respectively;  $P < 0.001$ ). Torque was decreased ( $P < 0.001$ ) at all stimulation frequencies over 10Hz after as compared to before fatigue. When the torque/frequency curves were normalized to the torques measured at 100Hz, we found a right-ward shift of the torque/frequency relationship after fatigue. **Discussion** The reduction in the post tetanic twitch amplitude was parallel to the reduction in the EMS-induced torque, which indicates that the loss of force observed during fatigue could mainly be attributed to a reduction in the force of the active MUs throughout fatigue rather than MUs derecruitment. **References** Place N et al. (2008). *J Physiol* 586: 2799-2805

**MODULATION OF SPINAL EXCITABILITY BY A SUB-THRESHOLD STIMULATION OF M1 AREA**

Grospretre, S., Papaxanthis, C., Martin, A.

*INSERM U1093*

**Introduction** In human, it is well known that muscle performance differs between shortening and lengthening contraction. This is not only due to the mechanical properties of the muscle (Katz 1939) but also to the characteristics of its activation (Enoka 1996). The command reaching the motoneuronal pool depends on the efficiency of the spinal transmission, that can be evaluated by the H reflex (Hmax/Mmax ratio). It has been previously shown that spinal efficiency decreases during passive muscle lengthening in comparison to passive shortening (Duclay & Martin 2005). These changes have been attributed to presynaptic inhibition of Ia afferent fibres. However, the decreased spinal efficiency observed during passive lengthening is reduced when the muscle is active (Duclay & Martin 2011). The aim of the present study was to examine how the cortico-spinal command can influence the spinal efficiency during lengthening contraction. To achieve this aim, H reflex stimulation was conditioned by a sub-threshold motor evoked potential. This has been done at rest and under isometric, shortening and lengthening voluntary contractions. **Methods** H reflexes of triceps surae (TS) muscles were elicited by stimulating the posterior tibial nerve, in 11 healthy young subjects. These H reflexes were conditioned by sub-threshold (intensity under motor threshold) Transcranial Magnetic Stimulation applied over M1 area of TS muscles, with a 5ms interval. Conditioned and unconditioned H-reflexes were elicited during different passive solicitations of the muscle (static rest, passive lengthening and shortening) and contraction modes with a force level corresponding to 20% of maximal voluntary contraction (in concentric, eccentric and isometric). **Results** Sub-threshold TMS pulse facilitated H responses only during passive and active lengthening of the muscle, increasing H amplitude by 62 % in eccentric condition and by 27 % in passive lengthening. During lengthening, Ia- $\alpha$  connection is subjected to presynaptic inhibitions, which reduce spinal efficiency. So, sub-threshold TMS pulse seems to act at a spinal level by partially cancelling these inhibitions. **Discussion** These results suggest the existence of a specific circuit in the spinal cord, involving an interneuron that could inhibit, at a presynaptic level, the connection between Ia afferent and motoneurons. The cortical command could increase muscle activation by reducing the amount of presynaptic inhibition, instead of modulating directly the motoneurone excitability. **References** Duclay J, Martin A. **FATIGUE RESISTANCE OF THE KNEE EXTENSOR MUSCLES IN PATIENTS WITH POST-POLIO SYNDROME**

Voorn, E.

*Academic Medical Center Amsterdam*

**FATIGUE RESISTANCE OF THE KNEE EXTENSOR MUSCLES IN PATIENTS WITH POST-POLIO SYNDROME** Voorn, E.1,2, Beelen, A.1, Nolle, F.1, Gerrits, H.L.2, de Haan, A.2, 1: Department of Rehabilitation, Academic Medical Center, University of Amsterdam 2: Research Institute MOVE, Faculty of Human Movement Sciences, VU University Amsterdam, The Netherlands **Introduction** Post-polio Syndrome (PPS) is a complex of late onset neuromuscular symptoms with new or increased muscle weakness or abnormal muscle fatigability as key symptoms. Several neuromuscular adaptations to the acute polio and the secondary decline have been described that may contribute to the abnormal muscle fatigability reported by many individuals with PPS. Capillary density and oxidative enzyme activity were found to be decreased in PPS, indicating a lower aerobic capacity. Although these factors may lead to premature muscle fatigue, the few studies that evaluated the muscular fatigability in PPS show contradictory results. Therefore the objective of this study was to compare fatigue resistance of the knee extensor muscles between patients with PPS and healthy subjects. **Methods** We assessed fatigue resistance of the knee extensor muscles in 34 patients with PPS (11 men, age  $59.5 \pm 6.6$  years) and 14 healthy individuals (7 men, age  $59.5 \pm 7.5$  years), using isometric contractions on a dynamometer evoked by percutaneous electrical stimulation (1 s on, 1 s off, 50 Hz during 5 min), leading to an initial torque level of 30-40% of maximal voluntary torque (MVT). Measurements were performed at a knee angle of 60°. Peak torque of each contraction was expressed as a percentage of the first contraction. Fatigue resistance was defined as the percentage torque that remained over the last 90 contractions of the protocol. A two-factor ("PPS" and "gender") analysis of variance was used to test for differences between groups. Gender was added as a factor since there are sex differences in muscle fatigue resistance (Wüst et al., 2008). **Results** MVT was higher in healthy subjects compared to PPS ( $183.4 \pm 35.9$  versus  $104.4 \pm 44.9$  Nm;  $p = 0.000$ ). Relative initial torque of the fatigue protocol was similar in both groups ( $30.2 \pm 5.7$  versus  $33.0 \pm 9.4$  %MVC;  $p = 0.308$ ). Fatigue resistance did not differ between patients with PPS and healthy subjects ( $51.9 \pm 9.8$  vs  $51.6 \pm 11.1$  %;  $p = 0.921$ ). Women had a significantly higher fatigue resistance compared to

men ( $54.1 \pm 10.0$  versus  $47.9 \pm 9.2$  %;  $p = 0.018$ ), but no significant interaction was found between "PPS" and "gender". Discussion Our findings do not support the hypothesis that fatigue resistance of the quadriceps muscles in patients with PPS is lower compared to healthy subjects. Therefore, muscle fatigability experienced by PPS patients can not be explained by an increased intrinsic fatigability of the muscle fibers and is more likely the result of muscle weakness that requires individuals to work at higher relative intensities, inducing early fatigue. ### COMPARISON OF NEUROMUSCULAR ADJUSTMENTS ASSOCIATED WITH SUSTAINED ISOMETRIC CONTRACTIONS PERFORMED WITH DIFFERENT MUSCLE GROUPS

Neyroud, D., Rüttimeann, J., Maffioletti, N.A., Millet, G.Y., Mannion, A.F., Place, N.

*University of Geneva*

COMPARISON OF NEUROMUSCULAR ADJUSTMENTS ASSOCIATED WITH SUSTAINED ISOMETRIC CONTRACTIONS PERFORMED WITH DIFFERENT MUSCLE GROUPS Neyroud D.(1), Rüttimeann J.(1), Maffioletti N.A.(2), Millet G.Y.(3), Mannion A.F.(2), Place N(1). (1) ISMMS, Faculty of Medicine, University of Geneva, Switzerland (2) Neuromuscular Research Laboratory, Schulthess Clinic, Zurich, Switzerland (3) Université de Lyon, F-42023, Saint-Etienne, France Introduction Time to exhaustion of a sustained submaximal isometric contraction (endurance time, ET) depends on several factors such as muscle phenotype, the extent of voluntary activation and/or muscle length. However, it is not known if the mechanisms underlying voluntary exhaustion and the reduction in maximal voluntary contraction (MVC) induced by a sustained fatiguing contraction are muscle group dependent. In the present study, we tested the hypothesis that neuromuscular adjustments associated to a sustained voluntary contraction until exhaustion depend on the muscle group considered. Methods Thirteen healthy men ( $25 \pm 2$  yrs) volunteered to participate in two testing sessions (at least 48-h apart) involving the performance of two sustained contractions at 50% MVC force (optimal joint angle) until voluntary exhaustion. In each session, one upper limb and one lower limb were tested (either the knee extensors and thumb adductor or the plantar flexors and elbow flexors). Muscle fatigability was measured via (i) ET of the sustained contraction and (ii) MVC force reduction. Changes in voluntary activation (index of central fatigue) and contractile properties (index of peripheral fatigue) were derived from doublet responses evoked during and after the MVC. Results ET differed ( $p < 0.05$ ) between muscle groups ( $220 \pm 64$  s for plantar flexors,  $114 \pm 27$  s for thumb adductor,  $77 \pm 25$  s for knee extensors and  $72 \pm 14$  s for elbow flexors). However, MVC force reduction at voluntary exhaustion was similar ( $p > 0.05$ ) for the different muscles (-30 to -40%). Voluntary activation was found to be altered only for plantar flexors (from  $95 \pm 5\%$  to  $82 \pm 9\%$ ,  $p < 0.05$ ). Potentiated doublet amplitude was more depressed for upper limb muscles ( $-60 \pm 20\%$ ,  $p < 0.05$ ) than for knee extensors ( $-28 \pm 15\%$ ,  $p < 0.05$ ), whereas the reduction was only marginal for plantar flexors ( $-7 \pm 12\%$ ,  $p < 0.05$ ). Conclusion The present findings confirm that ET is muscle group-dependent (Frey-Law & Avin 2010). More interestingly, the mechanisms underlying voluntary exhaustion differ with respect to the duration of the task. For example, plantar flexors showed the longest endurance time, which was associated with central fatigue and minimal peripheral fatigue in comparison to the other muscle. Finally, these results expand upon recent findings (Neyroud et al. in press) showing that maximal strength loss and ET represent two different indexes of muscle fatigability. ### SENSORIMOTOR TRAINING INFLUENCES BALANCE CONTROL AND PNP IN LYMPHOMA PATIENTS UNDERGOING THERAPY

Streckmann, F., Leifert, J.A., Kleber, M., Kneis, S., Bertz, H., Gollhofer, A.

*Department of Hematology/Oncology, Freiburg University Medical Center Freiburg, Germany; Department of Sport Science, University of Freiburg, Germany*

Introduction Lymphoma patients (pts) receiving therapy often suffer from severe balance problems corresponding with therapy induced peripheral neuropathy (PNP), progressive loss of lean muscle mass and weakness. Not only does this influence patients' quality of life, but also the dosage and schedule of therapy. Sensorimotor training is associated with neural adaptations that affect reflex pathways, improve proprioception and intermuscular coordination. In a prospective, randomized study, we assessed the improvement of balance control, reduction of therapy induced side effects. Methods 25 pts (median age 46, range 19-75) were randomized either to an intervention group (IG, n=13) or a control group (CG, n=12). The IG participated in an exercise program, consisting of aerobic endurance, strength and sensorimotor training, twice a week. Pts were evaluated four times: before therapy (T0), after 12 (T1), 24 (T2) and 36 weeks (T3). Balance control was determined by analysing sway paths and failed attempts during a bi- and monopodal stance in a static and dynamic (with a balancepad) condition on a force plate (GKS 1000) and in a perturbed condition on an oscillating measuring plate (Posturomed®). Status of peripheral deep sensibility was evaluated by tuning fork and medical reports. Results We found significant differences between the groups in cumulative sway paths, failure rates and the extent of PNP. Postural sway improved in the IG (-5cm) at all time points (T1:  $p = .001$ ; T3:  $p = .01$ ), compared to a decline (+29cm) in the CG. At T1/T3, 100% of the IG completed the monopodal static stance compared to only 50%/55% in the CG ( $p = < .001$ ;  $p = .001$ ). The failure rate (92%) in the CG rose under dynamic conditions, compared to 0% in the IG at T3 ( $p < .001$ ). The extent and diversification of PNP correlated with these results. At T0, both groups suffered from PNP (25%), compared to 8% (IG) and 50% (CG) at T3 ( $p = .001$ ). Conclusion Sensorimotor training is a feasible and very promising method to support cancer pts during therapy and help preserve their functionality for activities of daily living. It not only improves balance control but also reduces the intensity of therapy-induced PNP, associated with an improvement in quality of life. References Gisler-Hofmann T, (2008). ### OP-PM04 Brain and Exercise Performance

#### EFFECTS OF ACUTE INJECTION OF CAFFEINE ON EXERCISE PERFORMANCE, THERMOREGULATION AND BRAIN NEUROTRANSMISSION IN THE RAT

Xinyan, Z.

*Hiroshima University*

EFFECTS OF ACUTE INJECTION OF CAFFEINE ON EXERCISE PERFORMANCE, THERMOREGULATION AND BRAIN NEUROTRANSMISSION IN THE RAT Zheng, XY., Hasegawa, H. Hiroshima Univ (Hiroshima, Japan) Introduction In 2004, caffeine has been released from the list of banned substances by the International Olympic Committee, and widely used by athletes. The dose of caffeine, which can improve the endurance performance, ranges from 3 to 9 mg/kg. In addition, it has been reported that acute administration of caffeine (2-40 mg/kg) produced changes in the core body temperature of rats during rest. In the past, caffeine has been shown to increase dopamine (DA) concentrations in many regions of the brain. However, mechanisms of thermoregulation and central fatigue remain elusive. The purpose of this study was to clarify the effects of caffeine on thermoregulation, neurotransmitters in the preoptic area and anterior hypothalamus (PO/AH) and endurance exercise performance in rats. Methods To measure the core body temperature (Tcore), the changes in the extracellular monoamines in the PO/AH and the thermoregulatory responses of rats simultaneously, we combined *in vivo* brain microdialysis, biotelemetry and oxygen consumption. Tcore, tail skin temperature (Ttail) which is an index of heat loss, oxygen consumption (VO<sub>2</sub>) which is an index of heat production were measured. Brain microdialysis samples were collected every 10 min, and these samples analyzed by HPLC for DA, norepinephrine (NA) and serotonin (5-HT). On the day of the exercising experiment, after 1h of baseline collections on the treadmill, rats received intraperitoneally 10 mg/kg of caffeine or saline. After 1h of administration, the animals were exercised until fatigue at a speed of 18 m/min, 5% grade on the treadmill in a normal environment (23°C). Results Acute injection of 10 mg/kg caffeine increased run time to fatigue (Saline: 104 ± 36 min; Caffeine: 139 ± 34 min; p < 0.05). The combination of caffeine and exercise increased Tcore, VO<sub>2</sub>, Ttail and the extracellular DA in the PO/AH. In addition, NA increased during exercise, neither caffeine nor exercise changed 5-HT. Discussion We observed acute injection of caffeine improved the endurance exercise performance which is consistent with the previous study (Ryu et al., 2001). We firstly evidenced that caffeine increased the DA release in the brain during exercise, and supported the hypothesis of Davis et al. (2003). The present results indicated that caffeine has a hyperthermic effect and a performance-enhancing effect, which is mediated by increasing the extracellular concentrations of DA in the PO/AH (Roelands et al., 2011). #### BRAIN GLYCOGEN SUPERCOMPENSATION FOLLOWING EXERCISE IS ENHANCED WITH GLUCOSE SUPPLEMENTATION: IMPLICATIONS FOR BRAIN GLYCOGEN LOADING

Matsui, T.1,2, Soya, H.1

*1: University of Tsukuba (Tsukuba, Japan), 2: JSPS Research Fellow (Tokyo, Japan)*

Brain glycogen supercompensation following exercise is enhanced with glucose supplementation: Implications for brain glycogen loading Matsui, T.1, 2, Soya, H.1 1: University of Tsukuba (Tsukuba, Japan), 2: JSPS Research Fellow (Tokyo, Japan) Introduction Muscle glycogen (Gly) loading, 3 days of a hyper-carbohydrate diet, enhances endurance performance due to mitigation of muscle fatigue through increasing muscle Gly levels in humans and rats (Pitsiladis & Maughan, 1999). Muscle Gly loading was established based on the muscle Gly increase (supercompensation, SC) following exercise through blood insulin effect with glucose supplementation (Bergstrom and Hultman, 1966). The brain contains glycogen in astrocytes, which store energy for neurons. We recently found that brain Gly SC also occurs following exercise (Matsui et al. 2012). Here, to establish brain Gly loading for mitigation of central fatigue, we aimed to clarify the effect of glucose supplementation on brain Gly SC following exercise. Methods Rats were separated into 4 groups (Sedentary-Saline (S-S), Sedentary-Glucose (S-G), Exercise-Saline (E-S), and Exercise-Glucose (E-G)), and exercised on a treadmill at 20 m/min to exhaustion. Sedentary groups of animals were placed on a stationary treadmill. Immediately after exhaustion, rats were injected with 50% glucose or saline (0.2 ml/300 g B.W.) into the jugular vein through a previously inserted catheter. At 6 hours post-exercise, the brain was fixed by high-power microwave irradiation (MI), which can momentarily inactivate glycogenolysis enzymes. Following MI, samples from the five brain loci (the cortex and hippocampus etc.), and soleus muscle were collected to determine Gly. Results Blood glucose and lactate levels did not change in all groups. Soleus muscle Gly levels in S-G and E-G increased by approximately 40% compared with S-S and E-S (p < 0.01). In the brain, Gly levels in E-S and E-G were approximately 30% higher than in S-S and S-G (p < 0.01), and Gly levels of the hypothalamus and brainstem in E-G were approximately 30% higher than E-S (p < 0.01). Blood insulin levels correlated positively with soleus muscle Gly levels (r = 0.39, p < 0.05), but did not correlate with brain Gly levels. Discussion we have provided novel evidence that glucose supplementation is not prerequisite for brain Gly SC following exercise in contrast to skeletal muscles. Further, blood insulin levels correlated positively with soleus muscle Gly levels, but did not correlate with brain Gly levels. Therefore, brain Gly SC following exercise should occur irrespective of blood insulin unlikely in the skeletal muscles. However, brain Gly SC following exercise is enhanced with glucose supplementation like in skeletal muscles, suggesting the possibility of brain Gly loading for the enhancement of endurance performance due to mitigation of central fatigue. ## EFFECTS OF INDUCED ALKALOSIS AND CAFFEINE SUPPLEMENTATION ON 2000 M ROWING PERFORMANCE

Carr, A.1, Gore, C.2, Dawson, B.1

1. *The University of Western Australia (Perth, Australia)* 2. *Australian Institute of Sport (Canberra, Australia)*

**Introduction** Short-term, high intensity exercise performance can be enhanced with caffeine supplementation (Jackman et al., 1996) and sodium bicarbonate ingestion (Carr et al., 2011). Both agents may therefore improve performance in 2000 m rowing events, which require 6-8 min efforts at a high percentage of VO<sub>2</sub>max (Hagerman et al., 1978). The purpose of this study was to determine the effect of ingested caffeine, sodium bicarbonate, and their combination on 2000 m performance (mean power, Watts), as well as on induced alkalosis (blood and urine pH and blood bicarbonate concentration [HCO<sub>3</sub><sup>-</sup>]), blood lactate concentration ([La<sup>-</sup>]), gastrointestinal symptoms, and rating of perceived exertion (RPE). **Methods** In a double-blind, crossover study, 8 well-trained rowers performed 2 x 2000 m rowing-ergometer baseline tests and 4 x 2000 m rowing-ergometer tests after ingesting 6 mg/kg caffeine, 0.3 g/kg body mass (BM) sodium bicarbonate, both supplements combined, or placebo. Capillary blood samples were collected pre-ingestion, pre-test, and post-test. Pairwise comparisons were made between protocols, and differences were interpreted in relation to the likelihood of exceeding the smallest-worthwhile-change thresholds for each variable. A likelihood of >75% was considered a substantial change (Hopkins et al., 2009). **Results** Caffeine elicited a substantial improvement in 2000 m mean power, with mean (± SD) values of 354 ± 67 Watts vs. placebo with 346 ± 61 Watts; but not for caffeine + bicarbonate combined (352 ± 63 Watts). Pre-test [HCO<sub>3</sub><sup>-</sup>] reached 29.2 ± 2.9 mmol/L with caffeine + bicarbonate and 29.1 ± 1.9 mmol/L with bicarbonate supplementation. There were substantial increases in pre-test [HCO<sub>3</sub><sup>-</sup>] and pH, as well as post-test urine pH after bicarbonate and caffeine + bicarbonate compared with placebo. All subjects reported side effects after ingesting bicarbonate. **Discussion** The major finding was an improvement of ~2% in 2000 m rowing performance with 6 mg/kg BM caffeine supplementation, consistent with previously reported enhancements for competitive rowers (Bruce et al., 2000). However, when caffeine is combined with sodium bicarbonate, gastrointestinal symptoms may prevent performance enhancement. **References** Bruce C, et al. ## EXERCISE IN VIRTUAL REALITY: LPP RESPONSE AND COGNITIVE PERFORMANCE

Vogt, T.1, Schneider, S.1, Herpers, R.2, Strüder, H.K.1

1 *German Sport University Cologne*, 2 *Bonn-Rhine-Sieg University of Applied Sciences*

**Introduction** In today's digital age virtual reality is ubiquitous and often used to train skills under safe conditions (e.g. flight simulation). Thus, it has previously been used in the field of sport and exercise science to investigate motor learning and cognitive function [1]. In addition, psycho-physiological research on event-related brain potentials, e.g. late positive potentials (LPP), allow for neural interpretation of cognitive performance [2]. However, little is actually known about underlying neurological processes of exercise-affected cognitive performance in virtual reality. Therefore this study aimed to investigate neurophysiological effects of virtual reality on cognitive performance in relation to exercise. **Methods** Using a bicycle ergometer, 12 healthy volunteers (27.75 ± 3.05 years, 177.17 ± 8.34 cm, 72.58 ± 8.01 kg) performed self-paced exercise (HR 140 ± 24.05 bpm) or passive drive (constant automatic 15 km/h) in immersive visualisation (3D) and non-immersive visualisation (2D). At the same time, mental arithmetics were performed to assess cognitive performance. Consecutive EEG was recorded on 32 positions according to the international 10-20 system [3]. Positive peak values of LPP amplitude and latency were exported and analysed [2]. **Results** Analysis of LPP measured during 3D revealed significant increases for LPP amplitude (p<0.01) and latency (p<0.001) compared to 2D, related to exercise. In contrast, cognitive performance decreased (p<0.01) during 3D compared to 2D. **Discussion** With respect to previously shown effects of visual attention focussing on LPP [2], in relation to exercise, greater LPP amplitudes as well as delayed latencies can be regarded as indicators for mental function speed [4]. As to the literature our findings give reason to believe that exercising during immersive visualisation has overstraining neurophysiological effects on cognitive performance, indicated in late positive potential response. Therefore training recommendations need to beware overstraining in virtual reality. **References** [1] Holden MK. ## ACUTE COGNITIVE WORKLOAD HAMPERS SUBJECTIVE RECOVERY, BUT DOES NOT ACCELERATE EXHAUSTION IN A MAXIMAL EFFORT TEST ON A TREADMILL

Sanchez-Delgado, G.1, Conde-Gonzalez, J.1, Perales, J.C.2, Pinar, M.I.1, Cárdenas, D.1, De Teresa-Galvan, C.3, Ruiz, J.R.1

1,2: *University of Granada (Spain)*, 3: *Junta de Andalucía (Spain)*

**Aim:** The aims of the present study were: (1) To investigate the effect of acute mental workload on time-to-exhaustion and perceived exertion in a concomitant maximum effort test on a treadmill. And, secondly, (2) to check whether physical effort and recovery modulated performance in the mental workload task. **Methods:** The physical load task was an incremental maximum effort test on a treadmill, followed by an 8-minutes recovery period. The mental workload task was a working memory task (N-back), with two modalities: a highly loading one (3-back), and a less loading one (1-back). 14 men (aged 18-22) went through 5 conditions, run in counterbalanced order: 1) Physical load/high mental workload; 2) Physical load/low mental workload; 3) Physical load/no mental workload; 4) No physical load-high mental workload; 5) No physical load-low mental workload. Conditions 1-3 were carried out on the treadmill, and varied in the degree of mental workload. Conditions 4 and 5 included no physical task, and varied in the degree of mental workload. We measured time-to-exhaustion in conditions 1, 2 and 3. After every two minutes, participants reported their perceived exertion (RPE-CR10). In conditions 1, 2, 4 and 5, we registered accuracy in the cognitive task. **Results:** Mental workload had no effect on time-to-exhaustion in conditions 1-3 (M=683.28s, 711.00s, and 681.07s; SE=32.47s, 36.44s, and 36.07s, respectively). Perceived exertion during effort did not differ across those conditions either (M=6.79, 6.93, and 6.52; SE=.43, .41, and .47). However, perceived exertion during recovery was affected by mental workload (M=2.21, 2.35, and 2.52; SE=.17, .21, and .23; F(2,26)=2.38, p<.01), and perceived exertion decreased more slowly as mental workload increased (F(10,130)=3.96, p<.01, for the relevant interaction). Physical effort hampered performance in the mental workload task. Considering conditions 1, 2, 4, and 5, the difference between physical load conditions (1, 2) and no physical load condi-

tions (3, 4) was maximal around the exhaustion point [17 points for the difference between conditions 4 and 5, and .27 points for the difference between conditions 1 and 2,  $F(7, 91)=4.03$ ,  $p<.01$ , for the corresponding interaction]. Performance in the mental workload task was always above chance. Conclusions: i) concomitant mental workload did not accelerate exhaustion, yet slowed subjective recovery down; ii) the presence of physical workload affected performance in a concomitant cognitive, mentally loading task, without causing complete disengagement from it. \*This research has been carried out in collaboration with the Centro Andaluz de Medicina Deportiva (Consejería de Turismo, Comercio y Deporte, Junta de Andalucía) and funded by a Iniciación a la investigación grant from the University of Granada, for the first author, and by MICINN grant (PSI2009-13133) for the third one.

### IMPACT OF STRENUOUS EXERCISE ON THE RELEASE OF CARDIAC BIOMARKERS

Le Goff, C., Melon, P., Kaux, J.F., Fillet, M., Chappelle J.P.

*University Hospital of Liège*

Background: Cardiac troponins (cTn) are considered as the best biomarkers for detection of myocardial cell injury and NT-proBNP as the best for the cardiac insufficiency. In this study, cTnT was measured by new commercially available high-sensitive methods in subjects undergoing the Maasmaraathon. Our aim was to compare cTnT and NT-proBNP levels in sportive subjects before and after a strenuous exercise. Materials and Methods: Twenty eight subjects (26 ♂, 42.5±11yo) underwent a race of 42.195 kilometers between Visé (Belgium) and Maastricht (The Netherlands). We drew blood samples before (T0), just after (T1) and three hours after the race (T3). For all patients, cTnT concentrations were measured by high sensitive methods (hsTnT, Roche Diagnostics) on heparin plasma. The NT-proBNP was also determined with the kit Roche on heparin plasma. The protocol was approved by the ethics committee of the University of Liège (Belgium). All subjects gave their informed consent. All statistical analyses were performed using Medcalc version 8.1 for Windows.  $p$ -value  $<0.01$  was regarded as statistically significant. Results and discussion: A significant difference between hsTnT concentrations at T0 and T1 ( $p<0.0001$ ) was measured as well as between T0 and T3 ( $p<0.001$ ) for NT-proBNP, but not between T1 and T3. This observation appeared only after a strenuous exercise but today this type of exercise is not reproduced easier in a laboratory of sport. Moreover, at this moment, nobody knows if these observations would have cardiac consequences at long terms. Conclusions: Measurement of cardiac troponins by high sensitive methods allows detecting significant release of biomarkers from the heart during exercise. The levels of NT-proBNP were found significantly increased but in less extent than TnTs. We think that the TnTs could be an interesting marker in the future to help sport medicine to detect risk of developing a cardiac problem.

### PS-PL01 Cycling Economy: From Performance to Business

#### PROFESSIONAL ROAD CYCLING: A BUSINESS NETWORK PERSPECTIVE

Lagae, W., Dejonghe, T.

*KU Leuven - Lessius University College Antwerp*

Professional road cycling: a business network perspective Although cycling is (1) a very popular sport in core European countries, (2) is developing in other countries and (3) was one of the first commercial sports to be practised professionally, the business of professional road cycling has been insufficiently researched (Brewer, 2002, Rebeggiani & Tondani, 2008, Benijts, et al, 2011). The product 'professional road cycling' is an individual sport practiced in teams, rather capital intensive, outdoor sport organized on public ground. Professional cycling is built around the world calendar of the Union Cycliste International, that consists of a non-homogeneous set of one-day and stage races. An additional peculiarity, especially of relevance in media coverage and television broadcasts, is that teams are labelled through the name(s) of the title sponsor. Teams depend, within their business-to-business environment, strongly on sport sponsorship deals as revenues from television rights, prize money and gate revenues are limited (Lagae, 2005). In addition, road cycling is vulnerable to doping, which has become a more prominent issue for corporate sponsors, who are entitled to cancel their barter trade or sport sponsoring agreements if evidence (and sometimes only indication of speculative nature) is found of either a team's or a rider's involvement in doping. Cycling is also characterized by a large and heterogeneous set of stakeholders with various interdependencies. The influence of stakeholders on the governance of cycling, ownership and distribution of television and marketing rights and anti-doping policy are hot topics (Morrow & Idle, 2008; Benijts, T. & Lagae, W. (2012). References Benijts, T. and Lagae, W. #### WINNING THE TOUR DE FRANCE: A SPORT SCIENCE PERSPECTIVE

Martin, D.

*Australian Institute of Sport and Edith Cowan University*

Introduction The Tour de France is the most popular bike race in the world attracting ~15million spectators annually. In 2011 cyclists raced 3,430 km (1100-1200km per week) in 3wks. Of the 198 professional cyclist that began the race only 167 finished. For the first time, the winner of the 2011 Tour was an Australia (CE). From a sport science perspective the story of how a competitive teenage mountain biker became a Tour de France Champion is interesting because CE was involved with sport science teams throughout his development; first at the Aus-

tralian Institute of Sport and later with the MAPEI Sport Centre in Italy. The long-term relationship between CE and sport science allows many interesting questions to be addressed such as What is the physiological profile of a Tour de France Champion? What are the physiological demands of competition? What type of physical training leads to success? Physiology - Between 18-24yrs CE can be characterized as: 62-68kg; 172-173cm; 380-455 W and 6.1-7.3 W.kg<sup>-1</sup> at VO<sub>2</sub>pk; 4.59-5.65 L.min<sup>-1</sup> and 73-87 ml.kg<sup>-1</sup>.min<sup>-1</sup> VO<sub>2</sub>pk. Economy (mean±SD; range) was 80.2±1.9; 77.5-82.5 W.(VO<sub>2</sub> L.min<sup>-1</sup>)-1 or 401±10; 387-413W at 5 L.min<sup>-1</sup> VO<sub>2</sub>. GE was 22.6 ±0.6; 21.8-23.4% and DE was 23.6±1.1; 21.9-25.4%. Maximum Mean Power for 30minutes (MMP30min) was consistently 390-400W or 6.0-6.3 W.kg<sup>-1</sup>. These results were amongst the highest values recorded within the population of AIS cycling scholarship holders. Additionally, CE's aerobic power and his gross efficiency compared favourably to data published on other Tour de France Champions. Demands of Competition - CE frequently raced with a calibrated cycling power meter providing insight into physical demands of competition. In 1999, CE produced >6 W.kg<sup>-1</sup> for more than 40min when climbing to victory in the Tour of Tasmania. Research examining energy intake and energy expenditure during stage races provided rationale for feeding strategies and recovery practices. Early on, CE revealed he could perform well in Time Trials and Hill Climbs. Training - As a young AIS scholarship holder CE engaged in a high volume training program (~30,000-35,000k per year). Training was primarily composed of long slow distance (4-6hr rides), "strength endurance" intervals (low cadence hill climbing), threshold intervals and MTB racing. CE was exposed to altitude training, resistance training, heat acclimatisation, and tapering. CE had a high capacity for training volume and possessed a very competitive attitude and a desire to learn. Overall, CE was exposed to a supportive but incredibly competitive and challenging environment. Because other professional cyclists possess physiological traits similar to CE, it is likely environmental influences contributed substantially to his recent victory in the Tour de France.

### IS-PM11 Skeletal Muscle Stem Cells

---

#### **SKELETAL MUSCLE STEM CELLS: AN INTRODUCTION**

Kadi, F.

*Institution of Health and Medicine*

The systemic and local tissue benefits of exercise are generally accepted, although sometimes poorly understood. Muscle satellite cells are largely responsible for the regenerative capacity of skeletal muscle. In response to external stimuli, such as muscle loading, the activation of satellite cells is followed by (a) cellular proliferative expansion, which is necessary to maintain adequate pool of satellite cells for future rounds of regeneration, and (b) differentiation towards a myogenic lineage. Within the satellite cell niche, critical growth factors and support cells interact with satellite cells. The exact signals and pathways involved in the exercise-related satellite cell activation and differentiation are not well defined. The exact role of satellite cell proliferation in the initial stages of muscle hypertrophy deserves further attention.

#### **FIBER TYPE SPECIFICITY; THE ROLE OF SATELLITE CELLS IN THE SKELETAL MUSCLE ADAPTIVE RESPONSE**

Verdijk, L.B.

*Maastricht University Medical Centre+*

The regenerative capacity of skeletal muscle tissue depends on a pool of undifferentiated myogenic precursor cells, known as satellite cells. In adult muscle, satellite cells typically remain quiescent in their niche between the basal lamina and the sarcolemma. However, in response to injury and/or exercise stimuli, satellite cells become activated. After proliferation, satellite cells can fuse together with existing myofibers, or return to quiescence to replenish the resident pool of muscle stem cells by self-renewal. Changes in satellite cell content as well as satellite cell function have been suggested to represent key factors in regulating the skeletal muscle adaptive response to various stimuli, such as exercise, but also in response to different (pathological) conditions, such as aging and/or disuse. At present, much of the knowledge on satellite cell biology and their role in skeletal muscle fiber regeneration and growth stems from extensive *in vitro* and animal work. However, the molecular mechanisms that control satellite cell activation, proliferation and differentiation *in vivo* in humans remain to be elucidated. Previous research has shown differences in satellite cell content in humans depending on age, training status, and underlying disease. Few studies have also assessed satellite cell activation following exercise, using various markers indicative of different stages of the cell cycle (e.g. Ki67, MyoD, DLK1). However, the vast majority of studies investigating satellite cells in humans have typically assessed mixed muscle tissue without differentiating between type I and II muscle fibers. It has been well-established that the myocellular response to exercise and aging occurs in a muscle fiber type specific manner. Therefore, recent work in the field of satellite cell plasticity tends to focus more on muscle fiber type specificity. Our lab as well as others have shown that type II muscle fiber atrophy in the elderly is accompanied by a type II muscle fiber specific reduction in satellite cell content. More recently, we reported that 12 wk resistance type exercise training in elderly men results in specific hypertrophy of the type II muscle fibers and a concomitant increase in type II muscle fiber satellite cell content. We have now begun to assess satellite cell content as well as satellite cell activation, proliferation and differentiation status in a fiber type specific manner in response to different modes of physical activity and/or disuse in various populations. We believe that this work will further elucidate the role of satellite cells in regulating the fiber type specific skeletal muscle adaptive response to exercise and to various conditions of skeletal muscle atrophy and/or disuse in humans.

#### **REGULATION OF HUMAN MUSCLE STEM CELLS FOLLOWING EXERCISE**

Parise, G.

*McMaster University*

The role of muscle stem cells (satellite cells) in promoting muscle growth and adaptation in humans has largely been understudied. Nonetheless, excellent work has been reported by groups from around the world. The fact that a satellite cell response is triggered following an acute bout of exercise is generally accepted as fact. What remains a significant point of contention is whether or not satellite cells play a role in promoting growth in adulthood. Additionally, very little is known about the regulatory mechanisms that govern satellite cell function and fate. Over the last five years we and others have made a significant effort to reveal regulatory mechanisms that may govern satellite cell activation, proliferation and differentiation in humans. Modest progress has been made, however the regulatory mechanisms that drive the satellite cell response in humans are now being revealed. To date we have identified key roles for myostatin in the activation of satellite cells following exercise and IL6 in the proliferation of satellite cells. We have also identified how these factors are affected by age in their ability to promote satellite cell activation and proliferation. Collectively, we are just beginning to appreciate the complex regulatory mechanisms that govern human satellite cell function.

### OP-SH02 Sport and Exercise Psychology

#### COACH-PROVIDED AUTONOMY SUPPORT, INTRINSIC MOTIVATION AND ENJOYMENT AS PREDICTORS OF OBJECTIVELY MEASURED PHYSICAL ACTIVITY LEVELS IN GRASSROOTS FOOTBALLERS.

Fenton, S.A.M., Duda, J.L.I., Barrett, T.G.I., Quedsted, E.I

*1: University of Birmingham*

Introduction: Children who spend less time in moderate to vigorous activity (MVPA) are at higher risk for developing obesity and its associated co-morbidities. Therefore, it is important to understand factors that are predictive of children's physical activity patterns. Organised youth sport is a potential vehicle through which MVPA can be increased in children and adolescents. Guided by self-determination theory, this study tested a model which assumed links between perceptions of autonomy support provision by the coach, to the level of intrinsic motivation and enjoyment in grassroots footballers. These latter variables were examined in relationship to objectively measured MVPA and time spent engaged in sedentary behaviour (SB). Method: 92 male grassroots footballers aged 10-16 were recruited from 20 football clubs. All participants completed a multi-section questionnaire assessing their perceptions of the coach created climate (via a newly developed measure, pulling from previously validated measures of the psychological environment), intrinsic motivation (BRSQ-2) and their interest and enjoyment as related to football (IMI subscale). Measures of height and weight were taken (and BMI calculated) and players were asked to wear an accelerometer (GT3X; Actigraph) for 7 days. Results: Controlling for BMI, path analysis indicated players' perceptions of coach provided autonomy support to positively predict intrinsic motivation ( $\beta = .422, p < .001$ ) which in turn predicted enjoyment ( $\beta = .712, p < .001$ ). Enjoyment was found to be positively associated with overall levels of MVPA ( $\beta = .341, p < .001$ ) and negatively relate to SB ( $\beta = -.354, p < .001$ ). Mediation analysis demonstrated enjoyment fully mediated the relationship between intrinsic motivation and MVPA ( $z = 2.02, p < .05$ ) and SB ( $z = -2.22, p < .05$ ). Discussion: Results demonstrate that players who perceive their coaching environment to be more autonomy supportive are more likely to be intrinsically motivated to take part in sport, experience higher levels of enjoyment, and be more active in their daily lives (which includes their football participation). Given that physical activity habits formed in childhood often carry over into adulthood, it seems prudent to identify factors which can contribute to children leading a more physically active lifestyle. The development of theory-based interventions to foster the provision of autonomy support and enhanced intrinsic reasons for engagement, which can be implemented within organised youth sport, present a potential avenue through which overall physical activity levels of young people can be increased.

#### THE EFFECT OF CHALLENGE AND THREAT STATES ON PERFORMANCE: AN EXAMINATION OF POTENTIAL MECHANISMS

Moore, L.

*University of Exeter*

THE EFFECT OF CHALLENGE AND THREAT STATES ON PERFORMANCE: AN EXAMINATION OF POTENTIAL MECHANISMS Moore, L.J., Vine, S.J., Wilson, M.R., & Freeman, P. University of Exeter Introduction Challenge and threat states have been shown to predict future 'real-world' performance, with a challenge state resulting in superior performance relative to a threat state (Blascovich et al., 2004). However, no research has examined the immediate effect of these states on experimental performance. Therefore, the present study examined the influence of challenge and threat states on golf putting performance and the potential mechanisms through which these states operate (attentional, kinematic, and physiological). Methods One hundred and twenty seven participants (mean age = 19.47, SD = 2.48) were randomly assigned to a challenge or threat group. Challenge and threat states were manipulated via task instructions and were assessed using cardiovascular (challenge and threat index; Blascovich et al., 2004) and self-report (cognitive appraisal ratio; Tomaka et al., 1993) measures. Participants performed six golf putts whilst performance (mean radial error), gaze (quiet eye duration), putting kinematics (clubhead acceleration), and muscle activity (extensor carpi radialis) were continuously recorded. Results Results supported the effectiveness of the manipulation. The challenge group reported a ratio score less than one, reflecting a challenge state ( $M = 0.76, SD = 0.39$ ), whilst the threat group reported a ratio score greater than one, reflecting a threat state ( $M = 1.39, SD = 0.62$ ). Further, the challenge group exhibited a larger index value than the threat group, indicating greater challenge ( $M = 0.43, SD = 2.15$  vs.  $M = -0.44, SD = 1.69$ ). The challenge group displayed lower mean radial error ( $p < .001$ ), longer quiet eye durations ( $p < .05$ ), less clubhead acceleration (all  $ps < .05$ ), and less muscle activity (both  $p < .05$ ) than the threat group. Mediation analyses confirmed that only putting kinematic variables mediated the relationship between group and mean radial error. Discussion These results suggest that a performer's pre-competition psychophysiological state impacts upon their subsequent performance, with a challenge state likely to result in better performance than a threat state. Moreover, mediation results imply that these states impact performance at a kinematic level, influencing the quality of task-related movements. Thus, coaches and applied practitioners should encourage performers to perceive upcoming competitions as a challenge rather than a threat. #### THINKING TOO MUCH WHEN FACING PRESSURE? THE STORY OF DECISION REINVESTMENT

Laborde, S.

*German Sport University*

Thinking too much when facing pressure? The story of decision reinvestment S. Laborde German Sport University, Cologne, Germany University of Caen, France The role of decision reinvestment on performance breakdown under pressure was investigated in two studies, combining the field and the lab. Study 1. The aim of this study was to explore the relationship between decision reinvestment with stress and coping appraisals. From an initial screening of 243 regional handball players, 100 players were selected, and were divided into four

groups according to their gender (male vs. female) and to their reinvestment score (high vs. low). Their coping and stress appraisals were assessed during three competitions. Results showed that high reinvesters (HR) players perceive a stress intensity similar to low reinvesters (LR) players, but that they have a lower perception of stressor controllability, coping effectiveness and subjective performance than their LR counterparts. No differences were found in the use of coping strategies between HR and LR players. The tendency to choke under pressure of HR players is discussed according to the saturation of their working memory. Study 1 had two main limitations: 1) the physiological parameters linked with the stress and coping appraisals were not assessed; 2) the subjective performance measure does not reveal the underlying mechanisms explaining the influence of decision reinvestment on performance. Study 2 was designed to address these limitations. Study 2. The aim of this study was to explore the decision-making component of performance through the option-generation paradigm, as well as to assess the physiological reaction to stress based on heart rate variability. Thirty regional handball players (Mean=23.3 years, age range = 17-31 years) took part in this study. In a within-subject design, they were asked to complete an option-generation task with 31 3D videos in two conditions, low pressure and high pressure. In addition players were asked to fill in the decision-specific reinvestment scale, and were attributed after a median split to either the HR or the LR group. Results indicated that the pressure manipulation was successful. In the low pressure condition, no differences in decision-making performance were observed between LR and HR players, Wilks' Lambda=.801  $F(6, 23)=.954, p>.05$ . When comparing the low pressure and high pressure condition, a MANOVA indicated that the overall decision-making performance decreased significantly more in the HR group in comparison to the LR group, Wilks' Lambda=.583,  $F(6, 23)=2.740, p=.037, \eta^2=.42$ . Study 2 showed that decision reinvestment has an influence on the option-generation process of the athlete, and that this influence might be associated to a specific physiological activity under pressure. Findings are discussed according to the Thayer's neurovisceral integration model and to the Take-the-First heuristic.

### **PREDICTORS OF INTRA-INDIVIDUAL CHANGE IN THE PSYCHOLOGICAL DEVELOPMENT OF DISADVANTAGED YOUTH OVER THE COURSE OF AN EDUCATIONAL SPORTS PROGRAMME**

Cowan, D.T., Taylor, I.M., Baker, J.S.

*University of the West of Scotland*

**Introduction** The sports context represents a potentially fruitful vehicle for positive youth development to occur (Danish et al., 2005), however, merely the participation in organised sports programmes is not sufficient to facilitate positive psycho-social growth. Rather, the quality of adult mentoring within such programmes, usually carried out by the sports coach, is assumed to play a central role in this process (Vella et al., 2011). Nonetheless, the exploration of the specific interpersonal ingredients within the coach-participant relationship required to foster positive developmental outcomes is still in its infancy. Grounded in self-determination theory (Ryan & Deci, 2000), the purpose of this study was to longitudinally examine the relationships among disadvantage youth sports programme attendees' perceptions of the coach interpersonal environment, their own psychological need satisfaction, and three important developmental outcomes; namely self-esteem, resiliency, and goal setting. **Methods** 26 disadvantaged youth completed a weekly multi-section questionnaire over the course of the programme measuring perceptions of coach interpersonal styles, psychological need satisfaction, self-esteem, resiliency, and goal-setting. Results Multilevel growth models revealed that participants' self-esteem, resiliency, and goal setting increased over the course of the programme. Increases in relatedness need satisfaction beyond participants normal levels was positively associated with the three developmental outcomes. Further, increased perceptions of socio-emotionally involved coaching styles was the most consistent predictor of all three psychological needs (i.e., autonomy, competence, and relatedness), compared to autonomy supportive and structured coaching styles. **Discussion** This study contributes to the existing literature by suggesting theoretically sound mechanisms required to elicit change in important positive youth development outcomes amongst disadvantaged youth. From a theoretical standpoint, the role of interpersonal involvement in future self-determination theory-based interventions is emphasised. **References** Danish, S., Forneris, T., & Wallace I. ### **THE ASSOCIATION BETWEEN EXERCISE ATTITUDES AND EXERCISE BEHAVIOR PARTLY REFLECTS GENETIC EFFECTS UNDERLYING BOTH ATTITUDES AND BEHAVIOR**

Huppertz, C., Bartels, M., Jansen, I.E., Boomsma, D.I., Willemsen, G., de Moor, M.H.M., de Geus, E.J.C.

*Vrije Universiteit Amsterdam*

**AIM:** Based on social cognitive models of health behaviors it has been proposed that individual differences in leisure time exercise behavior are strongly determined by the perceived benefits and barriers to an individual. At first sight this appears to contrast with the results of large scale twin studies showing a major influence of genetic factors on exercise behavior in adults. We attempt to unite these findings by testing for potential underlying factors affecting both actual exercise behavior as well as the perception of its benefits and barriers. **METHODS:** Survey data were obtained from 5153 twins and siblings (18-50 years) who participate in research of the Netherlands Twin Register. Weekly MET hours spent on leisure time exercise behavior were assessed as well as perceived benefits of and barriers to exercising. A bivariate genetic model was fitted to the data in openMx, to estimate heritabilities and genetic correlations. **RESULTS:** Significant heritability was found for exercise behavior ( $h^2=47\%$ ), perceived benefits ( $h^2=26\%$ ) and the 5 main perceived barriers derived from a factor analysis: Facilities/Support ( $h^2=46\%$ ), Time Barriers ( $h^2=30\%$ ), Energy/Discipline ( $h^2=41\%$ ), Physical self-efficacy ( $h^2=44\%$ ), and Pleasure/Interest ( $h^2=47\%$ ). Attitudes were significantly associated with exercise behavior (for benefits:  $r=.33$ ; for the 5 barriers  $r$  ranged between  $-.46$  and  $-.21$ ) and explained 36% of its variance. Bivariate genetic modeling showed that for all six attitudes, the genetic correlations (range:  $-.73$  to  $.71$ ) and the unique environmental correlations ( $-.25$  to  $.21$ ) with exercise behavior were significant. **CONCLUSION:** We conclude that underlying genetic factors partly explain the association between exercise attitudes and exercise behavior. Potential mechanisms will be discussed.

### **IMPACT OF THRESHOLD MESSAGES ON THE PERCEIVED RELATIONSHIP BETWEEN PHYSICAL ACTIVITY AND HEALTH**

Knox, E.C., Webb, O.J.

*Loughborough University*

**Introduction** Mass media campaigns promoting physical activity typically recommend a 'threshold' level of participation (i.e. 150 minutes/week). Research into environmental hazards (e.g. radon gas) indicates that thresholds disrupt individuals' understanding of the

dose-response relationship between an exposure/behaviour and resultant health effects (Johnson, 2003). The risks/benefits of behavior can be perceived as negligible if performed below the threshold yet substantial where the threshold is met, producing a 'discontinuous' relationship between behaviour and perceived effects. This is the first study to explore if threshold messages produce discontinuity effects for physical activity. Method A convenience sample (N=825) was approached in a UK town centre and asked to participate in a structured interview. Individuals either received a 'threshold' message ("Regular physical activity protects your health. Each week adults should accumulate 150 minutes") or control message ("Regular physical activity protects your health. Each week adults should engage as regularly as possible"). Participants used a 15-point scale (-7 to +7) to report the health effects that they perceived from seven durations of physical activity which were presented in counterbalanced order (10, 70, 130, 150, 170, 230, and 290 minutes/week). For each duration, ANOVA assessed group differences in perception ratings. Additional moderators were examined, including demographics and current physical activity level. Results The control group showed an appropriate curvilinear dose-response association between duration and perceived health effects. At the threshold and above, perception ratings were consistent across groups. Conversely, for durations below 150 minutes perceived health effects were significantly lower in the threshold group versus controls (10 mins, -0.9 vs. -0.1; 70 minutes, +1.7 vs. +2.5; 130 minutes, +3.2 vs. +3.8, all  $p < .05$ ). As threshold recipients' perceptions 'caught up' with controls at the 150 minute mark they produced a discontinuous 's-shaped' association between duration and perceived health effects. Discussion Individuals receiving a threshold message perceived lower benefits from modest physical activity regimens. Evidence suggests that small behavioral changes are most feasible (e.g. stair use at work) and can improve specific health markers (e.g. fat mass) even if individuals' overall physical activity levels remain below 150 minutes/week (Meyer et al., 2010). Hence, it is vital that campaigns convey the value of accruing even small amounts of additional physical activity. Current threshold messages appear problematic in this regard and may not, therefore, deliver optimal behavior change. References Johnson BB (2003). Risk Anal, 23 (1), 91-103. Meyer P, et al (2010). ## Oral presentations

### OP-BN02 Gait and running patterns

#### ASSOCIATIONS BETWEEN DIFFERENT GAIT STRATEGIES AND KNEE ADDUCTION MOMENT

Kulmala, J.P., Äyrämö, S., Avela, J.

*University of Jyväskylä*

**Introduction** The gait-induced knee adduction moment reflects mechanical loading condition of the medial compartment of the knee joint. High knee adduction moments are linked with the development and progression of degenerative joint diseases such as knee osteoarthritis (1). Inter-subject variability in knee extensor-flexor moment pattern has been recognized in previous studies (2,3). However, only joint moments in the sagittal plane have been reported in these studies and therefore the relationship between knee extension-flexion moment pattern and knee adduction moment remains unknown. Therefore, the purpose of this study was to cluster subjects to different groups based on their knee joint moment profiles and then examine whether different gait patterns are associated with atypically high knee adduction moments. **Methods** Twenty-four healthy men underwent 3D gait analysis. Inverse dynamics was used to compute external joint moments. The subjects were divided into several groups using the K-means method based on the magnitude of knee joint moments. Kruskal-Wallis and Mann-Whitney with bonferroni correction were used to detect univariate group differences. **Results** Three clusters with clearly distinct knee joint moment profiles were identified. In the frontal plane, the subjects in cluster 1 (C1, n=11) had 43% and 44% lower peak knee adduction moment compared to cluster 2 (C2, n=7,  $P < 0.01$ ) and cluster 3 (C3, n=6,  $P < 0.05$ ), respectively. In the sagittal plane, C2 produced 33% higher knee flexion moment compared to C1 ( $P < 0.05$ ) and 59% when compared to C3 ( $P < 0.01$ ). The opposite pattern was present in the knee extension moment where C3 produced 76% and 44% higher peak values than the subjects in C2 ( $P < 0.01$ ) and C3 ( $P < 0.01$ ), respectively. **Discussion** To the best of our knowledge, this is the first study to use cluster analyses in order to show an association between the knee sagittal plane moment profile and magnitude of the knee adduction moment during the stance phase of gait. Similarly to previous studies, distinct knee moment patterns in the sagittal plane were found. Interestingly, those subjects who showed atypically high knee flexion (C2) or extension (C3) moments also produced higher knee adduction moments compared to the general gait pattern (C1). These findings suggest that both knee extensor and flexor dominated walking strategies lead to high knee medial compartment loading and thus may increase the risk of knee joint osteoarthritis. **References** 1) Andriacchi et al. 2004. #### EFFECT OF MIDSOLE THICKNESS ON RUNNING PATTERNS

Chambon, N.1,2, Delattre, N.1, Berton, E.2, Rao, G.2

*1: Oxylane Research (Villeneuve d'Ascq, France), 2: ISM (Marseille, France)*

**Introduction** Since emergence of highly cushioning shoes, the natural running pattern has changed. Observing habitually barefoot runners, Lieberman et al. (2010) showed that they tended to impact the ground with the forefoot and create less impact force. Using kinematics and dynamics variables, Hamill et al. (2011) showed that short-term adaptations when running barefoot differ from running with shoes of different thicknesses and higher midsole thickness at the heel than the forefoot (4mm drop). Therefore, this study aimed at analysing complete short terms adaptations (kinematics, dynamics, and muscular) occurring when habitually shod runners ran barefoot or with shoes of different thicknesses but no drop. **Methods** Fifteen subjects ran barefoot and with 5 different conditions of shoe sole thickness: 0mm, 2mm, 4mm, 8mm and 16mm. All shoes had identical upper, and no drop. In each condition, subjects performed 5 trials at 3.3m/s on a track after 3 minutes of adaptation on a treadmill at the same speed. Analog data (Kistler force plate, Endevco accelerometer and Delsys EMG electrodes over 11 lower limb muscles) were sampled at 2000Hz while segments positions (8 Vicon T40 cameras) were sampled at 125Hz. **Results** Results shown that stance phase duration was shorter for barefoot condition and 0mm shoe. In terms of kinematics and muscular activity, most changes took place at ankle joint with barefoot condition differing greatly from the others. At initial contact, the ankle joint was plantar flexed while running barefoot ( $-1.5 \pm 8.2$ deg) but dorsi flexed for all the shoes ( $9.7 \pm 9.3$ deg). No condition showed a rear-foot strike even if barefoot condition showed the lowest foot/floor angle. There was no effect on knee and hip

flexion angles. Pre-activation of gastrocnemius was most important for barefoot condition than for shoe conditions. However no difference was observed on tibial acceleration and vertical ground reaction force (VGRF) between conditions (including barefoot). Discussion While opposed to Hamill et al. (2011), the absence of difference between shod and barefoot conditions on VGRF and tibial acceleration can be explained by the absence of drop in our test shoes. Presence of a drop seems to modify the striking pattern. Our results also showed that kinematics and muscular short-term adaptations took place mainly at the ankle joint. These local adaptations were sufficient to accommodate for the absence of cushioning. A longitudinal protocol is needed to investigate whether habitually shod runner could retrieve a natural running pattern similar to that of habitually barefoot runners following long-term adaptation. References Lieberman DE, et al. (2010). *Nature*, 463(7280), 531-535. Hamill J, et al. (2011). *Footwear Science*, 3(1), 33-40.

### **BODY CENTER OF MASS TRAJECTORY SHOWS HOW RACE WALKERS ELUDE "FROUDE LAW"**

Pavei, G.

*Università degli Studi di Milano*

BODY CENTER OF MASS TRAJECTORY SHOWS HOW RACE WALKERS ELUDE "FROUDE LAW" Pavei, G.1, Cazzola, D.1, La Torre, A.2, Minetti, A.E.1 1: Human Physiology Department, University of Milan, 2: Department of Sport, Nutrition and Health Sciences, University of Milan. Introduction Froude number,  $Fr = v^2/gl$  (where  $v$  is the speed of progression (m/s),  $g$  is gravity acceleration ( $9.81\text{m/s}^2$ ),  $l$  is the leg length (m)) is used to compare dynamic similar gait (Alexander, 1989).  $Fr=1$  defines the maximal speed value for pendulum-like locomotion such as walking. Race Walking is an Olympic discipline, which is supposed to be the fastest expression of walking. Assuming athletes' leg length  $l = 1\text{m}$ , the maximal speed according to "Froude Law" is  $3.13\text{m/s}$  much lower than race pace (20km:  $4.16\text{m/s}$ ; 50km:  $3.61\text{m/s}$ ). Alexander (1984) suggested a possible explanation of this discrepancy by differences in kinematic: he suggested that the straight knee at heel strike and the back movements would maximise the radius of the inverted pendular motion. The aim of the study was to analyse the race walkers' Body Center of Mass (BCoM) pattern in order to find how they elude the "Froude Law". Methods 16 Athletes race-walked on a treadmill at incremental speed  $2.77\text{--}4.72\text{m/s}$  at a step of  $0.138\text{m/s}$  every minute. Kinematic acquisitions were made by 8 Vicon 1.3Mp Cameras at  $300\text{Hz}$ . The mathematical description of the BCoM pattern was done with 10 harmonics Fourier Analysis and Lissajous Contour as explain by Minetti and co-workers (2011) with a custom-written software in LabVIEW (National Instrument, USA). Results Athletes' leg length average  $0.93\pm 0.04\text{m}$ , which allowed for a theoretical ( $Fr=1$ ) maximal speed of  $3.02\text{m/s}$ . The Lissajous Contour of the BCoM during race walking showed a characteristic pattern different both from walking and running: during single support BCoM reached the lowest position, while it is highest during double support. At velocity  $\leq 4.4\text{m/s}$  two forward 'protrusions' were present in the lowest part of contour. Discussion The pattern of race walkers' BCoM was found to be dynamically opposite when compared to walking. In fact, during the single support phase of normal walking, BCoM shows the lowest speed and reaches the highest point of a contour resembling a circumference arc, as in an inverted pendulum. Also, the forward 'protrusions' of race walk contours indicate that speed increases in the middle of the support phase. This confirms that race walk rules constraint to adopt a trajectory different from walking but, by deviating from a circle arc, there is no issue of extending the radius. Although a variation of walking, race walking is not a pendulum-like gait, thus it does not undergo the "Froude Law". References Alexander RM. (1984). *American Scientist*. 72. 348-354. Alexander RM. ### **CONTROL OF PROXIMAL-TO-DISTAL AND DISTAL-TO-PROXIMAL RESISTIVE INTERACTION TORQUE DURING RHYTHMIC MULTI-JOINT COORDINATION**

Stosic, J.

*Centre for Sensorimotor Neuroscience, The University of Queensland, Australia*

When multi-joint movements are coordinated, interaction torques inevitably emerge between adjacent segments in both the proximal-to-distal (PD IT) and distal-to proximal direction (DP IT). Whether their control is the same is difficult to evaluate because mass-segmental differences between the two segments and the simultaneous occurrence of IT in two directions of either assistive (in the direction of movement) or resistive (that opposes the movement) type of IT. For the purpose of the present study, two-degrees of freedom (DOF) elbow joint complex that allows movement at two independent DOF, flexion-extension (FE) and supination-pronation (SP) was selected to test the effect of resistive PD and DP IT on coordination stability during rhythmic coordination. This part of the human body was chosen because natural IT is negligible in each of two DOF when either flexion-extension (FE) or supination-pronation (SP) is produced and therefore allows for artificial IT manipulation using the robot motor arm. Eight subjects were asked to produce in-phase movement pattern (simultaneous FS followed by EPI), while artificial IT promoted 90 degrees out of phase (i.e. supination was late in relation to flexion for PD IT, while extension was late in relation to pronation for DP IT). The level of interaction torque was equalized across DOF to account for segmental-mass differences in FE and SP DOF. This was achieved by evaluating the effort that IT causes when it is artificially induced on SP DOF as a function of FE movement, and vice versa (i.e. the same effort was targeted for both IT while subjects produced in-phase pattern). The effort was expressed as the percentage of maximal EMG values that were obtained from four muscles (biceps, triceps, brachioradialis, and pronator teres) during isometric MVC in eight directions: F, E, S, P and their combinations. To validate EMG procedure additional four levels of IT were used (80 %, 90 %, 110 % and 120 % of the baseline) across both IT directions (1 block -10 conditions fully randomized). In total, subjects produced 2 blocks (20 trials) of in-phase pattern. The main finding of the study is that there were no differences in coordination stability between PD and DP IT patterns. It may be that neural control of the two IT does not differ, since possible control differences due mechanical factors are neutralized by setting the same effort across both DOF. Alternatively, given that range of IT torques was small (baseline IT was set to represent only 10 % more of the EMG obtained in performing free in-phase pattern (i.e. without IT)), the question remains whether there would be differences in coordination stability of PD IT and DP IT if the broader range of IT was used.

### **THE IMPACT OF DIFFERENT FOOTWEAR ON RUNNING KINEMATICS AND JUMPING STABILIZATION IN YOUNG HEALTHY ATHLETES**

Zech, A., Argubi-Wollesen, A., Rahlf, A.L., Mattes, K., Reer, R.

*University of Hamburg*

Introduction Differences between barefoot and footwear situations have been shown for running kinematics or vertical force impact (e.g. Liebermann et al 2010). Based on the hypothesis that barefoot running is more flexible and natural as well as less injurious, the development of minimal (barefoot-like) footwear has recently gained increasing attention. The objective of this study was to compare running kinematics and jumping stabilization time between barefoot and different footwear situations (running socks, Nike free 3.0 and Asics).

**Methods** The trial was based on a randomized study design. 35 healthy athletes with an experience in long distance running volunteered for participation. The tests were performed under barefoot, running socks (Leguano® barefoot shoes), Nike free 3.0® and Asics GT-2160® conditions in randomized order. The test protocol included two minutes of treadmill running at 8, 10 and 12 km·h<sup>-1</sup> in each condition. 3-D kinematic analysis (Vicon Motion Systems) was used to assess ankle and knee joint kinematics as well as cadence and step length during running. Afterwards, the participants performed a unilateral jump-landing task on a force plate in which time to stabilization (TTS) was assessed. Differences between shoe conditions were analyzed by using ANOVA. Results Significant differences ( $p < 0.001$ ) between all footwear situations were found for ankle and knee kinematics under the three speed conditions. The ankle dorsiflexion at foot strike was highest during barefoot running (e.g. 12 km·h<sup>-1</sup>:  $6.62 \pm 5.65^\circ$ ), followed by running socks ( $8.42 \pm 6.01^\circ$ ), Nike free 3.0 ( $11.00 \pm 4.79^\circ$ ) and Asics ( $12.3 \pm 5.1^\circ$ ). Similar results were shown for knee flexion at foot strike as well as cadence and step length during running. No significant differences between all footwear conditions were found for TTS during jump landing. **Conclusions** The results showed that with increasing flexibility of footwear there are less differences to barefoot running kinematics. The most barefoot-like condition was shown for the running socks followed by the Nike free 3.0 and Asics. However, the footwear situation seems to have no influence on sensorimotor control during jump landing. Lieberman DE, Venkadesan M, Werbel WA, Daoud AI, D'Andrea S, Davis IS, Mang'eni RO, Pitsiladis Y. Foot strike patterns and collision forces in habitually barefoot versus shod runners. *Nature*. 2010;463(7280):531-5.

### LONGITUDINAL CHANGES IN GAIT PARAMETERS IN 4-6-YEAR OLD CHILDREN

Marusic, U., Gerzevic, M., Plevnik, M., Pisot, R.

*University of Primorska*

**Introduction** The understanding of age related changes in gait parameters is essential for early diagnosing of pathological gait in children. Following research findings in secular body size changes (Malina, 2004) we can also aspect changes of the period when children achieve adult-like gait parameters. These peculiarities and inactive lifestyles or inadequate adaptations of fundamental motor patterns (FMP) and developmental irregularities of FMP cause motor deformations. We focus our research into investigating FMP on a population of healthy children. We assume that inadequately developed FMP can have a negative effect on the upgrade of motor stereotypes and consequently on inadequate and irregular physical activity in adulthood. Incorrect functioning of the skeleto-muscular and/or neuro-muscular system could have numerous negative consequences reflected in an individual's work and life, but predominantly in their health. **Methods** Fifty-six healthy children (22 male, 34 female) were involved in a longitudinal study which lasted for three years. Each child's parents were fully informed about the possible risk and nature of the investigation, therefore, they signed an informed consent. Spatial-temporal gait parameters were measured on a treadmill (foot rotation, step width, step length, step time, stance phase, load response, single support, pre-swing, swing phase, total double support, stride length, stride time and cadence). A repeated measures ANOVA was used to test the differences among the parameters of the three years. Statistical significance was accepted as  $p < 0.05$ . **Results** Results showed that there were significant differences in all parameters among the three years, with the exception of foot rotation. Significant differences in step width, step length and step time, stance phase, total double support and cadence were observed between three age groups ( $p < 0.05$ ). Swing phase duration (%) between 4- and 6-year olds and 5- and 6-year olds was significantly longer ( $p < 0.05$ ) but there were no differences between 4- and 5-year-old children. When spatial gait parameters were normalised by the subjects' height similar significant differences were seen. **Discussion** The purpose of the present study was to examine how chosen gait parameters change in children gait pattern during a three-year period. We can conclude that some tendencies in connections with adult-like gait parameters are already present. In further analyses we will try to explain the presented data including other kinematics, kinetics and EMG data. We also have to consider the impact of treadmill which influences the specific adaptation of gait performance in children (Stolze et al., 1997). References Malina RM. (2004). *Antropol. ### OP-PM05 Training and Testing 1

#### ENERGY STORAGE CAPACITY DURING HOPPING AND JUMP PERFORMANCE BEFORE AND AFTER A 6-WEEK HIGH INTENSITY RESISTANCE TRAINING WITH OR WITHOUT WHOLE-BODY VIBRATION

Rosenberger, A., Beijer, A., Mester, J., Zange, J., Rittweger, J.

*German Aerospace Center*

Energy storage capacity during hopping and jump performance before and after a 6-week high intensity resistance training with or without whole-body vibration Rosenberger, A.(1,2), Beijer, A.(1,2), Mester, J.(2), Zange, J.(1,3), Rittweger, J. (1,3) 1: German Aerospace Center (Cologne, Germany), 2: German Sport University Cologne (Cologne, Germany), 3: University of Cologne (Cologne, Germany) **Introduction** Whole-body vibration training (WBVT) is highly investigated to optimize current training concepts in recreational and athletic sports (for review see Rittweger, 2010). However, little is known about the energy storage capacity of muscles after high intensity whole-body vibration training. We tested the hypothesis that 6 weeks of high intensity resistive vibration exercise (RVE) in comparison to resistive exercise (RE) improves the ability of leg muscles to store kinetic energy and consequently improves jump performance. **Methods** 26 healthy and recreationally active male subjects (age:  $25.2 \pm 4.2$  yrs.) were included in this two-group parallel-designed study. Subjects trained 2-3 times per week for 6 weeks with weights on a guided barbell. A session consisted of three sets of 8 squats and 12 heel raises. The initial training load was set at 80% of their 1-Repetition-Maximum and training weight (RE and RVE) and vibration frequency (RVE only) were incremented during the training period. Contact time was measured for drop jump (DJ) and multiple one leg hopping (M1LH). Peak force and power was measured for CMJ, DJ, and M1LH. Jump height was measured for CMJ and M1LH. Data was recorded using a force plate (Leonardo Mechanograph, Novotec Medical GmbH, Pforzheim, Germany). **Results** CMJ: jump height increased in both groups (RE:  $42.2 \pm 4.6$  cm vs.  $44.3 \pm 4.0$  cm, RVE:  $41.7 \pm 2.2$  cm vs.  $44.6 \pm 3.6$  cm,  $P < 0.001$ ) without any treatment\*time interaction ( $P = 0.56$ ). Similarly, peak power was increased after training in both groups (RE:  $47.7 \pm 6.5$  W/kg vs.  $50.2 \pm 5.7$  W/kg, RVE:  $48.5 \pm 4.0$  W/kg vs.  $52.4 \pm 4.6$  W/kg,  $P < 0.001$ ), but this time more in RVE than in RE ( $P = 0.043$ ). No effect of treatment, time or any interaction was found for peak force ( $P \geq 0.3$ ). DJ: A

significant interaction effect for post\*treatment contact time (RE:  $183 \pm 22$ ms vs. RVE:  $168 \pm 19$ ms,  $P=0.033$ ) was found. No main or interaction effects were found for peak power or peak force. MLH: No main or interaction effect was observed for hopping height, peak power, peak force or contact time ( $P \geq 0.1$ ). Discussion Both training interventions improved jump height in CMJ, but superposition of WBV increased jump power in CMJ and shortened contact time in DJ. The decreased contact time in DJ is most likely explained by a shortened reaction time or an improved inter- and intramuscular coordination, resulting in enhanced neuromuscular stiffness. Whether or not that effect was the mechanism behind the power-enhancing effect in the CMJ will be subject to future investigation. References Rittweger J (2010). *Eur J Appl Physiol*, 108, 877-904.

### SUBMAXIMAL POWER OUTPUT IS RELATED TO MAXIMAL PERFORMANCE IN ERGOMETER ROWING

Otter, T.A., Brink, M.S., Diercks, R.L., Lemmink, K.A.P.M.

*Hanze University of Applied Sciences Groningen*

Introduction Rowers and coaches are always looking for ways to improve training to optimize rowing performance. In order to monitor training status, it is necessary to evaluate rowing performance regularly. It is viable to test rowing performance in a way, which is less stressful than a maximal performance test. For that reason, the purpose of this study was to determine if performance parameters of a new submaximal ergometer rowing test (SERT) is related to 20 minutes of maximal ergometer rowing. Methods Eleven elite rowers (age:  $22.2 \pm 1.3$  years ; height:  $189.4 \pm 5.7$ cm ; weight:  $81.9 \pm 6.1$ kg) completed the SERT consisting of three stages at fixed predetermined heart rates on a rowing ergometer (Concept2, Model D). Based on the LSCT protocol for cyclists, rowers performed 6 minutes at 70% of maximal heart rate (HRmax) followed by 6 minutes at 80%HRmax and 3 minutes at 90%HRmax at a free chosen cadence (Lamberts et al., 2011). Power output was calculated by flywheel kinematics during the three stages of the SERT, which proved to have good validity on a Concept2 ergometer (Otter et al., in prep). Within three days after the SERT, a maximal rowing performance test of 20 minutes was performed on a rowing ergometer during which virtual boat distance (20minD) was recorded. Both tests were performed under standardized conditions (Temperature: 11-13°C – Humidity: 60-80%). Results Mean power output averaged over the last minute of the first, second and third stage of the SERT (PO70, PO80 and PO90) were  $166.9 \pm 18.0$ W,  $214.9 \pm 30.0$ W and  $285.9 \pm 34.8$ W, respectively. Mean 20minD was  $5836.5 \pm 96.4$ m. A good correlation was found between PO80 and PO90 and 20minD ( $r = 0.71$ ,  $p = 0.015$  and  $r = 0.86$ ,  $p = 0.001$ , respectively) with low typical errors of measurement (1.3% and 0.9%, respectively). Conclusion The submaximal ergometer rowing test is related to 20 minutes of maximal ergometer rowing. This suggests that rowing performance can be monitored more frequently and less stressful by using mean power output during the two last stages of the SERT. References Lamberts, R. P., Swart, J., Noakes, T. D., & Lambert, M. I. (2011). A novel submaximal cycle test to monitor fatigue and predict cycling performance. *British Journal of Sports Medicine*, 45(10), 797-804. ### CAN MATCH RUNNING PERFORMANCE BE AFFECTED BY AN IMPROVEMENT IN MAXIMAL AEROBIC SPEED?

Simpson, B., Buchheit, M., Al Haddad, H., Mendez-Villanueva, A.

*ASPIRE*

CAN MATCH RUNNING PERFORMANCE BE AFFECTED BY AN IMPROVEMENT IN MAXIMAL AEROBIC SPEED? Simpson, BM, Buchheit, M, Al Haddad, H, and Mendez-Villanueva, A ASPIRE (Doha, Qatar) Introduction Aerobic capacity is thought to be an essential quality for successful participation in soccer. Data from cross-sectional studies suggest that position-dependent correlations may exist between maximal performance in incremental tests (i.e., maximal aerobic speed, MAS) and very high intensity activities during soccer matches (VHIA) (Buchheit et al., 2010; Mendez-Villanueva et al, 2012). However, there is very limited data on longitudinal changes in MAS and their effect on VHIA. Therefore, and the aim of the present study was to examine, in highly-trained soccer players, whether substantial improvements in MAS can translate to improved VHIA. Methods Seventeen highly-trained youth male soccer players (age:  $14.1 \pm 0.8$ y; height:  $164.9 \pm 6.3$ cm) were selected based on data eligibility (i.e., players that showed substantial increases (greater than  $\Omega$  CV) in MAS between two consecutive testing periods) and have played a minimum of 2 international club games within 1-2 months from/to each testing period. Time-motion analyses were performed using a global positioning system (1-Hz). VHIA were calculated as running speed  $>16.1$ km.h<sup>-1</sup>. Results Substantial improvements in MAS were associated with a small increase in VHIA for full backs (ES = 0.35, 90%CI (0.09; 0.61)), small decrease in centre backs (ES = -0.51, 90% CI (-1.00; -0.01)) and no changes in midfielders and wingers (ES = 0.03 & 0.10, 90% CI (-0.45; 0.51) & (-0.30; 0.50), respectively). Discussion We found that improved MAS may not have a direct impact on high-intensity match running performance. One must consider the fine interaction between tactical, technical and psychological components. Our results confirm that playing structure (e.g., tactical choices) has an important role in influencing the expression of MAS during soccer match play, and hence, match running performance (Buchheit et al., 2010; Mendez-Villanueva et al, 2012). References Buchheit M, Mendez-Villanueva A, Simpson BM, and Bourdon PC. Match running performance and fitness in youth soccer. *Int J Sports Med* 2010. ### CLUSTER TRAINING VS SETS TO FAILURE: MONITORING MECHANICAL AND METABOLIC EFFECTS OF DISTRIBUTION OF REST BETWEEN REPETITIONS

Carballeira, E.I, Iglesias-Soler, E.I, Sánchez-Otero, T.I, Mayo Mouriz, X.I, Castro-Gacio, X.I

*1. UDC (A Coruña, Spain)*

Introduction The introduction of pauses between intra-set repetitions has been suggested as an alternative to resistance training by sets to failure (FS), so the mechanical performance improves (Haff et al., 2008; Iglesias-Soler et al., 2012) and a high number of repetitions are performed without losing velocity (Iglesias et al., 2010). This set configuration has been denominated as Cluster Training or Cluster set (CS). The purpose of this study was to compare acute mechanical and metabolic effects of two sessions of resistance training equated by volume and total resting time but with different set configuration: sets to failure (FS) versus distribution of rest between every repetition (CS). Methods Ten male judo athletes completed a session consisting of three sets to failure of parallel back squat with 4 repetition-maximum load and resting three minutes between sets. After at least 72 hours recovery period, subjects developed the same volume, but the total resting time was distributed between individual repetitions. Before and after session, isometric force and mean propulsive velocity (MPV) with a load corresponding to the maximum propulsive power were assessed. Results Average MPV during session was significantly higher in CS regarding FS (+19.84%,  $0.42 \pm 0.04$  vs  $0.35 \pm 0.08$  m.s<sup>-1</sup>,  $p=0.009$ ). Furthermore, CS produced lower blood lactate concentration after session (maximum average value  $1.52 \pm 0.77$  vs  $3.95 \pm 1.82$  mmol.l<sup>-1</sup>; session effect:  $p=0.001$ ) and higher MPV with a load corre-

sponding to the maximum propulsive power (MPV immediately after session  $0.64 \pm 0.09$  vs.  $0.59 \pm 0.12$  m.s<sup>-1</sup>); session effect:  $p=0.019$ ). Discussion This study showed differences on performance in output velocity along the sessions with volume and total resting time equated, as a consequence of set configuration in parallel back squat exercise. Moreover, comparison between FS and CS indicates that distribution of the resting time between every repetition leads to sessions with an improved mechanical stimulus (Haff et al., 2008), a reduced glycolytic involvement and a decreased acute loss of performance after the training session. ### THE INFLUENCE OF INTENSITY AND EXERCISE VARIABILITY IN MAXIMUM STRENGTH AND QUADRICEPS CROSS SECTION AREA GAINS IN A STRENGTH TRAINING PROGRAM

Ugrinowitsch, C., da Fonseca, R.M., Roschel, H., de Souza, E.O., Laurentino, G., Tricoli, V.

*School of Physical Education and Sport, University of Sao Paulo*

Introduction Several authors have advocated that periodized strength training programs produce greater strength gains and muscle hypertrophy than non-periodized programs. In addition, some exercise prescription entities suggest that varying strength training exercises across a training period is more effective than fixed exercise programs to produce such gains. However, empirical support to these suggestions is equivocal. Therefore, the aim of this study was to evaluate the variability of intensity and exercise of the strength training on strength gains and muscle cross-sectional area (CSA). Methods Forty-nine untrained male subjects were divided into five groups: constant exercise-varied intensity (ICEV), constant intensity-constant exercise (ICEC), varied exercise-varied intensity (IVEV), varying intensity-constant exercise (IVECO) and control (C). Strength training for the lower limbs was performed for twelve weeks. The maximal strength was assessed using the squat one repetition maximum test (1RM) and quadriceps femoris muscle CSA measured by MRI. Results All groups had significant gains both in maximum strength and CSA in relation to the pre-training ( $P < 0.05$ ). There were no significant differences between groups for both variables. Discussion The inclusion of the variation of exercise alone or combined with the variation in the stimulus intensity during a strength training program appears to produce no additional gains in muscle strength and AST. ### LOADING RATE DEPENDENCY OF IN VIVO PATELLAR TENDON MECHANICAL PROPERTIES

Kösters, A.1, Wiesinger, H.P.1, Müller, E.1, Seynnes, O.R.2

*1: Department of Sport Science and Kinesiology (Salzburg, Austria), 2: Norwegian School of Sport Sciences (Oslo, Norway)*

Introduction The mechanical properties of the patellar tendon (PT) are typically obtained in vivo by using ultrasonographic imaging during an isometric ramp contraction (MVC) over a predefined time window (e.g. 4-10sec). This technique is limited by the variability of self-paced torque development and by inter-individual differences in maximal torque. Studies addressing loading rate dependency of tendon mechanics in vivo are scarce and, due to methodological factors, indicate conflicting results (Kubo et al., 2002; Pearson et al., 2007). The purpose of this study was to investigate the effect of controlled loading rate on the mechanical properties of the PT. Methods 20 male subjects ( $24 \pm 3$  years,  $180 \pm 6$  cm,  $76 \pm 8$  kg) participated in this study. Real-time ultrasound imaging was used to record PT length changes during ramp contractions. A visual feedback enabled subjects to accurately pace their contractions at loading rates of 50, 80 and 110Nm/s. Two ramp contractions were performed at each loading rate in a randomized order. Knee extension torque and electromyographic activity of the biceps femoris were synchronized with ultrasound and recorded for off line calculation of PT force and mechanical properties at a common force level. Inter-day reliability was determined in a subgroup of 10 subjects. Results Partial results indicate that PT strain was systematically different at all loading rates. Significant differences in tendon stiffness were observed between 50Nm/s and 110Nm/s ( $2182 \pm 891$  versus  $3460 \pm 956$  N.mm<sup>-1</sup>). Reliability tests show that using the present methods, moderate to high reliability ( $ICC = 0.852$  to  $0.931$ ) can be obtained for measurements of PT force, strain, stress and stiffness. Discussion These results are in line with in vitro studies showing the influence of strain rate on tendon mechanical properties (Lieber et al., 2000). However, they demonstrate that rate dependency of tendon stiffness as measured in vivo is limited to broad variations in loading rate. Importantly, these findings also point out the limitations of the methodology used in the majority of studies to test tendon mechanics, where loading rate is uncontrolled and depends on individual maximal forces. #### EFFECT OF ACUTE EXERCISE ON MUSCLE SUBSTRATE UTILIZATION AFTER 2 WEEKS OF UNILATERAL LEG IMMOBILIZATION

Olsen, A.B., Hansen, A.V., Gram, M., Reihmane, D., Mogensen, M.H., Dela, F., Helge, J.W.

*Center for Healthy Aging*

EFFECT OF ACUTE EXERCISE ON MUSCLE SUBSTRATE UTILIZATION AFTER 2 WEEKS OF UNILATERAL LEG IMMOBILIZATION Olsen, AB., Hansen, AV., Gram, M., Reihmane, D., Mogensen, MH., Dela, F., and Helge, JW. Center for Healthy Aging, Dept. of Biomedical Sciences, University

of Copenhagen. Background Endurance training induces a shift towards a higher lipid oxidation at a given exercise intensity and this is indicated by a lower respiratory quotient (RQ) in trained compared to non-trained (Kiens et al., 1993). With increasing exercise intensity, fuel utilization changes towards carbohydrate oxidation. We studied the effect of immobilization on substrate utilization during moderate-intensity exercise. Our hypothesis was that with 2 weeks of immobilization the RQ would be increased in the immobilized leg (IM) and either decreased or unchanged in the control leg (C). Materials and methods 12 healthy males ( $23 \pm 0.7$  years, BMI  $23.6 \pm 0.7$ ,  $\text{VO}_2\text{-max}$   $46.7 \pm 1.7$  ml/min/kg, whole-body fat  $21.5 \pm 1.8\%$  [Mean $\pm$ SEM]) had one leg immobilized for 2 weeks. After immobilization subjects performed 45 min of dynamic knee-extension exercise with both legs in two kicking-ergometers (absolute workload  $18.1 \pm 0.6$  Watts; relative workload for IM  $62 \pm 5\%$  and for C  $52 \pm 3\%$ ). During exercise blood flow was measured by ultra sound Doppler and arterial and dual venous blood samples were obtained. Results After immobilization  $\text{VO}_2\text{-max}$  decreased by 6% ( $46.7 \pm 1.7$  vs.  $43.9 \pm 2.4$  ml/min/kg), whole-body fat and lean body mass were unchanged. Leg lean mass decreased in IM ( $10.2 \pm 0.4$  vs.  $9.8 \pm 0.3$  kg) and was lower in IM compared to C ( $9.8 \pm 0.3$  kg vs.  $10.4 \pm 0.3$  kg). During exercise oxygen uptake, arterial-venous oxygen extraction and arterial blood flow were similar in the two legs. The average RQ during exercise was not significantly different between IM and C ( $0.96 \pm 0.02$  vs.  $0.96 \pm 0.01$ ). There was no difference in glucose uptake between IM and C during exercise, however there was a significantly higher glucose uptake in IM at 45 min than at 15 min ( $p=0.03$ ). During exercise lactate release was significantly higher in IM compared to C after 30 min ( $0.45 \pm 0.13$  vs.  $0.12 \pm 0.11$  mmol/min,  $p=0.01$ ) and 45 min ( $0.45 \pm 0.11$  vs.  $0.01 \pm 0.11$  mmol/min,  $p=0.02$ ). Discussion In the present study the immobilization did not induce changes in RQ, and thus leg substrate utilization, during exercise despite the decrease in lean mass and higher lactate release in the immobilized leg. Even though the whole body fitness level was decreased, the local immobilization induced changes were, in contrast to our proposed hypothesis, insufficient to induce a change in leg substrate utilization in this exercise model. ### **METABOLIC CHARACTERISTICS AND MUSCLE DAMAGE PROFILE OF REPEATED BOUTS OF ECCENTRIC CYCLING IN COMPARISON TO CONCENTRIC CYCLING**

Penailillo, L., Blazevich, A., Numazawa, H., Nosaka, K.

*Edith Cowan University*

Introduction Metabolic cost of eccentric (ECC) cycling is lower at a given intensity (1), and ECC cycling training produces greater muscle mass and strength gains compared with concentric (CON) cycling (2). ECC cycling has been reported to result in prolonged strength loss and myofibrillar disruption (3). It is important to know muscle damage profile in ECC cycling to safely implement it in training. Although it is well known that the magnitude of muscle damage is attenuated when the same ECC exercise is repeated, it is unknown whether this is also the case for ECC cycling. Thus, this study compared the first and second ECC cycling bouts and a bout of CON cycling. Methods Ten men ( $28.4 \pm 8.2$  y) performed a single bout of CON cycling and two bouts of ECC cycling with a two-week interval between bouts. All bouts consisted of 30 min cycling at 60% of the maximal CON power output at 60 rpm ( $169.2 \pm 52.6$  W). Heart rate (HR), oxygen consumption ( $\text{VO}_2$ ), blood lactate (BLa) and rate of perceived exertion (RPE) were measured during cycling, and tympanic temperature (TEMP) was assessed before and immediately after cycling. Maximal voluntary isometric contraction strength of knee extensors (MVC), squat jump (SJ) and counter movement jump height (CMJ), muscle soreness and plasma creatine kinase activity (CK) were measured before, immediately after and 1-4 days after exercise. Changes in these variables over time were compared across the three bouts by a two-way repeated measures ANOVA. Results The average HR,  $\text{VO}_2$ , BLa and RPE were lower ( $P<0.05$ ) during the first ECC cycling (ECC1) than CON cycling, and HR and BLa were even lower ( $P<0.05$ ) during the second ECC cycling (ECC2) compared with ECC1. TEMP increased only after CON cycling by  $0.45^\circ\text{C}$ . Decreases in MVC, CMJ and SJ, and increase in muscle soreness were greater ( $P<0.05$ ) after ECC1 than CON and ECC2. Increases in CK were small after all bouts. Following ECC2, little changes in the variables were found such that MVC, CMJ and SJ did not decrease from baseline and no muscle soreness was developed, which were similar to those seen after CON. Discussion The results confirmed that ECC cycling is less metabolically demanding than CON cycling at the same work. The new findings of the present study were that metabolic demand was further reduced during the second than the first ECC cycling bout, and muscle damage was little or minimum after the second ECC cycling. This is in line with the repeated bout effect shown in other ECC exercises. Thus, muscle damage should not limit the use of ECC cycling. References 1) Perrey et al. ### **SKELETAL MUSCLE SATELLITE CELL RESPONSIVENESS TO A SINGLE BOUT OF EXERCISE IS BLUNTED IN THE ELDERLY**

Snijders, T.1, Verdijk, L.B.1, McKay, B.2, Parise, G.2, Greenhaff, P.3, van Loon, L.J.C.1

1. Maastricht University Medical Centre+, Maastricht, the Netherlands. 2. McMaster University, Hamilton, Canada. 3. University of Nottingham Medical School, Nottingham, United Kingdom.

BACKGROUND It has been suggested that the skeletal muscle adaptive response to resistance type exercise training is impaired in the elderly. Skeletal muscle satellite cells (SC) have been shown to be instrumental in the muscle adaptive response to exercise. After a single bout of exercise SC become activated, and proliferate/differentiate to allow the post-exercise muscle adaptive response to occur. The aim of the present study was to compare muscle fiber type-specific SC content and SC activation status at regular time intervals following a single bout of resistance type exercise between young and elderly men. METHODS Ten healthy young ( $22 \pm 1$ y) and 10 healthy elderly ( $73 \pm 1$ y) men performed a single bout resistance type exercise. Nutritional intake was standardized from 24h prior to exercise to 72h of post-exercise recovery. Muscle biopsies were collected before exercise and after 12, 24, 48 and 72h of post-exercise recovery. At all time points fiber type-specific SC content and activation status were assessed by immunohistochemical analyses. SC activation status was assessed by co-staining Pax7 with MyoD or Myostatin. In addition, mRNA and protein expression of key proteins (i.e. MyoD, myogenin and myostatin) in the regulatory pathways of SC lineage determination were determined at the different time points by rtPCR and western blotting. RESULTS Type I muscle fiber SC content had increased significantly after merely 12h of post-exercise recovery in both the young and elderly subjects ( $P<0.05$ ). In contrast, it took 48h and 72h for type II muscle fiber SC content to exceed baseline values in the young and older subjects, respectively ( $P<0.05$ ). The increase in type II muscle fiber SC content tended to be greater in the young compared with the elderly during the 72h of post-exercise recovery ( $P=0.095$ ). The number of myostatin+ SC in both the type I and II muscle fibers was significantly reduced after 12, 24 and 48h of post-exercise recovery in both groups ( $P<0.05$ ). However, after 24 and 48h of recovery the number of myostatin+ SC were significantly lower in the young compared with the elderly ( $P<0.05$ ). The number of MyoD+ SC had increased as early as 12h post-exercise in the young. In contrast, a delayed and blunted response in the increase in MyoD+ SC was observed in the elderly ( $P<0.05$ ). CONCLUSION A single bout of exercise increases type I and II muscle fiber SC content during 72 h of post-

exercise recovery in young and elderly males. The increase in type II muscle fiber SC content is delayed in the elderly when compared with the young, and is accompanied by a blunted SC activation response.

### REGULATION OF HUMAN SKELETAL MUSCLE MICROVASCULAR BLOOD FLOW: EFFECTS OF AGE, EXERCISE AND BIO-ACTIVE NUTRIMENTS

Phillips, B., Varadhan, K., Atherton, P.J., Rennie, M.J., Smith, K., Williams, J.P.

*University of Nottingham*

Introduction: Perfusion of the skeletal muscle microvasculature is crucial for control of whole-body glycaemia, maintenance of muscle proteostasis, and in the case of exercise; performance, recovery and adaptation (1). Yet, despite this crucial role of the micro-vessels within human skeletal muscles, little is understood in relation to: (i) how nutrition (amino acids/ carbohydrate) influences microvascular flow, (ii) whether microvascular flow is impaired in conditions of metabolic decline (i.e. ageing), and (iii) whether bioactive nutriment (cocoa flavonols) may influence it. Therefore, we adopted the novel approach of contrast-enhanced ultrasound (CEUS) to address these questions. Methods: We recruited 10 young ( $23 \pm 2$  y, BMI;  $24.1 \pm 1.7$  kg•m<sup>2</sup>) and 22 older men ( $71 \pm 1$  y, BMI;  $25.9 \pm 0.5$  kg•m<sup>2</sup>). Young and older men ( $n=10$ /group) were studied under both fasted and fed (IV Glamin 102 mg•kg<sup>-1</sup> and 20% dextrose; blood glucose  $\sim 7$  mmol•l<sup>-1</sup>) conditions with femoral artery 'leg' blood flow (LBF) being measured over 40 min in each condition, before infusion of Definity™ perflutren microbubbles to assess microvascular blood flow (indexed as microvascular blood volume; MBV) in m. vastus lateralis using CEUS (2). Additional older men ( $n=6$ /group) were recruited to assess the effects of 20 wk supervised resistance exercise training (RET) or bioactive vasodilatory supplements ( $\sim 1$  g.day<sup>-1</sup> cocoa-flavanol supplementation for 7 d prior to study) on MBV. Results: Increases in LBF after feeding were evident in young ( $0.51 \pm 0.02$  vs.  $0.57 \pm 0.04$  l.min<sup>-1</sup>,  $P < 0.05$ ) but not older men ( $0.32 \pm 0.04$  vs.  $0.33 \pm 0.03$  l.min<sup>-1</sup>, NS). Similarly, increases in MBV after feeding were observed in young ( $+20.68 \pm 7.19\%$ ,  $P < 0.05$ ) but not older men ( $+5.95 \pm 4.56\%$ , NS). Intriguingly, a regimen of RET ( $+67.29 \pm 14.04\%$ ,  $P < 0.05$ ) but not cocoa-flavanol supplementation ( $+4.61 \pm 13.82\%$ , NS) faithfully restored youth-like increases in MBV after feeding. Discussion: We conclude that RET, but not cocoa-flavanol supplementation rejuvenates age-related declines in postprandial microvascular hyperaemia. Therefore, RET-induced improvements in MBV likely underlie some of the established metabolic benefits of RET (i.e. improved vascular function/ glycaemic control) previously reported in ageing (3; 4). ### ASSOCIATION OF SNAP23 WITH THE MITOCHONDRIAL NETWORK IS REDUCED IN SKELETAL MUSCLE OF OBESE FEMALES

Clark, J.A., Shaw, C.S., Davis, E., Pilling, J., Wagenmakers, A.J.M.

*University of Birmingham*

Introduction SNAP23 has been implicated in the development of insulin resistance as hijacking of SNAP23 by lipid droplets (LD) has been shown to limit GLUT4 docking with the plasma membrane (PM) in oleate incubated cardiomyocytes. Further, a decreased content of SNAP23 has been observed in PM fractions of skeletal muscle of type 2 diabetic patients. Finally, it has been proposed that SNAP23 may also play a role in lipid oxidation through LD-mitochondria interactions. The aim of this study was to investigate the distribution of SNAP23 in skeletal muscle of non obese and obese women using immunofluorescence microscopy to further investigate the hijacking hypothesis and explore its potential role in fatty acid (FA) oxidation. Methods Participants were six non obese (NO) (age:  $62 \pm 3$  years, BMI:  $22.6 \pm 1.4$ , HOMA-IR  $3.9 \pm 1.2$ ) and six obese (OB) women (age:  $68 \pm 3$  years, BMI:  $33.3 \pm 1.6$ , HOMA-IR:  $6.2 \pm 1.3$ ) undergoing elective orthopaedic surgery. Biopsies were obtained from the m. gluteus maximus during hip arthroplasty. Cryosections ( $5\mu\text{m}$ ) were labelled with antibodies targeting SNAP23, mitochondria and the PM. LD were stained using oil red O. Results and Discussion SNAP23 partially colocalised with the PM in both NO and OB individuals (Pearson's correlation NO:  $r = 0.39 \pm 0.01$ , OB:  $r = 0.37 \pm 0.03$ ,  $P = 0.640$ ). SNAP23 also partially colocalised with mitochondria in the NO and OB individuals with significantly more colocalisation in NO than OB (NO:  $r = 0.34 \pm 0.03$ , OB:  $r = 0.27 \pm 0.03$ ,  $P = 0.037$ ). SNAP23 weakly colocalised with LD in both NO and OB individuals with no difference between groups (NO:  $r = 0.12 \pm 0.02$ , OB:  $r = 0.07 \pm 0.02$ ,  $P = 0.277$ ). There was no difference in LD or mitochondria content between NO and OB in either type I or type II fibres ( $P < 0.05$ ). However LD content was greater in type I fibres compared to type II fibres in both NO ( $P = 0.03$ ) and OB individuals ( $P = 0.01$ ) and mitochondria content was also greater in type I compared to type II fibres in both groups (NO:  $P = 0.02$ , OB:  $P = 0.02$ ). This study did not confirm the hijacking hypothesis as there was little association of SNAP23 with LD and the association of SNAP23 with the PM was not influenced by obesity or insulin sensitivity. The presence of SNAP23 at the mitochondria supports its proposed role to channel FA released from LD hydrolysis into the mitochondria for oxidation. The reduced association between SNAP23 and the mitochondrial network in obesity may point at a decreased capacity for FA oxidation and provide a mechanism for the reduced LD oxidation that occurs in obese individuals during exercise.

### SEVERE ACUTE HYPOXIA BLUNTS THR172-AMPKA PHOSPHORYLATION IN RESPONSE TO SPRINT EXERCISE THROUGH A SER485-AMPKA1/SER491-AMPKA2 PHOSPHORYLATION MECHANISM IN HUMAN SKELETAL MUSCLE.

Morales-Álamo, D., Ponce-Gonzalez, J.G., Guadalupe-Grau, A., Rodríguez-García, L., Feijoo, D., Perez-Suarez, I., De la Calle-Herrero, J., Fuentes, T., Dorado, C., Guerra, B., Calbet, J.A.L.

*Dep of Physical Education, Univ. of Las Palmas de Gran Canaria, Spain*

Aim: To determine if potential changes in sprint-exercise elicited Thr172-AMPKalpha phosphorylation are associated to the anaerobic component of the exercise, which is exaggerated when the sprint is performed in severe acute hypoxia. Moreover, by determining the glucose and plasma insulin response, combined with the assessment of Ser485-AMPKalpha1/Ser491-AMPKalpha2 and Ser473/Thr308-Akt phosphorylation, we expected to determine if the degree of Thr172-AMPKalpha phosphorylation is modulated by hypoxia in a Ser485-AMPKalpha1/Ser491-AMPKalpha2 phosphorylation-dependent mechanism. Methods: Ten healthy males (age:  $25 \pm 5$  yrs; VO<sub>2</sub>max:  $51 \pm 6$  ml.kg<sup>-1</sup>.min<sup>-1</sup>; means  $\pm$  SD) performed on separate days and random order two 30s-isokinetic Wingate tests at 100 rpm under N and H (FIO<sub>2</sub>=0.104, barometric pressure 730 mmHg). Immediately before the start, at the end of the test, and at 30 and 120 min into the recovery period, muscles biopsies and muscle signalling assessed by Western blot. On separate experiments, cycling economy, O<sub>2</sub> demand and the O<sub>2</sub> deficit incurred during the Wingate test was determined. Results: Peak power output, peak blood lactate and

fatigue index were similar in N and H. Mean power output and mean VO<sub>2</sub> were, respectively, 6% and 37% lower in H than in N. O<sub>2</sub> deficit (in ml of O<sub>2</sub>/w) was greater in H than N (P<0.05). Similar serum glucose and insulin responses were observed in both conditions. Serum glucose and insulin concentration was similarly elevated after the sprints in both conditions. Carbonylated plasma proteins were increased immediately after and during the 120 min following the sprint, but only after the hypoxic sprints (condition x time interaction P<0.05). Thr172-AMPKalpha phosphorylation was increased by 3.1 fold 30 min after the Wingate test in normoxia (P<0.05). Hypoxia prevented the exercise-induced Thr172-AMPKalpha phosphorylation. Ser485-AMPKalpha1/Ser491-AMPKalpha2 phosphorylation level was increased by 60% immediately after sprint performed in hypoxia (P<0.05), while it remained unchanged after the normoxic sprint (condition x time interaction, P<0.05). The AUC of the Thr308-Akt phosphorylation response was 87% higher after the sprint in hypoxia (P<0.05). Conclusion: we have shown that the signaling response to sprint exercise in human skeletal muscle is modified when the sprint is performed in severe acute hypoxia. Severe acute hypoxia blunted the expected increase in Thr172-AMPKalpha phosphorylation likely due to increased Ser485-AMPKalpha1/Ser491-AMPKalpha2 phosphorylation. Supported by MICINN (DEP2010-21866).

### **IS-SH03 Winning the Gold Medal War: The Production of Elite Sporting Success**

---

#### **THE MEASUREMENT AND FORECASTING OF SUCCESS IN ELITE SPORT**

Shibli, S.

*Sheffield Hallam University*

This presentation is concerned with the measurement and forecasting of performance in elite sport using the Olympic Games as a case study. There are two unusual features of performance that become apparent when examining Olympic Games' data. First, the International Olympic Committee does not recognise the Olympic Medals' Table as an order of merit, yet increasing numbers of nations are implementing policies to improve their standing in such tables (De Bosscher et al 2008). Second, more nations than ever before are winning medals in the Olympic Games and at the same time more nations than ever before are not winning medals at the Olympic Games. This strange fact is explained by the fact that more nations than ever before are taking part in the Olympic Games. The majority of nations that take in the Olympic Games will go home empty handed, but this does not mean that their athletes have in anyway failed. This presentation will demonstrate a variety of methods that can be used to demonstrate positive aspects of athletic performance that are not reliant on winning medals. For those nations that do win medals in the Olympic Games, to what extent is their success predictable? Ahead of the Athens 2004 Bernard and Busse (2004) stated that medal winning success was largely predictable and demonstrated a forecasting model that was 96% accurate. More recently, Shibli and Bingham (2008) forecast that China would win 46 gold medals in Beijing using simple linear regression and a quantified home nation effect. This forecast was 90% accurate (China actually won 51 gold medals) and significantly outperformed other forecasting models. Using the same technique a forecast will be made of how Great Britain and Northern Ireland should reasonably be expected to perform in London 2012. The presentation will conclude by demonstrating that as more and more nations pursue success in the Olympic Games and the number of medal winning opportunities remains essentially fixed, there are two consequences. First, the price of success increases. Second, as many nations are unable to produce medal winning athletes, they will increasingly need to look to other measures of achievement by which to assess their performance. An emerging issue in elite sport policy will be the need for effective management of nations' expectations. Perhaps Baron de Coubertin was right all along: 'it is not the winning that counts but the taking part.' Bernard, A., and Busse, M. (2004). Who wins the Olympic Games? Economic resources and medal totals. *Review of Economics and Statistics*, Vol. 86, No. 1, pp413-417 De Bosscher, V., Bingham, J., Shibli, S., Van Bottenburg, M and De Knop, P. #### **HIGH PERFORMANCE MANAGEMENT IN THE NATIONAL SPORT ORGANISATIONS: THE CASE OF CANOE/KAYAK**

Sotiriadou, P.

*Griffith University*

This study explored the high performance policies of Australia Canoeing in order to transfer and apply existing knowledge on factors that affect Olympic performance to sport specific context. Using the policy factors identified by De Bosscher et al. (2006) this study used semi-structured interviews with the Australian Institute of Sport and Australia Canoeing's high performance staff and athletes. The aims of the study were to examine the participants' personal views of the factors that contribute to international success, and to explore the participant's views of the importance of policy factors identified in previous research on international success. The findings highlight numerous sport-specific (e.g., boat technology) and country-specific (e.g., laid-back culture) factors that influence the potential of the sport to succeed internationally. These factors appear to drive the relative importance of the policy factors (e.g., coach education, planning systems, athlete pathways and support, competition opportunities). In conclusion studying HP policies on a sport-by-sport basis is essential in obtaining significant practical applications for policy directors. The results complement existing knowledge on the HP policy domain as they pinpoint the importance of country and sport-specific policy analyses. Acknowledgement: The author wishes to thank Lisa Gowthorp for her contribution in collecting the data.

**ISSUES OF PRIORITIZATION AND LEGITIMATION IN ELITE SPORT POLICIES**

Van Bottenburg, M., De Bosscher, V., Shibli, S., Westerbeek, H.

*Utrecht University (first author)*

**INTRODUCTION** As a result of the global sporting arms race (De Bosscher et al., 2008), governing organizations in elite sport are searching for increasing efficiency of their investments, for example by prioritizing policies and investing in a relatively small number of sports through identifying those that have a real chance of success at world level. This way of strategic thinking is now applied in many countries. **AIM** This study aims to identify if and how nations are adopting a prioritization policy of elite sports funding. **METHODS** Data were collected by researchers in 16 countries who took part in a large-scale "SPLISS-III" project. An overall sport policy inventory was used as a pre-defined framework to gather data from secondary sources via document review and primary sources such as interviews with national policy makers. Note: Data collection was only completed by 7 countries (BRA, EST, FIN, JAP, POR, ESP, SUI, NED) by the time of writing this abstract and will be finished by the time of the ECSS conference. **RESULTS** Interestingly, five countries do not fund non-Olympic sports as a priority sport (JAP, FRA, POR, BRA, EST). While only four countries indicated that there is a policy that sets out to prioritize particular sports for elite sport funding, closer analysis of the exact amounts of funding on a sport by sport basis shows that all countries prioritize: within the Olympic sports, all countries have spent over 60% of elite sports funding on 8 or fewer sports out of a total of 20 or more (i.e. CR8). For example in Japan and Finland, 21 elite sport disciplines receive 25% of the funding and 9 and 8 sports respectively receive the remaining 75% of the funding. The concentration ratio – CR4 is on average 40% (meaning that four sports receive 40% of the funding), ranging from 29% in Brazil to 52% in Denmark **DISCUSSION** Increasingly, countries are trying to invest 'smarter' in elite sport by implementing a prioritization policy of elite sport funding. National policies have taken this decision but not much is known about the possible unintended side-effects of this policy, for example in the sports that lost their funding, or for less welldeveloped sports; as well as the impacts on other sport policy goals, such as raising sport participation. Targeting strategies are performance-based, often using the number Olympic medals as a criterion for evaluation. This is a typical input-output evaluation. The question remains: (why) are medals important? Why would nations continue to take part in this global sporting arms race? The measurement of outcomes, or the long-term effects of success remain an unexplored area of research. **REFERENCES** De Bosscher, V., Bingham, J., Shibli, S., van Bottenburg, M., & De Knop, P. (2008). A global sporting arms race: An international comparative study on sports policy factors leading to international sporting success. **Invited symposia****IS-BN02 The Motor Control of Human Locomotion: the Role of Stretch Reflex in Natural Human Movement****THE STRETCH REFLEX IN HUMAN RUNNING**

Cronin, N.

*University of Jyväskylä*

During human running, short latency stretch reflexes (SLRs) have been observed at specific latencies after foot-ground contact in the gastrocnemius and soleus muscles. These responses are characterised by a short-lasting burst of muscle activity superimposed on the pre programmed activity that starts prior to ground contact, as measured with surface electromyography. The size of the SLR dramatically decreases in the presence of ischemia, which is known to suppress Ia afferent activity, confirming the major (but not exclusive) contribution of the Ia pathway to this reflexive component. The precise function of the SLRs observed in running is a matter of ongoing study. In cats, the SLR has been shown to compensate for transient decreases in muscle stiffness in response to a joint perturbation, thereby minimising muscle yielding. Evidence has also been presented in support of this hypothesis in humans using seated experimental paradigms. However, studies of SLR responses during the more complex task of human running have focused on the existence of the SLR, as well as variations in its timing and the neural pathways that contribute to it, but the functional importance of the SLR in this context is largely unexplored. In recent work we have attempted to address this issue by using Achilles tendon vibration to modify the size of the SLR during running. Achilles tendon vibration decreases the efficacy of Ia afferent activity, and although muscle spindle type II and Golgi tendon organ Ib afferents are also influenced by this method, they are much less sensitive to vibration than Ia afferents. Results obtained with this method showed that suppression of predominantly Ia afferent mediated SLR responses using Achilles tendon vibration led to evidence of ankle yielding at slow to intermediate running speeds (7-12 km/h), but not at the fastest speed of 15 km/h. These results provide strong evidence for a role of the SLR in ankle stiffness regulation during the early contact phase of human running. In addition, the results suggest that the functional importance of the SLR in triceps surae muscles is speed-dependent, being greater at slow to intermediate running speeds than at faster speeds.

**STRETCH REFLEXES IN HUMAN JUMPING MOVEMENTS**

Gruber, M., Gollhofer, A.

*University of Konstanz and University of Freiburg*

During jumping movements, that allow stretching and subsequent shortening of muscle-tendon units (SSC), like hopping or drop jumping, an early burst of EMG activity at a latency consistent with a simple monosynaptic reflex arc can be easily observed for the soleus muscle. Based on the onset-latency of about 35-45 ms from touch-down the burst was suggested to be a stretch reflex response, now commonly labelled short latency response (SLR). Besides the analogy of the SLR and the stretch-reflex latency, the high excitability of the H-reflex at the time of touch-down and the possibility to reduce the SLR with ischaemic blockade of the lower limb and with short-term inflation of a cuff placed directly over the muscle pointed towards a stretch reflex contribution to the SLR in hopping. In a recent study we provided more direct evidence for stretch reflexes indeed contributing to the SLR in soleus muscle. Shifting the height of a programmable

platform up or down between two hops, which advanced or delayed the touch-down without the subject's knowledge, consequently advanced or delayed the SLR. In a second study we could show that these reflexes work in concert with higher order structures. We inhibited the motor cortex with a magnetic stimulus and we were able to selectively suppress the SLR. Thus, it seems that sensory feedback and descending drive from the motor cortex are integrated to drive the motor neuron pool during the SLR. The functional relevance of stretch reflexes during the SSC in jumping movements has been discussed thoroughly over the years. From animal models and human studies there is good evidence that stretch reflexes potentially increase muscle force and stiffness at least in moderate to submaximal SSC tasks of moderate duration – like e.g. submaximal hoppings or drop-jumps from low to moderate fall heights.

### **STRETCH REFLEXES IN RESPONSE TO UNEXPECTED BALANCE DISTURBANCES**

Duysens, J.

*KU-Leuven*

During walking there is evidence that short latency stretch reflexes (SLRs) are important in given phases of the step cycle (for example hamstrings muscles at end swing) but during gait perturbations it is less clear how important such reflexes can be. For example, in stumbling or in walking on inverting surfaces there are SLRs but they are small and have little muscle specificity. It was argued that SLRs provide a brief stiffening of muscles that are stretched but these responses contribute little to the overall behavior following the perturbation. In contrast, stretch responses with a long (or medium) latency (LLR) are much larger and more muscle specific. In stumbling reactions these responses are very prominent in the hamstrings and they are smaller in elderly than in young adults. In responses to ankle inversion (caused by stepping on a trapdoor placed on a treadmill) the LLR responses can be part of a whole body response. However, these responses are late and cannot provide quick adjustments. For example in ankle inversions during walking these responses appear after the inversion is over and therefore they are not able to protect the subjects during the inversion. Instead it is argued that these responses may play a role in the phase immediately following inversion, when stability has to be regained. Subjects with chronic ankle instability (CAI) have often recurrent ankle sprains, indicating they are not dealing as efficiently with ankle perturbation as controls. In recent work we have examined whether this could be related to deficiencies in preparing and executing landing of the foot. The working hypothesis is that these subjects either show changes in muscle activations in anticipation of landing or they have deficient late stretch responses which causes instability after landing. To imitate as closely as possible the conditions which often lead to ankle inversion, an experiment was designed in which subjects with or without CAI were to jump on a hard floor on which occasionally an object was placed (a plate imitating the foot of a companion player). It was found that CAI subjects indeed showed differences both in preparatory EMG activity as in LLRs. In contrast there was no difference in SLRs.

### **EXERCISE AND TESTING IN PATIENT POPULATIONS; CORONARY HEART DISEASE AND HEART FAILURE**

Conrads, V.

*Antwerp University Hospital*

Regular physical activity has become an essential component of the 'feel good-look good hype'. Many healthcare workers, however, do not fully appreciate the direct benefits of exercise training. Being physically fit and 'working out' does not only prevent cardiovascular disease indirectly, by modifying risk factors such as overweight, hypertension and lipids. It also, for instance, directly reverses endothelial dysfunction, which is considered a key player in the development and progression of atherosclerosis. As a result, exercise training has evolved from a vague healthy lifestyle advice to a class I A indication for patients after myocardial revascularisation and for those with chronic heart failure. This lecture will touch upon both translational and clinical evidence that underscore the potential of exercise training as a valuable adjunct preventive measure and treatment modality. In addition, the value of exercise testing in order to assure safety and efficacy in these patients will be stressed.

### **TESTING, EXERCISE AND TRAINING IN OBESE PATIENTS; EFFECTS ON FITNESS AND FAT OXIDATION**

Helge, J.

*University of Copenhagen*

Obesity is increasing worldwide and unfavourable changes in lifestyle towards unhealthy diet and inadequate physical activity level are probably central to this increase. A key intervention in treatment and prevention of obesity is increasing daily physical activity and adapting regular daily exercise in this population. This requires particular knowledge on specificity and concerns of applying exercise, training and also testing in obese and severely obese subjects. An issue in this is the non-uniformity of the obese population indicated by NHANES data from 1999-2004 demonstrating that, as many as 32 % of obese individuals actually exhibit a metabolically healthy phenotype and the remainder an metabolically unhealthy phenotype (1). This talk will focus on the measurement of aerobic and metabolic fitness in the obese population. Subsequently the effects of acute exercise on substrate metabolism in obese subjects and the implications therefore on metabolic health will be discussed. Based on this the notion, that obesity is accompanied by an impaired ability to oxidize fat during exercise and a decreased mitochondrial function in skeletal muscle will be discussed. 1. Wildman,RP, Muntner,P, Reynolds,K, McGinn,AP, Rajpathak,S, Wylie-Rosett,J, Sowers,MR: The obese without cardiometabolic risk factor clustering and the normal weight with cardiometabolic risk factor clustering: prevalence and correlates of 2 phenotypes among the US population (NHANES 1999-2004). *Arch Intern Med* 168:1617-1624, 2008

**EXERCISE AND TESTING IN COP PATIENTS**

Ringbæk, T.

*Hvidovre University hospital, Copenhagen*

Pulmonary rehabilitation is a well-established treatment modality for chronic obstructive pulmonary disease (COPD). The rationale for its use is the observation that breathless people limit their exercise and become cardiovascularly deconditioned, leading to further exercise limitation and a spiral of decline. Exercise training breaks this cycle leading to an improvement in exercise capacity and health-related quality of life, and decreasing breathlessness. In contrast to physical training in healthy individuals, pulmonary rehabilitation is applied to patients with airflow limitation, and some have hypoxaemia and myopathy as well. These conditions influence the exercise training in COPD. The exercise interventions in COPD patients and their effectiveness are reviewed.

**08:00 - 09:30****Oral presentations****OP-PM07 Exercise and Cardiac Physiology****FACTORS EXPLAINING TRAINING-RELATED DIFFERENCES IN EPOC HALF LIFE**

Mann, T., Lambert, M.I.

*University of Cape Town*

**Introduction** Although post-exercise oxygen consumption (EPOC) has traditionally been investigated for its potential role in weight loss, EPOC may also be used as a measure of the time taken to reverse exercise-induced changes in homeostasis and how this changes with training. For example, trained individuals recover more rapidly following exercise at a set % of VO<sub>2</sub>max (Hagberg 1980, Short 1997). However, the effects of training are multi-faceted and it is unclear to what extent changes in metabolic recovery are related to changes in body composition, autonomic balance, muscle adaptation and absolute intensity of the exercise bout. Therefore the aim of this study was to investigate to what extent the half life (HL) of EPOC could be explained by participant characteristics, training status and responses associated with the exercise dose, following a standardized exercise bout. **Methods** Untrained individuals (n=11) and moderately-trained (n=13) and well-trained (n=12) runners were recruited and visited the laboratory on 2 occasions for the measurement of height and body mass, a Dual X-ray absorptiometry scan and 2 Bruce protocol maximal treadmill tests, 1 per visit. The 3rd and final visit involved a standardized protocol of 15min rest, a 3km treadmill run at 70% of VO<sub>2</sub>max and 65min of resting recovery. Respiratory gases and heart rate were measured for each phase of the protocol. A one-phase exponential decay curve was fitted to recovery oxygen consumption measurements and the HL of the curve used as the dependent variable for multiple regression analysis. The following variables were investigated for their ability to predict HL: age, gender, mass and body fat% (participant characteristics); weekly training km, VO<sub>2</sub>max and Bruce protocol time to exhaustion (training status); absolute oxygen consumption (ml/kg/min), energy expenditure (cal/kg), RER, %maximum heart rate, total exercise heart beats (ex hb's) and RPE (exercise dose). **Results** Variables within the participant characteristics, training status and exercise dose categories were able to explain 58%, 53% and 68% of the variation in HL respectively. The strongest single predictor of HL was ex hb's (R<sup>2</sup> = 0.56) and the best subset of 3-4 predictive variables consisted of body fat %, exercise RER and ex hb's. Each variable contributed significantly to the outcome (p < 0.05) and together accounted for 71% of variation in HL (SEE = 4.0 s). **Discussion** It may be concluded that decreased recovery HL with exercise training represents the integrated effect of altered body composition and substrate metabolism and decreased cardiovascular load during exercise. This study provides preliminary support for HL as an integrated measure of training adaptation. Understanding the remaining 29% unexplained variation could be the focus of further study as could the possible practical applications of the HL measurement for monitoring and assessment. **References** Hagberg J, Hickson R, Ehsani A, Holloszy J. **Introduction** It is discussed that a specific intertissue cross-talk between skeletal muscles and heart influences physiological cardiac hypertrophy in response to endurance training. However, the molecular nature of this process is unknown. Previous studies showed that exercising skeletal muscles release alpha-calcitonin gene-related peptide (CGRP) in close correlation with workload into the vascular system. In addition, CGRP incubation yielded larger cardiac myocytes in vitro (Vogel et al. unpublished). We therefore hypothesized that CGRP is involved in the onset of cardiac hypertrophy as a result of endurance training. **Methods** Two cohorts of C57BL/6-mice (n=8 each) were subjected to a 3-week period of treadmill exercise, consisting of five 45-min units per week with increasing velocity and incline to a maximum of 20 m/min at 9-degrees. Fifteen minutes prior to each training unit, one cohort of mice was injected s.c. with 20 nmol of the CGRP(8-37) peptide, a CGRP receptor antagonist, dissolved in 200 µl PBS, while the control mice received 200 µl PBS only. Two performance tests were conducted before and after the training period to determine peak power outcome (PPO) and time-to-exhaustion (TTE). To assess exercise-induced cardiac hypertrophy, heart dimensions were measured in vivo prior to and after the training period using magnetic resonance imaging (MRI), small animal MR system Bruker PharmaScan 47/16 (Bruker, BioSpin MRI, Ettlingen, Germany). A cine FLASH sequence was acquired using the self-gating technique IntraGate (ParaVision 5.0, Bruker BioSpin MRI) to enable determination of the myocardial volume (MV) as well as the endsystolic (ES) and enddiastolic (ED) volumes. Time points of maximal and minimal ventricular dimensions defined ES and ED volume, respectively. **Results** Treadmill training induced a significant increase in PPO and TTE of CGRP(8-37)-treated and PBS-treated mice with no significant differences between the cohorts. However, endurance training resulted in a significant enlargement (+13%) of the MV volume in PBS-treated mice, but not in CGRP(8-37)-treated animals. The ratio between ED volume and MV volume, that is not altered under physiological conditions, was significantly increased (+21%; P ≤ 0.05) in CGRP(8-37) but not PBS-

treated mice when comparing pre- and post-training measures. Discussion Administration of the CGRP antagonist CGRP(8-37) blocked exercise-induced cardiac hypertrophy in the mice. This suggests that CGRP might be a hitherto unrecognized effector system probably triggered by active skeletal muscles to promote physiological adaptation of the heart during exercise. MG and GR as well as JV and OB contributed equally to this study

### GENOTYPE X HYPOXIA INTERACTION IN ENDURANCE PERFORMANCE

Masschelein, E., Ramaekers, M., Van Thienen, R., Hespel, P., Thomis, M.

*KU Leuven*

**Introduction:** Physiological adaptations to hypoxia have been extensively studied. However, these adaptations are marked by strong variation (Martin et al., 2010). Factors that contribute to this variation are poorly understood. We examined the importance of genetic factors in inter-individual variability in responses to hypoxia using a monozygotic (MZ) genotype x hypoxia (G x H) interaction twin design. **Methods:** Twenty-seven healthy male subjects (age:  $24.9 \pm 4.4$  years) of which 12 MZ twins pairs and one MZ triplet participated in an experimental session in normoxia (20.93% O<sub>2</sub>) and severe hypoxia (11% O<sub>2</sub>, ~5000m altitude) in a normobaric hypoxic facility. During the first 5-h rest period, oxygen content was held constant at 20.93% in normoxia while in hypoxia oxygen content was progressively decreased from 20.93% to 11%. Following a 5-h rest period, a 3-h experimental protocol started consisting of a 1-h rest period, a 30-min reaction time test, a 20-min submaximal cycling exercise (SUB, 1.2 W/kg body weight) and a maximal incremental exercise (MAX, 50W + 20W/min). Acute mountain sickness (AMS) symptoms were assessed using the Lake Louise Scoring System at the end of the protocol. G x H was tested by a two-way analysis of variance for repeated measures (twins x hyp/normoxic condition) and refers to a phenotype for which the response to hypoxia is significantly influenced by genetic variation. **Results:** At rest and SUB, hypoxia per se increased heart rate (HR), minute ventilation (VE), carbon dioxide output (VCO<sub>2</sub>), respiratory exchange ratio (RER) and blood lactate (La) ( $P < 0.01$ ) and decreased oxygen saturation (SpO<sub>2</sub>) ( $P < 0.001$ ). At MAX, hypoxia decreased peak HR, SpO<sub>2</sub>, VE, VO<sub>2</sub>, VCO<sub>2</sub>, La and time to exhaustion ( $P < 0.001$ ) and increased RER ( $P < 0.05$ ). In hypoxia, the severity of AMS increased ( $P < 0.001$ ) and the incidence of AMS was 26%. In response to hypoxia, there were considerable differences between subjects. However, this was not randomly distributed among subjects. Significant G x H was found at rest for HR, SpO<sub>2</sub> and RER (ICC = 0.79 – 0.85, F-ratio = 3.8 – 5.6,  $P < 0.05$ ), at SUB for HR, SpO<sub>2</sub> and La (ICC = 0.75 – 0.89, F-ratio = 2.9 – 8.0,  $P < 0.05$ ) and at MAX for HR, SpO<sub>2</sub>, La, VO<sub>2</sub>, VCO<sub>2</sub>, RER (ICC = 0.74 – 0.91, F-ratio = 2.9 – 10.4,  $P < 0.05$ ). Significant G x H was found for change in time to exhaustion (ICC = 0.74, F-ratio = 2.84,  $P < 0.05$ ). Furthermore, significant G x H was found for the severity of AMS (ICC = 0.74, F-ratio = 2.84,  $P < 0.05$ ). **Conclusion:** These results strongly suggest that a genetic component is involved in the response to hypoxia. **References:** Martin, D.S., Levett, D.Z., Grocott, M.P., & Montgomery, H.E. (2010). Variation in human performance in the hypoxic mountain environment. *Exp Physiol*, 95, 463-470.

### A RANDOMISED TRIAL OF 6-MONTHS INTENSIVE ENDURANCE VS. RESISTANCE EXERCISE TRAINING IN HEALTHY HUMANS: IMPACTS ON CARDIAC AND VASCULAR REMODELING

Spence, A.1, Carter, H.1, Naylor, L.1, George, K.2, Green, D.1,2

*1.UWA (Perth, Australia) 2.LJMU (Liverpool, UK)*

**Introduction** Chronic exercise training is known to induce cardiac morphological changes (Spence et al. 2011 & Naylor et al. 2008), however no studies have directly compared the impacts of endurance and resistance training on cardiac and vascular remodeling. We present the first prospective, longitudinal, randomised study comparing the effects of these distinct exercise modalities on cardiac and vascular structure in healthy humans. **Methods** Following random assignment to either endurance (END n=10) or resistance (RES n=11) training groups, participants underwent an intensive, supervised, 24-week training program. Both programs followed a progressively overloaded, periodised approach with the END program involving running at individually prescribed intensities. The RES program included elements of Olympic weightlifting with loads given as percentage of maximal lifts. Measures were taken before and after training and included assessment of femoral artery (FA) diameter using high-resolution ultrasound and cardiac morphology using MRI. **Results** Aerobic fitness increased significantly in END ( $\Delta = 3.5 \text{ mL} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ ,  $P < 0.05$ ) but was unchanged in RES ( $\Delta = 0 \text{ mL} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ ,  $P = \text{NS}$ ). Muscular strength significantly improved in both groups, but to a greater extent in RES ( $27.3 \pm 4.6$  vs.  $37.5 \pm 4.9\%$ ,  $P < 0.001$ ). In the END participants, FA diameter was significantly larger following training ( $6.2 \pm 0.2$  to  $6.5 \pm 0.3 \text{ mm}$ ,  $P = 0.05$ ), but unchanged in response to RES ( $6.7 \pm 0.2$  to  $6.7 \pm 0.2 \text{ mm}$ ,  $P = \text{NS}$ ). Left ventricular end-diastolic volume (EDV) increased 3-fold more in END compared to RES ( $+8.9$  vs.  $+3.1 \text{ mL}$ ) although neither change achieved statistical significance. **Discussion** This is the first study to compare conduit artery and cardiac remodeling in response to divergent modalities of intensive, closely supervised exercise training. We observed distinct patterns of cardiac and large artery remodeling between these exercise modes. These findings suggest that endurance exercise training has impacts on the cardiovascular system, which enhance structural capacity, whereas resistance training is not associated with remodeling in the heart or femoral arteries. **References** Spence A, Naylor L, Carter H, Buck L, Dembo L, Murray C, Watson P, Oxborough D, George K, Green D. ### ACUTE EFFECT OF ISCHEMIC PRECONDITIONING ON LACTATE ACCUMULATION, TIME-TRIAL PERFORMANCE AND VASCULAR FUNCTION

Bailey, T.G., Birk, G.K., Jones, H., Gregson, W., Atkinson, G., Cable, N.T., Green, D., Thijssen, D.H.J.

*Liverpool John Moores University*

Repeated bouts of ischemia followed by reperfusion, known as ischemic preconditioning (IPC), protects against cardiac damage after a myocardial infarction or cardiac surgery. Recent studies have established that IPC also improves maximal exercise performance. In this study, we examined the hypothesis that the performance effects of IPC relate to changes in blood lactate accumulation (bLa) and endothelial function. In a randomised, crossover study, 13 healthy men performed exercise preceded by lower limb IPC (4x5 min 220 mmHg bilateral occlusion) or a sham occlusion (SHAM; 4x5 min 20 mmHg bilateral occlusion). Subjects performed a graded treadmill running test, with 5x3min submaximal stages (10-14 km·h<sup>-1</sup>), followed by increments of 1 km·h<sup>-1</sup> every 2 min until volitional exhaustion. Accumulation of bLa was examined at the end of each 3 min stage and the onset of blood lactate accumulation (OBLA) was calculated. Subsequently, subjects performed a 5-km time-trial (5kmTT). Brachial artery endothelial function was examined using flow-mediated dilation (FMD) prior to any exercise and immediately post 5kmTT. A novel covariate-controlling approach using Generalised Estimating Equations (GEE) was used to analyse the effects of trial (IPC vs. SHAM) and time on bLa and FMD. A student's t-test was used to assess any differences in OBLA and 5kmTT performance. Data are described as mean (95% CI). Accumulation in bLa was 1.1 (0.6 to 1.5) mMol·l<sup>-1</sup> lower at

14 km·h<sup>-1</sup> (P=0.023) when exercise was preceded with IPC compared to SHAM. This coincided with a trend for delayed OBLA after IPC (mean diff. of 1.5 km·h<sup>-1</sup>, -0.18 to 3.87, P=0.071). After IPC, the 5kmTT was completed 36.0s (5.0 to 64.1s, P=0.027) faster compared to SHAM. In SHAM, FMD decreased from 5.1% (4.4 to 5.9) to 3.7% (2.6 to 4.8) post 5kmTT (P=0.02), whereas it was maintained in the IPC condition; 5.4% (4.4 to 6.4) and 5.7% (4.6 to 6.8, P=0.60), respectively. This is the first study to show that IPC improves 5kmTT performance and attenuates the rise in bLa observed during running exercise. This suggests that prior IPC allows for higher work-rates for a given increase in bLa concentration. IPC also prevented the typical decrease in endothelial function associated with strenuous exercise. Taken together, our findings provide novel insight to support a physiological basis for IPC as an effective pre-exercise intervention to improve running performance in healthy males.

##### LOW-VOLUME HIGH-INTENSITY INTERVAL EXERCISE TRAINING IMPROVES BRACHIAL ARTERY FLOW-MEDIATED DILATION IN PATIENTS WITH CORONARY ARTERY DISEASE

Currie, K.D., McKelvie, R.S., MacDonald, M.J.

*McMaster University*

LOW-VOLUME HIGH-INTENSITY INTERVAL EXERCISE TRAINING IMPROVES BRACHIAL ARTERY FLOW-MEDIATED DILATION IN PATIENTS WITH CORONARY ARTERY DISEASE Currie, K.D.1, McKelvie, R.S.1-3, MacDonald, M.J.1 1: Department of Kinesiology, McMaster University (Hamilton, Canada), 2: Department of Medicine, McMaster University (Hamilton, Canada), 3: Hamilton Health Sciences (Hamilton, Canada) Introduction The physiological merits of low-volume high-intensity interval exercise training (HIT) have been established in healthy populations (Hood et al., 2011; Rakobowchuk et al., 2008); however, its significance in clinical populations requires further examination. This study examined the effects of 3-months of HIT and the current standard of care (moderate-intensity endurance exercise, END) on brachial artery endothelial-dependent dilation in patients with coronary artery disease (CAD). Brachial artery endothelial-dependent dilation was assessed using the flow-mediated dilation (FMD) test, and was selected as the primary outcome given its association with CAD severity (Kaku et al., 1998), and future risk (Yeboah et al., 2007). Methods Twenty-two men with documented CAD were stratified into END or HIT programs based on their pre-training FMD score. Both programs involved 2 supervised sessions per week on a cycle ergometer. HIT involved 10, 1-minute intervals at 80% peak power output (PPO) separated by 1-minute intervals at 10% PPO. END involved 30-50 minutes of continuous cycling at 55% PPO. Assessments were performed prior to starting (pre) and following 3-months of exercise training (post). Brachial artery diameters and velocities were collected using duplex B-mode and pulsed-wave Doppler ultrasound (12 and 4 MHz respectively) at baseline, and for 3-minutes following a 5-minute ischemic period. FMD is expressed in absolute (mm) and relative (%) terms. Results There was evidence of classical training adaptations, as fitness (relative peak oxygen consumption) was increased following HIT (21.3 ± 2.8 vs. 27.1 ± 4.3 ml·kg<sup>-1</sup>·min<sup>-1</sup>) and END (20.0 ± 7.0 vs. 23.7 ± 7.2 ml·kg<sup>-1</sup>·min<sup>-1</sup>). Brachial artery endothelial-dependent dilation was also improved following training. Absolute (HIT: 0.17 ± 0.12 vs. 0.24 ± 0.11 mm; END: 0.19 ± 0.13 vs. 0.27 ± 0.14 mm) and relative (HIT: 3.8 ± 2.5 vs. 5.3 ± 2.5 %; END: 4.2 ± 3.2 vs. 6.0 ± 3.4 %) increases in FMD were observed post-training (p≤0.001), with no differences between groups. Discussion FMD was improved following 3-months of HIT and END, despite the shorter training volume with the HIT program. Given that "lack of time" is the primary barrier to exercise adherence in cardiac rehabilitation programs, time-efficient and physiologically effective HIT may be an advantageous treatment strategy. ##### INFLUENCE OF EXERCISE INTENSITY ON PULMONARY OXYGEN UPTAKE KINETICS IN YOUNG AND OLDER PEOPLE

McNarry, M.A., Kingsley, M., Lewis, M.J.

*University of Swansea*

Influence of exercise intensity on pulmonary oxygen uptake kinetics in young and older people M.A. McNarry<sup>1</sup>, M. Kingsley<sup>1,2</sup> and M.J. Lewis<sup>1</sup> 1College of Engineering, Swansea University, UK. 2Institute for Health and Social Science Research, CQ University, Australia Considerable controversy continues to surround the influence of exercise intensity on the time constant (τ) describing the primary component of pulmonary oxygen uptake (VO<sub>2</sub>) kinetics. Whilst some studies report no influence (1), others have found a lengthening of the τ during heavy intensity exercise (3), a finding interpreted to suggest reduced O<sub>2</sub> availability (2). Such a limitation may be attributable to the central circulatory response, which is partly mediated by vagal withdrawal. Few studies have sought to specifically address the influence of exercise intensity and the conclusions of those that have are largely limited by small sample sizes. Furthermore, inter-study comparisons are thwarted by the assortment of exercise intensities, modalities and modelling techniques used. Whether age further modulates the influence of exercise intensity remains to be elucidated. The purpose of this study was to determine the influence of exercise intensity on the VO<sub>2</sub> kinetics and, subsequently, the importance of age in modulating this effect. Fifty younger (24±4 yrs) and 15 older (54±3 yrs) healthy participants (34 male) completed repeated bouts of moderate (Mod; 70% gas exchange threshold, GET) and heavy intensity exercise (Hvy; 30% of the difference between the GET and peak VO<sub>2</sub>). ECG and pulmonary gas exchange variables were measured throughout and parameters describing the dynamic responses of O<sub>2</sub>, heart rate (RR) and vagal withdrawal (HF) were subsequently derived using a mono-exponential model, with (VO<sub>2</sub>) or without (RR and HF) a time delay. The VO<sub>2</sub> τ was significantly greater during heavy compared with moderate exercise in both younger (Mod: 22±9 vs. Hvy: 29±9 s; P<0.001) and older people (Mod: 22±9 vs. Hvy: 30±8 s; P<0.001), as were the time delay (Young; Mod: 8±6 vs. Hvy: 11±7; Older; Mod: 6±6 vs. Hvy: 12±6 s; P<0.01) and mean response time (Young; Mod: 28±9 vs. Hvy: 45±11; Older; Mod: 27±10 vs. Hvy: 45±13 s; P<0.01). The RR τ was similarly slowed during heavy exercise (Young; Mod: 26±16 vs. Hvy: 32±15; Older; Mod: 30±20 vs. Hvy: 36±18 s; P<0.01), as was the HF τ (Young; Mod: 63±27 vs. Hvy: 100±21; Older; Mod: 63±22 vs. Hvy: 101±30 s; P<0.01), irrespective of age. This study suggests that the temporal components of VO<sub>2</sub> kinetics are significantly slowed during heavy compared to moderate intensity exercise. The present results support the notion that this may be attributable to an oxygen availability limitation given the slower RR and vagal withdrawal kinetics also observed during heavy intensity

### EXTREMELY SHORT DURATION HIGH INTENSITY TRAINING SIGNIFICANTLY IMPROVES ENDURANCE PERFORMANCE AND BLOOD LACTATE PROFILES IN TRIATHLETES

Jakeman, J.R.1, Adamson, S.2, Babraj, J.A.2

1. *Oxford Brookes University*; 2. *SPEC, University of Abertay, Dundee*

**Introduction** It has been demonstrated that high intensity training (HIT) involving 30 second sprints is an effective approach to improving aerobic performance (Burgomaster et al., 2005). The magnitude of this effect may be due to increased glycogen turnover (Babraj et al., 2007), and therefore, the same benefits should be achieved from shorter duration sprints. We investigated whether shorter duration HIT, involving 6 second sprints, improved aerobic performance. **Methods** Twelve competitive, male triathletes (35 ± 8 y, weight 82 ± 10 kg, BMI 26 ± 3 kg.m<sup>-2</sup>) participated in the study and were allocated to either a training group (n=6) performing two weeks of HIT, or a control group (n=6). The HIT intervention involved 10 x 6 sec sprints separated by 1 min rest, 3 x per week for 2 weeks (totalling 6 sessions, with a total exercise time of 6min). Before and after 2 weeks of HIT or normal activity (control), participants completed a self paced 10km time trial and a time to exhaustion (TTE) test on a cycle ergometer. Blood lactate concentration was taken throughout the TTE using finger prick blood samples. **Results** Two weeks of HIT resulted in an 11% decrease in self paced 10km time trial (p= 0.004) but no change in time to exhaustion. The time taken to reach onset of blood lactate accumulation (OBLA, defined as the point where blood lactate reaches 4mmol.l<sup>-1</sup>) was significantly increased following 2 weeks of HIT (p = 0.004). Total work done in a 10 x 6 second training session was 50 ± 9 kJ, in comparison with 64 ± 13 kJ for a 4 x 30 second training session (p = 0.05) **Discussion** In the present study we demonstrate for the first time that only 3 minutes of high intensity exercise per week over two weeks significantly improves aerobic performance with an attenuation of blood lactate accumulation normally seen following longer duration of sprints (Burgomaster et al., 2005). Though not quantified, all participants reported lower perceptions of exertion following sprints of 6 second than typically observed in our laboratory during 30 second sprints. The similarity of response between the 6 and 30 second sprint training regimens suggests that the performance adaptation to HIT is likely to be driven by glycogen depletion. **In conclusion**, lower duration sprints are a viable alternative to 30 second sprints for promoting improved aerobic performance in triathletes. **References:** 1. ### NO EXCESS VO<sub>2</sub> DURING WHOLE-BODY HIGH INTENSITY EXERCISE IN WELL-TRAINED CROSS-COUNTRY SKIERS

Björklund, G.1, Stöggl, T.1,2, Holmberg, H.C.1,3

1. *Mid Sweden University (Östersund, Sweden)*, 2. *University of Salzburg, (Salzburg, Austria)*, 3. *Swedish Olympic Committee (Stockholm, Sweden)*

**Introduction** Cross-country skiing competitions are performed close to 90% of VO<sub>2</sub>max (Mygind, Andersen, & Rasmussen, 1994). At this intensity O<sub>2</sub> extraction is close to its maximum in both arms and legs (Björklund, Stöggl, & Holmberg, 2010). Consequently, there is a limited possibility to further increase VO<sub>2</sub> at such a strenuous workload. However, an increased VO<sub>2</sub> has been reported during constant running speeds above the lactate threshold (Jones, Carter, & Doust, 1999). The aim of this study was thus to investigate whether VO<sub>2</sub> tends to increase during high intensity exercise that uses a large muscle mass. **Methods** Eight XC skiers (age 22±3yr; VO<sub>2</sub>max 69±3 ml•kg<sup>-1</sup>•min<sup>-1</sup>, obtained during diagonal stride (DIA) on a treadmill) performed a continuous protocol, of 3-min at 90% of DIA1 VO<sub>2</sub>max, 3-min at 90% of double poling (DP) VO<sub>2</sub>peak and a 3-min bout at 90% of DIA2 VO<sub>2</sub>max. Cardio-respiratory data was obtained continuously and determination of blood gases and metabolites from a. femoralis, v. femoralis and v. subclavia. Pole and plantar forces measured (Pedar Mobile, 100Hz) and EMG data from six lower and upper body muscles (Noraxon, 3000 Hz). One and Two-Way ANOVA were used to analyze data between the three different workloads. Alpha was set a priori to 0.05. **Results** VO<sub>2</sub> for DIA1 90% VO<sub>2</sub>max, DP 90% VO<sub>2</sub>peak and DIA2 90% VO<sub>2</sub>max, were 4.89 ± 0.13, 4.36 ± 0.49 and 4.99 ± 0.11 respectively. Lactate increased between DIA1, DP, and DIA2 with a greater increase in the femoral artery and vein (P<0.05). O<sub>2</sub> extraction was attenuated during DP (P<0.05) but remained constant during DIA1 and DIA2 (P>0.05). Sum average EMG and RMS over all muscles was lower during DP compared with DIA, with no difference between DIA1 and DIA2 (P<0.05). Peak pole force and RMS during DP was higher when compared to DIA (P<0.05). **Discussion** VO<sub>2</sub> was lower during DP compared to DIA, with no difference in VO<sub>2</sub> between the DIA workloads although there was a great increase in venous blood lactate in arms and legs as well as arterial blood throughout the protocol. Therefore our results do not support increased VO<sub>2</sub> above the lactate threshold when using a large muscle mass at a high exercise intensity. Muscle activation remained constant, as indicated by the absence of change in biomechanical characteristics, i.e. EMG in the indicator muscles, foot or plantar forces. The unchanged muscle activation along with VO<sub>2</sub> suggests that the work economy remained constant. **In conclusion**, in well trained cross-country skiers, VO<sub>2</sub> does not increase over time when both arms and legs are highly activated. ### THE EFFECT OF CARBOHYDRATE AVAILABILITY ON HIGH-INTENSITY INTERVAL RUNNING-INDUCED ALTERATIONS IN METABOLIC GENE EXPRESSION IN HUMAN SKELETAL MUSCLE

Bartlett, J.1, Joo, C.H.1, Cochran, A.J.2, Gibala, M.J.2, Gregson, W.1, Close, G.L.1, Drust, B.1, Morton, J.P.1

1. *Liverpool John Moores University* 2. *McMaster University*

**Introduction** Acute high-intensity interval run training (HIT) activates skeletal muscle signaling pathways associated with mitochondrial biogenesis (Bartlett et al. 2012). Performing HIT with reduced endogenous and exogenous carbohydrate (CHO) availability enhances the training-induced increase in skeletal muscle oxidative capacity (Morton et al. 2009) though the mechanisms underpinning enhanced adaptation remain unclear. We tested the hypothesis that performing acute HIT with reduced CHO availability before, during and after exercise enhances acute signaling and metabolic gene expression compared with traditional nutritional strategies advising CHO provision before, during and after exercise. **Method** Muscle biopsies (vastus lateralis) were obtained from eight active men pre-, post- and 3 h post- completion of an acute bout of HIT performed with normal (NORM) or low CHO availability (LOW). In NORM, subjects consumed 8 g/kg CHO in the day before exercise and were fed CHO 2 h before (2g/kg), during (1g/min) and hourly after exercise (1.2 g/kg/h). In LOW, subjects consumed 3 g/kg CHO the day before HIT, performed glycogen depleting exercise in the evening prior to HIT and also withheld CHO intake prior to, during and for 3 h after completion of HIT. **Results** Resting muscle glycogen was higher in NORM vs. LOW (374 ± 53

vs.  $103 \pm 9$ ;  $p=0.002$ ). Total CHO utilization was greater in NORM vs. LOW ( $177 \pm 6$  vs.  $122 \pm 9$  g;  $p=0.001$ ) and fat utilization was lower in NORM vs. LOW ( $8 \pm 0.2$  vs.  $23 \pm 3$  g;  $p=0.004$ ). PGC-1 $\alpha$  mRNA increased similarly 3 h following HIT (NORM:  $3.5 \pm 1.0$ ; LOW:  $3.0 \pm 0.5$ ;  $p=0.06$ ) with no difference between conditions ( $p=0.58$ ). Resting PDK-4 mRNA increased 40-fold in LOW ( $p=0.03$ ), a difference which persisted after HIT ( $p=0.01$ ). There were no differences in GLUT-4, CPT-1 or SCO2 mRNA before or after exercise ( $p>0.05$ ). Discussion Reduced CHO availability does not regulate contractile-induced PGC-1 $\alpha$  expression, suggesting this transcriptional co-activator may not regulate the enhanced training adaptation observed following low glycogen training. Reduced CHO availability augments lipid oxidation which may be due to early regulation of the pyruvate dehydrogenase complex. Biopsy samples are currently being analyzed to examine for phosphorylation of AMPK, p38MAPK and p53. ### **SIMILAR INCREASES IN SKELETAL MUSCLE OXIDATIVE CAPACITY AFTER LOW-VOLUME HIGH-INTENSITY INTERVAL TRAINING IN THE FED VS. FASTED STATE**

Gillen, J.B., Percival, M.E., Tarnopolsky, M.A., Gibala, M.J.

*McMaster University*

**SIMILAR INCREASES IN SKELETAL MUSCLE OXIDATIVE CAPACITY AFTER LOW-VOLUME HIGH-INTENSITY INTERVAL TRAINING IN THE FED VS. FASTED STATE** Gillen, JB.1, Percival, ME.1, Tarnopolsky, MA.1, Gibala, MJ.1 1: McMaster University, Ontario, Canada Introduction Low-volume high-intensity interval training (HIT) induces physiological adaptations typically associated with high-volume endurance training (END) despite a dramatically reduced time commitment (Burgomaster et al., 2008). END performed in the fasted state is reported to improve oxidative capacity to a greater extent than fed-state training in young healthy men (Van Proeyen et al., 2011). Fasted state low-volume HIT may thus represent a potent, time efficient exercise strategy to increase skeletal muscle mitochondrial content. We tested the hypothesis that 6 wk of low-volume HIT performed in the fasted state would enhance mitochondrial enzyme activity and protein content to a greater extent than training in the fed state in overweight women. Methods Sixteen overweight women (age:  $27 \pm 8$  yr, BMI:  $29 \pm 6$  kg/m<sup>2</sup>, VO<sub>2</sub>peak:  $28 \pm 3$  ml/kg/min) performed 18 sessions of HIT over 6 wk in either the fasted (FAST) or fed (FED) state ( $n=8$  each). Following an overnight fast, subjects consumed a standardized breakfast 60 min prior to exercise (FED) or 30-60 min following HIT (FAST). Each session consisted of 10 x 1 min cycling efforts at ~90% maximal heart rate ( $177 \pm 26$  W) interspersed with 1 min of rest. Skeletal muscle biopsies (vastus lateralis) were obtained at rest prior to training and again 72 hr following the final training bout. Results Citrate synthase maximal activity increased after training with no difference between groups (FAST:  $4.6 \pm 0.5$  vs.  $5.7 \pm 1.0$ ; FED:  $5.0 \pm 1.2$  vs.  $6.2 \pm 1.2$  mmol/kg protein/hr;  $p=0.01$ , main effect for time). Similarly, protein content of COXII and COXIV increased after training (21 and 26%, respectively) but there was no difference between FAST and FED ( $p=0.05$ , main effect for time). The capacity for lipid oxidation, as reflected by  $\beta$ -hydroxyacyl-CoA dehydrogenase maximal activity, tended to increase to a greater extent in FAST ( $2.1 \pm 0.5$  vs.  $2.6 \pm 0.7$  mmol/kg protein/hr) compared to FED ( $2.0 \pm 0.4$  vs.  $2.2 \pm 0.4$  mmol/kg protein/hr), but the difference was not significant ( $p=0.01$ , main effect for time). Discussion Contrary to what has been reported after END in young healthy men, fasted-state training did not enhance HIT-induced increases in mitochondrial capacity in overweight women. This could be attributable to the relatively short nature the exercise sessions performed, i.e., 10 min of intense exercise within a 20 min time commitment, and/or differences in substrate utilization pattern during HIT as compared to END. It is also possible that in our group of untrained, overweight women, the potency of the HIT stimulus may have overshadowed any potential effects associated with the nutritional intervention. #### **ERGOGENIC POTENTIAL OF BETA-ALANINE: AN UPDATE FROM THE 2011 GHENT CARNOSINE CONGRESS**

Derave, W.

*Ghent University*

Despite the large variety of so-called ergogenic supplements used by the sporting community, only few of them are effectively supported by scientific proof. One of the recent evidence-based supplements that entered the market is beta-alanine. Beta-alanine is the rate-limiting precursor for the synthesis of the dipeptide carnosine (beta-alanyl-L-histidine) in human muscle. The chronic daily ingestion of beta-alanine can markedly elevated muscle carnosine content, which results in improved exercise capacity, especially in sports that include high-intensity exercise episodes. The use of beta-alanine is exponentially growing in recent years. A dedicated international scientific congress on 'Carnosine in Exercise and Diseases' was organized at Ghent University (Belgium) in July 2011. The science behind the ergogenic potential of beta-alanine received a lot of attention on this meeting. This information, together with more recent insights and advances since the Ghent 2011 meeting, will be summarized and discussed in this lecture.

#### **SUPPLEMENTS IN THE TRENCHES: A BEHIND THE SCENES LOOK AT THE AIS SUPPLEMENTS PROGRAM**

Burke, L.

*Australian Institute of Sport*

The sports world is filled with products that claim to enhance performance. Unfortunately, sports science research is generally unable to keep pace with the number of new products that appear on the sports market. While some sports foods and supplements can provide true value in the nutrition program of the athlete, the majority of supplements and sports foods are either untested or have failed to live up to expectations in the studies that have been conducted. This provides a challenge for those working with elite athletes who eagerly seek products or strategies that might enhance their performance by even small margins. This session provides an overview of the Sports

Supplement Program of the Australian Institute of Sport (AIS), which was developed to educate athletes and coaches about supplements and manage the provision of supplements to AIS athletes and teams [www.ausport.gov.au/ais/nutrition/supplements](http://www.ausport.gov.au/ais/nutrition/supplements)

### SCIENCE IN PRACTICE: A SPORTS NUTRITION CASE-STUDY IN ELITE MARATHONERS

Stellingwerff, T.

*Canadian Sport Centre - Pacific*

One facet to marathon success is the role that fueling/hydration intake plays on marathon success, which is not a prerequisite for optimal endurance success over shorter racing distances (<90 min, including cycling and triathlon). Further to this, contemporary scientific studies have started to examine how a periodic lack of carbohydrate availability may further drive training adaptations, how the gastro-intestinal tract may also be adapted, how certain supplements may be utilized and how an individualized recovery strategy can all enhance training and competition effectiveness. Thus, the primary aim of this case-study is to characterize (via actual field data collection), several training and nutrition interventions leading to an individualized race-day fluid and fuel plan with three world-class male marathon runners.

### OP-BN03 Motor Learning

#### TASK-SPECIFIC EFFECTS OF TDCS ON MOTOR LEARNING

Zhang, X., Saucedo, C.M., Robijns, A., Zabrzaska, M., Wenderoth, N.

*KU Leuven*

**Introduction** Anodal transcranial Direct Current Stimulation (tDCS) applied to the human primary motor cortex (M1) facilitates motor skill learning in both healthy controls [1–2] and patients [3–4]. However, it remains unclear whether tDCS improves motor learning in a general manner or whether its effect is task-specific. In this study, we tested the effect of tDCS in two different motor tasks: (1) an explicit sequence learning task and (2) a visually guided force control task. We hypothesized that anodal tDCS would facilitate motor learning in both tasks, with the specific nature of the improvement dependent on task type. **Methods** Thirty-two healthy subjects participated in this double-blind, sham-controlled cross-over designed study. All subjects were randomly assigned to an anodal-tDCS group or sham-group. We applied tDCS over the primary motor cortex (M1) while subjects performed the motor task. Two different sessions (session interval > 1 month) were performed, with the task-order randomized across participants. Motor training of each task consisted of 20 min training for 3 continuous days. Retention tests were performed on the final training day and one week after the training. Results Learning scores were calculated and compared using a mixed model ANOVA analysis. The results showed that for both tDCS groups there was an overall improvement of scores across training (\*\*p < 0.001). Anodal tDCS showed more improvement compared to sham, in both motor tasks, but not to a significant level. In the explicit sequence task, a significant interaction between the TIME of stimulation (pre, training, post, RT) and TYPE of stimulation (anodal/sham) was found (p = 0.01), with the greatest improvement by anodal tDCS being at the 20 min retention test (p = 0.01). On the other hand, the visually guided control motor task showed the greatest improvement in the 1 week retention test (p = 0.03). **Conclusion** These findings suggest that anodal tDCS does lead to an increase in motor learning, most likely by improving consolidation. Further, the exact expression of this effect seems to be dependent on the motor task itself. **References** 1. #### FUNDAMENTAL MOVEMENT SKILL PERFORMANCE IN RELATION TO FAMILY CHARACTERISTICS, PARENTAL BEHAVIOUR, PARENTAL BELIEFS AND ENVIRONMENTAL CHARACTERISTICS IN PRESCHOOL CHILDREN

Cools, W., De Martelaer, K., Andries, C., Vandaele, B.

*Vrije Universiteit Brussel*

Cools W. 1,3, De Martelaer K.1, Andries C.2, Vandaele B.1 1 VUB/LK (Brussels, Belgium), VUB/PE (Brussels, Belgium) 3 VUB/IDLO (Brussels, Belgium) **Introduction** As the development of fundamental movement skills plays an essential role in the development of a fit and healthy lifestyle, it is important to understand the factors related to this development. The purpose of this study was to investigate main effects of family socialization processes on movement skill competence of 4 to 6-year-old preschool children. This study also explored whether the relationship between movement skill performance and those processes was moderated by gender. **Methods** A sample of 846 preschool children (471 boys, 375 girls) between 4 and 6 years of age participated in this study. Movement skill performance was assessed with the Motoriktest für Vier- bis Sechsjährige Kinder (MOT4-6). Data on the children's family context (concerning family characteristics, parental behaviour, parental beliefs, and environmental characteristics) were collected using self-administered parental surveys. All data were analysed using a moderated multiple regression analysis. Results The models all showed significant main effects and explained between six and eight per cent of the variance. Significant variables showing a positive relationship with children FMS competence were: father's and mother's education (family characteristics); frequency of providing new equipment; father's PA, the use of active transport (parental behaviours); relative importance of motor development; parental value of the child's physical activities (parental beliefs) and population density (environmental characteristic). Parental rating the importance of a child's sleep as well as parental inquiry on children's motor development with the preschool teacher were inversely correlated with preschool children's movement skill performance. No moderating effect was found for gender. **Discussion** The study demonstrated that several factors relate to the complex development of fundamental movement skills in preschool children. The results also underline that relationships may differ according to specific per-

formance areas (locomotion, stability and object control) in preschool children. All different models showed agreement on the association between low FMS performance and lower educated parents. Therefore these children in particular should be focused for interventions and efforts to lower participation barriers in the current offer are recommended.

### HOW MOVEMENT SONIFICATION ENHANCES MOTOR PERCEPTION

Effenberg, A.O., Schmitz, G., Münte, T.

*University of Hanover, University of Hanover, University of Lübeck*

Introduction: Efficiency of additional movement sonification on motor perception and control is documented by a growing number of studies, but there is still sparse knowledge on the functional background of audiovisually integrated gross motor motion perception [1]. Here some data about perceptual effects of audiovisual motion perception are reported and supplemented by a related fMRI study indicating clear differences on the processing of audiovisually divergent vs. audiovisually convergent stimuli. Method: 72 students (35F, 37M, 24.8 ±3.8 years) should estimate velocity differences of a swimmer on two consecutive stimuli each trial (study 1). Visual stimulus component consisted of a volume model feeded with kinematic data of a world class athlete. Congruent auditory stimuli (AV\_con) consisted of a movement sonification based on two kinematic parameters (relative distance of wrist joints to pelvis, relative distance between ankle joints and pelvis). The divergent auditory stimuli (AV\_div) combined two chords of the same timbre and frequencies as AV\_con. Relative velocity of the audiovisual stimuli (100%) was varied fivefold (98%, 94%, 92%, 90%, 88%) to achieve subtle temporal variations of swimming frequency. Temporal variations were reduced to 98%, 94% and 92% in the scanner session (study 2) due to task requirements. Results: Two-way ANOVA reveals that different treatments effect significantly absolute error (AE), constant error (CE) and Variable error (VE) (AE:  $F(3,207)=21.17, p<0.001, \eta^2=0.23$ , CE:  $F(3,207)=29.18, p<0.001, \eta^2=0.30$ , VE:  $F(3,207)=32.82, p<0.001, \eta^2=0.32$ ), as well as the treatment\*group interactions (AE:  $F(6,207)=8.49, p<0.001, \eta^2=0.20$ , CE:  $F(6,207)=4.38, p<0.001, \eta^2=0.11$ , VE:  $F(6,207)=10.22, p<0.001, \eta^2=0.23$ ). Within-group comparisons reveal that variable errors were significantly lower in purely auditory and AV\_con treatments than in purely visual and AV\_div treatments (post hoc test of treatment: all  $p<0.001$ ) (study 1). Univariate analysis on our fMRI data revealed an increased activation for congruent relative to incongruent stimuli for superior and medial posterior temporal regions, for the insula bilaterally and for the right precentral gyrus (study 2). Discussion: Behavioral data again indicate that motion perception is enhanced by convergent multi-sensory information. Additional functional data confirm the behavioral findings: The superior temporal region is involved in multisensory integration which is usually correlated to enhanced perceptual performance. Further research is required to explore in detail neural mechanisms perceiving audiovisually gross motor motion. [1] Scheef, L. et al. (2009). Multimodal motion processing in area V5/MT: Evidence from an artificial class of audio-visual events. *Brain Research*, 1252, 94-104.

### SPORT-SPECIFIC VIDEO-BASED REACTIVE AGILITY TRAINING IN RUGBY UNION PLAYERS

Engelbrecht, L., Welman, K.E., Terblanche, E.

*Stellenbosch University, South Africa*

Introduction In rugby union, players are constantly faced with a dynamic environment. Hence successful play requires a quick and accurate interpretation and response to these changing situations. Evasive reactive agility (RA) manoeuvres could lead to successful tackle breaks and advancing beyond the advantage line. More so RA can distinguish between higher and lesser skilled athletes (Wheeler et al., 2010). Purpose The study set out to investigate the effectiveness of a sport-specific video-based RA training programme for rugby union players in comparison to a field-based training programme. Methods 26 male rugby union players (18-24 years) participated in the study and were randomly divided into video-training (VT), field-training (FT) or control (C) groups. VT sessions included viewing and physically reacting to rugby attacking scenarios displayed on a 2.0m x 1.5m screen. FT sessions consisted of drills that included decision-making scenarios and mini-games. The players completed a 6 week intervention programme of 2 sessions per week. Anthropometrical measurements (height, body mass, % body fat, % lean body mass), linear speed, change of direction speed and RA, were assessed pre and post intervention and after 6 weeks to assess retention. Results Both VT and FT improved RA compared to C, with differences in the training effect of 13% (+6) and 17% (+4), respectively ( $p<0.01$ ). FT is possibly better than VT to improve RA (3+4%). Both training interventions were able to maintain its improvements in RA following the retention period. Discussion VT and FT produced significant improvements in RA performance of rugby union players. These changes were also significantly greater than with rugby training alone (C), indicating that short-term exposure to RA training may lead to improved RA performance. The improvements seen in the VT group was in accordance to the results of Serpell et al. (2011). The inclusion of mini-games in the FT group may have exposed the players to more decision-making scenarios than in VT, which may explain the slightly greater gains in RA in the FT group. Gabbett (2006) also found that skill-based conditioning games significantly improved rugby league players' attacking ability, which may be due to increased ability to read patterns of play. Conclusion VT and FT are valid sport-specific methods for conditioning RA in rugby union players. VT can be used as an effective alternative conditioning method or add-on to improve RA in rugby union. References Gabbett, T.J. (2006). *Journal of Strength and Conditioning Research* 20(2), 309-315. ### AUGMENT YOUR JUMPS WITH AUGMENTED FEEDBACK: SHORT- AND LONG-TERM EFFECTS

Keller, M., Lauber, B., Leukel, C., Gehring, D., Taube, W.

*University of Fribourg*

AUGMENT YOUR JUMPS WITH AUGMENTED FEEDBACK: SHORT- AND LONG-TERM EFFECTS Keller, M.1, Lauber, B.2, Leukel, C.1&2, Gehring, D.2, Taube, W.1 1: SMS (Fribourg, Switzerland), 2: IfSS (Freiburg, Germany) Introduction Augmented feedback (aF) is ever since accepted as a vital tool when learning or improving a motor skill. In long-term studies, subjects who received aF displayed greater increases in performance than controls. For example, service speed in tennis increased significantly more in a group that trained with aF (1). Furthermore, aF was shown to instantly influence motor performance so that subjects directly enhanced their force production in the presence of aF (2). As it seems unlikely that subjects have learnt to enhance force production within a few seconds, motivation seems to be influenced by aF. So far, all previous studies focused either on a short-term or a long-term effect. No previous study surveyed the influence of short-term and long-term effects in one study. The present study evaluates the interrelation of short-term (aF within one training session) and long-term effects (aF over 12 training sessions) of aF (jumping height) in drop jumps. Furthermore, to test whether the feedback frequency can potentially influence the training adaptation, three training groups with different frequencies of aF were tested. Methods and Results Subjects (n=36) were assigned to three training groups. One group received aF after every drop jump (100% group), a second group after

half of their jumps (50% group) and the 0% group trained without any aF. Short-term effects were analysed by comparing maximum drop jumps with and without aF from the pre-test (n=10). Significant differences were found for the jump height (JH; +4.6%;  $p < 0.01$ ) and the performance index (PI; +5.6%;  $p < 0.01$ ). Long-term adaptations were analysed by comparing pre to post data. Significant increases ( $p < 0.05$ ) as a function of aF frequency were found for JH (100% group: +18.1%; 50% group: +8.3%; 0% group: +4.7%) and PI (100% group: +22.5%; 50% group: +4.4%; 0% group: +5.3%). Discussion Short-term effects: Our data show that aF instantly enhances motor performance, i.e. from the first trial onwards. Thus, providing aF most likely motivated subjects to perform jumps with higher intensities. Long-term effects: The results show that a higher feedback frequency resulted in higher performance gains. It might be speculated that aF helped to differentiate better from worse trials and therefore guided learning. Alternatively, based on the short-term results it could be speculated that subjects were better motivated and thus, performed the drop jumps with higher intensity in trials with aF. This higher intensity may have augmented training outcome. Even though the exact mechanism(s) cannot be pointed out, the use of aF in the training of drop jumps effectively enhances performance gains. References (1) Moran K et al. (2011). *Med Sci Sports Exerc*, Epub. (2) Peacock B et al. (1981). *Ergonomics*, 24, 223-228

## EFFECT OF BALANCE TRAINING ON MUSCLE ACTIVITY AND JOINT MOMENTS DURING PERTURBED CUTTING MOVEMENTS

Oliveira, A., Silva, P.B., Farina, D., Kerting, U.G.

*Aalborg University*

Introduction: Many sports activities involve cutting movements which have been linked to injuries. The ankle and knee joints are particularly at risk when a sudden environmental change perturbs the planned movement. In order to reduce injury incidence, balance training has been used successfully in the past. However, the mechanisms that reduce the risk of injury at the moment of a threat are not completely understood. Therefore the aim of the present study was to verify the effects of balance training on postural reactions to sudden perturbations while cutting. Methods: Twenty-three subjects were randomly assigned to a control group (n=10) and a training group (n=13). The pre- and post-training measurements were based on electromyography (EMG), full-body kinematics and ground reaction force data collected during cutting movements. Subjects were asked to perform 10 cutting movements stepping with the right leg over a moveable force platform. Following these trials, the next trial was set for the force platform to elicit a unexpected rapid movement (10cm at 42cm/s) triggered by foot contact. Integraed EMG (iEMG) from vastus lateralis (VL), biceps femoris (BF), adductor longus (AD) and gluteus maximus (Gmax) as well as knee flexion moment (KFM) were calculated during the absorption period of stance phase (PRP). After pre-test the TG subjects performed six weeks of balance training (single standing on a soft mat/wobble board) for the right leg. Differences between groups and training (pre x post) were accessed by t-Student tests at a significance level of  $p < 0.05$ . Results: sudden perturbations do not alter VL iEMG before and after training for both TG and CG. Before training iEMG was significantly reduced during perturbations for BF (~22%), AD (~17%) and Gmax (~24%) for both TG and CG ( $p < 0.05$ ). After balance training, TG exhibited lower EMG reduction due to perturbations for BF (~6%,  $p = 0.2$ ), no changes for AD (~1%,  $p = 0.34$ ) and increased iEMG for Gmax (~9,  $p = 0.15$ ). In addition balance training induced KFM reduction (~20%,  $p < 0.05$ ) for both normal and perturbed cuttings. The CG showed a similar pattern as in the pre-test, with reduced EMG for BF (~16%,  $p < 0.05$ ), AD (~15%,  $p < 0.001$ ) and Gmax (~10,  $p = 0.11$ ), but no changes in KFM in the post-test. Discussion: This is the first study to indicate that balance training improves postural responses during perturbed cuttings. The substantial reductions on iEMG due to perturbations reveal that some presumably protective mechanisms [1] might not occur during a sudden slip, increasing injury risks especially for the knee. Balance training may have increased muscular coordination and facilitated neural drive, keeping muscular stabilization during the perturbation events. At the same time an improved landing strategies that reduce KFM. In conclusion, balance training is effective in improving muscular recruitment for hip and knee muscles, as well as reducing knee moments during sudden perturbations resembling slip episodes during cutting. ### OP-PM09 Measurement and analysis techniques

## BREATH SOUND ANALYSIS AS A SURROGATE FOR GAS EXCHANGE MEASUREMENT OF VENTILATORY AND RESPIRATORY COMPENSATION THRESHOLDS

Foster, C.1, Yee, N.B.2, Stamatopolous, C.2, Nacy, G.3

*1University of Wisconsin-La Crosse, USA, 2 Breath Research, Inc, USA, 3 Cycling Fusions, Inc, USA*

Introduction The measurement of the ventilatory (VT) and respiratory compensation (RCT) thresholds using respiratory gas exchange is a standard diagnostic tool in exercise laboratories and is capable of defining important markers of sustainable exercise capacity, which may then be linked to the power output (PO) or heart rate (HR) response for training prescription. Measurement of respiratory gas exchange is cumbersome and expensive. However since it is grounded in the volume, rate and pattern of breathing, it is theoretically possible to use high quality microphones to listen to breath sounds at the mouth, and to derive estimates of VT and RCT. This study represents pilot data designed to test this concept. Methods Well-trained non-athletes (PPO=241+25W) performed incremental cycle ergometer exercise (3 min stages) with measurement of respiratory gas exchange to define VT and RCT. They also exercised with measurement of respiratory rate, audio intensity and inhalation-exhalation ratio captured by a microphone positioned 5 cm in front of the mouth. VT and RCT were estimated from the audio data using an algorithm that combined information from the audio recordings. Results There were no significant differences in the mean values for PO at VT and RCT for Gas Exchange vs Breath Sound Analysis (176+34 vs 191+49W and 222+42 vs 226+48W, for combined PO data the  $R^2 = 0.69$ ). Similarly, there were no significant differences in the mean values for HR at VT and RCT for Gas Exchange vs Breath Sound Analysis (151+13 vs 145+17bpm) and 167+11 vs 164+11bpm, for the combined HR data the  $R^2 = 0.63$ ). Discussion The present results provide the first evidence that a comparatively simple algorithm derived by analyzing breath sounds (respiratory rate, audio intensity and inhalation-exhalation ratio) can identify the VT and RCT during incremental exercise, without the necessity for the technically more demanding analysis of respiratory gas exchange.

### MONITORING BRAIN TEMPERATURE – A CRITICAL THRESHOLD THAT CONTROLS CENTRAL FATIGUE?

Stahn, A.1, Krell, J.2, Benzinger, S.2, Boes, K.1, Kupka, D.1, Opatz, O.1, Steinach, M.1, Werner, A.D.2, Sattler, F.3, Koch, J.3, Gunga, H.C.1

1: Center for Space Medicine, Charité (Berlin, Germany), 2: Karlsruhe Institute of Technology (Karlsruhe, Germany), 3: Draegerwerke (Luebeck, Germany)

**Introduction** Hyperthermia has been suggested to control central fatigue by a threshold temperature (critical limiting temperature, CLT) and/or selective brain cooling, having a neuroprotective effect against lethal heat stress. Recently, however, the role of these mechanisms has been questioned (Marino 2011). Previous studies in this field have been limited to small sample sizes due to technical difficulties and inconveniences associated with core body temperature measurements such as rectal or esophageal recordings. In addition, present temperature monitoring technologies might not accurately reflect brain temperature, and specifically temperature in the hypothalamus where the center of thermoregulation is located. We therefore introduced a new non-invasive heatflux technology for determining core body temperature at the forehead (Gunga et al. 2009; Stahn et al. 2011). The aim of the present study was therefore to investigate whether there is a consistent CLT determined close to the hypothalamus during intense exercise in a large sample of young men and women with varying degrees of maximal aerobic capacity. **Methods** A total of 64 young subjects (43 men, 21 women) completed a graded maximal exercise until volitional exhaustion on a bicycle ergometer. In addition to oxygen uptake (breath-by-breath) core body temperature was continuously determined using a new non-invasive heatflux sensor (Double Sensor) positioned at the forehead. Results Average CBT at the time of exhaustion was 40.2 °C with men displaying slightly, but significantly higher CBT than women (40.3 vs. 39.9 °C,  $P < 0.05$ ). ANCOVA revealed that this difference could be attributed to higher maximal aerobic capacity in men. Comparing high and low fit subjects irrespective of gender demonstrated that CBT was significantly higher at submaximal (60% and 80%  $\dot{V}O_{2max}$ ) and maximal exercise (40.6 vs. 39.7 °C,  $P < 0.001$ ). In addition, CBT demonstrated a linear increase as a function of maximal aerobic capacity ( $r = 0.53$ ;  $P < 0.001$ ). **Discussion** While volitional exhaustion was reached around 40 °C irrespective of initial CBT and its rate of increase, suggesting a consistent CLT there was considerable variation in CBT between subjects. In addition this variation was characterized by a positive linear relationship between CBT during maximal exercise and maximal aerobic capacity. These data suggest that either subjects may adapt to higher levels of heat stress by increasing CLT or that neuroprotection from heat stress might not be the primary cause per se for the discontinuation of vigorous physical activity (Marino 2011). **References** Gunga HC, Werner A, Stahn A, Steinach M, Schlabs T, Koralewski E, Kunz D, Belavy DL, Felsenberg D, Sattler F, and Koch J (2009). *Respir Physiol Neurobiol*, 169, S63-68. ### A PRACTICAL SUBMAXIMAL TEST TO PREDICT MAXIMAL RUNNING PERFORMANCE IN THE HEAT

Lambert, M.1, Mann, T.N.1, Marino, F.E.2

University of Cape Town

**Introduction** The aim was to predict running performance in the heat from changes in heart rate, rectal temperature and perceived exertion during submaximal running in cooler conditions. **Methods** Twelve highly trained male distance runners were recruited for the study ( $24.2 \pm 3.5$  yrs). Subjects were tested on 3 separate days with a 30 min submaximal test followed by a 5 min rest and then a maximal self-paced 8 km time trial. The tests were randomised in either cool (15°C), moderate (25°C) or hot (35°C) conditions. Results Heart rate (HR) at the end of the submaximal trial during 15°C ( $154 \pm 10$  b/min) was significantly less than HR at the end of 25°C ( $161 \pm 9$  b/min) and 35°C ( $176 \pm 13$  b/min) ( $p < 0.003$ ). Running performance was impaired by  $13 \pm 5$  % in the hot conditions (range 2–21%). The best predictor of the decrement in running speed in 35°C was the increase in HR during the submaximal test (25 vs. 35°C) ( $r = -0.91$ ; 95% CI: -0.98 to -0.62). **Conclusion** The subjects who had the greatest increase in HR during the submaximal test (25°C vs. 35°C) were more likely to have had the greatest decrement in performance when exercising at high intensity in the 35°C.

### APPLYING LACTATE ANALYSIS TO INTERVAL TRAINING IN CORONARY HEART DISEASE

Christle, J.W.1, Wisloff, U.2, Pressler, A.1, Halle, M.1

1: Technical University of Munich (TUM), 2: Norwegian University of Science and Technology

Christle, J.W.1; Wisloff, U.2, Pressler, A.1; Halle, M.1 1: Technical University of Munich (TUM), Preventive and Rehabilitative Sports Medicine (Munich, Germany), 2: Norwegian University of Science and Technology, Department of Circulation and Medical Imaging (Trondheim, Norway) **Introduction** Relatively high-intensity aerobic interval training (AIT) has been shown to be effective in coronary artery disease (CAD) therapy (Rognmo et al, 2004; Cornish et al, 2011). Methods used to prescribe and monitor training intensity during interval training, percent heart rate (%HR) and ratings of perceived exertion (RPE) from exercise testing (CPET) have some limitations. Therefore the potential of arterial lactate kinetics to aid in the prescription and monitoring of exercise intensity during AIT were investigated. **Methods** Thirty-five clinically stable CAD patients (age  $64 \pm 7$ , 66% male) performed symptom-limited CPET to volitional exhaustion. Heart rates at 50%-60% and 80%-90% of peak aerobic capacity ( $\dot{V}O_{2peak}$ ) were calculated and used to establish interval training intensities. Patients performed one bout of AIT, during which HR, RPE and arterial blood lactate data were collected in the last 10 seconds of every interval. The kinetics-curves for lactate concentrations were compared to HR, RPE as well as a 4.00 mmol/L lactate steady-state threshold (Heck et al, 1985)LSST). Results Heart rate and RPE intensity targets were reached in over 85% of all intervals. Mean lactate was substantially over the 4.00 mmol/L LSST in both moderate-intensity phases (4.14 mmol/L) and high-intensity phases (4.65 mmol/L), and increased throughout the training bouts. Data for HR and RPE correlated well to changes in load (watts) during exercise training ( $r_2 = 0.953$  and  $0.978$ , respectively;  $p < 0.01$ ), whereas arterial lactate concentrations showed very poor and insignificant correlations to intensity parameters (watts:  $r_2 = 0.280$ ,  $p = 0.466$ ; RPE:  $r_2 = 0.407$ ,  $p = 0.277$ ; HR:  $r_2 = 0.548$ ,  $p = 0.126$ ). **Discussion** During aerobic interval training, an accumulation of lactate in both the high and low interval-phases results in the majority of training being performed at above the lactate steady state threshold. Arterial blood lactate kinetics do not match HR or RPE during aerobic interval training. **References** Rognmo O, Hetland E, Helgerud J, Hoff J, Slordahl SA (2004). *EJCPR*, 11, 216-222. ## NEAR INFRARED SPECTROSCOPY FOR NONINVASIVE ASSESSMENT OF VASCULAR AND MICROVASCULAR DISORDERS IN TYPE 1 DIABETES

Tagougui, S., Leclair, E., Fontaine, P., Matran, R., Marais, G., Oussaidene, K., Rasohamanana, P., Vambergue, A., Heyman, E.

*university Lille2*

Near Infrared Spectroscopy for noninvasive assessment of vascular and microvascular disorders in type 1 diabetes Semah TAGOUGUI, Erwan LECLAIR, Pierre FONTAINE, Régis MATRAN, Gaëlle MARAIS, Kahina OUSSAIDENE, Patrick RASOHAMANANA, Anne VAMBERGUE, Elsa HEYMAN Univ Lille Nord de France, EA 4488: physical activity – muscle – health, Lille, FRANCE INTRODUCTION Recently the Near-infrared spectroscopy (NIRS) technique has been used to identify peripheral vascular disease (Hamoka et al. 2011). Diabetes is one major risk factor for development of vascular disorders (Akbari et al. 1999). Pichler et al. (2004) using NIRS during a localized exercise (handgrip) found that patients with Type 1 diabetes (T1D) had lower forearm blood flow (reflected by HbO<sub>2</sub>) than healthy controls. The aim of this study was to measure oxygenation near vastus lateralis during a bicycle maximal exercise involving a large muscle mass to detect any possible vascular alterations in T1D without any overt complications. METHODS Six T1D with adequate glycaemic control (T1D-A) (HbA<sub>1c</sub><6.8 %) and two T1D with an inadequate glycaemic control (T1D-I) (HbA<sub>1c</sub> >8.7%) were compared to seven healthy subjects matched on physical activity level (accelerometry, questionnaires) and body composition (DEXA). All subjects performed an incremental exercise test to exhaustion to determine maximal oxygen uptake (VO<sub>2</sub>max). The NIRS uses laser light to calculate relative concentration changes in oxy-haemoglobin (HbO<sub>2</sub>), deoxy-haemoglobin (HHb) and total haemoglobin (tHb) near the vastus lateralis muscle. RESULTS VO<sub>2</sub>max levels did not differ between T1D-A or T1D-I and healthy subjects. tHb and HbO<sub>2</sub> were comparable between T1D-A and healthy subjects, while they were reduced from beginning of exercise in T1D-I suggesting a problem of muscle perfusion. Moreover, the increase in HHb during exercise was considerably delayed in T1D-I (with high HbA<sub>1c</sub>) appearing after 40% of VO<sub>2</sub>max (vs. about 20% of VO<sub>2</sub>max in the T1D-A and healthy subjects). No inter-group differences in blood 2,3DPG or pH were detected. This supports the hypothesis that glycation of hemoglobin may reduce oxyhaemoglobin dissociation. DISCUSSION NIRS could be an interesting method to detect subclinical problems of muscle perfusion and oxygenation during exercise in T1D patients without overt micro or macrovascular complications. ## EVALUATION OF A NEW APPROACH IN CYCLING POWER MEASUREMENT

Bruch, A., Bruch, H., Stapelfeldt, B.

*Albert-Ludwigs-Universität Freiburg*

Introduction: Traditionally power in cycling is measured at the crankset (SRM-system). Accuracy of the SRM system was tested in several studies (1). A new approach measures power output (PO) from technology attached to bike pedals. This Polar Look Keo Power system (Look Cycle International S.A., Never Cedex, France and Polar Electro Oy, Kempele, Finland) uses strain gauges on the pedal axis to measure the tangential pedal force. With known crank length and cadence power could be calculated. It is unknown, if this new principle is a valid and accurate method to measure cyclist's power. This study's aim is to compare a pedal based power-measuring system (PB) with a bottom bracket based measuring system (BBB) both in indoors and outdoors cycling. Methods: In an indoor lab-test a SRM cycle ergometer (SRM, Jülich, Germany) was equipped with a SRM-system and a Polar Look Keo Power system. 12 elite male cyclists (29,5 ± 4,7yrs; 77,1 ± 4,5kg) underwent a standardized incremental exercise test starting at 100W and increasing 20W every 3 minutes. Power was measured simultaneously with both systems throughout the complete test. The mean 60 sec value in the middle of each step was taken into results. In a second test conducted outdoors both systems were mounted on a race bike. Subjects performed a 2.9 km uphill time trial (TT). Mean PO data from 5 minutes at the beginning, middle and end of the TT was taken into consideration. Comparisons of PO were performed using Bland and Altman's 95% limits of agreement (2). Results: Maximum PO indoors was 420W and all subjects completed at least 300W. With an r-square of 0.997 a significant correlation between the two systems was revealed. The mean ± 2SD difference between PB and BBB was 8.0 ± 9.6 W (3.5 ± 4.2%). During the TT average PO of study group was 331W with mean ± 2SD power difference between PB and BBB of -7.4 ± 17.4W (-2.3 ± 5.5%). Conclusion: In the lab-test PB power method measured slightly higher values than BBB method and in the TT PB method measured less than BBB. The level of agreement in both conditions was sufficient based on previous studies suggesting that the difference in power measurements methods should be less than 5% (3). Therefore the pedal based power measurement system can be recommended as a method for monitoring performance in cycling. References: 1: Stapelfeldt et al. (2007). #### EFFECTS OF DIFFERENT TYPES OF ACUTE AND CHRONIC EXERCISE ON GLYCAEMIC CONTROL IN TYPE 1 DIABETES – A META-ANALYSIS.

Tonoli, C.1,2, Heyman, E.2, Roelands, B.1, Buyse, L.1, Cheung, S.3, Berthoin, S.2, Meeusen, R.1

*Vrije Universiteit Brussel. 1: VUB (Brussels, Belgium), 2: UL (Lille, France), 3: BU (Ontario, Canada).*

Introduction: Exercise has been accepted and generally recommended for the management of type 1 diabetes (T1D) and for improving the overall quality of life in affected individuals. In addition to increasing aerobic fitness, reducing cardiovascular risk factors, and reducing body weight and body fat, physical activity develops and maintains chronic glycaemic control. Exercise stimulates insulin sensitivity, muscle glucose uptake and improves insulin flexibility. This meta-analysis was conducted to determine the overall effects of exercise on acute and chronic glycaemic control and the conditions (frequency, intensity ...) which are required to obtain these effects in T1D patients. Methods PubMed, ISI Web of Knowledge and SPORTDiscus were consulted to identify studies on Type 1 Diabetes (T1D) and exercise. Cohen's d statistics were used for calculating effect sizes (ES), with effect sizes (d) defined as small = 0.3, medium = 0.5 and large = 0.8. Ninety-five percent confidence intervals (95% CIs) were used to establish the significance of our findings. Results From a total of 937 studies, 33 that met the inclusion criteria were selected. ES for exercise on acute glycaemic control were large, while they were small for chronic glycaemic control. Aerobic exercise, resistance exercise, mixed exercise (aerobic combined with resistance training) and high intensity exercise (HIE) decreased acute blood glucose levels. To prevent late onset hypoglycaemic episodes, the use of single bouts of sprints into an aerobic exercise can be recommended. This meta-analysis also showed that a regular exercise training program has a significant effect on acute and chronic glycaemic control, though, not all exercise forms showed significant results. Specifically, aerobic training is a favourable tool for decreasing chronic glycaemic control, while resistance training, mixed and HIE did not significantly decrease chronic glycaemic control. Conclusion. Aerobic training and strength training have different actions in the body and can therefore influence (acute and chronic) glycaemic control through different pathways. Based on this meta-analysis it is advised that regular aerobic exercise with the addition of bouts of HIE, strength exercise (or the combination of strength and aerobic exercise) will improve the glucose levels of T1D patients. Regular aerobic training will improve long term glycaetted haemoglobin.

#### EFFECTS OF HIGH INTENSITY TRAINING AND LONG SLOW DISTANCE TRAINING ON ENDOTHELIAL MICROPARTICLES AND ANGIOGENIC GROWTH FACTORS

Wahl, P.1, Achtzehn, S.1, Mester, J.1, Bloch, W.1, Werner, N.2

*German Sport University*

1: The German Research Centre of Elite Sport, German Sport University Cologne (Germany) 2: Department of Internal Medicine II, Cardiology, Pneumology and Angiology, Medical Faculty, University of Bonn (Germany). Introduction Endothelial microparticles (EMP) are complex vesicular structures shed from activated or apoptotic endothelial cells. They are considered to play a remarkable role in coagulation, inflammation, endothelial function, and angiogenesis. Besides their role as marker of cell damage, recent reports have underlined their role as signaling elements in cell-cell communication. It has been reported that profiles of EMP reflect endothelial status and that EMP are generated under certain blood flow conditions (shear stress). As endurance exercise alters the blood flow velocity and therefore shear stress at the vascular wall, the objective of the study was to examine changes in EMP following different endurance exercise protocols. Methods 12 subjects performed 3 different endurance exercise protocols: 1. LSD (120 min at 55% peak power output (PPO); 2. 4x4 min at 95% PPO; 3. 4x30 sec all out. For the determination of EMP, vascular endothelial growth factor (VEGF), migratory inhibiting factor (MIF) and hepatocyte growth factor (HGF) venous blood samples were taken pre, 0', 30', 60' and 180' after the interventions. EMPs were quantified (number/ $\mu$ l) using flow cytometry after staining platelet-poor-plasma with the cell surface markers CD31, CD42b and Annexin-V. Events positive for Annexin-V and CD31, and negative for CD42b, were classified as EMPs. Results All three interventions caused a significant decrease in EMP 60' and 180' post exercise compared to pre values. No differences between the interventions were observed. HGF significantly increased 180' after the 4x30 sec only. VEGF and MIF showed no significant changes. Discussion As exercise increases the blood flow/shear stress at the vascular wall, we expected EMP to be increased after endurance exercise, as increases in microparticles were described in diseases with altered shear forces in blood vessels. However EMP significantly decreased after exercise which might be due to an increased clearance from the circulation. Yet the mechanism of MP's clearance from the circulation is not known. It can be speculated that, EMP are taken up by active endocytosis in endothelial cells, as this process has already been described for platelet-derived microparticles modifying endothelial cell phenotype and function. Although a few other studies have investigated microparticles following exercise in humans, this has been the first to examine EMP, MIF and HGF after different endurance training regimes.

#### EXERCISE TRAINING IMPROVES CUTANEOUS MICROVASCULAR NITRIC OXIDE DYSFUNCTION IN PCOS WOMEN

Sprung, V.S., Cuthbertson, D.J., Pugh, C.J.A., Aziz, N., Kemp, G.J., Green, D.J., Cable, N.T., Jones, H.

*Liverpool John Moores University*

INTRODUCTION Polycystic ovarian syndrome (PCOS) is associated with a ~2 fold increased risk of coronary artery disease and a higher prevalence of hypertension in the post-menopausal period. Microvascular function contributes to hypertension by raising peripheral vascular resistance and arterial stiffness. However, the contribution of nitric oxide (NO) to cutaneous microvascular function in PCOS has not been previously explored. We hypothesised that PCOS women would exhibit impaired cutaneous microvascular NO function and that exercise training would induce an improvement. METHODS NO-mediated vasodilation in the cutaneous microvessels was examined in 11 PCOS women (29 $\pm$ 2yrs, 34 $\pm$ 2kg/m<sup>2</sup>) and 6 matched controls (29 $\pm$ 3yrs, 34 $\pm$ 2kg/m<sup>2</sup>) using laser Doppler flowmetry combined with intra-dermal microdialysis of L-NG-monomethyl arginine to assay the NO dilator system in response to incremental local heating of the forearm. Visceral and subcutaneous fat were quantified by whole body magnetic resonance imaging. Cardiorespiratory fitness, HOMA-IR and hormone profiles were also assessed. 6 PCOS women (30 $\pm$ 3yrs, 31 $\pm$ 2kg/m<sup>2</sup>) then undertook a 16-week exercise-training pro-

gramme. Upon completion, baseline measurements were repeated. Differences between PCOS and controls, and changes with exercise were analysed using t-tests. NO contribution to cutaneous blood flow in response to a heating stimulus was analysed using general linear modelling. Cutaneous blood flow data is presented as %CVCmax and all data are reported as mean $\pm$ SE. RESULTS PCOS and controls were matched for age, BMI, fat deposition and cardio-respiratory fitness ( $P>0.25$ ). NO contribution was attenuated in PCOS women at peak heating [42°C] ( $6.1\pm 4.3$  vs.  $16.4\pm 5.9\%$ CVCmax,  $P=0.06$ ) and during prolonged maximal heating [30 mins at 42°C] ( $1.4\pm 3.8$  vs.  $16.8\pm 5.8\%$ CVCmax,  $P=0.04$ ), compared with controls. Cardiorespiratory fitness improved by  $5\pm 1$  ml.kg $^{-1}$ .min $^{-1}$  following exercise training ( $P=0.03$ ). This was accompanied by increased NO contribution to cutaneous blood flow between 36.5-42°C ( $P<0.05$ ) and during prolonged maximal heating ( $1.4\pm 3.5$  vs.  $15.1\pm 6.6\%$ CVCmax,  $P=0.03$ ). DISCUSSION These novel findings indicate that cutaneous microvascular NO function is impaired in PCOS women compared with matched controls, and that exercise-training can up-regulate NO function in the cutaneous microcirculation in this population. Given that NO confers anti-atherogenic benefits, these data support the utilisation of exercise as a preventative strategy for microvascular dysfunction, and primary prevention for hypertension, in PCOS women.

## PHYSICAL TRAINING INFLUENCE THE SECRETION OF GASTRO-INTESTINAL HORMONES

Taudorf, L., Lund, M.T., Holst, J.J., Dela, F.

*University of Copenhagen*

**Introduction** There is an inverse relationship between insulin action and secretion. In athletes insulin sensitivity is higher compared with sedentary people, while the opposite is seen in glucose- and amino-acid induced insulin secretion. This is a remarkable adaptation of an endocrine gland to the level of fitness, and the mechanism behind is not fully known. With the discovery of the secretion of several new insulinotropic hormones from the gastro-intestinal (GI) tract the question: "Is there a global endocrine adaptation to physical training in the entire GI tract?", arise. **Methods** Ten trained (T) and ten untrained (UT) (max oxygen uptake:  $67\pm 2$  and  $42\pm 2$  ml $\cdot$ min $^{-1}$ kg $^{-1}$ , respectively) healthy men were included. Subjects, matched for age:  $25\pm 3$  and  $25\pm 3$  yrs and BMI:  $21\pm 2$  and  $22\pm 1$  kg $\cdot$ m $^{-2}$ , in T and UT respectively, reported to the lab after a 12h overnight fast. Here plasma concentrations of insulin, glucose, free fatty acids (FFA), glycerol, glucose-dependent insulinotropic peptide (GIP), glucagon-like-peptide-1 (GLP-1) and -2 (GLP-2), oxyntomodulin (OXM), obestatin (OBS), pancreatic polypeptide (PP), peptide YY (PYY) and total protein (PRO) were measured before and every 30 min for 180 min after ingestion of a liquid meal containing 1260 kJ (20g protein, 31g carbohydrates and 11g fat). **Results** There was no baseline difference in plasma concentration of insulin, glucose or GIP. Baseline GLP-1 ( $13.3\pm 1.1$  vs.  $10.2\pm 0.7$  pmol $\cdot$ l $^{-1}$ ) and OXM ( $1.2\pm 0.3$  vs.  $0.5\pm 0.1$  ng $\cdot$ ml $^{-1}$ ) plasma concentration were higher whereas GLP-2 ( $4.0\pm 0.2$  vs.  $4.5\pm 0.6$  ng $\cdot$ ml $^{-1}$ ), glycerol ( $56.3\pm 6.5$  vs.  $86.6\pm 11.4$   $\mu$ mol $\cdot$ l $^{-1}$ ) and FFA ( $371\pm 42$  vs.  $646\pm 79$   $\mu$ mol $\cdot$ l $^{-1}$ ) concentration were lower in T compared to UT. Insulin ( $11316\pm 800$  vs.  $18294\pm 1888$  a.u.), glucose ( $904\pm 31$  vs.  $988\pm 21$  a.u.) and GIP AUC ( $36212\pm 2543$  vs.  $52425\pm 3675$  a.u.) were significantly lower in T compared to UT. GLP-1, -2, OXM and Glycerol AUC defined as the increase measured from baseline (AUCinc) showed no difference between groups, but meal induced FFA suppression was lower (AUCinc:  $-39582\pm 6677$  vs.  $-70157\pm 9771$  a.u.) in T compared to UT. There was no difference in OBS, PP, PYY and PRO between groups. **Discussion** Here we confirm the well-established diminished insulin response in T vs. UT and the improved lipid tolerance in T. The GI hormones displayed a mixed response, with GLP-1 and OXM being higher at baseline in T, while the opposite was seen with GLP-2. GLP-1, -2 and OXM are all produced in the L-cell and interestingly none of the AUCinc differed between groups. Baseline GIP levels did not differ between groups, but AUC was higher in UT compared to T. Thus, it seems the L- and K-cells exhibit a difference response to training. In conclusion, we have demonstrated novel adaptations in the GI tract hormonal response to physical training.

## EXERCISE-INDUCED CHANGES IN PATELLA TENDON PROTEIN SYNTHESIS AND GENE EXPRESSION IN YOUNG ACL PATIENTS

Dideriksen, K.J., Sindby, A.K.R., Krogsgaard, M., Schjerling, P., Holm, L., Langberg, H.

*Institute of Sports Medicine Copenhagen*

**Introduction** Habitual loading can result in tendon hypertrophy (Couppé et al. 2008) and a single bout of strenuous kicking exercise has been shown to stimulate patella tendon collagen protein synthesis in young men (Miller et al. 2005). However, limited information exists regarding the underlying mechanisms that mediate this exercise-induced response. Recently, it was reported that the gene expression of growth factors and collagen in the tendon was unaffected by an identical kicking exercise bout (Heinemeier et al. 2011). Therefore, the effect of this kicking exercise bout on tendon gene expression alongside tendon collagen protein synthesis needs further investigation. **Methods** Twelve young ACL patients ( $31\pm 2$  yrs) were randomized to one of two groups: Control or Exercise (1-h unilateral knee-extension 67 % of maximal work (Wmax) 24 hours before operation). Two hours before operation a flooding-dose of L-[1-13C]proline was given. Patellar tendon tissue was obtained during surgery. Tendon collagen fractional synthetic rate (FSR) and mRNA abundances of TGF-beta-1, CTGF, and type I and III collagen were measured. **Results** CTGF and type I collagen expression were increased in Exercise compared to Control ( $p<0.05$ ). Type III collagen expression, TGF-beta-1 expression, and collagen FSR ( $p>0.05$ ) did not differ between groups. **Discussion** The knowledge about tendon responsiveness to exercise is blurred by contrasting findings. Here we demonstrate that despite no detectable changes on tendon protein synthesis rate, the expression of CTGF and collagen type I mRNA was elevated. This indicates that the tendon tissue is responsive to acute exercise and the elevated CTGF expression proposes the TGF-beta pathway should be involved. **References** Couppé, C. et al., 2008. ## EXERCISE OR MORE HABITUAL PHYSICAL ACTIVITY TO IMPROVE GLYCEMIC CONTROL IN PATIENTS WITH TYPE 2 DIABETES?

van Dijk, J., Venema, M., van Loon, L.

*Maastricht University Medical Centre+*

**Background:** Postprandial blood glucose excursions have been associated with the development of cardiovascular disease in patients with type 2 diabetes. Although exercise represents an excellent strategy to improve postprandial glycemia, many patients have difficulties adhering to strict exercise intervention programs. Besides exercise, also non-exercise associated physical activity has been related to improvements in glycemic control. In the present study we assessed the impact of a modest increase in habitual physical activity as

opposed to a single bout of exercise on postprandial blood glucose homeostasis in patients with type 2 diabetes. Methods: Thus far, 16 type 2 diabetic patients (age  $65 \pm 1$  y; BMI  $29 \pm 1$  kg/m<sup>2</sup>; HbA<sub>1c</sub>  $7.0 \pm 0.2\%$ ) participated in a randomized crossover study, consisting of 3 experimental periods separated by 1 week. During a 3-day experimental period, subjects were studied under sedentary control conditions (CON), under conditions where sedentary time was frequently interrupted by activities of daily living (ADL; totaling 45 min per day), and under conditions where prolonged sedentary time was preceded by a 45 min bout of moderate-intensity exercise (EXE). Subjects' diet was strictly standardized, with meals being provided at 8:30, 12:30 and 17:00 h. Blood glucose homeostasis was assessed by continuous glucose monitoring technique, whereas circulating insulin levels were assessed by frequent blood sampling. Treatment effects were assessed by repeated measures ANOVA. Results: Despite continued use of oral blood glucose lowering medication and an HbA<sub>1c</sub> level of  $7.0 \pm 0.2\%$ , type 2 diabetic patients experienced hyperglycemia (blood glucose  $>10$  mmol/L) for as much as  $7:14 \pm 1:14$  h:min throughout the day. The daily prevalence of hyperglycemia was strongly reduced during the EXE condition ( $-2:15 \pm 0:32$  h:min;  $P < 0.01$ ), but not during the ADL condition ( $-1:00 \pm 0:45$  h:min;  $P = 0.62$ ). Postprandial hyperglycemia, as assessed by the cumulative incremental AUC of breakfast, lunch and dinner, was  $19 \pm 6\%$  and  $38 \pm 6\%$  lower during the ADL and EXE condition, respectively, when compared with the CON condition ( $P < 0.05$  for both conditions). The postprandial insulin AUC was reduced by  $14 \pm 5\%$  and  $25 \pm 4\%$  during the ADL and EXE condition, respectively ( $P < 0.05$  only for EXE). The reduction in postprandial glucose and insulin levels was greater during the EXE condition when compared with the ADL condition ( $P < 0.05$ ). Conclusion: A single bout of exercise strongly reduces the daily prevalence of hyperglycemia and lowers postprandial insulin concentrations in patients with type 2 diabetes. Although a modest increase in habitual physical activity may slightly enhance postprandial glucose homeostasis, it cannot replace the benefits of exercise in the treatment of type 2 diabetes.

#### SHORT VERSUS LONG TERM GREEN TEA EXTRACT SUPPLEMENTATION ON FAT OXIDATION DURING EXERCISE.

Randell, R.K., Hodgson, A.B., Lotito, S.B., Jacobs, D.M., Boon, N., Jeukendrup, A.E.

*University of Birmingham*

Green tea consumption has been associated with protective effects against diseases such as cardiovascular disease, cancer and obesity. More specifically, the anti-obesity properties of green tea have been attributed to enhanced thermogenesis and increases in fat oxidation at rest and during exercise. Augmented fat oxidation, during exercise, is also beneficial for endurance-type athletes as the ability to oxidize fatty acids more efficiently has been linked to a muscle glycogen sparing effect and subsequent performance improvements. However, it remains unclear what supplementation strategy, of a green tea extract (GTE), is most effective in elevating fat oxidation during exercise. Therefore the aim of this study was to investigate the effects of short (1 day) and long term (7 days) GTE supplementation on fat oxidation during moderate intensity exercise. In a parallel, double-blind study design, 31 physically active male participants were recruited for the purposes of this study. Participants were randomly assigned to one of three supplementation conditions: 1) 7 days placebo (PLA); 2) 6 days of PLA followed by 1 day of GTE (GTE1); 3) 7 days GTE supplementation (GTE7). Prior to supplementation participants took part in a baseline experimental trial (Day 0) which consisted of a two hour rest period followed by a 60-min cycle exercise at 50% W<sub>max</sub> (55% VO<sub>2max</sub>). This experimental trial was repeated following the supplementation period (Day 8). To measure substrate metabolism respiratory breath samples were collected and analysed every 10 min during the exercise bout. Blood samples, to determine plasma glucose, glycerol and free fatty acids (FAs) were collected throughout rest and exercise. Short (GTE1) and long term (GTE7) GTE ingestion failed to increase whole body fat oxidation rates, compared to placebo, during the 60-min exercise bout ( $0.51 \pm 0.05$ ,  $0.50 \pm 0.05$ ,  $0.59 \pm 0.06$ g/min, respectively). Furthermore, respiratory exchange ratio (RER) did not differ between Day 0 and Day 8 in all three groups. Compared to baseline (Day 0), long term supplementation of GTE (GTE7) significantly increased plasma FAs and glycerol at rest and during exercise ( $P < 0.05$ ). There was no difference in plasma FAs and glycerol following short term GTE ingestion compared to Day 0. In conclusion, the present study showed no effect of 1 day GTE supplementation on lipolysis or fat oxidation during moderate-intensity exercise. Seven days of GTE supplementation increased lipolysis but this did not result in measurable changes in fat oxidation.

#### PROTEIN SUPPLEMENTATION AUGMENTS THE SKELETAL MUSCLE ADAPTIVE RESPONSE TO RESISTANCE-TYPE EXERCISE TRAINING

Cermak, N.M.1, Res, P.T.1, de Groot, C.P.G.M.2, van Loon, L.J.C.1

*1Maastricht University Medical Centre+, 2Wageningen University*

Introduction: Protein ingestion after a single bout of resistance-type exercise stimulates net muscle protein accretion during acute post-exercise recovery. Consequently, it is generally believed that protein supplementation is required to maximize the skeletal muscle adaptive response to prolonged resistance-type exercise training. However, there is much discrepancy in the literature on the proposed efficacy of dietary protein supplementation as a means to augment the skeletal muscle adaptive response to resistance-type exercise training. This meta-analysis addresses the issue of whether protein supplementation further augments the increase in muscle mass and strength following prolonged resistance-type exercise training in healthy young and older individuals. Methods: A systematic review of interventional evidence was performed through the use of a random effects meta-analysis model. Data from outcome parameters fat-free mass (FFM), type I and II muscle fiber cross-sectional area (CSA) and muscle strength (1-RM) were collected from randomized controlled trials (RCTs) investigating the impact of dietary protein supplementation during prolonged ( $>6$  wks) resistance-type exercise training. Results: Data from 24 RCTs (746 subjects) were included in May, 2011 and pooled for a random-effects meta-analysis. Protein supplementation demonstrated a positive effect for FFM (weighted mean difference (WMD): 0.75 kg, 95% confidence interval (CI) 0.53, 0.97 kg;  $P < 0.00001$ ) and 1-RM (WMD: 12.4 kg, 95% CI 6.4, 18.3 kg;  $P < 0.0001$ ) compared with a placebo during resistance-type exercise training in both young and older subjects. Protein supplementation further increased type I (WMD: 232  $\mu\text{m}^2$ ; 95% CI 128, 336  $\mu\text{m}^2$ ;  $P < 0.0001$ ) and type II muscle fiber CSA (417  $\mu\text{m}^2$ ; 95% CI 241, 593  $\mu\text{m}^2$ ;  $P < 0.00001$ ) following resistance-type exercise training in young subjects. Conclusion: Protein supplementation further improves the gains in fat-free mass and muscle strength during prolonged resistance-type exercise training. As

these effects are observed in both young and older subjects, it seems evident that protein supplementation represents an effective nutritional strategy to further improve the benefits of resistance-type exercise training to support healthy aging.

### EFFECTS OF CAFFEINE AND CARBOHYDRATE MOUTH RINSES ON REPEATED SPRINT PERFORMANCE

Beaven, C.

*Mid Sweden University*

EFFECTS OF CAFFEINE AND CARBOHYDRATE MOUTH RINSES ON REPEATED SPRINT PERFORMANCE Beaven, C.M.1,6, Cook, C.J.1,2,3, Maulder, P.4, Pooley, A.4, Kilduff, L.5 1: UK Sports Council (London, UK), 2: Imperial College (London, UK), 3: University of Bath (Bath, UK), 4: WINTEC (Hamilton, NZ), 5: Swansea University (Swansea, Wales), 6: Swedish Winter Sports Research Centre, Mid Sweden University (Östersund, Sweden) Introduction The beneficial effect of a carbohydrate mouth rinse (without ingestion) on exercise performance has been related to changes in brain activity (Chambers et al., 2009). Caffeine ingestion also demonstrates positive effects on exercise performance and antagonism of adenosine receptors has been identified as a possible mechanism of action (Davis & Green, 2009). However, neither the effects of carbohydrate nor caffeine mouth rinses on intermittent sprints have been examined previously. Methods Recreationally trained males (n = 12) performed 5 x 6 s sprints on a cycle ergometer interspersed by 24 s of active recovery. Twenty-five ml of either a non-caloric placebo, 6% carbohydrate (glucose), or 1.2% caffeine solution was rinsed in the mouth for 5 s prior to each sprint in a double-blinded and balanced, cross-over design. A second trial compared a combination of carbohydrate and caffeine with a carbohydrate only mouth rinse. Post-exercise maximal heart rate and perceived exertion were recorded along with power measures. Results Compared to the placebo, carbohydrate substantially increased initial peak power ( $22.1 \pm 19.5$  W; ES: 0.81) and both caffeine ( $26.9 \pm 26.9$  W; ES: 0.71) and carbohydrate ( $39.1 \pm 26.9$  W; ES: 1.08) improved initial mean power. Caffeine also enhanced initial peak power performance ( $103.8 \pm 116.5$  W; ES: 0.87) in a sub-group of responders (n = 6). Heart rate and rating of perceived exertion did not differ between the three trials (P > 0.05). The second trial confirmed that both carbohydrate alone and a combination of both caffeine and carbohydrate in a mouth rinse could improve initial power production in cycle sprints (ES range: 0.66 – 1.86) with the combination mouth rinse consistently out-performing the carbohydrate only condition in terms of peak (1.0 to 36.0 W) and mean power (1.0 to 35.4 W). Conclusion Carbohydrate and/or caffeine mouth rinses rapidly increased power production in a 6 s sprint which may have positive benefits for specific short sprint exercise performance. Improvements in maximal exercise performance in the absence of fatigue resulting from a mouth rinse suggests a central mechanism that is capable of enhancing the neural drive to the motor units and access the muscle recruitment reserve proposed by Gibson and colleagues (2001). ### CARBOHYDRATES AND EXERCISE PERFORMANCE IN NON-FASTED ATHLETES: A SYSTEMATIC REVIEW OF STUDIES MIMICKING REAL LIFE SITUATIONS

Colombani, P.C.1, Mannhart, C.2, Mettler, S.1,3

*ETH Zurich*

1: ETH Zurich, Switzerland; 2: consulting mannhart, Wolfhausen, Switzerland; 3: Federal Office of Sports, Magglingen, Switzerland Introduction Carbohydrate intake in the proximity of or during a sports event is often considered to influence sports performance in a positive way and substantial research to investigate this has been carried out. However, in many studies standardized laboratory situations were applied that did not necessarily mimic the situation of a real competition. In this systematic review, we aimed at summarizing all studies in which a setting was used that mimicked the real life situation of a competition. Method The PubMed was screened for randomized, crossover, and placebo-controlled studies in which the subjects were in a postprandial state (2 to 4 h), between 18 and 40 years old (both genders allowed) and their reported VO<sub>2</sub>max was equal to or higher than 50 mL/kg body mass. The tested drink had to contain carbohydrates of any type and water. Electrolytes were allowed, but no further components (e.g. caffeine, choline, protein, amino acids, fatty acids). The tested drink had to be supplied immediately before and/or during the performance test that had to be of a time trial character (e.g. fixed distance, fixed time). Results 16'658 PubMed abstracts were manually screened, yielding 17 articles with 22 carbohydrate interventions that fulfilled the inclusion criteria. The interventions covered test durations from 26 to 241 min (mostly cycling). In four of five interventions with duration to 68 min and in seven of 17 interventions with durations between 70 and 241 min no significant performance improvement was observed with the carbohydrate intervention. The improvement in performance with the 11 studies, in which an ergogenic effect was reported, was between 1 and 13 %. Conclusion A significant ergogenic effect of providing carbohydrates in the proximity or during an exercise session lasting up to 70 min and simulating a real life situation does not seem to occur with trained athletes. For longer exercise durations it seems that the ergogenic effect is at least not as clear as usually discussed, but it also generally seems unlikely that carbohydrate provision as mentioned deteriorates exercise performance. Unfortunately, many articles had to be discarded from this review because relevant information enabling a comprehensive evaluation of the study was missing. Further well described studies with a real life setting and with well-trained athletes are needed to clarify the question about the magnitude of performance enhancement through carbohydrate provision immediately before/during an exercise bout simulating a competitive event. Acknowledgement The study was supported by a grant of the Federal Commission of Sports, Switzerland.

### THE EFFECT OF SODIUM PHOSPHATE SUPPLEMENTATION ON APPETITE AND ENERGY INTAKE IN TRAINED INDIVIDUALS

Guelfi, K.J., West, J.S., Ayton, T., Wallman, K.E.

*The University of Western Australia*

Introduction Ingestion of an acute dose of phosphate has been shown to attenuate energy intake in the subsequent meal (Obied et al., 2010). This raises the question of whether the practice of phosphate supplementation over a number of days by athletes to enhance performance also influences appetite and energy intake. The aim of this study was to investigate the effect of 6 days of phosphate supplementation on appetite and energy intake in trained individuals. This may have implications for athletes that frequently supplement with sodium phosphate to ensure that energy intake is sufficient to support optimal exercise performance. A secondary aim was to confirm the previously observed benefits of sodium phosphate supplementation for aerobic capacity. Methods Twenty moderately trained individuals participated in two, 6 day phases of supplementation with either sodium phosphate (50 mg/kg of fat free mass per day) or a placebo, in a double-blinded, counterbalanced design. To assess the effect of supplementation on energy intake, a laboratory breakfast meal was provided on days 1, 2 and 6 of supplementation from which ad libitum energy intake was determined. Energy intake

from all other food and drink intake during each supplementation period was determined from self-recorded food diaries. Following the 6 days of supplementation, peak aerobic capacity was assessed. A 2-3 week wash-out was imposed between supplementation phases. Results There was no significant effect of an acute dose of sodium phosphate on energy intake or perception of appetite (hunger, fullness, desire to eat or prospective food consumption) at the initial laboratory breakfast meal (i.e. day 1 of supplementation;  $p > 0.05$ ). Likewise, there was no effect of supplementation on energy intake or perception of appetite at the laboratory breakfast meal on day 2 or day 6 of supplementation ( $p > 0.05$ ). There was also no effect of supplementation on daily energy intake from the self-recorded food diaries ( $p > 0.05$ ). With respect to the effect of supplementation on peak aerobic capacity, there was no difference between trials ( $p > 0.05$ ). Discussion In summary, 6 days of sodium phosphate supplementation does not appear to influence energy intake. Therefore athletes supplementing with sodium phosphate can do so without hindering nutritional status. However, given that phosphate supplementation failed to improve aerobic capacity, the ergogenic benefit of this supplement remains questionable. References Obeid OA, Dimachkie S, Hlais S. (2010). *Int J Obes*, 34, 1446-1448.

### THE EFFECTS OF CREATINE SUPPLEMENTATION ON THE RELIABILITY OF BODY COMPOSITION AND BONE DENSITY MEASUREMENT USING DXA

Wallace, J.A.

*Aberystwyth University*

Introduction Increased cell hydration observed during periods of creatine loading (Powers et al. 2003), may affect the imaging quality of DXA scans. The extra cellular water may falsely elevate fat and muscle masses by adding artefacts to the scan analyses, resulting in erroneously low bone mineral density values, due to disruption of the x-ray beam attenuation (Horber et al. 1992). Studies investigating bone health or body composition without controlling for this nutritional supplement may have failed to address this issue, therefore reducing the accuracy, validity and legitimacy of their findings. Method Body composition (total mass, fat mass, lean mass, and percent body fat) and whole-body, proximal femur and lumbar spine bone mineral density (BMD), of 18 active subjects (Males:  $n=10$ ; Female:  $n=8$ )  $22.7 \pm 6.4$  years;  $70.1 \pm 9.3$  kg;  $1.72 \pm 0.09$  m, were measured using dual-energy X-ray absorptiometry (DXA). Measures were taken in a fasted state at baseline, following 1 week of supplementation and again 3 weeks post supplementation. Supplementation consisted of 20g creatine monohydrate (Creapure, Alzchem, Germany) with 30g dextrose, taken once a day for 7 days. Data were analysed using SPSS v19, by means of a 1-way within groups ANOVA. Results There were no significant changes in whole-body, total proximal femur or total lumbar spine BMD ( $P>0.05$ ). Whole-body mass significantly increased after supplementation and subsequently returned to baseline post washout ( $P>0.05$ :  $70.3 \pm 2.2$  kg;  $71.1 \pm 2.3$  kg and  $70.5 \pm 2.2$  kg). Lean tissue mass significantly increased by  $1.2 \pm 0.9$  kg after supplementation ( $p < 0.05$ ), yet failed to return to baseline post washout. Fat mass decreased after supplementation and again failed to return to baseline ( $p < 0.05$ :  $17.9 \pm 1.0$  kg;  $17.5 \pm 1.0$  kg and  $17.3 \pm 1.1$ kg). Discussion The gains in body mass and lean mass observed are likely due to water retention during supplementation. Creatine is an osmotically active substance. Thus, any increase in the body's creatine content should result in increased water retention and consequent gains in body mass, originating from the lean tissue. DXA is sensitive enough to detect changes in soft tissue mass related to fluid gain. Thus, body composition changes that are observed during periods of creatine loading, are possibly linked to an increase in total body water, rather than functional gains of a tissue type. Therefore, studies using DXA to measure or compare soft tissue components should consist of a washout period prior to scanning, or control for these fluid changes in their interpretation of data. #### IS-SH04 Martial Arts from a Multidisciplinary Perspective: Historical, Sociological and Psychological

##### LOOKING AT MARTIAL ARTS INVOLVEMENT AMONG YOUTH

Theeboom, M.

*Vrije Universiteit Brussel*

Youth participation in martial arts (e.g., judo, karate, taekwondo, kickboxing) has universal appeal. In several countries martial arts are listed in the ten most practiced sports among youth in general. Studies in Europe have also revealed that in several countries martial arts participation in a club-related context is very high and many members are under the age of 18 (van Bottenburg et al., 2005). This popularity has led to an increased interest in martial arts research over the past decade. However, despite the growing body of martial arts research, to date, many questions remain unanswered, specifically with regard to the meaning and impact of martial arts involvement to young participants. By and large, the relation between youngsters and martial arts is often viewed in controversial terms. On the one hand, youth participation has been associated with negative effects to personal and social well-being often emphasising the promotion of aggressive and violent behaviour of those involved. On the other hand however, there is also a belief that martial arts practice among children and adolescents can lead to positive socio-psychological outcomes and can be regarded as a means of education in general. Both perspectives have been supported by scientific research. It can however be argued that a 'good versus bad' point of view with regard to youth involvement in martial arts in general is questionable. By providing an overview of the most relevant research on martial arts and youth, as well as critically looking at a number of trends that can be detected in various parts of Europe, this paper will emphasise the need for a discerned view of the perceived or proclaimed outcomes of martial arts involvement among youth. Future research directions, as well as policy recommendations in relation to martial arts and youth will also be described. References Bottenburg, van M., Rijnen, B. and van Sterkenburg, J. (2005). **THE CREATION AND TRANSFORMATION OF ASIAN MARTIAL ARTS IMAGINARY IN THE WEST**

Gutiérrez-García, C.

*University of León*

This presentation aims at analyzing the historical evolution of Asian Martial Arts (AMA) in the West from the perspective of their imaginary. Imaginary – or social imaginary – is considered here as cognitive schemas widely shared by ordinary people which legitimate and make possible common practices (Taylor, 2004). Although some Asian martial traditions were known many centuries ago in Western countries, modern AMA imaginary started to be created since the mid 19th century after the opening of Japan to the outside world. Japan became an internationally recognized military power in a few decades after defeating China (1894-95) and Russia (1904-95), thus rising the interest in the West about Japanese martial culture. Japanese MA – particularly jujutsu/judo – soon built a strong imaginary as ancient, bushido inspired, complex self-defense systems “that would allow a weak person to be capable of defeating a stronger opponent with minimal effort” (Gutiérrez et al., 2010: 26). Also, they were perceived as sports and physical and moral education means. This first, powerful imaginary, has irregularly evolved until present day. Foreign policies between Japan and Western countries, Japanese emigration, the inclusion of MA in military training, MA sportification processes or MA films have defined different historical and regional rhythms. Also, it is noteworthy that new MA imported in the West such as Karate or Taekwondo embraced this imaginary although trying to enhance their peculiarities (Green & Svinth, 2010). Since the middle of the 20th century, countercultural movements added a new set of images to AMA. Examples include New Age, Human Potential Movement or Holistic Health Movement (Campbell, 2007). AMA were seen as means for achieving holistic health and harmony with the self, nature and the universe. Many of these ideas came in fact from Asian religious-philosophical systems, but were soon westernized. While many AMA have usually incorporated countercultural imaginary to some degree, such as Zen meditation, some Chinese MA have adhered quite closely to this imaginary so that they are considered as countercultural typical practices. That is the case of the so-called “inner martial arts” such as Taijiquan (a.k.a. Tai Chi). Nowadays the social imaginary of AMA in the West is mainly refreshed by their practice as sports/health activities and by mass media, particularly films and TV series. This imaginary makes possible that AMA are so widely spread as social practice among population of different regions, ages and sex. **SPORT PSYCHOLOGY DELIVERY SERVICES TO OLYMPIC TAEKWONDO**

Sanchez, X.

*University of Groningen*

Taekwondo, an Olympic combat sport since Sydney 2000, is a discipline in which opponents are directly, deliberately and systematically confronted against each other in a dynamic environment (Pieter & Heijmans, 1997). Based on previous experience, the present communication illustrates how Taekwondo questions had been answered through sport psychology and how these answers had been applied in the sporting arena. We focus on the work we developed around the tactical component of competitive Taekwondo. We adopt Bishop's (2008) three-phase, eight-stage applied research model for the sport sciences (ARMSS) as a framework that is of particular interest when identifying performance predictors in such new disciplines. Sanchez and Wautier (2003) developed the Taekwondo Combat Assessment System (TCAS), a tool to study Taekwondo combatants' interactions during combats. By video-analysing the combats with TCAS, combatants' technical-tactical changes are detected and specific patterns of fighting are identified. First, by profiling the performance of the athletes, their temporal evolution in a competition is monitored (round by round, combat by combat) as well as their combat-learning development (throughout competitions). Second, by profiling the performance of the adversaries, the self-confidence of the athletes increases (self-reports), and the causal attributions of their performances become adaptive and modifiable (i.e. rather internal and controllable). In addition, by considering these causal attributions players and coaches provide to explain performance during a competition, the sport psychologist is able to assess the factors that are believed influence performance (Sanchez et al., 2003). Finally, athletes' emotional states are individually assessed to (1) build up 'optimal profiles' from which athletes have, in theory, the greatest chances to perform at their best, and (2) train those athletes how best manage these optimal levels. The presentation is supported with specific case-examples for both in-between-rounds, such as active recovering (rehydrating, attentional focus, effective communication) and in-between-combats, such as active recovering (skipping), competition modes (pre-, post-, no-fight), and optimal emotional-arousal regulation (use of music). **09:50 - 11:20****Invited symposia****IS-BN03 Neuroplasticity: From Basic Sciences to Sport Performance****BRAIN-DERIVED NEUROTROPHIC FACTOR AND EXERCISE, AN UPDATE**

Knaepen, K., Goekint, M., Meeusen, R.

*Vrije Universiteit Brussel*

Introduction: Neurotrophins are important regulators of neuronal survival, development, function, and plasticity. They are capable of signaling neurons to survive, differentiate or grow. Neurotrophic factors are also important in processes of central and peripheral energy metabolism. Their effect on synaptic plasticity in the central nervous system involves elements of cellular energy metabolism and in the periphery they take part in metabolic processes. Physical activity, and in particular, acute exercise and training play a key role in process-

es through which neurotrophins mediate energy metabolism and in turn neural plasticity. Brain-derived neurotrophic factor (BDNF) is the most susceptible to regulation by physical activity. Objectives: To give an update on the current research on peripheral BDNF following acute exercise or training interventions in healthy subjects and in people with a chronic disease or disability. Methods: Systematic literature review. Results: Most studies showed a transient increase in serum or plasma BDNF following acute exercise, both in healthy subjects and in people with a chronic disease or disability. Except for one study, strength and aerobic training interventions have no effect on BDNF concentrations. Discussion & Conclusion: Exercise temporarily elevates basal BDNF concentrations and possibly upregulates cellular processing of BDNF (i.e., synthesis, release, absorption and degradation). Acute exercise influences serum and plasma BDNF concentrations, although the affect is transient. No acute exercise or training protocol has a long lasting influence on peripheral BDNF concentrations in healthy subjects or people with a chronic disease or disability. Evidence of effects of acute exercise or training protocols on BDNF in people with a chronic disease or disability is inadequate to draw firm conclusions whether these effects differ from the effects in healthy subjects. Whether the use of acute exercise and training is viable in the treatment of neurodegenerative and metabolic diseases, seen from its effects on BDNF, still remains to be elucidated.

### **THE MUSICIAN'S BRAIN AS A MODEL OF BENEFICIAL AND MALADAPTIVE BRAIN PLASTICITY**

Altenmüller, E.

*HMTM-Hannover*

Performing music at a professional level is probably the most complex of human accomplishments. Music, as a sensory stimulus, is highly complex and structured along several dimensions. Moreover, making music requires the integration of multimodal sensory and motor information and precise monitoring of the performance via auditory feedback. In the context of classical music, musicians are forced to reproduce highly controlled movements almost perfectly with a high reliability. These specialized sensory-motor skills require extensive training periods over many years, starting in early infancy and passing through stages of increasing physical and strategic complexities. The superior skills of musicians are mirrored in plastic adaptations of the brain on different time. At one extreme, years of musical experience, especially in those musicians who begin training early in life, might lead to an increase in gray and white matter volume in several brain regions, including sensory-motor and auditory areas, the cerebellum and the anterior portion of the corpus callosum. These anatomical alterations appear to be confined to a critical period. The fact that in several of the studies a correlation was found between the extent of the anatomical differences and the age at which the musical training commenced strongly argues against the possibility that these differences are pre-existing and the cause for rather than the result of practicing music. There is a dark side to the increasing specialisation and prolonged training of modern musicians, namely loss of control and degradation of skilled hand movements, a disorder referred to as musicians' cramp or focal dystonia. The first historical record, from 1830, appears in the diaries of the ambitious pianist and composer Robert Schumann. As was probably the case for Schumann, prolonged practice and pain syndromes due to overuse can precipitate dystonia, which is developed by about 1% of professional musicians and usually ends their career. Neuroimaging studies point to dysfunctional (or maladaptive) neuroplasticity as its cause. Support for this theory comes from a functional brain imaging study performed in musicians with focal dystonia. Considering 1) the historical advent of the disorder in the nineteenth century with rapidly increasing technical demands imposed on musicians, 2) the epidemiological data with biomechanical load as a risk factor, and 3) neurobiological findings of the blurring of hand representations, one is tempted to state that focal dystonia finally marks the natural limits of a process of refinement of manual dexterity over a million years.

### **THE IMPORTANCE OF AUGMENTED FEEDBACK IN MOTOR LEARNING**

Leukel, C.

*University of Freiburg*

We are permanently informed by sensory feedback about the state of our own body and the state of the environment we are moving in. This is essential to adequately control motor task as well as to learn new and refine existing behaviour. Several types of feedback exist. For classification, feedback can simply be divided in intrinsic internal feedback, informing us about the state of our body, and intrinsic external feedback, informing about the state of our environment. A third type of feedback, called extrinsic or augmented feedback, provides explicit quantitative information about the performance of an accomplished motor task. This type of feedback has been shown to facilitate learning-related performance in many practical settings. In the first part of this talk, it is explained how augmented feedback may help to improve learning-related performance in different learning processes like error-based learning or reinforcement learning. As improvements in performance are based on neural plasticity within the central nervous system, the second part of the talk is concerned with the underlying neural changes when learning with augmented feedback. Finally, a specific subtype of augmented feedback is mentioned which may have great potential to modify behaviour. This subtype is subconscious (also termed subliminal) information, presented at stimulus intensities below conscious perception but strong enough to be processed within the central nervous system. Previous investigations show that motor performance can be improved by subconscious information. This finding may have practical implications when appropriately applied in specific settings.

### OP-BN04 Muscle/Tendon/Bone

#### BONE MICRO-ARCHITECTURE, ESTIMATED BONE STRENGTH, AND MUSCLE STRENGTH IN ELITE FEMALE ATHLETES: A HR-pQCT STUDY

Schipilow, J., Liphardt, A.M., Kan, M., Buie, H., Macdonald, H., Boyd, S.

*University of Calgary*

Bone micro-architecture, estimated bone strength, and muscle strength in elite female athletes: a HR-pQCT study Schipilow, J.1, Liphardt, A.M.1, Kan, M.1, Buie H.1, Macdonald H.2, Boyd, S.1 1: Schulich School of Engineering, University of Calgary, Canada 2: University of British Columbia, Canada Introduction Athletes participating in sports characterized by specific loading modalities show different levels of bone adaptation [1]. It is unclear how these loading environments affect bone macro- and micro-architecture and estimated bone strength, all contributors to bone quality. Furthermore, the relative role of impact versus muscle forces in determining bone quality remains a topic of debate [2]. The purpose of this study was to (1) investigate the differences in bone macro- and micro-architecture and estimated bone strength in elite female athletes; and (2) gain further insight into the muscle-bone relationship. Methods Elite female athletes (N=54) participating in high-impact (alpine skiing, n=10), moderate-impact (soccer, n=11), and non-impact sports (swimming, n=11), and 9 controls were measured at the dominant distal tibia using high-resolution peripheral quantitative computed tomography (HR-pQCT). Outcomes included total volumetric bone mineral density (vBMD), total area (Tt.Ar), and cortical area (Ct.Ar). Finite element analysis was used to estimate failure load (FL) of the bone. Muscle strength was assessed by measuring isokinetic knee extension torque (KET) with a Biodex dynamometer. Means were compared using a one-way ANOVA. Pearson correlations were used to identify any relationships between muscle strength and bone parameters. All reported differences and correlations are significant at  $p < 0.05$ . Results Swimmers exhibited a vBMD of  $281.0 \pm 41.4$  mg HA/cm<sup>3</sup> (mean  $\pm$  SD), which was 19%, 20%, and 15% lower than skiers, soccer players, and controls, respectively. Swimmers displayed a Tt.Ar of  $808.1 \pm 122.5$  mm<sup>2</sup>, which was 20% larger than controls; however, swimmer Ct.Ar ( $109.8 \pm 11.3$  mm<sup>2</sup>) was 17%, 18%, and 14% lower than skiers, soccer players, and controls, respectively. The FL calculated for swimmers ( $6.0 \pm 0.6$  kN) was 24% lower than skiers and 15% lower than soccer players. Skier KET ( $159.0 \pm 22.0$  Nm) was 24% higher than controls. After pooling the data, weak to moderate correlations were found between KET and vBMD ( $r=0.32$ ), Ct.Ar ( $r=0.42$ ), and FL ( $r=0.55$ ). Discussion Differences in bone parameters are shown between impact and non-impact sports, leading to the inference that impact loading is highly associated with bone quality. The results also show a relationship, albeit a weak to moderate one, between muscle strength and bone parameters. These data suggest that impact loading plays a larger role than muscle strength in determining bone quality; however, longitudinal prospective studies are required to support this. References [1] Nikander et al. (2006). Bone. 39(1), 886-894. [2] Robling, AG. (2009). Med Sci Sports Ex. 41(11), 2044-2049.

#### DEVELOPMENTAL DIFFERENCES IN DYNAMIC MUSCLE AND TENDON BEHAVIOUR: IMPLICATIONS FOR MOVEMENT EFFICIENCY

Waugh, C.M., Blazeovich, A.J., Korff, T.

*Brunel University*

Children perform cyclic motor tasks less efficiently than adults; however, the mechanisms underlying such differences are not fully understood. One mechanism that may contribute to age-related differences in task efficiency is the differential movement of muscles and tendons for a given muscle-tendon unit (MTU) length change. In adults, the majority of an MTU length change is performed by the tendon, which minimises energy expenditure by maximising elastic energy utilisation and enabling the muscle to operate near-isometrically. Previously observed age-related differences in tendon stiffness between children and adults may affect MTU dynamics and could influence movement efficiency. The aims of this study were to a) compare muscle and tendon length changes as a function of MTU length during two-legged hopping between children and adults and b) examine the relationship between such changes and tendon stiffness. 10 children ( $8.8 \pm 0.3$  years) and 10 adults ( $26.3 \pm 2.2$  years) performed 20-s of two-legged unshod hopping at a self-selected frequency. Gastrocnemius medialis (GM) muscle-tendon junction movement was imaged using ultrasonography whilst reflective markers placed on the hip, knee and foot provided sagittal movement kinematics. MTU length changes were estimated from anthropometric and kinematic data, and individual muscle and tendon length changes were derived using a combination of 3D-motion capture and ultrasonography. Length change profiles were averaged for the ground contact phase of 6 consecutive hops for each participant. Achilles tendon stiffness was calculated as the slope of the tendon force-elongation curve between 10-90% of maximum isometric plantarflexor force. The degree to which the tendon traced MTU movement was quantified as the difference between MTU and tendon length change at each participant's maximum MTU length change. Group means were examined using an independent t-test ( $p < 0.05$ ). The relationship between such changes and tendon stiffness was examined using a linear regression analysis. In relation to MTU movement, tendon length change was 30% lower in children compared to adults ( $p=0.021$ ). Moreover, the difference in MTU and tendon length changes were moderately correlated with tendon stiffness ( $r=0.64$ ). The present data demonstrate that the tendon component of the GM MTU lengthens to a lesser extent than that observed in adults during two-legged hopping. This difference is related to developmental differences in tendon stiffness, which lets us speculate that greater elastic energy utilisation and slower muscle shortening velocities contribute to age-related differences in cyclic task efficiency. These results have extensive implications for optimising sporting performance or improving movement disorders in children and should be the subject of future research.

## FOOT DEFORMATION INDUCED BY PASSIVE ANKLE MOTIONS IS DIFFERENT BETWEEN BOYS AND YOUNG ADULT MEN: IMPLICATIONS FOR THE JOINT ANGLE-MUSCLE-TENDON UNIT LENGTH RELATIONSHIP

Iwanuma, S.1, Hashizume, S.1, Kanehisa, H.2, Yanai, T.1, Kawakami, Y.1

*Waseda university*

[Introduction] The length of the muscle-tendon unit (MTU) is an important parameter that influences its mechanical functions. The foot deformation during ankle joint rotation affects the triceps surae MTU length-ankle joint angle relationship (Iwanuma et al., 2011). The foot deformation is associated with the elasticity of connective tissues within it (Ker et al., 1987). Since the connective tissues in children are more compliant than those in adults (e.g., O'Brien et al., 2010), we tested a hypothesis that the foot deformation for a given ankle dorsiflexion in boys is larger than that in young adult men, and it induces age-related difference in joint angle-MTU length relationship. [Methods] Thirteen boys (BOYS, 12 - 14 years) and 13 young adult men (ADULTS, 22 - 29 years) participated in this study. An MRI scanner was used to take a series of sagittal images of the foot at rest with four ankle positions of 10° dorsiflexion (DF10), neutral position, 10° and 20° plantar flexion (initial position). The MTU elongation was determined from the displacement of the calcaneal tuberosity, and it was normalized by lower leg length. The dorsiflexion angles of the anterior segment (the line connecting metatarsal to navicular bones,  $\theta_{ant}$ ) and posterior segment (the line connecting talus to calcaneus,  $\theta_{post}$ ) relative to the longitudinal direction of tibia were measured in each ankle position. In addition, the length of posterior segment ( $L_{post}$ ) and the displacement of the anterior vertex of talus ( $D_{tal-X}$  and  $D_{tal-Y}$ ) were measured. [Results and Discussion] The foot deformation at DF10 in BOYS ( $9 \pm 4^\circ$ ) was significantly larger than that in ADULTS ( $5 \pm 2^\circ$ ), which was caused by the difference in the  $\theta_{post}$  between BOYS ( $20 \pm 3^\circ$ ) and ADULTS ( $23 \pm 4^\circ$ ), and was independent of  $\theta_{ant}$ . The MTU elongation at DF10 in BOYS ( $15 \pm 3$  mm,  $4.1 \pm 0.9\%$ ) was significantly smaller than that in ADULTS ( $19 \pm 3$  mm,  $4.9 \pm 0.8\%$ ). The MTU elongation was more closely correlated to  $\theta_{post}$  (.82) than  $D_{tal-X}$  (-.26) and  $D_{tal-Y}$  (.32) as a result of partial correlation analysis, but it was not related to  $L_{post}$ . These results indicate that the foot is more flat during ankle dorsiflexion in BOYS than in ADULTS, and it induces an age-related difference in the MTU length change relative to a given ankle joint angle change. ## NON-INVASIVE MEASUREMENTS OF THE TENSION DEVELOPED IN THE PATELLAR TENDON DURING SQUATTING - A CASE STUDY WITH A NOVEL SENSOR

Djordjevic, S.

*TMG-BMC d.o.o.*

Non-invasive measurements of the tension developed in the patellar tendon during squatting - a case study with a novel sensor Djordjevic, S. 1, Meglic, A. 1, Tomazic, S. 2, Morrissey, D. 3, Langberg, H. 4: 1: TMG-BMC, Ljubljana, Slovenia 2: Faculty of Electrical Engineering, University of Ljubljana, Slovenia 3: Queen Mary University of London, Centre for Sports and Exercise Medicine, UK 4: Institute of Sports Medicine, University of Copenhagen, Denmark Introduction The dynamic squat exercise is an integral part of strength and conditioning programs in many sports that require high levels of strength and power. The squat primarily strengthens hip, thigh, and calf musculature – all of which are key muscles for running, jumping and lifting. There are limited methods for characterization of dynamic muscle function and tendon force. Various methods do exist to measure muscle function however dynamic, non-invasive measurement of muscle or tendon tension is very challenging and, to our knowledge, no direct methods exist to quantify in vivo tendon and muscle forces that can be used on the field. In our study we aimed to measure quadriceps muscle and tendon forces during squatting using a novel force sensor in order to better understand dynamic tissue behavior during the squat movement. Methods To measure vastus medialis and lateralis muscle and tendon tension we used a new mechanical contraction (MC) sensor and data logger (TMG-BMC, Slovenia), adapted for muscle or tendon measurements (Djordjevic et al., 2011). Simultaneous EMG was measured using a 4-channel analog input device (National Instruments, USA) and knee angle with a 6D ACC-GYR (TMG-BMC, Slovenia). The subject performed 4 squatting movements, descending until the thighs were approximately parallel to the floor (thigh angle from perpendicular to app. parallel to the floor) without additional load. Results There was a significant correlation between the MC sensor data from the patellar tendon, knee joint torque and angle. MC measurement of tension recorded from vastus lateralis and medialis corresponded to the timeline of the EMG signal. The data also shows differences in amplitude of tension of vastus lateralis and medialis, potentially yielding insight into how both muscles mechanically contribute to the generation of tension in the patellar tendon. Discussion The new sensor shows potential utility for measurement of the dynamic properties of accessible tendons and muscles. There are strong correlations with generally accepted measurement tools e.g. EMG, revealing a proportional relationship to muscle force output and range of joint movement. Further reliability and validity studies are underway to reveal the full potential of these dynamic in-vivo perpendicular force sensors as a measure of contractile tissue and tendon function. ## NONINVASIVE ESTIMATION OF MYOSIN HEAVY CHAIN COMPOSITION IN HUMAN SKELETAL MUSCLE

Simunic, B.1, Degens, H.2, Rittweger, J.3, Mekjavic, I.3, Pisot, R.1

*University of Primorska*

NONINVASIVE ESTIMATION OF MYOSIN HEAVY CHAIN COMPOSITION IN HUMAN SKELETAL MUSCLE Šimunič, B.1, Degens, H.2, Rittweger, J.3, Mekjavic, I.3, Pisot, R.1 1: UP (Koper, Slovenia), 2: MMU (Manchester, UK), 3: IJS (Ljubljana, Slovenia) Introduction Information on muscle fiber type composition is of great importance in muscle physiology and athletic performance. Because there are only a few techniques available that noninvasively and accurately provide an estimate of muscle fiber type composition, the development of additional and alternative approaches is required. Therefore, the aim of our study was to evaluate the correlation between radial twitch delay time (Td), contraction time (Tc) and half relaxation time (Tr) measured by Tensiomyography (TMG) and percentage of myosin heavy chain 1 (%MHC-I) in the human vastus lateralis muscle. Furthermore, we used a multiple regression analysis of %MHC-I versus Td, Tc, and Tr to establish noninvasive estimators of %MHC-I in human skeletal muscle. Methods Twenty-seven participants with an average age of 43 (18) years, height of 175 (7) cm, and mass of 74 (12) kg participated in the study. Td, Tc, and Tr were calculated from TMG radial twitch responses of the vastus lateralis muscle. Univariate and multiple linear regression analyses were used to correlate the proportion of %MHC-I in a biopsy obtained from the same muscle with a single and all three radial twitch parameters. Results Td, Tc, and Tr all correlated with %MHC-I ( $r = 0.612, 0.878, \text{ and } 0.669$ , respectively, at  $P < 0.001$ ). When all three parameters were included in a multiple linear regression, the correlation with the %MHC-I was even higher ( $R = 0.933, P < 0.001$ ). The result of multiple regression analysis is an equation: %MHC-I

$= 2.829Tc + 2.98Td + 0.127Tr - 121.023$ . Discussion TMG is a simple-to-use, reliable (Križaj et al., 2008), noninvasive, and selective method for the determination of skeletal muscle contractile parameters. The method could be easily applied in superficial human muscles. Our finding suggests that TMG method could be used for valid estimation of the %MHC-I in the human vastus lateralis muscle and most likely also in other human muscles. TMG upgrades other mechanomyographical methods for non-invasive and selective assessment of skeletal muscle contractile parameters (Valenčič and Knez, 1997). Several mechanomyographic methods have been proposed that are based on measuring lateral vibrations and thickening of the muscle during a contraction, for instance phono or soundmyography and vibromyography. Promising results have been obtained using mechanomyographic methods, but there are several difficulties: such as a low signal-to-noise ratio and consequently high variability, complex measuring setup and/or expensive hardware, and necessary postprocessing of the signals. ### **AUTOGRAFT OR BIOIMPLANT WHEN REPAIRING TRAUMATIC CARTILAGE DEFECTS IN A RABBIT MODEL**

Intzoglou, K., Papaparaskeva, K., Koulalis, J.

*Athens University*

**Objectives:** We designed a laboratory study in order to analyze histologically and immunoistochemically the results of two wide spread one staged techniques, which are used for traumatic osteochondral repair: osteochondral autografting and biosynthetic osteochondral implantation. **Methods:** Thirty skeletally mature New Zealand White rabbits were used. With a hand drill, an osteochondral defect was created (4,5 mm diameter and 7mm depth) in the right knee of each rabbit. The defect was restored using osteochondral autograft (group A, ten rabbits), biosynthetic osteochondral graft (group B, ten rabbits) or was left untreated (group C, ten rabbits). The ICRS score was used to evaluate the restored tissue of the osteochondral defects 24 weeks post-op. **Results:** Statistical difference ( $p < 0,05$ ) was observed as far as the ICRS categories matrix, cell distribution, subchondral bone and cartilage mineralization are concerned. No statistical difference was noticed in the surface and cell viability category. Histochemical stains (Blue Toluidine and Van Giesson) and immunohistochemical results (antibody for collagen II) came in agreement with morphological results (ICRS score). **Conclusions:** Restoring osteochondral knee defects continues to challenge the present orthopaedician. Choosing the autograft looks like a better choice than the biosynthetic material, which in turn is a better choice than no treatment. The lack of statistical difference as far the surface category (macroscopic appearance) and the cell viability are concerned should be especially pointed out. As long as morbidity of the donor site is attached to the technique of autografting itself, combination of the two compared methods- autografting while restoring donor site with biosynthetic implant- constitutes a good surgical option today.

#### **AN OLD QUESTION REVISITED: IS MOVEMENT OR MUSCLE CODED IN THE MOTOR CORTEX? IMPLICATIONS FOR MOTOR REHABILITATION.**

Zijdewind, I., Ampomah, I., Bianchi, F.

*UMCG, University of Groningen*

**Introduction** At present motor imagery (MI) is advocated as a mean for motor rehabilitation. Stroke patients are encouraged to imagine goal-directed movements to help them relearn motor programs. Up to now, no attention has been paid to the importance of posture of the patient during motor imagery. In the present study we tested whether position is an important parameter that needs to be controlled during motor imagery. **Methods** Right-handed subjects (14, 10 females, age 20-31) were included. Subjects sat in a chair with their arms flexed (ca. 135°), their forearms resting on plateaus in front of them so that their hands were free. Subjects looked at a computer screen, which randomly showed alternating hand positions of the left and right hand (prone [P], halfway between prone and supine with thumbs up [HW], supine [S], and halfway between prone and supine with thumb down [HI]). Subjects placed their hands similarly to the hand positions on the screen. After a beep, they imagined moving their right index finger in the direction that was also shown on the screen (up, down, left, right); only imaginary abduction and flexion movements were used. A session consisted of 3 blocks of 32 imaginary contractions (5 s contractions, 15 s rest). During the imaginary contraction, the contralateral motor cortex was stimulated with transcranial magnetic stimulation. Motor evoked potentials (MEPs) were recorded in the right first dorsal interosseus (index finger abductor, FDI). Modulation of the MEPs was analysed with separate repeated measures ANOVA's 1) with movement (2), left (4) and right hand position (4) as within subjects factors and 2) with movement (2), direction (4) and left hand position (4) as within subjects factors. **Results** During the experiment the MEP amplitudes of the FDI were significantly modulated by movement ( $F(1,13)=16.806$ ,  $p=0.001$ ), right hand position ( $F(3,39)=4.370$ ,  $p=0.03$ ) and movement direction ( $F(3,39)=5.240$ ,  $p=0.004$ ). Post hoc analysis showed that imaginary performance of an abduction movement resulted in significantly larger MEPs than during flexion movements. Furthermore, larger MEPs were seen during right hand positions P and HI, than during S and H. For the movement direction, larger MEPs were mainly seen during downward movements. **Conclusions** The results show that corticospinal excitability is affected by different factors. The present data suggests that the coding of movements in the motor cortex depends on both the movement direction as well as on the involved muscles. We assume that a greater corticospinal activation would result in better training effect and thus these results data suggest that it is important to control the position of the patient during motor imagery.

**EFFECT OF REGULAR ENDURANCE TRAINING ON TELOMERE LENGTH IN HUMAN SKELETAL MUSCLE.**

Ponsot, E., Welin, L., Langberg, H., Kjaer, M., Kadi, F.

*University of Örebro*

**EFFECT OF REGULAR ENDURANCE TRAINING ON TELOMERE LENGTH IN HUMAN SKELETAL MUSCLE.** Ponsot E.1, Welin L.1, Langberg H.2, Kjaer M.2, Kadi F.1: 1: School of Health and Medical Sciences, Örebro University (Örebro, Sweden), 2: Institute of Sports Medicine - Copenhagen, Bispebjerg Hospital, (Copenhagen, Denmark). Introduction The length of telomeres is known to be an important indicator of the cell proliferative potential. It is likely that the regulation of telomeres in-vitro cannot fully mimic the behavior of telomeres in human tissues. The effect of regular training on in-vivo telomere length is poorly studied in human skeletal muscle. When satellite cells, the skeletal muscle stem cells, are heavily recruited for regenerative events as in skeletal muscle of athletes, telomere length has been found to be either dramatically shortened (overtrained athletes) or maintained compared to non-trained individuals (for review, see Kadi and Ponsot, 2010). The present study aims to address the question of whether the regular practice of endurance training is associated with alterations in telomere length in skeletal muscle of healthy athletes. Methods Skeletal muscle telomere lengths from a population of 12 healthy athletes regularly involved in endurance training (END) were compared to those of a population of 10 healthy, active individuals (CON). Mean and minimum telomere lengths were determined using southern blot. Results The mean telomere length in END ( $11.1 \pm 1.0$  kbp) did not differ significantly from the values collected in CON ( $10.5 \pm 0.5$  kbp). On the opposite, the minimum telomere length was significantly longer in END ( $5.5 \pm 0.4$  kbp) than in CON ( $4.7 \pm 0.3$  kbp,  $P < 0.001$ ). Discussion Our findings suggest that physical training, when not accompanied by excessive oxidative stress, is not harmful for telomeres and may positively influence telomere length regulation in skeletal muscle as previously suggested in skeletal muscle of strength-trained athletes (Kadi et al., 2008) and in leucocytes (Cherkas et al., 2008; Ludlow et al., 2008). This also suggests that telomeres can be regarded as dynamic structures under the influence of their environment and their length can be maintained as long as the environmental disturbances do not exceed the telomere regulatory capacities. The dynamic equilibrium can even be displaced towards longer telomeres in athletes compared to untrained individuals. The existence of such telomere regulatory mechanisms in well-trained skeletal muscle requires to be further investigated. **COGNITIVE ENHANCEMENT IN RESPONSE TO CHRONIC PHYSICAL TRAINING ON A DOPAMINE-DEPLETION ANIMAL MODEL OF ADHD**

Felszeghy, K., Hart, N., Radák, Z., Nyakas, C.

*Semmelweis University, Faculty of Physical Education and Sport Sciences*

Introduction Attention deficit hyperactivity disorder (ADHD) is a heterogeneous, highly heritable, behavioural disorder that affects 5 to 10% of children worldwide. Basically two forms of the disorder are manifested: inattentive and hyperactive-impulsive forms. Methylphenidate is the preferred treatment for this disorder and has been used for long term management, although its adverse effects have been also detected. Since the brain dopaminergic system is highly involved in the development of ADHD, a neonatal dopamine (DA) depletion rat model has been extensively used for studying this disorder. Methods At neonatal age (postnatal day 4) animals were DA-depleted by intraventricular injection of  $20 \mu\text{g}$  6-hydroxydopamine. This intervention resulted in 70-90% decrement of extracellular DA content in dopaminergic brain areas. Control animals were sham operated. Adult rats at the age of 4 months were trained by daily 1 hour swimming 5 times per week for 10 weeks. On the 11th week animals were tested in a stress situation for hyperactivity and impulsivity in a conditioned fear test. Attention and memory function were assayed in spontaneous alternation and in novel object recognition paradigms. Results Dopamine-depletion resulted in hyperactivity in the conditioned fear stress situation, and a decrement in freezing behaviour, which indicates impulsive response to stress. Ten-week physical training, however, increased the measures of freezing behaviour towards control level. Depleted animals showed impaired attention and memory function during both in spontaneous alternation and novel object recognition. The swimming training significantly enhanced the number of correct alternation as compared to control animals in the spontaneous alternation test. In the novel object recognition test the recognition index of trained animals showed significant improvement in attention as compared to controls. Discussion Our results indicate that 10 weeks of regular swimming training decreased impulsivity of ADHD rats. Moreover, the regular exercise improved attention and memory function of DA-depleted animals comparing to those of untrained and DA-depleted rats. These results suggest that long-term and regular exercise may result in treatment effects in ADHD alone or in combination with the pharmacological intervention. It may be proposed that sport during early childhood development seems to be preventive against emotion driven hyperactivity and the consequent attention and learning problems even in cases of manifest diseases like ADHD. **TWO WEEKS OF MUSCLE DISUSE INDUCES SPECIFIC TYPE II MUSCLE FIBRE ATROPHY WITHOUT A DECLINE IN SATELLITE CELL CONTENT**

Wall, B., Snijders, T., Verdijk, L., van Loon, L.

*Maastricht University*

Muscle disuse leads to a considerable loss of skeletal muscle mass and strength. At present, it is not clear whether this loss of muscle mass is attributed to type I or type II muscle fibre atrophy, or a combination of both. Furthermore, the underlying cellular mechanisms of muscle disuse atrophy remain to be elucidated. The present study assessed the impact of 2 weeks of muscle disuse on quadriceps muscle mass, leg strength, muscle fibre size and muscle fibre type specific satellite cell content. Nine healthy, young ( $23.8 \pm 1.0$  y) men were subjected to 2 weeks of one legged knee immobilization via a full leg cast. Three days before and immediately after the immobilization period, a single slice CT-scan of the immobilized leg was performed to assess quadriceps cross sectional area. In addition, muscle biopsies were obtained from the vastus lateralis to determine muscle fibre type characteristics via immunohistochemistry and fluorescence microscopy. Furthermore, 1-RM leg extension strength of the immobilized leg was determined 3 days prior to and 2 days after the immobilization period. Quadriceps cross sectional area of the immobilized leg declined from baseline by  $7.6 \pm 2.3$  % ( $P < 0.01$ ). In the immobilized leg, type I muscle fibre cross sectional area did not change significantly following immobilization whereas type II muscle fibre cross sectional area declined by  $14.9 \pm 4.3$  % ( $P < 0.05$ ) from baseline. Both type I and II muscle fibre satellite cell content (expressed as satellite cells per muscle fibre) remained unaffected following immobilization. In addition, the immobilization period had resulted in a

22.1±2.9 % decline in 1-RM leg extension strength of the immobilized leg ( $P<0.01$ ). We conclude that 2 weeks of muscle disuse leads to considerable loss of muscle mass and strength. The loss of muscle mass is mainly attributed to specific type II muscle fibre atrophy, and is not accompanied by a decline in satellite cell content.

### EFFECT OF REDUCED TRAINING FREQUENCY ON MUSCLE MASS AND SERUM TESTOSTERONE IN OLDER MEN

Matsutani, K., Sato, K., Takahashi, K., Tsujino, M., Kurihara, T., Iemitsu, M., Hamaoka, T., Fujita, S.

*Ritsumeikan University*

**Introduction** Age-associated loss of muscle mass and function (sarcopenia) leads to weakness of the lower extremities, slowing of gait speed, and increased risk of falls. Progressive resistance training (PRT) has been shown to counteract sarcopenia. Although the exercise guidelines have been proposed to induce muscular hypertrophy, minimum training volume and frequency of training to maintain the increased muscle mass induced by preceding training has not been clearly defined. Therefore, the purpose of the current study was to investigate the effect of PRT and reduced frequency of training on muscle mass and androgenic-anabolic hormone (testosterone) level in healthy older men. **Methods** Eleven healthy older men participated in a PRT program consisting of leg extension and flexion exercises (70% 1-RM, 10 reps  $\times$  3 sets), 3 times per week for 3 months. After the initial 3-month training period, subjects were divided into either control group (CON, N=4; without training) or reduced-training group (RT, N=7; trained once every two weeks) for 12 months. Blood samples were drawn after an overnight fast to assess serum testosterone (TST) levels. Lean mass of both legs (LLM) and muscle cross-sectional area (CSA) of mid-thigh were evaluated using DXA and MRI, respectively. All assessments were performed before the initial training (baseline), three months post-training (3M-post), 12 month after the second training period (1Y-post). **Results** After the initial training period, LLM and muscle CSA have increased by 4.8±0.8% and 7.3±1.1%, respectively. After the second training period, LLM and muscle CSA for CON group were decreased by 2.6±2.3% and 5.9±1.3%, respectively. Similarly, LLM and muscle CSA for RT group decreased almost to the baseline level by 1.1±1.0% and 3.6±0.8%, respectively. Serum TST at rest increased significantly at 3M-post (8.6±0.5 and 11.3±0.9 pg/ml for baseline and 3M-post, respectively;  $P<0.05$ ), but returned to baseline level at 1Y-post in both groups (8.6±0.6 and 8.6±1.6 pg/ml for RT and CON, respectively). No significant group difference in LLM, muscle CSA or serum TST was observed at 1Y-post. There was a significant correlation between %changes in muscle mass and resting TST concentrations after the initial training period ( $r=0.856$ ,  $P<0.001$ ) as well as the second training period ( $r=0.83$ ,  $P=0.002$ ). **Discussion** These results indicated that the training frequency of once every two weeks was not sufficient to maintain the increased muscle mass induced by preceding training in healthy older men. Furthermore, changes in resting serum TST concentrations had significant correlations with changes in muscle mass, suggesting an important association between serum TST level and muscle anabolism during PRT.

### EFFECTS OF THREE WEEKS OF INTENSIFIED TRAINING AND TWO WEEKS OF TAPER ON MITOCHONDRIAL RESPIRATION IN HUMANS

Granata, C.A.

*Victoria University*

**Effects of three weeks of intensified training and two weeks of taper on mitochondrial respiration in humans** Granata C.A. 1, Oliveira R.S.F. 1, Stepto N. 1, Renner-Sattler K. 2 and Bishop D.J. 1, 1 School of Sport and Exercise Science and Institute of Sport, Exercise and Active Living (ISEAL), Victoria University, Melbourne, Australia 2 Institut für Hämatologie und Onkologie Universitätsklinikum Regensburg, Deutschland **Introduction** Mitochondrial respiration has been reported to be an important determinant of endurance performance [1], and interval training (IT) has been shown to induce increases in maximal ADP-stimulated mitochondrial respiration [2]. Despite this, little is known about the effects of a period of intensified training on mitochondrial respiration. Furthermore, to our knowledge, the effects of reduced training workload (i.e., taper) on mitochondrial respiration have not been reported to date. Hence, the purpose of our study was to measure mitochondrial respiration following intensified training and taper, and to determine if changes were associated with changes in cycling performance (20-km time trial). **Methods** Ten active men ( $\text{VO}_2\text{Peak}= 47.0 \text{ mL}\cdot\text{min}^{-1}\cdot\text{kg}^{-1}$ ) took part in an intensified cycling training program (INT), performing an IT protocol twice a day for twenty consecutive days, followed by a two-week exponential taper (TP) consisting of 6 training sessions. Carbohydrate supplementation was used in order to prevent overreaching during the INT phase [3]. Muscle biopsies were taken from the vastus lateralis muscle before the study and after the INT and TP phases. Maximal (5 mM ADP) ADP-stimulated mitochondrial respiration was determined on permeabilised muscle fibers. **Results** Maximal ADP-stimulated and non-coupled respiration simultaneously increased and decreased significantly during the INT and TP phase, respectively. Interestingly ADP sensitivity (0.25 and 0.5 mM ADP) showed no significant change during either phase. Finally complex IV reserve respiration increased significantly but to a lesser extent than maximal respiration during INT and dropped below initial levels after TP. The changes in maximal respiration tended to mirror performance changes. **Discussion** Our study demonstrates that three weeks of INT increased maximal and non-coupled mitochondrial respiration by 30 and 40% respectively, and this was associated with a 5% increase in 20-km TT performance. Surprisingly, the exponential TP resulted in a non-significant decrease in performance; this was accompanied by a marked decrease in maximal respiration (15%), underlining the remarkable plasticity of skeletal muscle oxidative capacity. **References** 1. ### OP-PM13 Pacing and Perception

#### EFFECTS OF COOLING DURING CYCLING ON PHYSIOLOGICAL AND COGNITIVE RESPONSES

Brandenburg, J.P., Gaetz, M.

*University of the Fraser Valley*

**Introduction** Cooling strategies applied during exercise often result in improved performance. The effect of these strategies on cognitive and brain function remains unclear. This study examined the effects of cooling on physiological and perceptual responses, cognitive function, and the electroencephalogram (EEG) during vigorous cycling. **Methods** Nine active males ( $21 \pm 3$  y;  $76.9 \pm 7.7$  kg;  $179.6 \pm 3.8$  cm) completed two trials in a randomized order: a control (CTL) and a cooling (COOL) trial. In each trial, subjects performed 30 min of cycling at a constant power output ( $2.4 \pm 0.2$  W•kg<sup>-1</sup>). During COOL, subjects wore a cooling vest, cooling collar, and received fan cooling while cycling. No cooling was provided in CTL. Heart rate (HR), core (TC) and tympanic (TTY) temperatures, thermal sensation (ThS), and RPE were measured throughout. Cognitive function was measured using the Stroop test and EEG. In both trials water was ingested at a rate to match sweat losses. Air temperature ( $\sim 23^\circ\text{C}$ ) and humidity ( $\sim 50\%$ ) were similar in both trials. **Results** The maximum attained HR was lower in CTL ( $166 \pm 15$  b•min<sup>-1</sup>) than in COOL ( $161 \pm 14$  b•min<sup>-1</sup>) ( $p=0.005$ ). TC rose by  $1.1 \pm 0.3^\circ\text{C}$  to a high of  $38.3 \pm 0.4^\circ\text{C}$  in CTL and by  $0.9 \pm 0.2^\circ\text{C}$  to peak at  $38.2 \pm 0.4^\circ\text{C}$  in COOL (no difference). The rise in TTY was larger in CTL ( $1.1 \pm 0.3^\circ\text{C}$ ) than in COOL ( $0.8 \pm 0.3^\circ\text{C}$ ) ( $p=0.018$ ). ThS was lower throughout COOL ( $p<0.001$ ) while there were no differences in RPE. No significant changes were observed for the Stroop reaction time and errors in the CTL and COOL trials. In CTL, but not COOL, the number of Stroop errors immediately post-cycling was significantly correlated with the rise in TTY ( $r=0.59$ ;  $p=0.025$ ) and the rise in TC ( $r=0.78$ ;  $p=0.004$ ). During cycling differences between CTL and COOL in EEG ratios of low/higher frequency EEG bandwidths emerged (e.g. Theta/Beta1 ratio,  $p=0.019$ ). Significant correlations were observed between EEG ratios and the number of Stroop errors (e.g. ratio of alpha/beta1 activity vs. Stroop errors;  $r=0.63$ ;  $p=0.01$ ). **Discussion** Cooling, during 30 minutes of cycling, moderated the cardiovascular, thermal, and perceptual responses, the increase in low/higher frequency EEG ratios, but did not produce differences in Stroop test variables. Generally, the increase in low/higher frequency ratios during cycling reflects a neural state that is sub-optimal for cognitive functioning (e.g. increased theta, decreased beta activity). The significant correlations between the low/higher frequency EEG ratios and number of Stroop errors support this interpretation. It may be the case that increases in body temperature, as seen with TC and TTY, lead to the changes in the EEG and cognitive functioning. The significant relationships between the number of Stroop errors and the increases in TTY and TC support this observation.

#### EFFECT OF WARM-UP AND PRECOOLING ON 15-KM CYCLING PERFORMANCE IN THE HEAT

Levels, K.1,2, Teunissen, L.P.J.1,2, de Haan, A.1,3, de Koning, J.J.1,4, van Os, J.A.1,2, Foster, C.1,4, Daanen, H.A.M.1,2

1: MOVE, VU University (Amsterdam, The Netherlands), 2: TNO (Soesterberg, The Netherlands), 3: MMU (Manchester, UK), 4: UWLAX (La Crosse, USA)

**Introduction:** Both warm-up and precooling have proved to be beneficial for exercise performance. However, it remains unclear which preparation regime is optimal for endurance exercise in conditions of high environmental heat stress. Especially the combination of internal and external cooling can have beneficial effects on performance by lowering body heat content and creating a sensation of coolness. Therefore, the aim of this study was to analyse the effect of different preparation regimes on pacing and performance during a 15-km cycling time trial in the heat. **Methods:** Ten male subjects ( $24 \pm 5$  yrs) completed four 15-km time trials ( $30^\circ\text{C}$ , 50% relative humidity), preceded by different preparation regimes: 10 min cycling at 2 W/kg BM (WARM/UP), 30 min scalp cooling of which 10 min cycling at 2 W/kg BM (WARM/UP+SC), 2g/kg BM ice slurry ingestion (COOL), and 2g/kg BM ice slurry ingestion + 30 min scalp cooling (COOL+SC). During the trials, power output (PO), rectal (Tre) and skin (Tsk) temperature, thermal sensation (TS), heart rate (HR) and RPE were measured. **Results:** Tre at the start of the time trial was lower ( $P<0.05$ ) for COOL+SC ( $36.7 \pm 0.2^\circ\text{C}$ ) and COOL ( $36.8 \pm 0.3^\circ\text{C}$ ) than for WARM/UP ( $37.2 \pm 0.3^\circ\text{C}$ ) and WARM/UP+SC ( $37.1 \pm 0.3^\circ\text{C}$ ). Tsk and TS were lower at the start for COOL+SC than for the other conditions (mean difference Tsk:  $0.7 \pm 0.4^\circ\text{C}$ ;  $P<0.05$ ). During the time trial, a main difference in Tre was found between WARM/UP+SC and both COOL and COOL+SC ( $P<0.05$ ). Tsk was lower for COOL+SC than for WARM/UP ( $P<0.05$ ). Differences in Tre and Tsk between precooling and warm-up were significant during the first part of the time trial. No differences were found in finish time ( $P=0.28$ ) and mean PO ( $P=0.32$ ), although PO was higher for COOL+SC during the final part of the time trial (km 13-14;  $P<0.05$ ). HR was significantly higher for WARM/UP ( $170 \pm 9$ ) than for WARM/UP+SC ( $165 \pm 10$ ;  $P=0.04$ ). No overall effect of RPE was observed ( $P=0.19$ ). **Discussion:** Main finding of this study is that precooling by ice slurry ingestion and scalp cooling before the start of a 15-km cycling time trial after is beneficial for performance in the latter stages of the trial, although physiological and perceptual changes have completely disappeared at that moment. This indicates that internal and external cooling before the start of endurance exercise in the heat should be preferred over warming-up, especially since a higher work rate near the finish may be of great benefit in practice, when inter-individual differences are small.

#### PHYSICAL PERCEIVED EXERTION AND MENTAL AWARENESS WHEN EXERCISING IN THE HOT CONDITIONS

Lamberts, R.P.1, Noakes, T.D.1

1: UCT/MRC Research Unit for Exercise Science and Sports Medicine, Department of Human Biology, University of Cape Town, South Africa.

**Introduction** In a recent publication Swart et al. differentiated between physical sensations and the psychic sensations generated during exercise, measured by an adapted RPE scale (P-RPE) and a Task Effort Awareness scale (TEA), respectively. During a self paced 100km time trial (100km TT) and a 100km TT test performed at 70% of this intensity, they found that TEA scores were attenuated in relation to P-RPE scores, indicating a lower awareness of task effort when exercising at a lower intensity. It is unknown however whether factors other than intensity can also influence this task effort sensation. Therefore, the aim of this study was to determine whether task effort awareness would change when performing a time trial in differing environmental conditions. **Methods** Ten experienced well-trained male cyclists between 18 and 45 years ( $393 \pm 23$  W) completed four 40km TT in 20, 25, 30 and  $35^\circ\text{C}$  in a randomized order. Rating of physical exer-

tion (P-RPE) and task effort awareness were recorded every 5 km. Subjects randomly assigned to different environmental conditions, while data was collected over a 2 week period. To minimize the effect of the season of the year, all data was collected within a 6 week testing period. Results Time to complete the 40km TT increased significantly with temperature ( $p < 0.001$ ) from  $3874 \pm 92$  s in 20 degrees Celsius to  $4199 \pm 99$  s in 35 degrees Celsius. Physical rating of perceived exertion (P-RPE) were similar during all 4 time trials in 20, 25, 30 and 35 °C, starting at approximately 16 and finishing at approximately 19 or 20. Task effort awareness levels (TEA) differed significantly between the four different temperatures, being higher in warmer environmental conditions. Differences in task effort awareness were seen from 5 km (ranging from  $7.5 \pm 0.4$  in 20 degrees Celsius to  $8.6 \pm 0.2$  in 35 degrees Celsius) and finished at a similar task effort awareness level of 9 to 9.5 in all the trials. Discussion Although that self paced time trial performance decreases with a rise in environmental temperature, physical ratings of perceived exertion (P-RPE) were similar during the all 4 trials, as reported before (Swart et al., 2009; Crewe et al., 2008). In contrast, levels of task effort awareness were higher when performing the time trials in warmer environmental conditions. This finding supports the capacity of the TEA scale to differentiate between physical and psychic sensation during exercise. We hypothesize that increased afferent feed-back when cycling in warmer conditions results in higher task effort awareness levels, as seen in this study and that rising task effort is responsible for the reduction in exercise intensity in an attempt to maintain the P-RPE within the constraints of the pre-determined P-RPE template. ## EVIDENCE OF PACING DURING REPEATED SHUTTLE SPRINTS

Christie, C., Armstrong, S.

*Rhodes University*

Introduction As there is limited data on pacing models in intermittent sports, the main purpose of this study was to establish how the knowledge of shuttle number would influence pacing during repeated sprints between the wickets while batting. Methods Ten batsmen performed three trials: Deceptive Trial (DT), Unknown Trial (UT), and Control Trial (CT). Each consisted of 14 shuttle runs although the information provided at the start of each differed. With the DT, players' were told they would be running 7 shuttles but, were doing 14. With the UT trial, players' were not told how many shuttles they would sprint but were stopped after 14. With the CT the players' were correctly informed of the fact that they would be doing 14 shuttles. Sprint times, surface EMG and perceptions of effort were the outcome measures. Results The non-significant trend was for faster shuttle times overall during the DT (6.96s) compared to the other two trials (7.01s and 7.11s for the CT and UT). There was evidence of an end spurt at the 7th and 14th shuttle in the DT. An end spurt was also evident at the end of the CT; this end spurt was not evident in the UT. Hamstring activation was lowest throughout the DT and there was a significant decrease in hamstring recruitment over time in all trials. Central RPE was similar in all trials while local RPE was lowest for the DT. All perceptions of effort increased significantly over time in all trials. Discussion It is highly plausible that during the DT there was a greater subconscious neural drive, resulting in the fastest times (Billaut et al., 2011). The more conservative approach during the UT is an indication that inhibition may have occurred (St Clair Gibson et al., 2006). The CT probably allowed speed to be predetermined using teleoanticipatory factors to affect performance (St Clair Gibson et al., 2006). There were indications of an 'end spurt' in the DT and CT suggesting reserve was available (Tucker, 2009). The drop in hamstring activation over time in all trials could be indicative of fatigue. This study suggests that pacing may occur in batting although more research is needed to validate this. References Billaut F, Bishop DJ, Schaerz S, Noakes TD. (2011). ## THE EFFECT OF MANIPULATING THE PRE-EXERCISE TEMPLATE ON TIME-TRIAL PERFORMANCE

Jaime, S., Nyberg, K., Condello, G., Casolino, E., Dodge, C., Marroyo-Rodriguez, J., Mikat, R., Porcari, J.P., Wright, G., Foster, C.

*University of Wisconsin-La Crosse*

Introduction Responsive control of power output (PO) is essential in order to achieve optimal performance with acceptable homeostatic disturbances. It is known that an athlete will decrease their PO following a decrease in arterial oxygen saturation (SaO<sub>2</sub>), and that during this decrease in PO, the athlete regulates the sense of perceived exertion (RPE) (Johnson et al., 2009; Joseph et al., 2008). The purpose of this study was to understand whether homeostatic disturbances prior to a time trial influence competitive exercise intensity would reset the pre-exercise template, reflected by the PO during the first 1 km of a 5 km time trial. Methods Seven well-trained subjects performed a VO<sub>2</sub> max test, two habituation trials, and four randomly ordered, single blinded 5 km cycle ergometer time trials with warm-up (WU) and time trial (TT) conditions. Including NN (normoxic WU/hypoxic TT), NH (normoxic WU/hypoxic TT), HH (hypoxic WU/hypoxic TT), or HN (hypoxic WU/normoxic TT) (hypoxic FIO<sub>2</sub> = 0.15, normoxic FIO<sub>2</sub> = 0.21). Results The hypoxic WU (HR: 163bpm, RPE: 5.9, HLa: 7.6 mmol/L, SaO<sub>2</sub>: 84%) was much more challenging than the normoxic WU (HR: 162bpm, RPE: 4.2, HLa: 5.2mmol/L, SaO<sub>2</sub>: 97%). Despite this, there was no significant difference ( $p > 0.05$ ) between the warm-up conditions in PO during the first 500m of the time trial (NN:  $272W \pm 76W$ , NH:  $283W \pm 67W$ , HH:  $270W \pm 54W$ , HN:  $284W \pm 79W$ ). During the second 500m, PO was decreased in the hypoxic racing conditions ( $264W \pm 46W$  vs  $244W \pm 49W$ ), without reference to hypoxia/normoxia during WU. The SaO<sub>2</sub> was significantly different ( $p < 0.00$ ) during normoxic ( $96\% \pm 0.59\%$ ) compared to hypoxic ( $83\% \pm 0.61\%$ ) at all time points. Discussion The central governor concept suggests that PO might be reduced following a more challenging WU (attributable to hypoxia) on the premise that the exerciser might expect a greater challenge to homeostasis. However, the results demonstrate that despite much more challenging conditions during the hypoxic WU, the PO during the opening part of the time trial was not affected, demonstrating the robustness of the pre-exercise template. ## RATE OF PERCEIVED EXERTION CHANGES NON-MONOTONICALLY IN CONSTANT-POWER EXERCISE UNTIL EXHAUSTION

Balagué, N.1, Aragonés, D.1, Hristovski, R.2, Tenenbaum, G.3, Garcia, S.1

1: INEFC (Barcelona, Spain), 2: Skopje Univ. (Rep. of Macedonia), 3: FSU (Florida, USA)

Introduction Rate of perceived exertion (RPE) increases linearly with workload in incremental exercises; however, RPE changes under constant workload are unclear. The aim of this study was to reveal and study the non-monotonic changes of RPE in constant-power exercise performed until volitional exhaustion. Methods A pilot study and a main experiment were carried out. The same cycling test (Sport Excalibur 925900) was performed in both cases. After a progressive warming-up, twenty seven participants pedaled at a constant-power (RPE= 15, 70 RPM) until volitional exhaustion. The pilot study compared the cardinal RPE dynamics during the exercise using three different measurement strategies: (1) CR10 scale sampling RPE every min (n = 9), (2) CR10 scale sampling every 15 sec (n = 8), and (3) RPE 6-20 scale sampling every 15 sec (n = 10). In the main experiment 13 participants reported their ordinal RPE non-monotonous changes (increases/decreases) when noticed during the same cycling exercise. The data series of the participants were divided into 10 non-overlapping temporal windows to obtain the RPE non-monotonic changes probabilities. Results In the pilot study, where 3 measurement strategies were used, 10%, 30% and 60% of the participants, respectively, presented non-monotonic changes in RPE. In the main experiment all participants showed such RPE non-monotonic changes, which were identified in three different time scales (15 sec, 30 sec, min). The 10 exertion time windows repeated-measures Friedman ANOVA (N = 13, df = 9) revealed a significant effect,  $\chi^2(13, 9) = 41.41$   $p < .0001$ , of exertion time on RPE non-monotonic changes probabilities. Three effort phases were distinguished: The beginning and ending were characterized by RPE monotonic changes and the mid phase by RPE non-monotonic changes. Discussion The findings, relevant for a nonlinear dynamic approach to exercise tolerance, reveal the existence of non-monotonic changes in RPE during constant-power exercise, highlight the interest of its evaluation for recognising non-invasively effort tolerance phases and provide information for clarifying the role assigned to perceived exertion in previous psychobiological models.

### PS-PL02 Performance in the Heat: What Happens in your Head?

#### THE HOT BRAIN - CEREBRAL METABOLISM AND MOTOR PERFORMANCE DURING EXERCISE IN THE HEAT

Nybo, L.

University of Copenhagen

During prolonged exercise in the heat, the brain temperature may increase to well above 40°C as heat removal by the cerebral circulation becomes inadequate to match the cerebral metabolic heat production (Nybo et al., 2002). Heat is consequently stored in the brain and the mental effort associated with exercise increases in step with the rise in brain temperature (Nybo & Secher NH, 2004). Under such exercise conditions, intra nasal cooling, specific cooling of the neck or cooling of the face does not affect the average brain temperature (Nybo & Secher, 2011). Also, the cerebral metabolic rate for oxygen increases as consequence of the elevated temperature, but paradoxically the cerebral blood flow becomes reduced as hyperthermia-induced hyperventilation lowers the arterial carbon dioxide tension. Hence, the cerebral mitochondrial oxygen tension becomes reduced, but the reduction is modest and apparently not the main factor influencing the central fatigue that arises secondary to hyperthermia (Rasmussen et al., 2010). The present presentation provides an up-to-date overview of the cerebral changes occurring during prolonged exercise in the heat – with special reference to those of importance for fatigue and motor performance. #### PLEASURE AND OPTIMIZATION OF MUSCULAR EXERCISE

Cabanac, M.

Laval University

The results of experiments with human subjects showed that pleasure was the optimizer of all decision making. In the case of muscular work, maximization of sensory pleasure optimized physiological functioning. What was most defended against the excess heat produced by muscular work was brain temperature.

**CHANGES IN EMG AND GAIT CHARACTERISTICS WHEN WALKING WITH THE REEBOK EASY TONE UNSTABLE SHOE CONSTRUCTION**

Horsak, B.1, Baca, A.2

1: University of Applied Sciences (St. Pölten, Austria), 2: University of Vienna (Vienna, Austria)

**Introduction** In the last few years, several authors have conducted research in the field of instable shoe constructions, especially focusing research on the effects of Masai barefoot technology and similar sole constructions. Recently, a relatively new instable sole construction was introduced by Reebok, the Easy Tone Technology (ET), which uses two built-in balance pods in the forefoot and heel areas, in order to create micro-instability during each step. Purpose of this study was to investigate the immediate effects of using ET footwear on kinetic, kinematic and muscle activation patterns during gait. **Methods** Five healthy female and seven healthy male subjects (N=12) volunteered to participate in this study (age: 25±4years, height: 172±11cm, mass: 67±11kg). 3D gait analyses were performed using a motion capture system (VICON) at 200Hz, the VICON Plug-In-Gait model, one force plate at 1000Hz (KISTLER) and surface EMG at 1000Hz (DELSYS) for assessing mean activities of Mm. gluteus maximus (GM), biceps femoris (BF), gastrocnemius medialis (GMM), vastus medialis (VM) and lateralis (VL), tibialis anterior (TA) and peroneus longus (PL). Six walking trials per subject were captured, time normalized over one gait cycle and averaged for walking with ET and normal footwear. **Results** Concerning time-distance parameters, walking with ET footwear slightly increased walking speed (3.2%, p=0.021) and stride-length (3.1%, p=0.009), whereas step time was somewhat reduced (-1.1%, p=0.028). Small but significant increase of hip flexion during initial contact (3.3%, p=0.031), decreases in maximum knee flexion (-4.5%, p=0.009), knee range of motion (-4%, p=0.027), ankle plantar-flexion (-21.6%, p=0.016) and ankle range of motion (-16%, p=0.009) in sagittal plane were found. Kinetics showed slightly increased maximum hip flexion moments (3.6%, p=0.013) and maximum ankle plantar-flexion moments (13.1%, p=0.036). Mean muscle activation showed some trends towards an increase especially for late stance phase of VM and TA (44.9% and 32.8%, p>0.05), whereas BF showed trends towards a reduction of up to 41.7% (p>0.05) during stance. GM showed a moderate increase of 4.6% (p>0.05) and PL of 12.4% (p>0.05) during initial contact. **Discussion** To the authors' knowledge, this study was the first investigating immediate effects of the recently proposed ET technology on gait characteristics. The unstable shoe produced some changes in kinematic, kinetic as well as trends in EMG characteristics. Trends especially for mean muscle activation suggest that walking with ET shoes can possibly increase muscle activation during late stance phase while slightly increasing external sagittal moments in hip and ankle joints. Results need to be validated through further studies.

**DEFINITION OF FOOTSTRIKE PATTERN DURING RUNNING BASED ON STRIKE INDEX**

Mann, R.1,2, Urhausen, A.1,3, Meijer, K.2, Statham, A.4, Brunner, R.1, Gette, P.1, Theisen, D.1

CRP-Santé

**Introduction** It has been suggested that running style, classified as rear-foot (RFS), mid-foot (MFS) or forefoot (FFS) strike, is closely related to the risk of running-related injury occurrence (1). Foot strike pattern during running is by definition determined by the initial foot contact angle (CA) with respect to the ground. It can also be assessed using strike index (SI), the initial point of contact on the foot sole with the ground (2). Previous definitions are arbitrary, with SI values up to 33% taken as a RFS, between 33 and 66% as a MFS and above 66% as a FFS (2). The aim of this study was to provide a clear definition of running style based on the relationship between SI and the initial foot contact angle (CA). **Methods** A pressure-sensitive insole, the Runalyser (by TNO Eindhoven, The Netherlands) was used to record pressure data (247 Hz) in 11 participants on a treadmill, each instructed to run in the following conditions: warm-up, FFS, MFS and RFS. SI was determined for each condition from 30-s Runalyser acquisitions and expressed as a percentage of total foot sole length. Active markers were placed at the heel and lateral metatarsophalangeal joint of the right shoe. A high-speed (200 Hz) motion analysis system (CODAmotion, Charnwood Dynamics, UK) was used to calculate the CA of the sole of the running shoe with the surface of the treadmill in the sagittal plane. Average SI and CA were calculated on >30 steps during each condition and analysed in a least squares linear regression with SI as the dependent variable. **Results** SI during warm-up varied between 22.5 and 32.3%. SI values across the different running styles ranged between 20.7 and 65.5%, while CA ranged between 32 and -23°. The two variables had a strong (R<sup>2</sup>=0.83) linear relationship: SI(%)=-0.8.CA(°)+43.2. The 95% confidence interval of the y-intercept was [40.7, 45.6]. **Discussion** This study provides a rationale for foot strike pattern definition based on the relationship between SI and CA. The 95% confidence interval of the y-intercept provides the boundaries to define MFS (0° CA), the SI values below and above defining RFS and FFS, respectively. This definition allows for the relationship between running style and injury occurrence to be studied in a large cohort using the Runalyser. **References** 1. **ESTIMATION OF FRONT-CRAWL VELOCITY BY INERTIAL SENSORS**

Dadashi, F.1, Crettenand, F.2, Millet, G.P.2, Aminian, K.1

1. Laboratory of Movement Analysis and Measurement, EPFL 2. ISSUL Institute of Sport Sciences, UNIL

**Introduction** Velocity is the main parameter of performance in swimming. To date, practical assessment of velocity is possible by using tethered apparatus that disturbs the swimmers' technique and measures the velocity only in one direction. Our study aimed to design a new system to measure the swimming velocity in front-crawl, using a single light waterproofed body-worn inertial sensor. **Methods** 10 well-trained swimmers (17.5±2.3 yr., 174.2±9.8 cm and 66.1±10.3 kg) performed 25-m front-crawl trials in four different speeds, equipped with one inertial sensor (Physilog®, 3D accelerometer, 3D gyroscope, 500Hz) worn on the sacrum. A tethered device (SpeedRT, APLab, Rome, 100Hz) was attached to the swimmers as reference. An accurate and drift-free integration of the acceleration measured by the inertial sensor was achieved by considering biomechanical constraints of front-crawl. First, sensor orientation was determined by strap-

down integration of gyroscope's data (Sabatini, 2005). The effect of drift was compensated by assuming that main angular velocity direction in body anatomical frame should be in sagittal plane of motion. Any deviation from this condition was considered to be the drift and removed. Finally the instantaneous velocity was calculated by integrating forward swimming acceleration. Results N=421 cycles were compared between the two systems and range of velocities was [0.91, 1.95] m/s. A significant correlation was observed between the two systems in measuring cycle average velocity (Spearman's  $\rho=0.94$ ,  $p<0.001$ ). The difference in cycle average velocity measured by the two systems was  $0.4\pm 6.9$  cm.s<sup>-1</sup>. Concurrent validity of our method, assessed by normalized pair wise variability index (nPVI) (Sandnes & Jian, 2004), was 4.3%. Discussion No significant difference between the two systems confirms the accuracy of our speed assessment method. The nPVI value shows that the two systems have in average 4.3% difference in detection of average cycle velocity variation. Most of the difference can originate from the elasticity of the nylon cord of the reference system, especially during high transient accelerations and decelerations. A technical problem that hinders the comparison of instantaneous velocity is the synchronization of the two systems, while for cycle average velocity comparison an ordinal association of cycles is needed. The accurate measurement of cycle average velocity allows the determination of the inter-cycle velocity variability that is a key determinant of swimming economy. Further step can be towards modification of proposed method to make it applicable for other swimming stroke techniques. References Sabatini, A. M.(2005). ## GENDER DIFFERENCES DURING CHANGES OF DIRECTION IN COLLEGE SOCCER PLAYERS

Condello, G., Kernozek, W.T., Suchomel, T., Tessitore, A., Foster, C.

*University of Rome Foro Italico*

**Introduction** Despite studies of the physical demands of the ability to change direction, a deep understanding of how soccer players exactly perform changes of direction is still unclear. The purpose of this study was to evaluate the differences between male and female soccer players for kinetic and kinematic parameters during a change of direction, using either the dominant and non-dominant leg. **Methods** Male and female college soccer players (NCAA Division III) (male: n=14, age  $19.6 \pm 1.5$  y, height  $179 \pm 5$  cm, weight  $73.1 \pm 7.2$  kg, experience in soccer  $13.7 \pm 2.6$  y; female: n=12, age  $21 \pm 2.7$  y, height  $167 \pm 4$  cm, weight  $61.9 \pm 6.2$  kg, experience in soccer  $15.1 \pm 2.6$  y) performed 10 trials (5 for each leg) of a 10m sprint with a 60° change of direction at 5m. A motion capture system and embedded force plate were used to assess vertical (VGRF), horizontal (HGRF) ground reaction force, contact time (CT), impulse (IMP), performance cutting angle (PERFANG - angle calculated using the pelvis markers during a window from 1.50m before force plate contact and from force plate contact to 1.50m), plate cutting angle (PLAANG - angle calculated using the pelvis markers during the contact time of the foot with the force plate), and minimal horizontal distance (DIST) of the pelvis markers from the foot contact point with the force plate (normalized by leg length). The dominant leg was defined as the athlete's preferred kicking leg. Associations between each kinetic and kinematic parameter, differences between dominant (DL) and non-dominant (NDL) leg and gender differences were assessed using the mean value of the 5 trials for each leg. Results Significant correlations were found between PERFANG and CT (DL:  $r = -0.62$  and NDL:  $r = -0.74$ ) and between DIST and HGRF (DL:  $r = -0.46$  and NDL:  $r = -0.39$ ). Significant differences were determined between male and female for DIST ( $p = 0.02$ ), PERFANG ( $p = 0.043$ ) and HGRF ( $p = 0.005$ ). Significant differences were evident between DL and NDL for DIST ( $p = 0.012$ ), PERFANG ( $p = 0.011$ ) and VGRF ( $p = 0.029$ ). No interaction between leg dominance and gender were found in these kinematic and kinetic parameters. **Discussion** The results of this study highlighted that the less acute PERFANG resulted in a higher CT needed to change direction. GRF was not well associated with the ability to perform a greater change of direction. Even though the male performers were able to generate a greater GRF, the females showed a greater ability to perform a sharper change of direction. The NDL showed a sharper change of direction than the DL across all players. This appears reasonable since the primary role of the NDL may be to perform changes of direction so that the DL can be used to perform skills with the ball.

## COMPARISONS BETWEEN HERRINGBONE AND DIAGONAL STRIDE TECHNIQUES IN CROSS-COUNTRY SKIING

Andersson, E.1, Pellegrini, B.2, Stöggl, T.1,3, Sandbakk, Ø.4, Holmberg, H.C.1

*(1) Swedish Winter Sports Research Centre, Mid Sweden University; (2) University of Verona, Italy; (3) University of Salzburg, Austria; (4) Norwegian University of Science and Technology*

**INTRODUCTION:** Diagonal stride (DS) is the commonly used technique for classical uphill skiing. Herringbone (HB) is a technique that generally resembles DS in arm and leg motion but in contrast to DS, HB is used mainly on steeper inclines. For HB, skis are laterally angled and slightly edged in order to maintain ski grip and propulsive forces without gliding. The present study was aimed to compare biomechanical differences between HB and DS. **METHOD:** Eight male elite cross-country skiers performed DS and HB skiing on a 7.5° uphill at a velocity of  $3.7 \pm 0.3$  m/s, equivalent to 65% of their previously measured maximal DS velocity. Pole and plantar forces (Pedar Mobile) were recorded and cycle characteristics were obtained from these data. A paired t-test was used to identify differences between DS and HB. Significance was set at  $\alpha<0.05$ . **RESULTS:** Cycle rate was 46% higher and cycle length 32% shorter in HB than DS (1.30 vs. 0.89 Hz and 2.8 vs. 4.1 m; both  $P<0.05$ ). In HB, skiers used a lateral ski angle of 17° in the absence of a gliding phase, whereas in DS a gliding phase of 0.42 s was used. The leg thrust durations (0.31 and 0.26 s) differed between HB and DS, respectively ( $P<0.05$ ), with a similar leg swing of 0.47 s. Relative phase durations for the leg actions were: 40% thrust and 60% swing in HB and 36% gliding, 23% thrust and 42% swing for DS (both  $P<0.05$ ). The peak leg force and the rate of force development (RFD) was 17% and 18% lower in HB vs. DS (both  $P<0.05$ ), with a similar time to peak force (~150 ms). For the arm action, poling times (0.31 and 0.43 s) and arm swing times (0.46 and 0.70 s) differed between the HB and DS, respectively (both  $P<0.05$ ), resulting in similar relative poling and arm swing phases of ~39% and ~61%. The peak pole forces were similar at ~101 N, with a 62% shorter time to peak and a 2.6 times higher RFD in HB vs. DS (both  $P<0.05$ ). The pole force impulse was 39% lower in HB, with similar leg thrust force impulses between the techniques resulting in pole to leg force impulse ratios of 5% in HB and 9% in DS ( $P<0.05$ ). **CONCLUSION:** The primary differences between HB and DS were: 1) a substantially higher cycle rate and shorter cycle length due to the absence of gliding and 2) longer absolute and relative leg thrusts. These results demonstrate that DS should be used on most uphill inclines to effectively glide and increase cycle length. Additionally, as the uphill becomes steeper, HB is likely to be more effective in order to maintain propulsion.

## NEUROMECHANICAL COUPLING BETWEEN THE TRUNK, HIP AND KNEE DURING LATERAL REACTIVE JUMPS

Weltin, E., Mornieux, G., Gollhofer, A.

*Albert-Ludwigs University Freiburg*

Neuromechanical coupling between the trunk, hip and knee during lateral reactive jumps Weltin E, Mornieux G, Gollhofer A Department of Sport and Sport Science, University of Freiburg (Germany) Introduction It is well documented that female athletes are at a 2- to 10-fold greater risk of anterior cruciate ligament (ACL) injury than male athletes. Video analysis revealed that lateral trunk motion might play a role in the mechanism of noncontact ACL injuries in female athletes (Hewett et al. 2009) and that possibly higher knee loads and motions result from reduced neuromuscular control of the trunk. Thus analysis of neuromuscular control of the trunk seems to be an interesting new perspective regarding ACL injury mechanisms. Therefore, the aim of the present study was to clarify if female athletes suffer from different neuromechanical coupling between the trunk, hip and knee during lateral reactive jump. Methods 3D whole body kinematics were recorded (Vicon) for 12 men and 12 women during lateral reactive jumps performed over a forceplate (AMTI). EMG data was collected for the following muscles: vastus lateralis (VL), vastus medialis (VM), biceps femoris (BF), semitendinosus (ST), and gluteus medius (GM). Trunk, hip and knee kinematics at the time of the maximal knee joint abduction moment as well as muscles onset and mean activation were compared between males and females by means of unpaired Student T-tests. Results Analysis of the EMG data revealed a later onset of GM (male  $127 \pm 41$  ms vs. female  $74.7 \pm 60$  ms,  $p=0.019$ ) and a trend towards greater VL activation for female athletes ( $p=0.053$ ). Female showed significantly lower trunk abduction angle ( $1.9 \pm 5^\circ$  vs.  $6.4 \pm 5.1^\circ$ ,  $p=0.026$ ), higher hip external rotation ( $-3 \pm 6.4^\circ$  vs.  $3.3 \pm 5^\circ$ ,  $p=0.008$ ) and higher knee valgus angle ( $-4.3 \pm 4.1^\circ$  vs.  $1.9 \pm 2.7^\circ$ ,  $p=0.001$ ) than male. No significant differences could be observed for knee joint abduction moment. Discussion Although no difference in knee joint abduction moment were found between males and females, the increased knee valgus and hip external rotation could be associated with higher knee injury risk (McLean et al., 2004). The later onset of GM observed by females could be associated with less hip control in the frontal plane and higher activation of lateral thigh muscles may explain the reported higher knee valgus angle since a balanced activation pattern is necessary to stabilize the knee joint. According to the present trunk abduction angle values, females did not present any deficit in the coupling between the trunk and pelvis segments. Different testing conditions focusing more on dynamic stabilization of the trunk (e.g. by application of perturbation upon initial contact) would further help to understand the influence of the trunk control during lateral movements. ## THE EFFECT OF INCREMENTAL TRAINING INTENSITIES ON JOINT DYNAMICS IN ELITE ROWERS

Buckeridge, E., Bull, A., McGregor, A.

*Imperial College London*

Introduction Rowers train at a range of work intensities in order to develop aerobic fitness as well as explosive leg power and strength. Changes in lumbo-pelvic (LP) kinematics have been noted when rowing at higher intensities (McGregor et al., 2004), however, little is known about the changes in joint loading patterns that occur at various work rates. Therefore the aim of this study was to quantify the effects of incremental work rates on lower limb and LP loading during ergometer rowing. Methods Twelve elite female rowers performed an incremental step test on a rowing ergometer. Each rowed for 3 minutes at the following strokes rates; 18, 24, 28 strokes per minute and free rate (i.e. maximum effort). A motion tracking system recorded 3D kinematic data of rowers' ankle, knee, hip and LP joints. External forces were measured by load cells incorporated at the handle, seat and foot stretchers. Intersegmental joint moments were calculated using inverse dynamics. Changes in joint loading and performance parameters, with respect to work rate, were examined using repeated measures ANOVA. Results No change in maximum handle force, vertical foot force or horizontal foot force were observed as work rate increased, whilst maximum seat force increased from 11.9 to 13.2 N/kg ( $p<0.05$ ). All joints exhibited significantly increased extension moments at the catch and increased peak flexion moments during the recovery phase. Peak ankle extension moments increased from 1.16 to 1.22 Nm/kg ( $p<0.05$ ). There was a small reduction in peak knee extension moment from 3.84 to 3.66 Nm/kg ( $p<0.05$ ), whilst peak hip extension moments were stable across all rates. Peak LP extension moments increased from 12.55 to 13.11 Nm/kg ( $p<0.05$ ) and this was coupled by proportional increases in LP flexion and pelvis range of motion ( $p<0.05$ ). Discussion Large LP extension moments were present during the rowing stroke and increased with respect to work rate. Flexion moments also increased during recovery, as higher stroke rates meant they had less time to slide naturally into the catch position. There was an increase in the ratio of peak hip to peak knee extension moments, which was due to reduced effort at the knee rather than increased effort at the hip. Consequently, the increase in LP loading at higher work rates is unlikely to be a measure of greater performance, as corresponding increases in handle and foot stretcher forces were not observed. Alternatively, it may be an indicator of technique decline at higher work rates, as larger peak LP extension moments occurred alongside increases in LP flexion and posterior hip range of motion. ## FOOT POSITIONING IN CYCLING: SELF SELECTION AND VARIABILITY

Disley, B.X., Li, F.X.

*University of Birmingham*

Introduction: Correct fit on a bicycle is essential for improved performance and comfort. At the pedal Q Factor (the horizontal distance between the cranks) and position of the cleats determine the location and range of movement of the foot. Commercial cleat and pedal systems limit the amount of rotation allowed at the foot ("float") without any supporting experimental data. As the pedalling action is constrained, increasing the degrees of freedom at the pedal should highlight inter-individual differences in pedalling mechanics. Previous research has shown that novice cyclists are more unstable and less proficient at executing a consistent movement pattern whilst cycling. There is no available data indicating if this difference remains when float is manipulated. Aims: The aims of this study were to a) examine whether commercial cleat and pedal systems provide the cyclist with sufficient freedom of movement during the pedal stroke, and b) whether stable and unstable cyclists respond differently to this increased freedom. It was hypothesised that individual differences in pedalling mechanics will result in situations where commercial systems limit freedom of movement, and that unstable cyclists will require a greater range of movement at the foot than stable cyclists. Methods: 29 male and female cyclists pedalled on an adjustable bicycle equipped with custom floating pedals. Pedals were able to move freely laterally towards and away from the bicycle (lateral and free conditions) and free to rotate (rotation and free conditions). 2 groups of 12 were selected based upon knee variability in the free condition: stable (ST) and unstable (UST). 3D kinematic data was taken in 4 conditions – fixed, lateral, rotation and free. Results: UST become 2.5mm more unstable (in terms of knee variability) as more degrees of freedom were introduced ( $p=.035$ ). Self selected Q Factor was lower in ST compared to UST in the free condition ( $p=.049$ ,  $ST=137.3 \pm 16.8$ mm,  $UST=152.6 \pm 18.9$ mm). ST trained for more hours than

UST ( $p=.008$ ,  $ST=8.8\pm 4.0$ hrs,  $UST=4.4\pm 3.3$ hrs), had less variability in float during the pedal stroke ( $p=.030$ ,  $ST=2.0$  deg,  $UST=2.6$  deg), and a lower maximum foot angle ( $p=.014$ ,  $ST=15.5$  deg,  $UST=19.6$  deg). There was no effect of gender on pedalling mechanics. Conclusions: Commercial cleat and crank systems present limitations for foot positioning in both stable and unstable cyclists. Pedal systems that provide more float than standard ( $\sim 15$ - $20$ deg vs.  $6$ deg) will not constrain the foot during the pedal stroke, which may affect power production and/or injury prevention. All cyclists exhibit different levels of variability that have an effect upon optimum foot positioning, and which must be taken into account during the selection and set up of equipment. ## THE SHOULDER RANGE OF MOTION OF ALTERNATIVE SPIKE/SERVE TECHNIQUES AS A POTENTIAL INJURY PREDICTOR IN VOLLEYBALL

Seminati, E.

*Post Doc*

THE SHOULDER RANGE OF MOTION OF ALTERNATIVE SPIKE/SERVE TECHNIQUES AS A POTENTIAL INJURY PREDICTOR IN VOLLEYBALL. Seminati E.1, Marzari A.2, Vacondio O.3, Minetti A.E.1 1: Università degli Studi di Milano (Milano, Italy), 2: Niguarda Ca'Granda Hospital, (Milano, Italy), 3 Federazione Italiana Pallavolo (Milano, Italy) Introduction Volleyball is at the third place after Soccer and Basket within the sport activities causing injuries. Overuse and stresses during the traditional spike and serve movements, make the shoulder one of the most commonly exposed body part (Chan et al. 1993, Verhagen et al. 2004). Pain, reduced range of motion and mobility, bring often the athletes to prematurely interrupt their career. Different spike techniques are supposed to be associated to different risk damage of the shoulder joint. Here we compared two of them by also regarding the skills and fitness necessary for the athletes' performance. Methods 21 volleyball players, from high-level National categories, performed the spike movement using a traditional and an alternative technique, (TT and AT respectively), in 3 different conditions: without jumping, jumping with and without hitting the ball. Upper limb and trunk were modelled, as multilink segment structures (Murray, 1999). 3D positions of 16 reflective markers were recorded with a 6-camera optoelectronic system ( $f=250$ Hz). Glenohumeral centre was viewed as the centre of an imaginary sphere described by the distal end of the humerus, with a radius of 200 mm. The spatial relationships between humerus and trunk (considered as a relative system, to have data independently on the investigated condition) were described on this sphere in terms of an angle of azimuth (longitude on the sphere), elevation (latitude on the sphere) and axial rotation (intra-extra rotation) of the humerus about its longitudinal axis (An et al 1991). Ball speed was measured with a high-frequency camera (200Hz). Results Preliminary results showed that the two techniques (TT and AT) travel along two significantly different trajectories on the imaginary sphere. Maximal humerus elevation was reduced by the 15% in AT, while the azimuth angular amplitude was significantly higher for the AT, compared to the TT. Ball Speed, arm velocity and maximal arm height had higher values for the AT, in each of the three considered conditions. Discussion We performed a quantitative 3D comparison of two different spike techniques in the volleyball game. Our results suggest that the AT could be potentially a preventive solution to the shoulder chronic pathologies, while maintaining, or even enhancing, athletes' performance. ## INFLUENCE OF OPTIC FLOW STIMULI ON POSTURAL RESPONSES. I. ELECTROMYOGRAPHY

Piras, A., Persiani, M., Raffi, M., Squatrito, S.

*University of Bologna*

Introduction The direction of optic flow stimuli is an important cue for heading perception (Gibson, 1954). Several studies addressed the influence of visual stimuli on upright position, because vision provides the necessary information about the surrounding environment (Peterka & Benolken, 1995). However, little is known about the optic flow modulation on postural muscles. Aim of this study was to verify if the optic flow direction evokes different postural responses. We analyzed the bilateral muscular activation of two leg muscles, tibialis anterior and gastrocnemius medialis, during full field optic flow stimulation. Methods sEMG were recorded in 24 healthy right-handed volunteers (12 M and 12 F, mean age  $24.5\pm 2.9$ ). Experiments were performed in the dark. Stimuli were presented on a wide screen, placed 115 cm from the subjects' eyes, covering  $135 \times 107^\circ$  of visual field. Stimuli were two full screen optic flow, expansion and contraction, and random dots motion as control stimulus. sEMG data were acquired by a 16 channels Pocket EMG (BTS@ Bioengineering Inc.). Data acquisition included 5 trials per stimulus for about 30-s each. Results The muscle was considered significantly activated when its signal was greater than the baseline mean + 3SD (Hodges & Bui, 1996). Results showed that the great majority of the subjects had a different modulation on muscles activity depending on the type of optic flow stimulus. The right tibialis anterior was the most activated muscle. We also analyzed the highest amplitude values to evaluate if optic flow differently modulated the amplitude of the muscle responses. Results showed a significant effect ( $p<0.05$ ) of the stimulus in 14 subjects (58%). The stimulus effect on lower limb muscles was significantly different in 23 subjects (96%). We also found a strong effect of sex and muscle and interaction of sex by muscle upon the optic flow stimulus effect ( $p<0.05$ ). Discussion Visual input influences the neural control of body sway. One emerging interesting idea is that neural sensitivity to different afferent inputs in response to disturbances of the body balance, is highly dependent on the visual feedback. This theoretical framework may help us to understand fall prevention programs and to explain some of the mechanical and neural factors which contribute to the balance impairment. In these experiments subjects likely used an ankle strategy to maintain standing posture. Forward and backward sway may result in an increased compensatory muscular activity of the posterior and anterior lower extremity muscles respectively. References Gibson JJ (1954). *Psychol. Rev.*, 61, 304-314. Hodges PW & Bui BH (1996). *Electroencephalogr Clin Neurophysiol*, 101, 511-519. Peterka RJ & Benolken MS (1995). *Exp Brain Res*, 105, 101-110.

## INFLUENCE OF OPTIC FLOW STIMULI ON POSTURAL RESPONSES. II. STABILOMETRY

Persiani, M., Piras, A., Raffi, M., Squatrito, S.

*University of Bologna*

Introduction Several researches have been aimed at studying the balance control looking at the variation of the center of pressure (COP) trajectory induced by variation of the visual field (Collins & De Luca, 1995; Accornero, 1997). Indeed, presence of a visual stimulus produce less sway speed than the dark (Lee & Lishman, 1975). However, little is known about the modulation of optic flow stimuli on the body sway. Aim of this study was to verify how the direction of optic flow can affect the COP parameters like speed, trace length, equivalent area and equivalent radius. Methods Stabilometric data were recorded in 24 healthy right-handed volunteers (12 M and 12 F, mean age

24.5±2.9) who stood on two Kistler force platforms. Experiments were performed in the dark. Stimuli were presented on a wide screen, placed 115 cm from the subjects' eyes, covering 135 x 107° of visual field. Stimuli were two full screen optic flow, expansion and contraction, and random dots motion as control stimulus. Postural responses data were acquired by the SMART BTS® at 1000 Hz (BTS® Bioengineering Inc.). Data acquisition included 5 trials per stimulus for about 30-s each. Results We performed a repeated measure ANOVA on the 24 subjects for each COP parameter. Speed: we found significant differences across the optic flow stimuli ( $p=0.042$ ) and significant interaction between stimulus and sex ( $p=0.009$ ). Trace length: results showed significant interaction between stimulus and sex ( $p=0.001$ ). Equivalent area: we found significant interaction between stimulus and sex ( $p<0.001$ ). Equivalent radius: results showed significant interaction between stimulus and sex ( $p=0.002$ ). These results indicate that the direction of optic flow stimuli strongly modifies the upright posture. Male and female populations are differently affected by the optic flow direction. Discussion These experiments confirmed that the optic flow input modulates the neural control of body sway. Because the sensitivity to the body sway is greatly dependent on the visual feedback, results of this research may allow to lead rehabilitation programs in patients with visual deficits responsible of postural modification. Furthermore, the described changes in the sway parameters due to the optic flow stimulus direction could allow to develop specific sport visual training. ### PP-BN02 Motor Learning and Coaching 1

#### TIME MATTERS: CONTRALATERAL TRANSFER OF INTERFERENCE DEPENDS ON TRAINING DURATION

Lauber, B.1, Keller, M.2, Gollhofer, A.1, Lundbye-Jensen, J.3, Taube, W.2, Leukel, C.1,2

1 Department of Sport Science, University of Freiburg, Freiburg, Germany 2 Department of Medicine, Movement and Sports Science, University of Fribourg, Fribourg, Switzerland 3 Department of Neuroscie

Introduction It has long been known that practice of motor tasks with one limb improves not only the performance of the trained but also of the opposite untrained limb (e.g. Carrol et al. 2008). However, learning-related improvements in performance may also be hindered if we are engaged in subsequent learning of a different, interfering motor task. Specifically, the motor performance of a recently learned task A can be reduced if a second task B is learned shortly afterwards (Brashers-Krug et al. 1996, Lundbye-Jensen et al. 2010). So far, the interference effect was only demonstrated for the limb actively involved in the training and not for the contralateral untrained limb. Therefore, the aim of the present study was to test learning-related interference in the limb contralateral to the trained one. Methods In the present study, 46 subjects practiced ballistic isometric contractions with their index finger (task A). Subsequently, subjects were split into 4 groups practicing a visuomotor tracking (interference) task (task B) for either 6min (group A), 12min (group B), rested for 6min (group C) or 12min (group D), respectively. Results Ballistic training caused an improvement in performance of the trained hand of  $41.5 \pm 4.5\%$  ( $p < 0.001$ ) and in the untrained contralateral hand of  $23.8 \pm 3.8\%$  ( $p < 0.001$ ) in all subjects. Interference training of 6min (group A) caused a significant reduction of performance only for the trained hand ( $-22.7 \pm 4.3\%$ ;  $p < 0.001$ ) but not the untrained contralateral hand. The 12min visuomotor tracking (group B), however, showed a significantly reduced performance of the trained ( $-22.72 \pm 4.1\%$ ;  $p < 0.001$ ) and untrained contralateral hand ( $-19.1 \pm 4.8\%$ ;  $p < 0.001$ ). Groups C and D did not show significant interference effects. Discussion The results of the present study show for the first time that subsequent learning of an interfering motor task can not only cause reduced performance in the trained limb but also in the untrained contralateral limb. This interference effect was shown to depend on the training duration of the interference task. These findings might have important clinical implications for movement rehabilitation programs in patients suffering from hemiparesis, e.g. after stroke. Lit. Brashers-Krug T, Shadmehr R, Bizzi E. #### THE EFFECT OF AGING ON MANUAL AIMING PERFORMANCE

Van Halewyck, F., Lavrysen, A., Levin, O., Helsen, W.F.

KU Leuven

The Effect of Aging on Manual Aiming Performance Van Halewyck, F., Lavrysen, A., Levin, O., Helsen, W.F. Movement Control and Neuroplasticity Research Group, KU Leuven (Belgium) Introduction Aging influences the ability to move. During manual aiming, for instance, older adults are thought to apply a 'play-it-safe' strategy to ensure endpoint accuracy. This strategy is characterised by a reduction of hand movement speed (Teeken et al., 1996) and a higher proportion of time spent after peak velocity, a period typically associated with corrective submovements based on visual and proprioceptive feedback (Elliott et al., 2010). However, due to the well-documented age-related decline in proprioception (Skinner et al., 1984), we hypothesised that older adults rely particularly more on visual information for online guidance of the hand. In the present study, we therefore examined the contribution of visual feedback during manual aiming in young and older physically active and non-active participants. It was also expected that older adults showed a disproportional drop of accuracy when vision was (partially) blocked. Methods Manual aiming performance of a group of young (aged 20-29yrs) and older (aged 60-69yrs) physically active and inactive adults was compared under different visual conditions. The synchronous registration of eye and hand movements allowed us to examine the eye-hand coupling and the underlying mechanisms of visual control during discrete and cyclical hand movements. In addition, levels of physical activity as well as cognitive abilities were determined using questionnaires. Results A significant age-related motor slowing was revealed during the execution of rapid discrete aiming. As predicted, older adults had longer movement times when vision was available and a lower accuracy rate when vision was (partially) blocked. Also in agreement with the proposed play-it-safe strategy, older adults generally undershot the targets while young adults ended more accurately. The tight eye-hand coupling and the greater number of corrective saccades in older adults confirmed our main hypothesis as well. Remarkably, there was an interaction between age and physical activity level, showing that physically inactive older adults were even more dependent on visual information. Discussion Compared to younger adults, older adults adopted a play-it-safe strategy characterised by more

time-consuming visual guidance. They were also more affected by the (partial) withdrawal of visual information. Interestingly, the notion of major differences in aiming strategy between physically active and inactive older adults highlights the importance of a physically active lifestyle. ### **FOCUS OF ATTENTION INFLUENCES QUIET-EYE BEHAVIOR AND MOVEMENT PATTERNS AT VARYING SKILL LEVELS IN FEMALE BASKETBALL PLAYERS**

Rienhoff, R., Strauss, B., Fischer, L., Baker, J., Schorer, J.

*Institute of Sport and Exercise Sciences*

**Introduction** Different foci of attention have varying influences on different expertise levels in motor control situations (Wulf, 2007). On another level, the quiet eye period also affects motor performance and seems to differentiate between expertise and performance levels (Vickers, 2007). This study investigated the possible association of focus of attention and quiet eye as well as their interacting effect on throwing performance. **Methods** Basketball experts, advanced players and novices (n = 9 per group) performed 40 free throws, subdivided in blocks of ten throws. The first block provided baseline data while in blocks two to four participants performed external focus, internal focus, and no-focus conditions in a counterbalanced order. Gaze behavior was captured by an eye tracking system. Throwing accuracy and quiet eye duration were measured. **Results** Clear difference between skill groups could be revealed for throwing performance during baseline,  $F(2,24) = 42.3$ ,  $p < .01$ ,  $f = 1.88$ . The analysis of the counterbalanced blocks showed differences between groups,  $F(2,24) = 44.0$ ,  $p < .01$ ,  $f = 1.91$ . Additionally the repeated measure instruction revealed significant differences,  $F(2,48) = 3.63$ ,  $p = .03$ ,  $f = .39$ , but not for the interaction,  $F(2,24) = .71$ ,  $p = .59$ ,  $f = .24$ ,  $1-\beta = .64$ . For quiet eye duration, analysis of variance showed no significant differences between groups,  $F(2,24) = .88$ ,  $p > .05$ ,  $f = .29$ ,  $1-\beta = .32$ , nor for the interaction (group x instruction)  $F(2,24) = .51$ ,  $p > .05$ ,  $f = .22$ ,  $1-\beta = .55$ , but significant differences for instructions as repeated measures,  $F(2,24) = 5.91$ ,  $p < .01$ ,  $f = .53$ . The post-hoc showed significant shorter quiet eye duration for external instruction in comparison to both other conditions. Furthermore significant differences in quiet eye duration can be revealed for hits vs. misses,  $F(1,15) = 3.72$ ,  $p = .04$ ,  $f = .50$ , and further the interaction of hits with skill groups,  $F(1,15) = 2.80$ ,  $p = .05$ ,  $f = .61$ . Hits are in total longer, caused by differences in advanced players. **Discussion** Our results show an influence of instruction on throwing performance, thus all skill levels performed worst under external instruction, what might be explained by personal preference (Weiss, Reber, & Owen, 2008). Furthermore the quiet eye period influences the throwing performance with longer quiet eye durations for hits in comparison to misses in the not yet automated advanced players. It seems that only in a specific skill level (advanced players) the interaction of quiet eye and focus of attention has influence on throwing performance. **References** Vickers, J. N. (2007). ### **QUIET-EYE IN OLDER SKILLED BASKETBALL PLAYERS AND ITS TRANSFERABILITY**

Fischer, L., Rienhoff, R., Strauss, B., Baker, J., Schorer, J.

*Institute for Sport and Exercise Sciences*

**Introduction** There is mounting research to suggest that cognitive and motor expertise are more resistant to age-related decline than more general capacities (Schorer & Baker, 2009). Two theoretical frameworks are commonly used to explain the maintenance of peak performance: compensation and selective-maintenance (Baker & Schorer, 2010). The primary aim of this study was to investigate the retention of quiet-eye skills in elderly experts with continued training at a lower league. We hypothesized that highly skilled older athletes would outperform novices and have little decrement in their perceptual processes in comparison to highly skilled younger athletes. Secondly, we wanted to explore the transferability of this skill to a different domain like dart. **Methods** The study investigated the retention and transfer of skill in skilled-older athletes (n=13) by comparing them with skilled-younger (n=13) and novice-younger participants (n=13). They performed basketball free throws and dart throws under standardized conditions. Motor performance (accuracy) and perceptual performance (quiet-eye) were examined across the three groups. **Results** There were significant differences between groups in throwing accuracy on both throwing tasks, basketball,  $F(2,37) = 45.35$ ,  $p < .01$ ,  $f = 1.56$ , and dart,  $F(2,37) = 6.90$ ,  $p < .01$ ,  $f = .61$ , with skilled groups outperforming novices but not differing from each other. There were medium sized, non-significant effects for quiet-eye, with skilled groups having longer quiet-eye durations than the novice group on the basketball tasks,  $F(2,35) = 1.23$ ,  $p = .30$ ,  $f = .27$ ,  $TP = .27$ , but younger groups having longer durations than the older group on the transfer task,  $F(2,35) = 2.50$ ,  $p = .10$ ,  $f = .38$ ,  $TP = .50$ . **Discussion** The results indicate expertise in a perceptual-motor task like basketball free throw can be retained in older athletes. But the perceptual skill was not transferred into dart throwing, although a better throwing accuracy was obtained. These results raise questions concerning current hypotheses of skill maintenance, which should be re-evaluated to consider the issue of transfer. **References** Baker, J., & Schorer, J. (2010). ### **ANALYSIS THE TRACKING EYE OF ONE EXPERT SAILOR IN A VIRTUAL SIMULATOR.**

Manzanares Serrano, A., Menayo Antúnez, R., Segado Segado, F.

*Universidad Católica de San Antonio Murcia*

**Introduction** In a boat race, sailors are constantly receiving information about the environment thanks to the senses. The most determining sense in a sailor and other sports is his sight (Reina, Moreno & Sanz, 2007), since thanks to it, stimuli present in sailing environment are received, determining his response. The approach we have used aims to describing the visual conduct of an expert racer for the minute before the start signal. **Methods** The competitor in the current research was the first in Rankin of Optimist Class, in the Region of Murcia (Spain). Was used an automated system of measurement which integrates the following instruments: a) VSail-Trainer® sail simulator and b) Eye Tracking System®. Research variables were the number of fixations, the location of the fixations and the fixations time on each location made by the competitor. The event was made up by 2 starts of simulated race, with stable conditions of wind, competitor and sea. The simulated race reflected the same conditions as a real start. **Results** The total number of eye fixations performed in the first

start were 94, while in the second one were 86. In the first start, the greatest number of fixations, were located in tack of the sail, the remaining of the sail, sea, and rivals, while in the second start, the most frequent locations were, tack of the sail, the remaining of the sail, sea, rivals, and buoys of start. It is worth mentioning that eye fixations carried out during the second start were distributed in a more homogeneous way than in the first start. In the same way, the average fixations time is higher in the second start than in the first one. Discussion The results show that, in the second start the sailor performed a lower number of eye fixations, together with an increment of average fixations time, regarding the first start. As it is upheld by many authors, a visual search strategy is more effective when the number of fixations carried out is lower, as well as a greater length of the latest (Ávila & Moreno, 2003; Williams, Davids & Williams, 1999). Improvement in visual search strategy on the part of the sailor can be a consequence of his learning, due to the short period between the first and the second start and the resulting error assimilation. ### UN-LEARNING A MOTOR TASK: BRIEF REACTIVATION ALLOWS TO ERASE MOTOR MEMORIES

de Beukelaar, T., Alaerts, K., Woolley, D.G., Wenderoth, N.

*KU Leuven*

Learning new skills is inherent to many sports such as golf, playing tennis, but also sailing, mountain biking and many more. Much is known about how these motor skills are learned and consolidated in the human brain, but how can we un-learn movements, for example, when a wrong technique has been acquired? A decade ago, Walker et al. showed that a motor skill that has been stabilized and consolidated, can become fragile again after brief reactivation [1]. This fragile state renders it again vulnerable to interference from a competing motor task and allows the motor memory to be partly erased. Here we tested whether similar interference effects can be induced when movement observation instead of physical execution is used to reactivate the motor memory. Subjects were assigned to different experimental groups. All acquired a fixed 5-element sequence at day 1 by practicing the sequence for 12 blocks (30s each). At day 2 they briefly rehearsed the same sequence for 3 blocks either by physical execution or movement observation. Immediately after rehearsal, subjects performed an interfering motor task (learning a new sequence during 12 training blocks). At day 3, retention was tested for the sequence learned initially. Results show that reactivating the memory by mere observation followed by the interfering motor task, did not improve nor decrease performance. Also, the group that reactivated the motor memory physically was only minimally affected by the interfering task. However, we observed that 3 blocks of reactivation (approx. 75 trials) were sufficient to trigger a second phase of motor learning at day 2 in most of our subjects. Based on animal studies, showing that one-trial-reactivation is enough to render an acquired fear memory fragile and susceptible to interference [2], we designed a new experiment such that the sequence was reactivated only very shortly (performing it 5 times instead of approx. 75 times). When this brief reactivation was followed by the interfering motor task, we found a clear decrease in performance on day 3, indicating that we successfully destabilized and partly erased the motor memory of the initially acquired sequence. We conclude that if a motor memory is only briefly reactivated, not initiating new learning, stable motor memories are rendered fragile and susceptible to interference. This mechanism is highly relevant for athletes who want to un-learn wrong techniques. 1) Walker MP, Brakefield T, Hobson JA, Stickgold R (2003), *Nature*, 425, 616-620. 2) Nader K, Schafe GE, Le Doux JE (2000), *Nature*, 406, 722-726.

### FUNCTIONAL PROPERTIES OF MOTOR-RELATED CORTICAL OSCILLATIONS DURING A VISUOMOTOR TASK IN ATHLETES AND NON-ATHLETES

Hülsdünker, T., Mierau, A., Hannemann, M., Strüder, H.K.

*German Sport University Cologne*

Introduction Recent publications analyzed cortical processes in the Alpha and Beta frequency bands during visuomotor tasks related to the level of experience or quality of movement. The aim of the present study is to extend these findings by further considering higher frequency bands in the Gamma range from 30-40Hz which are thought to be involved in motor processes. Moreover, we modulate the sensory input to distinguish between sensory and motor-related cortical oscillations. Methods We compared 9 right-handed elite athletes to 7 right handed non-elite athletes in a visuomotor task. Each group performed 60 air pistol shots. The elite athletes additionally performed 30 blind shots with eyes closed 0.5s before the shot. Electroencephalographic (EEG) activity was recorded from four electrode positions (C3, Cz, C4, Fz) with FCz as reference. EEG data was re-referenced to the mean potential of C3, Cz, C4 and Fz. Alpha and Beta frequency bands were based on the individual Alpha peak frequency (IAF) and individual Beta peak frequency (IBF). Gamma1 and Gamma2 we defined as 30-35Hz and 35-40Hz, respectively. Absolute power values were log-transformed and calculated for a baseline level (BAS) and four time intervals in the last three seconds before the shot. We conducted two-way repeated measurement analysis of variance (Group\*Time; Condition\*Time) for the C3 electrode representing the contralateral motor cortex. Significance level was  $p < 0.05$  Results For the Group\*Time analysis we found a main effect for Time in the lower Alpha and upper Beta frequency bands showing significantly enhanced lower Alpha power as well as reduced Beta power. For Gamma1 and Gamma2 there were main effects for Group revealing higher power values for non-elite athletes. Additionally, we found a significant interaction of Group and Time in the Gamma2 frequency band. Non-elite athletes showed a decrease in power from BAS to the last 0.5s prior to the shot while no changes occurred in the elite athletes. Comparing conditions (eyes opened/eyes closed) we found increased power in both Beta frequency bands while Alpha and Gamma remained unchanged. Discussion Enhanced lower Alpha and reduced upper Beta power for the group comparison suggest a process of inhibition prior to the shot. Group effects in both Gamma frequency bands may indicate that reduced Gamma power represents the level of experience. Due to the absence of condition effects in both Gamma frequency bands, we propose a motor-related function of Gamma rhythms probably representing reduced movement activity of the arm before the shot being in line with the group effects showing elite athletes having lower Gamma power than non-elite athletes. Hence we further suggest that the differences between the groups primarily represent motor control and may be less due to cognitive processes. The sensitivity of the Beta rhythm to visual input can be interpreted as enhanced attentional demand compensating for the absence of visual information.

## GAIT VARIABILITY AS REPRESENTATION OF THE FUNCTIONALITY OF THE SENSORIMOTOR SYSTEM

Hamacher, D., Grabau, C., Singh, N.B., Schega, L., König, N., Taylor, W.R.

*Otto-von-Guericke-Universität Magdeburg*

Gait variability as representation of the functionality of the sensorimotor system Hamacher, D.1,2, Grabau, C.1,2, Singh, NB.1, Schega, L.2, König, N.1, Taylor, WR.1:1: JWU, Charité (Berlin, Germany), 2: OvGU (Magdeburg, Germany) Introduction Falls in the elderly constitute a high socio-economic burden. Effective methods for evaluating human sensorimotor system (HSMS) deficits are thought to aid in predicting fall risk in a geriatric population, where the assessment of task performance over longer durations contributes important information regarding the HSMS (Taga et al., 1991). Fall prone individuals also display higher levels of variability during dynamic activities such as walking compared to their healthy counterparts (Hamacher et al., 2011). However, the kinematic parameters that best represent optimal functioning of the HSMS remain unclear. The aim of this study was to evaluate the effectiveness of various gait parameters for distinguishing elderly fallers from non-fallers. Methods 3D kinematics of the right foot of 34 elderly female non-fallers (69.5±4.6 years) and 33 fallers (69.2±4.8 years) were captured with a marker based optical system while walking on a 10-meter walkway. A minimum of 6 walks were used to calculate the variability (coefficient of variance; CV) of 6 spatiotemporal parameters (stride time (StrT), double support time (DST), stance time (ST), stride length (SL), step width (SW) and minimum toe clearance (MTC)). To examine the magnitude of the difference between cohorts on CV of parameters, effect sizes (ES) were calculated using Cohen's d. Results Variations of all parameters except SL were larger in fallers than in non-fallers. Differences in CV between groups were moderate for DST (ES=0.41) and high for StrT, SW and ST (ES =0.64-0.65). The largest differences between fallers and non-fallers were found in CV of MTC variations (ES=0.99). Discussion The results confirm that variability of stride parameters is suitable in differentiating fallers from non-fallers. The variability of StrT and SW represent measures of rhythmicity (Hausdorff et al., 2007), while ST is a measure of balance (Gabell & Nayak, 1984). The HSMS is involved in control of rhythmicity during swing phases and balance during stance phases, which seem to be more variable in fallers, thus indicating diminished functionality of the HSMS. Variations in foot clearance seem to play a critical role in detecting deficits of HSMS, possibly due to the foot's extended distance from the body's core, where proprioceptive errors could be most apparent. Assessment of MTC variability in a clinical setting may aid in early identification of subjects at risk of falling. References Taga G, Yamaguchi Y, Shimizu H (1991). *Biol Cybern*, 65, 147-9. ## EXERCISE PERFORMANCE DURING REPETITIVE SPRINTS IS CAREFULLY REGULATED BY THE CENTRAL MOTOR DRIVE TO LIMIT THE DEVELOPMENT OF PERIPHERAL FATIGUE UPON A CRITICAL THRESHOLD

Hureau, T.1, Olivier, N.1, Millet, G.Y.2, Meste, O.3, Blain, G.1

*1: UDSL2, EA 4488 (Lille, France), 2: UJM, EA 4338 (St Etienne, France), INSERM U1042 (Grenoble, France), 3: CNRS-UNS, I3S (Nice, France)*

Introduction Recently, Amann et al. (2009) demonstrated that somatosensory feedback from working muscle plays a metabo-meter role for the central nervous system so that the central motor drive is adapted to limit the peripheral fatigue development upon a critical threshold. Because during 5 km time trials voluntary muscle contractions are submaximal it is argued that the central motor command and power output are much more dependent upon a conscious self-paced cycling strategy rather than feedback from the contracting muscles (Marcora, 2010). We asked whether inputs from the fatiguing locomotor muscles reduce the maximal voluntary drive of central motor command, in order to tightly regulate the total degree of peripheral fatigue development during all-out sprints. Methods Twelve healthy subjects randomly performed, at least 72 h apart, two sets of 10 all-out 10 sec sprints intersped with 30 sec of passive recovery. One test was performed in the fresh state (control condition), the other with pre-induced quadriceps fatigue using neuromuscular electrical stimulation (NMES). NMES – and exercise – induced quadriceps fatigue was quantified via pre vs. post changes in potentiated quadriceps twitch force in response to supra-maximal femoral nerve stimulation (Qtw-pot) and in maximal isometric voluntary contraction (MVC). Central motor drive was estimated using the integral of each burst of the quadriceps EMG (iEMG). Mean power output was assessed for every sprint as an index of performance. Results NMES pre-induced quadriceps fatigue ( $\Delta Qs-pot = -28.9\% \pm 3.9$ ;  $\Delta MVC = -15.0\% \pm 3.1$ ) resulted in a significant reduction in central motor drive ( $-8.6\% \pm 2.5$ ) and performance ( $-3.2\% \pm 1.9$ ) compared to control, which was more pronounced during the first five sprints of the test. Despite these significant differences, the magnitude of locomotor muscle fatigue following sprints was not different between control and pre-fatigue conditions ( $\Delta Qs-pot = -50.6\% \pm 2.8$  vs.  $-50.6\% \pm 3.4$ ;  $\Delta MVC = -18.3\% \pm 3.4$  vs.  $-20.0\% \pm 4.2$ ). Discussion Our findings demonstrate that power output is tightly regulated during repetitive all-out sprints to avoid the development of peripheral muscle fatigue upon an individual critical level. We thus suggest that feedback from the fatiguing locomotor muscles exerts an inhibitory effect on the central motor drive and plays a key role in exercise performance. ## THE EFFECT OF TIME OF DAY ON VESTIBULAR FUNCTION AND POSTURAL CONTROL

zouabi, a.

*University of Caen, Basse-Normandie*

Introduction During daytime activity, individuals must run their posture, their perception of verticality and orientation in space. Few studies (Avni et al., 2006; Forsman et al., 2007) examined the effect of time of day on postural control. These studies have found contradictory results. The vestibular system is continuously involved in equilibration reaction. Only one study has tried to identify the circadian rhythmicity of the vestibular system (Wolf et al., 1990) and showed a maximum amplitude of the vestibular nystagmus in the morning. The aim of our study was to evaluate the effect of time of day on vestibular function and postural control. Methods 16 male subjects of intermediate chronotype underwent a discontinuous circadian rhythm protocol: they had one session of test per week at 2:00, 6:00, 10:00, 14:00, 18:00, 22:00 and 2:00 h. Each session consisted of 2 tests (i) static and dynamic postural control using a force platform with eyes-open and eyes-closed. The coordinates of center of pressure (COP) was recorded using a platform Posturewin® (Technoconcept, France) (ii) vestibular-ocular exploration using a rotatory chair in darkness. The stimulation used, stimulates the vestibulo-ocular reflex (VOR) and induces a vestibular nystagmus. This nystagmus can be characterized by its initial velocity (Vi) and its time constant (TC). Eye movements were recorded using an infrared video camera system Chronos® (Skalar, Netherlands). Results (i) The results of our study show that the COP was not influenced by the time of day ( $F=0.69$ ,  $P=0.63$ ). (ii) Vi was not influenced by the time of day ( $F = 0.65$   $P = 0.66$ ). By contrast, the interaction of the time of day and TC was statistically significant ( $F=3.55$ ,  $P<0.005$ ), with a longer TC at 06:00 than 02:00h. Discussion The results of our study show that postural control in young adults is not influenced by the time of the day but that VOR duration varies

during 24 hours. It is interesting to note that even if vestibular responses fluctuate during the day, postural control has no daily fluctuations. These results suggest that the vestibular variations don't influence the postural control during the day. Compensatory mechanisms could be involved. References Wolf M., Ashkenazi IE, Leventon G. #### TRAINING LOAD AND LOW BACK PAIN IN GERMAN ELITE ROWERS

Winzen, M., Voigt, H.F., Hinrichs, T., Platen, P.

*Ruhr-University Bochum, Faculty of Sports Science*

**Introduction:** Training load and biomechanical impact on the musculoskeletal system in elite rowing on international level are considerable. On the middle and long term, they can lead to severe chronic disorders of the musculoskeletal system, and especially of the lower back. The aim of this study was to evaluate training load as well as prevalence and characteristics of lower back pain in German elite rowers during the Olympic year 2008. **Methods:** 29 female rowers aged 22.2±3.1 (18-30) years and 38 male rowers aged 22.3±3.1 (18-32) years of the German national team have been interviewed about their mean training volume and training content. Furthermore, they have been asked about pain at the lower back (LBP) at the time of the interview and over the past 12 months (self-administered questionnaire). Indicated percentages refer to the number of athletes who answered the respective question. **Results:** The rowers began their career at the age of 12.2±1.9 (8-17) years. Elite rowers trained on average 22.8±5.3 (11-38) hours in 16.0±4.6 (8-32) training sessions per week. They spent 10.3 hours (46.3% of the whole training volume) with rowing on the water, 4.7 hours (21.7%) with weight training and 2.8 hours (12.3%) with rowing on an ergometer. The training distance on the water was 3961±1062 (1500-6000) km. 18 rowers (27.3%) stated to suffer from LBP at the time of the interview. Within the past 12 months, another 14 rowers (21.9%) had suffered from LBP. 25 of the 32 rowers with LBP (78.1%) stated to have pain during rowing, 23 (71.9%) subsequent to rowing, and 20 (62.5%) at rest, independent from rowing (multiple answers permitted). 21 rowers (65.6%) with LBP stated that they had consulted a physician for that reason within the past 12 months. 12 rowers (37.5%) with LBP had to pause their training for that reason. The duration of the training break was 3.4±3.0 (0.5-10) weeks. According to the athlete's individual estimation, the most frequent reason for LBP was "overuse" (24 rowers; 75%); while "acute injury" was only named by 4 rowers (12.5%) (multiple answers permitted). **Conclusions:** The high prevalence of LBP in German elite rowers supports the demand for adequate preventive and therapeutic measures. Technically exact chains of movement and motion patterns of rowing and rowing specific weight training have to be learned at an early age and have to be regularly monitored later on to prevent overuse of specifically stressed structures. The knowledge on pathophysiology of LBP is essential for the education of trainers at all stages and especially for trainers who engage in the formation of children and junior elite rowers.

#### WHY HEART FAILURE PATIENTS DO NOT MEET CRITERIA OF DAILY PHYSICAL ACTIVITY GUIDELINES

Dontje, M.L., van der Wal, M.H.L., Stolk, R.P., Brügemann, J., Jaarmsa, T., Wijnvliet, P.E.J.P., van der Schans, C.P., de Greef, M.H.G.

*Hanze University of Applied Sciences*

**Background** Heart failure (HF) is one of the most prevalent cardiovascular diseases all over the world. Physical activity is the only non-pharmacological therapy which is proven to be effective in HF patients in reducing morbidity. Although physical activity consists of exercise and daily physical activity, most studies focus on exercise training. Little is known about daily physical activity of HF patients. Studies using self-report methods to assess daily physical activity, suggest that inactivity is common in HF patients, but data on objectively measured daily physical activity is scarce. Therefore, the purpose of this study was to examine performance-based daily physical activity in heart failure (HF) patients using physical activity guidelines (10000 steps/day and 30 minutes of activity/day) and to identify related factors. **Methods** Daily physical activity of 68 HF patients was measured using an accelerometer (SenseWear®) for 48 hours. Steps/day and time spent on physical activities at least at moderate intensity (≥3 METs) in minutes/day were the primary daily physical activity outcomes. Following the 10000 steps standard; <5000 steps/day was considered as a sedentary lifestyle, 5000-10000 steps/day as a moderate physically active lifestyle, and >10000 steps/day as a physically active lifestyle. Following the 30 minutes guideline; <30 minutes/day physical activity (≥3 METs) was considered as a sedentary lifestyle; and >30 minutes as a physically active lifestyle. Psychological characteristics (self-efficacy, motivation, and depression) were measured using questionnaires. **Results** Fifty percent took <5000 steps/day, 35% took 5000-10000 steps/day, and 15% took >10000 steps/day. Forty-four percent were active for <30 minutes/day; 56% were active for >30 minutes/day. A linear regression model using NYHA classification, age, and self-efficacy explained 42% of the variance in steps/day ( $F=11.86$ ;  $p<0.001$ ). **Conclusion** The prevalence of a sedentary or a physically active lifestyle in HF patients depends on which guideline—10000 steps/day versus 30 minutes of activity/day—is used. This illustrates the discrepancy between the guidelines and presents a major dilemma, since such mismatches cause difficulties in interpreting data and in drawing conclusions. When both guidelines are combined, 40% of patients can be classified as sedentary, 45% as semi-active and 15% as physically active. The large variance in daily physical activity can partly be explained by NYHA classification and self-efficacy.

## HIGH INTENSITY EXERCISE TRAINING IN PATIENTS WITH CHRONIC KIDNEY DISEASE

Weston, K.

*University of Queensland*

High intensity exercise training in patients with chronic kidney disease Weston Kassia S1, Howden Erin J1, Krishnasamy Rathika2, Isbel Nikky M2, Coombes Jeff S1 School of Human Movement Studies, University of Queensland, Australia 2School of Medicine, University of Queensland, Australia Introduction This aim of this study was to investigate the feasibility, efficacy and determinants of incorporating high intensity exercise in a 12 month exercise training intervention in patients with chronic kidney disease (CKD). It was hypothesised that high intensity exercise would be a feasible and effective option for patients with CKD. Furthermore, it was hypothesised that baseline exercise capacity and haemoglobin would predict participation in high intensity exercise. Methods This is an observational sub-study of a randomised controlled trial. 41 patients with stage 3 & 4 CKD (eGFR 25-60 mL/min/(1.73 m<sup>2</sup>)) were randomised to undertake a 12 month individualised aerobic and resistance training exercise intervention. The goal of the intervention was for all subjects to participate in high intensity interval training or vigorous exercise if capable. Pre and post intervention measurements included; Physical Activity Questionnaire, maximal treadmill test with VO<sub>2</sub>, blood analysis and arterial stiffness indices. Results Results from the 12 month Physical Activity Questionnaire allowed allocation of the following groups: meeting exercise guidelines but only completing moderate activity (150 mins/week) (n=9), not meeting guidelines (n=14), and meeting guidelines and including at least some high intensity activity (n=18). Patients who reported high intensity exercise had a higher exercise capacity both at baseline (9.3±3.8) and 12 months (11.6±3.6) measured in MET's than both patients reporting moderate exercise (6.3±2.1, 8.2±2.1) and those not meeting guidelines (5.8±2.5, 7.4±3.1). Patients reporting high intensity exercise also had significantly higher baseline haemoglobin levels (138.9±14.8 g/L) than patients reporting moderate (126.2±11.3 g/L) and not meeting guidelines (127.3±12.5 g/L). Independent correlates (p<0.05) of METs at 12 months included haemoglobin and pulse wave velocity and together they explained 51% of the variance (p<0.001). Discussion The study was successful in increasing high intensity physical activity in patients with CKD. Patients who reported high intensity exercise were more likely to have higher haemoglobin levels and exercise capacity at baseline. These findings suggest that in CKD patients haemoglobin levels are a strong predictor of exercise capacity at one-year and have a likely influence of fatigue on motivation.

## THE RE-AIM FRAMEWORK OF A JUMP LANDING TRAINING PROGRAM FOR THE PREVENTION OF LOWER EXTREMITY INJURIES IN BASKETBALL.

Aerts, I.

*SOMT - Stichting opleiding musculoskeletale therapie*

The RE-AIM framework of a jump landing training program for the prevention of lower extremity injuries in basketball. 1,2Aerts Inne, 2Cumps Elke, 1,3Verhagen Evert, 1Meeusen Romain. 1Vrije Universiteit Brussel, Faculty of Physical Education and Physical Therapy, Department of Human Physiology and Sports Medicine, Brussels, Belgium. 2SOMT Stichting Opleidingen Musculoskeletale Therapie, Department of the Master Sport Physical therapy, Amersfoort, Netherlands. 3EMGO Institute for Health and Care Research, Department of Public and Occupational Health. VU University Medical Center, Amsterdam, Netherlands. Introduction Jump-landing sports are often accompanied by a high rate of injuries (Dufek et al. 1991). To investigate the translatability and feasibility of a coach supervised injury prevention program, a randomized controlled trial was established during one season. Methods Exercises of the prevention program were chosen to ensure a progressive degree of difficulty. Particularly the lower extremity alignment was emphasized, while educating a proper jump-landing technique. Both the control (CG) and intervention group (IG) continued their normal training routine. The IG was asked to carry out the additional prevention program. Injuries and exposure hours were registered. The results of the prevention program were based on the five dimensions of the RE-AIM framework (Glasgow et al. 1999). Results The participation rate of the athletes was 62.5% (reach). Furthermore, the risk of lower extremity injuries was significantly lower in the IG compared to the CG (HR= 0.4 [95% CI: 0.16-0.99]) (effectiveness). Of the 12 teams in the IG, 10 teams (83%) agreed to participate in the study (adoption). Coaches and trainers (100%) stated that they had implemented the training sessions of the program as intended (implementation). All trainers, except one, intend to continue the prevention programme the following season (maintenance). Conclusion Overall, reach, adoption, implementation and maintenance of this coach supervised jump-landing prevention programme was high. Most trainers found the jump-landing programme to be easily compatible with their trainings. They indicated to make this programme part of regular routine. In addition, overall significant decreased injury risks were found for lower extremity injuries in the IG compared to the CG. These findings are promising for the achievement of injury prevention in jump-landing sports. References Dufek JS, Bates BT. ## STRENUOUS RUNNING EXERCISE IS ASSOCIATED WITH ACTIVATION OF HEMOSTATIC PATHWAYS IN HUMANS

Eijvogels, T., Veltmeijer, M., van Geffen, M., Thijssen, D., van Heerde, L., Hopman, M.

*Radboud University Nijmegen Medical Centre*

BACKGROUND: Retrospective studies indicated that patients with heat stroke have a sustained activation of coagulation, fibrinolysis and platelets. However, little is known about the impact of exercise on haemostatic parameters in athletes without exertional heat stroke and whether possible (physiological) changes in haemostatic parameters relate to changes in core body temperature. Therefore, the aim of this study was to determine changes in thrombin and plasmin generation as well as core body temperature after running a 15-km race. METHODS: Core body temperature was measured before and at the finish line of a 15 km run in a large, heterogeneous group of moderate- to highly-trained athletes (n=63, 44±11 years). Venous blood samples were collected pre- and post-race. The Novel Haemostasis Assay was used to measure thrombin and plasmin generation simultaneously. This allows insight in the interaction between coagulation and fibrinolysis. RESULTS: Core body temperature increased from 37.7±0.5°C to 39.4±0.9°C. The time to thrombin peak decreased from 9.0±1.3 min to 8.0±0.9 min (p<0.001), while the thrombin peak height did not change (baseline: 207±29 nM, post-exercise: 208±25 nM). In contrast, plasmin peak-time was not different between baseline (36.6.4±9 min) and post-exercise (35.4±8.1 min), while the plasmin peak height decreased significantly from 19.1±12.2 nM to 9.9±8.9 nM (p<0.001). Thrombin and plasmin responses were not different between subjects with a low (<39°C, n=21), average (39-40°C) and high (>40°C) finish core body temperature. CONCLUSION: Our study revealed that a 15-km running race was associated with an activated coagulation pathway via a faster thrombin generation and a reduced plasmin capacity. These findings were independent of the increase in core body temperature, and may have important implications for the insight into the development of exertional heat stroke.

## LOCAL MUSCLE METABOLISM DURING WHOLE BODY VIBRATION

Friesenbichler, B.

*University of Calgary*

**LOCAL MUSCLE METABOLISM DURING WHOLE BODY VIBRATION** Friesenbichler, B.1, Nigg, B.M.1, Dunn, J.1 1: UofC (Calgary, Canada) Introduction Whole body vibration (WBV) platforms have become popular tools for fitness and health improvement. However, studies about the platforms' effectiveness are inconclusive (Rittweger, 2010). One reason for the inconsistent findings is that the proper platform settings, that are required to elicit the desired improvements of the musculoskeletal system, are yet to be determined. A clear understanding of the immediate and local energetic demand of muscle tissue, while being exposed to vibration, is needed as a foundation to recommend effective long-term vibration training protocols. Therefore, the aim of this study was to quantify the local metabolic cost and muscle activity during whole body vibration. Methods Sixteen healthy male subjects were instructed to stand on a Galileo® vibration platform, while being exposed to vibrations of 0, 10, 17 and 28 Hz at  $\pm 2.5$  mm amplitude for one minute in randomized order. Changes in oxygenized haemoglobin (O<sub>2</sub>Hb) and muscle activity (EMG<sub>rms</sub>) of the vastus lateralis (VL) and medial gastrocnemius (GM) muscles were quantified using near infrared spectroscopy (NIRO 200-NX®) and surface EMG electrodes (Norotrode ®), respectively. Results The rate of O<sub>2</sub>Hb desaturation in the VL was (mean $\pm$ SD)  $-1.2\pm 1.4$ ,  $-2.5\pm 2.0$ ,  $-3.0\pm 1.7$ , and  $-5.6\pm 3.0$   $\mu\text{mol}\cdot\text{cm}/(\text{l}\cdot\text{s})$ ; and in the GM was  $-1.1\pm 0.8$ ,  $-1.9\pm 1.5$ ,  $2.6\pm 1.6$ , and  $6.3\pm 2.7$   $\mu\text{mol}\cdot\text{cm}/(\text{l}\cdot\text{s})$  at 0, 10, 17 and 28 Hz, respectively. EMG<sub>rms</sub> of the VL was  $0.04\pm 0.05$ ,  $0.11\pm 0.08$ ,  $0.18\pm 0.15$ , and  $0.25\pm 0.12$  V and of the GM was  $0.01\pm 0.01$ ,  $0.05\pm 0.04$ ,  $0.09\pm 0.04$ , and  $0.20\pm 0.15$  V at 0, 10, 17 and 28 Hz, respectively. The correlation between normalized O<sub>2</sub>Hb and EMG<sub>rms</sub> for the VL was  $r^2 = 0.69$  and for the GM was  $r^2 = 0.82$ . Discussion It was previously shown that WBV increased respiratory oxygen uptake during WBV at 26 Hz and  $\pm 2.5$  mm amplitude about 2-fold compared to control (standing, no vibration) (Rittweger et al., 2002). On the local level of individual muscles, the current study showed that relative metabolic cost during vibration exposure at similar platform settings increased roughly 4.5-fold (VL) and 5.5-fold (GM) relative to control. This means that although the entire body's energy expenditure only doubles during WBV compared to normal standing, the local oxygen demand can be considerably higher. The strong correlation of muscle activity and local metabolic cost ( $r^2 = 0.82$  for GM) may be used to estimate muscle metabolism of individual muscles during WBV. Vibration parameters can then be tuned properly to enhance the effectiveness of vibration training. References Rittweger J. (2010). Eur J Appl Physiol, 108, 877-904. ## MUSCLE FATIGUE AFFECTS DUAL TASK PERFORMANCE IN PATIENTS WITH MULTIPLE SCLEROSIS

Wolkorte, R.1, Kaspar, M.1, Heersema, D.J.2, Zijdwind, I.1

*University Medical Center Groningen*

**Introduction** Multiple sclerosis patients suffer from symptoms of fatigue and reduced information processing speed. Several experiments have been performed that investigated these symptoms. However, studies that investigate the relation between these symptoms are scarce. **Methods** MS patients (relapsing remitting; EDSS range 0-3; mean age 42) and age, sex and education matched controls participated in experiments performed on three occasions separated by a week. Experiment one was a practice session. In experiment two and three subjects performed a cognitive task concurrently with either a fatiguing or a non-fatiguing motor task. The motor task consisted of a contraction of a hand muscle (FDI, abduction of the index finger). The cognitive task consisted of an auditory choice-reaction-time task (CRT) in which subjects had to respond to two different tones with either their left index- or middle finger. Each session consisted of: 1) practice of the cognitive task. 2) Assessment of the maximal voluntary force (MVC). 3) A single cognitive task (auditory CRT task), followed by 4) a fatiguing or less-fatiguing dual task. The dual task consisted of the cognitive task combined with a muscle contraction at 30% MVC (fatiguing dual task) or 10% MVC (less-fatiguing dual task). Finally, 5) repetition of the single cognitive task. Task performance was measured as percentage of correct responses, and reaction times. **Results** Preliminary analysis (10 MS patients, 5 females; 6 controls, 3 females) with repeated measures ANOVA showed that the dual task was more difficult than a single task (main effect of task for MS-patients on number of errors,  $p=0.024$ , on reaction time,  $p=0.014$ , for controls on reaction time,  $p=0.036$ ). Furthermore, performance during the fatiguing dual task was more affected than during the less-fatiguing dual task (interaction effect of task\*fatigue on number of errors for MS patients,  $p=0.021$ , on reaction time,  $p=0.039$ , for controls on reaction time,  $p=0.049$ ). **Conclusions** The concurrent execution of a motor task decreases performance on a simple cognitive task; this effect is more pronounced in MS patients than in controls. During muscle fatigue, cognitive performance in MS patients deteriorates even more. It is known that during muscle fatigue, supraspinal motor centres increase their activity (Steens et al 2012), presumably to compensate for fatigue downstream of the motor cortex. This increased activation of motor areas could be responsible for a deterioration of cognitive task performance. Since MS patients show a lower capacity to compensate for fatigue-related changes (Steens et al 2012) a larger decline in cognitive performance is expected. **References** Steens et al. (2012). Neuroimage 59, 3110-3118

## WHAT ARE THE BENEFITS OF PHYSICAL EXERCISE IN PEOPLE WITH HIV INFECTION?

Bonato, M., La Torre, A., Bossolasco, S., Pavei, G., Merati, G., Galli, L., Cinque, P.

*Università degli Studi di Milano*

**Introduction** Since the introduction of Highly Active Antiretroviral Therapy (HAART), the number of patients dying from AIDS has fallen by more than two thirds. However, treatment causes a number of side effects, especially metabolic problems. Aim of this study was to evaluate fitness and health benefits of fitwalking, as moderate aerobic exercise, with or without strength exercise, in people with HIV infection receiving HAART. **Methods** Twenty HIV-infected, HAART-treated, sedentary male subjects performed an outdoor 12-week protocol consisting of 60 min of fitwalking at 65-75% of HR<sub>max</sub>, 3 sessions a week. Eight subjects also performed, at each session, 30 min circuit training at 65% of 1RM. Subjects were tested at baseline (BL) and 12 weeks (W12) by: 6 Min Walking Test (6MWT); maximal number of crunches in 30 sec; 1 RM test (lat machine, chest press, leg extension, sitting calf, leg press); general and morphometric examination (heart rate, blood pressure, BMI, waist, hip and leg circumference); blood examination (cytometry, fasting total, HDL and LDL cholesterol, tryglicerides, glucose, insulin; AST/ALT, ALP, gGT, creatinine, CPK, HbA1c; CD4+ lymphocytes and plasma HIV-RNA level). Differences between groups were tested by the Mann-Whitney test and differences over time by the Wilcoxon-signed rank test. BL differences between groups; results are expressed as [median (Q1-Q3)]. **Results** Out of 20 subjects, 18 [49.45 (43.75-54.33) yrs; BMI 24.95 (21.35-26.18) kg/m<sup>2</sup>] completed the 12-week training protocol and 9 (50%) attended  $\geq 65\%$  of the training sessions. In the whole group, 6MWT distance improved significantly at W12 compared to BL [722.5 (695-830) vs. 675 (627.5-691) m,  $p=0.002$ ]. At W12 a significant reduction was observed in BMI [24.95 (21.35-26.18) vs. 25.20 (22.71-26.87) kg/m<sup>2</sup>,  $p=0.009$ ], waist circumference [92.00 (85.75-96.00) vs. 93.00 (86.25-97.25) cm,  $p=0.03$ ] and LDL cholesterol [121 (102-135.5) vs. 131 (115-154) mg/dL,  $p=0.035$ ]. The 8 subjects of the fit-strength group showed

a significant increase of strength performance at W12. W12 changes of distance at 6MWT, waist and LDL level did not differ significantly between these subjects and those performing fitwalking only; BMI reduction was more marked in the latter subjects [23.95 (21.08-26.95) vs. 23.89 (21.53-27.13) kg/m<sup>2</sup>, p=0.054]. Discussion Fitwalking, with or without strength exercise, improved the aerobic fitness, morphometric variables and LDL cholesterol level in HIV-infected treated subjects. It can be offered to these patients to control the side effects of HAART. References Hand GA et al. *Am J Lifestyle Med.* 2009;3:489-99

### HEALTH-RELATED QUALITY OF LIFE: COMPARISON BETWEEN TRANSPLANTED AND HEALTHY MASTER ATHLETES

Totti, V.1,2, Roi, G.S.1, Coustere, O.3, Nanni Costa, A.4

*Isokinetic Medical Group*

1. Isokinetic Medical Group (Bologna, Italy), 2. Foundation for the Increase of Organ and Tissue Transplanted (Padova, Italy) 3. World Transplant Games Federation (Paris, France) 4. Italian National Transplant Centre (Rome, Italy) Introduction Health-related quality of life (HRQL) is an important marker in many chronic diseases. It allows the quantification of the patient's subjective perception and enables comprehension to their physical, emotional and social needs (1). The aim of this preliminary study was to compare the level of HRQL between a group of transplant athletes (TA) who participated in the World Transplant Games 2011 (WTG) and a group of healthy athletes who participated in master competitions through administration of the SF-36 questionnaire. Methods The SF-36 questionnaire was filled by 39 males (46±15 yrs; 75±13 kg; 177±0 cm; 24.0±3.2 kg/m<sup>2</sup>) TA (heart n=6; liver n=7; kidney n=25; bone marrow n=1) participating in cycling (n=3), swimming (n=16), track and field (n=14), tennis (n=4) and golf (n=2) competitions of WTG, and by 20 males healthy master athletes (MA) (36±11 yrs; 74±10 kg; 176±0 cm; 23.7±2.4 kg/m<sup>2</sup>) participating in national master swimming (n=17) and cycling (n=3) competitions. Results TA participated in sports competitions from 8±9 years, training 4±1 times/week for an average of 1±1 hour per session, while MA from 13±9 years and they trained 4±1 times/week for an average of 1±1 hours for each training session. The two groups achieved similar scores in the scales of general health (75±20 TA vs 75±11 MA), vitality (67±17 TA vs 69±12 MA), social functioning (85±18 TA vs 84±16 MA) and mental health (76±18 TA vs 75±14 MA). TA showed significant difference in scales of physical functioning (81±29 vs. 99±2 MA, t=3.858, P<0.01), role limitations due to physical problems (83±31 vs 96±12 MA, t=2.304, P<0.05), body pain (79±19 vs 88±18 MA, t=1.784, P<0.05) and role limitations due to emotional problems (84±28 vs 98±8 MA, t=2.324, P<0.05) compared to healthy athletes. Conclusions In a selected group of transplanted patients practicing sports, the physical component and a part of the mental component (role limitations due to emotional problems) were worse than that of healthy athletes, while the other scales of the general health were similar to that of healthy athletes. In particular vitality and general health scales that are part of both the physical and mental components, are similar to MA. Despite TA is not representative of the general transplant population, the data suggests that near-normal level of health-related quality of life is possible after transplantation in TA. ### LACK OF ENDOGENOUS PAIN INHIBITION DURING EXERCISE IN PEOPLE WITH CHRONIC WHIPLASH: AN EXPERIMENTAL STUDY

Van Oosterwijck, J.1,2,3, Nijs, J.1,2,3, Meeus, M.1,2, Van Loo, M.4, Paul, L.5

1: *Vrije Universiteit Brussel (Belgium)*, 2: *Artesis University College Antwerp (Belgium)*, 3: *University Hospital Brussels (Belgium)*, 4: *Red Cross Flanders (Belgium)*, 5: *University of Glasgow (UK)*

INTRODUCTION: Evidence for altered central pain processing and hypersensitivity of the central nervous system, i.e. central sensitization, in chronic whiplash associated disorders (CWAD) is accumulating. Dysfunctional descending inhibitory action is one of the major characteristics of central sensitization and has been studied during exercise in some chronic pain conditions, but no data regarding the response of people with CWAD to exercise are available. Therefore the purpose of this study was to examine the efficacy of the endogenous pain inhibitory systems during exercise, and exercise response in CWAD patients during two different types of acute exercise. METHODS: Twenty-two women with CWAD and 22 healthy sedentary controls performed a submaximal and a self-paced, physiologically limited exercise test on a cycle ergometer on two separate occasions. The exercise tests were undertaken with cardiorespiratory monitoring. Before and after the exercise bouts, subjects filled out questionnaires to assess health status, and underwent pain pressure threshold (PPT) measurements. Throughout the study, subjects' activity levels were assessed using accelerometry in order to monitor potential influences of daily activity levels. Possible changes in any of the outcome measures in response to exercise were compared between the two groups, and between the two types of exercise, using repeated measures ANOVA. RESULTS: In CWAD PPTs decreased following submaximal exercise, whereas they increased in healthy subjects (between group difference p-value between .021 and .044). The same effect was established in response to the self-paced, physiologically limited exercise, with exception of the PPTs measured at the calf which increased (p=.291). A worsening of the CWAD symptom complex was reported post-exercise (p<.05). Fewer symptoms were reported in response to the self-paced, physiologically limited exercise. In addition, no differences in submaximal exercise capacity or daily physical activity were observed between people with CWAD and controls (p>.05). DISCUSSION: The present study is the first to examine and suggest an impaired descending endogenous pain inhibition during exercise in CWAD patients, and hence provides additional evidence for the presence of central sensitization in CWAD. Submaximal exercise triggers post-exertional malaise, while a self-paced and physiologically limited exercise will trigger less 'severe' symptoms, and therefore seems more appropriate for CWAD patients. These finding highlights the fact that one should be cautious when evaluating and recommending exercise in people with chronic WAD, and that the use of more individual, targeted exercise therapies is recommended.

### HIGHER HABITUAL PHYSICAL ACTIVITY LEVELS ARE PROTECTIVE OF FUNCTIONAL CAPACITY AND QUALITY OF LIFE IN FEMALE PATIENTS WITH RHEUMATOID ARTHRITIS REGARDLESS OF DISEASE ACTIVITY

Prioreschi, A.

*University of the Witwatersrand*

Rheumatoid Arthritis (RA) is a chronic condition resulting in persistent pain, limiting the ability of patients to function normally and therefore decreasing their physical activity levels. Physical activity is difficult to assess, as subjective measures are often inaccurate. Actical accelerometers have been developed to objectively assess physical activity levels. Our study therefore aimed to use accelerometry to objectively assess habitual physical activity levels in a group of patients with RA, and to compare these measures to quality of life and disease activity indices. Seventy-two black, female participants with a mean age of 47±12 years were recruited, 50 of which were patients from a local hospital confirmed as having RA, that were divided into a physically active group (n=25) and a physically inactive group (n=25)

according to their average activity counts recorded on the accelerometer over a two week period. The remaining 22 participants were healthy age and socioeconomically matched controls. All participants wore an Actical on their right hip for two weeks during the day. Participants with RA completed the Short Form-36 (SF-36) and Health Assessment Questionnaires (HAQ-DI), and were assessed for disease activity using the Simplified Disease Activity Index (SDAI). All Acticals were calibrated before the data were analysed. The physically inactive group spent significantly more time in sedentary activities than did the physically active group ( $p=0.003$ ) or the control group ( $p<0.0001$ ), and significantly less time in light and moderate activities than both the physically active group and the control group. HAQ-DI was significantly greater in the physically inactive group than in the physically active group ( $p<0.0001$ ), indicating a greater degree of functional impairment. There were no differences between the two groups for SDAI, yet the physically active group scored better than the physically inactive group on every component of the SF-36, and significantly better for vitality ( $p=0.039$ ), overall mental health ( $p=0.049$ ), overall physical health ( $p=0.049$ ), and total SF-36 score ( $p=0.026$ ). Accelerometry is able to detect habitual physical activity in patients with RA, and indeed confirmed that they lead a significantly more sedentary lifestyle than healthy controls. Higher levels of physical activity were not associated with disease activity, but were protective of functional capacity and highly associated with improved quality of life in RA patients.

### REVASCULARISATION IN PERIPHERAL ARTERIAL DISEASE : EFFECT ON LEG BLOOD FLOW, WALKING TOLERANCE AND CALF MUSCLE FUNCTION.

Stefanovic, B., Russell, F.D., Walker, P.J., Green, S., Askew, C.D.

*University of the Sunshine Coast*

REVASCULARISATION IN PERIPHERAL ARTERIAL DISEASE (PAD): EFFECT ON LEG BLOOD FLOW, WALKING TOLERANCE AND CALF MUSCLE FUNCTION. Stefanovic, B. 1, Russell, F.D. 1, Walker, P.J. 2, Green, S. 3, Askew, C.D. 4. 1: University of the Sunshine Coast, 2: School of Medicine, Discipline of Surgery and Centre for Clinical Research, University of Queensland, 3: University of Western Sydney, 4: Institute of Health and Biomedical Innovation, Queensland University of Technology (Australia). Introduction Haemodynamic and non-haemodynamic factors are believed to contribute to walking intolerance in patients with PAD. Whilst revascularisation leads to improvements in walking tolerance, the mechanisms of improvement and its influence on calf muscle function are not clear. This study aimed to determine the effect of revascularisation on walking tolerance, calf muscle function and leg blood flow in PAD. Methods 12 men and 3 women (age  $63 \pm 8$  y) with PAD scheduled to undergo revascularisation were included. Resting ankle to brachial index (ABI) of the limb to be revascularised (VASC) was  $0.72 \pm 0.11$  compared to  $0.95 \pm 0.19$  for the non revascularised limb (NON-VASC). Before and 2-4 weeks after revascularisation, six minute walking distance (6MWD) was assessed, as was calf muscle strength, endurance, and fatigue using an isometric plantar flexion dynamometer in both VASC and NON-VASC limbs. Leg blood flow was measured during calf exercise using strain gauge plethysmography. The biphasic responses of the muscle blood flow and fatigue responses were quantified by fitting distinct equations to these data. Results Revascularisation lead to a non-significant increase in 6MWD (pre  $352 \pm 90$ ; post  $408 \pm 77$  m,  $p = 0.07$ ). There was an increase in ABI for VASC (pre  $0.72 \pm 0.11$ ; post  $1.05 \pm 0.22$ ) compared with NON-VASC limbs (pre  $0.96 \pm 0.17$ ; post  $1.00 \pm 0.21$ ). Exercise blood flow magnitude increased (pre  $26.2 \pm 11.7$ ; post  $38.1 \pm 13.9$  ml.100ml<sup>-1</sup>.min<sup>-1</sup>) in the VASC limbs, and there was an increased amplitude for both the early and late phases of the exercise blood flow response. The time delay preceding the late blood flow phase decreased in the VASC (pre  $22.4 \pm 13.3$ ; post  $15.4 \pm 6.2$  s) compared with the NON-VASC limbs (pre  $14.4 \pm 6.5$ ; post  $17.4 \pm 8.5$  s). Muscle endurance, but not strength, was increased in VASC (pre  $259 \pm 160$ ; post  $525 \pm 382$  s) but not the NON-VASC limbs (pre  $516 \pm 373$ ; post  $586 \pm 316$  s). There were no significant changes in muscle fatigue, although there tended to be an increase in the time delay prior to the late fatigue phase for the revascularised limbs (VASC: pre  $152 \pm 77$ ; post  $202 \pm 115$ . NON-VASC: pre  $221 \pm 129$ ; post  $207 \pm 139$  s,  $p = 0.09$ ). Discussion Revascularisation resulted in a significant improvement in exercise blood flow and plantar flexion endurance. These data support the notion that exercise blood flow is an important determinant of exercise capacity in PAD.

#### BETA-ALANINE SUPPLEMENTATION FOR 10 WEEKS WAS UNABLE TO IMPROVE TRAINING AND COMPETITION PERFORMANCE IN ELITE SWIMMERS

Chung, W.1, Shaw, G.1, Anderson, M.2, Pyne, D.B.1, Saunders, P.U.1, Bishop, D.J.3, Burke, L.M.1

1: Australian Institute of Sport (Canberra, Australia), 2: Queensland Academy of Sport (Queensland, Australia), 3: Victoria University (Melbourne, Australia)

Introduction Although some laboratory-based studies show an ergogenic effect with beta-alanine supplementation, there is a lack of field-based research in training and competition settings. This study investigated the effects of beta-alanine supplementation on training and competition performance in international level swimmers. Methods Elite swimmers ( $n = 27$  males and 21 females, age =  $21.7 \pm 3.1$  yr; mean  $\pm$  SD) were supplemented with either beta-alanine (BA; 4 week loading phase of  $4.8$  g.day<sup>-1</sup> with a maintenance dose of  $3.2$  g.day<sup>-1</sup> thereafter) or placebo (PLA) for 10 weeks. Competition performance was evaluated before (National Championships; CPRE) and after (World Championships or national selection meet; CPOST) supplementation using IPS points. Swimmers also completed three standardised sessions (sprinters  $4 \times 50$  m, 100 m; middle-distance  $6 \times 50$  m, 200 m; distance  $8 \times 50$  m, 200 m) in training at baseline (TPRE), 4 weeks (TMID) and 10 weeks (TPOST) of supplementation. Capillary blood was analysed for pH, bicarbonate and lactate concentration in both competition and training. We employed a contemporary analytical approach involving magnitude-based inferences to detect small effects of practical importance in an elite athlete group. Precision of estimation expressed as 90% confidence limits (CL) to evaluate differences within and between groups. Results There was a trivial effect ( $-1.2 \pm 2.3\%$ ; mean  $\pm$  90% confidence limits) of BA on race performance compared with PLA and no meaningful effect on blood measures (post race pH ( $0.2 \pm 0.8\%$ ); post race bicarbonate ( $-6.7 \pm 22.6\%$ )). For training performance with all three groups combined, there was no substantial effect of BA at TMID and TPOST ( $-0.1 \pm 1.2\%$ ;  $-0.1 \pm 1.4\%$ ). There were also no meaningful effects on post training blood pH at TMID and TPOST ( $-0.1 \pm 0.7\%$ ;  $0.2 \pm 0.7\%$ ) or bicar-

bonate ( $3.6 \pm 13.5\%$ ;  $2.7 \pm 16.4\%$ ). However, post-training blood lactate concentration at TPOST was reduced by  $-11.0 \pm 9.9\%$ . Discussion We were unable to demonstrate an ergogenic effect of beta alanine supplementation in elite level swimmers due to the trivial or unclear results in our study. More work is required to clarify how the results of laboratory-based studies showing positive effects of beta alanine can be transferred effectively into improved real world training and competitive performance.

### **METABOLIC RESPONSE TO GREEN TEA EXTRACT DURING REST AND MODERATE INTENSITY EXERCISE**

Hodgson, A.B.1, Randell, R.K.1, Boon, N.2, Garczarek, U.2, Mela, D.J.2, Jeukendrup, A.E.1, Jacobs, D.M.2

1. *University of Birmingham (Birmingham, UK)* 2. *Unilever R&D (Vlaardingen, The Netherlands)*

**Introduction** Green tea catechins have been hypothesized to increase energy expenditure and fat oxidation by inhibiting catechol-O-methyltransferase (COMT) and thus promoting more sustained adrenergic stimulation. Metabolomics may help to clarify the mechanisms underlying their putative physiological effects. The study investigated the effects of seven days ingestion of green tea extract (GTE) on the plasma metabolite profile at rest and during exercise. **Methods** In a placebo-controlled, double-blind, randomized, parallel study, 27 healthy physically active males consumed either GTE ( $n=13$ , 1200mg catechins, 240mg caffeine / day) or placebo ( $n=14$ , PLA) drinks for seven days. After consuming a final drink (day 8) they rested for two hours and then completed 60 minutes moderate intensity cycling exercise ( $56 \pm 4\%$  VO<sub>2</sub>max). Blood samples were collected before and during exercise. Plasma was analyzed using untargeted 4-phase metabolite profiling and targeted profiling of catecholamines. **Results** Using the metabolomic approach we observed that GTE did not enhance adrenergic stimulation (adrenaline and noradrenaline) during rest or exercise. At rest, GTE led to changes in metabolite concentrations related to fat metabolism (3- $\beta$ -hydroxybutyrate), lipolysis (glycerol) and TCA cycle intermediates (citrate) when compared to PLA. GTE during exercise caused reduced 3- $\beta$ -hydroxybutyrate concentrations as well as large increases in lactate and Cori cycle metabolite concentrations (alanine) when compared to PLA. **Discussion** GTE supplementation resulted in marked metabolic differences during rest and exercise. Yet these metabolic differences were not related to the adrenergic system, which questions the in vivo relevance of the COMT inhibition mechanism of action for GTE.

### **HYDRATION ASSESSMENT OF BASKETBALL PLAYERS DURING FIBA EUROPE U20 EUROPEAN CHAMPIONSHIP**

Andjelkovic, M.1, Vukasinovic-Vesic, M.1, Dikic, N.1,2, Radivojevic, N.1, Curcic, D.J.1, Antic, T.1, Barlic, I.1, Turner, R.2, Stokes, R.2, Gunter, H.2

*Sports Medicine Association of Serbia, FIBA Europe2*

**Introduction** Hydration is the condition of having adequate fluid in the body tissues. Field research suggests that approximately 50% of individual and team athletes are hypohydrated. Thus, the aim of this study was to analyze the hydration status of male basketball players. **Method** Ninety-six basketball players of eight national teams were assessed during the official FIBA Europe U20 Championship Men 2011 - Division B held in Sarajevo in July 2011. In order to estimate hydration we collected three morning urines of each player on consecutive days and once after the game, then we measured body mass of all players before and after one game, the quantity of consumed fluid and urine output during the game, as well as temperature and humidity in the sports hall. Hydration assessments were evaluated by urine specific gravity (Usg), urine color (Ucol), urine osmolality (Uosmol), sweat rate (SR), fluid intake (FI) and urine output (UO). **Results** Players age was  $19 \pm 0.79$  years. After the game body mass loss was  $0.9 \pm 0.7$  kg, percentage of dehydration  $0.99 \pm 0.7\%$ , total fluid intake  $1868 \pm 816$  ml (range 435 – 3987) and sweat rate  $2.7 \pm 0.9$  L/h (range 1.16 – 5.54). Urine output during the game was  $55 \pm 61$  ml. Mean morning Usg was  $1024 \pm 6$  and after the game  $1026 \pm 6$ , mean morning urine color was  $5.67 \pm 1.12$  and after the game  $5.97 \pm 1.37$ , mean morning urine osmolality was  $883 \pm 229$  osmol/L and after the game  $852 \pm 228$  osmol/L. Ambient temperature was  $30 \pm 2^\circ\text{C}$  and humidity  $55 \pm 4\%$  on average. We found statistically significant correlation between sweat rate with Usg ( $p < 0.05$ ), Uosmol ( $p < 0.01$ ), body mass loss ( $p < 0.01$ ), FI ( $p < 0.01$ ), BSA ( $p < 0.01$ ) and percentage of dehydration ( $p < 0.01$ ). **Discussion** Most athletes did not intake enough fluids to match sweat losses during the game and they were significantly dehydrated which was proven by measuring Usg and Uosmol, as well as by body mass loss and percentage of dehydration. Even more players begin the day in a hypohydrated state which is indicated by morning Usg, Uosmol, Ucol. Finally we might conclude that players were chronically dehydrated. The results of this study support idea that trainers and team doctors should be educated to help athletes to be properly hydrated. It seems that only a proactive role and awareness of all participants in basketball could contribute to a better hydration and sports performance. Players should receive encouragement and educational information about suitable hydration strategies. **References** Maughan R.J., Shirreffs S.M. Development of hydration strategies to optimize performance for athletes in high-intensity sports and in sports with repeated intense efforts. *Scand J Med Sci Sports*. 2010.

### **ENERGY BALANCE AND FOOD SOURCES DURING AN ULTRA ENDURANCE CYCLING EVENT**

Geesmann, B.1, Kramer, F.1, Koehler, K.1,2, Mester, J.1,2

1. *German Sport University (Cologne, Germany)* 2. *German Research Centre of Elite Sport (Cologne, Germany)*

**Introduction** Ultra endurance events are among the largest physiological challenges on the human body. One of the biggest tasks is the sufficient energy supply from solid and liquid foods and a successful completion is only possible with adequate dietary strategies. Most scientific reports describing the energetic demands of such events are single case studies (Knechtle et al., 2005) or studies with a small amount of subjects (Hulten et al., 2010), so that only little is known about the inter-individual variance in energetic demands and eating habits of such events. In the present study the cycle marathon Paris-Brest-Paris (PBP) which leads over 1.200 km was analyzed from an energetic point of view. Hence, the aim was to assess the energy balance of a whole team participating in this event and to analyze the energy intake (EI) under terms of nutritional composition and energy supply. **Methods** Fourteen well-trained male athletes ( $74.1 \pm 6.8$  kg,  $43.6 \pm 7.8$  y) participated in this study and finished PBP in 54 hours with a mean cycling time of 42h 48min. In the preparation period, the cyclists performed an incremental test on a cycle ergometer to determine the ratio between power output (PO) and energy expenditure (EE) individually. EE was measured by indirect calorimetry. All riders were equipped with an SRM system to assess PO continuously, which was later converted into EE using the previously determined individual regression. Diet was continuously recorded by trained staff. The nutrient content was obtained from the Federal German Nutrient Database or the manufacture. Immediately before and after the event body weight, body fat and skin fold thickness were measured. **Results** The total EE was  $25303 \pm 2436$  kcal ( $11245 \pm 1083$  kcal/24h). EI was  $19749 \pm 4502$  kcal ( $8777 \pm 2001$  kcal/24h). This resulted in an average energy deficit of  $5554 \pm 4567$  kcal. Of the total EI,  $15634 \pm 4310$  kcal ( $6948 \pm 1916$  kcal/24h) derived from solid food and  $4115 \pm 1850$  kcal ( $1829 \pm 822$  kcal/24h) from liquid nutrition. Analyzing the macronutrient content revealed that 57% were taken up from carbohydrates, 30% from fat and 13% from proteins. Total carbohydrate intake was  $3011 \pm 525$ g ( $40.6 \pm 7.1$  g/kg BW). The loss of body weight in pre-post comparison was  $0.1 \pm 1.4$  kg. Total body fat was reduced by  $0.9 \pm 0.5$

kg, skinfold thickness by  $9.8 \pm 4.6$  mm. Discussion In relation to other ultra endurance events the energy deficit was rather low, which verifies a successful realization of the individual dietary strategies. The nutritional composition can be used for further events with similar energetic and physiological challenges. References Hulton A.T., Lahart I., Williams K.L., et al. (2010). *Int J Sports Med*, 31, 463-467. Knechtle B., Enggist A., Jehle T. (2005). *Int J Sports Med*, 26, 499-503.

### EFFECTS OF SHORT-TERM ENERGY RESTRICTION WITH AND WITHOUT TRAINING ON PHYSIOLOGICAL AND PSYCHOLOGICAL MEASURES OF PERFORMANCE

Koehler, K., Pilger, N., Zinner, C., Braun, H., Kleinert, J., Mester, J., Schaenzer, W.

*German Sport University*

Introduction Apart from potential long-term effects on body mass and composition, a restriction of the dietary energy intake leads to acute changes in metabolic and hormonal profiles, which indicate a catabolic state (Loucks, 2004). These acute effects of low energy availability have primarily been reported in moderately trained females, but data on the effects in trained male athletes is lacking. Furthermore, little is known about the acute effects of energy restriction on performance capacity. Hence, the purpose of our study was to characterise the effects of a short-term energy restriction on physiological and psychological performance measures. Methods In a preliminary study, four male athletes ( $26 \pm 3$  y,  $79 \pm 8$  kg) underwent four interventions in a randomized, cross-over-design. Dietary energy intake (EI) and exercise energy expenditure (ExEE) were predefined to regular energy availability (EA; 40 kcal/kg FFM) or reduced EA (15 kcal/kg FFM). In two of the four study arms, the athletes underwent a daily training program with an ExEE of 15 kcal/kg FFM, which was compensated for by raising EI by 15 kcal/kg FFM. EA was controlled for 4 consecutive days and pre and post measures included assessment of body weight and composition, strength tests, submaximal and maximal performance tests on a cycle ergometer, and questionnaires to assess the perceived physical and psychological state. Results Regardless of exercise, energy restriction caused a reduction in body mass by  $2.3 \pm 0.7$  kg ( $p < 0.001$ ). There was a trend towards greater fat mass losses and smaller fat-free mass losses when the subjects exercised during energy restriction. Peak power in bench press, leg curl and leg extension and peak power output during a 30-sec all-out cycle ergometer test were not significantly affected by energy restriction with or without exercise. During the submaximal cycling test, heart rate was elevated during energy restriction ( $p < 0.05$ ) but ratings of perceived exertion were only slightly higher. Energy restriction caused a significant reduction in subjective scores of the perceived physical and motivational state, but training significantly reduced the negative effects of energy restriction on perceived physical fitness, social acceptance and positive mood. Discussion The present data show that dietary energy restriction for four days with or without exercise leads to massive changes in body mass and has negative effects on submaximal but not on peak performance. Energy restriction also caused changes in psychological measures, but for several items, the combination of energy restriction and exercise blunted the negative effects. References Loucks AB. (2004). *J Sports Sci*, 22, 1-14.

### OPTIMISING AN ORAL INSULINOTROPIC FORMULATION FOR L-CARNITINE FEEDING IN HUMANS

Shannon, C.E., Greenhaff, P.L., Stephens, F.B.

*University of Nottingham*

Aims Carnitine facilitates the mitochondrial entry of long-chain fatty acids and also buffers pyruvate-derived acetyl group accumulation during intense exercise in humans. Increasing skeletal muscle carnitine content alters fuel metabolism but requires prolonged (>24 wks), daily feeding of L-carnitine in a carbohydrate beverage (Wall et al., 2011) to raise serum insulin to a concentration sufficient (>50 mU/L) to augment muscle carnitine retention (Stephens et al., 2006). In an attempt to improve the efficacy of muscle carnitine loading, this study used oral insulinotropic beverages to extend the time period during which serum insulin concentration was >50 mU/L in the presence of elevated plasma carnitine. Methods On four randomised 6-hour visits following an overnight fast, seven healthy males (age  $23 \pm 4$  yr, BMI  $24 \pm 2$  kg/m<sup>2</sup>) ingested 4.5g L-carnitine-tartrate in 200ml water (0 h) followed by 3x700ml beverages containing either flavoured water (CON), 80g carbohydrate (CHO), 40g carbohydrate + 40g whey protein (PRO), or 30g carbohydrate + 14g whey protein + 7g leucine + 7g phenylalanine (AA) at 1, 2.5 and 4 h. Blood was sampled every 20 min for the determination of serum insulin and plasma total carnitine (TC) concentration. Six-hour area under the concentration x time curve (AUC) and peak concentration values were compared using ANOVA. Results Serum insulin concentration AUC >50 mU/L during CHO ( $3.3 \pm 1.3$  U/L·min) was 265% greater than AA ( $0.9 \pm 0.4$  U/L·min;  $P < 0.05$ ) and tended to be 211% greater than PRO ( $1.1 \pm 0.6$  U/L·min;  $P = 0.07$ ). Peak insulin concentration after the first drink was similar between CHO, PRO and AA ( $86 \pm 16$ ,  $91 \pm 23$  and  $80 \pm 18$  mU/L, respectively), but was greater after the second and third drinks in CHO ( $98 \pm 15$  and  $80 \pm 9$  mU/L, respectively) than PRO ( $52 \pm 6$  and  $46 \pm 9$  mU/L, respectively; both  $P < 0.01$ ) and AA ( $49 \pm 5$  and  $53 \pm 11$  mU/L, respectively; both  $P < 0.05$ ). Plasma TC AUC during PRO ( $7.6 \pm 0.9$  mmol/L·min) was 32% ( $P < 0.01$ ) and 25% ( $P < 0.05$ ) greater than AA and CON ( $5.7 \pm 0.6$  and  $6.0 \pm 0.8$  mmol/L·min, respectively) and tended to be 16% greater than CHO ( $6.5 \pm 0.7$  mmol/L·min;  $P = 0.08$ ). Conclusions Serum insulin concentration was >50 mU/L for longer in CHO. Furthermore, the blunted insulin response to repeated ingestion of PRO and AA may abate the stimulation of muscle carnitine uptake relative to CHO. This study affirms a high-carbohydrate beverage as a potent insulinotropic option for carnitine loading. The greater plasma TC AUC during PRO may improve temporal matching between peak concentrations of TC and insulin. ### PROTEIN SUPPLEMENTATION DOES NOT FURTHER AUGMENT THE BENEFITS OF PROLONGED RESISTANCE TYPE EXERCISE TRAINING IN HEALTHY ELDERLY MEN AND WOMEN

Leenders, M., Verdijk, L.B., van der Hoeven, L., van Kranenburg, J., Nilwik, R., van Loon, L.J.C.

*Maastricht University Medical Centre+*

Background: Resistance type exercise training has been well established as an effective intervention strategy to increase skeletal muscle mass and strength in the elderly. Objective: To assess whether dietary protein supplementation can further augment the adaptive response to prolonged resistance type exercise training in healthy, elderly men and women. Design: Healthy, elderly men ( $n=31$ ;  $70 \pm 1$ y) and women ( $n=29$ ;  $70 \pm 1$ y) were randomly assigned to a 24-wk, progressive resistance type exercise training program with (protein group) or without (placebo group) additional protein supplementation (15 g/day). Strength was assessed regularly by one-repetition maximum (1RM) testing. Muscle hypertrophy was assessed at whole-body (DXA), muscle (CT) and muscle fiber (biopsy) level. Functional performance was assessed with a sit-to-stand test. Blood glucose and lipid profiles were assessed as markers for metabolic health.

Results: 1RM strength increased by  $45 \pm 6$  vs  $40 \pm 3\%$  (women) and  $41 \pm 4$  vs  $44 \pm 3\%$  (men) in the placebo vs protein supplemented group, respectively ( $P < 0.001$ ), with no differences between groups. Muscle mass increased similarly in the placebo and protein groups, both at whole-body ( $2 \pm 1\%$ ) and muscle level ( $9 \pm 1\%$ ). In agreement, type II muscle fiber size increased significantly in both placebo and protein groups ( $25 \pm 13$  vs  $30 \pm 9$  and  $23 \pm 12$  vs  $22 \pm 10\%$  in the women and men, respectively), with no changes in type I muscle fiber size. Sit-to-stand time improved by  $18 \pm 2$  and  $19 \pm 2\%$  in the women and men, respectively ( $P < 0.001$ ) with no differences between groups. Glucose homeostasis as measured by HbA1c, OGIS, and ISI improved in all groups. Furthermore, significant decreases in plasma LDL and total cholesterol concentrations were observed in both placebo and protein group. Conclusion: Prolonged resistance type exercise training muscle mass and strength, augments functional capacity, and improves glycemia and lipidemia in healthy elderly men and women. Additional protein supplementation (15 g/d) does not further increase muscle mass, strength, and/or functional capacity in healthy elderly men and women.

### THE EFFECT OF HIGH DOSE VITAMIN C AND E SUPPLEMENTATION ON VO<sub>2</sub>MAX, HEMOGLOBIN MASS AND ENDURANCE PERFORMANCE IN WELL TRAINED SUBJECTS

Holden, G., Landgraff, H., Raastad, T., Hallén, J., Paulsen, G.

*Norwegian School of Sport Sciences, Oslo, Norway*

The effect of high dose vitamin C and E supplementation on VO<sub>2</sub>max, hemoglobin mass, and endurance performance in well trained subjects Holden, Geir., Landgraff, Hege., Raastad, Truls., Hallén Jostein., and Paulsen, Gøran. Norwegian School of Sport Sciences, Oslo, Norway Introduction There is a widespread use of antioxidant supplementation in general population and among athletes. A growing body of evidence indicates detrimental effects of high-dose antioxidant supplementation on health and performance benefits of training (Gomez-Cabrera et al., 2008). The aim of this study was to investigate the effects of high-dose of antioxidant supplementation (vitamin C and E) during an 11 week endurance training regiment on maximal oxygen consumption (VO<sub>2</sub>max), running performance (beep-test; 20m shuttle run), blood volume (BV) and total hemoglobin mass (HbM), as well as oxygen consumption (VO<sub>2</sub>), heart rate (HR) and blood lactate concentration (La) on submaximal performance on motorized treadmill. Methods Seventeen endurance trained subjects (12 females and 5 males; age:  $24.4 \pm 2.9$  yrs, VO<sub>2</sub>max  $55.0 \pm 7.9$  (ml.kg<sup>-1</sup>.min<sup>-1</sup>) were recruited and randomized in an antioxidant group (AG) and a placebo group (PG). The AG (n=8) received 1000 mg vitamin C and 235 mg vitamin E daily, while the PG (n=9) received placebo pills. The study was a double blinded design. The training protocol consisted of 3-4 endurance training sessions every week for 11 weeks, combining interval (4 x 4 up to 6 x 6min; > 90% HRmax) and continuous running sessions (30 and 60 min; ~85% HRmax and ~75% HRmax), respectively. The subjects were tested before and after 5 and 11 weeks of training and supplementation. Results VO<sub>2</sub>max increased by  $8.9 \pm 2.9\%$  in AG and by  $7.8 \pm 4.0\%$  in PG ( $p < 0.01$ ). PG significantly reduced HR at a workload corresponding to 60% of initial VO<sub>2</sub>max test by  $4.4 \pm 4.6\%$  ( $p = 0.02$ ), while AG had a small increase in HR by  $1.3 \pm 3.1\%$  ( $p = 0.3$ ). At a workload of 85% of initial VO<sub>2</sub>max, PG significantly reduced HR by  $4.7 \pm 5.0\%$  ( $p = 0.02$ ), with AG increasing HR by  $1.6 \pm 3.1\%$  ( $p = 0.3$  within and  $p = 0.01$  between groups). There were no significant changes in blood (La) at the submaximal workloads for either group. Performance in the beep-test did not change significantly in AG  $3.4 \pm 8.2\%$  ( $p = 0.3$ ), but improved distance in PG by  $14.3 \pm 14.1\%$  ( $p = 0.02$ ). No significant changes were observed for BV or HbM in the two groups. Discussion The 11 week endurance training program increased VO<sub>2</sub>max in both AG and PG, with no changes in BV or HbM. Supplementation with large doses of vitamin C and E hindered the training induced reduction in HR at submaximal workloads. Even though there were no group differences in performance changes in the beep-test, only the PG increased significantly their performance. Our results suggest that antioxidant supplementation may hamper endurance training induced adaptations related to performance. References Gomez-Cabrera, M. et al. (2008) *Am J Clin Nutr*, 87(1), 142-149.

### THE FATE OF CHRONICALLY INGESTED BETA-ALANINE RETENTION IN HUMANS.

Everaert, I., Blancquaert, L., Derave, W.

*Ghent University*

Introduction: Beta-alanine is a popular nutritional supplement, which enhances muscle carnosine synthesis and likely high-intensity exercise performance. Urinary retention of beta-alanine after acute ingestion is very high, namely 96.3% for pure beta-alanine and 98.9% for slow-release (1). The retention of both creatine (from 60 to 32% (2)) and carnitine (from 97.8 to 90% (3)) decreases after 3 days supplementation but can be enhanced by co-ingestion of carbohydrates and proteins, as insulin stimulates the muscular accumulation of these compounds. Therefore, the aim of this study was to investigate the effect of 5 weeks beta-alanine supplementation on whole body beta-alanine retention and whether this could be enhanced by co-ingestion of carbohydrates and proteins. Methods: 7 young healthy male subjects were supplemented for 5 weeks with slow-release beta-alanine (3 x 1.6g/day (Powerbar)). Beta-alanine retention was measured weekly, by ingestion of 1.6g slow-release beta-alanine in fasted subjects and collection of urine up to 6h post-ingestion. From week 2, subjects performed the retention test twice on consecutive days: 1/ control as described above, 2/ with intake of 2 energy bars (10min post beta-alanine intake: Power C2max (= 39.1g CHO + 5.8g protein) and 55min post beta-alanine intake: Protein Plus (= 22.2g CHO + 16.6g protein), Powerbar). Results: The mean ( $\pm$  SD) urinary beta-alanine excretion before supplementation was  $25.63 \pm 22.53$  mg, which corresponds with a beta-alanine retention of  $98.40 \pm 1.41\%$ . Long-term supplementation with beta-alanine did not affect beta-alanine retention (week 1 - 5:  $97.98 \pm 1.45\%$ ,  $98.45 \pm 1.20\%$ ,  $98.05 \pm 0.85\%$ ,  $98.53 \pm 0.66\%$ ,  $98.79 \pm 0.59\%$ , respectively,  $p > 0.05$ ). Logically, co-ingestion of beta-alanine with carbohydrates and proteins did not enhance beta-alanine retention (week 2:  $98.37 \pm 0.92\%$ , week 3:  $98.71 \pm 0.83\%$ , week 4:  $98.54 \pm 0.98\%$ , week 5:  $97.56 \pm 1.74\%$ ,  $p > 0.05$ ). Discussion: During chronic beta-alanine supplementation, only ~ 2-3% of ingested beta-alanine was excreted in urine and only ~ 5-6% of ingested beta-alanine is converted into muscle carnosine (calculated from Stellingwerff et al.(4) ), demonstrating that the long-term supplementation of 100g (= 1.12mol) beta-alanine results in an increase of muscle carnosine of 2 mmol/kg muscle mass). Thus, a large amount of ingested beta-alanine is currently not accounted for muscle carnosine, and is probably metabolized. Further research on the effect of insulin on muscle carnosine loading is necessary. References: 1. Decombaz et al. *Amino Acids*, 2011. 2. Harris et al. *Clin Sci (Lond)*, 83(3):367-74, 1992. 3. Stephens et al. *J Appl Physiol*, 102:1065-1070, 2007. 4. Stellingwerff et al. *Amino Acids*, 2011.

**EFFECT OF BETA-ALANINE SUPPLEMENTATION ON 2000 M ROWING ERGOMETER PERFORMANCE**

Ducker, K., Dawson, B., Wallman, K.E.

*The University of Western Australia*

**Introduction** Beta-alanine has been shown to potentially improve exercise performance in short-term, high intensity efforts. However, limited research has reported whether serial supplementation with beta-alanine is ergogenic to many actual sporting events. Therefore, the aim of the current study was to assess if beta-alanine supplementation could improve race simulation 2000 m rowing ergometer performance in well trained male rowers. **Methods** Sixteen competitive male rowers were recruited to participate in the study (mean  $\pm$  SD; age  $26 \pm 9$  y, body-mass  $83.4 \pm 8.3$  kg; height  $186.9 \pm 4.7$  cm; lightweight  $n = 4$ ; heavyweight  $n = 12$ ). Participants completed duplicate trials (2 x pre-supplementation and 2 x post-supplementation) of a 2000 m rowing ergometer race, separated by 28 days of either beta-alanine ( $n = 7$ ;  $80 \text{ mg} \cdot \text{kg}^{-1} \text{BM} \cdot \text{day}^{-1}$ ) or placebo ( $n = 9$ ; glucose) supplementation. **Results** Race times for the beta-alanine group (pooled data) improved by  $2.9 \pm 4.1$  s while times for the placebo group slowed by  $1.2 \pm 2.9$  s ( $p = 0.055$ ). Race split times and average power outputs improved significantly ( $p < 0.05$ ) following supplementation with beta-alanine at the 750 and 1000 m distances (750 m time  $-0.7$  s, power  $+3.6\%$ ; 1000 m time  $-0.5$  s, power  $+2.9\%$ ). This was supported qualitatively (smallest worthwhile change) by an 87% likely benefit for the 750 m race time and 80% likely benefit for the average power output. Further, performance was significantly impaired ( $p < 0.05$ ) following placebo supplementation at both the 750 and 1000 m distances (time 750 m  $+0.7$  s, power 750 m  $-3.2\%$ ; time 1000 m  $+0.6$  s, power 1000 m  $-2.8\%$ ). **Discussion** Twenty eight days of beta-alanine supplementation ( $80 \text{ mg} \cdot \text{kg}^{-1} \text{BM} \cdot \text{day}^{-1}$  / mean dose =  $6.72 \text{ g} \cdot \text{day}^{-1}$ ) significantly improved 2000 m rowing ergometer performance in well trained rowers. The 2.9 s improvement in race time is similar to the 2.7 s improvement reported by Baguet et al. (2010) following 7 weeks of beta-alanine supplementation ( $5 \text{ g} \cdot \text{day}^{-1}$ ). This improvement in performance is likely due to improved intramuscular  $\text{H}^+$  buffering however, other proposed roles of carnosine within the body (increased sensitivity of the calcium release channels and contractile apparatus to calcium, vasodilatory and protective effects due to the role of carnosine as a multifunctional antioxidant) cannot be excluded. **In conclusion**, supplementing with beta-alanine for 4 weeks is sufficient to improve 2000 m rowing ergometer performance. **References** Baguet, A., Bourgois, J., Vahnee, L., Achten, E., & Derave, W. (2010). Important role of muscle carnosine in rowing performance. *Journal of Applied Physiology*, 109, 1096-1101.

**THE EFFECT OF N-ACETYLCYSTEINE ON CYCLING PERFORMANCE FOLLOWING INTENSIFIED TRAINING IN WELL-TRAINED TRIATHLETES: A DOUBLE BLIND PLACEBO CONTROLLED STUDY**

Slattery, K., Dascombe, B., Wallace, L., Bentley, D., Coutts, A.

*University of Technology, Sydney*

**Introduction** The antioxidant N-acetylcysteine (NAC) has been demonstrated to reduce muscle contractile fatigue in a laboratory setting (Reid et al., 1994). This investigation aimed to examine the ergogenic effect of short-term oral NAC supplementation and associated changes in red-ox balance and inflammation during intense training. **Methods** A double blind, randomised placebo-controlled crossover design was used to assess 9 d oral NAC supplementation (1200 mg/day) in 8 well-trained triathletes (age  $23.6 \pm 3.2$  yrs,  $\text{VO}_2\text{peak}$   $63.3 \pm 4.8$  ml/kg/min). For each supplement trial (NAC and placebo), baseline venous blood and urine samples were taken and a pre-supplementation cycle ergometer race simulation was performed. Following the loading period, further samples were collected pre-exercise, post-exercise, 2 h and 24 h following the post-supplementation cycle ergometer race simulation which consisted of sprint and time trial efforts. Changes in plasma total antioxidant capacity (TAC), ferric reducing ability of plasma (FRAP), thiobarbituric acid-reactive substances (TBARS), interleukin-6 (IL-6), monocyte chemoattractant protein-1 (MCP-1) were assessed. Nuclear factor- $\kappa$ B (NF- $\kappa$ B) in peripheral mononuclear cells extracts and urinary 15-isoprostane F<sub>2t</sub> concentration (F<sub>2t</sub>isoprostanes) were measured at the same time points. Training load was matched for each trial and the Daily Analysis of Like Demands for Athletes (DALDA) was used to monitor well-being. The experimental procedure was repeated with the remaining supplement after a 3 week washout. Changes in biochemical and performance parameters were analysed using a factorial two-way analysis of variance. **Results** NAC improved sprint performance during the cycle ergometer race simulation ( $P < 0.001$ ), but not time trial performance. Supplementation with NAC augmented post-exercise plasma TAC ( $P = 0.005$ ), reduced exercise-induced oxidative damage, [plasma TBARS ( $P = 0.002$ ); urinary F<sub>2t</sub>isoprostanes ( $P = 0.010$ )] and attenuated inflammation [plasma IL-6 ( $P = 0.002$ ); MCP-1 ( $P = 0.012$ )]. NAC increased post-exercise NF- $\kappa$ B activity ( $P < 0.001$ ). A greater number of 'worse than normal' responses in the DALDA ( $P = 0.050$ ) was reported in the placebo trial. **Discussion** Oral NAC supplementation improved cycling performance via an improved red-ox balance and promoted adaptive processes in well-trained athletes undergoing strenuous physical training. This finding supports the use of NAC as an ergogenic aid in a practical sporting setting. Moreover, in agreement with previous research, athletes displayed a greater ability to cope with intense physical training with antioxidant supplementation which did not interfere with physiological adaptive processes (Palazzetti et al., 2004). **References** Reid M, Stokic D, Koch S, Khawli F, Leis A. **Objectives** To investigate the impact of the CHANGE! curriculum-based intervention across time on children's weekday and weekend day physical activity (PA) levels and to report effect of covariates on the outcome measures. **Methods** Twelve primary schools were randomised to an Intervention ( $N = 6$ ) or Control condition. Baseline, 20-week post-intervention and 10-week follow-up measures of PA (7-day

accelerometry), cardiorespiratory fitness (CRF) and anthropometric measures were completed. Outcome measures were total physical activity (TPA; counts•min<sup>-1</sup>), minutes per weekday and weekend day spent being sedentary (SED), and in moderate (MPA), vigorous (VPA), and moderate-to-vigorous physical activity (MVPA). Multilevel modelling was used to assess the effect of the intervention on the outcome variables, as well as the influence of school level (temperature, rainfall, playground area per child, and number of children on roll) and child level (sex, maturation, weight status, accelerometer wear time, CRF, and socioeconomic status (SES)) covariates. Results There was a significant intervention effect for weekday TPA with children in the Intervention group recording 88.71 cpm more than Control children ( $p=0.02$ ). The Intervention group engaged in more weekday SED, MPA, VPA, and MVPA, and more bouts, for a longer duration. At weekends Intervention children accrued more SED and VPA mins than Control children, and less TPA, MPA, and MVPA. Boys did significantly more MPA (9.55) and MVPA (13.95) on weekdays and engaged in 5.49 and 2.69 mins MPA and VPA, respectively, during school hours ( $p<.01$ ). Weekday PA was significantly influenced by maturation, CRF and playground area per child ( $p<.05$ ). Specifically, school-time MVPA mins were predicted by number of children on roll (0.02), temperature (1.19) and maturity offset (7.57), whereas children in the high BMI group engaged in 1.73 mins less VPA ( $p<.05$ ). Out of school weekday PA was influenced by CRF, SES and maturity ( $p<.05$ ). High MVPA Intervention children increased weekday bouts and had less SED mins during school hours, whereas low SES Intervention children engaged in more weekday bouts and increased TPA ( $p<.05$ ). Discussion A significant intervention effect was observed for weekday TPA, but Intervention children did less on weekends than those in the control group. This suggests that the intervention may have influenced the Intervention children's PA behaviours differently on weekdays and at weekends.

## IS PARENTAL PHYSICAL ACTIVITY AN INFLUENTIAL FACTOR ON PA IN CHILDREN?

Fischbach, N.

*University of Ulm, Medical Center*

Nanette Fischbach<sup>1</sup>, Susanne Kobel<sup>1</sup>, Sarah Kettner<sup>1</sup>, Clemens Drenowatz<sup>1</sup>, Jürgen Michael Steinacker<sup>1</sup> <sup>1</sup>Sports- and Rehabilitation-Medicine, Ulm University, Germany Purpose The increasing prevalence of overweight and obesity in children and adolescents has been associated with a decline in physical activity (PA). The majority of children display insufficient activity levels (Trojano et al, 2008). Various environmental and biological constraints have been shown to influence children's PA but only limited information is available on the effects of parental behaviour. Therefore, this study examined the effect of parental sports participation on children's PA and body composition. Methods Baseline data from the school-based health promotion programme "Komm mit in das gesunde Boot" (Join the Healthy Boat) in south-west Germany funded by Baden-Württemberg-Stiftung was used. The initial sample size was 1943 (50,2% boys) first and second grade children, but due to missing data only 1437 subjects (50,6% boys) 7.1 ± 0.6 years of age were entered in the analysis. Children's bodyweight and height was measured by trained technicians and BMI was calculated and converted to BMI percentiles (BMIPCT). Parent questionnaires were used to determine parental sports participation and children's PA. Three parental activity groups were created (both sportily active, one parent sportily active, both inactive). ANCOVA, controlling for age and sex was used to examine differences in children's PA and BMIPCT. Results On average children reached the 60 min of MVPA on 2.8 ± 1.7 days a week. Boys spent significantly more days with 60 minutes MVPA than girls. 44.1% of parents reported both being active, 28.3% both being inactive and 27.7% reported that one parent is active. Children of active parents displayed significantly lower BMIPCT compared their peers with one or both inactive parents. There was, however, no significant difference between the parental activity groups in children's PA. Conclusion Reported activity levels are in line with previous research. Children whose parents were both active displayed lower BMIPCT however no difference in PA was found. One reason for this result could be that active parents may be more conscious about the activity level of their children and, therefore, their reports were more accurate. It is, however, also possible that children at this age are inherently active and do not require additional support from their parents. The difference in body composition could then be due to an overall healthier lifestyle of active parents. Even if PA does not differ, a healthier diet may lead to a healthier body composition. Overall more research is needed to enhance the understanding of parental influence on children's PA and body composition. References Troiano RP et al (2008). Physical activity in the United States measured by accelerometer. *MSSE*. 2008;40:181-188.

## EVALUATING THE LONG-TERM EFFECTIVENESS OF THREE PHYSICAL ACTIVITY PROGRAMS AMONG OLDER ADULTS.

Van Hoecke, A.S., Delecluse, C., Bogaerts, A., Boen, F.

*KU Leuven*

There is a lack of consensus on the most appropriate counseling format to assist older adults in pursuing and maintaining a physically active lifestyle. This study evaluated the relative impact of an individualized need-supportive physical activity program, based on the self-determination theory (SDT), compared with less intensive counseling formats. A total of 442 Flemish sedentary adults over the age of 60 were randomly assigned to: 1) an exercise promotion condition, consisting of a single advice session in which the coach clarified existing local opportunities; 2) a walking condition, consisting of a single advice session in which the coach additionally explained a prestructured individually-tailored walking program; and 3) a need-supportive condition, consisting of additional regular contacts in which an individualized exercise plan was set up. Furthermore, the coach fostered the SDT-related psychological needs for autonomy, competence and relatedness in order to increase autonomously motivated physical activity. Autonomous motivation, self-reported and objective physical activity were measured before (pre), after (post) and one year after the beginning of (follow-up) the ten-week intervention by the Behavioural Regulation Exercise Questionnaire, Godin Leisure-Time Exercise Questionnaire and pedometers respectively. Perceived need-support was assessed at post-test by a modified version of the Teacher As Social Context Questionnaire. Linear mixed model analyses demonstrated an increase in self-reported physical activity post-intervention and in the long term in the three interventions. However, the walking and need-supportive program yield larger increases than the exercise promotion. Results on objective physical activity showed an increase in daily steps from pre- to post-test in all conditions. However, the walking condition increased significantly more compared with the exercise promotion condition. Long-term analyses (i.e. from pre- to follow-up-test) did not demonstrate significant time by condition interaction effects. Nevertheless, the walking and need-supportive condition increased their daily number of steps, whereas no changes were found in the exercise promotion condition. Bootstrapping analyses revealed that, irrespective of condition, higher levels of perceived need-support resulted in higher levels of physical activity at post- and follow-up-test. These effects were mediated by autonomous motivation. The findings demonstrate post-intervention as well as long-term effectiveness of three physical activity programs varying in counseling intensity among sedentary older adults. Providing a specific and individually-tailored physical activity plan seems to be more effective than referring older adults to wide-spread existing physical activity opportunities. Furthermore, the different patterns in self-reported and objective physical activity after the intervention need further consideration. Finally, the mediation effects imply the importance of self-determined motivation to perform short- and long-term behavior.

### THE IMPACT OF CHILDREN'S HEALTH ACTIVITY AND NUTRITION: GET EDUCATED PILOT STUDY ON CARDIORESPIRATORY FITNESS, CARDIOMETABOLIC RISK AND BODY SIZE IN 10 TO 11 YEAR OLD CHILDREN.

Gobbi, R.1,2, Davies, I.G.2, Fairclough, S.J.1,3, Abayomi, J.C.2, Mackintosh, K.A.1,2, Warburton, G.L.1,2, Stratton, G.1,3, George, K.P.3, Boddy, L.M.1,3

1. REACH Group; 2. Faculty of Education, Community & Leisure, & 3. Research Institute for Sports & Exercise Sciences, Liverpool John Moores University.

**Objectives:** To investigate the impact of the CHANGE! Curriculum based intervention on cardiorespiratory fitness (CRF), cardiometabolic risk and body size in 10-11 year old children. **Methods:** Twelve primary schools were randomised into an Intervention (n=6) or Control condition. Baseline, 20 week post-intervention and 10 week follow-up measures of body composition, CRF and cardiometabolic risk were assessed in a subsample of participants (n=55). Outcome measures were: anthropometrics (stature, sitting stature, weight, waist circumference [WC] and hip circumference [HC]), resting blood pressure (SBP and DBP), CRF (VO<sub>2</sub>peak), fasting capillary blood total cholesterol (TC), high density lipoprotein cholesterol (HDL-C) and glucose, left ventricular diastolic filling (E/A Ratio), septal myocardial tissue velocities (E'A'), and left ventricular mass (LV mass index). Change scores between time points were calculated for each measure. Group differences between mean change scores were assessed using one way analysis of covariance (ANCOVA), with covariates of gender, somatic maturation, and change in maturation, Indices of Multiple Deprivation (IMD) and the dependent variable. Results: There was a significant group difference in WC at 20 week post-intervention with children in the intervention group reducing WC and children in the control group increasing WC (Adjusted mean (SE) change in WC for control =+1.3 (0.3) cm; intervention -0.2 (0.4) cm, p=0.006). At follow up the intervention group maintained WC, however there were no significant group differences in mean change at follow up. Although there was no significant intervention effect on CRF at post intervention, there were significant group differences at follow up (adjusted mean (SE) change in VO<sub>2</sub>Peak control = -1.96 (1.43) ml/kg/min; intervention = +3.6 (1.53) ml/kg/min, p=0.014). There were no significant intervention effects on cardiometabolic risk markers at post-intervention or follow-up. **Discussion:** There was a significant effect on WC at post-intervention and this reduction in WC in the intervention group was maintained at follow up. At 10 week follow-up the intervention group had significantly improved CRF, however there were no significant intervention effects on cardiometabolic risk markers. This suggests that these improvements in CRF and WC did not have clinical implications on cardiometabolic risk markers. Further investigation is warranted to elucidate these findings.

### A CROSS-CULTURAL COMPARISON OF ADOLESCENTS' PHYSICAL ACTIVITY AND SEDENTARY BEHAVIOURS IN SPAIN AND FRANCE ACROSS A SCHOLAR YEAR.

Aibar, A.1,2, Bois, J.2, Zaragoza, J.1, Generelo, E.1, Julián, J.A.1, Paillard, T.2

<sup>1</sup> University of Zaragoza (Spain) <sup>2</sup> University of Pau and Countries of Adour (France)

**Introduction** Evidences show that physical activity (PA) has important health benefits in youth. However, incidental PA and exercise declines during adolescence (Van der Horst et al., 2007). There is also an emerging concern about the negative effect that sedentary lifestyles are having on the health of youth (Pate et al., 2011). The main aim of this study is to describe and compare levels of moderate to vigorous physical activity (MVPA) and sedentary activity (SA) in adolescents in two European countries throughout one scholar year. **Method** The sample consisted of 179 adolescents (48% Spanish; 58,7% girls) with a mean age of 14.40 ± 0.66 years. The GT3X accelerometer was used to assess PA intensities continuously during waking hours of two 7 day periods, at the beginning and at the end respectively, of the scholar year. Two 2x2x2x2 (country by gender by period of the week by moment of the measure) ANCOVA with repeated measures on the two last factors were conducted with MVPA and SA as dependant variables. BMI, socioeconomic status, temperatures and precipitations were used as co-variables. Results No significant differences were found nor MVPA neither SA according to the moment of the measure in the scholar year. However, Spanish adolescents revealed significant higher levels of MVPA than French subjects. Significant effects of gender (more engaged time of boys than girls) and period of the week (higher levels during weekdays) were also found. High levels of SA were appreciated, but no main significant effects were found. MVPA and SA showed a significant negative correlation in both moments of measure. **Discussion** Consistently with other studies our results offer evidence for the low MVPA levels in adolescents, being lower in girls (Nader et al., 2008). High levels of SA levels are also reported in our study (Pate et al., 2011), underlying one of the biggest concerns of our society. Moreover, our results seem to be consistent with the hypothesis that sedentary behaviours replace PA (Van der Horst et al., 2007). References Nader, P. R., R. H. Bradley, R. M. Houts, S. L. ### COMBINED INFLUENCE OF HEALTHY DIET AND ACTIVE LIFESTYLE ON CARDIOVASCULAR DISEASE RISK FACTORS IN ADOLESCENTS: THE HELENA STUDY

Cuenca García, M., Ortega, F., Ruiz, J., Labayen, I., Jago, R., Martínez-Gómez, D., Dallongeville, J., Bel-Serrat, S., Moreno, L.A., Kersting, M., González-Gross, M., Castillo, M., Sjöström, M. et al

1,12-FM-UGR(Granada), 2,13-PREVNUT-KII(Huddinge), 3-FCAFD-UGR(Granada), 4-UPV/EHU (Vitoria), 5-CENHS(Bristol), 6-CTAN/CSIC(Madrid), 7-FACHRU(Lille), 8,9-UNIZA(Zaragoza), 10-FKE (Bonn), 11-PUMI(Madrid)

**Aim:** To investigate the combined influence of diet quality and physical activity on cardiovascular diseases (CVD) risk factors in European adolescents. **Method:** Cross-sectional study that included 1513 adolescents aged 12.5 -17.5 years (45% boys) from eight European countries participating in the HELENA study. Dietary intake was registered using a 24h recall (on two non-consecutive days and a diet quality index was calculated. Daily physical activity was assessed by accelerometry. Lifestyle groups were computed as follows: 0=healthy diet and active, 1=unhealthy diet but active, 2= healthy diet but inactive, 3=unhealthy diet and inactive. CVD risk factors measurements included cardiorespiratory fitness, adiposity indicators, lipid profile, blood pressure and insulin resistance. A CVD risk score was computed by mean of z-scores of the following risk factors: cardiorespiratory fitness, sum of four skinfolds, triglyceride, total cholesterol/high-density lipoprotein cholesterol ratio (TC/HDLc ratio), systolic blood pressure and homeostasis model assessment (HOMA). Results: The healthy diet and active group had a more favourable cardiorespiratory profile, fat mass index and triglycerides and high-density lipoprotein cholesterol levels (all p≤0.05). Overall, active adolescents showed higher cardiorespiratory fitness, lower fat mass index, healthier TC/HDLc ratio and blood pressure and lower HOMA levels than their inactive peers with either healthy or unhealthy diet (all p≤0.05).

Healthier CVD risk score was observed in the healthy diet and active group compared with the inactive groups (all  $p \leq 0.02$ ). Conclusion: A combined influence of healthy diet and active lifestyle could be the key to prevent the risk of CVD. Moreover, an active lifestyle may reduce the adverse consequence of an unhealthy diet, but a healthy diet does not seem to overcome the adverse consequences of an inactive lifestyle.

### **DOES THE SCHOOL-BASED INTERVENTION "JOIN THE HEALTHY BOAT" PROMOTE PHYSICAL ACTIVITY IF MEASURED OBJECTIVELY?**

Kettner, S., Kobel, S., Drenowatz, C., Fischbach, N., Dreyhaupt, J., Steinacker, J.M.

*Ulm University*

**Introduction** It is well known, that sufficient physical activity (PA) is essential for childhood development and highly relevant to health. The school-based intervention "Komm mit in das gesunde Boot – Grundschule" (Join the Healthy Boat) focuses on the promotion of PA and other health related topics (e.g. healthy food, screen media use). Current international guidelines encourage children to achieve 60 min moderate to vigorous PA per day (WHO, 2010). The purpose of this study was to examine whether the intervention of the "Healthy Boat" shows a positive effect in PA after one year and how much time children spend in moderate and vigorous PA. **Methods** The study is a prospective, cluster-randomised, longitudinal study with an intervention (IG) and control group (CG). At baseline as well as at follow-up one year later, PA was measured on 323 children. Data used in this analysis includes 117 children ( $8.0 \pm 0.7$  yrs; male: 43.6%; IG: 44.4%) for baseline and follow-up. Participants wore an accelerometer (Actiheart®, CamNTEch, Cambridge, UK) for six consecutive days with recording intervals of 15 sec. First and last recording days and individual sleeping time were excluded from analysis. On the basis of heart rate (HR) data different activity levels were categorised as follows: light =  $HR < 140$  bpm, moderate =  $HR > 140$  and  $< 160$  bpm, vigorous =  $HR > 160$  bpm (Armstrong & Welsman, 2006). Data were analysed by ANCOVA, controlling for sex and age, and paired t-test. **Results** First analysis of 117 participants including all four days reveal that children spent 12.9 h (SD 1.0) per day in light, 32.2 min per day (SD 14.4) in moderate and 18.5 min per day (SD 12.8) in vigorous intensity. On average 35.9% of the children achieved the guidelines. There was no significant difference between IG and CG. There was, however, a significant decline in moderate physical activity in the CG while the IG maintained their activity levels. **Conclusion** Even though no group differences in PA could be shown results indicate that a low-dose school-based intervention can attenuate the age-related decline in PA. To increase PA a stronger intervention may be necessary. The analysis, however, is not completed yet and only the recorded heart-rate has been used to determine PA. **References** Armstrong N, Welsman JR (2006). The physical activity patterns of European youth with reference to methods of assessment. *Sports med*, 36(12), 1067-1086. World Health Organization (WHO) (2010). Global Recommendations on Physical Activity for Health. WHO, Geneva.

### **PHYSICAL ACTIVITY LEVELS DURING THE SCHOOL DAY OF GERMAN SECONDARY SCHOOL STUDENTS**

Kretschmann, R.

*University of Stuttgart*

**Introduction:** Students spend a huge amount of their daytime in school. Furthermore, school plays a significant role in children's physical activity (PA) (Trost et al., 2002). However, to date, physical activity levels (PALs) of school students in German schools are unclear. Hence, the aim of this study was to investigate PALs of students during the school day, including school way, recess time, physical education (PE), and leisure time in contrast. **Material and Methods:** PA was objectively measured via combined accelerometry and heart rate monitoring using the Actiheart device (Crouter et al., 2008). 26 ninth class school students ( $M=15.28$  years;  $SD=0.47$ ) of a German secondary school wore the Actiheart the whole day for one week, including weekend. **Results:** The way to school significantly ( $p < 0.01$ ) adds above-average PALs ( $M=2.8$  MET;  $SD=0.49$ ), although, active transportation wasn't common for the German sample. However, active transportation didn't accumulate higher amounts and levels of PA. Students showed significantly ( $p < 0.01$ ) higher amounts of PA during recess time ( $M=2.4$ ;  $SD=0.36$ ) as compared to mere lesson time ( $M=1.58$  MET;  $SD=0.17$ ). According to Total Energy Expenditure (TEE), days with PE lessons ( $M=2444$  kcal;  $SD=525$ ) reached significantly ( $p < 0.01$ ) higher PALs compared to school days without PE ( $M=2173$ ;  $SD=625$ ). Leisure time's PALs ( $M=1.94$  MET;  $SD=0.17$ ) were slightly higher compared to school time's PALs ( $M=1.68$ ;  $SD=0.20$ ), but don't show a statistically significant difference. Surprisingly, students showed significantly ( $p < 0.05$ ) lower PALs during the weekend ( $M=1.7$  MET;  $SD=0.28$ ) than during the school week ( $M=1.86$  MET;  $SD=0.21$ ). Compared to the Expert Consultation of Human Energy Requirements (2004), 21 students showed an active/ moderately active or vigorous/ vigorously active lifestyle for the assessed whole week. **Discussion and Conclusion:** School, as an institution that has a major effect on children's lifestyle, doesn't only play an influencing role in the daily routine of students, it also serves as a main socializing agent and environment, especially in terms of getting children in touch with PA. Moreover, study results indicate that school is an important source for overall PA. Therefore, school should be a focus point in PA interventions, also and naturally including PE (Slingerland et al., 2011). **References:** Crouter et al. (2008). ### **ASSOCIATIONS OF DAILY ENERGY EXPENDITURE AND PHYSICAL ACTIVITY WITH BODY FAT IN 11-YEAR OLD CHILDREN**

Soric, M.1, Borer, K.T.2, Misigoj-Durakovic, M.1

*The Faculty of Kinesiology*

<sup>1</sup>Faculty of Kinesiology, University of Zagreb, Croatia; <sup>2</sup>University of Michigan, Ann Arbor, Michigan, USA; **Introduction** Physical inactivity, alongside inadequate nutrition, is one of the main reasons of the growing prevalence of obesity. Therefore, the purpose of this study was to describe the associations between body fat and physical activity in 11-year old children. **Methods** The sample consisted of 142 fifth grade students (66 boys and 76 girls, mean age (standard deviation) = 11.2 (0.3), from Zagreb (Croatia) and Ann Arbor (Michigan, USA) volunteered to participate in this study. Energy expenditure and physical activity were assessed during two weekdays and two weekend days using a multiple-sensor body monitor (SenseWear Armband; BodyMedia Inc., Pittsburgh, PA, USA) (1). Percent body fat (%BF) was calculated using triceps and calf skinfolds according to the equation proposed by Slauther et al. (2). The associations between %BF and energy expenditure or physical activity was assessed by Pearson's correlation coefficients. In addition, children were divided in high and low %BF groups based on the gender specific median split. After that, differences in energy expenditure and physical activity between the

high and low %BF groups were assessed using t-tests for independent samples. Results Percent body fat was inversely related to the amount of moderate physical activity in both boys ( $r=-0.35$ ,  $p=0.005$ ) and girls ( $r=-0.25$ ,  $p=0.03$ ). In contrast, the association between %BF and vigorous activity was noted in boys ( $r=-0.33$ ,  $p=0.005$ ), but not in girls ( $r=-0.12$ ,  $p=0.26$ ). The amount of time spent sleeping and lying down were not related to %BF in either gender. Daily energy expenditure expressed per unit of fat free mass was correlated with %BF in both boys ( $r=0.40$ ,  $p=0.002$ ) and girls ( $r=0.28$ ,  $p=0.02$ ). On the other hand, energy expended on physical activity was not related to %BF in either gender ( $r=-0.18$ ,  $p=0.18$  in boys and  $r=0.03$ ,  $p=0.79$  in girls). Similarly, high %BF group exhibited lower levels of both moderate and vigorous activity in boys, while in girls no differences in physical activity between the two groups were noted. However, energy expended for daily physical activity did not differ between the groups in neither boys nor girls. Conclusion The findings of this study indicate that %BF is inversely related to the amount of physical activity with the associations being stronger and more consistent in boys. Still, more physical activity did not result in higher active energy expenditure in children with more body fat. References 1. Arvidsson D, Slinde F, Hulthen L. *Clin Nutr* 2009; 28: 305–12. 2. ## PHYSICAL ACTIVITY AND HEALTH-RELATED QUALITY OF LIFE OF ADOLESCENTS IN DISASTER AREAS

Suzuki, K.1, Okazaki, K.1, Sasaki, K.1, Takahashi, S.1, Sakamoto, Y.2

1:Tohoku Gakuin University (JAPAN), 2:Tohoku Institute of Technology (JAPAN)

**Introduction** The environment related to physical activity in children was dramatically changed by The Great East Japan Earthquake in 2011. Deterioration in the physical activity environment might affect health-related quality of life (HRQL) in adolescents. The purpose of this study was to clarify the present state of physical activity and HRQL in Japanese adolescents living in regions affected by the earthquake and tsunami in 2011, and to examine the differences in the relationship between physical activity and HRQL in adolescents living in different regions affected by the disaster. **Methods** The participants were 349 adolescents aged 11-13 (184 boys, and 165 girls) in East Matsushima city (where housing damage affected 10% of participants: low damage group) and 183 adolescents aged 11-13 (95 boys, and 88 girls) in the town of Onagawa (where housing damage affected 60% of participants: high damage group). The survey was performed in July (for East Matsushima) and September (for Onagawa), 2011. Survey items included time spent on physical activity (min/wk), HRQL (the 23-item Pediatric Quality of Life Inventory Version 4.0 Generic Core Scales). **Results** The results of a chi-square test showed that there were no significant differences in the rate of time spent category (less than 60min/wk, from 60 to less than 420 min/wk, more than 420min/wk) between the low damage group and the high damage group. However, the rate of less than 60min/wk in both groups showed higher percentages than in the general population (MEXT, 2011) in Japanese adolescents (low damage group: boys 15.2%; girls 44.2%, high damage group: boys 17.9%; girls 43.2%, general population: boys 9.3%; girls 31.1%). The results of an unpaired t-test indicated that there was a statistically significant difference in HRQL total score between the low damage group (81.4+/-12.5) and the high damage group (77.1+/-12.7) for girls. Also, the average HRQL total score for girls in the high damage group was especially low compared to a previous study (adolescents: 83.7+/-13.3, Varni et al., 2003). On the other hand, the difference in boys was not significant (low damage group: 84.1+/-13.1, high damage group: 83.9+/-12.6). One-way ANOVAs for each physical activity level showed significant differences between those whose rate was less than 60min/wk and those whose rate was more than 420min/wk in all groups except girls in the high damage group. **Conclusions** These findings might suggest the following: 1) the physical activity level of adolescents living in disaster areas is decreased by a tsunami and earthquake hit regardless of the damage situation, 2) the HRQL level of adolescent girls varies depending on the damage situation, 3) an increase in physical activity level is associated with an improvement of HRQL for adolescent boys and girls over normal HRQL level, 4) an increase of physical activity level in the group with low HRQL level might not affect improvement of HRQL for adolescents living in disaster areas. ## RIGHT AND LEFT VENTRICULAR ADAPTATION TO REGULAR PHYSICAL ACTIVITY IN ELITE MALE ATHLETES

Major, Z., Kneffel, Z., Csajági, E., Tóth, M., Pavlik, G.

Semmelweis University, Faculty of Physical Education and Sport Sciences

**Introduction** The athlete's heart undergoes morphological and functional changes as a result of regular physical activity. Left ventricular dimensions, wall thicknesses and function are echocardiographic measurements widely used in research, but the functional adaptation of the right ventricle remains unknown. The aim of this study was to assess left and right ventricular function and enlargement in elite athletes and in healthy sedentary non-athletes. **Methods** The study population consisted of 20 elite highly-trained male athletes and 15 age-matched normotensive healthy non-athletes. In addition, left and right ventricular systolic (S') and diastolic functions (E peak, A peak, E/A ratio, E', A' velocities and E'/A' ratio) were determined by conventional PW Doppler echocardiography and Pulsed wave Tissue Doppler imaging at the septal and lateral corners of the mitral and tricuspid annulus. Tricuspid and mitral inflow velocities were obtained in a four-chamber view by placing a cursor at the tips of the mitral and tricuspid valve. Right and left ventricular longitudinal diameters were also determined. Measurements represent the average of three cycles. Comparisons among data were performed with Student's test. **Results** The athletes and members of the control group did not differ significantly in mean body surface area ( $p<0,3$ ). The group of athletes showed highly but not statistically significant velocity of mitral and tricuspid E ( $p<0,5$ ;  $p<0,6$ ) wave, and the tricuspid E/A ( $p<0,4$ ) ratio than non-athletes. Mitral and tricuspid annulus Am (both  $p<0,005$ ), and Aa ( $p<0,0001$  and  $p<0,001$ ) were significantly smaller in athletes than in non-athletes. E/Em ratio on the right side ( $p<0,05$ ) was also significantly less in athlete's group than in controls. Em/Am ratio (both  $p<0,05$ ), and Ea/Aa on either side ( $p<0,001$  and  $p<0,005$ ) were significantly higher in athletes than in sedentary controls. In the group of non-athletes and in the competitors of several kind of sport the right ventricular systolic function was not statistically significant, although, we found significant difference between the two groups in the left ventricular dimensions ( $p<0,05$ ). In the end-diastolic dimension of the right ventricle between the two groups proved to be significant as well ( $p<0,05$ ). **Discussion** Regular and extensive training results in similar changes in right ventricular function to that of the left ventricle.

**13:45 - 14:45****Poster presentations****PP-PM04 Physiology and Biochemistry****GLUT4 PROTEIN EXPRESSION AND LOCALISATION IN HUMAN SKELETAL MUSCLE FOLLOWING ENDURANCE AND HIGH INTENSITY INTERVAL TRAINING**

Bradley, H., Shepherd, S.O., Cocks, M., Shaw, C.S., Wagenmakers, A.J.M.

*University of Birmingham*

Glucose transporter 4 (GLUT4) is responsible for insulin-mediated glucose uptake in skeletal muscle. GLUT4 storage vesicles (GSVs) translocate from intracellular stores to the plasma membrane upon insulin stimulation, allowing glucose uptake into the muscle cell. In a previous study from our lab (Shepherd et al. ECSS abstract 2011) we have shown that both endurance training (ET) and high intensity training (HIT) increase insulin-mediated glucose uptake. Here we use immunofluorescence microscopy to investigate muscle fibre type specific GLUT4 content and localisation in the basal state before and after 6 weeks of ET or HIT. Sixteen young sedentary males ( $21 \pm 0.7$  years, BMI  $23.7 \pm 0.8$  kg.m<sup>-2</sup>) were randomly assigned to ET (40-60 min of cycling at  $\sim 65\%$  VO<sub>2</sub>peak, 5 times per week) or HIT (4-6 Wingate tests per session, 3 times per week). Muscle biopsies were taken from the m. vastus lateralis before and after 6 weeks of training. GLUT4 content and localisation were assessed using confocal immunofluorescence microscopy. Statistical significance was determined using a repeated measures ANOVA. GLUT4 staining presents bright punctuate spots located throughout the cell interior and around the plasma membrane and nuclei. Total GLUT4 fluorescence intensity increased following ET (type I fibres  $15\% \pm 6\%$ , type II fibres  $16\% \pm 6\%$ , training effect  $P = 0.037$ ) and HIT (type I fibres  $14\% \pm 5\%$ , type II fibres  $16\% \pm 5\%$ , training effect  $P = 0.014$ ). The number of intracellular GLUT4-containing spots per fibre, likely representing GSVs, increased following ET (type I fibres  $25\% \pm 9\%$ , type II fibres  $26\% \pm 13\%$ , training effect  $P = 0.05$ ) and HIT (type I fibres  $36\% \pm 16\%$ , type II fibres  $48\% \pm 16\%$ , training effect  $P = 0.03$ ). There was a trend for an increase in GLUT4 colocalisation with the plasma membrane marker dystrophin which failed to reach statistical significance (training effect,  $P = 0.075$ ). There were no fibre type specific differences or differences between the effect of ET and HIT on GLUT4 content. In summary, we have successfully used immunofluorescence microscopy techniques to show that 6 weeks of HIT is at least as efficient as ET to increase total GLUT4 content. The increase occurred in both type I and type II fibres and was due to an increase in the number of GLUT4-containing spots, likely representing GSVs. Future studies will further investigate GLUT4 content and localisation, which are important factors in determining rates of glucose uptake, as a function of training status in response to exercise and insulin stimulation.

**EFFECT OF EPIGALLOCATECHON-3-GALLATE ON TUMOR METABOLISM IN BREAST CANER CELLS.**

Huang, H.P., Wang, H.S., Chang, J.M.

*National Taiwan Normal University*

**Introduction** The "Warburg effect" is hypothesized that tumor cells have a high rate of glycolysis in spite of oxygen-rich conditions with a high level of lactate. In addition, up-regulation expression of hypoxia inducible factor 1  $\alpha$  (HIF-1 $\alpha$ ), which is a consequence of hypoxia condition as well as alters in certain oncogenes or mutations in tumor suppressor genes, resulting in increase of gene transcription involved in glucose transport, glucose metabolism, lactate formation, and lactate efflux from cells. However, lactate efflux across the plasma membrane is mediated by monocarboxylate transporter (MCT). The aim of this study was to investigate the effect of epigallocatechin-3-gallate (EGCG), a MCTs inhibitor, on breast cancer whether mediate through the MCT and HIF-1 $\alpha$  molecules. **Method** MDA-MB-231 cells were incubated with L-15 medium containing 10 % fetal bovine serum but absence of glucose. Thereafter, cells were treated with EGCG (0.1 mM) for 30 minutes, and glucose (10 mM) was treated to MDA-MB-231 cells for additional 3 hours after drug treatment following the assessments of MCT1, HIF-1 $\alpha$ , CD147 protein amount and lactate level. **Results** In biochemical analysis, the intracellular lactate level was increased to 34% in glucose treatment, 14% in EGCG treatment and 46% in EGCG combined with glucose treatment compared with cell only control. However, the protein amount of MCT1, HIF-1 $\alpha$  and CD147 were not altered in response to glucose, EGCG and glucose plus EGCG. **Discussion** It has been reported that some MCT play an important role in cancer metabolism (Kennedy & Dewhirst, 2010). In this study, the high level of intracellular lactate might be increased in EGCG treatment, a possible MCTs inhibitor. The both transporters, MCT1 and MCT4, functionally interact with chaperone CD147 and co-expressed on the plasma and mitochondrial membranes (Kirk et al., 2000; Pinheiro et al., 2010). In additionally, the expression of the membrane transporters MCT1 and CD147 was not altered in breast cancer cells. It is suggested that inhibition of MCTs resulted in the lower intracellular pH value, which might lead to cell death. Moreover, the changes of MCTs expression could inhibit cell migration. In the future, targeting to CD147 and MCT molecules might be beneficial to cancer patient in therapy. Further investigation on the CD147/MCT in the cancer treatment will be addressed. **References** Kennedy, K. M., & Dewhirst, M. W. (2010). *Future Oncol*, 6(1), 127-148. Kirk, P., Wilson, M. **INTRODUCTION:** Satellite cells (SCs) are instrumental for repair, regeneration and growth of human skeletal muscle tissue. Following a single bout of exercise skeletal muscle SC can activate, proliferate and differentiate to form new SCs. In accordance, increases in mixed muscle SC content have been reported after 24-48 h of recovery from a single bout of exercise. So far, little data exists on the fiber type-specific changes in SC content and activation status during post-exercise recovery. The present study investigates the impact of a single bout of eccentric exercise on skeletal muscle fiber type specific SC content and activation status following 24 h of post-exercise recovery. **METHODS:** Skeletal muscle biopsies were collected from the m. vastus lateralis of 10 healthy, recreationally active males ( $23 \pm 1$ y) prior to

and 24 h after performing 300 high-force eccentric actions using the knee extensors. Muscle fiber type-specific SC content and activation status were assessed by immunohistochemical analyses. SC activation status was assessed by co-staining CD56 with DLK1 and Ki67. Statistical analysis was performed using a two-factor repeated measures analysis of variance (ANOVA) with the level of significance set at  $P < 0.05$ . RESULTS: At baseline, no differences in SC content were observed between type I and type II muscle fibers. In addition, no differences were observed in the number of DLK1+ and Ki67+ SCs between fiber types. Following 24 h of post-exercise recovery, type II muscle fiber SC content had increased substantially from  $0.085 \pm 0.012$  to  $0.133 \pm 0.016$  ( $P < 0.05$ ). In contrast, no changes were observed in the type I muscle fibers ( $0.099 \pm 0.009$  to  $0.092 \pm 0.011$ ; interaction between fiber types  $P < 0.05$ ). The number of DLK1+ SCs increased in the type II muscle fibers only (from  $0.027 \pm 0.008$  to  $0.070 \pm 0.017$  DLK1+ SCs per fiber;  $P < 0.01$ ). No significant differences were observed in the number of Ki67+ SCs over time or between fiber types. CONCLUSION: A single bout of eccentric exercise induces a type II muscle fiber type-specific increase in both SC content and activation status within 24h of post-exercise recovery.

#### IDENTIFICATION OF TWO METABOLICALLY DISTINCT POPULATIONS OF MYOSIN HEAVY CHAIN TYPE I EXPRESSING MUSCLE FIBERS IN HUMAN SKELETAL MUSCLE

Gómez-Cabello, A., Ploug, T., Nordby, P., Andersen, J.L., Dela, F., Helge, J.W., Prats, C.

*GENUD Research Group. University of Zaragoza*

Identification of two metabolically distinct populations of myosin heavy chain type I expressing muscle fibers in human vastus lateralis and characterization of exhausting exercise-induced intracellular energy stores utilization Gómez-Cabello A 3, Ploug T 1, Nordby P 1, Andersen JL 2, Dela F 1, Helge JW 1, Prats C 1 Center for Healthy Aging, 1 Dep. of Biomedical Sciences and 2Dep. of Sports Medicine Copenhagen, Faculty of Health Sciences, University of Copenhagen, Denmark 3 GENUD Research Group. Faculty of Health and Sport Science, Dep. of Psychiatry and Nursing, University of Zaragoza, Spain Introduction: Skeletal muscle metabolism has been subject of extensive research for decades. Skeletal muscle is a heterogenic tissue; it consists of different proportions of different muscle fiber types. Muscle fibers have been traditionally classified based on the expression of the predominant myosin heavy chain (MHC) isoforms. According to such classification, human skeletal muscle consists of three fiber types (I, IIA, and IIX). The aim of the present study was to optimize a fluorescence histochemical technique to semi-quantify glucose and lipid intracellular stores and their relative use during exhausting exercise. Material and Methods: Ten healthy males ( $26.4 \pm 0.9$  years, BMI  $24.4 \pm 0.7$  kg/m<sup>2</sup>) participated in the study. On the first day, one leg was glycogen-depleted (D) by exhaustive intermittent exercise following by low carbohydrate diet. Next day, muscle biopsies were excised from vastus lateralis before and after exhaustive exercise from both D and control leg (C) (I). Muscle cryosections were used to optimize a histochemical technique to fiber-type muscle and, semi-quantify glycogen and lipid content. Results: Analysis of C basal muscle reveals 4 metabolically distinct muscle fiber types: two MHC type I expressing populations, which we name I-high and I-low, and two MHC type II populations, which correspond to IIA and IIX expressing fiber types. Fibers I-high have a smaller cross-sectional area and a higher lipid droplet (LD) density than fibers I-low. After exhaustive exercise, muscle glycogen content was decreased in type IIA and IIX muscle fibers in the C leg and only in type IIX muscle fibers in the D leg ( $p < 0.05$ ). Exhaustive exercise-induced IMTG utilization was detected in type I-high muscle fibers from both C and D legs, as a decrease in LD size and density. Only in the C leg a significant decrease in LD density was detected in type I-low muscle fibers. Conclusion: The presented data show the existence of two metabolically distinct type I human muscle fibers and characterize their fiber type specific metabolic response to exhausting exercise. References: 1. Nordby P et al. Muscle ceramide content in man is higher in type I than type II fibers and not influenced by glycogen content. *Eur J Appl Physiol*, 2010.

#### EXPLOSIVE-TYPE OF MODERATE-RESISTANCE TRAINING IN THE ELDERLY: BIOLOGICAL AND FUNCTIONAL EFFECTS

Beltran Valls, R.M.1, Brunelli, A.1, Dimauro, I.1, Caserotti, P.2, Di Salvo, V.1, Ciminelli, E.1, Quaranta, F.1, Tranchita, E.1, Parisi, A.1, Caporossi, D.1

*Università degli Studi di Roma Foro Italico*

Introduction Despite explosive-type heavy-resistance training does increase muscle strength and power in the elderly (Caserotti, 2008), little is known on the effect of explosive-type moderate-resistance training (EMRT) on cardiovascular capacity, functional performance and biomarkers of aging. Therefore, the aim of the study was to analyse the effects of 12 weeks low frequency (2days/week) EMRT on cardiovascular fitness, muscle power, daily living activities (ADL) performance, and on molecular markers related to cardiovascular risk (MPO, BNP) and cellular stress response (HSPs) in older adults. Methods Twenty-one medically stable men and women ( $72 \pm 3$  yrs) were divided into training ( $n=13$ ) and control group ( $n=8$ ). Training included lower and upper body exercises performed at 70%1RM with the concentric and eccentric phases of the movement executed at maximal intentional acceleration and moderate speed, respectively. Cardiovascular fitness (ECG, heart rate, blood pressure) was assessed by maximal graded exercise stress test (GXT). Muscle power was assessed with a standardized countermovement jump (CMJ) and during leg extension, leg curl, low row and chest press devices with load at 70% 1RM recorded at baseline (FreePower, Sensorize). Functional performance was measured by 6-m maximum walking (6MW) and stairs climbing (SC) tests (Ergotimer, Globus). HSP70,  $\alpha$ B-cry and HSP27 expression in PBMC was analyzed by western blot. MPO and BNP were quantified by ELISA. Results Training significantly increased maximum GXT load (16%,  $p < 0.05$ ) without affecting heart rate and blood pressure recorded at the same relative work intensity. Peak power measured on the 4 training devices and during the CMJ increased significantly (20-30%,  $p < 0.05$ ) along with increase in the 6MW and SC speed ( $p < 0.05$ ). Preliminary results indicate no significant modification induced by training on biomarkers ( $p > 0.05$ ), which levels remained unchanged or improved in the trained group. Conclusion These findings show that EMRT improves endurance capacity, functional performance and muscle power in older adults. Endurance improvement obtained during maximal exercise, along with the muscle power increase, may facilitate ADL performance, as observed with other type of resistance training protocols (Henwood, 2008). The trend to reduced heart rate, blood pressure and CDV risk although not significant, indicate that EMRT may be safe for this age population. References Caserotti et al. (2008) *Scand J Med Sci Sports*. 18(6):773-82 Henwood et al. (2008) *J Gerontol A Biol Sci Med Sci*. 63(1):83-91 Grant 2009 by Foro Italico University

#### EFFECTS OF COLD EXPOSURE ON ENERGY METABOLISM DURING SUBMAXIMAL EXERCISE

Gagnon, D.D., Rintamäki, H., Gagnon, S.S., Herzig, K.H., Kyröläinen, H.

*University of Jyväskylä*

Introduction Cold environments may modify the use of carbohydrates and fat during exercise (Hurley & Haymes 1982; Layden et al. 2002). This has mostly been observed in cycling studies, which do not represent whole-body energy metabolism as accurately as walk-

ing and running. The purpose of this study was to examine energy availability and utilization during treadmill exercise at low (walking) and moderate (running) intensities in the cold. Methods Ten male subjects, dressed in shorts and t-shirt, completed 4 trials during which they exercised for 60-min at 50% (walking) or 70% (running) of maximal oxygen consumption (VO<sub>2</sub>) in a climatic chamber set at either 0°C (cold) or 22°C (warm). Core temperature (T<sub>core</sub>), weighted mean skin temperature (T<sub>skin</sub>), VO<sub>2</sub>, heart rate (HR), and respiratory quotient (RQ) were continuously recorded and averaged over the last 10-min of every 15-min period during exercise. Blood samples were collected before entering the chamber (baseline) and at 30- and 60-min, to determine changes in availability of serum energy biomarkers (non-esterified fatty acids [NEFA], glycerol [GLY] and glucose [GLU]). Data was analyzed using a three-way ANOVA (factors: temperature, exercise intensity and time) for repeated measures with significance at  $p < 0.05$ . Results Low ( $48 \pm 1\%$  VO<sub>2</sub>) and moderate ( $70 \pm 1\%$ ) exercise intensities affected HR, which was lower in the cold from 15-min to the end of exercise ( $p < 0.001$ ). A modest increase in T<sub>core</sub> was seen over time ( $p < 0.05$ ), which was greater in moderate ( $37.87 \pm 0.03^\circ\text{C}$ ) compared to low ( $37.36 \pm 0.07^\circ\text{C}$ ) exercise intensity ( $p < 0.001$ ). An interaction in T<sub>skin</sub> was observed indicating lower T<sub>skin</sub> in cold vs. warm within both exercise intensities at each time point during exercise ( $p < 0.05$ ). Neither NEFA, GLY nor GLU were influenced by cold exposure at any time point ( $p \geq 0.11$ ). Meanwhile, RQ was modulated by temperature, as cold exposure lowered RQ values across time and exercise intensities (cold  $0.85 \pm 0.01$ ; warm  $0.88 \pm 0.01$ ,  $p < 0.05$ ). Conclusion The large contribution of tissue mass (muscle and adipose) in walking and running, demonstrated a greater energy reliance on fat sources independently of exercise intensity when the body was cold exposed. This occurred despite no changes in substrate availability. This phenomenon may stem from a centrally mediated enhanced fat uptake mechanism initiated by the increase in sympathetic nervous activity due to skin cooling during whole-body exercise. References Hurley BF & Haymes EM (1982). *Aviat Space Environ Med*, 53(12), 1193-7 Layden JD et al. (2002). *Med Sci Sports Exerc*, 34(5), 774-9

### THE CAPACITY TO RECRUIT AND STORE LIPIDS IN SKELETAL MUSCLE DOES NOT ADAPT TO 14 DAYS OF VERY PROLONGED ENDURANCE EXERCISE

Hansen, A.V., Morville, T., Larsen, M.R., Munch-Andersen, T., Riis, P., Kjær, K., Dela, F., Helge, J.W.

*University of Copenhagen*

Introduction Endurance training leads to high levels of intramuscular triacylglycerol (IMTG). This includes a high capacity to recruit, store, and oxidize both endogenous and exogenous fatty acids during exercise. In recent years, lipid droplet associated proteins and their interactions with enzymes have been demonstrated to influence IMTG storage and breakdown capacity. This study investigates changes in expression of the primary proteins and enzymes in fatty acid uptake, lipid droplet storage and mobilisation for oxidation after very prolonged endurance exercise at moderate intensity. Methods Six healthy (61±/−4 yrs), cycle-trained (VO<sub>2</sub>-max: 48±/−2 ml kg<sup>-1</sup> min<sup>-1</sup>) males completed a 2770 km bike ride in 14 days. A muscle biopsy (m. vastus lateralis) was obtained before and 30-34 hours after completing the bike ride. The biopsies were taken at rest and after overnight fasting. Muscle samples were analysed by Western-blotting for expression of: endothelial lipase (EL), lipoprotein lipase (LPL), fatty acid binding protein (FABP), diglyceride acyltransferase 1 and 2 (DGAT 1 and 2), perilipin 2, 3, and 5, adipose triglyceride lipase (ATGL), and hormone-sensitive lipase (HSL). The Western-blotting was normalised to the average arbitrary unit of a standard control homogenate. Results Across the 14 days body weight remained unchanged ( $77.4 \pm 4.6$  to  $77.7 \pm 4.8$  kg). The expression of EL, LPL, FABP, DGAT 1 & 2, Perilipin 2, 3 & 5, ATGL and HSL were unchanged after 14 days of prolonged ( $580 \pm 30$  min/day) endurance exercise at moderate intensity ( $53 \pm 1\%$  VO<sub>2</sub>-max). However, the expression of LPL tended ( $P = 0.08$ ) to be increased by two fold. Discussion In the present study there was no adaptation in capacity for fatty acid recruitment, storage in lipid droplets and promotion for oxidation, after 14 days of very prolonged exercise. It is intriguing that the major increase in energy turnover was insufficient to induce changes in muscle lipid recruitment and storage pathways even though the body weight remained unchanged. The trend towards an increased muscle LPL expression implies that the exogenous supply of plasma derived triacylglycerol was important to generate the increased muscle substrate turnover during the 14 days.

### CHANGES IN FAT OXIDATION AFTER VOLUNTARY WEIGHT LOSS IN MORBIDLY OBESE PATIENTS WITH OR WITHOUT TYPE 2 DIABETES

Lund, M.1,2, Hansen, M.1, Dela, F.1, Helge, J.1

*1: University of Copenhagen, 2: Koege Hospital.*

Introduction Obesity and type 2 diabetes is accompanied by intramyocellular lipid accumulation. This may in part be explained by an impaired mitochondrial fat oxidation and increased availability of plasma free fatty acids. Our aim was to examine and compare fat oxidation changes after a voluntary weight loss in morbidly obese patients with or without T2DM. Patients included were losing weight prior to a scheduled gastric bypass operation. Methods 28 morbidly obese patients (6M/22F; 9 with (T2DM) and 17 (OB) without type 2 diabetes) reported twice to the lab after an 12 hr overnight fast: After signing up for surgery prior to any weight loss and two months later just prior to the operation. Dual Energy X-ray Absorption Scan was performed to measure body composition, followed by measurement of the maximal fat oxidation (MFO) rate and the intensity where this occurred (FATmax) by indirect calorimetry during a graded exercise test on a stationary bike (15W warm-up 4 min., increase 25W/3 min.) (Modified after Achten J et al. 2002). Results There were no baseline differences in age: 39±10 vs. 40±7 yrs; BMI: 42.5±1.0 vs. 42.1±1.6 Kg·m<sup>-2</sup>; Fat Free mass (FFM): 59.8±2.3 vs. 64.2±3.9 kg in OB and T2DM, respectively. Weight loss was similar in the two groups: 6.0±0.7 vs. 5.3±0.9 kg and there were no significant changes in VO<sub>2</sub>Max: 2.7±0.2 and 2.5±0.2 L O<sub>2</sub>·min<sup>-1</sup> or MFO rate: 0.3±0.03 and 0.3±0.04 g·min<sup>-1</sup> in OB and T2DM, respectively. However, the weight loss always resulted in FATmax at a lower relative workload: 39.3±1.8 vs. 36.0±1.1 %VO<sub>2</sub>max, ( $p = 0.004$ ) and 41.4±1.4 vs. 37.4±2.1 %VO<sub>2</sub>max ( $p = 0.018$ ), in OB and T2DM, respectively. Discussion We have found that morbidly obese patients with or without type 2 diabetes achieve their MFO rate at a lower relative workload after only a modest (<7 kg) weight loss. There were no differences in FFM, MFO rate, VO<sub>2</sub>max, before and after the weight loss. An earlier study by our group testing a weight stable obese and postobese group (Ara I et al. 2010) did not find any differences in MFO rate and FATmax between the two. In contrast, in the present study the patients were still in a catabolic state losing weight which might cause the different findings. It is well known that weight loss reduces intramuscular triglyceride level, and our results is most likely due to a lower availability of fatty acids in plasma and muscle during exercise, consistent with the observed and ongoing weight loss. **FRAIL ELDERLY WITH FALL-RELATED HIP FRACTURES SHOW GREATER TYPE II MUSCLE FIBER ATROPHY AND CONCOMITANT LOWER MUSCLE FIBER SATELLITE CELL CONTENT**

Kramer, I.F.1,2, Snijders, T.1, Poeze, M.2, Verdijk, L.B.1, van Loon, L.J.C.1

*NUTRIM, School for Nutrition, Toxicology and Metabolism, Maastricht University Medical Centre+, Maastricht, The Netherlands*

**Introduction** The incidence of hip fractures will increase exponentially to an estimated 6.3 million per year in 2050. The progressive loss of skeletal muscle mass and function with aging may be an important risk factor for the elderly patient to suffer a fall-related hip fracture. Yet, the myocellular phenotype that characterizes hip fracture patients remains to be determined. This study compares the muscle fiber type characteristics of elderly hip fracture patients with healthy young and elderly control subjects. **Methods** Percutaneous needle biopsies were collected from the vastus lateralis muscle in 15 elderly women admitted with fall-related hip fractures, 15 healthy elderly women, and 15 young women. Immunohistochemical analyses were performed to assess muscle fiber size and satellite cell (SC) content in a fiber type-specific manner. **Results** So far, data were obtained from 12 hip fracture patients ( $85 \pm 2$  y), 12 healthy elderly ( $73 \pm 2$  y), and 10 healthy controls ( $21 \pm 1$  y). Type I muscle fiber size did not differ between the groups. In contrast, type II muscle fiber size was significantly smaller in the hip fracture patients ( $2327 \pm 163 \mu\text{m}^2$ ) when compared with the healthy elderly ( $3348 \pm 263 \mu\text{m}^2$ ) and young ( $4460 \pm 364.4 \mu\text{m}^2$ ) controls ( $P < 0.05$ ). Furthermore, type II muscle fiber size was also significantly smaller in the healthy older compared with the young women ( $P < 0.05$ ). In all groups, the number of SC per muscle fiber was significantly smaller in the type II vs type I muscle fibers. Whereas type I muscle fiber SC content did not differ between groups, type II muscle fiber SC content was significantly lower in the hip fracture patients compared with the healthy elderly females ( $0.024 \pm 0.003$  vs  $0.051 \pm 0.007$  SC per fiber, respectively;  $P < 0.01$ ). More results from the total group of participants (i.e.  $n=45$ ) will be presented at the conference. **Conclusion** Frail elderly with fall-related hip fractures show greater type II muscle fiber atrophy and a further reduction in type II muscle fiber SC content when compared with healthy elderly subjects. This type II muscle fiber atrophy might be responsible for reduced muscle strength and functional capacity, increasing the risk of falling and sustaining a fracture. Exercise and nutritional intervention strategies should be defined and implemented to prevent the prevalence of fall-related fractures in this frail population.

**13:45 - 14:45****Poster presentations****PP-PM05 Neuromuscular Physiology 1****POSTACTIVATION POTENTIATION IN TRICEPS SURAE MUSCLES AFTER HOPPINGS CONTRIBUTES TO INCREASED PERFORMANCE IN SUBSEQUENT MAXIMAL JUMPS**

Bergmann, J., Gruber, M.

*University of Konstanz*

**Introduction** Many top athletes use hops to prepare for a subsequent sprint or jump. A possible mechanism that could explain enhanced performance is post activation potentiation (PAP) (for review see Tillin & Bishop 2009). However, there is no scientific proof for its occurrence or effectiveness. We hypothesized to find i) PAP after a bout of maximal hoppings, ii) increases in jump height in subsequent maximal drop jumps (DJ) and iii) a correlation between the amount of PAP and increases in DJ height. **Methods** 12 healthy subjects (7 woman and 5 men, age  $25 \pm 3$  years, height  $175 \pm 9$  cm, weight  $71 \pm 11$  kg) participated in the study. To quantify PAP, twitch peak torques (TPT) were measured with and without 10 preceded maximal hoppings as conditioning contractions. Muscle twitches were evoked by supramaximal stimulation of the tibial nerve and TPT of the triceps surae muscles were determined in an ankle dynamometer. Thereafter, 8 maximal DJ were performed with and 8 were performed without conditioning hops in a randomized order on a force plate. DJ height was calculated by the flight-time method. To examine potential underlying mechanisms we analyzed background EMG activities of gastrocnemius, soleus, tibialis anterior, vastus medialis and biceps femoris muscles in distinct time intervals during the DJ (PRE=150 ms before touchdown (TD) until TD; SLR=30–60ms after TD; LLR=90–120ms after TD). Additionally, we elicited M- and V-waves, so that they coincided with the SLR and LLR. TPT, jump height, RMS values of background EMG and V/M-ratios were compared by means of one-way ANOVA and post hoc Bonferroni analysis. Pearson analysis was used to correlate changes in TPT and DJ height. Statistical significance was set at  $P < 0.05$ . **Results** After 10 maximal hops TPT of triceps surae muscles was  $32 \pm 8\%$  ( $P < 0.01$ ) higher compared to baseline values. In DJ, in which a preceded bout of maximal hops was performed, jump height increased by  $12 \pm 11\%$  ( $P < 0.05$ ). Higher TPT and changes in DJ heights were positively correlated ( $R^2 = .263$ ,  $P < 0.05$ ). Neither background EMG data nor V/M-ratios revealed any statistical differences between the conditions. **Discussion** In the present study we were able to induce a clear PAP effect with 10 maximal hops and to demonstrate increased DJ height. Based on the correlation analysis, it can be concluded that PAP contributed to the higher performance in DJ. Unchanged EMG data and V/M-ratios indicate that neural control remained unaffected. Therefore, enhanced performance in DJ after PAP is more likely the result of intramuscular mechanisms, like e.g. phosphorylation of regulatory light chains (Houston et al. 1985). **ACTIONS OF  $\beta_2$ -ADRENOCEPTOR AGONIST DRUG ON HUMAN SOLEUS MUSCLE CONTRACTION**

Crivelli, G.1, Capt, R.1, Borrani, F.1, Maffioletti, N.A.2

*University of Lausanne*

**ISSUL, University of Lausanne (CH) 2Neuromuscular Research Laboratory, Schullthess Clinic (CH)** **Introduction** In animal models, the stimulation of  $\beta_2$ -adrenergic receptors is able to modulate the contractility of slow skeletal muscle fibers. For example,  $\beta_2$ -agonists enhanced twitch relaxation rate and reduced force level in subtetanic contractions of the cat soleus muscle in vivo (Bowman, 1980). In humans, the effects of  $\beta_2$ -agonists are unclear as it remains to be ascertained whether (1) the alterations of contractile properties in vivo are compatible with those observed in animal preparations, and (2) central motor drive (CMD) during voluntary contractions could compensate for the contractile changes. The aim of this study was to investigate central and peripheral neuromuscular effects induced by the  $\beta_2$ -agonist terbutaline on the human soleus muscle. **Methods** Twelve healthy men (age  $31 \pm 5$  years) ingested either a single dose of 8 mg of

terbutaline or placebo in a randomized double-blind order (two sessions). Isometric plantar flexion torque of electrically evoked twitch and tetani (10 and 100 Hz) as well as of submaximal and maximal voluntary contractions (MVC) was measured while the subjects were seated with hip, knee and ankle angles of 90°. Half-relaxation time was also calculated from twitch torque traces. CMD was estimated via soleus electromyographic recordings obtained during steady submaximal (50% MVC) voluntary contractions. Results MVC and peak twitch torque were unaffected by terbutaline. Twitch half-relaxation time was 28% shorter after terbutaline administration compared to placebo ( $P < 0.001$ ). Tetanic torques at 10 and 100 Hz were significantly depressed after terbutaline ingestion, respectively by -40% and -24% (both  $P < 0.001$ ). Although the mean torque of the submaximal voluntary contraction was comparable for the two conditions, CMD was 9% higher after terbutaline intake compared to placebo ( $P < 0.001$ ). Discussion This study provided evidence that stimulation of  $\beta_2$ -adrenergic receptors via terbutaline ingestion is able to modulate the contractility of human slow skeletal muscle in vivo. The effect of terbutaline on muscle relaxation may be due to an increased rate of sarcoplasmic reticulum  $Ca^{2+}$  uptake (Ha et al., 1999). The same mechanism could also be responsible for the weakening action of  $\beta_2$ -agonist on slow skeletal muscle, which may have affected evoked tetanic torque by decreasing the permanence of  $Ca^{2+}$  in the cytoplasm. The increase in CMD during submaximal contractions may be viewed as a compensatory adjustment of the central nervous system to counter the weakening effect of terbutaline on slow muscle fibers (Roatta et al., 2008). References Bowman (1980). Handbook of Experimental Pharmacology, 47-128. Ha et al. (1999). Br J Pharmacol, 126, 1717-1724. Roatta et al. (2008). J Physiol, 586, 5561-5574.

### SUBTHRESHOLD ELECTRICAL NOISE STIMULATION REDUCES THE FLUCTUATIONS IN THE INDEX FINGER MOVEMENTS

Nagata, K., Kouzaki, M.

*Kyoto University*

Introduction Accurate movement of the fingers is an important functional skill that greatly influences our ability to perform skillful activities, e.g., grasping and lifting the objects. Thus, deteriorations in this accuracy become serious problem in our daily living. Age-related decrease in this becomes serious problem. However, it is not well obvious that factors for improvement of accurate movement of the hand muscles. Therefore, the aim of this study was to examine whether the index finger steadiness increases due to subthreshold electrical noise stimulation, which is based on the concept of stochastic resonance (SR). Methods The experiments were performed on the left hand of 8 healthy male subjects. Each subject performed six trial position-holding tasks with a submaximal load at ~5% of MVC for 50 s while giving subthreshold electrical noise stimulation for 40 s. Electrical stimulation (ES) applied to the ulnar nerve of innervation of the first dorsal interosseous (FDI) muscle at the left wrist. The ES intensity was determined based on the recruitment threshold of the FDI muscle. The lowest intensity that caused the motor unit action potential to start firing was identified as the ES intensity (ES-1). Such an electrical signal consisted of a randomly varying white noise signal with bandwidth between near 1 and 100 Hz. The ES intensity was decided 0.0 (without stimulation) to 1.0 times of ES-1 with 0.2 steps. To assess the magnitude of fluctuations in the index finger movement during the position-holding tasks, the path length (PL) of finger displacement were calculated with a charge coupled device laser displacement sensor with a spatial resolution of 10  $\mu$ m (Nagata et al. 2012). Results The finger displacement fluctuated around the target position in not only the adduction-abduction but the extension-flexion directions. The ES intensity at which the PL is local minimal value was found except for two subjects. For two subjects, there was no influence of electrical stimulation on PL values. Discussion The subthreshold electrical noise stimulation used in the present study does not excite the motor nerve fiber, but it might do affect the afferent fiber because the ES intensity was below recruitment threshold. Thus, such stimulation appropriately enhances the sensitivity of the  $\alpha$ -motoneuron pool via the afferent fibers than motor nerve fibers. Therefore, the subthreshold electrical noise stimulation would modulate  $\alpha$ -motoneuron properties via afferent fibers. In addition, according to the concept of SR, the subthreshold electrical noise stimulation was likely effective in enhancing the function of the sensorimotor system because of the electrical nature of information transfer in sensory neurons. ### EFFECTS OF AGING ON THE DEVELOPMENT OF FUNCTIONAL CONSEQUENCES OF CENTRAL AND PERIPHERAL FATIGUE DURING LOCOMOTOR EXERCISE

Elmer, S., Bohn, J., Amann, M., McDaniel, J., Martin, D., Martin, J.

*Swedish Winter Sports Research Centre-Mid Sweden University, University of Utah*

Introduction Results from a recent systematic review and meta analysis of skeletal muscle fatigue and aging indicate that older individuals develop greater fatigue than young individuals during dynamic muscle contractions. However, the relative importance of central and peripheral factors in fatigue during dynamic contractions in the elderly is unclear. Our purpose was to evaluate the effects of aging on the development of functional consequences of central and peripheral fatigue induced via dynamic exercise involving a large muscle mass. Specifically, we used high-intensity single-leg cycling to induce fatigue and evaluated associated effects on maximum cycling power ( $P_{max}$ ) in the fatigued ipsilateral leg (FATleg) as well as the rested contralateral leg (RESTleg). Methods On separate days, 12 young ( $26 \pm 4$  yr) and 12 masters ( $57 \pm 5$  yr) cyclists performed right leg  $P_{max}$  trials before and again 30s, 3, 5, and 10min after a cycling time trial (TT, 10min) performed either with their right or left leg. Fatigue was estimated by comparing exercise-induced changes in  $P_{max}$  as quantified via inertial-load cycling. Pre-to post-TT changes in maximum handgrip isometric force ( $F_{max}$ ) were also assessed. Results Relative power produced during the right and left leg TT's did not differ between young and masters cyclists (~33% vs. 36% of  $P_{max}$ ; leg effect,  $P=0.70$ ; leg x age,  $P=0.73$ ). Compared to pre-TT, FATleg  $P_{max}$  was reduced by  $22 \pm 3\%$  and  $21 \pm 3\%$  for young and masters cyclists at 30s post-TT, respectively, (time effect,  $P < 0.01$ ; time x age,  $P=0.48$ ). At 10min post-TT, FATleg  $P_{max}$  was similar to pre-TT values for both young and masters cyclists ( $P=0.06$ ). Post-TT  $P_{max}$  produced by the RESTleg did not differ from pre-TT values for young and masters cyclists (time effect,  $P=0.45$ ; time x age,  $P=0.53$ ).  $F_{max}$  increased for young and masters cyclists at 10min post-TT (time effect,  $P < 0.05$ ; time x age,  $P=0.12$ ). Discussion Even with  $> 30$  yr difference in age, masters cyclists exhibited nearly identical levels of fatigue compared to young cyclists in the FATleg and also exhibited similar recovery patterns. Further, despite considerable fatigue in the FATleg, both young and masters cyclists were able to maintain maximum cycling power in the RESTleg. This suggests that a cross-over of fatigue (likely central in origin) was either not present or not large enough to impair maximum cycling power in the RESTleg. These results along with the lack of changes in  $F_{max}$  indicate that impairments in maximal voluntary neuromuscular function were specific to the working muscles for both young and masters cyclists. We conclude that fatigue induced via high-intensity single-leg cycling has similar functional consequences for endurance trained young and masters cyclists. Finally, these results likely represent a best case scenario for highly active aging.

## NEUROMUSCULAR FATIGUE DEVELOPMENT AND BIOMECHANICAL CHANGES DURING CONSTANT-LOAD, HIGH-INTENSITY CYCLING EXERCISE

Overton, A.J., Abbiss, C., Blazevich, A.J.

*Edith Cowan University*

**Introduction** Neuromuscular function during fatiguing exercise has primarily been examined at the onset and termination of an exercise bout. However this does not capture the time course, or relative contribution, of central and peripheral fatigue mechanisms and assumes a linear progression to exhaustion. Importantly, associated biomechanical (muscle activity and kinematic) changes have not been simultaneously investigated. **Methods** Nine well trained male cyclists performed seven testing sessions; session 1: incremental cycling test to exhaustion; session 2: constant-load cycling time to exhaustion (TTE) test; sessions 3-6: constant-load cycling tests to 20, 40, 60 and 80% (T20-T80) of the time taken to complete the TTE test (T100) in random order; session 7: a TTE test. Cycling tests were performed at a constant cadence ( $89 \pm 10$  rpm) at 90% Pmax (PO that elicits a  $\text{VO}_2$  reading  $< 2.1 \text{ ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$  of the subsequent reading despite increasing workload;  $337 \pm 38$  W). EMG activity of seven lower limb muscles and 3D joint kinematics were recorded at the beginning (T0) and termination (T100) of the first TTE test, and in the final 20 s of the remaining constant-load cycling tests (T20-T80). Neuromuscular assessments (mechanical and EMG responses of the quadriceps to voluntary and electrically stimulated (femoral nerve) contractions) were made before and after exercise. **Results** The participants cycled for  $5:49 \pm 0:51$ . Twitch contraction time increased to T20, and peak twitch torque and the average rate of torque development and relaxation increased to T40 then declined to T100. Neither M-wave amplitude (Mmax) and duration nor twitch one-half relaxation time changed. No changes were observed in peak torque and the rate of torque development measured during voluntary knee extension. Increases in vastus lateralis EMG amplitude and EMG:Mmax from T80-T100 were not significant. No significant changes were observed in %VA, peak EMG amplitudes, rate of EMG rise or EMG mean frequency (MeanF). During cycling, EMG onset and offset times and duration did not change, although peak vastus medialis and gluteus maximus (GMax) EMG amplitude, GMax mean EMG amplitude and GMax EMG impulse significantly increased. No significant changes were observed for EMG MeanF. Increases in trunk flexion from T60, trunk lateral flexion and hip abduction/adduction from T80 and trunk lateral flexion and knee valgus/varus at T100 were observed. **Discussion** Peripheral neuromuscular fatigue mechanisms developed early in the exercise bout and were significant by T60, but were temporarily dissociated from significant kinematic changes. As the exercise bout progressed, efferent drive to the muscle increased from T80-T100 and was associated with a significant change in kinematics at the trunk, hip and knee joints.

## POSTACTIVATION POTENTIATION IS AFFECTED BY PASSIVE SHORTENING AND LENGTHENING DURING TWITCH CONTRACTION

Fukutani, A.1, Hirata, K.1, Miyamoto, N.1, Kanehisa, H.2, Yanai, T.1, Kawakami, Y.1

*1: Waseda University (Tokorozawa, Japan), 2: National Institute of Fitness and Sports in Kanoya (Kanoya, Japan)*

**Introduction** The magnitude of twitch torque increases after a high intensity contraction (conditioning contraction) of the same muscle. This phenomenon is called postactivation potentiation (PAP). Previous studies reported that a conditioning contraction enhanced subsequent maximal voluntary concentric torque (Miyamoto et al. 2011) whereas maximal isometric force was not enhanced (Vandenboom et al. 1993). We hypothesized that this discrepancy be caused by the difference in the behavior of muscle fibers during twitch contraction. Therefore, the purpose of this study was to examine the effect of changing muscle fiber behavior on the magnitude of PAP by imposing length changes during twitch contraction. **Methods** In 15 subjects, twitch contraction of plantar flexion was evoked at the same ankle joint angle (0 deg) during isometric, passive shortening (+120 deg/s) and passive lengthening (-120 deg/s) conditions before and after the maximal voluntary isometric plantar flexion as a conditioning contraction. During twitch contractions, the behavior of the fascicle of the medial gastrocnemius was determined by ultrasonography to confirm the shortening velocity of the fascicle. **Results** The magnitude of PAP in the isometric condition was significantly smaller than that in the passive shortening condition, but significantly larger than that in the passive lengthening condition ( $p < 0.05$ ). Likewise, the shortening velocity of the fascicle of the medial gastrocnemius during a twitch contraction in the isometric condition was significantly smaller than that in the passive shortening condition, and larger than that in the passive lengthening condition ( $p < 0.05$ ). **Discussion** The fascicle shortening velocity was higher in the order of passive lengthening, isometric and passive shortening conditions. In addition, the magnitude of PAP became larger in a similar fashion to that of fascicle shortening velocity. These results support our hypothesis that the magnitude of PAP is related with the shortening velocity of the fascicle during a twitch contraction. A primary mechanism of PAP is myosin regulatory light chain phosphorylation induced by conditioning contraction, which facilitates actin-myosin interaction (Sweeney et al. 1993). Our results suggest that this mechanism is operative more conspicuously when the fascicle shortens at a higher velocity during a twitch contraction. **References** 1. ## H-REFLEX AND DELAYED-ONSET MUSCLE SORENESS IN THE TRAPEZIUS MUSCLE

Vangsgaard, S., Søgaard, K., Taylor, J.L., Madeleine, P.

*Aalborg University*

**H-REFLEX AND DELAYED-ONSET MUSCLE SORENESS IN THE TRAPEZIUS MUSCLE** Vangsgaard, S.1, Søgaard, K. 2, Taylor, J. L.3, Madeleine, P.1.1: Aalborg University (Aalborg, Denmark), 2: University of Southern Denmark (Odense, Denmark), 3: Neuroscience Research Australia and the University of New South Wales (Sydney, Australia) **Introduction** The separation of the efferent and afferent fibres to trapezius enables H reflexes to be evoked by electrical stimulation without the influence of direct activation of the motor axons (1). Delayed-onset muscle soreness (DOMS) often occurs in relation to sports activities as a result of high-intensity eccentric exercise (2). No studies have investigated the effects of DOMS on the H reflex in the trapezius muscle. The objective of this study was to investigate the modulation of the H reflex 24 h after eccentric exercise in the presence of DOMS. **Methods** H reflexes were recorded from the dominant middle trapezius muscle by electrical stimulation of the C3/4 cervical nerve in 10 healthy subjects. DOMS was induced by eccentric exercise of the dominant shoulder. H reflexes were obtained in three sessions: "24h before", "Pre", and "24h after" eccentric exercise. Ratios of maximal H reflex and M wave responses ( $H_{\text{max}}/M_{\text{max}}$ ) were compared between sessions. Additionally, a between session comparison was done for the ratios of H reflex amplitudes ( $H_{i75}/M_{\text{max}}$ , and  $H_{i50}/M_{\text{max}}$ ) obtained from the stimulus intensity needed to obtain 75% and 50% of  $H_{\text{max}}$  at "24h before". Muscle soreness was assessed using a visual analogue scale (VAS) score and measures of pressure pain threshold (PPT). **Results** A decrease in both  $H_{i75}/M_{\text{max}}$  and  $H_{i50}/M_{\text{max}}$  were observed at "24h after", ( $P < 0.05$ ). VAS scores were

significantly higher at "24h after" compared with "24h before" and "pre", ( $P < 0.05$ ). PPT values were significantly lower "24h after" compared to "24h before" and "pre", ( $P < 0.05$ ). Discussion This study presented evidence that at 24h after exercise stronger stimulus intensity was needed to reach the same magnitude of the H reflex as the recruitment curve was shifted to the right. This modulation of the stimulus-response relationship could be caused by presynaptic inhibition of Ia afferent fibres' input to the motoneuron by group III and IV afferents. ### REFLEX EXCITABILITY: IS IT A CONTRIBUTOR FOR POST-ACTIVATION POTENTIATION?

Xenofondos, A.

*Aristotle University of Thessaloniki*

**Introduction** The influence of post-activation potentiation (PAP) to enhance subsequent athletic performance after a conditioning contraction has received considerable attention in the past years. However, our knowledge and understanding of the neurophysiology of PAP is limited. Only few studies, have examined the twitch torque and the soleus and gastrocnemius H-reflex after PAP (Guellich and Schmidtbleicher, 1996; Hodgson et al., 2008; Trimble and Harp, 1998). In these studies there are several methodological considerations and their findings seem inconclusive. **Methods** Fourteen healthy, recreationally active male and female participated in this study. The measurement procedures included familiarization for the participant with the tests, the determination of the soleus H- and M-wave amplitude/stimulus intensity curve and the measurement of the MVC. The Mmax and H-reflex were measured before and after a 10 s isometric MVC (conditioning stimulus). We examined the twitch torque properties and H-reflex amplitude, 5 minutes before and for 20 minutes after the conditioning contraction. Results Immediately after a 10 s isometric MVC the twitch torque was significantly increased ( $p < 0.05$ ) while the H-reflex amplitude of both muscles significantly decreased ( $p < 0.05$ ), compared to that before the 10 s isometric MVC. After one minute the H-reflex amplitude returned to baseline levels and remained unchanged. The Mmax did not change significantly during the whole experiment, whereas peak twitch torque was potentiated immediately after the contraction. **Discussion** Recreationally active adults exhibit an inhibition in excitability of motor neurons activated through the Ia afferent pathway. This inhibition gradually recovers with no potentiation above baseline. This neural inhibition could be attributed to the post-activation depression of Ia afferents, and could be a counteracting factor limiting the mechanism of PAP. ### INFLUENCE OF AN ACUTE INCREMENTAL EXHAUSTIVE EXERCISE ON EXECUTIVE FUNCTION: A STUDY ON THE DURATION OF ITS EFFECTIVENESS.

Ochi, G., Akahori, M., Hyodo, K., Soya, H.

*University of Tsukuba (IBARAKI, JAPAN)*

**Introduction** It is important for athletes to maintain cognition during athletic performance in competitive sports. Such cognition could be affected by both peripheral and central fatigue. A previous study had shown that executive function as one of cognitive functions was declined after an acute incremental exhaustive exercise (LaManca et al., 1998). However, it is not known as to physiological and psychological conditions during exercise by which executive function is declined. Also, it is not known how long a decline in cognitive function after exhaustive exercise would last. The purpose of the present study was to examine the duration of the effectiveness of and the influence of acute incremental exhaustive exercise on executive function. **Methods** Eighteen healthy young male subjects who had experiences of exercise participated in this study. There were two sessions of experiments on two separate days. On the first day, they performed a color-word Stroop task (CWST) one of the most commonly used tests for examining executive functions, before cycle ergometer exercise (pre), immediately after (post), and 10 (P10), 20 (P20) and 30 (P30) minutes after exercise. On the second day, all subjects followed the same procedure as for day one, including sitting on the ergometer, but without exercise. Cognitive performance was evaluated by reaction time (RT) for incongruent and neutral tasks of CWST. The exercise intensity that was started at 25 W was increased with a 25W increment in every minute to exhaustion. At baseline and during exercise, expired gas, rate of perceived exertion (RPE), heart rate and blood lactate concentration were determined. Criteria for exhaustion were respiratory exchange ratio was greater than 1.5, RPE was 20, the predicted maximum heart rate was more than 90%, blood lactate was more than 10mmol/l and a clear plateau of O2 uptake with increment of work load. We assumed that subjects who met three out of five of the criteria for exhaustion reached exhaustion in this study. **Result and Discussion** No significant difference was found in RT between the control and exercise experiments in the results of the CWST of 12 subjects who met the exhaustion conditions. Four of twelve subjects did not meet the RPE condition for exhaustive exercise. A previous report had shown that RPE is highly correlated with exhaustion (Presland et al., 2005). Therefore, we hypothesized that RPE 20 may be an important determinant factor effecting executive function. We re-analyzed the CWST RT of eight subjects whose exhaustive exercise condition included RPE 20. In these subject, the incongruent task performance decreased at P10 and P20 ( $p < 0.05$ ). These results suggest that an acute exhaustive exercise impairs executive function, only when the exhaustion criterion included RPE 20, and the effect continued until 20 min after exhaustive exercise. ### ACUTE NEUROMUSCULAR AND HORMONAL RESPONSES TO SINGLE-SESSION COMBINED STRENGTH AND ENDURANCE LOADINGS

Taipale, R.S., Schumann, M., Mikkola, J., Nyman, K., Kyroläinen, H., Nummela, A., Häkkinen, K.

*University of Jyväskylä, KIHU – Research Institute for Olympic Sports, Central Hospital of Central Finland*

**INTRODUCTION** Conflicting adaptations have been observed when strength and endurance training are combined (Hickson 1980), which has been attributed to a high intensity and volume of training and as well as training modes (Wilson et al. 2011). Acute responses to the order of exercise in a single session has not been thoroughly investigated, thus this study examined the acute responses and recovery of force production and serum hormone concentrations to single-session combined strength (S) and endurance (E) loadings in which the order of exercises is randomized. **METHODS** Twenty-two recreationally endurance trained subjects 10 women (W) and 12 men (M) ( $36 \pm 8$  years) completed two loadings [S followed by E (SE) and E followed by S (ES)]. The S loading focused on the leg extensors including maximal and explosive exercises while E consisted of moderate intensity running for 60min. Maximal isometric force (MVC), countermovement

jump (CMJ) and serum hormone concentrations (total testosterone, T and cortisol, C) were measured pre, mid, and post loadings as well as at 24h and 48h of recovery. RESULTS Significant decreases were observed in MVC of M at mid and post in both ES ( $p < 0.05$ ) and SE ( $p < 0.001$ ). In W, a significant decrease in MVC was observed at mid only in SE ( $p < 0.01$ ) and at post in both ES ( $p < 0.01$ ) and SE ( $p < 0.05$ ). MVC remained decreased in M at 24h and 48h in both ES and SE ( $p < 0.01-0.09$ ) but recovered in W. A significant decrease in CMJ height was observed in M after S in both loadings. CMJ height did not change during the loadings in W, but was significantly decreased at 24h and 48h of recovery after ES. T concentrations did not change significantly over time in M or W during SE or ES; however, in M (the increase in) concentration of T was significantly higher in ES than in SE at 24h and 48h ( $p < 0.05$ ). C concentrations did not change significantly over time in M, but were slightly higher ( $p = 0.072$ ) in M following SE than ES. Concentrations of C in W decreased during the loadings but were statistically unaltered during recovery. DISCUSSION The present combined S and E loadings induced more decreases in MVC and CMJ height and greater hormonal responses in M than in W. The present ES and SE loadings produced differing neuromuscular and hormonal responses suggesting that the order of concurrent S and E exercise has an influence on acute physiological responses. These findings may have important implications for training in recreational endurance athletes. REFERENCES Hickson (1980) Eur J Appl Physiol. 45: 255-263. Wilson et al. (2011) J Strength Cond Res (Published ahead of print).

## HOW DOES EXTREME-DURATION HEAVY LOAD CARRIAGE AFFECT NEUROMUSCULAR FUNCTION?

Grenier, J.G., Millet, G.Y., Messonnier, L., Morin, J.B.

*University of Saint-Etienne.*

HOW DOES EXTREME-DURATION HEAVY LOAD CARRIAGE AFFECT NEUROMUSCULAR FUNCTION? GRENIER JG (1,2), MILLET GY (1), MESSONNIER L (3), MORIN J-B (1). (1) University of Lyon, F-42023, Saint Etienne, France. Laboratory of Exercise Physiology (EA4338), F-42000, Saint-Etienne, France. (2) Safran Group, Sagem, Land Warfare, F-91300, Massy, France. (3) University of Savoie, Laboratory of Exercise Physiology (EA4338), F-73376, Le Bourget du Lac, France. INTRODUCTION Heavy load carriage for moderate duration exercises (Clarke et al., 1955; Blacker et al., 2010) or exercises of extreme duration but with light equipments carriage (Martin et al., 2010; Millet et al., 2011) can alter the neuromuscular function (NMF). To our knowledge, the combined effects of heavy load carriage and extreme duration of exercise has never been studied so far. This was done in the present study in soldiers performing a simulated military mission (SMM). METHODS Ten experienced infantrymen performed a 21-h SMM in a middle-mountains environment with equipments weighting ~27 kg during simulated battle phases and ~43 kg during road marches. They were allowed 2 \* 3 h of sleep and disposed of a 1-day food ration (3200 kcal). Knee extensors (KE) and plantar flexors (PF) mechanical responses during maximal voluntary contractions (MVC) and nerve electrical stimulations, as well as EMG recordings and ratings of perceived exertion were measured before and immediately after the SMM. RESULTS MVC declined by  $10.2 \pm 3.6\%$  for KE ( $P < 0.01$ , effect size of 0.50) and  $10.7 \pm 16.1\%$  for PF ( $P = 0.06$ , effect size of 0.82) after the SMM. The origin of fatigue was essentially peripheral for both muscle groups. Low frequency fatigue, which has been linked to excitation-contraction coupling failure, was only detected for KE. Finally, these moderate NMF alterations came with a large subjective fatigue. DISCUSSION This study based on a military context reports novel data about the neuromuscular consequences of exercises of extreme duration with heavy load carriage. Surprisingly, the results showed that the NMF alterations due to the 21-h SMM were close to those reported after load carrying exercises lasting less than 3 h (Clarke et al., 1955; Blacker et al., 2010). It is however likely that the mission chronology and the subjects' high capacities for load carriage explained this unexpected result. Finally, the observed large subjective fatigue was attributed to the environmental stress inherent to the outdoor SMM but was not coupled with central alteration of the NMF. REFERENCES 1. ## EFFECTS OF GRADED HYPOXIA ON THE TIME COURSE OF NEUROMUSCULAR ADJUSTMENTS DURING MAXIMAL, INTERMITTENT LEG EXTENSIONS

Christian, R., Girard, O., Billaut, F., Bishop, D.

*Aspetar - Qatar Orthopaedic and Sports Medicine Hospital, Doha, QATAR, Victoria University, Melbourne, AUSTRALIA*

Effects of graded hypoxia on the time course of neuromuscular adjustments during maximal, intermittent leg extensions Christian R1,2, Girard O1, Billaut F2, Bishop D2 1Aspetar – Qatar Orthopaedic and Sports Medicine Hospital, Doha, QATAR 2Victoria University – School of Sport and Exercise Science, Melbourne, AUSTRALIA Introduction: Fatigue during high-intensity intermittent exercise has been shown to occur as a result of both neural and muscular factors. However, due to neuromuscular assessments usually being restricted to pre- and post-exercise only, the time course, interplay and regulation of neural and muscular adjustments during such exercise is not well understood. Aim: To investigate the effect of hypoxia severity on the time course of neuromuscular adjustments during maximal intermittent leg extensions. Methods: Twelve trained, team-sport athletes (age:  $28 \pm 6$  y; stature:  $180 \pm 6$  cm; mass:  $82 \pm 6$  kg) performed 4 bouts of intermittent exercise (separated by 100 s of rest); each bout included 6 sets (separated by 15 s of rest) of 5 maximal, continuous, isokinetic leg extensions at 300 °/s. There were 3 conditions: normoxia (simulated altitude/fraction of inspired oxygen = 0 m/0.21%), moderate (3000 m/0.14%) and severe hypoxia (5400 m/0.10%) which were performed in a randomised counterbalanced order. Arterial oxygen saturation (SpO<sub>2</sub>), heart rate (HR) and rating of perceived exertion (RPE) were recorded 10 s after each contraction set. Neuromuscular assessments including voluntary and evoked contractions of the knee extensors using both peripheral motor nerve and transcranial magnetic stimulations were completed prior to exercise, in-between each set, immediately, 5, 15 and 30 minutes post-exercise. Results: Preliminary data ( $n=7$ ) show that average peak power output during the first set was similar among the three conditions ( $180.9 \pm 35.7$  N.m-1, all conditions compounded;  $p=1.00$ ). Irrespectively of the conditions average peak power output decreased ( $p < 0.05$ ) from the first to the fourth exercise bout (percentage decrement score: -4.6%, -6.0% and -8.1% in normoxia, moderate and severe hypoxia, respectively), while HR and RPE (+9% and +23%, respectively; all conditions compounded; both  $p < 0.01$ ) increased. RPE values during the fourth bout (+5.0% and +4.2%, respectively) were higher in severe hypoxia than in normoxia or moderate hypoxia. Compared to baseline, SpO<sub>2</sub> remained constant in normoxia (98%) but decreased in moderate and severe hypoxia (91% and 80%, respectively; both  $p < 0.05$ ) after 10 min wash-in. SpO<sub>2</sub> did not further decrease throughout exercise in any condition. Conclusion: During maximal, intermittent leg extensions, preliminary evidence suggests that larger performance decrements occur with increases in hypoxia severity. With our complete sample size, additional data will help to shed more light on the time course of neuromuscular adjustments that may eventually explain the larger performance decrement observed with severe hypoxia.

**EFFECTS OF WHOLE BODY VIBRATION IN THE LEAN MASS OF ADOLESCENTS WITH DOWN SYNDROME.**

González-Agüero, A., Gómez-Cabello, A., Matute-Llorente, A., Gómez-Bruton, A., Morales, S., Vicente-Rodríguez, G., Casajús, J.A.

*GENUD Research Group, University of Zaragoza, Spain*

**Introduction:** Persons with Down syndrome (DS) are characterized by lower levels of lean mass(1) which, together with their physiological characteristics, lead them to a concerning low strength levels and lack of autonomy when performing daily activities. This low lean mass may be counteracted through exercise, and it has been demonstrated that whole body vibration (WBV) is an effective method to improve body composition(2). Therefore, our aim was to observe the effect of 20 weeks of WBV in the lean mass of adolescents with DS. **Material and methods:** Thirty adolescents (15.8±2 yr) with DS (11 females) were randomly assigned to the WBV or control groups. Previous to the WBV intervention and immediately after, participants were heighted and weighed; dual energy X-ray absorptiometry (DXA) scans were performed to evaluate lean mass of the whole body, upper and lower limbs, and Tanner stage was also assessed. The intervention consisted in WBV (squatting position) in a platform 3 days per week for 20 weeks (frequency 25-30 Hz; amplitude 2-4mm; duration 30-60 s). Analyses of covariance (ANCOVA) for repeated measures (with Tanner stage and height as covariates) were performed to evaluate possible group by time interactions. Adjusted values were recorded and percentages of change (from pre to post-WBV) were calculated from these adjusted values. **Results:** No group by time interactions were found for any studied variable; however the WBV group showed significantly greater percentages of change for whole body (2.3±1.6 vs. 0.36±2.5), upper (2.7±2.1 vs. 0.59±3.3) and lower limbs lean mass (2.9±3.1 vs. -0.51±4.3) compared with the control group (all p<0.05). **Discussion:** Since our results showed a rather consistent 2-3% increment in lean mass in the WBV compared with 0.5% in the control group; it can be assumed that the WBV training may have a positive effect on the lean mass of adolescents with DS. Other type of training has also been demonstrated as effective for enhancing lean mass in this population (1); however, WBV takes less time and is easily performed by the participants. Therefore, WBV could be a good implementation to any other activities that these adolescents carry out. It is possible to hypothesize that the low intensity and/or absolute duration (20 weeks) of the training, made the analyses not to reach significant interaction. Also the low number of participants could be another reason. Further studies with longer and/or more intense WBV trainings could corroborate our findings. **References:** (1) González-Agüero, A., et al. *Res Dev Disabil*, 2011. **MUSCULAR POWER OUTPUT AND EFFICIENCY IN AN ELITE ATHLETE WITH CEREBRAL PALSY** Prins, L.F.1, Wolters, P.C.M.1, De Koning, J.J.1,3, Casolino, E.2, Foster, C. 1,3, Porcari, J.P.3, Zimmerman, D.3 1: VU University (Amsterdam, Netherlands), 2: University of Rome "Foro Italico" (Italy), 3: University of Wisconsin-La Crosse (USA) **Introduction** One of the critical issues in rehabilitation is understanding how patients adapt to pathological conditions to achieve relatively normal function. In this regard, studies of athletes with disabilities can prove instructive regarding the limits of adaptive possibilities. We report the case of an elite runner with cerebral palsy (CP) (T37 class) who participated in the 1996 & 2000 Paralympics in 800m, 1500m and 5000m, silver medal in 1500m in 2000. Personal best: 800m=132s=102.3s=77.5%=WR; 1500m=269s=207.7s=77.2%=WR; 5000m=1060s=769.6s=72.5%=WR. **Methods** He was studied 11 years after his Olympic medal, although he still trained regularly both running and cycling. To assess differences between his affected (A) and normal (N) legs he performed both incremental and steady state (50%PPO) cycle ergometer exercise with both two legs (2L) and single legs (1L). Respiratory metabolism was measured with open-circuit spirometry. **Results** His incremental PPO was 300W, 105W & 190W with 2L, A, & N, respectively. His VO2max (3.74, 3.78 & 3.71 l\*min<sup>-1</sup>) was remarkably constant during both 2L and 1L exercise, potentially secondary to a very much 'whole body' style of riding with both A & N legs. His VO2@VT (2.65, 2.30 & 2.40 l\*min<sup>-1</sup>) & RCT (2.87, 2.75 & 2.75 l\*min<sup>-1</sup>) were also remarkably similar, suggesting that one of his adaptations to his CP was to support his A leg by use of accessory muscles. His gross efficiency (GE) at 50% of the leg specific PPO was 18.4% (2L), 9.3% (A) & 12.2% (N). **Discussion** In a formerly elite, but still well-trained runner with CP, there was little evidence of a central oxygen transport limitation to 1L exercise capacity, potentially because his adaptation to his CP was to make extensive use of accessory muscles. Normally the VO2max during one leg exercise is 70% of 2L VO2 max (Davies & Sargeant, 1974), versus 100% with A and N 1L exercise. However, the reduction in PPO with the A leg appeared to be attributable to a marked reduction in GE during exercise with the A leg. Likewise, the normal expectation with 1L versus 2L exercise is a decrease in GE from ~19% to ~16%. Compared to able bodied persons our subject uses more accessory muscles, resulting in a decrease in GE and increase in aerobic power. **Reference** Davies, C.T.M., Sargeant, A.J. (1974). Physiological responses to one-and two-leg exercise breathing air and 45% oxygen. *JAP*, 2, 142-148.

**DESCRIPTION AND FIRST INSIGHT INTO THE EFFECTIVENESS OF AN EXERCISE-BASED PHYSICAL THERAPY PROGRAM FOR PATELLAR TENDINOPATHY PATIENTS AFTER PLATELET-RICH PLASMA INJECTION: A CASE-SERIES STUDY**

van Ark, M., van den Akker-Scheek, I., Meijer, L.T.B., Zwerver, J.

*University Medical Center Groningen*

**Introduction** Patellar tendinopathy is a common and hard to treat injury. A PRP injection followed by a physical therapy program seems promising for the treatment of patellar tendinopathy in the degenerative phase. However, descriptions of physical therapy programs are often limited and incomplete (van Ark et al, 2011). The first aim of this study was to describe a post platelet-rich plasma (PRP) injection, exercise-based physical therapy program, based on current evidence and expert opinion. The second aim was to investigate feasibility and provide a first insight into the effectiveness of combining a PRP injection with subsequently the physical therapy program. **Methods** Five patellar tendinopathy patients (six knees) in the degenerative phase received a PRP injection followed by a specifically designed

physical therapy program. The main outcome measures were VISA-P score and pain ratings on a VAS during ADL and functional tests. These were assessed before treatment (baseline) and 6, 12, 16 and 26 weeks after injection. Results Five of the six tendons showed an improvement of at least 30 points on the VISA-P after 26 weeks. The VISA-P score increased from a mean of  $49.3 \pm 12.7$  at baseline to  $80.1 \pm 20.4$  at 26 weeks follow-up. Friedman tests revealed statistically significant differences for all outcome measures between the five measurements ( $p=0.004$  for VISA-P). Post-hoc Wilcoxon Signed-Rank tests, with Bonferroni correction, did not show statistically significant differences between baseline and a follow-up measurement. Close to significant results were found 12, 16 and 26 weeks after injection. Discussion This is the first study to extensively describe a physical therapy program after PRP injection for patellar tendinopathy patients. Muscle strength, endurance, power and retraining sport-specific function form the basis for the program aimed at improving the load capacity of the knee. The combination treatment investigated in this study is feasible and seems to be promising for patients in the degenerative phase of patellar tendinopathy. The combination of treatment modalities seems essential because healing of a tendinopathic tendon is interplay of mechanical and biological factors (Khan & Scott, 2009; Rees et al., 2009). To be able to compare results of future research, this physical therapy program can be used in patellar tendinopathy patients after PRP injection. van Ark M, Zwerver J, van den Akker-Scheek I. ## PREDICTION OF PEAK OXYGEN UPTAKE FROM PEAK POWER OUTPUT DURING ARM CRANKING IN ABLE-BODIED AND PARAPLEGIC INDIVIDUALS

Al-Rahamneh, H., Eston, R.

*University of Jordan, University of South Australia*

Prediction of Peak Oxygen Uptake from Peak Power Output during Arm Cranking in Able-bodied and Paraplegic Individuals Al-Rahamneh, H.1, Eston, R. 2 1: Faculty of Physical Education, University of Jordan 2: School of Health Sciences, University of South Australia Introduction Peak oxygen uptake ( $\dot{V}O_{2peak}$ ) is a valuable indicator of cardiorespiratory fitness (1) and a strong predictor of death in patients with heart disease as well as in all-cause of deaths (2). This study aimed to assess the validity of predicting  $\dot{V}O_{2peak}$  from peak power output (POpeak) during arm cranking exercise using the equation described by the ACSM (i.e.,  $\dot{V}O_2 \text{ ml.kg}^{-1}.\text{min}^{-1} = 3 \times \text{work rate (kg.m.min}^{-1})/\text{body mass (kg)} + 3.5 \text{ ml.kg}^{-1}.\text{min}^{-1}$ ). Methods Thirteen able-bodied men ( $27.2 \pm 4.3$  y;  $174 \pm 5$  cm;  $74.5 \pm 11.8$  kg) and 13 paraplegic men ( $31.6 \pm 5.8$  y;  $170 \pm 6$  cm;  $63.7 \pm 11.1$  kg) took part in the study. Each participant completed an arm cranking graded exercise test (started at 30 W and increased by 15 W every 2 min) and a ramp exercise test (started at 0 W and increased by 15 W.min<sup>-1</sup>) designed to measure  $\dot{V}O_{2peak}$ . All exercise tests were performed on the same Lode arm ergometer. The midpoint of the ergometer was set at shoulder level and the distance was set to allow slight flexion in the elbow when the arm was extended. Participants were asked to keep the pedal cadence at 60 rpm. On-line respiratory gas analysis occurred every 10 s in both tests. Results Able-bodied and paraplegic participants achieved a higher POpeak during the ramp (136 cf. 106 W) compared to the GXT (118 cf. 92 W), respectively. For the GXT, there was no significant difference between measured  $\dot{V}O_{2peak}$  (34 cf. 31 ml.kg<sup>-1</sup>.min<sup>-1</sup>) and predicted  $\dot{V}O_{2peak}$  from POpeak (33 cf. 30 ml.kg<sup>-1</sup>.min<sup>-1</sup>) for able-bodied and paraplegic participants, respectively. However,  $\dot{V}O_{2peak}$  predicted from POpeak during the ramp test (38 cf. 34 ml.kg<sup>-1</sup>.min<sup>-1</sup>) was higher than measured  $\dot{V}O_{2peak}$  (33 cf. 29 ml.kg<sup>-1</sup>.min<sup>-1</sup>) for able-bodied and paraplegics, respectively. Discussion The higher POpeak values observed during the ramp exercise test may be attributed to the more frequent increase in the work rate compared to the GXT. The significantly higher predicted  $\dot{V}O_{2peak}$  from the ramp exercise test for both the able-bodied and paraplegic participants in this study is not surprising. The ACSM equations were derived during steady-state sub-maximal aerobic exercise. Thus, and as reported by the ACSM (2006), they are only appropriate for predicting the  $\dot{V}O_2$  during steady-state, sub-maximal aerobic exercise. The high  $\dot{V}O_{2peak}$  predicted from the ramp protocol, further confirms that the  $\dot{V}O_2$  is overestimated when it is based on non-steady-state exercise conditions, when the contribution from anaerobic metabolism is large (1). ## LEARNING WITH THE NUDRIVE LEVER-PROPELLED WHEELCHAIR: THE EFFECTS OF 1 DAY LEARNING ON MECHANICAL EFFICIENCY AND PUSH FREQUENCY.

Jaspers, E.G., Hettinga, F.J., Monden, P., Van der Woude, L.H.V.

*University of Groningen*

Learning with the NuDrive lever-propelled wheelchair: the effects of 1 day learning on mechanical efficiency and push frequency. Jaspers EG, Hettinga FJ, Monden P, Van der Woude LHV Center for Human Movement Sciences, University Medical Center Groningen, University of Groningen, The Netherlands Purpose: Previous research has shown that lever-propelled wheelchairs are more efficient but also less practical than hand-rim propelled wheelchairs (van der Woude et al., 2001). The NuDrive lever-system tried to make lever propulsion more practical by designing the levers lightweight and detachable. However experience shows that people need some time to get acquainted with the NuDrive. Therefore, the present study investigates 1 day of learning lever-propulsion with the NuDrive. Methods: 15 able-bodied participants (age: 24.1 (2.4) yr) were randomly assigned to an experimental (EXP, N=7) and control (CON, N=8) group. EXP performed 7 low-intensity NuDrive practice trials on a treadmill (0.22 W/Kg, 1.11 m/s). Each trial consisted of 2 blocks of 4 minutes with 2 minutes of rest in-between. Energy expenditure was calculated from oxygen uptake and respiratory exchange ratio (Garby L & Astrup A, 1987). Gross and net mechanical efficiency (GME and NME), push frequency, RPE and local perceived discomfort (LPD) were assessed during a pre- and post-test (0.22 W/Kg, 1.11 m/s) consisting of 3 blocks of 4 minutes with 2 minutes of rest in-between. Push frequency was measured using accelerometry. Groups were compared using a Repeated Measures Anova ( $p < 0.05$ ). Results: GME and NME improved in EXP compared to CON (GME EXP vs. CON pre: 4.00 (0.62) vs. 4.25 (0.68); post: 4.76 (0.60) vs. 4.15 (0.60); NME pre: 5.23 (1.00) vs. 5.45 (1.10); post: 6.60 (1.01) vs. 5.29 (0.92)). Push frequency (push/min) showed a small downwards trend in both EXP and CON (EXP vs. CON pre: 68.1 (25.6) vs. 77.8 (13.2); post: 55.7 (18.0) vs. 70.3 (14.5)). RPE and LPD did not differ between groups. Conclusions: The present study is the first that focuses on learning mechanisms in lever-propelled wheelchairs. Efficiency improves with practice, and a clear learning effect was present after 1 day of practice with the NuDrive. Decreasing push frequency might attribute to this learning mechanism. Based on the present results a proper learning period is advised before using or evaluating the NuDrive system as an alternative for hand-rim propulsion. **THE EFFECTIVENESS OF SWIMMING FOR BREAKING THE VICIOUS CYCLE OF DECONDITIONING IN CEREBRAL PALSY.**

Declerck, M., Daly, D., Verheul, M., Sanders, R.H.

*University of Edinburgh*

THE EFFECTIVENESS OF SWIMMING FOR BREAKING THE VICIOUS CYCLE OF DECONDITIONING IN CEREBRAL PALSY. Declerck, M.1, Daly, D.2, Verheul, M.1, Sanders, R.H.1 1: University of Edinburgh (Edinburgh, UK), 2: KULeuven (Leuven, Belgium) Introduction Youth with Cerebral Palsy (CP) are considerably less active and have lower physical fitness than their able-bodied peers. This leads to a cycle of deconditioning resulting in deterioration of health and physical function and subsequently more inactivity. Influencing and contributing to this vicious cycle are different factors of the International Classification of Functioning, Disability and Health (ICF) such as pain, coordination, walking, fatigue, quality of life (QoL), self-esteem and functional independence. The implementation of community-based exercise and sport programs into the therapy program can be a solution for breaking and reversing this cycle. Swimming is a community-based activity that can be introduced at a young age. Therefore, the aim of this study was to investigate the effect of a swimming intervention on the factors contributing to the vicious cycle of deconditioning of youth with CP. Methods Fifteen children aged 7 to 17 years and diagnosed with CP participated in a randomized controlled trial comparing a swimming intervention (10 weeks, 2/wk, 30 to 60 minutes) to no extra therapy. The primary outcome measures were pain, fatigue, walking capacity and coordination. Secondary outcome measures were functional independence, self-esteem, QoL and swimming skills. All measurements were taken prior to and after the intervention and after a five week follow-up period. Results A pilot study (n=7) showed a significant improvement ( $p < 0.0001$ ) of 7% in swimming skills after a 6-week intervention with a participation level of 89%. Non-significant increases were found in walking speed (11%), manual performance speed of the dominant (9%) and non-dominant (14%) hand, gross motor function (2%). A non-significant decrease of pain (6%) was also noted. The main intervention was in progress at the time of abstract submission. Results will be presented at the ECSS conference. Participation level to the program was 95%. Discussion The results of the pilot study suggest that the 10-week swimming intervention may have positive effects on various aspects of functioning in children with Cerebral Palsy. If the 10-week swimming intervention improves different contributing factors of the vicious cycle, it can encourage specialists, physiotherapists and parents to promote participation in physical activities in the community and it could potentially replace part of the tiresome intensive therapy program with swimming in order to increase adherence to therapy and physical activity in adolescence and adulthood.

**SURFACE ELECTROMYOGRAPHIC ACTIVITY OF VASTUS INTERMEDIUS MUSCLE DURING QUADRICEPS SETTING AND KNEE EXTENSION EXERCISE**

KAGAYA, Y., Nakada, T., Endo, H.

*Showa University*

Introduction The vastus intermedius (VI) muscle is important for the knee extensor mechanism, but its activation remains unclear because it is located deep in the rectus femoris (RF) muscle region, making activity recording using surface electromyography (EMG) nearly impossible. Watanabe & Akima (2010, 2011) recently developed a technique to record VI muscle activation using surface EMG. The aim of this study was to determine VI activation during quadriceps setting and knee extension exercises. Methods Thirteen healthy male volunteers participated in this study. Their mean age was  $21.8 \pm 1.1$  years, and their height and weight were  $171.9 \pm 4.6$  cm and  $61.6 \pm 4.7$  kg, respectively. The subjects performed quadriceps setting in three different positions (supine, long sitting, and standing). Surface EMG data was recorded for VI, vastus medialis (VM), vastus lateralis (VL), and RF muscles. In addition, subjects performed maximal voluntary contractions (MVC) at two hip and three knee joint angles during isometric knee extensions. The two hip joint angles were  $90^\circ$  and  $30^\circ$ , and the three knee joint angles were  $75^\circ$ ,  $45^\circ$ , and  $15^\circ$ . Each surface EMG recording was found via integration over a 2-second time period and was indicated as %MVC. Results During quadriceps setting, VI activity while in the supine position and standing was significantly higher than that while long sitting ( $p < 0.05$ , and  $p < 0.01$ , respectively). VM and VL activity while standing was significantly higher than that while long sitting and in the supine position ( $p < 0.05$ , and  $p < 0.01$ , respectively). During isometric knee extension, VI activity while a knee joint angle of  $75^\circ$  was significantly higher than that at  $45^\circ$  and  $15^\circ$  for both hip joint angles ( $p < 0.05$ , and  $p < 0.01$ , respectively). RF activity at a hip joint angle of  $90^\circ$  was significantly higher than at  $30^\circ$  for knee joint angles of  $75^\circ$  and  $45^\circ$  ( $p < 0.05$ , and  $p < 0.01$ , respectively). Discussion The important finding in this study is that VI muscle activity over various knee and hip joint angles is not consistent with that of quadriceps femoris muscle groups. Thus, suggesting that RF activity as a two-joint muscle depends on the hip joint angle, and VI activity as a one-joint muscle depends on the knee joint angle. VI activity at the flexed knee position was higher than that at the extended knee position, and thus differed from other quadriceps femoris muscle groups. The results of our study may help in designing a rehabilitation and exercise program for patients with knee dysfunction. References Watanabe K, Akima H. (2010). *J Electromyogr Kinesiol*, 20, 661-666. Watanabe K, Akima H. (2011). *Scand J Med Sci Sports*, 21, 412-420.

**EFFECTS OF LOWER LIMB STRENGTHENING ON BALANCE AND FUNCTION IN PERSONS WHO SUFFERED A STROKE**

Fernandes, B.1, Batista, F.2, Beckert, P.2, Evangelista, I.2, Ferreira, M.J.2, Prates, L., Sérgio, J.S.1

1: *ESTeSL (Lisbon, Portugal)*, 2: *HFF (Amadora, Portugal)*

Introduction Postural control dysfunctions are one of the most common and devastating consequences of a stroke interfering with function and autonomy (Shumway-Cook & Woollacott, 2011). Neurological physiotherapy plays a central role in the recovery of movement and posture, however it is necessary to study the efficacy of techniques that physiotherapists use to treat these problems (Pollock et al., 2005). The aim of this study was to investigate the effects of a physiotherapy intervention program, based on oriented tasks and strengthening of the affected lower limb, in balance and functionality of individuals who have suffered a stroke. Methods The participants were 16 male subjects, aged 50 to 65 years, who suffered a single stroke, in the middle cerebral artery territory, during the month prior to the enrollment in the study. Subjects were randomly allocated to one of two groups: experimental group (N=9) or control group (N=7). Experimental group performed an intervention program based on oriented tasks plus strengthening of the affected lower limb. Control group followed a program based on oriented tasks only. Outcome measures were Berg Balance Scale, Modified Barthel Index and Modified Ashworth Scale. Both groups completed 4 treatment sessions per week, during 12 weeks. Results At the end of 12 weeks the experimental group had significantly greater increases in balance compared with the control group. Both groups improved function levels, muscle tone did not increase in any of the groups and there was a strong positive correlation between balance and function. Discussion The results suggest that the physiotherapy intervention program with oriented tasks and strengthening of the affected lower limb, seems to be more effective in increasing balance than a program based on oriented tasks only. It is important to point out that these individuals

did not show increase in muscle tone in the affected lower limb. Function levels also show an increase, however it is not significantly different from the increase produced by the control program. Positive correlation between balance and functionality suggests the importance of early starting of physiotherapy intervention programs, focused on treating balance dysfunctions after stroke, in order to promote autonomy and functional independence. References Pollock, A., Baer, G., Pomeroy, V., & Langhorne, P. (2005). Physiotherapy treatment for the recovery of postural control and lower limb function following stroke. Cochrane Review. ### MEASURING SWEAT SODIUM CONCENTRATION USING THE REGIONAL ABSORBENT PATCH METHOD: A ROBUST FIELD TEST

Dziedzic, C.E.1,2, Ross, M.L.1,3, Dunn, P.2, Slater, G.2, Burke, L.M.1

1: Australian Institute of Sport (Canberra, Australia), 2: The University of the Sunshine Coast (Maroochydore, Australia), 3: Edith Cowan University (Joondalup, Australia)

**Introduction** It has been suggested that sodium be included in individualized hydration plans (Maughan & Shirreffs, 2008). While more precisely measured by whole-body washdown technique (Shirreffs & Maughan, 1997), the regional absorbent patch method (RAPM) provides a practical approach to undertaking sweat testing in the field. The aim of this study was to investigate the variability of measurements of sweat sodium concentration considering potential differences in RAPM protocols. **Methods** The RAPM (Tegaderm+Pad) was used to collect sweat samples from the forearms, chest, scapula and thigh of 12 trained cyclists during four standardised cycling time trials. The sweat collection protocol was employed to allow site selection, including estimation of results [left and right forearm average or weighted four-site equation (Patterson et al., 2000)] and application time (30 vs. 60 min) to be investigated in either hot (32°C, 30-40% r.h.) or thermoneutral (TN) (21°C, 50-60% r.h.) conditions. Single measure analysis of sodium concentration was conducted immediately by ion-selective electrode method (Hitachi, Model 911). **Results** A repeated measures analysis of variance revealed no significant effect of application time ( $p=0.24$ ) or environmental testing conditions ( $p=0.11$ ) on sweat sodium concentration results (TN30 min:  $59 \pm 24$  vs. TN60 min:  $61 \pm 22$  mmol/L; Hot30 min:  $64 \pm 24$  vs. Hot60 min:  $67 \pm 26$  mmol/L). No interaction was detected between application time and environmental condition ( $p=0.77$ ). A paired t-test highlighted a significant difference ( $p<0.05$ ) in estimates of sweat sodium concentration when calculated from forearms alone ( $66 \pm 24$  mmol/L) compared to using a four-site equation ( $71 \pm 21$  mmol/L). **Discussion** This study shows a significant difference in the estimation of sweat sodium concentrations depending on the number of sites included in result interpretation. Nevertheless, RAPM appears to be a robust field test, withstanding protocol variations in relation to sweat rates (achieved via changes in thermal load in different environmental conditions) and sweat collection time. Care should be taken when deciding on which sites to include in testing, as the sampling protocol will determine which estimation of sweat sodium concentration can be made (i.e. forearm average or four-site equation). **References** Maughan R, Shirreffs S. ### INFLUENCE OF FITNESS HABITS ON THE PHYSIOLOGICAL CONDITION OF FACIAL SKIN

Aoki, R., Suwabe, K., Hyodo, K., Soya, H.

UNIVERSITY OF TSUKUBA

**Introduction** In modern society, stress is inevitable. A recent report indicated that chronic stress may increase the risk of developing various psychosomatic diseases, including acne vulgaris on the face. Since most women care about cosmetic problems, it is interesting to study how fitness habits affect the physiological condition of facial skin. Sebaceous hyperplasia is one of the main causes which form acne vulgaris. The stress regulation which brain function mediated involves sebaceous secretion. Recent studies have suggested that a person with a lot of sebum secretions showed that the right prefrontal cortex dominates the regulation of the stress response system, including the hypothalamic-pituitary-adrenal axis. And, it is thought that exercise may have a positive effect on skin health. Therefore, we hypothesized that people with good fitness habits are more stress-resistant than those who are sedentary, and that they also have better skin condition. The purpose of this study was to examine the influence of different fitness habits on physiological skin conditions. We especially focused on lipid metabolism and moisture conditions of facial skin as reflections of chronic stress response. **Methods** A total of 79 healthy female college students were investigated. We divided subjects into three groups, high fitness group, medium fitness group, and sedentary group, by using the International Physical Activity Questionnaire (IPAQ). The experimental environment was air-conditioned and the temperature and humidity were maintained at approximately 22 degrees celsius and 50%, respectively. After washing each subject's face, the sebum level, moisture level, pH, and trans-epidermal water loss (TEWL) were measured by Vapometer **Results** The amount of physical effort was revealed to be intensity-dependent ( $p < 0.001$ ). For sebum, the high fitness group was significantly lower than other two groups ( $p < 0.05$ ). Both fitness habit groups had lower pH values than did the sedentary group, and the medium fitness group had the lowest value. **Discussion** These results demonstrate that subjects with high-intensity fitness habits have better skin condition compared with the other groups, since both sebum and pH were lowered in high-intensity fitness compared to those of sedentary group. The mechanism behind it is uncertain, although the small amount of sebum in hi-intensity fitness might be due to their higher stress resistance; animals underwent chronic intense exercise training have been shown to be resistive to any of psychological stress (Watanabe et al., 1992). Thus, the amount of sebum secretion could be controlled with certain exercise regimen. Collectively, it appears that skin condition improves with high-intensity training and this may shed light on possibilities for new beauty regimens. 1992) **References** Tanida M, Katsuyama M, Sakatani K. ### SMOKING HABITS OF BRITISH ARMY TRAINEES AND THE INFLUENCE OF SMOKING ON PHYSICAL FITNESS PARAMETERS

Siddall, A., Bilzon, J., Thompson, D., Greeves, J., Stokes, K.

University of Bath

Smoking habits of British Army trainees and the influence of smoking on physical fitness parameters Siddall, A.1, Bilzon, J.1, Thompson, D.1, Greeves, J.2, Stokes, K.1. 1: Department for Health, University of Bath, BA2 7AY, UK. 2: Department of Occupational Medicine, Army Recruiting and Training Division, SN9 6BE, UK Cigarette smoking adversely effects long-term health and is associated with reduced cardiorespiratory fitness. Smoking has also been reported to impair physical performance adaptations and increase injury risk during military

training. Despite this, smoking prevalence in military populations has typically been observed to be higher than in the general population. This study aimed to examine smoking characteristics of British Army infantry trainees and the potential effect of habitual smoking on physical fitness parameters. A validated lifestyle questionnaire was administered to trainees (aged 18-33) at entry to training (n=2087) to determine smoking characteristics. In a sub-sample (n=1182), measures of physical fitness routinely conducted in weeks 1, 14 and 24 of training were also obtained. A linear mixed model was used to identify any differences over time between habitual smokers (S) and non-smokers (NS) in 2.4 km run time, and the number of press-ups and sit-ups performed in two minutes. At entry to training the population comprised habitual smokers (48%), occasional smokers (5%), former smokers (9%) and non-smokers (37%) (1% non-responders). The sub-sample used in physical performance analysis was comprised solely of habitual smokers (58%) and non-smokers (42%). Estimated marginal means for weeks 1, 14 and 24 of training showed that NS performed significantly better than S in press ups (NS: 48 (0.6), 55 (0.6), 57 (0.7); S: 44 (0.5), 52 (0.5), 55 (0.6);  $P < 0.001$ ), sit ups (NS: 57 (0.5), 62 (0.6), 66 (0.6); S: 54 (0.4), 61 (0.5), 63 (0.5);  $P < 0.001$ ) and 2.4 km run time (NS: 612 (2), 579 (2), 567 (2) s; S: 621 (2), 586 (2), 571 (2) s;  $P < 0.01$ ). Physical performance improved significantly as a result of training irrespective of smoking group ( $P < 0.001$ ) but no interaction effects were evident ( $P > 0.05$ ). Smoking prevalence in British infantry trainees is substantially higher than both the British general public and values typically reported in similar non-infantry military populations. Twenty-four weeks of military training resulted in similar significant improvements in physical fitness parameters irrespective of smoking status. However, habitual smokers were significantly less physically fit than non-smokers, both at entry and throughout infantry training. Ultimately, poorer physical fitness might hinder performance in future occupational tasks.

## WORK INTENSITY AND ENERGY EXPENDITURE OF ENDURO- CYCLING RACE IN RECREATIONAL CYCLISTS

Nakagata, T., Murade, S., Fukao, K., Katamoto, S., Naito, H.

*Juntendo University*

**Introduction** Recently, the enduro-cycling race has become increasingly popular in Japan. Previous studies have estimated the work intensity and energy expenditure (EE) during competitive road race in professional cyclists based on heart rate (HR). However, the available data on the work intensity and EE during enduro-cycling race in recreational cyclists are very few. Therefore, we aimed to clarify the work intensity and EE during enduro-cycling race. **Methods** Ten healthy Japanese male recreational cyclists (age: 25-63 y-o, height: 172.4 ± 5.4 cm, mass: 63.4 ± 6.1, Vo<sub>2</sub>max: 52.9 ± 6.8 ml/kg/min) participated in this study. They had trained 2-3 days/wk, and cycled over 120-240 km/wk. Each subject raced over 2-4 hrs in an enduro-cycling race held in a circuit course. Blood lactate (LA) and glucose levels were measured before and after the race, and HR was continuously recorded (Polar) throughout the race. The EE during the race was calculated from the HR-Vo<sub>2</sub> relationship pre-determined in a laboratory before the race. **Results** The mean total distance covered and cycling speed were 126.7 ± 40.7 km and 36.3 ± 3.2 km/h, respectively. The mean HR during the race was 158.9 ± 10.6 bpm corresponding to a work intensity of 83.3 ± 6.1 % Vo<sub>2</sub>max. The estimated EE during the race was 2880.6 ± 1037.8 kcal, ranging between 1509-4125 kcal depending on the total distance covered. The energy cost was 0.36 ± 0.04 kcal/kg/km, which was relatively consistent regardless of distance covered. LA and glucose levels after the race increased slightly from 1.8 to 2.2 mmol/L and 108.4 to 118.3 mg/dl, respectively. However, the increases from the pre-race values were not significant, and were not related to the total distance covered. This result was not agreed by Costill (1970), who reported an inverse relationship between LA and distance covered during an open-distance running). **Discussion** A previous study estimated that work intensity during a road cycling race was approximately 70 % Vo<sub>2</sub>max for professional cyclists<sup>2</sup>). In the present study however, the work intensity recorded during enduro-cycling race for recreational cyclists was 83.3 % Vo<sub>2</sub>max. This variation could be attributed to the difference in race profile and cycling skills, and imply that enduro-cycling race in recreational cyclists might impose a higher relative load on their cardiorespiratory functions than that imposed during a competitive road race in professional cyclists **Conclusion** Work intensity of enduro-cycling race in Japanese recreational cyclists were estimated to be 83.3 % Vo<sub>2</sub>max. The energy expenditure varied between 1509-4125 kcal depending on total distance covered. **Reference** 1) Costill DL, J Appl Physiol, 1970 2) Benjamin FZ, Med Sci Sports Exer. 1999

#### INDIVIDUAL VARIABILITY IN HEART RATE RECOVERY AFTER STANDARDIZED SUB MAXIMAL EXERCISE

van der Does, H.T.D.

*Hanze University of Applied Sciences*

**Individual variability in heart rate recovery after standardized sub maximal exercise** Does, H.T.D van der<sup>1,2</sup>, Brink M.S.<sup>1,2</sup>, Visscher, C.2& Lemmink K.A.P.M.<sup>1,2</sup> **1**School of sport studies, Hanze University of Applied Sciences (Groningen, Netherlands)**2**Center for Human Movement Sciences, UMCG (Groningen, Netherlands) **Introduction** To optimize performance, coaches and athletes are always looking for the right balance between training load and recovery. Therefore, closely monitoring of athletes is important. Heart rate recovery (HRR) after standardized sub maximal exercise has been proposed as a useful variable to monitor (Lamberts et al., 2004). However, it is well known that heart rate, next to biological variability, is influenced by several factors such as training load and psychosocial stress. So, the purpose was to look at individual variability in HRR from one week to another using the heart rate interval monitoring system (HIMS). **Methods** Eight elite Dutch female indoor hockey players (age: 23.9±3.91yr, length: 155.0±7.01cm, weight: 56.6±6.16kg) completed the HIMS two weeks in a row (Lamberts et al., 2004). The heart rate at the end of the last stage (HREnd) was determined and the HRR was calculated one minute after the end of the last stage. Furthermore, training load and psychosocial stress and recovery were monitored using the Foster-method (1998) and the RESTQ-Sport (Nederhof et al., 2008), respectively. **Results** A strong correlation was found between the HREnd from one week to the other ( $r=0.984$   $p < 0.01$ ). No correlation was found for the HRR after one minute between the first and second week. Comparison of the means of HREnd and HRR revealed a significant ( $p < 0.01$ ) difference between the mean HRR of the first week ( $M= 57.24$ ,  $SD=14.05$ ) compared to the second week ( $M=54.43$ ,  $SD=11.12$ ). Different individual patterns were also found for training load and psychosocial stress and recovery in these weeks. **Discussion** HREnd shows no difference over the two weeks, illustrating that athletes reach the same intensity at the end of the test each time. However, in contrast to earlier research (Borresen et al., 2007), HRR in our study shows

clear differences over two weeks. Individual differences in training load and psychosocial stress and recovery may explain these differences. So, when using the HRR regularly to monitor athletes, it is important to take training load and psychosocial stress and recovery into account before interpretation. ## EVALUATION OF A 2.000 M PERFORMANCE PREDICTION MODEL FOR ELITE ROWERS BASED ON ANAEROBIC THRESHOLD AND MAXIMUM SPRINT POWER

Falke, A.K., Hanakam, F., Grabow, V., Ferrauti, A.

*Ruhr-Universität Bochum*

EVALUATION OF A 2.000 M PERFORMANCE PREDICTION MODEL FOR ELITE ROWERS BASED ON ANAEROBIC THRESHOLD AND MAXIMUM SPRINT POWER Falke, AK.1, Hanakam, F.1, Grabow, V.2, Ferrauti, A.1. Ruhr-University Bochum, Department of Coaching Science (Bochum, Germany), 2. Technical University Dortmund, Department of Sport and Sport Science (Dortmund, Germany) Introduction In elite rowing a 2.000 m maximum test performed on a rowing ergometer is generally used for monitoring individual physical abilities and team selection. Due to the high physical and psychological load and lactate accumulation of such tests a regular examination isn't recommendable. Different performance prediction models based on various anthropometric and metabolic parameters have been proposed (Mäestu et al. 1999, Ingham et al. 2002, Riechman et al. 2002). Aim of the study was the development and evaluation of a 2.000 m performance prediction model for elite rowers based on anaerobic threshold and maximum sprint power. Methods 18 male and 7 female elite rowers performed each a 2·8 min submaximal incremental test for the determination of power at 4 mmol·l<sup>-1</sup> blood lactate level (P4mmol·l<sup>-1</sup>) and a 20 s sprint for the determination of maximum sprint power (P20s) and maximal lactate formation rate (VLamax). The 2.000 m race simulation time (T2.000) was measured separately in the course of a team selection competition. Using linear (multiple) regression analysis various combinations of parameters (also for gender specific subgroups) were tested for the prediction of T2.000. Results The prediction model based on the parameter combinations P4mmol·l<sup>-1</sup> and P20s and the combination P4mmol·l<sup>-1</sup>, P20s and VLamax revealed the most precise predictions of T2.000 (with R<sup>2</sup> = 0.97 and R<sup>2</sup> = 0.98, respectively). The standard deviation SD of residuals for both prediction models was 4.6 s and 3.8 s, respectively, for the entire group. Gender specific subgroups revealed a standard deviation SD of 4.7 s and 3.2 s, respectively, for the male and 2.7 s in both models for the female subjects. The distribution of residuals for both prediction models considering the entire group displayed a Gaussian distribution with a standard deviation  $\sigma$  of 3.5 s for the parameter combination P4mmol·l<sup>-1</sup> and P20s and  $\sigma$  of 3.8 s for the combination P4mmol·l<sup>-1</sup>, P20s and VLamax. Discussion The combination of a submaximal incremental test and a maximum sprint test allows for a precise prediction of the individuals 2.000m race time. We recommend the test procedure of our prediction model for regular examination of the athlete's ability. To further improve the prediction quality or enable a gender-specific model additional investigations with a larger and more diverse sample are needed. ## THE INFLUENCE OF ANTHROPOMETRIC AND FITNESS COMPONENTS ON YOYO INTERMITTENT RECOVERY TEST 2 RESULTS

Schwindling, S.1, Faude, O.1,2, Görgen, C.1, Kraushaar, J.1, Meyer, T.1

*1: Saarland University, 2: University of Basel*

The YoYo intermittent recovery test 2 (YYIRT2) has been developed to determine the ability to recover from repeated anaerobic exercise in soccer players (Bangsbo et al., 2008). In this regard, the YYIRT2 may give additional information beyond typical tests of aerobic capacity. The present study aimed at analyzing the degree by which the YYIRT2 result can be predicted from anthropometric parameters and basic fitness components in amateur soccer players. 43 youth and amateur soccer players (19.4±3.2y, 177.6±7.8cm, 71.4±10.6kg) were tested on three occasions separated by one week. On the first (familiarization) and the last test day, the subjects conducted the YYIRT2 and one hour later a repeated sprint ability test (RSA, 10x30m with 30s active rest). On the second test day players carried out a 30m sprint (3 repetitions, 2 min rest in between), vertical jump tests (counter movement jumps, drop jumps), an agility test (20 m with 6 sharp turns), and an incremental running test (MAX, starting at 10 km/h, increase 2 km/h every 3 min) to determine the individual anaerobic threshold (IAT) and the maximal running velocity (vmax). For RSA the fatigue index (FI) and the percentage decrement score (Sdec, Girard et al., 2011) were calculated. Subjects ran on average 652±173m during the YYIRT2 and had a vmax of 17.4±1.0 km/h in MAX. A significant correlation of YYIRT2 distance was found with body fat (r=0.38), sprint (0-30m: r=-0.47, 0-10m: r=-0.41, 10-30m: r=-0.49), RSA (0-30m: r=-0.42, 10-30m: r=-0.51), IAT (r=0.57) and vmax (r=0.61). For all other parameters no significant correlation (-0.30<r<="" p=""></r

## TETHERED SWIMMING AS AN ESTIMATOR OF ANAEROBIC CAPACITY

Morouco, P.1,2, Neiva, H.2, Marinho, D.2,3, Marques, M.C.2,3

*1: IPL-CIMH (Leiria, Portugal), 2: CIDESD (Portugal), 3: UBI (Covilhã, Portugal)*

Introduction Relationships between tethered swimming (TS) and swimming performance have been previously studied. Nevertheless, most of these approaches studied heterogeneous groups. West et al. (2005) stated that to remain stationary, the swimmer relies mostly on fast glycolytic muscle fibers increasing the production of lactic acid. This was not verified in a recent study, reinforcing the importance of more studies under this scope. Methods 3 homogeneous groups (variation of Personal Best 100-m Free < 2.5%) of 8 male swimmers (G1: 13.0±0.7y-of-age, 54.5±3.9kg, 164.8±6.8cm; G2: 14.9±0.6y-of-age, 60.7±6.9kg, 172.1±6.6cm; G3: 19.9±1.7y-of-age, 75.6±7.6kg, 180.6±10.4cm) took part in the study. Maximum 30-s front crawl TS assessed maximum (Fmax) and mean force (Fmean). One day after, subjects performed 2 maximal front crawl swims (FS) with an underwater start (100- and 50-m) to obtain swimming velocity (v100 and v50). Blood samples from earlobe were taken after warm-up and at the terminus of the tests allowing the estimation of  $\delta$ [La<sup>-</sup>]. After Shapiro-Wilk normality test, parametric procedures were applied. The statistical significance was set at p<0.05. Results TS variables were higher in G3 than G2, than G1 (Fmax - 316.7±27.3N > 260.7±27.4N > 221.8±19.9N, p<0.05; Fmean - 126.6±10.9N > 102.9±11.3N > 93.9±12.1N, p<0.001). In  $\delta$ [La<sup>-</sup>] higher differences were obtained between TS with 100-m (p<0.0001) than with 50-m FS (p<0.05). Fmax presented a high correlation with v50 in G3 (r=0.87, p<0.001). In G2 relationships were observed between v50 with Fmax (r=0.77, p<0.001) and Fmean (r=0.73, p<0.05). Fmean correlated significantly with v50 (r=0.63, p<0.05) and v100 (r=0.68, p<0.05) for G1.  $\delta$ [La<sup>-</sup>] presented moderate to high (r=0.55-0.86) correlations both with TS values and FS velocities. Discussion As expected upper level swim-

mers presented superior values of force exerted in water, corroborating the validity of the methodology used. In groups alike,  $\delta[La-]$  in TS did not exceed the values of FS, contrasting the statement of West et al. (2005). For the different groups, correlations between force parameters and performance were estimated and differ according to age, force parameter and distance swam. These data could corroborate the idea that TS may be useful to discern between "sprinters" and "distance" swimmers profiles. The associations between  $\delta[La-]$  with force exerted in water and swimming velocities support the idea that the capacity to obtain higher values of force production and swimming velocities, is related with an enhanced production of energy through the glycolytic system. Our data suggest that TS may be useful to monitor and evaluate anaerobic training. References West S, Drummond M, VanNess J., Ciccolella M. (2005). J. Strength Cond. Res, 19(4),772-776.

### VALIDITY OF A REPEATED-SPRINT ABILITY TEST DERIVED FROM MATCH TIME-MOTION ANALYSIS IN YOUNG SOCCER PLAYERS

Jabes, M.1, Chamari, K.2, Wong, D.P.3, Dellal, A.4, Castagna, C.5, Ahmaidi, S.1

1:PJVU (Amiens, France), NCMSS (Tunis, Tunisia), HKIE (Hong Kong), OLSO (Lyon, France), FTBL (Florence, Italy)

Introduction It has been shown in soccer that the repeated sprint ability (RSA) is essential in the physical performance of soccer (Dellal et al. 2010). The literature, however, reports little field researches on the RSA in young soccer players reflecting the absence of a reference standardized protocol to assess their ability to repeat sprints (Girard et al. 2011). Therefore, the aim of this study was to develop and validate an RSA test protocol in young soccer players and examine its reliability in this context. It was hypothesized that an RSA protocol with a logical validity based on match time-motion analysis with seven 15-meter sprints and 25 seconds of active recovery between sprints would be appropriate for the assessment of the ability to repeat sprints in young soccer players. Methods Seventeen Under-15 soccer players participated in the study. All subjects have performed in random order 3 RSA tests: 2 seven 15-meter test with 25 sec of active recovery and a six 40-meter (20-meter/20-meter shuffle) with 20 seconds of passive recovery. Results Measurements of the mean total time, best time and rating of perceived exertion of each test showed high reliability in terms of ICC (RSA mean: 0.93, RSA best: 0.80, and RPE: 0.83), low CV (RSA mean: 1.18, RSA best: 1.97, and RPE: 1.14) and the small effect size for the test/retest of 7x15m RSA testing trials (RSA mean: 0.08, RSA best: 1.17, and RPE: -0.06). Furthermore, the RSA test's construct validity was confirmed by its ability to discriminate between goalkeepers and field players (RSA mean:  $p=0.03$  and RSA best:  $p=0.02$ ). Discussion Reliability results showed that the mean total time, best sprint time and the RPE were highly reliable. The sprint decrement, mean heart rate, and blood lactate measures showed lower reliability. The low reliability of fatigue through RSA dec measurements is probably related to the fact that rather than being measured, fatigue is derived from data that have their own inherent variability. In the present study we focused (for construct validity) on differentiation according to the players' field positions. Indeed, analyses of the mean total time and best time in the present protocol were able to discriminate between field players and goalkeepers which support the construct validity of this RSA protocol in young soccer players. The correlation between the total mean times in the 7x15m and 6x40m tests was moderate and not statistically significant. This lack of correlation may be due to the sprinting distance/time, sprint's form or the difference in the nature of recovery. In conclusion, the RSA test with logical validity developed here has also a construct validity and showed sufficient reliability to assess the repeated-sprint ability in young soccer players. ### ONLINE VIDEO-BASED RESISTANCE TRAINING IMPROVES THE PHYSICAL CAPACITY OF JUNIOR BASKETBALL ATHLETES

Klusemann, M.J.1,2,3, Pyne, D.B.2, Fay, T.4, Drinkwater, E.J.3

1:Basketball Australia (Sydney, Australia), 2:Australian Institute of Sport (Canberra, Australia), 3:Charles Sturt University (Bathurst, Australia), 4:University of Jyväskylä (Finland)

Introduction Junior basketball athletes require a well-designed resistance training program to improve their physical development. Lack of expert supervision and resistance training in junior development pathways may be overcome by implementing an online video-based program. The aim of this study was to compare the magnitude of improvement in physical performance, strength and functional movement patterns of junior basketball athletes employing either a fully supervised, or an online video-based resistance training program. Methods Thirty-eight junior basketball athletes (males  $n=17$ ; age  $14\pm 1$ y; height  $1.8\pm 0.1$ m; mass  $67\pm 12$ kg; females  $n=21$ ; age  $15\pm 1$ y; height  $1.7\pm 0.1$ m; mass  $62\pm 8$ kg; mean  $\pm$  SD) were assigned into a supervised resistance training group (SG,  $n=13$ ), video training group (VG,  $n=13$ ) or control group (CG,  $n=12$ ) and participated in a six week controlled experimental trial. Pre- and post-testing included measures of physical performance (20 m sprint, step-in vertical jump, agility, sit and reach, line drill, Yo-Yo intermittent recovery level 1), strength (15 s push up and pull up) and functional movement screening (FMS). Results Training logs revealed 96% compliance from the supervised group and 77% compliance from the video group. Both SG and VG achieved 3-5%  $\pm$  2-4% (mean  $\pm$  90% confidence limits) greater improvements in several physical performance measures (vertical jump height, 20 m sprint and Yo-Yo endurance performance) and a 28  $\pm$  21% greater improvement in push up strength compared to the CG. The SG attained substantially larger gains in FMS scores than both the VG (12  $\pm$  10%) and CG (13  $\pm$  8%). Discussion Both short-term supervised and online video-based resistance training were effective in improving physical performance measures and strength. Supervised training remains the best method of program delivery to achieve maximum compliance, improvements in physical performance and functional movement patterns. In circumstances where supervised training is not available, online video-based training could be used to elicit substantial improvements in physical performance and strength in junior basketball athletes. This form of media-based training is a cost-effective and practical solution to apply resistance training to a large and/or remote athlete group. Sporting bodies could utilise this strategy to educate coaches and athletes on how to implement resistance training exercises into their daily training environment and enhance the short-term physical development of junior athletes.

### EVALUATION OF AN EYE-HAND COORDINATION TEST TO DISCRIMINATE BETWEEN TALENTS AND NON-TALENTS

Faber, I.R., Nijhuis-van der Sanden, M.W.G., Oosterveld, F.G.J.

Saxion University of Applied Science

Introduction Motor tests to assess specific sport skills which are proposed key-predictors for success are often included in talent identification programs (TID) (Régner et al., 1993). A valid test for a TID can discriminate talented from non-talented athletes and predict at least to some extent success. The test should contain tasks which are comparable to, but not exactly the same as the specific sport skills, to

diminish the influence of training-experience on the measurement outcomes. In this study, an eye-hand coordination test was examined on its capacity to discriminate between talented and non-talented athletes from different sports. TID for e.g. racket sports, handball, volleyball or basketball could use such a valid test for eye-hand coordination, because this is considered to be a necessary trait in these sports. Methods In total 231 young talented and non-talented athletes (age 7-14 years) from handball (n=38), tennis (n=28), gymnastics (n=36), soccer (n=49), volleyball (n=37) and table tennis (n=43) were tested. The children were instructed to throw a table tennis ball to a vertical positioned table tennis table with one hand and to catch the ball correctly with the other hand as frequently as possible in 30 s. The best of two attempts was registered as final score. The distance to the table tennis table was 1 m. An unpaired t-test was used to test if the test could discriminate between talented and non-talented athletes for each sport separately. A one-way ANOVA and post-hoc tests (Bonferroni) were used to compare only the talented athletes from all sports. Results The means of the talented athletes (T) was significantly higher ( $p < 0.001$ ) than that of the non-talents (N) for handball ( $T=24(SD4.5)$ ,  $N=16(SD4.8)$ ), tennis ( $T=27(SD5.3)$ ,  $N=3(SD3.5)$ ), soccer ( $T=26(4.7)$ ,  $N=17(SD4.3)$ ), volleyball ( $T=24(SD6.7)$ ,  $N=15(5.4)$ ) and table tennis ( $T=24(SD5.5)$ ,  $N=14(SD5.4)$ ). No significance difference was found for talents and non-talents in gymnastics ( $T=13(SD7.3)$ ,  $N=14(SD6.9)$ ;  $p=0.544$ ). Only the talented gymnasts scored significantly lower than talents from other sports ( $p < 0.001$ ). Discussion The test was able to discriminate between talented and non-talented athletes for handball, tennis, soccer, volleyball and table tennis. Implementation in a test battery for motor skills in a TID for these sports seems legitimate. Further research is desirable to obtain evidence about the predictive value and individual interpretation of test scores. References R gnier G, Salmela JH, and Russell SJ (1993). ### **FAST START STRATEGY INDUCES DIFFERENT INDIVIDUAL RESPONSES IN VELOCITY REGULATION DURING A 10KM RACE.**

Carmo, E.C.1, Gil, S.1, Kobal, R.1, Roschel, H.1, Ugrinowich, C.1, Bertuzzi, R.1, Tricoli, V.1

*University of S o Paulo*

Introduction The pacing regulation has an important impact on running performance. The fast start strategy (FS) has been frequently observed in 10km racing; but if this strategy is advantageous for performance is still controversial. Pacing regulation occurs with the purpose of protecting the body from harmful changes in homeostasis and a FS may induce premature fatigue subsequently hampering runner's performance. It seems that the RPE may be an efficient way to monitor pacing regulation (Abiss and Laursen, 2008). Thus, the aim of this study was to verify the regulation of pacing strategy and the associated RPE when a FS was applied. Methods Fifteen runners participated in two simulated 10km races. Running velocity (GPS Polar, RS800CX, Finland) and RPE (Borg 6-20) were measured every 400m. The pacing strategy was evaluated by the velocity-distance curve. The first race was a free pacing (FP) running (runners were instructed to complete the race as fast as possible) and in the 2nd race a FS was applied (runners performed the 1st km 6% faster than the FP). Results There was no difference in 10 km performance between strategies ( $45.0 \pm 4.1$  vs  $45.2 \pm 4.8$  min). In the FP running the first 400m were faster than rest of the race ( $p < 0.001$ ). In the FS velocity was higher in initial 1000m ( $p < 0.001$ ). Afterwards there was no difference in velocity between groups. The FS presented a higher RPE in the first 1600m when compared to FP ( $10.5 \pm 1.8$  vs  $12.3 \pm 1.8$ ,  $p < 0.04$ ). Seven runners improved performance in 2.4% using FS ( $43.9 \pm 2.9$  vs  $42.9 \pm 2.4$ ,  $p < 0.01$ ) while the other eight showed a 3.2% decrement ( $46.2 \pm 5.2$  vs  $47.8 \pm 5.6$ ,  $p < 0.001$ ). Discussion We found that the regulation of the pacing strategy was not affected by the use of FS. There was no difference in performance between FP and FS. However, dividing the subjects into positive (PR) and negative responsive (NR) we observed that the PR group ran faster than the NR group during the FS race. Interestingly, the 10km RPE was similar between groups. During running the momentary RPE is compared to the runners' expected RPE which is affected by their previous experience and the remaining running distance (Tucker, 2009). Thus, it seems that individual differences in pacing regulation cannot be monitored by the RPE. References Abiss C, Laursen PB (2008). Sports Med, 38 (3). Tucker R (2009). Br J Sports Med, 43.

### **DIFFERENT CONTROL STRATEGIES IN THE TIMING OF RAPID INTERCEPTION TASK IN WHICH MULTIPLE TIME-TO-CONTACT IS ANTICIPATED**

Ijiri, T., Shinya, M., Nakazawa, K.

*The University of Tokyo*

Introduction In a rapid interception task such as hitting in baseball, ideal time to contact is not necessarily anticipated (e.g. actual ball speeds of a pitcher are not always the same but highly variable in baseball). It may be important for good performance to be able to adjust interception timing accurately in the conditions that multiple ball speeds are anticipated. Interception timing is conceived to be controlled by changing swing onset and/or swing duration. The purpose of this study was to investigate whether interception strategies are different between single-speed conditions and multiple-speed conditions. Methods Twenty-six young males participated in the study. The participants were asked to intercept a moving virtual ball on a computer screen with a virtual arm controlled by real movement of their left elbow joint. There were three different ball speeds for which ideal times to contact were 410 (F: fast), 540 (M: medium) or 670 ms (S: slow). The experiment consisted of single-speed conditions (S, M and F) and two paired-speed conditions (SM and MF) in which ball speed varied between trials. In single-speed conditions, we calculated Pearson product moment correlation coefficient within each participant between swing onset and constant timing error. In paired-speed conditions we calculated the difference in swing onset between the faster and slower ball speeds. Results In single-speed conditions there were significant correlations between swing onset and constant timing error (S:  $r = 0.81 \pm 0.21$ , M:  $r = 0.86 \pm 0.11$ , F:  $r = 0.85 \pm 0.22$ ). In two paired-speed conditions, the distribution of the difference was bimodal especially in SM (-22.1-41.4, 76.4-111.1 ms), so we divided participants into two subgroups. Then, we calculated absolute timing error as an index of performance. The absolute timing error were smaller in the group which had larger difference in swing onset (SM:  $59.4 \pm 4.2$  vs  $75.9 \pm 6.1$ , MF:  $65.6 \pm 7.2$  vs  $82.4 \pm 14.4$  ms), suggesting that those who controlled interception timing mainly by changing swing onset outperformed those by changing swing duration. Discussion In single-speed conditions almost all participants used the same strategy changing swing onsets. On the other hand, in paired-speed conditions interception strategies were divided into two types between which the temporal accuracy was different. This result suggests that some factors such as ability to detect the difference in ball speeds earlier play an important role in the choice of the control strategies and the performance of the rapid interception task. Our future study will investigate the factors of highly skilled baseball players.

## SOMATOTYPE AND BODY COMPOSITION OF UNDER-19 WOMEN BRAZILIAN BEACH VOLLEYBALL PLAYERS IN RELATION TO PLAYING FUNCTION

Araripe Medeiros, A.

*Universidade do Porto - Faculdade de Desporto*

Somatotype and body composition of under-19 women Brazilian Beach Volleyball players in relation to playing function Medeiros, A.1; Lopes, R.2; Silva, F. T.2; Mesquita, I.1; Afonso, J.1; Palao J.M.3 1: University of Porto – Faculty of Sport - Portugal 2: Integrated Faculty of Ceara - Brazil 3: University of Murcia – Faculty of Sport Science - Spain Introduction The athletes' anthropometric and physical characteristics may be a determining factor for success in any sport (GUALDI-RUSSO e ZACCAGNI, 2001). However, so far most studies available in specialized literature concerning beach volleyball have focused in adult categories. Therefore, the purpose of this study was to compare body composition and somatotype of under-19 women beach volleyball players according to their playing function (blocker versus defender). Methods Twenty-two under-19 women Brazilian beach volleyball players were analyzed. Ten were blockers (aged 17.4±0.7 years) and twelve were defenders (aged 17.2±0.6 years). The players were compared according to their playing position, contrasting the blocker and defender specialists. Measures included height, obtained by a stadiometer (Sanny) with an accuracy of 0.1cm, and body mass, recorded by a portable scale (G-TECH), accurate to 100g. Percentage body fat was assessed using skinfold measures of seven sites applying Cescorf skinfold callipers and the Mcardle et al. (1998) skinfold equation. Somatotypes were calculated using the Heath-Carter method (CARTER e HEATH, 1990). Descriptive statistics were calculated and Mann-Whitney test was used to determine differences between groups (blockers and defenders). SPSS version 19.0 was used for all analyses. Results Blockers were significantly taller (1.73±3.9 m versus 1.65±4.5 m) and heavier (63.1±7.6 kg versus 58.4±7.5 kg) than defenders ( $p \leq 0.05$ ). As for body composition, no significant differences were found between blockers (20.0±3.6 %) and defenders (19.1±2.8 %). Blockers and defenders were classified according to somatotype as being mesomorph-endomorph (4.8-5.7-3.3 and 4.9-5.8-2.3 respectively). Blockers were significantly more ectomorph than defenders (3.3 and 2.6 respectively). Conclusion Blockers were significantly taller and heavier than the defenders. Blockers and defenders tend to be endomorph-mesomorph. These results indicate that anthropometric characteristics may be an important tool in the process of talent selection. ## HEART RATE, BLOOD LACTATE AND PERCEIVED EXERTION IN SYNCHRONIZED SWIMMING ROUTINES DURING COMPETITION

Rodríguez Zamora, L.1, Iglesias, X.1, Barrero, A.1, Chaverri, D.1, Erola, P.2, Rodríguez, F.A.1

*1: INEFC-Barcelona Sport Sciences Research Group, University of Barcelona (Barcelona, Spain), 2: DEIM, Universitat Rovira i Virgili (Tarragona, Spain)*

Introduction In modern synchronized swimming (SS) athletes need to combine sets of technically, physically, and esthetically very demanding exercises, lasting about 2 to 5 minutes, both breathing freely and holding breath (BH) for almost 50% of the time (Homma, 1994). In each program, swimmers competing above junior level must perform both a technical and a free routine. This study aims to describe selected physiological responses during an official competition. Methods 34 high-level senior (21.4 ± 3.6) and junior (15.9 ± 1.0 years) synchronized swimmers were monitored while performing a total of 96 routines during an official national championship in the technical solo (TS), free solo (FS), technical duet (TD), free duet (FD), technical team (TT), and free team (FT) programs. Heart rate (HR) was continuously monitored. Peak blood lactate (Lapeak) was obtained from serial capillary samples during recovery (minutes 3, 5, 7, and 10). Post-exercise rate of perceived exertion (RPE) was assessed using the CR10 Borg's scale. Total competition scores (TCS) were obtained from official records. Mixed model MANOVA and Bonferroni post-hoc tests were used for comparisons. Results Senior swimmers attained higher TCS than juniors (87.0 ± 4.7 vs. 79.1 ± 3.4 points). Pre-exercise mean HR (beats•min<sup>-1</sup>) was 129.1 ± 13.2, and quickly increased during the exercise to attain mean peak values of 192.0 ± 8.6, with frequent interspersed bradycardic events down to 88.8 ± 28.3. Lapeak (mmol•L<sup>-1</sup>) was highest in the FS (8.5 ± 2.1) and FD (7.6 ± 1.8) and lowest in the FT routines (6.2 ± 1.9). Mean RPE (0-10+) was higher in the junior (7.8 ± 0.9) than in the senior group (7.1 ± 1.4). Discussion Cardiovascular demands of competitive routines are remarkably high and are characterized by intense anticipatory HR pre-activation and rapidly developing exercise tachycardia, with interspersed periods of marked bradycardia during the exercise bouts performed at apnea. Autonomic neural cardiovascular response to BH and face immersion (i.e. bradycardia) was powerful enough to counteract exercise tachycardia during the apneic phases of intense exercise (Andersson et al., 2002). Moderate Lapeak suggests a minor role of the glycolytic anaerobic metabolism. Competitive routines are perceived as very to extremely intense, particularly in the FS and FD, and less so in the technical and team programs. The role of BH and diving during very intense dynamic exercise needs to be further investigated. References Homma M. (1994). Med Sport Sci 39, 149-154. ## A LONGITUDINAL ANALYSIS OF GROWTH AND PERFORMANCE IN SELECTED AND NON-SELECTED YOUTH RUGBY LEAGUE PLAYERS

Waldron, M., Worsfold, P., Twist, C., Lamb, K.

*University of Chester*

Introduction Talent in team sport is often identified using longitudinal assessments of players' functional performances and anthropometric variables during adolescence. As little data exist in the sport of rugby league, there is scope to examine the factors that characterise higher ability, thus discriminating between selected and non-selected players at the youth level. Therefore, the purpose of the current study was to: (i) monitor the changes in anthropometric and performance measures in selected players over a three-season period, and (ii) identify the factors that differentiate between selected and non-selected players. Method Following ethical approval, 28 under-15, -16 and -17 year-old elite youth rugby league players were assessed over three seasons of competition. The players, who were either coach-selected or coach-non-selected at the end of each season, were annually tested for aerobic capacity, jump height, 10-30 m sprinting (velocity, acceleration, force and power) and anthropometric variables. Nine of the original sample were retained and played for the club at each age group. Results A step-wise discriminant function analysis identified the selected players by 30 m sprinting force at under-15 ( $P=0.001$ ) and squat jump height at under-16 ( $P=0.009$ ). No factors characterised the selected players at under-17. Analysis of variance identified developments ( $P < 0.05$ ) in 10 m speed ( $\Delta=6.3\%$ ), 10 m ( $\Delta=13.9\%$ ) and 30 m force ( $\Delta=10.8\%$ ), 10 m ( $\Delta=19.9\%$ ) and 30 m power

( $\Delta=14.5\%$ ), and concomitant changes in maturity ( $\Delta=32\%$  and  $\Delta=25\%$ ) and stature ( $\Delta=0.36\%$  and  $\Delta=0.12\%$ ) between the under-15 and under-16 seasons. Improvements ( $\Delta=8.2\%$ ) in predicted VO<sub>2</sub>max between the under-16 and under-17 seasons were also evident alongside developments in quadriceps muscle cross-sectional area ( $\Delta=16.3\%$ ) and lean mass ( $\Delta=3.2\%$ ). Discussion The results show the relative importance of force generation and explosive movements, such as vertical jumping, in identifying players of higher ability in the under 15 and 16 age groups which become less discriminative at the under 17 group. The results also show expected developments in physical size and aspects of performance in the under 15s to 16s group, which become limited to muscular growth at later stages. Practitioners should use the current results as a guide for developmental norms and consider the measurement of such performance characteristics to contribute to the identification of higher ability players, which will vary according to the age group. Given the disparity between players of the under 17 age group and adult populations, future research should evaluate the rate of development in growth and performance at more advanced age groups.

#### **A LONGITUDINAL INVESTIGATION OF COACH PSYCHOLOGICAL HEALTH AND INTERPERSONAL BEHAVIOUR: THE MODERATING EFFECTS OF GENDER AND SPORT TYPE.**

Stebbings, J., Taylor, I.M., Spray, C.M.

*Loughborough University*

A longitudinal investigation of coach psychological health and interpersonal behaviour: The moderating effects of gender and sport type. Introduction. Within a self-determination theory (Deci & Ryan, 2000) framework, the effects of coaches' interpersonal behaviours on various athlete outcomes (e.g., need satisfaction, motivation, well-being) are well researched (Amorose, 2007). The antecedents of such behaviours, however, have scarcely been examined. In a cross-sectional study, Stebbings, Taylor and Spray (2011) demonstrated that coaches' psychological well-being was positively associated with autonomy supportive behaviours, and negatively associated with controlling behaviours. The current study expanded this line of inquiry by longitudinally exploring these relationships and exploring ill-being as an additional predictor of interpersonal behaviour. In addition, we aimed to assess the moderating effects of gender and sport type (individual versus team sports). Method. At three time points across an 11-month period, 195 coaches (79% male) from a variety of sports completed measures of positive and negative affect, and autonomy supportive and controlling interpersonal styles. Results. Multi-level modelling demonstrated a significant positive relationship between coaches' positive affect and autonomy supportive behaviours, and this relationship was stronger for females ( $b = .73$ ,  $p < .001$ ), compared to males ( $b = .43$ ,  $p < .001$ ). The significant positive relationship between coaches' negative affect and their controlling behaviours was stronger for males (males,  $b = .47$ ; females,  $b = .25$ ;  $p < .001$ ) and coaches of team sports (individual,  $b = .28$ , team,  $b = .54$ ;  $p < .001$ ). Discussion. The results extend previous research by discriminating between psychological well-being (positive affect) and ill-being (negative affect) in the prediction of coach autonomy supportive and controlling behaviours. The results also highlight the value of assessing the differences in these relationships across various demographic variables. In particular, females may be more prone to an autonomy supportive style when experiencing positive affect, whereas males and team sport coaches may be more likely to exhibit controlling behaviours when experiencing negative affect. Overall this study highlights the importance of coaching contexts that facilitate coaches' well-being, thereby increasing the likelihood of adaptive coaching styles. A particular focus on reducing negative affect in male and team sport coaches may be warranted to diminish maladaptive coach interpersonal behaviours towards athletes. References. Amorose, A.J. #### **DIFFERENCES IN THE COACH-CREATED PSYCHOLOGICAL ENVIRONMENT ACROSS TRAINING AND COMPETITION IN YOUTH SPORT**

Smith, N., Quested, E., Appleton, P., Duda, J.

*University of Birmingham (UK)*

Introduction According to achievement goal theory (AGT; Nicholls, 1989) and self-determination theory (SDT; Deci and Ryan, 2000), the psychological environment created by a coach can impact upon the quality of an athlete's motivation and experience in sport. When the environment is more task-involving, relatedness supportive and autonomy supportive and less ego-involving, relatedness thwarting and controlling, adaptive outcomes are expected to follow. However, past work suggests that under pressure situations, leaders are more likely to adopt an interpersonal style higher in ego-involving and controlling characteristics (Mageau and Vallerand, 2003). Extending previous research, this study used an observational methodology (which captured aspects of the environment emphasised in AGT and SDT) to examine whether there were any differences in the objective psychological environment created by coaches across competitive contexts (i.e., training and matches). Method Participants were 22 grassroots football coaches (21 males and 1 female). Coaches were filmed during a training session and match during the first 8 weeks of the season. Trained coders independently rated filmed footage in continuous 5-minute intervals, in terms of the extent to which the coach's interpersonal style was autonomy supportive, controlling, task- and ego-involving, and relatedness supportive and thwarting. Results Preliminary analyses suggest that during training, coaches adopt an interpersonal style that is significantly more autonomy supportive ( $M = 1.07$ ,  $SD = 0.66$ ) than controlling ( $M = 0.40$ ,  $SD = 0.37$ ),  $t(9) = 2.34$ ,  $p = .044$ , and significantly more task-involving ( $M = 1.22$ ,  $SD = 0.65$ ) than ego-involving ( $M = 0.39$ ,  $SD = 0.44$ ),  $t(9) = 3.78$ ,  $p = .004$ . Coach-emphasised autonomy support is significantly lower in matches ( $M = 0.32$ ,  $SD = 0.23$ ) than in training ( $M = 1.20$ ,  $SD = 0.69$ ),  $t(6) = 2.94$ ,  $p = .026$ . There was a trend for controlling strategies to be emphasised more during matches ( $M = 1.31$ ,  $SD = 0.70$ ) than in training ( $M = 0.48$ ,  $SD = 0.038$ ),  $t(6) = 2.33$ ,  $p = .058$ . Discussion These findings suggest that competition may lead coaches to withdraw their support for autonomy, and adopt a more controlling and coercive interpersonal style. This holds negative implications for athlete motivation and has been shown to lead to more maladaptive psychosocial outcomes. To ensure children are getting the most out of sport and

developing optimally, coaches should be educated to create adaptive psychological environments in training sessions and in matches. References Deci EL, Ryan RM. ### THE EFFECT OF SUPPORT TYPE AND SUPPORT VISIBILITY ON PERFORMANCE IN A FOOTBALL AIMING TASK: EVIDENCE FROM TWO EXPERIMENTAL STUDIES

Moll, T., Rees, T., Freeman, P.

*University of Exeter*

**Introduction** Prior to matches, football players often receive final words of encouragement and/or advice from coaches or fellow players. Though this is presumed to help, the effects of provided support are frequently mixed (Uchino, 2009). Providing support might alleviate distress and enhance problem-solving but may also come across as pressuring and threaten a recipient's sense of efficacy and autonomy (Bolger & Amarel, 2007). Recent research suggests that both the type of support (e.g., esteem or informational) and the way support is delivered (visibly or invisibly) may influence the effectiveness of support (Bolger & Amarel, 2007). We explore the effect of support type and support visibility in a performance setting. **Method** In two experiments (study one,  $n = 68$ , study two,  $n = 84$ ), we examined the effects of support type and support visibility on a football aiming task. Type of support was manipulated by changing the content (esteem or informational support) of the supportive message. Visibility was manipulated by addressing the support directly (visible) to the participant or indirectly by addressing the support to one of the experimenters (invisible). Experienced football players were randomly assigned to one of four support conditions: informational-visible, informational-invisible, esteem-visible, and esteem-invisible support. The players were told that an expert in penalty taking would be watching the task. In reality, this expert was a confederate scripted to provide one of the four support manipulations. Following the support manipulation, the players performed ten kicks towards a target. Performance was assessed as the average distance from the target. **Results** Two-way ANOVAs revealed a significant main effect for type of support on kicking performance (Study 1,  $F(3,64) = 12.72, p < .01$ ; Study 2,  $F(3,80) = 7.48, p < .01$ ). There were no significant main effects for support visibility and no interaction effects ( $p > .05$ ). **Discussion** The results suggest that, regardless of support visibility, participants in the informational support conditions outperformed those in the esteem support conditions. That is, giving advice (in a visible or invisible manner) prior to a kicking task appears to be more effective than giving encouragement. It may be that in a sports environment athletes are used to receiving (and expect to receive) advice from coaches. Furthermore, the quality of the informational advice ('Focus on the target') may have aided performance and not come across as pressuring or threatening; conversely, the esteem encouragement ('I'm sure you can do well') may have led to pressure and poorer performance. ### SOCIAL-PSYCHOLOGICAL DETERMINANTS OF PERFORMER'S IMMUNE RESPONSES: A SELF-DETERMINATION THEORY APPROACH

Quested, E.I, Bosch, J.A.2, Burns, V.E.1, Cumming, J.1, Duda, J.L.1

1. *University of Birmingham, UK*; 2. *University of Amsterdam, The Netherlands*

**Introduction** Research grounded in self-determination theory (SDT; Deci & Ryan, 2000) has implicated basic need satisfaction as a determinant of dancers' hormonal stress responses during performance (Quested et al, 2011). The current study extends this focus to include motivation-related determinants of immune function. The immune factor salivary S-IgA is a reliable predictor of susceptibility to upper respiratory tract infections (Gleeson, 2000) and is amenable to psychological influence (Bosch et al, 2002). To have a better understanding of the determinants of health, this study will also consider the social environment as a predictor of need satisfaction, as well as vocational dancer's reasons for engaging in dance (i.e., their motivation regulations), as determinants of S-IgA in anticipation of an important performance. **Method** One month prior to a ballet solo performance, 51 dancers (18 male, 1 unreported; M age = 19.00 SD = 1.93 yrs) completed questionnaires measuring their perceptions of autonomy support provision, need satisfaction, and motivation regulations for dance, in terms of their "typical" experiences in school. 60 or 15 minutes prior to the solo, saliva samples were collected using salivettes. Path analyses tested the fit of the data to the hypothesized model: 'Autonomy support-need satisfaction-motivation regulations- S-IgA'. **Results** The path model (controlling for S-IgA sampling time) showed a good fit to the data ( $\chi^2(6) = 8.50, CFI = .96, RMSEA = .09$ ). Perceived autonomy support positively predicted dancers' need satisfaction ( $\beta = .75, p = < .001$ ). Need satisfaction predicted the degree to which dance motivation was self-determined ( $\beta = .50, p = < .001$ ), which in turn predicted levels of S-IgA ( $\beta = .31, p = < .05$ ). Need satisfaction mediated the relationship between perceived autonomy support and self-determined motivation. **Discussion** Findings support the application of SDT as a framework to examine social-psychological predictors of immune function. Dancers with less self-determined (more controlled) motivation for training have alterations in immune function that may increase risk of infections. Present results suggest that autonomy supportive teaching may facilitate performers' need satisfaction and resulting self-determined motivation which in turn may have downstream effects on physical health. ### COACHES HEALTH PROMOTION PERCEPTIONS IN SPORT CLUBS: WHAT IS DONE, WHAT IS EXPECTED AND DOES IT IMPACT THEIR MOTIVATION FOR COACHING?

Van Hoya, A., Heuze, J.P., Sarrazin, P.

*Université Joseph Fourier*

Sports clubs could be recognized as health promoting organization, regarding the psychological, social and physical benefits of physical activity practices. As the Ottawa Charter (1986) has proposed a shift from individual health behavior to institutional development of health promotion (HP), sports clubs can influence healthy behaviors, as the « Setting in Health Promotion » Model has shown in schools, hospitals and cities (Whitelaw, Baxendale, Bryce, Machardy, Young, & Witney, 2001). Grounded on this model, Kokko et al. (2009) developed the Health Promotion in Sport Clubs scale (HPSC) to assess 4 dimensions: policy, practices, environment and ideology. In a sample of Finnish sport clubs, respective score of 56%, 42%, 64% and 80% were found. This study extends this line of research, by (1) measuring both coaches' perceptions (i.e., what is made in my club) and expectations (i.e., what my club should make) of the HP in their club, and (2) examining the links between these perceptions and their motivation for coaching. Based on the self-determination theory (Deci & Ryan, 2002), we presumed that the more the coach perceived HP in his club, the more his motivation would be self-determined because his

psychological needs are more satisfied. 125 French coaches have completed a questionnaire containing an adapted version of the HPSC and a scale assessing their motivation to coach. Results showed that in comparison to hospital (Lin & Lin, 2010) scores were lower, specifically for policies (75% vs. 36%) and practices (72% vs. 32%). Moreover, ideology scored higher (0.80 for perceptions and 0.91 for expectations), before environment (0.76 and 0.87), policy (0.36 and 0.66), practices (0.32 and 0.63) and partnership (0.20 and 0.50). Coaches' perceptions were lower than their expectations, the mean differences were 0.31, 0.30, 0.30, 0.11, 0.11 ( $t_s < .01$ ), for practices, policy, partnerships, ideology and environment respectively. In other words, coaches of this sample consider there is a need for HP improvement in their club. Finally, confirming our hypothesis, HPSC score was related to self-determined motivation ( $r = .30$ ,  $p < .01$ ), and with policies, practices and environment ( $r_s = .32$ ,  $.23$ ,  $.22$ ,  $p_s < .01$ , respectively). There is a need for development to understand the discrepancies between coaches' representations and expectations. Deci, E. L. & Ryan, R. M. (2002). *The Handbook of Self-Determination research*. ## **TRANSFORMATIONAL LEADERSHIP AND LEADER INSPIRED EXTRA EFFORT: THE MEDIATING ROLE OF COACH AND ATHLETE RELATIONSHIP IN FOOTBALL PLAYERS**

Gorgulu, R.

*Hacettepe University*

**Introduction** In early stage, transformational leadership researchers have begun to examine the mechanisms by which transformational leadership exerts its impact on followers (Charbonneau et al., 2001). Recent years, it has emphasized that the type of leadership behaviours displayed by the coach play an important role in successful sporting performance (e.g., Gould, Greenleaf, Chung, & Guinan, 2002). However, there is no research that has been conducted within sporting domain to discern any mediational role between the transformational leadership and athletic effort at the current time. Therefore, the purpose of the present study was to examine the relationship between transformational leadership and leader inspired extra effort and the potential mediating role of the coach-athlete relationship in football players. **Methods** The participants were 124 male professional football players from the UK (mean age = 22.9,  $SD = 5.0$  years) completed the Differentiated Transformational Leadership Inventory (DTLI; Callow et al., 2009) the Coach and athlete Relationship Questionnaire (CART-Q; Jowett & Ntoumanis, 2004) and indices of follower effort. Results Most of the alpha coefficients for the transformational leadership sub-components ranged from .70 to .91 and were deemed to be internally reliable based on criterion of .70 set for the psychological domain (Raykow & Marcoulides, 2010). Overall the findings show that regression analysis failed to support mediation for any of the relationships examined except the direct effects between transformational leadership and leader inspired extra effort ( $\beta = .550^{**}$ ,  $SE = .131$ ,  $p < 0.01$ ). **Discussion** In conclusion, the results demonstrated that transformational leadership was positively associated with leader-inspired extra effort in a sport context and support the calls from Arthur et al., (2011). Based on this, it is essential that coaches may want to consider that the full extent of transformational behaviours has an impact on the athletic performance. However, effectiveness of transformational leader behaviours was not mediated by the coach and athlete relationship in the current study. Due to lack of research of the transformational leadership in sport, future research should seek to investigate underlying explanatory process of this relationship. **References** 1. ## **TO LEAD OR NOT TO LEAD? IDENTIFYING ATHLETE LEADERSHIP ROLES IN SPORT TEAMS.**

Fransen, K., Vanbeselaere, N., Vande Broek, G., De Cuyper, B., Boen, F.

*KU Leuven (University of Leuven)*

**Introduction** Research in sport leadership has mainly focused on the leadership of the coach. However, players within the team can also occupy leadership roles and become crucial for an optimal team functioning. The few studies that did examine the different roles of athlete leaders have distinguished between three leadership roles; task leader, social leader, and external leader (Loughead, Hardy, & Eys, 2006). However, these athlete leadership roles and their characteristics have not yet been thoroughly elaborated. Further investigation in this emerging area is needed considering the possible overlap between the different leadership roles as well as their relative influence on team outcomes. **Aims** In this study, we want to extend the current research knowledge on two points. First, we want to extend the previous categorization of leadership roles by exploring the existence of an additional leadership role, namely the motivational leader on the field. In our opinion, consideration of this motivational role can enhance our understanding of the complex nature of athlete leadership. In this study, the occurrence of the four athlete leadership roles within sport teams will be tested. We predict that the team captain overlaps with the social leader at the recreational level, but with the task leader at the highest performance level. In addition, we assume that the influence of the team captain is overrated and that other players within the team will occupy equally important leadership roles. Second, we will examine athlete leadership in a broader framework. In analogy with models of coach leadership, we will evaluate the qualities of the four leader roles on three domains: (a) personal characteristics (e.g. experience, competence), (b) behaviours (e.g. communicating, encouraging) and (c) athlete outcomes (e.g. collective efficacy). In particular, we expect that the motivational leader has the strongest influence on the collective efficacy beliefs of his/her teammates. **Method** The database of the Flemish Trainer School's (VTS) was used to contact 4500 qualified coaches of all the different team sports in Flanders (Belgium). These coaches were also asked to motivate their players to participate by referring them to the player-specific on-line version of the questionnaire. Data collection will be finished by March 2012, after which the data will be analyzed by correlational and regression analyses. **Discussion** Good athlete leaders are crucial for an optimal team functioning. Knowledge about athlete leaders' characteristics and the different roles that they occupy can be used to identify and guide athlete leaders in a sport team. **References** Loughead, T. M., Hardy, J., & Eys, M. A. (2006). The nature of athlete leadership. *Journal of Sport Behavior*, 29, 142-158.

### OPERATIONAL DECISION MAKING IN SPORTS: WHAT DETERMINES WHETHER A VOLLEYBALL PLAYER GOES FOR A SET OR A DIG?

Ntoloopoulou, M., Bootsma, R.J.

*ISM-AMU (Marseille, France)*

**Introduction** Often a particular situation offers multiple operational possibilities. For instance, a volleyball player may choose to play a ball using a set or a dig technique. In this research project we seek to identify the constraints harnessing the operational choices made by expert players. To this end, we confront them with a range of situations in order to determine to what extent the choices made are systematically related to the situations encountered, as is predicted by an affordance-based account of behaviour (Fajen, Riley, & Turvey, 2008). After having identified the particular constraints (e.g., time available, distance to covered) that separate the solutions adopted, we examine the relations between the visual information used to guide the movement toward the point of interception (Michaels & Oudejans, 1992) and the players' action capabilities in order to pinpoint the informational support for operational decisions making. **Method** Tested separately, six top-level French volleyball players attempted to play machine-launched balls into a circular goal positioned at the passer's position near the net. Each trial had the player start from one of 5 different initial positions (between 2 and 8 m from the net) and play one of 4 different balls trajectories (varying in landing position for a constant flight time of 1.9 s). Each player performed 80 trials (5 initial positions x 4 ball trajectories x 4 repetitions). For each trial, the action mode chosen (set or dig) was recorded. When a given ball trajectory gave rise to a change in action mode as a function of the player's initial position, motion of the ball and player was analysed from video recordings using the SIMI motion system operating at 25Hz. Data processing is currently underway. **References** Fajen, B. R., Riley, M. A., & Truvey, M. T. (2008). ### STRATEGIES FOR DEFENDING DRIBBLER: DEFENDER AND DRIBBLER INTERACTION DURING A 1-ON-1 BASKETBALL SITUATION

Fujii, K.1,2, Yamashita, D.1,2, Yoshioka, S.3, Kouzaki, M.1

*1. Kyoto University (Kyoto, Japan), 2. Japan Society for the Promotion of Science (Japan), 3. Ritsumeikan University, (Shiga, Japan).*

**Introduction** Defenders in 1-on-1 basketball situation anticipate the dribbler's motion and react to stop the advance. In recent years, researchers have focused on the anticipation in replicated ball game situations by using video clips; however, two problems have been revealed with regard to defending the dribbler: (1) the dribbler's decision making and (2) the defender's skilled reaction movement. In the former case, both dribbler and defender should be captured in a real time 1-on-1 situation, instead of on video. In the latter case, split step (Uzu et al., 2009), a preliminary action in which both feet are unweighted, can be one of the skillful reaction movements. The purpose of this study was to reveal how a defender can defend a dribbler in a 1-on-1 basketball situation. **Methods** Six basketball players participated in this study as 12 dyads of dribblers and defenders. They played a real-time 1-on-1 game according to the rules of basketball. Three dimensional coordinates of the markers attached on bony landmarks of each player were obtained with a motion capture system. We then calculated for argument as order parameter by using their centre of mass (CoM) medio-lateral displacement, which represents the state of the dyad system, and categorised successful attack trials and effective defence trials. After the categorization, both the dribbler's and the defender's peak velocities, time to peak velocities and launch time were obtained by using their CoM medio-lateral velocity and acceleration data. **Results & Discussion** The differences in launch time and peak velocity between the dribbler and the defender for the effective defence trials were smaller than that for the successful attack trials. This means that both anticipation and reaction skill are important to effectively defend the dribbler. Additional categorisation of effective defence trials reinforced this idea. After the additional categorisation on the basis of the launch time and peak velocity, we found 'good anticipation' trials, 'split step (good reaction)' trials and 'dribbler's stop' trials. The results suggest that there were three defending strategies and that one strategy would be insufficient, because the defender's skilled reaction movement and the dribbler's decision making should be taken into account. In real basketball situations, even if the defender's anticipation fails, doing a split step may make it possible to defend the dribbler. The dribbler may also stop for many reasons, such as bad ball handling or failure in the dribbler's decision making. **Reference** Uzu, R., Shinya, M., & Oda, S. (2009). *J Sports Sci*, 27(12), 1233-1240.

### EFFECT OF TASK DURATION ON SUSTAINED ATTENTION, AN ELECTROPHYSIOLOGICAL STUDY

Fontenelle, V.1, Knaepen, K.1, Fernandez, H.1,2, Pattyn, N.1,2, Nagels, G.1,3, Meeusen, R.1

*1. VUB (Brussels - Belgium) 2. Royal Military Academy (Brussels - Belgium) 3. NMSC (Melsbroek - Belgium)*

**Introduction** Impairments of sustained attention (or vigilance) may have dramatic consequences in our daily life. Little is known about the mechanisms underlying vigilance decrement. Vigilance impairment due to task duration is commonly described as a result of mental fatigue. Recently, a new hypothesis has emerged suggesting that vigilance impairment related to underload task is due to boredom instead of mental fatigue. **Purposes** The main purpose was to study the effects of time-on-task on sustained attention using oddball event-related potentials. We also investigated if vigilance decrement was due to boredom or mental fatigue. **Material and Methods** Subjects performed a one-hour 3-visual stimuli oddball paradigm. The Go- and Nogo-ERPs referred respectively to the target and to the distracter. Mental task engagement was calculated using the engagement index ( $EI = 20 \times \beta / (\alpha + \theta)$ ). **Results** VAS scores for fatigue and reaction time significantly increased over time. Nogo-P300 amplitude significantly decreased with time-on-task, whereas Go-P300, Go- and Nogo-N2 amplitudes, as EI were not modulated. **Discussion** Evidences of engagement index values demonstrated that subjects experienced mental fatigue. **Conclusion** One-hour oddball paradigm increases subjective feeling of fatigue, impairs behavioral performance and affects attentional resources related to the distracter. **KINKING OF THE EXTERNAL ILIAC ARTERY IMPAIRS ENDURANCE CYCLING PERFORMANCE BUT NOT PEAK POWER OUTPUT: A CASE STUDY**

Lamberts, R.P.1, Noakes, T.D.1

*1: UCT/MRC Research Unit for Exercise Science and Sports Medicine, Department of Human Biology, University of Cape Town, South Africa.*

**Introduction** Kinking of the common or external iliac artery is most commonly seen in professional cyclists, who spend a substantial amount of their training time in an aerodynamic position and flexing their hips as much as 8 million times per year (Schep et al., 2002), which causes limited blood flow to the lower extremity resulting in underperformance and complains about pain and powerlessness. It is unknown however if this pathology mainly restrict endurance cycling capacity or also peak power output (PPO). **Methods** A 32 year old professional cyclist (460 W; 6.1 W•kg<sup>-1</sup>) and participated in a monitoring/observation study, was diagnosed with kinking of both the left and right external iliac artery, after underperforming and complaining about painful/powerless legs. During the monitoring period the cyclists performed two PPO tests, including respiratory gas analysis (VO<sub>2</sub>max), and two 40km time trials (40km TT). Before all performance tests, the cyclists performed the LSCT, a submaximal cycle test which is able to predict cycling performance (Lamberts et al., 2009). After surgery of both left and right external iliac artery and a rehabilitation period, a third PPO and 40km TT test, including the LSCT, was performed. Actual performance and predicted performance of the cyclist was compared to normative data of 74 healthy cyclists (Lamberts et al., 2009) Results No meaningful differences were found between actual PPO (460W, 484W and 410W, respectively) and predicted PPO based on the LSCT (456W, 486W and 410W, respectively). No differences were also found between actual VO<sub>2</sub>max (5.4, 5.5, 4.7 l•min<sup>-1</sup>, respectively) and predicted VO<sub>2</sub>max (5.4, 5.7, 4.7 l•min<sup>-1</sup>, respectively). Meaningful differences (Lamberts et al., 2009) were found between actual and predicted 40km TT performance before surgery during which the cyclist under-performed by 3 minutes and 32 seconds and 4 minutes and 15 seconds, while after surgery no meaningful differences were found (9 seconds) **Discussion** The main finding of this case study is that meaningful discrepancies were found between actual and predicted 40km TT performance with kinking of the external iliac arteries in a professional cyclists. These finding suggest that kinking of the iliac artery mainly impairs endurance performance and not or less PPO and VO<sub>2</sub>max. Therefore additional measurements such as ankle systolic blood pressure measurements, echo doppler and magnetic-resonance imaging either with or without angiography (Schep et al., 2001, 2002), seem to be crucial for diagnosing kinking of the iliac artery within a PPO test. In addition this study shows that a discrepancy between predicted 40km TT performance, from the LSCT, and actual 40km TT performance can possibly be used as an early screenings tool. **References** Schep G, et al. (2002). *Lancet*. 359, 466-473 Lamberts RP (2009). Book (ISBN: 978-90-9024959-9), Enschede, The Netherlands, Ipskamp Drukkers Schep G, et al (2001). *Physiol Meas*. 22, 475-487

**TIMING AT PEAK LENGTHS AND FORCES OF HIP JOINT MUSCLES DURING SPRINT RUNNING**

Nagano, Y., Higashihara, A., Takahashi, K., Fukubashi, T.

*Niigata University of Health and Welfare*

**Introduction** The biceps femoris is the most commonly injured muscle among the hamstring muscles (Woods et al., 2004). Increased biceps femoris muscle-tendon force carries the risk of hamstring strain injury. Moreover, it is possible that other hip joint muscles influence biceps femoris mechanics. The opposite iliacus are suggested to influence the mechanics of biceps femoris (Riley et al., 2010). The purpose of this study is to investigate the relation of muscle lengths and muscle-tendon forces of hip joint muscles during sprint running and particularly, to examine the relationships with the peak of biceps femoris muscle-tendon force. **Methods** We obtained three-dimensional kinematics during 1 running cycle from 8 healthy sprinters sprinting at maximum speed. These data were used to drive musculoskeletal models by using nMotion musculous (NAC Image Technology, Inc.JAPAN). Muscle lengths and muscle-tendon forces were calculated for iliacus, rectus femoris, gluteus maximus, biceps femoris, opposite iliacus, and opposite rectus femoris. The time at muscle lengths and muscle-tendon force peaks as percent running cycle were measured and compared with muscle-tendon force peak of biceps femoris by using Bonferroni multiple comparison test. **Results** The peak muscle-tendon force of the biceps femoris occurred at 80.5 (2.9)% of the running cycle. It was significantly different from the peak muscle lengths of iliacus, rectus femoris, gluteus maximus, opposite iliacus, and opposite rectus femoris ( $p < 0.01$ , respectively) and the peak muscle-tendon forces of rectus femoris and opposite rectus femoris ( $p < 0.01$ , respectively). However, it was not significantly different from the peak muscle lengths of biceps femoris, peak muscle-tendon forces of opposite iliacus, and the second peak of iliacus and gluteus maximus. **Discussion** The results of this study showed that the peak muscle-tendon force of biceps femoris synchronised with the peak muscle-tendon forces of opposite iliacus and the second peak of iliacus and gluteus maximus. A previous study reported that muscles in the lumbo-pelvic region had great influence on hamstring stretch (Chumanov et al., 2007). It is possible that the contraction and flexibility of these muscles influence the mechanics and injury risk of biceps femoris. **References** Woods C, Hawkins RD, Maltby S, Hulse M, Thomas A, Hodson A. **RELEVANCE OF BONE MASS, BONE MINERAL DENSITY AND BONE METABOLIC MARKERS IN LONG-DISTANCE RUNNERS**

Asano, S.1, Torii, S.2, Iida, Y.2, Iizuka, S.1

*1)Graduate School of Sport Sciences,Waseda University 2)Faculty of Sport Sciences,Waseda University.*

**Introduction** The osseous tissue is maintained through continuous formation and resorption. Many studies have reported that bone metabolism is altered in accordance with the type, intensity and frequency of the exercise. Recently, the usefulness of the bone metabolism markers evaluating bone turnover quantitatively attracts attention as screening tool for bone injury such as the stress fracture. How-

ever, few studies have analyzed the bone metabolism marker of the competitive athletes, continuously. We measured whole body bone mass, bone mineral density of the lumbar spine and bone metabolism markers in 16 male athletes belonging to a business group long-distance running team, longitudinally and cross-sectionally. Method We measured BAP as a bone formation marker and TRACP-5b as a bone resorption marker in serum, and whole body bone mass and bone mineral density of the lumbar using DXA (Delphi-A QDR). Result The levels of BAP and TRACP-5b in a few subjects exceeded beyond their normal range of young male. In addition, a negative correlation tendency was seen between bone mineral density of the lumbar and product of BAP multiplied by TRACP-5b, which expressed bone metabolism states. Discussion Uncoupling of the bone metabolism may exist in athletes performing high intensity exercise like a long-distance running continuously. These results showed that bone mineral density of the lumbar spine was low in athletes with high bone metabolic turnover, resulting in high frequency of stress fracture. We suggested that bone metabolism markers are useful from a point of view assessing bone states of athletes and preventing their bone injury.

### THE EFFECTS OF HYPERBARIC OXYGEN EXPOSURE ON RECOVERY AFTER HIGH-INTENSITY EXERCISE.

Horie, M.1, Shimoda, M.1, Imai, T.2, Watanabe, K.2, Enomoto, M.1, Miyakawa, S.2, Yagishita, K.1

*Institution: 1: Hyperbaric Medical Center, Tokyo Medical and Dental University Hospital, Japan. 2: Graduate School of Comprehensive Human Sciences, University of Tsukuba, Japan*

The Effects of Hyperbaric Oxygen Exposure on Recovery after High-intensity Exercise. Horie, M.1, Shimoda, M.1, Imai, T.2, Watanabe, K.2, Enomoto, M.1, Miyakawa, S.2, Yagishita, K.1 1: Hyperbaric Medical Center, Tokyo Medical and Dental University Hospital, Japan. 2: Graduate School of Comprehensive Human Sciences, University of Tsukuba, Japan. Introduction: Hyperbaric oxygen therapy (HBO), which can dissolve oxygen in serum in population to atomic pressure and transport oxygen to ischemic tissue, is an established therapy for treatment of several conditions, including decompression illness, carbon monoxide poisoning, and acute artery occlusion. Recently, it has become an increasingly popular treatment for athletes suffering from muscle or ligament injury. However, the effect of HBO is not clear on recovery from sports activities. The purpose of this study is to determine how HBO exposure effects on physiological responses and recovery after high-intensity exercise in athletes. Methods: Healthy male volunteer subjects (age:  $21.0 \pm 1.2$  years) were randomly divided into the two groups of the HBO group (n=11) and the non-HBO treatment (control; CT) group (n=11). All subjects underwent the high-intensity cycle exercise of 75% heart rate max for 60 minutes. After the exercise, the subjects of HBO group were placed in hyperbaric chamber with inhalation of 100% oxygen at 2.5 atmospheres absolute (ATA) for 60 min. The total duration of the procedure was 120 min (including compression and decompression). The subjects of CT group seated rest for 120 min. Subjective evaluation of fatigue after exercise was assessed using a visual analogue scale (VAS). In addition, blood counts, blood lactate, serum IL-6 concentration, natural killer cell (NK) activity, and oxidative stress markers (d-ROM, BAP) were measured at pre-, post-exercise and after HBO or non-treatment. Results: VAS value was significantly increased after exercise, and decreased after HBO or non-treatment. VAS values in HBO group were lower than that in CT group after the treatment. In the blood test, serum IL-6 concentration was significantly increased after exercise in both groups and then significantly decreased after HBO treatment compared with that before HBO treatment. Lymphocyte was significantly increased after HBO treatment in HBO groups, but not changed in CT group. There were no differences between HBO and CT groups in terms of NK cell activity value, d-ROM, BAP and lactate. Discussion: The HBO treatment did not only reduce high-intensity exercise-induced fatigue, but also showed anti-inflammation response and high level of lymphocytes in the blood. These findings indicate that HBO treatment was effective for recovery from High-intensity exercise. As a next step, we need to clarify the physiological mechanisms of these effects by HBO treatment.

### EFFECTS OF ACUPUNCTURE ON ISOMETRIC AND ISOTONIC EXERCISE OF ELBOW FLEXOR: A RANDOMIZED, CROS-OVER DESIGN

Kaneko, Y.1,2, Kime, R.1, Takagi, S.1, Murase, N.1, Osada, T.1, Katsumura, K.1, Kihira, A.2, Uehara, A.2, Furuya, E.2, Sakamoto, A.2

*1: Tokyo Medical University (Tokyo, Japan) 2: Kuretake College of Medical Arts & Sciences (Tokyo, Japan)*

Introduction Acupuncture is frequently used therapy for several musculoskeletal disorders in complementary and alternative medicine. In sports medicine, acupuncture may have beneficial effects for athletes not only to treat injury but also to keep better performance, such as relieving delayed onset muscle soreness (Hubscher et al. 2008, Kaneko et al. 2009), or improving maximum isometric voluntary force (Hubscher et al. 2010). However, it is not clear if acupuncture improve muscle function on isotonic voluntary contraction. The aim of this study was to examine the effects of acupuncture on maximum isometric voluntary contraction (MIVC) and muscle power (MP) with repeated isotonic voluntary contraction of elbow flexor. Method Ten healthy male were participated in this study (age  $30.2 \pm 4.7$  yrs; height  $173 \pm 4.1$ cm; weight  $70.5 \pm 7.9$ kg). MIVC of elbow flexor was measured prior to stimulation (MIVC1). Subjects received acupuncture (ACU) before the exercise on their biceps brachii, or no stimulation as control (CONT). Subjects were treated with ACU and CONT in randomized order in 1 week between trials. The acupuncture (0.25\*60mm) was inserted in the belly of biceps brachii into 1 cm depth for 5 min. MIVC2 was measured after the stimulation. The exercise protocol were 5 sets \* 10 repetitions of maximum isotonic voluntary contraction (0 – 90 deg) of elbow flexion at 50% MIVC1. After the exercise, MIVC3 was measured (MIVC3). MP of every repetition was measured. The changes in MIVC and MP between ACU and CONT were evaluated. Result For the mean MIVC, ACU changed from  $7.9 \pm 1.3$ kg to  $7.5 \pm 1.3$ kg and  $6.5 \pm 1.2$ kg. CONT changed from  $7.9 \pm 1.0$ kg to  $8.0 \pm 0.9$ kg and  $6.5 \pm 0.9$ kg (MIVC1, MIVC2, MIVC3, respectively). MIVC3 decreased compared to MIVC1 and MIVC2 ( $p < 0.01$ ) in both group. There was significant difference between ACU and CONT at MIVC2 ( $p < 0.05$ ). The mean MP was significantly higher at ACU than CONT (ACT:  $44.8 \pm 10.5$  W, CONT:  $43.2 \pm 8.4$  W,  $p < 0.01$ ). MP of latter repetitions (7th to 10th) of ACU were significantly higher than CONT ( $p < 0.05$ ). Discussion These results suggest that acupuncture stimulation may suppress the decrease of muscle power at repeated maximum isotonic voluntary contraction at 50%MIVC. On the other hand, MIVC was suppressed after acupuncture. Effect of acupuncture on muscle function varies and it could be beneficial or adverse for athletes. References Hubscher M et al. (2008). ## COOLING AND RECOVERY FROM INTENSE EXERCISE – A SYSTEMATIC REVIEW OF STUDIES WITH TRAINED ATHLETES

Poppendieck, W., Faude, O., Wegmann, M., Meyer, T.

Saarland University, Saarbrücken, Germany

Cooling and recovery from intense exercise – a systematic review of studies with trained athletes W. Poppendieck<sup>1,2</sup>, O. Faude<sup>1,3</sup>, M. Wegmann<sup>1</sup>, T. Meyer<sup>1</sup> 1 Institute of Sports and Preventive Medicine, Saarland University, Saarbrücken, Germany 2 Department Medical Engineering & Neuroprosthetics, Fraunhofer IBMT, St. Ingbert, Germany 3 Institute of Exercise and Health Sciences, University of Basel, Basel, Switzerland Introduction Cooling after exercise has been suggested as a method to improve recovery during intensive training periods or competitions lasting several days to weeks. It has been investigated in various studies and has also found its way into practice. However, many existing studies include untrained subjects to induce a higher degree of muscle soreness and fatigue due to a reduced fitness level. It is not clear if the results of those studies can be transferred to trained athletes. Although recent review articles on the topic of cooling and recovery exist, none of those has focused especially on trained athletes (Halson, 2011; Leeder et al., 2011). The purpose of this work was to fill this gap. Methods A literature search was conducted using the following databases: PubMed, ISI Web of Science, AMED and EMBASE. Inclusion criteria were: a) explicit analysis of trained subjects, b) cooling after exercise, c) performance measurement, d) existence of a control group or condition, e) performance evaluation at least 2 h after cooling to exclude potential pre-cooling effects. In total, 14 studies with 153 subjects were located and analyzed. For all studies, the effect of cooling on performance was determined, and effect sizes (Hedges'  $g$ ) were calculated. Results In order to determine under which circumstances cooling may be most beneficial, several parameters of the study design were more closely examined. Regarding performance measurement, the best effects were found for endurance parameters (3 studies/30 subjects, 3.7%,  $g=0.35$ ), while for jump (3/35, 3.4%,  $g=0.13$ ), strength (10/113, 2.4%,  $g=0.12$ ) and sprint performance (4/46, 2.7%,  $g=0.10$ ), effects were smaller. The effects were most pronounced when performance was evaluated 48 h after exercise (7/71, 5.0%,  $g=0.34$ ). With respect to the exercise which was used to induce fatigue, effects after strength training (4/39, 3.6%,  $g=0.18$ ) were slightly larger than after endurance-type exercise (10/114, 2.2%,  $g=0.16$ ). Cold water immersion (10/117, 2.9%,  $g=0.19$ ) and cryogenic chambers (2/18, 3.8%,  $g=0.14$ ) seemed to be more beneficial than cooling packs (2/18, 0.3%,  $g=0.00$ ). Discussion Overall, the effects of cooling on recovery were rather small (2.8%,  $g=0.17$ ). Under appropriate conditions, however, cooling after exercise may have relevant positive effects on performance recovery of trained athletes. Especially for the recovery of endurance performance, relevant beneficial changes were reported. Halson SL (2011) *Int J Sports Physiol Perform* 6: 147-59. Leeder J et al. ## PREDICTION OF A HALF MARATHON RACE TIME IN RECREATIONAL LONG DISTANCE RUNNERS

Alvero-Cruz, J.R.1, Trujillo Mamely, A.1, Fernández Vázquez, R.1, Fernández García, J.C.2, Correias Gómez, L.2, Carnero, E.A.2

1. Faculty of Medicine. University of Málaga. 2. University of Málaga.

Introduction Running is a popular sports discipline that can be performed over various distances. Different physiological, anthropometric and training characteristics seem to influence running performance (race time), which is dependent of distance race. The aim of this study was to analyze predictor variables as anthropometry, functional stress test and training test to predict a half marathon race time in male amateur distance runners Methods Thirty-two male recreational runners finishers in the same half marathon were studied (Age:  $41.6 \pm 7.4$  years, height:  $172.5 \pm 6.3$  cm, body mass:  $70.4 \pm 8.14$  kg,  $VO_{2max}$ :  $55.73 \pm 8.33$  ml/kg/min). They completed the race distance in a mean time of  $91.2 \pm 10$  min. Fat mass and skeletal muscle mass were calculated by anthropometry. A treadmill progressive exercise test (TT) was performed to assess maximal aerobic power, also the distance of a Cooper's Test (CT) was recorded in a different day. Stepwise multiple regression analyses were performed to obtain predictor variables (CT, TT and anthropometry). Results Stepwise multiple regression analysis showed that the distance of CT was the best predictor of the final race time. Race time in a half marathon might be predicted by the following equation. Race time (min) =  $214.34 - 0.03829$  (CT (m)) ( $R^2$ : 0.92, SEE: 3.04 min,  $p < 0.0001$ ). Other significant model included the maximal speed obtained on the TT and maximal oxygen uptake ( $VO_{2max}$ ) as significant predictors; Race time (min) =  $185.8341 - 3.7709$  (msTT) -  $0.4145$  ( $VO_{2max}$ ), ( $R^2$ : 0.79, SEE: 4.80 min,  $p < 0.001$ ) Discussion Our main finding was that a simple CT test is a good predictor of the final time in a half marathon, namely for amateur runners. This should be an important concern for coaches and athletes, so a simple test, which last only 12 minutes, can be used to regulate the pace during the race, in order to improve the final time. However, we may manage this equation cautiously since it was developed only with the time of one race. Future studies should be carried out to confirm our equation, which must be cross-validated with different runners and races. ## HAMSTRING MUSCLE KINEMATICS DURING THE ACCELERATION PHASE OF SPRINTING

Higashihara, A., Nagano, Y., Takahashi, K., Fukubayashi, T.

Waseda University

Introduction Recent video analysis of hamstring strains showed that many injuries involve trunk flexion while running at high speed, an action usually seen during acceleration (Orchard, 2002; Verrall et al., 2005). Based on this observation, trunk flexion during sprinting is therefore a risk for hamstring strain injury. However, thus far this hypothesis has not been scientifically validated. The purpose of this study was to investigate hamstring muscle kinematics during the acceleration phase of sprinting, and compare it with the maximum speed phase. Methods Eight male track and field athletes (age,  $18.6 \pm 7.9$  years) performed maximal sprint from 2 starting lines, set approximately 15 and 60 m from the center of the measurement area. A three-dimensional musculoskeletal model was used to compute muscle lengths and muscle-tendon forces of the biceps femoris (BF), semitendinosus (ST), and semimembranosus (SM) muscles during the sprinting gait cycle. Hip flexion, knee flexion, and pelvic anterior tilt angles were also calculated. Results Hip and knee flexion angles at foot strike were significantly greater during the acceleration phase than during the maximum speed phase ( $p < 0.001$ ). A similar trend was observed for the pelvic anterior tilt angle (foot strike,  $p < 0.01$ ; maximum,  $p < 0.001$ ). Hamstring muscle lengths peaked during the terminal swing of the gait cycle, and at foot strike, they were significantly greater during the acceleration phase than during the maximum speed phase (BF,  $p < 0.01$ ; ST and SM,  $p < 0.001$ ). The hamstring muscle-tendon forces showed no significant difference between the 2 phases. Peak muscle-tendon forces of the BF muscle and the ST and SM muscles occurred during the terminal swing and initial stage of the gait cycle, respectively. Discussion The results of this study showed that compared to the maximum speed phase of sprinting, sprinters tend to have more forward trunk lean during the acceleration phase, and this may cause stretching of the hamstring muscles at foot

strike. The results also showed that peak muscle-tendon forces of the BF muscle occurred during the terminal swing of the gait cycle, simultaneous with the maximal stretching of the BF muscle. The BF muscle, the most commonly injured among the hamstring muscles (Woods et al., 2004), is subjected to excessive loads during the terminal swing of the gait cycle when it is in its most elongated position. ## THE INFLUENCE OF CONTINUOUS 100 PITCHES ON EXTREMITIES AND TRUNK MOTIONS IN BASEBALL THROWING KINEMATICS

INOUE, N.1, WATANABE, H.2, TORII, S.3

*waseda university 1, kitasato university 2, waseda university 3*

**INTRODUCTIONS** Shoulder and elbow injuries in baseball players have been reported many previous studies. One of the causative factors of the injuries have been expressed by a large number of pitching in game or practice. The purpose of this study was to compare baseball throwing kinematics before and after continuous 100 pitches and to investigate correlation between kinematic variations of extremities and trunk motions. **METHODS** Ten collegiate baseball players (baseball history  $8.7 \pm 3.1$ y, ball speed  $103 \pm 7.3$  km/h, age  $21.5 \pm 1.1$ y, height  $175.6 \pm 5.2$ cm, weight  $70.8 \pm 9.8$ kg) participated in this study. At first, reflective markers were placed at 11 bony landmarks. Then, we collected 3D coordinates of the points during throwing motion by using a 4-high speed camera of 300Hz and 3D digitizing system (Frame-Dias IV) before and after continuous 100 pitches. From those data, angles and angular velocities of shoulder, elbow, trunk, pelvic and thigh from foot contact (FC) to ball release (BR) were calculated. A statistics analysis of variance ( $P < .05$ ) was used to compare the kinematic variables before and after continuous 100 pitches. **RESULTS** Significant increase was observed in maximum shoulder external rotation angle (MER-A), maximum shoulder internal rotation angular velocity (Max SIR-V) during acceleration phase (AC), elbow extension angle (EE-A) at MER and BR, and thigh horizontal angle (TH-A) at FC after continuous 100 pitches compared with before. Moreover, there was a significant decrease in shoulder external rotation angle (ER-A) at BR and maximum elbow extension angle velocity (Max EE-V) during AC. On the other hand, trunk and pelvic kinematic variables showed no significant differences. There was no significant correlation between TH-A at FC and the upper extremity variables, either. **DISCUSSIONS** The significant increase of MER-A, Max SIR-V during AC, and EE-A at MER and decrease of ER-A at BR passively induce higher throwing injury risk after continuous 100 pitches. Moreover, it is thought that the increase of TH-A at FC changed throwing motion to inside step. There was no significant correlation between TH-A at FC and the upper extremity variables, thus, TH-A at FC on inside had no influence on upper extremity motions as pelvic and trunk motions doesn't changes.

## EFFECT OF ELECTROACUPUNCTURE ON EXERCISE-INDUCED OXIDATIVE STRESS

Fujimoto, H., Hayashi, T., Hanaoka, Y., Sakai, T., Mukai, N., Ajisaka, R., Miyamoto, T.

*University of Tsukuba, Tokyo Ariake University of Medical and Health Sciences, Meiji University of Integrative Medicine*

**Introduction** Oxidative stress is induced by high-intensity exercise (Sen, 1995). Therefore, oxidative stress has been used to evaluate the physical condition of athletes (Schippering et al, 2009). In athletics it is important to prevent fatigue for peak performance. In Japan, acupuncture has been used for fatigue prevention of Japanese athletes (Akimoto et al 2003). However, there is little scientific evidence to prove the effect. The purpose of this study is to examine the effects of electroacupuncture (EA) on exercise-induced oxidative stress. **Methods** In this crossover study, the EA and control (CONT) groups each included 12 healthy male volunteers. EA at 2 Hz and optimum intensity was performed on each subject at both the SP10 (Xuehai) and SP11 (Jimen) locations for 10 min before exercise. Respiratory metabolism was recorded during bicycle ergometer exercise by ramp rate. Blood samples were collected from the fingertip of each subject before and after exercise. Plasma oxidized glutathione (GSSG) and total glutathione (tGSH) concentrations were biochemically determined as a marker of oxidative stress. The degree of fatigue before and after exercise was evaluated by the visual analogue scale (VAS). **Results** The ventilatory threshold (VT) and the respiratory compensation point (RC), parameters of respiratory metabolism during exercise, did not differ significantly between the EA and CONT groups. The level of oxidative stress (GSSG/tGSH) after exercise was significantly lower than that before exercise in the EA group. In contrast, this level did not change significantly in the CONT group. The VAS values increased significantly after exercise in both groups; however, the VAS value in EA group showed a low tendency in comparison with that in CONT group. **Discussion** VT and RC did not differ between the two groups, indicating that the level of exercise was nearly the same for both groups. The GSSG/tGSH and the VAS values after exercise were lower in the EA group than in the CONT group. The low GSSG/tGSH and VAS values indicated EA-mediated suppression of exercise-induced oxidative stress and exercise-induced fatigue, respectively. It has reported that acupuncture stimulation increases glutathione concentration in skeletal muscle (Toda 2009). In this study, EA was performed at a location where muscle fatigue was predicted to occur. Therefore, our results might suggest that EA-mediated suppression of oxidative stress bear some related to suppression of fatigue. We propose that EA might be useful for fatigue prevention. **References** Sen CK. (1995), *J Appl Physiol*, 79(3), 675-86. Schipperinger G, Fankhauser F, Abuja PM, et al. ## PP-BN05 Coaching 1

**CURRENT COACH EDUCATION PROGRAMS FAIL TO FOSTER QUALITATIVE LEADERSHIP IN DUTCH YOUTH SPORT TEAMS**

Decroos, S., Ceux, T., Boen, F., De Backer, M., Vande Broek, G.

*KU Leuven*

Introduction In youth sports, coach education programs should aim at building leadership qualities, because it is not merely 'playing the game' that promotes positive trajectories (Fraser-Thomas, Côté, & Deakin, 2005). It is much more the quality of the coaches' leadership that yields positive and sustainable development of the players' autonomous motivation, performance, enjoyment and personal strengths (Larson & Rusk, 2011; MacDonald, Côté, Eys, & Deakin, 2011; Theokas, 2009). Since basic need support is currently seen as one of the most qualitative leadership behaviors, we examine in this study whether coaches of youth sport teams benefit from current education programs to be more need supportive and fine-tune their leadership behavior in favor of the players' autonomous motivation. Methods Youth handball, volleyball, basketball and football players (N=1050, M=12,54) completed multiple questionnaires assessing the quality of their motivation, their need satisfaction and the need support of their coaches. The coaches (N=126, M=33,15) reported their age, years of experience and highest sport education degree. Results Regression analysis revealed that neither the coaches' years of experience nor their sport education degree could predict their perceived need support by the players, players' need satisfaction or players' autonomous motivation. All standardized beta-coefficients ranged from -.083 to .039 (all p-values above .12). Discussion Our results reveal that current coach education programs fail to foster coaches' need supportive leadership. Therefore we argue to revise current curricula. Rather than building years of experience, coaches need new tools and revised education to regulate their leadership behavior in favor of the athletes' autonomous motivation, performance and overall thriving. **FACTORS INFLUENCING ARTISTIC PERFORMANCE OF TRANSITIONS WITH SPATIAL VARIATION TO INDIVIDUAL WOMEN IN AEROBIC GYMNASTICS**

LIANG, Y.

*Waseda University*

Factors influencing artistic performance of Transitions with spatial variation to individual women in Aerobic Gymnastics Liang, Y.1, Tang, Hb.3, Kanosue, K.4 1: Graduate School of Sports Sciences, Waseda University (Saitama, Japan) 2: Faculty of Anhui Normal University (Wuhu, China) 3: Faculty of Beijing Union University (Bei Jing, China) 4: Faculty of Sports Sciences, Waseda University (Saitama, Japan) Introduction Aerobic Gymnastics requires the ability to perform complex and high intensity movement patterns to music. It originates from traditional aerobic exercise. (Aerobic Gymnastic Code of Points 2009-2012). The aim of this study was to give a quantitative description of one component of Aerobic Gymnastics, which is "Transitions" performed by the champion of the 11th Aerobic Gymnastics of World Championships, who won the highest artistic score ever in the category of Individual Women, and also was given high evaluation by many international judges. We especially focused on the special variation of her transitions. As a comparison we also analyzed the performance of the athlete who ranked eighth in the final of the same competition. Methods The video images of the routines of the two athletes were taken with a usual video camera at the frame rate of 30 Hz. The images were analyzed from three aspects; 1) duration, 2) work patterns and sequences, and 3) trajectory and location. Results The two players used similar duration for transition in their routine. The champion performed longer on difficulty elements and upward movements, while the eighth utilized more in jump and the downward movements. In addition, the two routines choreographed in almost the same sequences of Transitions. However, the routine of the champion was composed of more variety of movements, supporting points, and degrees of rotation around three axes, including the usage of compound axis. For trajectory of transitions, the champion performed circular, diagonal and anterior-posterior movements more, while the eighth tended to complete transitions at the same place. Likewise, the champion effectively mixed transitions with long and short trajectories, and also used all the zones evenly. In contrast, the eighth stayed in limited zones most of time and not using the left-top zone at all. Discussion The routine of the champion had more varieties in many aspects such as duration, movements, sequence, compounding axis, supporting point, trajectory and location. Of course, this may give an indication of the good physical ability of the champion. But present analysis showed that the choreography of the champion was excellent as well. Therefore, in conclusion, an excellent choreography of spatial variation in transition should be composed of varieties in all aspects. With this point of view, coaches would be able to make innovations in choreography, if it was correctly combined with the physical ability of players. **AN EXAMINATION OF HOME-FIELD ADVANTAGE IN GAELIC FOOTBALL 2001-2010**

Carroll, R.1, Collins, D.K.2

*Toca Sports (Ireland)1, ITT Dublin (Ireland)2*

Introduction The existence of home-field advantage has been examined and established in a number of international sports (Clarke, 2005; Pollard, 2006). The aim of the current study was to examine if home-field advantage applied in Gaelic Football, both in the National League competition and All-Ireland Championship Qualifiers. Methods In total 1,393 (1,143 National League and 250 All-Ireland Championship Qualifiers) games were analysed, beginning from the 2001 season when the All-Ireland Championship qualifying system was

introduced. The study includes results from 34 teams. The teams, the result and the venue were listed for each game. The home team was identified in each game except where games took place in a neutral venue. The number of home wins, away wins, draws and neutral venues was then recorded. The approach of calculating home advantage using the percentage of games won by home teams throughout the competition was deemed a suitable statistical analysis (Nevill and Holder, 1999). Results The results from the National League competition (n=1143) from 2001-2010 show that presence of a home-field advantage (Home win: 56.62%; Away wins: 34.85%; Draw: 8.53%). The results from the All-Ireland Championship Qualifiers (n=250) from the same period does not support the presence of home-field advantage (Home wins: 47.17%; Away wins: 48.43%; Draw: 4.4%). Discussion The current study is the first to describe home-field advantage in Gaelic football. The study identified the presence of home-field advantage in the National League competition. The study was however inconclusive in regard of the All-Ireland Championship Qualifiers where teams are not segmented according to their standard of play unlike the National League competition. Due to variance in ability, the home-field advantage may not be a determining factor for success in the All-Ireland Championship Qualifiers. Future research should look at factors relating to success in the All-Ireland Championship. References Clarke, S.R. (2005) *J Sports Sci*, 23, 375-385. Nevill, A.M., Holder, R. (1999) *Sports Med*, 28, 221-236. Pollard, R. (2006) *J Sports Sci*, 24, 231-240.

### **A TEAM IS NOT ALWAYS A DREAM: HOW CAN COACHES REDUCE SOCIAL LOAFING IN TEAM SPORTS?**

De Backer, M.

*KULeuven*

A TEAM IS NOT ALWAYS A DREAM: HOW CAN COACHES REDUCE SOCIAL LOAFING IN TEAM SPORTS? De Backer, M. 1, Vande Broek, G. 1, De Cuyper, B. 1, Høigaard, R., 2, Boen, F. 1 1: KULeuven (Belgium), 2: University of Agder (Norway) Introduction Like managers, coaches have to distinguish between players in terms of functions, status, etc. This differentiation leads to concerns about a fair treatment, usually referred to as organizational justice. Studies in business contexts have continually demonstrated the power of justice judgments to shape people's thoughts, feelings, and actions. Consequently, this research aims at testing the relationship between coach-related justice and a behavior-related variable (i.e., social loafing) in elite sport teams. Social loafing has been defined as the reduction in motivation and effort when individuals work collectively, compared with when they work individually (Latané, 1979) and will usually result in a decreased team performance. However, we are not simply interested in the direct relation between coach characteristics and the individual behavior of athletes. The main purpose of this study is to develop a model that explains the effects of perceived justice of the coach on a series of intervening group-oriented variables (i.e., the motivational climate, team identification and team cohesion) leading to perceived and self-reported social loafing in interactive sport teams. Method Norwegian top level female handball players (N = 110; M = 22.8) filled in mail surveys assessing perceived justice, the motivational climate, team identification, team cohesion, and social loafing. Structural equation modeling (i.e., both confirmatory and exploratory) was used to investigate our research model. Results The confirmatory path analysis indicated a poor fit of the hypothesized model ( $\chi^2 = 64.52$ ,  $df = 22$ ,  $p = .00$ ; GFI = .90; AGFI = .80; CFI = .84; RMSEA = .14). Consequently, an exploratory path analysis was performed using structural equation modeling. Results of the revised model provided a good fit to the data ( $\chi^2 = 33.45$ ,  $df = 19$ ,  $p = .02$ ; GFI = .94; AGFI = .86; CFI = .95; RMSEA = .08). Discussion The revised model showed that the more the coach is perceived as fair, the more a mastery climate is experienced and the less an ego-oriented climate. A mastery climate in turn was positively related to athletes' team identification, while a performance climate was not significant related to it. Furthermore, our results confirmed that task and not social cohesion mediates the relation between team identification and both forms of social loafing in elite female sport teams. From a more practical standpoint, our results showed that the coach himself can guide the group processes and consequently reduce social loafing, even in world-class teams. References Latané, B., Williams, K., & Harkins, S. (1979). Many hands make light the work: The causes and consequences of social loafing. *Journal of Personality and Social Psychology*, 37, 822-832.

### **THE RELATIONSHIP OF A SEATED CHEST THROW TO A ONE REPETITION MAXIMUM BENCH PRESS**

Roberts, J., McCleary, S.

*Edinboro University of PA*

THE RELATIONSHIP OF A SEATED CHEST THROW TO A ONE REPETITION MAXIMUM BENCH PRESS Roberts Jr., J., McCleary, S.: Edinboro University of PA (Edinboro, PA, USA) Introduction Although the seated chest throw is a power measurement and the one repetition maximum bench press is a muscle strength measurement, there is little known about the relationship between the two tests. Other studies have compared the validity and reliability of a medicine ball throw with vertical jump power (Stockbrugger and Haennel, 2001) as well as the backward overhead medicine ball throw to vertical jump power production (Mayhew et al., 2005). However, the purpose of this study was to determine the strength of the relationship of a seated chest throw with a 12 pound and a 16 pound medicine ball to a one repetition maximum (1RM) bench press. Methods Data were collected from a sample of 55 participants; 30 males (age 19.73±2.03yr) and 25 females (age 17.08±2.34yr) between the ages of 14 and 24. Participants completed the 1RM bench press and the seated chest throws in randomized groups. In accordance with the procedures outlined by the American College of Sports Medicine, each participant completed 4 lifts of the bench press. Height and weight were measured using a calibrated Detecto® physician's scale and stadiometer. During the seated chest throw, participants threw a 12 pound and a 16 pound medicine ball at a force plate. The best of four trials for each ball was recorded. Descriptive data, Pearson's correlation and mean differences of the two tests were used to determine the strength of the relationship. Results With male subjects, correlations of  $r=0.612$  and  $r=0.614$  ( $p<0.001$ ) were found for the 1RM bench press as compared to a seated throw, as measured in ft. lbs, of a 12 pound and 16 pound medicine ball respectively. The female participants had stronger correlations for both of the chest throws ( $r=0.777$  and  $r=0.705$   $p<0.001$ ). Discussion With a randomized order of testing, the correlation of a 1RM bench press to the seated chest throw in young athletic males is moderately strong and significant. The correlation in young athletic females is equally significant with a stronger relationship than that observed in the male participants. In addition, these data suggest that females may elicit a stronger relationship to a 1RM bench press by using a 12 pound medicine ball while males could use either. ## DIFFERENCES IN BALL HANDLING PERFORMANCE, AMONG VARIOUS SIZES OF BALLS IN 13 AND 14 YEARS OLD BASKETBALL PLAYERS

Zacharakis, E.I, Apostolidis, N.I, Kostopoulos, N.I, Bolatoglou, T.I

*UNIVERSITY OF ATHENS*

DIFFERENCES IN BALL HANDLING PERFORMANCE, AMONG VARIOUS SIZES OF BALLS IN 13 AND 14 YEARS OLD BASKETBALL PLAYERS Zacharakis, E.I, Apostolidis, N.I, Kostopoulos, N.I, Bolatoglou, T.I 1: Faculty of Physical Education and Sport Science, Dpt of Games and Sports, University of Athens Introduction: The Comity International for Mini-basketball (CIM), proposes the use of small size ball (No5) for the facilitation of the young players (under 12 years old) ball-handling. On the other hand, the Federation International Basketball Association (FIBA) recommend for cadets (15-16y), juniors (17-18y) and men (>18y) the use of big size ball (No7), and for women the intermediate size (No6) (fibaeurope.com, 2010). These restrictions, force the cadet basketball players to conform the use of the big size of the ball, in a very short period. The aim of the present study was to investigate the possibility of the regular passage of the 13-14y players from the small to the big ball size, through the intermediate one (No6). Methods: A total sample of 105 basketball players 13 and 14 years old (n1=54, n2=51), volunteered to participate in the following tests: (a) speed dribble (28m) with both hands and both ball sizes, (b) obstacle dribble (A.A.H.P.E.R., 1984) with both hands and both ball sizes, (c) free throws shooting with both ball sizes and (d) speed spot shooting (A.A.H.P.E.R., 1984) with both ball sizes. For the data analyses six separate one sample t-tests were conducted, in order to investigate possible differences among the two ball sizes, for all of the skill tests. Statistical significance was accepted at  $p < .05$  level. Results: In none of the applied shooting skill tests revealed differences between the two ball sizes (No6 and No7). Reversely, it was revealed significant differences in the three of the four dribbling skill tests ( $p < .05$ ) Discussion/Conclusions: The results of the study revealed that in skill tests regarding shooting performance no differences were detected in the use of the 6 and 7 ball sizes. Reversely, in the dribble skill tests were detected differences in the three of the four trials with the two ball sizes and it was evident that the young players perform better ball-handling with the smaller ball. Conclusively, there are no sufficient findings that may justify the use of the intermediate (No6) basketball size, in the age of 13 and 14 years, so the young basketball players can pass strait from the use of the small basketball to the bigger one. ## 2ND TO 4TH DIGIT RATIO AND PERFORMANCE IN SWISS YOUTH TRACK AND FIELD ATHLETES

Romann, M., Heyer, L., Fuchslocher, J.

*Swiss Federal Institute of Sport Magglingen*

Introduction The ratio of the second and fourth digit (2D:4D) is a biomarker for performance in various sports such as fencing, rugby, football, alpine skiing, sprinting, middle- and long-distance running (Hönekopp & Schuster, 2010; Manning & Hill, 2009). The underlying reason is a putative correlation between 2D:4D and prenatal testosterone. 2D:4D has been proposed as a predictor of performance and a helpful criterion for the talent identification (TID) process. The Swiss track and field federation (Swiss Athletics) uses a multidimensional TID-tool, but 2D:4D has to date not been taken into account. The aim of the present study was therefore to examine whether the 2D:4D of Swiss youth track and field athletes is related to the personal best performance exhibited during competition. Methods 180 track and field athletes (75 girls and 105 boys) were recruited during the annual Swiss Athletics talent selection day. The mean age of subjects was  $16.6 \pm 1.4$  years. The personal best performance was taken from the Swiss Athletics database. All performance data were transformed into points and adjusted for age according to Swiss Athletics standards. Second and fourth digit finger length was measured blind to performance data. Measurements were made from photocopies of the ventral surface of the right hand. Measurements were made to the nearest 0.1 mm from the midpoint of the finger crease proximal to the palm to the tip of the finger using steel vernier calipers. Results Mean 2D:4D was  $0.95 \pm 0.03$  for the whole sample,  $0.96 \pm 0.03$  for female and  $0.94 \pm 0.03$  for male athletes. Significant ( $p < 0.05$ ) negative correlations were observed between 2D:4D and performance in the whole sample ( $r = -0.24$ ) and significant ( $p < 0.05$ ) negative interclass correlations were found in female ( $r = -0.26$ ) and male ( $r = -0.25$ ) athletes. Effect sizes (ES) were small for both females and males. Subgroups of female middle-distance runners ( $r = -0.43$ ) as well as male sprinters ( $r = -0.61$ ) showed highest ES. Discussion Our data indicate that 2D:4D is a predictor of performance in track and field for both female and male athletes. This in turn suggests that fetal testosterone exposure has long-term effects on traits associated with physical performance in track and field. However it should be kept in mind that performance is closely related to maturity. Given that 2D:4D is fixed before birth and remains constant during life, 2D:4D might be used as a selection criterion in the TID process of female middle-distance runners and male sprinters. Digit ratio (2D: 4D) and sprinting speed in boys. *American Journal of Human Biology*, 21, 210-213.

## STEP ADJUSTMENT APPROACHING THE FIRST HURDLE

Smirniotou, A., Panteli, F., Argeitaki, A., Roussos, T., Katsikas, C.

*Kapodistrian University of Athens*

INTRODUCTION "Hurdling" involves running towards successive targets-hurdles placed at specific distances, which necessitate step adjustment using a visual control strategy (Smirniotou et al., 2010). During training hurdle's height is regulated to improve the approach run and hurdle's clearance stride. The purpose of this study was to examine if step pattern to the first hurdle changes 1. by modifying the height of the hurdle, 2. after a period of task-specific training. METHODS 11 students (M age  $18 \pm 0.8$  years) with no hurdling experience participated in the study. Pre- and post-tests were conducted. After the pre-test, participants attended 10 specific training sessions. In both tests they performed the approach phase to the first hurdle by sprinting 13m and striking a non-visible "target" (take-off point) prior to the hurdle. They completed 4 trials under each condition (A,B,C): A–run over hurdle (0.76m), B–run across flat mark, C–run over an upside-down hurdle. Trials were recorded using a panning camera (50Hz). Standard deviation (SD) of the Toe-Hurdle Distance (THD) for each step across trials for each participant was taken as a measure of footfall variability for a particular step. RESULTS Findings revealed an initial ascending footfall variability followed by a descending one as the participants approached the hurdle, suggesting the use of visual control. The onset of visual control (point of max SD of THD) occurred closer to the hurdle at the post-test (4th, 2nd, 4th support phase prior to the hurdle, for conditions A,B,C respectively) compared to the pre-test (6th, 4th, 5th support phase prior to the hurdle, for conditions A,B,C respectively). The mean max SD of THD recorded at post-test was lower compared to the pre-test, for all conditions (Pre-test: A:29.92cm, B:41.12cm, C:39.19cm. Post-test: A:25.37cm, B:15.12cm, C:14.39cm). DISCUSSION A visual control strategy seems to be applied during the approach phase to the first hurdle. In A and C vision was used for a greater distance compared to B, where partici-

pants commenced using visual control closer to the target probably due to its characteristics-height (Bradshaw & Sparrow, 2001). After a period of hurdles training visual control emerged closer to the hurdle for all conditions. The lower values of max SD of THD recorded in post-test indicate that even a small amount of task-specific training contribute to a more consistent run-up. The effect of running speed should be also examined in future research. REFERENCES Bradshaw, E.J. and Sparrow, W.A. (2001). Effects of approach velocity and foot-target characteristics on the visual regulation of step length. *Human Movement Science*, 20, 401-426. Smirniotou, A., Panteli, F., Argeitaki, P., Kesoglou, I. and Katsikas, C. (2010). Visual control of step length during the approach phase to the first hurdle. Abstracts, 15th ECSS Congress (p. 178).

### A STUDY OF IMAGING TIME OF PROFESSIONAL GOLFERS AND AMATEUR GOLFERS

Yoshihara, S., Ichikawa, D., Kita, T., John, S., Takahashi, M., Kawakami, T., Yamamoto, T., Kato, Z.

*Toyo university*

**Introduction** In order to have consistent performance in golf it is important to have a stable time between addressing the ball and the start of the swing (imaging time), and also between the start of the swing and impact on the ball (swing tempo). In order to realize the ideal ball flight that you want while playing on a golf course, you must have a complete image of the swing rotation, swing width, and power at impact before you begin the swing. It is considered that each individual has a relatively consistent time between the start of the swing and the top (top of swing time) and also between the top and impact (down swing time). However, it is considered that amateur golfers (AG) have a longer and more inconsistent imaging time compared to professional golfers (PG). The purpose of this study is to investigate difference in length of necessary imaging time of the tee shot, second shot, approach, and putting of PG and AG by measurement during an actual round of golf on a golf course. **Methods** The time between addressing the ball and ball impact (imaging time) of the tee shot, second shot, approach and putt of 2 PG and 1 AG was measured by taking video using a digital camera and measuring the time by inserting a time counter into the recorded video images. Putts of a distance less than 30cm were not included as they are considered a tap in for PG. Averages and standard deviations were calculated and the relationship between imaging time and golf performance evaluated. **Results** Table 1 shows the measured time of tee shot, second shot, approach and putting of PG and AG. Over 18 holes, the average tee shot time for PG was  $1.17 \pm 0.1s$  and for AG  $2.60 \pm 0.3s$ . For the 2nd shot it was  $1.19 \pm 0.1s$  for PG and  $2.74 \pm 0.4s$  for AG. For the approach shot it was  $0.90 \pm 0.2s$  for PG and  $3.06 \pm 0.4s$  for AG. For putting it was  $0.80 \pm 0.3s$  for PG and  $1.72 \pm 0.7s$  for AG. It was shown that in PG imaging time tended to decrease with each shot from the tee shot to putting but oppositely increased with each shot in AG. **Discussion** After comparing imaging time of PG and AG, the following trend was recognized. Over 18 holes, PG only need half the imaging time that is necessary for AG. The standard deviation for imaging time was also approximately half for PG compared to AG. Furthermore, a decrease in imaging time for each shot from the tee shot until putting was apparent in PG whereas in AG the imaging time for each shot from the tee shot to putting showed a tendency to increase. These results indicate that PG have already virtually completed their imaging by the time they actually address the ball resulting in a decrease in imaging time and a reduction in inconsistency of imaging time. It can therefore be deduced that imaging time for PG decreases as the distance from the place of the shot and the cup becomes closer, resulting in a reduction of the amount of psychological pressure on the golfer. Oppositely, it was recognized that AG require more time for various thoughts as the place of the shot becomes closer to the cup, reducing the potential for golf performance.

#### PP-SH03 Sport Management

#### JUDO AND SWIMMING TRAINING COACHES OPPORTUNITIES IN BRAZIL

Mazzei, L., Siva Filho, F., Böhme, M.T.

*Universidade Nove de Julho (University July Nine) - São Paulo/Brazil*

**Judo and Swimming Training Coaches Opportunities in Brazil** MAZZEI, L.1, SILVA FILHO, F.J.2, BÖHME, M.T.S.2 1: University July Nine (UNINOVE, São Paulo/Brazil); 2: Universidade de São Paulo (São Paulo/Brazil) **Introduction** For a country to achieve international sporting success, beyond financial investment, is necessary to develop some strategic points in national sport structure. The training of coaches is a strategic factor that can optimize the international sport results. (GRENN & OAKLEY, 2001; DE BOSSCHER et al 2006). According Erickson et al (2008) formal education of coaches is one of the possible ways of purchase knowledge. The aim of this study was to identify the training coaches opportunities in swimming and judo in Brazil. **Methods** A total of 18 elite sport coaches of São Paulo sport clubs (7 of judo and 11 of swimming) answered the following question: 'What is the entity's policy to training human resources for elite sport?' This paper is part of a research which is being conducted in São Paulo/Brazil. Data was obtained through personal interviews. Results were analyzed through "Group Character Speech Method" (GCS), as proposed by Lefèvre & Lefevre (2003). Results There was a similarity in some "Central Ideas" between judo and swimming, as the 'The club itself promotes actions' was cited by 66,6% of coaches. However, other "CI" were specific to each modality, how "no exist" (33.3%) for the judo coaches and 'is a coach responsibility' (16.6%) for swimming coaches. **Discussion** The results show that some clubs promote training coaches through their own actions, for example, study groups, guest speakers and subsidies for participation in international events. Another important point in the survey is that judo coaches reported that 'there is any one' policy or training coaches activities. In some countries with international success there are training programs for coaches in various forms, which are developed by a national sporting organization. **Conclusion** There is no proposed action related to the training of coaches in judo and swimming conducted by national bodies responsible for the organization of sport in Brazil. Clubs and coaches responsible for their own training **References** De Bosscher, V.; De Knop, P.; Van Bottenburg, M.; Shibli, S. (2006). ## THE DEVELOPMENT OF SUPPORTING THE ELITE ATHLETES IN THE UK: FROM ATHLETE AND CAREER EDUCATION PROGRAM TO PERFORMANCE LIFESTYLE

LEE, P., Jiang, R.

*National Taichung University of Education*

**Introduction** This discussion is about elite, or high performance, sport and primarily about how the UK provides life support for the elite athletes with a concern of major contributions of implementing ACE UK program in the 1999-2004 period and later the Performance Lifestyle program since 2004. **Methods** The documentary-based element takes the form of qualitative content analysis, which applied to the form of analysis of a number of British sport official reports, academic articles, and media commentaries. In total, 107 references were reviewed and 53 commentaries were identified to conduct this research. The data was subject to analysis and coding employing the NVivo 9 software package. **Results** In 1999 UK Sport, as the government agency with a remit for elite sport, administers an Athlete and Career Education (ACE UK) program based on a similar scheme that has been in place in Australia. ACE UK was set up to provide athletes with the skills to cope with the special demands of higher-level sport and to help them prepare for life after sport (UK Sport, 2001). Five major services were provided through the ACE UK program, namely, Personal Development Courses, Education Guidance, Career Planning, Olympic and Paralympic Employment Network (OPEN) (North & Lavallee, 2004). Since its inception in 1999, the ACE UK program has had a relatively high level of usage amongst the elite UK athlete population (UK Sport, 2001). In 2004, the ACE UK program has been replaced with the Performance Lifestyle program which covers the following three main areas: Lifestyle support, Careers and Employment Advice, and Education Guidance. Since 2009 the Performance Lifestyle service has been delivered through the English Institute of Sport. **Discussion** The above programs of lifestyle support and preparation for life after sport contain all or some of the following elements: career advice; educational support, along with personal finance; and media and presentation skills training (Green & Oakley, 2001, 262). This implies that Performance Lifestyle is a program designed to help athletes balance all other aspects of their life with their sport. And, the major contributions of the Performance Lifestyle are concluded as the followings: contributions to medals, athlete welfare, athlete focus, self-efficacy balance, and maybe transferable to other domains. **References** Green M, Oakley K. ## THE COVERAGE OF HANDBALL NEWS IN TURKISH PRINT MEDIA

Celiksoy, S.

*Anadolu University*

Celiksoy, S, Argan, M., Celiksoy, M.A. *Anadolu University- Eskisehir/Turkey* **Introduction** Using the medium of television, Duncan and Brummet; identified three dimensions of spectating that pleasurable experiences are presumed to be derived from. These are the technological, discourse, and social dimensions (Duncan et al., 1998). The frequency of print media coverage of handball started to decrease after 1995. According to Celiksoy's research, some factors such as media, institutionalization, advertisements, and organizations are very important. There might be some ways to enlarge print media coverage of handball (Çeliksoy et al., 2008). The aim of the research is to analyze contents of 2008 print media coverage of handball in three national newspapers *Hürriyet*, *Milliyet* and *Sabah*. **Methods** A content analyze form, which has 20 subjects, has been used in the analyze and evaluation process. SPSS 15 program has been used. Frequency and percentage analyzes have been used in evaluation process. **Results** These newspapers are outstanding in respect to their selling and editions. The most coverage of handball is in *Hürriyet* with the rate of 52.4%. The coverage range on weekdays is 61.2% but at weekends it is 38.8%. The highest range in months is as follows; October (14.6%), November (18.4%), December (10.7%). The most coverage is on the sports page of the newspapers, 95.1%. According to range of the location of coverage, left bottom corner is 30.1%, mid page is 27.2%. The size of the coverage; 1-25 cm<sup>2</sup>. 45.6%, 26-41cm<sup>2</sup>. 39.8%. 61.2 % of the coverage of handball is on weekdays. The coverage of handball is only on sports page with the rate of 95.1%. Most of the coverage size is 10-41cm<sup>2</sup>, on the left bottom corner and it makes up of reports, teams, scores, neutral and positive news. **Discussion** The most coverage of handball is in *Hürriyet* with the rate of 52.4%. 61.2 % of the coverage of handball is on weekdays. Football has more coverage than other sports at the weekends. The coverage of handball is only on sports page with the rate of 95.1%, because teams weren't successful in 2008-2009 seasons championships. Most of the coverage size is 10-41cm<sup>2</sup>, on the left bottom corner and it makes up of reports, teams, scores, neutral and positive news. Besides, most of coverage consists of simple and short articles which have common headlines. The correlation between men-women national teams and men-women teams in leagues is nearly same. Men and women teams didn't success in the championships. Because of this reason, all the news usually appear under one headline on the page. **References** Duncan and Brummet, (1998). *Media Sport*, 7-8. Routledge 11 New Fetter Lane, London. Gamst,G; Sutherland,Y.N. and Evans, B.A. (1993). A Profile of Newspaper Sports Section Readers and Nonreaders, *Journal of Sport Behavior*, 8-9. Vol.16.

## THE RELATIONSHIP BETWEEN COACHING LEADERSHIP STYLE AND TEAM COHESION OF MALE AND FEMALE ATHLETES IN TEAM AND INDIVIDUAL SELECTED DISCIPLINES

Sarpira, M., Khodayari, A.

*Islamic Art University- Tabriz, Iran, Islamic Azad University, Karaj, Iran*

**Introduction** The present study aims to review the relationship between coaching leadership style and Team cohesion. **Method and Subjects** The subjects of the study were all the elite athletes of team and individual disciplines in Tabriz in 2011 that would be sent to the provincial championships. 250 athletes were randomly selected. The instruments for the research were: standard leadership scale for sport questionnaire (LSS) and Team cohesion questionnaire (TCQ). The questionnaires were reviewed and their validities were approved by 15 academic experts and professors. Using Cronbach's alpha coefficient, the researchers calculated the reliabilities of 95%, 90% respectively. This study is a descriptive -correlative one which is performed using field study method. Descriptive-Statistical method was used to present the information in tables and graphs and inferential statistical method (Spearman Correlation) was used to determine the relationship between coaching styles and Team cohesion and finally Mann-Whitney U test method was utilized to statistical comparison between coaches and male and female athletes in team and individual sports. **Results and Discussion** The results showed that there was a clear and significant positive relationship between all aspects of team cohesion and training and practice leadership, task-oriented leadership, and relationship-oriented leadership styles. But there is no significant positive relationship between team cohesion dimen-

sions and directive leadership style. The behavior of coaches in leadership style has a determining role in team cohesion, so coaches can improve the team cohesion by choosing an appropriate leadership style which consequently leads to success of athletes and achievement in competitions.

### **NATIONAL AND TRANSNATIONAL MODELS FOR DEVELOPMENT OF MARTIAL ARTS AND COMBAT SPORTS**

Zhuravlev, P.

*Russian Union of Martial Arts*

Introduction Martial arts (MA) and combat sports (CS) have always been popular. Millions of people practice MA and CS in the world. Because of the unprecedented growth of interest in traditional and modernized MA and CS and an increasing diversity by the almost daily creation of new disciplines there appear umbrella institutions which structure and guide the activities of various schools and federations. The aim of this study was to analyse national - oriented and transnational non-governmental institutions which focus their activities on general support for various MA and CS federations and organizations as well as on promotion of martial arts and combat sports as a whole. Methods The comparative analysis presented here is focused on national and transnational umbrella non-governmental organizations which serve for development of MA and CS on the regional or interregional level. Results In a modern global society whose various elements have become ever more interdependent MA and CS have been always the most instrumental means of fostering mutual understanding and friendly ties between the nations of the world. MA and CG world in all their diversity has enormous potential of educational and cultural values to contribute to social change and to youth development in the regions. National and transnational umbrella organisations are created to better face MA and CS' present challenges and to develop MA and CS as a whole like the following: - National level: Russian Union of Martial Arts (Russia), Organization of Eastern Combat Sports (Kyrgyzstan), Republic Union of Combat Sports (Estonia), Kazakhstan Union of Martial Arts (Kazakhstan), and others; - Transnational level: 1. Eurasia Convention of Martial Arts (that convenes nongovernmental umbrella organizations from 11 countries); 2. SportAccord (currently unites 14 both Olympic and non-Olympic International Federations of MA and CS); and others. Both national and transnational umbrella organizations organize nationwide or world-wide sporting, educational and cultural events which promote values of MA and CS. Discussion We'd like to discuss the following topics: 1. Similarities and diversities of the MA and CG umbrella organizations acting at the national and transnational levels. 2. Multi-sports games (like the SportAccord World Combat Games, and others) like a model for MA and CS development. ### **THE REPRESENTATION OF SPORTS IN TURKISH PRESS**

Katirci, H.

*Anadolu University*

Introduction Sports have become an important part of mass print media. Sports coverage has been increasing in recent years in the mass print media in Turkey. The aim of this study was to analyze the representation of sports in Turkish press. Methods The study sample consisted of national newspapers which are highest circulation in Turkey. Sport pages of these newspapers analyzed by the method of Content Analysis. The number of sports news, type of sports categories in news, distribution of reviews, comments and sports categories in sport pages, photos and their surface area are examined. Results Results showed that football is main sport branch (92% of content) in Turkish newspapers. Almost other sport branches are not covered by newspapers in Turkey. Discussion Without question one of the great passions of the twentieth century has been sport (Boyle and Hayne, 2009). Today's sports have relations with many industries. One of these industries is defined as media. The relationship between sport and the media as a commercial connection for both industries start at the beginning of the twenty-first century. The media has transformed sport from an amateur structure into a hyper-commercialized industry (Matthew, 2006). Sport and media relations are so important for developing sports industry and media coverage (Boyle, 2006). Because of this; sports media should include all sports in their structure. But in Turkey sport media, especially newspapers, located just football in their pages. References Boyle, R. (2006). Sport Journalism: Context and Issues. Los Angeles: Sage Publications. ### **FUTSAL AND ITS RULES IN SPAIN. OPINION OF PLAYERS**

Cachón-Zagalaz, J., Torres-Luque, G., Lara-Sánchez, A.J., Zagalaz-Sánchez, M.L.

*University of Jaén*

Introduction Futsal in Spain has introduced some rules of FIFA rules. In such an attractive sport for the children and young women it is very important to know well the rules by which it is ruled and his differences and similarities with other countries (Totes-Luque et al., 2011). This adaptation has been produced since 2006. The new rules applied causes a negative influence on different aspects. This influence affects the people involved in the game and the loss of sight. Methods Undertake a descriptive whereby study is designed and applied an ad hoc closed the players found in Granada (Spain). Different groups of people will take part: coaches, players, managerial, referees... We intend to conduct a descriptive study. We designed a closed questionnaire. Then we applied this questionnaire to the groups involved. The questionnaire includes views on the rule change since 2006 (Calahorra et al., 2011). The distribution by professions is: 9 technicals; 67 players; 1 manager; 9 referees; 34 spectators; 2 physiotherapists; 6 journalists; total 128 subjects. Results The research subjects were 104 players of which 67 are surveyed. SPSS 15 statistical package for Windows was used for the analysis of quantitative data. The higher percentage of respondents is players. The subjects involved in the FS believe the change in the laws referring to misconduct, game harms the spectator sport. Discussion Also modification of rules and, especially, reduction strategies has slowed down it. The results also match values and qualities of the FS: passing, perfection, passion, possession, keys to the spectator sport, as he retires in the initial investigation (Cachón-Zagalaz et al., 2010). New rules are complex and make it more difficult to make decisions. The game is less dynamic and more limited strategies. Lost spectacle and mark fewer goals. References Cachón-Zagalaz, J. (2011). ### **MEASURING THE SUCCESS OF NATIONS IN JUDO: EVOLUTION AT OLYMPIC GAMES AND WORLD CHAMPIONSHIP IN PERIOD 2000 TO 2011**

Mazzei, L., Silva Neto, A., Vieira, D., Bastos, F., Böhme, M.T.

*Universidade Nove de Julho (University July Nine) - São Paulo/Brazil*

Measuring the Success of Nations in Judo: Evolution at Olympic Games and World Championship in period 2000 to 2011 MAZZEI, L.I.; SILVA NETO, A.; VIEIRA, D.; BASTOS, F. C2; BÖHME, M. T.2 1: University July Nine (UNINOVE, São Paulo, Brazil), 2: University of São Paulo (São Paulo, Brazil) Introduction Judo is a very popular sport. Around 200 countries are affiliated in the International Judo Federation. It's disputed in Olympics Games (OG) and has a adult World Championships (WC), suggesting a universalization of this sport. Therefore, Judo has been the target of investment by many nations that seek international elite sport success. The aim of this study is to analyze the concurrence of countries in greater international Judo events (OG and adult WC). Methods This study was conducted in the period 2000 to 2011. The following variables were analyzed: number of countries that have athletes in the top 8, in the top 4 (medalists) and the countries market share. To calculate the market share was used a points system according to De Bosscher et al (2008). Results There was an increase 18.5% of countries that have athletes ranked in top 8 in WC from 2001 to 2009, while the number of nations that have medalists increased 3.8%. In events of 2010 and 2011, there was a decrease in number of countries that have athletes ranked in top 8 and in medalists in WC (-31%, -16%). Already in OG, the increasing of countries that have athletes ranked in top 8 from 2000 to 2008 was 16%, while the number of nations have medalists has been stable. The market share analyses shows a great superiority of Japan (average of 23% and 21%) followed by France (10%; 7%), Cuba (7%; 9%), China (5%; 9%) and Korea (5%; 7%). Discussion There was a rise of concurrence in judo (VILLAMON et al, 2004), which explain the number of countries and the growing number of athletes in the top 8 in both events and in top 4 in WC. On the other hand, some changes in the competition rules caused a decrease in the number of athletes have possibility of a significant classification in WC. With respect to the market share, the results demonstrate that judo is a Japanese sport, followed at a distance by some countries. Although the difference has decreased, before the changes that occurred in competition rules. Conclusion Many countries seek the international success in judo, but the recent changes in the competition rules go against the real universalization in this sport. However, is an expectation to increase the market share of some countries in London 2012. References De Bosscher, V.; Shibli, J. B.; Van Bottenburg, M.; De Knop, P. (2008). ### **MAXIMIZING ACHIEVEMENT IN SPORT ORGANIZATIONS: A MULTI-STYLE LEADERSHIP APPROACH**

Schneider, R.

*The College at Brockport, State University of New York*

ABSTRACT In consideration of adopting an approach to sport leadership that supports Andrew's (2009) recommendation of altering leadership behavior to meet the requirements of the organization and its members, this presentation will offer insights as to how sport leaders might effectively utilize various components of multiple leadership styles to maximize organizational efficiency. Varying forms of influence are at the disposal of the leader when dealing with the complexities and dynamic nature of organizations (Bolden, Petrov, & Gosling, 2008). The achievement of maximum outcomes from sport organization members calls for a multi-style approach to leadership. Successful leadership of sport organizations can and does take place in many forms. A multi-style approach to leadership incorporates components of all leadership styles as needed to achieve maximum organizational efficiency. Adopting a multi-style approach to sport leadership requires an understanding of the various approaches to leadership and the ability to implement specific components of leadership theories that are germane to varying objectives, circumstances, and missions of sport organizations. The extent to which sport leaders can identify and apply appropriate components of different leadership theories will help elevate the success of the organization. In the interest of effective leadership, Simplicio (2011) explored the benefits and detriments of incorporating specific leadership styles into one's management approach. Adopting selected components of various leadership styles also requires the ability of sport leaders to periodically assume a leadership style that may not be a natural "fit" with their personality traits. To that end, this presentation will also provide a structure, including examples, that supports the sport leader's utilization of various components of leadership theories when leading a sport organization. ### PP-SH04 Sport Statistics and Analysis I

#### THE VOLLEYBALL PERFORMANCE IN SIDE-OUT AND DEFENSE ACCORDING SCORING SKILL AND PLAYERS EFFECTIVENESS

João, P.V., Pires, P., Vaz, L.

*Research Center for Sports Sciences, Health and Human Development (CIDESD) UTAD - Vila Real, Portugal.*

THE VOLLEYBALL PERFORMANCE IN SIDE-OUT (KI) AND DEFENSE (KII) ACCORDING SCORING SKILL AND PLAYERS EFFECTIVENESS João, P.V.1, Pires, P. 2, Vaz, L. 1 1Research Center for Sports Sciences, Health and Human Development (CIDESD) UTAD - Vila Real, Portugal. 2University of Trás-os-Montes and Alto Douro. Introduction Match Analysis is a particular importance in the process team's preparation, to the extent to increase the chances of coach's success to enhance their knowledge on skills teams' performance. Thus and with respect to identify possible constraints assigned to the defensive game procedures (in KI and in KII) we have developed the present study. Methods The sample was composed of 743 actions of reception and by 482 defense actions, belonging to 5 games of Play-off of the National Championship 2009-2010. The dependent variables considered were the effectiveness of the reception and the defense effectiveness, while, the intervenient player at the reception, the service type, the reception area, the defense player intervenient, the defense area and the attack zone were the independent variables. The statistical procedures used were the descriptive statistics and the multinomial logistic regression to obtain the estimated probability of occurrence of the dependent variable, based on values of the independent variables. The reliability intra and inter-observer were cleared using the Cohen's kappa values. Results The results show that the player who has done more receptions which allow all the attack options was the priority reception player. The receptions that occur in the central zone distant are those which provide more situations with all the attack options and the floating jump service is allowing a higher percentage of receptions with all the attack options. Discussion The results showed that the player who has done more defenses that allow all the attack options was the Libero, proving its importance in the offensive organization of team in KII. The areas' most exploited by attacks opponents were the zones 1, 6 and 5 respectively. In this sense in the training process team, and to increase the effectiveness of defensive procedures (in KII), must be considered to be effective coordination of the line of teams receptions and priority reception player establish regularity routines of double function what they practice. To increase the levels of effectiveness of defensive procedures in KII, training routines must be established at the level of the block, which difficult the attack in zone 1, thus freeing the setter for the implementation of distribution action.

#### HEIGHT IS AN OVERRATED FACTOR IN ELITE LEVEL WOMEN'S VOLLEYBALL

Afonso, J., Medeiros, A., Mesquita, I.

*University of Porto - Faculty of Sport*

Height is considered a nuclear component for achieving success in sports such as basketball and volleyball. Therefore, it has been considered as one of the major factors to be included in any talent detection program applied to these sports. However, concerns have arisen as to how important height really is, and to what extent performers are able to play in elite-level national teams without being tall. We analyzed the height of women volleyball players who have participated in the FIVB World Grand Prix, editions 2004 to 2011. This competition gathers the best twelve national teams in women volleyball around the world (16 in 2011) and possesses high prestige. Data were collected directly from the FIVB online platform ([www.fivb.org](http://www.fivb.org)), including values from a total of 1708 participants across those years. Average height was  $182.61 \pm 7.57$ cm, ranging from  $181.92 \pm 8.04$ cm in 2011 to  $183.53 \pm 7.40$  in 2007, and has been diminishing consistently since 2007 until 2011. Relatively to the total number of participants, 7.96% of the players were under 170cm, while 17.27% were under 175cm. Per year, an average of 4 players under 165cm was registered. On the other end of the spectrum, an average of 6 players above 196cm were registered each year. When average team height was crossed with team ranking (1st to 4th ranked; 5th to 8th; 9th to 12th; the 13th to 16th ranked teams were excluded, since only the 2011 edition presented that many teams), significant differences emerged ( $F=7.064$ ,  $p=0.001$ ). Bonferroni pairwise comparisons revealed that the teams ranked in the top four spots presented superior height (184.16cm) compared to the teams ranked in the lower end of classification (181.22cm), with a mean difference of 3cm. In conclusion, even though height is an important factor for high-level volleyball, and still makes a difference between top-level teams and near top-level teams, there is wide space for shorter players to incorporate national teams participating in World-class competitions such as the FIVB World Grand Prix. Certain game functions, such as the libero and the setter, are less dependent on height than being a middle-attacker, for example. This might explain why almost 18% of the players registered in such competitions fall short of 175cm, but players under this height were also found for wing-spikers. Yet, many national teams for the youth and junior players stipulate a minimum value of 175cm as a cut value, under which the player is excluded of the process. If nothing else, these data should advise coaches that height is being overrated as a factor of selection in women's volleyball. Furthermore, average height in this World-class competition has been decreasing, suggesting that other factors are being privileged in making the team's rosters.

#### THE ROLE OF AGE IN PERFORMANCE IN ELITE LEVEL WOMEN VOLLEYBALL TEAMS

Afonso, J., Medeiros, A., Mesquita, I.

*University of Porto - Faculty of Sport*

Age is a core concept for achieving high performances. Foremost, age allows gathering experience and acquiring quality in performance. On the other hand, physical decrements may impair performance. Therefore, volleyball teams should balance their roster, mixing experienced, older players with younger players. Our purpose was to analyze the age of women volleyball teams who have participated in the FIVB World Grand Prix, from 2004 to 2011. This competition selects the best twelve national teams in women volleyball in the world (16 in 2011). Data were collected directly from the FIVB online platform ([www.fivb.org](http://www.fivb.org)), including values from a total of 1708 participants across those years. Average age was  $24.28 \pm 4.21$  years, ranging from  $23.64 \pm 3.41$  in 2005 to  $24.79 \pm 4.33$  in 2007. This is an evident evolution of age according to the Olympic cycle. Teams' age decreases in the year immediately following the Olympic Games, progres-

sively increases until the next Olympic Games, and again falls. Teams were further divided into three groups according to their ranking in the competition: 1st to 4th ranked teams, 5th to 8th, and 9th to 12th. Teams ranked 13th to 16th were excluded, since this situation happened only in the 2011 edition of this competition. There are significant differences between the teams according to their ranking ( $F=5.009$ ,  $p=0.009$ ). Bonferroni pairwise comparisons revealed that the teams ranked 1st to 4th were older (24.84 years) than the teams ranked 9th to 12th (23.63 years). Overall, World-class women volleyball teams present an average age varying from 23 to 25 years, mixing experienced players with younger, up and coming players. Age fluctuations accompanying the Olympic cycles reveal there is a concern in national teams to renew their roster, which then goes on acquiring experience until the next Olympic Games. Furthermore, the four best-ranked teams in each World Grand Prix are, in average, one year older than the worst four ranked teams. So, ideally, top-level women volleyball teams should present a mixture of experience and youth, but achieving the best four spots implies a trend towards experience. The renovation of teams following the Olympic cycles is evident in this sample.

## EVALUATION OF CERTAIN PHYSICAL FEATURES RELATED TO JUMPING ABILITY OF VOLLEYBALL PLAYERS OF NATIONAL VOLLEYBALL TEAMS OF AGE 16-19 YEARS, IN ALBANIA.

Lleshi, E.1, Kokoneci, G.2

*University of Sport, Tirana*

Introduction Albania's participation in Balkan Volleyball Cup 2011 for age group 16-19 is an important event in our country. The evaluation of physical features, especially jumping ability in the force platform (Ergo Jump System) has a special importance in the progress of these volleyball ages. Methods The research is focused in four teams: Junior Women 12 girls, Youth Girls 12 girls, Junior Men 12 boys, Youth Boys 12 boys. Based on or measurements, we calculated the average for each team: Birthday (AGE), Body Height (BH), Body Weight (BW), Body Mass Index (BMI), Jump Attack (JA), Jump Block (JB), Squat (SJ) and Counter movement Jump (CMJ), Repetitive Jump (RJ 15sec). The three tests for C. Bosco were performed in the Ergo Jump System platform. The difference in % of (CMJ-SJ) the calculation of the elasticity index. Elastic energy (CMJ-SJ) x 100 / CMJ the capacity for subsequent reuse of accumulated elastic energy resulting from the elastic stretch preceding muscular contraction. The average RJ 15sec / CMJ gives the resistance index of explosive force. Results The measurements showed the following results: Junior Women; Age 18.3, BH 179.8cm, BW 66.5kg, BMI 20.5, JA 288.2cm, JB 277.3cm, SJ 25.3cm, CMJ 30.6cm, Elasticity 17.3%, Resistance 0.8: Youth Girl; Age 16.5, BH 174cm, BW 61kg, BMI 20, JA 280.3cm, JB 266.9cm, SJ 26.9cm, CMJ 32.5, Elasticity 17.2%, Resistance 0.8: Junior Men; Age 18.5, BH 191cm, BW 79.8kg, BMI 21.8, JA 323.7cm, JB 305.3cm, SJ 43.3cm, CMJ 43.2cm, Elasticity 16.3%, Resistance 0.7: Youth Boys; Age 17.5, BH 190.8cm, BW 79kg, BMI 21.9, JA 322.5cm, JB 303.8cm, SJ 36.4cm, CMJ 43.2cm, Elasticity 15.7%, Resistance 0.8. Discussion The collected evidence presents the BMI of 16-19 females within the comparative parameters of references, whereas the BMI of males is >(10-20%) for the same age. The elasticity index deriving from the difference in % of CMJ-SJ as Reactive Strength Index is low in these volleyball players. (CMJ-SJ) x 100 / CMJ; the elasticity index is presented in % as an indicator of the accumulated energy capacity resulting from the elastic stretch preceding muscular contraction. This index shows unexploited reserves of muscle elastic energy in sportsmen. The mechanical strength during jumping RJ 15sec proved to be a very sensible functional parameter which individualizes the features and characteristics of alaktik anaerobe element pertinent to training. Capacity of reactive strength index CMJ (h15/h CMJ) in collective sports in teams, these values reach up to 0.90-0.95. This data suggests that the values of teams 16-19 years reach up to 0.8. The national volleyball teams of 16-19 years have a low capacity of reactive strength resistance, which derives from lack of their plyometric and power training. Reference C. ## ADOLESCENT MALE VOLLEYBALLERS' SERVE PROFICIENCY IN ESTONIAN CHAMPIONSHIPS IN 2005, 2006 AND 2008

Stamm, M., Stamm, R., Koskel, S.

*Tallinn University*

ADOLESCENT MALE VOLLEYBALLERS' (AGED 13-15, N=197) SERVE PROFICIENCY IN ESTONIAN CHAMPIONSHIPS IN 2005, 2006 AND 2008 Meelis Stamm<sup>1</sup>, Raini Stamm<sup>2</sup>, Säde Koskel<sup>3</sup> <sup>1</sup>Institute of Educational Sciences, Tallinn University, Tallinn, Estonia <sup>2</sup>Institute of Health Sciences and Sport, Tallinn University, Tallinn, Estonia <sup>3</sup>Centre for Physical Anthropology, Institute of Anatomy, Faculty of Medicine, University of Tartu, Tartu, Estonia Introduction The study analyses volleyballers' performance at Estonian championships for Class C (up to 16-year-olds) in three tournaments – Tartu 2005, Viljandi 2006 and Rakvere 2008. The participants were members of the eight best teams of Estonia at the moment. Methods To record the games an original computer program Game (Nõlvak, 1995) was used, which was first presented by R. Nõlvak (Stamm) in 1995 and has been introduced in the International Journal of Volleyball Research (Stamm et al, 2000). For simultaneous recording of the performance of two opposing teams, two computers equipped with the program Game were used. Parallel recordings were made by volleyball experts – Meelis Stamm and Raini Stamm. Twenty-eight indicators of proficiency in the game were registered, but in this study we focus only on the element of serve. Results From our results we can conclude that in 2005 there were 278 serves which earned a point at once (aces) in 2006 – 204 serves, and in 2008 – 309 serves. When we look at the mistakes during the serves, we can see that in 2005 there were 308, in 2006 were 197 and in 2008 were 246 mistakes during the serve. From these numbers we can summarize, that boys serving quality is increasing. The same thing is when we look the proficiency of serve during the different years. It has been changing from 0,38 to 0,45. As long as it is not a longitudinal study but cross sectional, then we can't say that the boys were getting better but we can say that the quality of coaching was improved. Discussion The serve is playing more important role in the game from year to year. The meaning of serve has been changed. It has become a real attacking element and it is not any more simply the element for beginning the ball rally. References Nõlvak R. (1995) A system for recording volleyball games. Papers on Anthropology VI. Proceedings of the 7th Tartu International Anthropological Conference 29 May – 2 June. Tartu 1995, 171-175. Stamm R., Stamm M., Oja A. (2000) A system of recording volleyball games and their analysis. Int J Volleyball Res, 2 (1), 18-22.

## THE DIFFERENCE IN SPORTIVE PERFORMANCES BETWEEN THE NATIONAL WOMEN'S VOLLEYBALL AND WOMEN'S BASKETBALL TEAMS IN ALBANIA.

Lleshi, E., Selencia, R.

*Sport of University of Tirana*

Introduction Women's National Volleyball and Basketball teams have a diverse performance from each others. Their specific training leads to the diversity of physical qualities and individual or team's sportive performance. Methods This study is concentrated on two teams: Women's Volleyball Team (V) and Women's Basketball Team (B) 12 members each, focusing on 24 subjects. We estimated the average of every team from data such as: Birthday (AGE), Body Height (BH), Body Weight (BW), Body mass (BMI), Body Fat (BF), Squat and Counter-movement Jump (SJ, CMJ), Repetitive Jump (RJ15sec). The C. Boscos tests (3) were performed on the ErgoJump system platform. From the data we were able to calculate the average differences between the two teams. The difference in percentage of (CMJ-SJ) the calculation of the coefficient of the reutilization of the elastic force.  $(CMJ-SJ) \times 100 / CMJ$  percentage of the capacity of reutilization of the accumulated energy as a result of the elastic retraction that proceeds the muscular contraction. The average RJ15sec/CMJ, that is the resistance coefficient of the explosive force. Results These are the results from the evaluations: The differences between Women's V Team with Women's B Team: Age 22.3 < 26.4, BH 180 < 180.2 cm, BW 68.4 > 68.3 kg, BMI 21.12 > 21.04, SJ 28.5 > 25.07 cm, CMJ 34.6 > 30.8 cm, % elasticity 17.71 < 21.54%, BF 25.10 < 26.37%. Average RJ15sec/CMJ = Volleyball is 0.9 and Basketball 0.7. Discussion The team members were tested and the results are displayed in pre designed tables and considered for the team's average estimation. The National teams do not have any differences in the general physical performance considering the parameters of BH, BW, BMI. The formula use in Body fat  $\% = (1.20 \times BMI) + (0.23 \times Age) - 10.8 \times gender - 5.4$  the gender female = 0 have difference. The formula  $(CMJ-SJ) \times 100 / CMJ$  indicates the coefficient of elasticity expressed in percentage of muscular contraction have difference between V and B. Mechanical strength during the jumping at RJ15 sec identifies the qualities and characteristic of aerobic power alaktacide with the adaption of the training. The capacity of resistance of speed power.  $CMJ / (h15 / hCMJ)$  in the case of sports that there is a team involvement reaches values at 0.90-0.95, so from the data we can see that values of these teams have differences between them. Nation Women's V Team 0.9 has relatively better capacity in resistance of speed power compared with nation Women's B Team 0.7. This comes as a consequence of the deficiency in Plyometric and Explosive force training. Still some of the team members are able to reach optimal results after have completed proper training phase. References C. Bosco Ph.D. "La forza muscolare" Aspetti Fisiologici ed Applicazioni Pratiche (Rome 2006) Capitolo IV-La Forza Esplosiva, Capitolo VIII-Applicazioni pratiche del test di Bosco; G. ## TACKLE CHARACTERISTICS THAT MAY INCREASE THE LIKELIHOOD OF A SUCCESSFUL TACKLE OUTCOME IN RUGBY UNION

Hendricks, S., Matthews, B., Rhode, B., Lambert, M.I.

*University of Cape Town*

Introduction The tackle in rugby union is a dynamic and high impact contact situation that occurs frequently during matches and exposes players to high risk of injury and muscle damage. Given the nature and frequency of the tackle situation, tackle contact skills are a prerequisite for participation in rugby union. Most techniques described in training manuals and injury prevention programs are based on anecdotal evidence. Retrospective analysis of the tackle has characterized common injury mechanisms for both the ball-carrier and tackler, and effective ball-carrying techniques. In spite of this, no retrospective analysis from a tackler perspective and its association with successful tackle outcomes in rugby union has been investigated to date. Aim The purpose of this study is to identify tackler characteristics that may increase the likelihood of a successful tackle outcome in rugby union. Methods Two thousand and ninety-two tackles from 18 matches of the 2010 Super 14 were analysed. Tackles were coded using characteristics and definitions described in previous research, and characteristics and definitions developed specifically for this study. Characteristics were divided into the three tackle phases i.e. pre-contact (0.5s preceding contact), contact and post contact. The outcomes of the contact event were divided into tackle outcome, possession, territorial change and result. Multinomial logistic regression was used to determine which tackler characteristics increased the likelihood of a successful outcome. Results Pre contact: Tracking decreased the tacklers' chances of a successful tackle (Relative Risk Ratio (RRR) 2.24, 95% CI 1.72-2.92,  $p < 0.001$ ) relative to an up and forward head position. Contact: Arm tackles (RRR 2.32, 95% CI 1.62-3.32,  $p < 0.001$ ), collision tackles (RRR 4.98, 95% CI 2.17-11.42,  $p < 0.001$ ) and jersey tackles (RRR 2.56, 95% CI 1.87-3.49,  $p < 0.001$ ), significantly reduced the chances of a successful result relative to shoulder tackles. Post-tackle: A moderate (RRR 0.36, 95% CI 0.26-0.50,  $p < 0.001$ ) or strong (RRR 0.39, 95% CI 0.11-1.35) leg drive by the tackler after contact increased the likelihood of a successful tackle. Using the arms for either pulling (RRR 0.30, 95% CI 0.21-0.43,  $p < 0.001$ ) or wrapping (RRR 0.19, 95% CI 0.13-0.27,  $p < 0.001$ ), improved tacklers' probability for success in contact. Discussion The characteristics identified in this study are comparable to most training manuals and injury prevention programs. Nonetheless, key characteristics that may require more attention than other characteristics have been identified. The authors of this study propose that coaches and players focus on these key characteristics in training to improve their tackle ability in matches.

## RELIABILITY OF TRUNK STABILITY MUSCLE REACTIONS IN THE CONTEXT OF NUMBER OF CONSECUTIVE TRIALS

Sarabon, N.

*University of Primorska*

Introduction Central lumbo-pelvic stability plays an important role in postural, locomotion and manipulation activities of all kinds. In order to evaluate neuromuscular functions of the LPSM two types of tests (i.e. motor tasks) are commonly used. First, quick voluntary movements of the limbs which involve anticipatory (Ramprasad et al., 2010) and second, sudden unexpected mechanical perturbations which evoke reactive automatic trunk muscles stabilisation actions (Pedersen et al., 2009). The aim of this study was to test intra-session repeatability of automatic neuromuscular responses of three muscles which are involved in lumbo-pelvic stability (LPSM). Methods Sixteen young healthy volunteers participated in the study. Each of them performed four consecutive trials of: (1) a test of self-initiated quick shoulder flexion to test the anticipatory pre-activation patterns of the LPSM, (2) a test of neuromuscular reaction of LPSM on unexpected loading, and (3) a test of neuromuscular reaction of LPSM on unexpected unloading of upper extremities. The latency of the neuromuscular responses (LAT) and the rate of LPSM increase in activation (RMS50) were analysed in all of the responses. The dependence of parameters' repeatability on the number of trials averaged was analysed using ANOVA, ICC, SEM, and CV. Results For all the three observed muscles and all the motor tasks ICCa values of the RMS50 was generally higher than that of LAT. Eighteen or more trials of the same task are needed to achieve acceptable ICCa values. Results of SEM and CV showed progressive decrease with the increasing number of the

trials being averaged. The most reduction in SEM and CV took place with averaging the first 10 consecutive trials. Discussion Based on our results we can conclude that averaging of 20 or more trials of the same lumbo-pelvic stability test will bring us a repeatable measure. However, in order to work with fewer trials also other methodological approaches such as signal averaging should be considered. References Pedersen MT, Randers MB, Skotte JH, Krstrup P. (2009). ### PP-PM16 Rehabilitation 1

#### THE EFFECT OF AQUATIC EXERCISE ON THE PEAK TORQUE OF KNEE JOINT OF ELDERLY WOMEN

Dong-hyun, S., Gi Duck, P.

*Namseoul University*

**Introduction** The application of aquatic exercise for elderly persons does not require any special skills, and exercise on the ground can be used underwater as they are in most situations. Taekowndo Poomsae motions are composed of standing, steps for punching as well as kicking motions, and thus, they can improve lower extremity health related to physical strength and can be effective in preventing falling as they reduce balance sway. In this respect, this study is intended to examine the effects of Taekowndo Poomsae motions applied underwater on knee joint peak torque. **Methods** This study was conducted with 23 elderly women divided into an Aquatic Exercise Group(AEG, n=12) and a Control Group(CG, n=11). The knee joint Peak torque was assessed using an ISOMED 2000(D&R GmbH, Germany). The aquatic exercise program was implemented using a N Aquatic Rehabilitation Swimming Pool in Chonan, Korea. The aquatic exercises performed were Taekowndo motions, including Poomsae chapters 1-3, and basic kicks (front kick, side kick and back kick). **Result** With regards to changes in knee joint peak torque, the AEG showed significant differences between before and after the application in all items, including Right knee flexion, Right knee extension, Left knee flexion and Left knee extension( $p<0.05$ ), while the CG did not show any significant differences between before and after the application. **Discussion** When comprehensively considering the aforementioned previous studies, the results indicating that the application of aquatic exercise using Taekowndo Poomsae motions improved knee joint Peak torque is supported, suggesting the applicability of these exercises as a new exercise program for elderly women. **Reference** Maki, B. E., McLroy, W.E.(2006). Control of rapid limb movements for balance recovery: Age-related changes and implications for fall prevention. *Age Ageing*, 35: M126- M134. Larger center of pressure minus center of gravity in the elderly induces larger body acceleration during quiet standing. *Neuroscience Letters*, 422, 202-206.

#### SLOWED EXERCISE-ONSET VO<sub>2</sub> KINETICS DURING LOW-TO-MODERATE-INTENSITY ENDURANCE EXERCISE IN SUBJECTS WITH MULTIPLE SCLEROSIS

Hansen, D., Wens, I., Kosten, L., Verboven, K., Eijnde, B.O.

*Hasselt University*

**Background** In multiple sclerosis (MS) patients, a lowered skeletal muscle oxidative capacity is present. It might be relevant to be able to assess skeletal muscle oxidative capacity in MS patients without the need of invasive techniques and/or maximal exercise testing. For this purpose, the exercise-onset oxygen uptake (VO<sub>2</sub>) kinetics during endurance exercise is measured. The objective of this study was to assess exercise-onset VO<sub>2</sub> kinetics in MS patients vs healthy subjects. **Methods** From 38 MS patients and 17 healthy subjects, exercise-onset VO<sub>2</sub> kinetics (mean response time (MRT)) was determined during two subsequent 6-minute low-to-moderate-intensity exercise bouts. Blood lactate, heart rate, expiratory volume and Borg ratings of perceived exertion was assessed during exercise, and compared between groups. Relations between muscle strength, body composition, EDSS score, physical activity, and MRT were assessed in MS patients. **Results** During exercise blood lactate, heart rate, and expiratory volume were equal between groups ( $p>0.05$ ), but MRT was significantly slower in MS patients vs healthy subjects ( $p<0.05$ ). In total population, MRT was independently related to MS presence ( $p<0.05$ ). In MS patients, no independent relations were found between muscle strength, body composition, physical activity, EDSS score, and MRT ( $p>0.05$ ). **Discussion** Because of the observation of slowed exercise-onset VO<sub>2</sub> kinetics during endurance exercise in MS patients vs healthy subjects, and because no clinical parameters were related to exercise-onset VO<sub>2</sub> kinetics, these findings might suggest that MS patients suffer from molecular skeletal muscle dysfunctioning (such as lowered oxidative capacity) during endurance exercise. By applying such exercise tests, we are now capable of estimating (changes in) oxidative capacity of skeletal muscle in MS patients, without the need of maximal exercise tests or invasive procedures.

#### INDIVIDUALIZATION OF EXERCISE PRESCRIPTION BY THE USE OF THE PERCEIVED EXERTION RELATED TO THE CROSS-OVER POINT IN WOMEN WITH METABOLIC SYNDROME

Garcin, M.

*University Lille Nord de France*

**INDIVIDUALIZATION OF EXERCISE PRESCRIPTION BY THE USE OF THE PERCEIVED EXERTION RELATED TO THE CROSSOVER POINT IN WOMEN WITH METABOLIC SYNDROME** Garcin, M.1 2, Borel, B.1 2, Coquart, J.3, Matran, R.1 4, Delsart, P.5, Mounier-Vehier, C.5 1: Univ Lille Nord de France (Lille, France), 2: UDSL, EA4488 (Ronchin, France), 3: Univ Rouen, EA 3832 (Rouen, France), 4: Service des Explorations Fonctionnelles et Respiratoires, Hôpital Calmette, CHRU Lille (France), 5: Service de Médecine Vasculaire et Hypertension Artérielle, CHRU Lille (France) **Introduction** The use of indirect calorimetry in effort which allows to determine the crossover point of substrate utilization (COP) is used in order to individualize the prescription of exercise intensity (Brun et al., 2007). Furthermore, the use of a perceived exertion scale (RPE, Borg, 1970) can be proposed to prescribe the exercise intensity (Dunbar et al., 1992). The study's aim was to examine 1) the feasibility of the use of the RPE to prescribe a rehabilitation program individualized at COP, and 2) the effects of this program on the maximal work capacity and RPE in women with metabolic syndrome (MS). **Methods** Fifteen women with MS (age = 56.0 ± 8.2 yrs; mass =

87.7 ± 12.7 kg; height = 160 ± 6 cm) performed a test to exhaustion to estimate the peak of oxygen uptake (VO<sub>2</sub>peak) and the power output peak (Ppeak), and an indirect calorimetry test to determine COP and the related RPE. These women followed a rehabilitation program (3 sessions of 45 min.wk<sup>-1</sup> at the target RPE related to their COP on cycle ergometer during 12 wks). After the rehabilitation program, the tests were performed again. Results The target RPE was 11.8 ± 3.0 (i.e. light). The power adjusted was not significantly different from the target power (40 ± 15 vs 41 ± 17 W; p=0.60). For the same prescribed target RPE, the power output adjusted by the women increased with the rehabilitation duration (P<0.001). VO<sub>2</sub>peak and Ppeak were increased (17.3 ± 3.9 vs 18.5 ± 4.3ml.min<sup>-1</sup>.kg<sup>-1</sup>; 101 ± 25 vs 122 ± 29 W, respectively; p=0.01) whereas RPE was lower after the rehabilitation period during the indirect calorimetry test (p=0.006). Discussion These women did success to regulate the power output to COP from their target RPE. Moreover, the use of target RPE allowed these women to increase the power output during the rehabilitation program, and so to significantly improve their maximal work capacity. Both the increase of maximal work capacity and the decrease of RPE for a same relative power output after the rehabilitation program showed the beneficial effects of this program prescribed from RPE in these women with MS. ## VALIDATION OF ACTIHEART ENERGY EXPENDITURE MEASUREMENT IN COPD PATIENTS

Oomen, J., Gosens, W., Brage, S., Borghouts, L.

*Fontys University of Applied Sciences*

Introduction Assessment of physical activity energy expenditure (PAEE) outside the standardised laboratory is complex. Thompson et al.1 showed that motion sensors do not provide an accurate estimation of PAEE whereas the combined motion and heart rate sensor Actiheart does. However, measurement of PAEE with Actiheart has never been evaluated in patients with COPD. Therefore this study examined the validity of the Actiheart against indirect calorimetry for PAEE measurement in patients with COPD. Methods 27 patients with COPD (FEV1/FVC <70%, age 58 ± 7 years) were selected for the study. Patients were asked to perform five simulated Activities of Daily Living (ADL) (Walking, Watering plants, Walking with a load, Stocking laundry and Cycling) for 8 minutes. These activities were selected from a study of Ainsworth et al 2 and expected to represent a range in PAEE. There was an 8 minutes resting period between activities. Energy expenditure was estimated during the activities using the Actiheart 3 with indirect calorimetry (Cosmed K4B2) as the reference measurement. Results PAEE measured with Cosmed was in a very small range (13,3 vs 16,3 kJ/min) and most activities did not differ significantly from each other in energy expenditure. Using the algorithms valid in healthy subjects, the Actiheart was not able to correctly estimate PAEE in the individual tasks (p < 0,001) and the protocol as a whole (P < 0,001). After manually 'tweaking' the algorithms there was no significant difference in PAEE between the Cosmed and the Actiheart in the individual activities (p > 0,4) and the protocol as a whole (total PAEE) (p > 0,9). Discussion Actiheart was not able to calculate PAEE in patients with COPD using the algorithms validated for healthy adults. After we adapted these, PAEE calculated from Actiheart did not differ from indirect calorimetry. However, the HR-range (HRmax symptom limited - HRrest) in which patients performed their activities was very small. Therefore, the PAEE range was also small. COPD patients are symptom limited due to shortness of breath and the use of medication (e.g. Beta blockers). As a result, all activities were performed at an intensity between Flex- and Transition heart rate. This may limit the use of branched algorithms in COPD. 1. ## MECHANICAL EFFICIENCY IN COPD

Gosens, W., van 't Hul, A.J., Oomen, J.M., van Ranst Hesselink, M.K.C., Borghouts, L.B.

*Institute of Human Movement and Sports, Fontys University of Applied Sciences, Tilburg, The Netherlands & Maastricht University, Maastricht, The Netherlands.*

Mechanical efficiency in COPD Gosens, W.1,2, van 't Hul, A.J.3,4, Oomen, J.M.1, van Ranst D.3, Hesselink, M.K.C.2, Borghouts, L.B.1  
1Institute of Human Movement and Sports, Fontys University of Applied Sciences, Tilburg, The Netherlands 2Department of Human Movement Sciences, Maastricht University, Maastricht, The Netherlands 3Revant, Rehabilitation Centre, Breda, The Netherlands 4Department of Pulmonary Diseases, VU Medical Centre, Amsterdam, The Netherlands Introduction Chronic Obstructive Pulmonary Disease (COPD) is a disease clinically characterised by breathlessness on exertion, fatigue and exercise intolerance. The underlying mechanisms of symptoms and exercise intolerance are complex. Exercise tolerance decreases with increasing severity of the disease. Therefore, it can be hypothesised that ME declines with increasing severity of the disease and that indices of the severity of the disease are independent predictors for ME in COPD. However, absolute work rate explains about 90% of the gross ME in healthy subjects (Ettema et al., 2009). Therefore, the primary aims of this study were: 1) to evaluate whole body ME in a large group of COPD patients with a wide range of degree of illness, 2) to examine how ME in COPD is related to absolute work rate and indices of disease severity. Methods 569 patients (301 male, 268 female) with COPD (28 GOLD stage I; 166 GOLD stage II; 265 GOLD stage III and 110 GOLD stage IV) were included in the data-analysis. Body composition and pulmonary functions were determined according to recommended standards. Ventilatory and metabolic response parameters were collected during the constant work rate test at 75% Wmax. The gross mechanical efficiency was calculated from the ventilator parameters, using the abbreviated Weir formula. Results The mean whole body gross ME was 11.0 ± 3.5% at 75% peak power. The ME declined significantly (P<0.001) with increasing severity of the disease when measured at the same relative power. Log transformed absolute work rate (r = 0.87, p<0.001) was the strongest independent predictor of gross ME. Discussion This study demonstrates that when patients are compared at the same relative work load, gross mechanical efficiency (ME) seemingly declines with increasing severity of disease in COPD. However, when gross ME is expressed as a function of absolute work rate, there is no relation between gross ME and indices of disease severity. Conclusion Gross ME in COPD is largely predicted by the absolute work rate (r = 0.87, p<0.001) and indices of the severity of the disease do not predict ME in COPD. **MOVING FORWARD PROJECT: REHABILITATION OF HEART FAILURE PATIENTS IN A REGIONAL HOSPITAL.**

van Berkel, S., de Vries, S.T., Vegter, W.H., van 't Hof, A.J.W.

*Isala klinieken Zwolle*

Introduction Heart failure is an increasing problem in today's society because people are getting older, are surviving a heart attack, are obese and/or are diabetic. Therefore the number of people that develop heart failure is increasing. The prevalence is 3.0% at 65 to 74 years to 16.8% above 85 years(1). The first mortality is 40%(2). Physical inactivity is very common among heart failure patients and will lead to further decrease of physical condition and progression of heart failure. The goal of this study is to examine whether an early, both clinical and home-based, intensive rehabilitation program in a regional hospital has a positive effect on exercise capacity, quality of life and hospital admissions in heart failure patients. Methods Sixty-two patients were included in 2009 and 2010 in the "Moving Forward Project", a 12 month intensive rehabilitation program. The rehabilitation consisted of both endurance and weight training. The patients exercised 4 days per week at home and on two days per week at the hospital under supervision. Maximal oxygen uptake capacity was measured during a cycle ergometer test. Quality of life was measure with the Minnesota Living with Heart Failure questionnaire. The hospital admissions and other adverse events were registered. All measurements were performed at baseline and after 3, 6 and 12 months. Results The preliminary results show that maximal oxygen uptake capacity increased by 14% (= 2.2 ml/min/kg, n=41) after 3 months and by 26% (= 4.0 ml/min/kg, n=29) after 6 months. Quality of life did not improve after 3 months (41.8 to 39.7; n.s.), but did improve after 6 months (40.8 to 34.0; p=0.03). The average number of hospital admissions during the 12 months of the program was  $2.0 \pm 1.4$ . The primary reason for admission was heart failure (50%). Conclusion and discussion An intensive rehabilitation program in a regional hospital leads to improvement of physical condition and quality of life in heart failure patients. Whether this will also lead to a better long-term survival is a question that remains to be answered in future studies. 1 Cowie MR, Wood DA, Coats AJS, Thompson SG, Poole-Wilson PA, Suresh V & Sutton GC. **PREVALENCE AND TRENDS OF OVERWEIGHT AND OBESITY IN YOUNG ITALIAN ATHLETES: DIFFERENCE BETWEEN YEARS OF COMPETITIVE SPORT PRACTICE**

Attisani, G., Attisani, I., Castagna, A.

*Centro Medico Fisios*

Objective: To provide current estimates of the prevalence and trends of overweight and obesity in Italian children and adolescents who play sports from a different amount of years. Research, Methods and Procedures: This was a cross-sectional study of 2344 athletes (M/F:1682/662) aged 12 to 18 years. Height and weight were measured in a Sport Medicine Clinics during the period between 2009 and 2006 (1017 subject, 69.5% male). To classify the athletes were used the International Obesity TaskForce cut-offs (IOTF)-2. The IOTF classify BMI in children as thin, normal weight, overweight or obese, depending on the child's age and sex, based on adult BMI cut-offs at 18 years. Normal weight or thin for BMI range at 18y <25, overweight for BMI range at 18y from 25 to 30 and obesity for BMI range at 18y >30. Then the athletes were divided into two groups. A: athletes at the first physical fitness examination for competitive sport; B: athletes who have made six consecutive annual visits. The data was obtained through a questionnaire and subsequent verification by medical records. The data of group A was compared with data of group B. A probability level of  $p < 0.05$  was used to indicate statistical significance. Results: The prevalence of overweight in group A was 24.3% (273) in male and 19.5% (93) in female. The prevalence of obesity in group A was 4.8% (54) in male and 5.1% (24) in female. The prevalence of overweight in group B was 20.3% (88) in male and 8.9% (33) in female. The prevalence of obesity in group B was 2.1% (9) in male and 1.7% (6) in female (Tab. 1). We observed a decrease of overweight of 4% in male ( $\chi^2$  Yates corrected=3.57;  $p=0.0590$ ; odds ratio=0.76) and of 10.6% in female ( $\chi^2$  Yates corrected=19.56;  $p=0.0000$ ; odds ratio=0.38); a decrease of obesity of 2.7% in male ( $\chi^2$  Yates corrected=6.18;  $p=0.0129$ ; odds ratio=0.39) and 3.4% in female ( $\chi^2$  Yates corrected=7.94;  $p=0.0048$ ; odds ratio=0.27) (Tab. 2). Conclusions: The prevalence of overweight and obesity in group B is less than the prevalence in group A. This proves that sport practiced continuously during the adolescent period is useful to maintain or gain normal weight. References: 1. Cole TJ, Bellizzi MC, Flegal KM and Dietz WH. **13:45 - 14:45****Poster presentations****PP-PM17 Physiotherapy****AGE-RELATED CHANGES IN TOE GRIP STRENGTH AS MEASURED BY A TOE GRIP DYNAMOMETER: RELATIONSHIPS BETWEEN TOE GRIP STRENGTH AND PHYSICAL FUNCTIONS**

Uritani, D., Fukumoto, T., Maeoka, H., Okada, Y., Matsumoto, D.

*Kio University*

Introduction Toe grip strength (TGS) is associated with physical functions such as balancing (Endo et al., 2002) and walking (Hughes et al., 1990), and TGS decreases with aging (Endo et al., 2002). However, a reference value for TGS is not clear because a standard method of measurement of TGS has not been developed. Thus, the relationships between TGS and physical functions are unclear. The aim of this study was to clarify age-related changes of TGS, to develop a prediction equation of TGS, and to investigate relationships between TGS and physical functions using a toe grip dynamometer developed by us. Methods Participants were 1194 subjects (mean (standard deviation) age, 56.2 (14.4) years; age range, 20-79 years; 437 males and 757 females). Outcome measures were TGS, hand grip strength (HGS), isometric knee extension strength (IKES), vertical jump, and functional reach. Participants were divided into three groups: young (Y) group (aged 20-39 years), middle age (M) group (aged 40-59), and old (O) group (aged 60-79 years). Correlations between TGS and

other outcomes with age, height and weight were examined using Pearson's correlation coefficient. Outcomes were compared among three groups using one-way ANOVA with post-hoc test by gender. A prediction equation of TGS was developed based on stepwise multiple-regression analysis including gender, age, height and weight as explanatory variables. The significance level was set at 5%. Results TGS was correlated with age ( $r = -0.48$ ), height ( $r = 0.56$ ), weight ( $r = 0.41$ ), HGS ( $r = 0.61$ ), IKES ( $r = 0.61$ ), vertical jump ( $r = 0.66$ ) and functional reach ( $r = 0.35$ ). In males, TGS of the O group (10.9 kg) was significantly lower than that of the Y group (16.6 kg) and M group (14.4 kg), and TGS of the M group was significantly lower than that of the Y group. In females, TGS of the O group (7.2 kg) was significantly lower than that of the Y group (10.5 kg) and M group (9.4 kg). Other outcome measures also decreased significantly with aging in both genders. A prediction equation was  $TGS = 0.688 - 2.587 \times \text{gender (male: 0, female: 1)} - 0.112 \times \text{age} + 0.097 \times \text{height} + 0.033 \times \text{weight}$  ( $R^2 = 0.42$ ). Discussion Our results showed that TGS decreased with aging, especially after 60 years of age. TGS was predicted by gender, age, height and weight. TGS was associated HGS and IKES, and may represent extremity muscle strength, as well as HGS and IKES. TGS was associated with not only balancing ability, but also jumping performance. ### **SIGNIFICANCE OF THE ELDERLY LIVING IN THE COMMUNITY BEING ABLE TO STAND ON ONE LEG WITH EYES OPEN: A STUDY OF PHYSICAL, COGNITIVE, AND PSYCHOLOGICAL FUNCTIONS**

MURATA, S., KUBO, A., KAI, Y.

*Nishikyushu University*

**Introduction** The simplest form of balance function test is to measure the time of being able to stand on one leg. Although measurement of the time of being able to stand on one leg with eyes open is of significant convenience as a test of the balance function, few studies have been conducted to support the validity of the measurements as criteria for judgment, or examine their relationships with physical, cognitive, and psychological functions in a comprehensive manner. In this study, which is based on the criteria set by previous studies, we examined the significance of the elderly (with a mean age in the seventies) living in the community to be able to stand on one leg for fifteen seconds, focusing on their physical, cognitive, and psychological functions. **Methods** We categorized the subjects into two groups: 304 people who were able to stand on one leg with eyes open for fifteen seconds or longer and 203 people who were unable to do so. We conducted age-adjusted covariance analyses of physical (grip, quadriceps strengths, foot-grip strength, sit-ups test, sit-and-reach flexibility, walking speeds, 10-m obstacle walk, 6-minute walk, 3-m time up to go test), cognitive (Mini mental state examination, Trail making test), and psychological (Sense of health, Sense of satisfaction of life, Purpose of life) functions between the two groups. **Results** All scores for muscle strength and walking ability were markedly lower in the unable group. No significant difference in the cognitive functions was noted between the two groups. Scores for a subjective sense of well-being and the purpose of life were lower in the unable group. **Discussion** Thus, we concluded that the test to examine elderly people's ability to stand on one leg is a simple and effective method for identifying a decrease in their physical functions. It is also suggested that if an elderly person is unable to stand on one leg for fifteen seconds with eyes open, it might indicate a decrease in his/her psychological functions, such as a subjective sense of well-being and the purpose of life. It is important to conduct comprehensive assessment to examine the psychological as well as physical functions of the elderly in the "unable" group. The subjects of the study were elderly people who were living an independent life in the community. A study involving the fragile elderly should be conducted to examine whether the results are applicable to the case of physically weak elderly people. As this was a cross-sectional study, it is difficult to determine whether the time of being able to stand on one leg influenced the psychological functions or the time was affected by the functions. This point should be clarified by a longitudinal study.

### **A DISCUSSION ON DYNAMIC BALANCE DIFFERENCES UPON USAGE OF KINESIO TAPE AMONG COMMUNITY-DWELLING ELDERLS**

Lai, C.H., Lin, C.W., Chiang, Y.L., Chen, C.L.

*TZU-HUI INSTITUTE OF TECHNOLOGY (Pingtung, Taiwan)*

**Introduction** It had been shown that the ability to maintain balance could help to reduce the risk of falls in elders, which might be associated with activity limitation and have influences upon one's quality of life. Poor balance control could result in physical changes among elderly population. Hence, falling prevention should be taken into consideration along with joint stability and muscle strength. Kinesio taping method has been a preferred taping method by athletes, physical therapists and further medical practitioners. It provides applied area full range of motion, stability, and support. An appropriate kinesio taping method meant for improving dynamic balance control among community-dwelling elders was examined through this study as a result. **Methods** 20 active and healthy community-dwelling elders (10 men, 10 women, aged 65 and older) participated in this study. After completing a questionnaire of baseline characteristics, all participants were asked to view an instructional demonstration of SEBT. Each participant accomplished 6 trials on dominant leg in each of the 3 reach directions (anterior, posteromedial, and posterolateral) during the first day; followed by taking the same 3 pre-taping data trials and another 3 post-taping data trials with kinesio tape on the second day. Kinesio tapes were applied to stance leg by an experienced physical therapist in order to facilitate gluteus medius, vastus medialis and stability of ankle joints. Numbers noted of greatest reach distance upon each direction of pre- and post-taping were summed to analyze outcome efficacy of kinesio tape applying in related to dynamic balance of elderly people. Paired sample t-test was used to identify differences among pre-taping and post-taping trials. **Results** The mean reach distance (sum of the 3 reach distances in centimeters) of pre-taping trial is 171.6cm; along with the mean reach distance of post-taping trial is 174.9cm. Significantly greater mean reach distance was found between pre-taping and post-taping trials ( $p < .01$ ). **Discussion** This was the first study focused on using kinesio tape to enhance dynamic balance performance of elders. There was no control group in this study, therefore limb length measurements for normalization the reach distances were not required. Post-taping trials showed greater mean reach distance suggested positive assists in maintaining dynamic balance control. Further study is needed to observe if kinesio tape could reduce the threat of fall. We propose this easy-to-learn, easy to use as well as effective kinesio taping method to provide solutions for enhancing activity levels and living quality in support of older adults. ## PHYSICAL ACTIVITY AND LOW BACK PAIN DURING PREGNANCY

Santos, P.C.1,2, Abreu, S.2, Lopes, D.3, Moreira, C.2, Couto, M.1, Ferreira, M.2, Alves, O.4, Santos, R.2, Vale, S.2, Marques, A.I.2, Moreira, P.2,5, Mota, J.2

1. *Escola Superior de Tecnologia da Saude do Porto\_IPP;2. FADEUP\_UP; 3 Clinical Practice; 4. ULSAM; 5. FCNA\_UP*

Background: Pregnancy-related low back pain is an increasingly reported condition, with substantial costs on health. Prevention of this condition is an explicit need, and physical activity during pregnancy may play an important role. Aim: To evaluate the proportion of non-specific pregnancy-related low back pain (NSPLBP) and its association with type and intensity level of PA during pregnancy. Methods: A longitudinal prospective cohort study was developed in a consecutive sample of 118 pregnant women with a mean age of  $28.8 \pm 4.85$ . Participants were evaluated in the first, second and third trimester. A questionnaire was used to collect socio-demographic data and lifestyle variables, and to determine the presence of NSPLBP. Type and intensity level of PA were evaluated using the Pregnancy Physical Activity Questionnaire (PPAQ). Chi-square test and Fisher's test were used to analyze the association between variables, using the Statistical Package for Social Sciences (SPSS®). Results: It was found a proportion of 40.7%, 52.2% and 66.7% for NSPLBP at first, second, and third trimester respectively and a prevalence of 76.3% NSPLBP at any time during pregnancy (period prevalence). Analyzing the incidence of NSPLBP, there were found 10, 28 and 24 new cases in the first, second and third trimester. Intensity and type of physical activity were not associated with this condition, except in household/caregiving activities where it was found statistically significant differences between the tertiles. In second trimester, women who were in third tertile had a lower prevalence of low back pain compared with the other tertiles (tercil1 40.0%; terci2 38.3; terci3 21.7,  $p=0.042$ ); in third trimester, in leisure except sport, there were statistically significant differences in the frequency of NSPLBP between tertiles, being the lowest frequency found in second tertile (tercil1 37.2% ; terci2 20.5; terci3 42.3,  $p=0.019$ ). Conclusion: Non-specific pregnancy-related low back pain represents a common condition among pregnant women and should thus be faced as a major public health issue. This condition was not associated with type and intensity of physical activity during pregnancy except in household/caregiving and leisure except sport in a specific period.

## DIFFERENTS ISOKINETICS BETWEEN INJURED AND UN-INJURED SEMI-PROFESSIONAL SOCCER PLAYERS

Marfínez-Ruiz, E.1, Esparza-Ros, F.1, Marfínez-Pardo, E.2, Rubio-Arias, J.A.2, Alcaraz, P.E.2

*Catholic University of San Antonio*

Introduction The muscle injuries are characterized by high injury and re-injury rate. Therefore, is necessary to improve understanding is necessary to improve our understanding about the functional modifications after muscle injuries, that would allow to developing more effective rehabilitation and prevention programs. So, the aim of this study was analyzed differences in the muscle strength isokinetic between injured and un-injured semi-professional soccer players. Methods Twenty-four male soccer players ( $26.08 \pm 4.71$  years,  $179.75 \pm 4.46$  cm and  $76 \pm 5.59$  kg) were tested at the same day, in January (mid-season). An isokinetic concentric test flex/extension knee at angular velocities of  $60^\circ/s$ ,  $180^\circ/s$  and  $270^\circ/s$ , obtaining the peak torque (Nm), coefficient of variation, hamstring/quadriceps ratio (H:Q ratio), acceleration time (m/s) and power (W). The muscle injuries of the players were monitored during the competitive season. This data was analyzed with Independent Samples T- Test, the priori level of statistical significance was set at  $p \leq 0.05$ . Results The injury players showed significantly higher values in the coefficient of variation for knee flexion at angular velocity of  $180^\circ/s$  that un-injured players. Not significative differences was found between groups of injured and un-injured subjects for the peak torque, H:Q ratio, acceleration time and power at angular velocities of  $60^\circ/s$ ,  $180^\circ/s$  and  $270^\circ/s$ . Discussion Our result suggest that the coefficient of variation for knee flexion at angular velocity of  $180^\circ/s$  could be related to muscle fatigue. This risk factor has been frequently suggested as a possible etiology of muscle injuries (Croisier, 2004; Devlin, 2000). Other isokinetic variables, as stated by Bennell et al. (1998), were no significant difference between injuries and un-injuries players. In summary, the isokinetic concentric test can be useful in the identification of subjects with muscle injuries. References Bennell, K., Wajswelner, H., Lew, P., Schall-Riaucour, A., Leslie, S., Plant, D., et al. (1998). ## EFFECTIVENESS OF A THERAPEUTIC EXERCISE INTERVENTION COMBINING MCGILL PROTOCOL AND MOTOR-SENSORY EXERCISES ON BACK PAIN INTENSITY

Shalaj, I.1, Tishukaj, F.1, Gjaka, M.1, Tschan, H.2

1: *University of Prishtina, 2: University of Vienna*

Introduction Inadequate body posture may lead to the development of spine deformities and result in back pain which is highly prevalent in all age groups and presents an enormous socioeconomic burden. Purpose The aim of this study was to determine the relationship between the quality of body posture (based on spinal muscular imbalance) and back pain syndromes and to examine the effectiveness of a therapeutic exercise intervention on pain and postural control markers, respectively. Methods 43 patients (13 male and 30 female, respectively) aged 18-50 yrs suffering from back pain (stage 2 and 3 according to Oswestry Disability Index) were included and volunteered to participate in this exercise intervention study using the McGill protocol combined with motor-sensory exercises (12 weeks; 3 times per week; 40 min per session). To monitor treatment effectiveness the disability score the Oswestry Disability Index (ODI) was assessed before and after the intervention, as were balance parameters (MTF) and postural parameters (IDIAG, MediMouse). Descriptive and analytical procedures were performed using SPSS. Results Exercise treatment significant decreased pain intensity as assessed by ODI ( $p < 0.000$ ). Initially there had been 30 patients (69.8%) diagnosed with back pain stage 2, and 13 subjects (30.2%) with back pain stage 3, respectively. Following the exercise intervention 31 patients (72.1%) improved to stage 1 according to ODI, 9 (20.9%) improved to ODI stage 2, and only 3 patients (7%) did not improve and remained in stage 3 according to ODI. Body-stability and functional movement symmetry characteristics both improved significantly ( $p < 0.01$ ) following 12 weeks of exercise treatment. Conclusion Based on these results it appears that a therapeutic exercise intervention combining the McGill protocol combined with motor-sensory exercises is effective in reducing pain-related disability of individual activities of daily living and improve body posture parameters. These results allow speculating that spine muscle imbalances and weaknesses are causally related with the development of back pain.

**PAIN INHIBITION AND POSTEXERTIONAL MALAISE IN CHRONIC FATIGUE SYNDROME : AN EXPERIMENTAL STUDY**

Van Oosterwijck, J.1,2,3, Nijs, J.1,2,3, Meeus, M.1,2, Lefever, I.1, Huybrechts, L.2, Lambrecht, L.4, Paul, L.5

**Introduction:** CFS patients show severe symptom and pain exacerbation following physical exercise [1-3]. It seems that the pain inhibitory systems in these patients do not respond to exercise as they do in healthy subjects and the underlying mechanisms of symptom exacerbation following exercise in CFS still remain unclear. Therefore this study aimed at examining 1) the efficacy of the pain inhibitory systems in CFS patients during 2 different types of exercise, 2) whether the (mal)functioning of pain inhibitory systems is associated with symptom increase following exercise. The knowledge can be used to steer the content of physical exercise programs used in the rehabilitation of CFS patients. **Methods:** Twenty-two women with CFS and 22 healthy sedentary controls performed a submaximal exercise test and a self-paced, physiologically limited exercise test on a cycle ergometer with continuous cardiorespiratory monitoring. Subjects their health status and pressure pain thresholds (PPTs) were assessed before and after each exercise bout. Activity levels were assessed using accelerometry. Possible changes in any of the outcome measures in response to exercise were compared using repeated measures ANOVA. **Results:** In CFS patients, pressure pain thresholds decreased following both types of exercise, whereas they increased in healthy subjects (between group differences p-value varying between .077 and .002). This was accompanied by a worsening of the CFS symptom complex post-exercise ( $p < .05$ ). Decreased pressure pain thresholds during submaximal exercise were associated with postexertional fatigue in the CFS group ( $r = .454; p = .034$ ). Although CFS patients reported increased fatigue post-exercise, their level of actual physical activity remained unchanged ( $F = .838; p = .365$ ). **Discussion:** These observations indicate the presence of abnormal central pain processing during exercise in CFS patients and demonstrate that both submaximal exercise and self-paced, physiologically limited exercise trigger postexertional malaise in these patients. These observations indicate the presence of abnormal central pain processing during exercise in CFS patients and demonstrate that both submaximal exercise and self-paced, physiologically limited exercise trigger postexertional malaise in these patients. Further study is required to identify specific modes and intensity of exercise that can be performed in people with CFS without exacerbating symptoms. These results highlight the fact that one should be cautious when evaluating exercise in people with CFS. Exercise programs should be individually tailored, keeping in mind that even minimal over-exertion may be counterproductive by increasing pain and symptoms, thus prolonging recovery. **References:** 1.Jammes et al. *J Intern Med* 2005;257:299-310. 2.Lapp CW. *Am J Med* 1997;103:83-84. 3.Bazelmans et al. *J Psychosom Res* 2005;59:201-208.

**THE EFFECT OF STRENGTH AND BALANCE TRAINING IN WOMEN WITH KNEE OSTEOARTHRITIS**

Gulsen, M., Koz, M.

*Baskent University*

The aim of this study is to investigate the effect of strength and balance training on muscle strength, balance and disability. The participants were 32 female between the ages of 45-70, who were graded II and III knee OA according to "Kellgren-Lawrence Scale". The participants were divided into four groups as each group had 8 participants: strength training, balance training, both strength and balance training and control groups. Sociodemographic features were recorded. Then their muscle strength tests (by isokinetic dynamometer (Cybex 770 Norm Lumex Inc, Ronkonkoma, NY, USA), balance tests (by SPORTKAT 3000 (LLCVista CA 92083)) and disability tests (by West Ontario and McMaster University Osteoarthritis index (WOMAC)) were applied. The participants in strength group performed 6 days in a week for 4 weeks strength training with a physical therapist observation. The participants in balance group performed 30 minutes, 6 days in a week for 4 weeks balance training with a physical therapist observation with KAT system. The participants in both strength and balance group performed both 6 days in a week for 4 weeks strength training and 6 days in a week for 4 weeks balance training with a physical therapist observation with KAT system. The participants in control group didn't take any training programme. After 4 weeks, the evaluations were repeated. According to strength training measurement results, better muscle strength improvements were found in both strength and balance group than balance and control groups, and in strength group than both strength and balance group, balance and control group ( $p < .05$ ). In balance group, no significant difference was found with other groups in strength training. According to balance training measurement results, in balance group better improvements observed than strength group, strength-balance group and control group, and in strength-balance group showed better improvements than strength and control groups ( $p < .05$ ). No significant difference was found in WOMAC values by strength-balance training, strength training, balance training ( $p > .05$ ). We think that appropriate physio-therapy program that is prepared for knee OA patients will contribute the improvements about protecting and improving knee muscle strength and correcting patients' balance according to this study.

**Poster presentations****PP-PM18 Nutrition 2****TAURINE SUPPLEMENTATION: EFFECTS ON ENERGY METABOLISM IN OBESE.**

Freitas, E.C., Rosa, F.T., Suen, V.M.M., Pfrimer, K., Ferrioli, E., Marchini, J.S.

*School Physical Education and Sport of Ribeirão Preto*

**Introduction:** Taurine is an amino acid present in large quantities in mammalian tissues. However, the studies showed that plasma levels of taurine are significantly lower in obese subjects. It is suggested that taurine supplementation increases the consumption of oxygen, thereby increasing energy expenditure. The purpose of the study was to investigate the concentration of taurine and changes in total energy expenditure (TEE) of obese women after taurine supplementation. **Methods:** A double-blind study was conducted with 16 obese sedentary women, BMI 48.2 (35-54) kg / m<sup>2</sup>. Participants were divided into two groups: placebo (PL) (3 g flour starch / day, n = 8) and taurine supplementation (TS) (3 g of taurine / day, n = 8). All women participated in the Nutrition Education Program. Nutritional assessment included weight, body mass index, composition of fat-free mass (FFM) and fat mass (FM) measured by the method of dilution of deuterium oxide. Taurine plasma was analyzed using quantitative and qualitative analysis of plasma amino acids, total energy expendi-

ture (TEE) by doubly labeled water (DLW) technique. All participants were evaluated before (baseline) and after 8 weeks of supplementation. The analysis of variance (ANOVA) followed by post hoc Bonferroni tests were applied to Statistical analysis. Results: The mean weight of each group was 120 (97 -135) and 126 kg (152-100). The mean weight loss in the TS and PL groups was 4 kg after 8 weeks. There was no significant difference between groups in weight loss after 8 weeks. Fat mass and fat-free mass was not significantly different between the groups after the supplementation period. The levels of plasma concentration of taurine were significantly different after the period of supplementation in group TS ( $p = 0.02$ ). Referring to TEE, there was no significant difference between groups, but when comparing the percentage change of data between the groups, results were significantly different ( $p = 0.05$ ). Conclusion: There were significant changes in plasma levels of taurine in the TS group after 8 weeks. Moreover, the results of TEE were no significant after supplementation of taurine, however, when the variations were made between groups was observed an increase of 34% in the group TS and 6% reduction in the PL group showing evidence of the involvement of taurine in energy metabolism. The number of study participants can be a limiting factor in the results, it is suggested that further studies are needed to elucidate the energy metabolism in obese patients. Key-words: supplementation taurine, energy metabolism, obesity, energy expenditure. Acknowledgments: This work received financial support by the Research Foundation of the State of Sao Paulo (FAPESP - process number: 08/53747-8)

### **SITTING TIME INCREASES THE RISK OF SUFFERING OVERWEIGHT AND OBESITY INDEPENDENTLY OF WALKING TIME IN NON-INSTITUTIONALIZED PEOPLE AGED 65 OR OVER FROM SPAIN: THE ELDERLY EXERNET MULTI-CENTER STUDY**

Gomez-Cabello, A., Pedrero, R., Olivares, P.R., Hernandez, R., Rodriguez, J.A., Mata, E., Aznar, S., Villa, J.G., Espino, L., Gusi, N., Gonzalez-Gros, M., Casajús, J.A., Ara, I., Vicente-Rodriguez, G.

*GENUD Research Group. University of Zaragoza*

Sitting time increases the risk of suffering overweight and obesity independently of walking time in non-institutionalized people aged 65 or over from Spain: The Elderly EXERNET Multi-center Study Gomez-Cabello A1,2, Pedrero-Chamizo R3, Olivares PR4, Hernandez-Perera R5, Rodriguez-Marroyo JA6, Mata E7, Aznar S8, Villa JG6, Espino L5, Gusi N4, Gonzalez-Gross M3, Casajús JA1,2, Ara I1,7, Vicente-Rodríguez G1,2 on behalf of EXERNET Study Group 1 GENUD Research Group, University of Zaragoza, Spain 2 Faculty of Health and Sport Science, Department of Psychiatry and Nursing, University of Zaragoza, Spain 3 ImFINE Research Group. Department of Health and Human Performance, Technical University of Madrid, Spain 4 Faculty of Sport Sciences, University of Extremadura, Spain 5 Unit of Sports Medicine, Cabildo of Gran Canaria, Spain 6 Institute of Biomedicine, University of León, Spain 7 GENUD Toledo Research Group, University of Castilla-La Mancha, Spain 8 PAFS Research Group, University of Castilla-La Mancha, Spain Introduction: obesity, defined as an excess of total body fat, is a matter of concern all over the world, and its prevalence is still increasing among elderly people (1). Aim: to examine whether a sedentary behaviour (hours sitting per day) is associated with higher risk of central obesity, overweight-obesity and overfat in a representative sample of non-institutionalized Spanish elderly population and if so, whether physical activity (hours walking per day) modified this association. Methods: a cross-sectional study was carried out in a sample of 3136 people  $\geq 65$  years of age. Anthropometric measurements were obtained using standardized techniques and equipment. Active and sedentary behaviors were recorded by means of a questionnaire. Binary logistic regression was used to test the association among overweight-obesity, central obesity and overfat and the sedentary independent variable (hours per day sitting) by sex. Results: for both men and women, the higher prevalence of overweight-obesity, central obesity and overfat was found in those who spent sitting more than 4 hours per day and walk less than 1 hour, compared with those who spent sitting less than 4 hours per day and walk more than 1 hour (all  $p < 0.001$ , except for central obesity in women). In men, more than 4 hours sitting per day was associated with 1.7-fold higher odds of having central obesity compared with those sitting less than 4 hours per day ( $p < 0.01$ ). In women, this sedentary behaviour increased the risk of overweight-obesity and overfat by 1.5 and 1.4, respectively ( $p < 0.01$ ). Age or time spent walking did not significantly change these results. Conclusion: sitting time increases the risk of overweight-obesity and overfat in women and the risk of central obesity in men, independently of walking time. References: 1. Gomez-Cabello A. et al. **INTRODUCTION** Recently, several studies have been trying to relate eating behaviors with the development of obesity in adults and children (Bryant et al., 2008; Vogels et al., 2006). Some studies have already shown that a positive correlation between disinhibited behaviors and increased levels of BMI and obesity are present in adults. However, these relationships have been less studied in children. Some data indicate that high scores of the dietary restraint factor (Cognitive Restraint) in children can predict high BMI and elevated percentage of body fat (%BF) (Vogels et al., 2006). **MATERIAL AND METHODS** Forty three boys ( $11.3 \pm 0.3$  yrs;  $49.1 \pm 3.1$  kg;  $151.8 \pm 1.8$  cm;  $20.6 \pm 0.9$  kg/m<sup>2</sup>) and 51 girls ( $11.5 \pm 0.3$  yrs;  $49.4 \pm 2.6$  kg;  $150.0 \pm 1.5$  cm;  $21.4 \pm 0.8$  kg/m<sup>2</sup>) participated in this study. Body composition was measured by dual-energy X-ray absorptiometry (Hologic, Serie Discovery QDR, Bedford, USA). An extended version of the Three Eating Factor Questionnaire (TFEQ-R21) was used in order to obtain information related to the children's eating behavior (Cappelleri et al., 2009). **RESULTS** Three 2-way independent groups ANOVAs were used to examine differences between the genders and weight status on TFEQ scores. Upon examination of TFEQ-UE (uncontrolled eating), a main effect of adiposity level was found whereby lean children had a higher score ( $p = 0.001$ ). Conversely, a main effect of obesity status on TFEQ-CR (cognitive restraint) demonstrated that those in the overweight/obese category had higher TFEQ-CR scores ( $p = 0.021$ ). No further main effects or interactions were found. TFEQ-UE was found to correlate negatively with age ( $r = -0.34$ ,  $p < 0.001$ ) and weight ( $r = -0.36$ ,  $p < 0.001$ ). Whereas, TFEQ-CR was found to correlate positively with weight ( $r = 0.25$ ,  $p = 0.014$ ), total fat mass ( $r = 0.24$ ,  $p = 0.02$ ), %BF ( $r = 0.38$ ,  $p < 0.001$ ) and trunk fat mass ( $r = 0.31$ ,  $p = 0.003$ ). After controlling for age and gender, only the correlations with TFEQ-CR remain. No correlations were found for TFEQ-EE (emotional eating). After controlling for sex, age, sleep hours and hours watching TV, a higher TFEQ-CR score was found to significantly predict a higher body weight, increased %BF and higher trunkal fat mass (all  $p < 0.001$ ). **DISCUSSION** Data for the present study seems to strongly suggest that increased cognitive restraint (CR) is related to an increased body weight, percentage of body fat and trunkal body fat in children. **REFERENCES** Bryant EJ, et al. ### ENERGY BALANCE-RELATED BEHAVIOURS IN PRESCHOOLERS: FOCUS GROUPS WITH PARENTS AND TEACHERS

De Craemer, M., De Decker, E., De Bourdeaudhuij, I., Deforche, B., Vereecken, C., Duvinage, K., Grammatikaki, E., Iotova, V., Fernández-Alvira, J.M., Zych, K., Manios, Y., Cardon, G.

*Ghent University*

Introduction Qualitative research – and in particular the execution of focus groups – is a good way to collect ideas and strategies for future interventions. Focus groups with parents and teachers have already been executed to obtain information on preschoolers' physical activity levels and nutrition habits. However, no focus groups have ever been executed to investigate what these caregivers think about how these behaviours can be changed. Based on these insights, effective interventions could be developed. Methods Focus groups were carried out between October 2010 and January 2011 in six European countries: Belgium, Bulgaria, Germany, Greece, Poland and Spain. In total, 24 focus groups with 122 parents and 18 focus groups with 87 teachers were executed. Data were analyzed, using qualitative data analysis software. Results Both parents and teachers considered preschool children sufficiently active. They did not perceive the need to increase preschoolers' physical activity levels. Furthermore, parents did not think it is necessary to decrease the intake of sugared milk drinks and fruit juices. They consider them as healthy because of the vitamins/minerals these beverages contain. Discussion The European focus group results indicated misperceptions of caregivers on preschoolers' physical activity levels and nutrition habits. This resulted in low perceived needs to change these behaviours. Consequently, the awareness of parents and teachers has to be raised concerning the need to change these behaviours and regarding the shared responsibility of parents and teachers to promote these healthy behaviours in preschoolers. Providing teachers with ready-to-use classroom material, and involving parents in preschoolers' school activities, are perceived as promising ways in trying to change the behaviours of preschool children. ### COMPARATIVE STUDY OF BLOOD LEVELS IN RATS UNDERGOING RESISTANCE TRAINING COMBINED WITH HIGH PROTEIN DIET AND HIGH CARBOHYDRATE DIET

Furukawa, M., Neiva, C.M., Peinado, A.B., Romero, B., Zapico, A.G.

*Universidad Politécnica de Madrid*

Comparative study of blood levels in rats undergoing resistance training combined with high protein diet and high carbohydrate diet Furukawa, M1; Neiva, CM2; Peinado, AB1; Romero, B1; Zapico, AG3 1: Universidad Politécnica de Madrid, Spain; 2: UNESP – Rio Claro, Brazil; 3: Universidad Complutense de Madrid, Spain Introduction Resistance training (RT) has been known as the best method to promote hypertrophy in synergistically involved muscles [1]. Combined with this technique, high protein diets (HPD) have shown positive effects on muscle hypertrophy and strength [2]. While high carbohydrate diets (HCD) present similar results [3], both diets may change negatively or positively the blood levels of certain lipids, carbohydrates and proteins. The aim of this study was to show the changes in blood levels in rats after a HPD and HCD combined with RT. Methods Forty-two male rats (Wistar), 75 days old and with an initial weight of 192±17g were separated into six groups: trained and HPD (THP), trained and HCD (THC), trained control (TC), sedentary HPD (SHP), sedentary HCD (SHC) and sedentary control (SC). All of the trained groups had to perform two weeks of adaptation swimming training followed by 5 weeks of RT. Blood samples were collected before and after the intervention. Glucose, cholesterol, triglycerides and urea were analyzed in this study. One way ANOVA with repeated measures was used to study the differences between pre-post values. Probability level for statistical significance was set at  $\alpha=0.05$ . Results Significant changes occurred in glucose levels in the groups THC (149% of change measured as final value - initial value/initial value\*100), TC (155%), SHP (180%), SHC (121%) and SC (200%). There was no change in the THP group ( $p>0.05$ ). Changes in urea occurred in groups THP (55%), THC (-24%), SHP (19%), SHC (-28%) and SC (11%) ( $p<0.05$ ). Triglyceride levels changed in groups THP (67%), THC (70%) and SHC (129%) ( $p<0.05$ ). No changes in cholesterol were found ( $p>0.05$ ). Discussion Diets enriched with proteins and carbohydrates significantly increase levels of glucose, urea and triglycerides in rats trained in a RT, although the THC and SHC groups presented significant reduction of urea. This can be explained by the fact that HCD has the lower quantity of protein in its composition [4]. The HCD groups presented values significantly higher on glucose levels and these findings suggest that a HCD may be harmful according to metabolic risk factors[5]. References 1. ### EFFECT OF FISH OIL SUPPLEMENTATION ON LIPID PROFILE IN PARAPLEGIC ATHLETES BEFORE AND AFTER BASKETBALL PLAY

Cury-Boaventura, M.F., Marques, C.G., Santos, V.C., Levada-Pires, A.C., Pithon-Curi, T.C., Gorjao, R.

*Institute of Physical Activity and Sports Sciences, Cruzeiro do Sul University*

EFFECT OF FISH OIL SUPPLEMENTATION ON LIPID PROFILE IN PARAPLEGIC ATHLETES BEFORE AND AFTER BASKETBALL PLAY Introduction: Spinal cord injury causes metabolic disorders such as dyslipidemia. The engaging of paraplegics in sports programs combined with an adequate food plan can minimize the risk of related diseases. Evidence suggests that fish oil rich in n-3 polyunsaturated fatty acids (n-3 PUFA) has a beneficial effect on lipid profile. We investigated the effect of fish oil supplementation on lipid profile in athletes with spinal cord injuries at rest and after basketball play. Methods: Eleven paraplegic athletes were supplemented with 3g of fish oil per day (FO group) and three paraplegic athletes were supplemented with 3 g of soy lecithin (PL group). The athlete's blood samples were collected on rest and immediately after basketball play (60 minutes) before and after supplementation. The following determinations were carried out: total cholesterol, triglycerides, HDL-c and LDL-c. Results: There was no significant difference in age, height, body mass and % of fat mass between the groups. We observed no significant differences on total cholesterol, triglycerides, HDL-c, LDL-c plasma concentration in the PL and FO group. However, FO group showed a trend to decrease total cholesterol ( $\Delta C = 25$  to  $-17$  mg/dL and  $8$  to  $-36$  mg/dL, respectively) and LDL-c ( $\Delta C = 25$  to  $-34$  mg/dL and  $-7$  to  $-55$  mg/dL, respectively) before and after the basketball play and HDL-c ( $\Delta C = 1$  to  $-20$  mg/dL) after the basketball play. Conclusion: The FO supplementation associated to the training had a tendency to improve lipid profile in paraplegics and may minimize the risk to dyslipidemia.

## PP-PM19 Adapted Physical Activity 1

**THE TRAINING OF THE MONITORS THAT WORK IN ADAPTED PHYSICAL ACTIVITY PROGRAMS IN SPAIN**

González, M.D.1, Campos, A.2

*1: Alcalá University (Alcalá de Henares, Spain), 2: Polytechnic University of Madrid (Madrid, Spain)*

**Introduction** An essential factor that contribute to the appropriate development of adapted physical activity programs are the monitors, because if these professionals are not good trained, the effects in general health could have a boomerang effect (Campos, 2010). The objective of this study is to analyse the training of the physical activities professionals who work in adapted physical activity programs in Spain by age, gender and sport associations. **Methods** The quantitative methodology consisted of a cross-sectional survey. Cluster sampling was used. The final sample size was 241 monitors. Data were collected through structured questionnaires with face-to-face interview between January and November 2011. All the statistical analyses were done using the SPSS/Windows 19.0 statistical software. The inferential analysis with Cronbach's was .802. Signification levels were set at  $p < 0.05$ . **Results** 31,5% of the sports monitors that work in adapted physical activity programs are not qualified. 68,5% of monitors have a sports qualification. By gender, 69% of men have a sport qualification and 31% of them do not have any sport qualification. Regarding to women, 67,4% have a sports qualification and 32,6% of them do not have any sport qualification. By age, 30,1% of the physical activities monitors under 30 years are qualified and 69,9% are not; 27,6% between 30 and 45 years are qualified and 42,3% of the monitors older than 45 years are qualified. By organizations, 80,2% of the monitors who work in private organizations are not qualified and 19,8% of them have a sports qualification; in public organizations, 27,6% of the monitors do not have any sport qualification but 72,4% have sport qualification. **Discussion** One third of this monitors do not have any sport qualification and women show slightly higher values of non qualified staff than men. In private sport organizations, the number of non qualified sport monitors is higher than in public sport organizations. According to these results, it is necessary to improve the training of monitors (Le Roux & Frosberg, 2000; Campos, 2010) to ensure the proper development of adapted physical activity programs, especially in private organizations. **References** Campos, A. (2010). Dirección de recursos humanos en las organizaciones de la actividad física y del deporte. Síntesis, Madrid. Le Roux, N. & Frosberg, K. (2000). The research reported is a part of the Fundamental Research Project I+D+i DEP2009-12 828 which has been funded by the Ministry of Science and Innovation.

**OBJECTIVE PHYSICAL ACTIVITY IN CHILDREN WITH DOWN SYNDROME**

Matute-Llorente, A., González-Agüero, A., Gómez-Cabello, A., Gómez-Bruton, A., Morales, S., Vicente-Rodríguez, G., Casajús, J.A.

*GENUD Research Group, University of Zaragoza, Spain*

**Introduction** Children with Down Syndrome (DS) have been demonstrated as being less active<sup>1</sup> and have showed lower levels of physical fitness<sup>2</sup> than children without DS. To date, the information regarding physical activity (PA) and persons with DS is limited and inconclusive. Therefore, the aim of this study was to assess objectively the levels of PA in children with DS comparing with children without disabilities. **Methods** Forty two children (27 with DS) aged 12-18 years participated in this study. A uni-axial accelerometer (Actigraph GT1M) was used to register PA and steps of children during seven consecutive days. Accelerometer data to be valid had to present at least four days with eight hours of valid time. Minutes of valid time and minutes of sedentary, light, moderate, and vigorous physical activity were established by using the cut-offs proposed by Sirard<sup>3</sup>. Time of bouts (period of at least 5 min of consecutive moderate PA) and number of bouts were also measured. Differences between groups were established by 2-sided Student's t test. **Results** No significant differences between children with and without DS regarding sedentary, light, and vigorous times were observed neither in minutes (698.9 vs. 741.9; 49.7 vs. 49.4; 2.9 vs. 6.1 min/day) nor in the percentages of valid time (91.8 vs. 91.1; 6.5 vs. 6.1; 0.3 vs. 0.7 %) spent on those activities. However, children with DS engaged significantly less minutes in moderate (9.2 vs. 15.4 min/day) and moderate-vigorous physical activities (12.1 vs. 21.5 min/day) than their counterparts without DS. Similarly, the percentages of valid time (1.9 vs. 1.2 %) and (1.6 vs. 2.7 %) spent in those activities were lower. Moreover, lower time and number of bouts and steps were observed in the DS group compared with the control group (all  $p < 0.05$ ). **Discussion** Similar levels of sedentary and light PA were registered in children with and without DS; children with DS did not show a more sedentary behaviour than those without. Nevertheless, children with DS spent not only less total minutes of valid time participating in moderate and vigorous PA, but also lower percentage of their total valid time. Following ACSM guidelines children and adolescents should do at least 60 minutes of moderate PA 5 days a week; however, none of the two groups achieved these recommendations. Strategies aiming to increase moderate and vigorous activities in children with DS should be promoted as they may be at higher risk of developing diseases associated with physical inactivity such as osteoporosis or metabolic syndrome. **References** 1. Sharav, T. et al. Clin Pediatr (Phila). 1992. 2. Fernhall, B. et al. Clin Exer Physiol. 2001. 3. Sirard, J.R. et al. Med Sci Sports Exerc. 2009.

**PEAK POWER OUTPUT PREDICTS TT PERFORMANCE, IRRESPECTIVE OF TRAINING PHASE, IN NATIONAL CYCLISTS WITH PHYSICAL DISABILITIES.**

Boer, P., Terblanche, E.

*North West University, Stellenbosch University*

**Purpose** The purpose of this study was to ascertain which physiological or mechanical variable best predicts time trial (TT) performance (measured as TT time or TT average power) and whether the predictors of performance change according to training phases of the competition year amongst national cyclists with physical disabilities. **Methods** Seven male and two female cyclists ( $19 \pm 2$  yrs;  $169.6 \pm 10.1$  cm;  $64.7 \pm 10.8$  kg) were tested during the competition phase of their training year, as well as pre-season of the following training year (six months later). Methodological procedures were strictly adhered to and identical on both occasions. Participants performed a ramped (20W/min) exercise protocol to exhaustion and a self-paced, 20-km TT on two consecutive days on the Velotron cycle ergometer. Maximal, as well as sub-maximal responses ( $\dot{V}O_2$ , heart rate and power output) at the anaerobic threshold (AT) were determined for the

maximal exercise test. AT was defined as the point where the R-value was equal to 1.0. Relationships between 20-km TT performance (measured as TT time and TT average watts) and relative peak power output (PPO) (W), absolute PPO (W/kg), VO<sub>2</sub>max (ml/min/kg), power output (PO) at the AT, heart rate (HR) at the AT, and VO<sub>2</sub> at the AT were determined. Results Highly significant correlations ( $P < 0.05$ ) were found between absolute PPO of the maximal exercise test and average watts during the TT, in both in-season ( $r = 0.97$ ) and out-of-season ( $r = 0.94$ ). Slightly weaker, but still significant correlations were found between PPO and cycling performance measured as TT time (in season- 0.94 and out of season- 0.90;  $P < 0.05$ ). When accounting for body mass in PPO (W/kg), the relationships were also weaker in both training phases for both TT time and TT average watts. Likewise, correlations between VO<sub>2</sub> max-, PO at the AT-, HR at the AT-, VO<sub>2</sub> at the AT-, and TT time or TT average watts provided relationships much weaker than when absolute PPO was used. Conclusions This is the first study to show that there is a similar strong relationship between PPO and TT performance in cyclists with physical disabilities and able-bodied cyclists. This strong relationship held true even in the pre-season training phase. This study has also reiterated the fact that PPO is generally a better predictor of performance compared to VO<sub>2</sub> max and variables associated with the AT. It is concluded that absolute PPO, irrespective of training phase, is the best predictor of endurance cycling capacity in cyclists with physical disabilities.

## INFLUENCE OF PHYSICAL ACTIVITY ON CARDIOVASCULAR FITNESS IN CHILDREN AND ADOLESCENTS WITH DOWN SYNDROME

Matute-Llorente, A., González-Agüero, A., Gómez-Cabello, A., Gómez-Bruton, A., Morales, S., Vicente-Rodríguez, G., Casajús, J.A.

*University of Zaragoza*

**Introduction** Aerobic fitness during adolescence has a strong association with present and future health and cardiovascular diseases. Previous research has shown that persons with Down syndrome (DS) have impaired cardiovascular fitness, however; whether it depends on the levels of physical activity (PA) remains unknown in this population. Therefore, the aim of this study was to assess the relationship between the levels of PA and cardiovascular fitness in children with DS. **Methods** 27 children with DS aged 10-18 years participated in this study. A uni-axial accelerometer (Actigraph GT1M) was used to register PA during seven consecutive days. As recommended, accelerometer data to be valid had to present at least four days with eight hours of valid time. Percentage of valid time in sedentary, light, moderate, and vigorous physical activity were established by using the cut-offs proposed by Sirard<sup>1</sup>. Maximal oxygen uptake (VO<sub>2</sub>peak) and maximal heart rate (HRmax) were measured with a breath-by-breath gas analyzer in a treadmill. Pearson's bivariate correlations were applied to identify possible relationships between percentage of time spent in different levels of PA and the cardiovascular parameters (VO<sub>2</sub>peak and HRmax). Results VO<sub>2</sub>peak showed an inverse correlation with the percentage of time spent in sedentary activities ( $r = -0.39$ ,  $p < 0.05$ ). VO<sub>2</sub>peak and HRmax were correlated with the percentage of time spent in moderate intensity activities ( $r = 0.48$  and  $r = 0.39$  respectively, both  $p < 0.05$ ). **Discussion** As expected, spending more time in sedentary activities was associated with lower levels of VO<sub>2</sub>peak in children with DS. On the other hand, moderate correlations between VO<sub>2</sub>peak, HRmax and moderate activities have been observed. No correlation between VO<sub>2</sub>peak and percentage of time spent in vigorous intensity activities were observed. It could be due to the low time spent in vigorous intensity activities (with Sirard cut-offs) of children with DS. It might be also thought that this cut-offs are not suitable for children with DS, so it would be good to establish specific cut-offs for this type of population. Despite this, we could suggest that cardiovascular fitness could be improved in children with DS by enhancing time spent in moderate activities and decreasing sedentary time, this could be relevant to reduce the risk of cardiovascular diseases. **References** 1. ## GIRL POWER IN HAND CYCLING: GENDER DIFFERENCES IN PHYSICAL EXERCISE CAPACITY

Kerkhof, F., Hettinga, F., van Ballegooijen, M., van der Woude, L.

*Centre for Human Movement Sciences, Groningen University*

Faes D. Kerkhof 1, Floor J. Hettinga 1, Marloes van Ballegooijen 1, Luc H.V. van der Woude 1. 1 Center for Human Movement Sciences, UMCG, Groningen **Introduction:** Wheelchair dependency is often accompanied by a low physiological exercise capacity which may lead to secondary health problems and a decreased participation in daily life. Pursuing an active and healthy lifestyle is often straining for wrist and shoulders. Hand cycling (HC) is a promising low impact training alternative. However, little is known about HC exercise, in particular for women. Therefore, the present study aims to gain insight into gender differences in exercise capacity during HC in order to customize exercise guidelines. **Method:** Ten male and 10 female able-bodied participants conducted an incremental exercise test (IET: 65 rpm, 5.0 km/h, resistance increased with 7 watt/min) on a hand cycle to determine peak exercise capacity. A bicycle incremental exercise test was used to determine maximal exercise capacity. VO<sub>2</sub>, HR, VE and power output (PO) were measured during all tests. **Results:** Peak female HC values were: VO<sub>2</sub> 2.03 L/min (SD 0.302), HR 169 (SD 15), VE 78.94 L/min (SD 18.91), PO 92.79 (SD 17.76). Peak male HC values were: VO<sub>2</sub> 2.69 L/min (SD 0.229), HR 160 (SD 37), VE 100.96 L/min (SD 19.73), PO 132.34 (SD 11.44). Bicycling maximum values for females: VO<sub>2</sub> 3.35 L/min (SD 0.489), HR 186 (SD 12), VE 92.74 L/min (SD 20.69), PO 254 (SD 26.75). Bicycling males scored: VO<sub>2</sub> 4.59 L/min (SD 0.693), HR 190 (SD 8), VE 156.62 L/min (SD 26.52), PO 368 (SD 13.98). Gender differences were found in HC for RPE, VO<sub>2</sub> and VE. No differences were found for HR. Peak HC capacity as a percentage of maximum cycling exercise capacity shows similar ratios in men and women for VO<sub>2</sub> (60% vs. 66%) and HR (90% vs. 84%) and PO (36% vs. 37%). However, VE<sub>peak</sub>/VE<sub>max</sub> ratio was much higher in females (85%) than in males (64%). **Conclusion:** Although peak/max ratios of Vo<sub>2</sub>, HR and PO were similar in men and women, absolute peak hand cycling values (VO<sub>2</sub>, HR, PO, VE) were 33%, 2%, 30% and 41% lower for females. This largely due to their smaller muscle mass. Besides a lower exercise capacity, the higher VE<sub>peak</sub>/VE<sub>max</sub> ratio in females indicates a relatively high respiratory strain at peak intensity. These findings suggest that females should exercise on a 33% lower absolute PO than males to achieve the same ventilatory load. However, considering the 2% difference in heart rate, training at lower PO level might not be high enough to achieve optimal cardiovascular load. Based on the results of the present study, there is a gender-related difference in hand cycling exercise capacity, that has to be kept in mind prescribing training intensities for females in a rehabilitation setting. In addition, different handicaps can affect exercise capacity differently. More research is needed for tailored exercise guidelines.

## IS IT POSSIBLE TO ADAPT ISOMETRIC LEG STRENGTH TEST TO MENTALLY RETARDED POPULATION?

Bofill-Ródenas, A.1, Corbi, F.2, Solana-Tramunt, M.3, Cartes, M.A.4, San, J.1

1:Universitat de Girona, 2:INEFC-Lleida, 3:University Ramon Llull, 4:ACELL-Special Olympics Catalunya

**Introduction** Isometric leg strength test (ILST) is the most common test used to evaluate leg strength and is commonly performed back leaning slightly forward and knees bend to about 120 degrees making it difficult to test execution in populations with disabilities as mental retardation (MR). We investigated if ILST performed at 120° and back leaning forward is superior to performance at 90° and keep back straight which is expected to reduce the compensatory muscle participation and increase the comfort to perform the test. **Methods** 45 adults, 15 with Down Syndrome (DS) (age=27+/-7.48yrs), 17 without DS (age=29+/-6.68yrs) and 15 general population (GP) (age=31+/-7.85yrs) acting as controls, participated in this study. We performed a familiarization process consisting of a session with all the individuals that comprised the study sample. After the familiarization they completed two ILST tests, on different days, for both at 120° and 90°. **Results** No significant differences were found between tests performed on different days. There was not a significant difference between ILST120° and ILST90° (85.34+/-45.60Kgw vs. 95.69+/-51.49Kgw), but by population the results obtained were 37.24Kgw vs. 30.67Kgw for DS, 44.86Kgw vs. 39.46Kgw for without DS and 87.45Kgw vs. 71.88Kgw for GP. The correlation obtained is 0.875 if considering all days test. **Discussion** These data show that ILST testing in this population is reliable from day to day. All populations got better results on the dynamometer at 120°, although this difference is not significant. In this position the results are better due the co-activation of the kinetic chain. It is possible to adapt ILST to mentally retarded population being the proposal testing at an angle of bending deeper than normally used in the administration of these tests and consider a wall support in guiding the movement to continue for traction without involving other muscle groups. **References** Fernhall, B., Tymeson, G. (1987). Graded exercise testing of mentally retarded adults: a study of feasibility. *Archives of Physical Medicine and Rehabilitation*, 68, 363-365. ## PASSIVE GLIDING OF SWIMMERS WITH DISABILITIES REGARDING IMPAIRMENT, FUNCTIONAL CLASSIFICATION AND PERFORMANCE

Karger, K.

*Chemnitz University of Technology*

**Introduction** In recent years swimming of people with disabilities became more importance in research. Competitions are organized by using the Functional Classification System (FCS). Both fairness and procedure are discussed controversially (Daly et al., 2003). Quantitative investigations improve information and can support further validation of FCS. Analysis of gliding phase, as an integral part of swimming efficiency, is accepted in competitive swimming (Lyttle et al., 1998). For swimmers with disabilities these studies are underrepresented (Chatard et al., 1992). **Methods** Swimmers with diverse locomotor disabilities (n = 98) took part in this study. Two passive towing trials in a standardized gliding position were performed, the first trial with a standard velocity (1.0 m/s) and the second with the individually best performance. To measure passive drag in water (FPD) we used a strain-gauge beam arrangement in a rope drum. The registration of frontal surface area (FSA) was carried out with a camera, placed under water. Additionally the coefficient of drag (CD) was evaluated. For impairment specific analysis the swimmers were separated in 5 disability groups. To investigate the relationship to FCS we used the functional class (FC) of the athletes. The division in 2 groups (participation in Paralympics or not) was accomplished to analyze performance specific differences. **Results** Regarding impairment specific the FPD of athletes with paralysis (FPD = 42,64 N; SD = 12,61 N) and with multiple dysmelia (FPD = 40,66 N; SD = 14,26 N) were higher than for swimmers with above-knee amputation on one side (FPD = 25,93 N; SD = 1,62 N). Concerning FCS the FPD decreased with increasing FC (r = -0.63). Nevertheless, there were no significant differences between adjacent classes and a wide range within classes was observed. Furthermore participants of Paralympics had a lower CD (CD = 0,68; SD = 0,19) than swimmers with nonattendance (CD = 0,86; SD = 0,27). **Discussion** Athletes with paralysis and multiple dysmelia had more inappropriate frontal resistance areas during gliding phase than swimmers with above-knee amputation on one side because of their streaming advantageous drop form (Bixler, 1999). These findings can contribute to enhancements regarding the FCS. The relation between CD and performance level leads to the assumption, that a specialized training program can optimize the impairment-specific hydrodynamic drag for swimmers with disabilities. **References** Bixler B. ## TITLE: EFFECTS OF COMBINED EXERCISES ON PHYSICAL PERFORMANCE, MOTION FUNCTION, AND EXPANDED DISABILITY STATUS SCALE IN MULTIPLE SCLEROSIS

Golzari, Z., Shabkhiz, F., Mojtahedi, S.

*university of tehran*

**Introduction** Several years ago, exercise was forbidden for MS patients due to the increase of the body temperature as a result of exercising but recently most of reports have noted that exercise therapy is safe and beneficial for patients with MS. The effect of exercise is particularly obvious regarding daily activities, and physical fitness. **Objective:** To determine the effectiveness of an eight-week combined exercise program on physical and motor function fitness indices, maximum oxygen consumption, Expanded Disability Status Scale (EDSS) in multiple sclerosis (MS) patients. **Methods and Materials:** In this randomized clinical trial, 24 female MS patients with EDSS ≤ 4 were divided into two groups: case (experimental) (13 patients) and control (11 patients). Patients in case group participated in 24 sessions (each session, 60-90 minutes) of combined exercise program (running, endurance training, resistance and stretching) for eight weeks. Patients of control group continued their normal activities. Following completion of eight-week program, both groups underwent post-tests and re-measurement of EDSS. **Statistics:** mean (±standard deviation) were used to express data. For comparison of continuous variables, the Mann-Whitney U test and the Wilcoxon test were used (P:0/05). **Results:** Significant statistical decreases were observed after combined exercises in case group in body fat mass [21.67 (±6.03) to 20.90 (±5.62); P = 0.01] and percent body fat [34.21 (±4.80) to 33.33 (±4.79); P = 0.006]. Except for motion function and endurance which showed significant decreases, there were statistically significant increases in flexibility [1.88 (±8.01) to 11.03 (±6.81); P = 0.002], strength [37.53 (±13.47) to 69.61 (±18.25); P = 0.002], and balance [37.69 (±36.98) to 117.87 (±121.6); P = 0.004]. There was a statistically significant decrease in EDSS in case group before [2.34 (±1.06)] and after study period [1.65 (±1.12)]; P = 0.04. None of changes in control group was significant. **Conclusion:** An eight-week combined exercise program was safe and improved flexibility, strength, and balance, EDSS, and maximum oxygen consumption in MS patients.

## 200-M BACKSTROKE RACE ANALYSIS AT THE 5TH DOWN SYNDROME SWIMMING WORLD CHAMPIONSHIPS

Junior, V.1, Querido, A.1, Araújo, D.1, Vilas-Boas, J.P.1,3, Corredeira, R.1, Daly, D.2, Fernandes, R.J.1

1: CIFI2D, Faculty of Sport, University of Porto (Portugal), 2: Faculty of Kinesiology and Rehabilitation Sciences (Leuven, Belgium), 3: Porto Biomechanics Laboratory, University of Porto (Portugal)

**Introduction** Down syndrome (DS), a genetic cause of intellectual disability, presents physical impairments that may affect their motor performance behavior. Race video recording is essential both to provide feedback of swimmers' performances and to analyze performance influencing factors. Since this has never been done for DS exclusively, the aim of this study is to analyze the 200-m backstroke event from the 5th DS World Championships. **Methods** The event was videotaped with two side view cameras, and 28 swimmers (15 men and 13 women) from the preliminary heats were analyzed for start, turn and swim times and stroke length (SL), rate (SR), and index (SI). Mean and SD were obtained, and Student t-tests were computed to compare gender groups. Pearson correlation analysis was performed between race components, stroking variables and end results ( $p < .05$ ). **Results** Differences were found between male and female swimmers on start ( $7.22 \pm .77$  &  $8.42 \pm 1.17$ s), swim ( $94.63 \pm 12.03$  &  $109.68 \pm 12.98$ s), turn ( $98.67 \pm 7.86$  &  $113.53 \pm 10.11$ s), finish ( $10.74 \pm 1.35$  &  $12.98 \pm 2.88$ ), and final times ( $211.25 \pm 18.94$  &  $244.53 \pm 24.91$ s), SL ( $1.59 \pm .18$  &  $1.33 \pm .17$ m), SI ( $1.34 \pm .25$  &  $.96 \pm .14$ ), and speed ( $.86 \pm .09$  &  $.74 \pm .07$ m/s). No differences between genders were observed for SR ( $32.85 \pm 4.86$  &  $34.51 \pm 6.01$ st/min). Higher significant ( $P < .05$ ) correlations with final time were found for swim (.93), finish (.81), turn (.78), and start times (.76), for men, and swim (.97), followed by turn (.92), start (.84), and finish times (.72), for woman. Inverse correlations were found between SR and SL (-.62 men & -.83 woman). **Discussion** As observed in previous studies with other populations (Arellano et al., 1994; Daly et al., 2003), male DS swimmers are significantly faster than their female counterparts in the 200-m backstroke event and demonstrated longer SL and higher SI, for a similar SR, implying that SL is more important for swimming speed than SR. For this event, swim and finish times are most determinant for final time in men, and swim and turn times in woman. In accordance with Chatard et al. (2003), starts were not of major importance for the final time. Since swimmers spend more time turning in a 25m pool than in free swimming, and considering that this race component is also related to final time, coaches should emphasize turning on the training process, so that swimmers will be able to improve their performance. **References** Arellano R, Brown P, Cappaert J, Nelson R. ## PHYSICAL ACTIVITY AND AEROBIC FITNESS: DIFFERENCES BETWEEN CHILDREN AND YOUTH WITH AND WITHOUT CHRONIC ILLNESS?

Klasson-Heggebø, L.1, Kolle, E.2, Steene-Johannessen, J.3, Robsahm, T.E.4

1:Valnesfjord Rehab. Centre (Valnesfjord), 2:Norwegian School of Sport Science (Oslo), 3:Sogn og Fjordane University College (Sogndal), 4:The Cancer Registry of Norway (Oslo)

**Introduction:** Children with disabilities and/or chronic illnesses should be given the same opportunity as their able-bodied peers, for mastery and participation in school-, leisure- and sports activities (1). The present study aims to explore differences in physical activity and aerobic fitness between 9- and 15-year-olds reporting to be chronically ill and their healthy peers. **Methods:** In 2005-2006, a nationally representative sample of 2299 Norwegian 9- and 15-year-olds was randomly recruited to a cross-sectional study. Physical activity was assessed by accelerometers and aerobic fitness was directly measured, using a cycle ergometry test. In total, the participation rate was 82%, of whom 14.2% reported to be chronically ill. Independent T-tests assessed the equality of means between children and youth with and without a chronic illness. **Results:** The most commonly reported illnesses were asthma and allergy. Weight, height or body mass index did not differ between children with and without a chronic illness. In 15 year old boys/ girls and 9 year old boys, no variation in physical activity or aerobic fitness was observed between healthy and ill subjects. In chronically ill 9 year old girls the aerobic fitness level was significantly lower compared to their healthy peers,  $41.1$  ( $6.3$ )  $\text{ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$  and  $43.3$  ( $6.7$ )  $\text{ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$  respectively ( $p < 0.05$ ). Moreover, the physical activity level tend to be lower in chronically ill 9 year old girls ( $p = 0.07$ ). **Discussion:** Physical activity and fitness will, regardless of functionality level, influence children's health and the risk of secondary conditions (2, 3). Knowledge about objectively assessed physical activity and aerobic fitness in children with disabilities and/or chronic illnesses are scarce, and the level is suggested to be lower than in healthy peers (4). We only revealed differences among 9 year old girls. This can be due to: the inclusion in school setting of children with chronic illnesses, relatively small groups, or low levels of physical activity in 15 year olds which may weaken contrasts between subgroups. Further studies aiming to increase knowledge about children and youth with disabilities and/or chronic illnesses are important. **References:** 1. United Nations. (2006). Resolution 60/232. ## RELATIONSHIPS BETWEEN UPPER-BODY MAXIMAL STRENGTH, POWER AND SPRINT PERFORMANCE IN SLEDGE ICE-HOCKEY

Skovereng, K.1, Ettema, G.1, Welde, B.2, Sandbakk, Ø.1

1Norwegian University of Science and Technology, Trondheim, Norway; 2North-Troendelag University College, Levanger, Norway.

**Introduction** A high importance of upper body strength and power on double poling performance in cross-country skiing has been shown in several previous studies (1, 2). In order to examine the influence of strength and power on upper-body propulsion more isolated, sledge ice-hockey provides a good model as it is performed exclusively by upper body work. Furthermore, sledge ice-hockey requires high capability of acceleration and maximal speed which suggest that high maximal strength and power has an important impact on performance. Therefore, the purpose of the present study is to investigate the relationships between upper-body maximal strength and peak power on 30 meter sprint performance in sledge ice-hockey. **Methods** 13 male sledge ice-hockey players from the Norwegian national team performed three 30-m maximal sprint tests recorded by fixed light sensors. Acceleration was calculated during the first 10 m assuming constant acceleration and mean speed during the last 10 m was considered top speed. Cycle length and rate was measured by video analyses. In addition, 1 repetition maximal strength and peak power was assessed in the bench press (BPr), bench pull (BPu) and pull-down (PD) exercises using a barbell, and a linear encoder. **Results** Both maximal strength and peak power for all three strength exercises showed strong correlations with performance in the 30 meter sprint test ( $r = 0.748 - 0.861$ , all  $p < 0.005$ ). Total 30 meter sprint time correlated most strongly with maximal strength in PD ( $r = 0.861$ ,  $p < 0.001$ ) and with peak power in BPu ( $r = 0.812$ ,  $p = 0.001$ ). Also

acceleration and top speed correlated strongly with maximal strength and peak power in all tested exercises ( $r=0.597-0.834$ , all  $p<0.05$ ). Acceleration showed the strongest correlations with maximum strength ( $r=0.720$ ,  $p=0.005$ ) and peak power ( $r=0.672$ ,  $p=0.012$ ) in the PD and the BPr exercises respectively, whereas top speed showed the strongest correlations with maximum strength ( $r=0.824$ ,  $p=0.001$ ) and peak power ( $r=0.834$ ,  $p<0.001$ ) in PD and the BPr respectively. There were no significant relationships between kinematics in the sprint versus maximal strength and power. Discussion and conclusion The main findings of the present study are significant relationships between maximal strength and peak power upon sprint performance in sledge ice-hockey. Overall, these results indicate that all investigated exercises are relevant for performance in sledge ice-hockey, with maximal strength in the PD exercise as most influential. In order to further understand the specific requirements of strength and power in different exercises in sledge ice-hockey, and to determine the cause and effect relationship, future interventions studies are needed. #### PREVALENCE OF OVERWEIGHT AND OBESITY IN 9 AND 15 YEAR OLD CHILDREN FROM PRISHTINA

Gjaka, M.1, Tishukaj, F.1, Shalaj, I.1, Brestovci, B.1, Berisha, A.1, Selimi, M.1, Tschan, H.2, Froberg, K.3

1: University of Prishtina, 2: University of Vienna, 3: University of Southern Denmark

**Introduction** In last decades the prevalence of obesity and overweight has been increased substantially, and it is becoming one of the biggest health concerns for all age groups in developed and developing countries. High prevalence of obesity, overweight and the high body fat percentage have proven to have adverse effects on childhood and adolescent's health. **Objectives** The main objective of this study was to determine the prevalence of obesity, overweight as well as body fat percentage in Prishtina's schoolchildren. Another goal of this study was to see in which gender and age group, obesity, overweight, and body fat percentage was more prevalent. **Methods** 467 volunteer school children in Prishtina / Kosovo participated in the current cross sectional study. 250 of them have been 9 yrs old and 217 were 15 years of age. Following measurements were performed: height, weight, and BMI was calculated, waist circumference, skinfold measurements were performed at four sites of the upper region of the trunk (biceps brachii (BB), triceps brachii (TB), suprailiac (SI) and subscapular site (SS)). **Results** The overall prevalence of overweight among 9 and 15 year old children was 11.3%, whereas the prevalence of obesity was 3%. The prevalence of overweight in 9 year old children was 7.6% in girls and 16.6 % in boys, respectively and the prevalence of obesity was 5.7% in girls and 2.8% in boys, respectively. 8.7% of 15 year old girls and 10.5 % of boys were categorized as overweight, and 1% of 15 year old girls and 2.6% of 15 year old boys were classified as obese. Sum of measured skinfolds was higher among girls in both age groups. **Conclusion** In conclusion, the prevalence of overweight and obesity was found to be higher in 9 year old children compared with 15 years old is surprising and need further investigation. The prevalence of obesity was higher among 15 year old boys and girls from Prishtina compared to same age groups from Denmark, Portugal and Estonia. However, the prevalence of overweight 15 year old girls was reported to be higher than their age matched counterpart from Denmark, Portugal and Estonia, whereas the occurrence of overweight among 15 year old boys was lower than in Denmark and Portugal, but higher than they counterpart from Estonia.

#### CARDIO-RESPIRATORY FITNESS, FATNESS AND BLOOD PRESSURE AMONG 9 AND 15 YEAR OLD CHILDREN AND ADOLESCENTS IN PRISTINA, KOSOVO

Tishukaj, F.1, Gjaka, M.1, Brestovci, B.1, Shalaj, I.1, Berisha, A.1, Selimi, M.1, Tschan, H.2, Froberg, K.3

1: University of Prishtina, 2: University of Vienna, 3: University of Southern Denmark

**Introduction** Excess weight and body fat are currently recognized as the major determinants of high blood pressure in children and adolescents. Also, low cardio-respiratory fitness is a strong predictor for clustering of cardiovascular disease risk factors in children independent of age and sex. **Aim** This study aimed to assess whether overweight, obesity and resting blood pressure (RBP) are associated with the cardio-respiratory fitness level and to examine how does this association might appear. **Methods** 467 children volunteered in this cross-sectional study. The subjects were 250 (9 yrs) and 217 (15 yrs) school children, selected randomly within five different schools in Prishtina. A cross-sectional analysis of a school children urban sample was carried out with regard to; height, weight, waist circumference (WC), skin folds in four regions of the upper body; systolic and diastolic resting blood pressure; Andersen test was used as an indirect measurement for cardiorespiratory fitness (CRF). **Outcome measures** included BMI and waist to height ratio (WHR). **Results** Distance covered in the Andersen-Test was significant higher ( $p<0.001$ ) in 15 year-old ( $950\pm 138m$ ) compared to nine year old ( $846\pm 138m$ ). There was a significant gender difference ( $p<0.001$ ) in both age groups with higher values for boys compared to girls, respectively (9 yrs:  $877\pm 83$  boys;  $802\pm 71m$  girls; 15 yrs:  $1019\pm 136m$  boys;  $873\pm 93m$  girls). The correlation between CRF and fatness parameters was strongest among the 9 year old overweight/obese boys, and the sum of skinfolds provided the strongest correlation coefficient ( $Cc=.730^{**}$ ). Mean SBP was 95 mmHg for boys and 98 mmHg for girls, whereas, 119.2 mmHg for boys, and 119.8 for girls. Mean DBP was 59.3 mmHg for boys and 60 mmHg for girls. The strongest correlation between CRF and BP was noticed among 9 year old boys ( $Cc=.415^{**}$  for SBP, and  $Cc=.569^{**}$  for DBP). Significant gender differences were found only in SBP, between 9 year old groups. There was a low to moderate association between CRF and BP among all age and gender groups. **Conclusion** Cardiorespiratory fitness was inversely correlated with BMI and all other fatness parameters, Therefore it might be speculated that overweight/obesity is a predictor of CRF, among all age and gender groups included in the study.

### **BOTH RESISTANCE AND ENDURANCE EXERCISE TRAINING INCREASES CHANGES IN IL-10/TNF- $\alpha$ RATIO IN OVERWEIGHT SEDENTARY MALES**

Nikseresht, M., Taheri, A.

*Islamic Azad University, Ilam Branch*

Both Resistance and Endurance Exercise Training increases Changes in IL-10/TNF- $\alpha$  Ratio in Overweight Sedentary Males Mahmoud Nikseresht and Abdolhossein Taheri Islamic Azad University, Ilam Branch, Department of Exercise Physiology, Ilam, Iran Introduction Overweight and obesity are associated with increased plasma levels of pro-inflammatory cytokines such as TNF- $\alpha$  and decreased anti-inflammatory cytokines such as IL-10. The beneficial effects of physical activity-induced reduced cardiovascular risk are, in part, mediated by an exercise-induced amelioration of inflammation. Methods A sample of 31 sedentary subjects were assigned to a resistance group (n=10), an endurance group (n=11), or a control group (n=10). Before and after intervention, subjects were involved in muscular strength and aerobic fitness measurements and further provided a resting fasted venous blood sample for measure of IL-10 and TNF- $\alpha$ . The resistance and the endurance groups completed a respective 10-wk supervised and periodized training program, whereas the control group maintained sedentary lifestyle and dietary patterns. Results Both exercise training programs had no effect on baseline IL-10 and TNF- $\alpha$  concentrations, but did significantly increase IL-10/TNF- $\alpha$  ratio ( $p < 0.05$ ). Compared with the control group, the resistance and endurance groups exhibited significant ( $p < 0.05$ ) improvements in all aerobic fitness measures and significant reductions in body mass. Compared with the endurance and the control groups, the resistance group significantly ( $p < 0.05$ ) improved upper (46.3%) and lower (56.6%) body strength. Conclusion We demonstrate that IL-10/TNF- $\alpha$  ratio concentrations in plasma is affected by 10 wk of endurance and resistance training in overweight sedentary young male. There is no consensus in the literature about the effect of exercise training upon IL-10 and TNF- $\alpha$  production as some studies show increase in IL-10 and decrease in TNF- $\alpha$  (Jung et al, 2008), no change (Polak et al 2006) of this parameters. The anti-inflammatory effects of regular exercise may be mediated via both a reduction in visceral fat mass (with a subsequent decreased release of adipokines) and the induction of an anti-inflammatory environment with each bout of exercise (Gleeson et al, 2011). Taken together, our results suggest that increase in IL-10/TNF- $\alpha$  ratio by resistance and endurance training in sedentary male may lead to a shift towards decreased inflammation. ### **SHORTENING AND MUSCULAR IMBALANCES IN MIDDLE AND HIGH SCHOOL STUDENTS IN A SPANISH POPULATION**

Pablos, A., Elvira, L., Esteve, H., Blasco, E., Gonzalez, M.D., Martin, M.

*Universidad Católica de Valencia*

Introduction Back pain in children and adolescents is a common cause of medical consultation. These problems are caused many times by muscle imbalances. The main reasons that lead to muscle imbalances are the poor and/or inadequate muscular work, the adoption of poor posture in performing everyday tasks and ongoing efforts to cause depletion of certain muscles. Therefore, the purpose of this study was to quantify muscle shortening and bilateral limb differences in Middle and High School students in a Spanish population. Methods It has applied a test of shortening and muscle imbalances to a population of 311 male subjects who were in middle and high school. The test has five measurements (Diagonal Posterior Chain (DPC), pectoral muscle stretch (PEC), Internal Hip Rotators (IHR), External Hip Rotators (EHR), Iliopsoas (IP) and Hamstrings (HAM)). Results The percentage of students with shortening and muscle imbalances was 46.9% for DPC, 24.1% for the PEC, 1.6% for the IHR, 0.3% for the EHR, 41.2% for HAM and 22.2% for IP. Discussion Bad postural habits and a sedentary lifestyle of the students can cause shortening and muscle imbalances. Staying seated for long hours and poor posture will involve the shortening of certain muscle groups and the relaxation of others. This we have been corroborated in our study. We found worrisome shortening of the muscles that moves the shoulder girdle, reaching percentages around 50% for the diagonal posterior chain and above 24.1% in pectoral stretch. These results are still lower than obtained in the study of Ramos et al. (2007), which include values of 85% for PEC. We also find percentages above 40% for knee flexor muscles (HAM), coinciding with Ramos et al. (2007). Their results show percentages of 55% for similar populations. Regarding the shortening and limb differences at the level of the hip flexor muscles (IP) values are reached 22.2%. These being lower than those found in the study of Ramos et al. (2007) exceeding 50% of the population in this age group. Showing the results we can see it is essential keep an active lifestyle, stretch the postural muscles and build the dynamic muscles. ### **EFFECTS OF LISTENING MUSIC AND WATCHING IMAGES ON ENERGY EXPENDITURE, HR, PER, AND LACTATE IN ACCORDING TO EQUIPMENTS DURING EXERCISE**

LEE, H.K., KIM, M.J.

*SANGMYUNG UNIVERSITY*

EFFECTS OF LISTENING MUSIC AND WATCHING IMAGES ON ENERGY EXPENDITURE, HR, PER, AND LACTATE IN ACCORDING TO EQUIPMENTS DURING EXERCISE Hyung Kook Lee 1 Myung Ju Kim 2 1: Sangmyung University (Cheonan, Korea) 2: Seoul National University (Seoul, Korea) Introduction Listening music during exercise as a way of feeling or emotional techniques has been used to improve athletic performance (Simpson, et al, 2006). Also, during steady-state exercise, VO<sub>2</sub>, Q, SV, VE and Fb significantly increased while listening to fast music compared to the slow music and no music (Birnbbaum, et al, 2009). Recently, it has become a common practice to listen music and watch images while exercising in gym. We used to choose the favorite equipment for aerobic exercise. The aim of this study was to compare the effects of listening music and watching images on Calory, HR, PER, and Lactate during aerobic exercise. Methods 20 healthy university male students volunteered to participate in this research. They were divided into 3 groups at random. They have exercised with 3 equipment (treadmill, bicycle, arm) respectively and under 3 experimental conditions (no-music, music, images) repeatedly. Each exercise was performed during 25min with moderate intensity. It were measured energy expenditure (EE) and total heart rate (HR), total perceived exertion rate (PER) with Borg's Scales (6-20), and blood lactate concentration difference (DLA). Statistical analyses were completed

using repeated measures ANOVA. Results In case of treadmill, EE, tHR, tPER, and dLA were not significant difference between 3 conditions. But all of factors showed the highest in the case of no music condition. In case of bicycle ergometer, there were significant difference on EE( $p<.05$ ) and dLA ( $p<.05$ ) in the case of listen to music condition. Also, EE, tHR, and dLA at music listening condition and tPER at no music were the highest. In arm ergometer, also there were not significant difference, but EE, tHR at music listening condition and tPER, dLA at no music were showed the highest. Discussion In the case of treadmill, there were unlike the findings of previous studies (Hasan et al, 2008; Brownley, et al 1995; Birnbaum, et al, 2009). In this study, EE at no music listening condition was measured the highest. That is because audio or visual stimulator may interrupt to focus performance in treadmill. On the other hand, in exercising used bicycle ergometer, the results of this research have shown that it was increased on EE and dLA at music listening condition than others. In order to get the listen to music' positive effect, it is good to use the equipment as bicycle ergometer. References Birnbaum, L., Boone, T., & Huschle, B.(2009). ### **THE JOURNEY TO MARS: VARIOUS KINDS OF EXERCISE LEAD TO DIFFERENT EFFECTS ON THE BRAIN CORTICAL ACTIVITY, MOOD AND COGNITIVE PERFORMANCE**

Jacobowski, A., Abeln, V., Schneider, S.

*German Sport University Cologne*

Introduction A general psychological model assumes that during long term spaceflights mood and cognitive functioning are impaired because of isolation. As physical activity has a strong influence on brain activity, mood and cognitive function it is hypothesized that exercise would be able to counteract mood and cognitive changes during isolation<sup>1,2</sup>. It is also known that the influence is stronger when people exercise at their chosen intensity and it is likely, that the effect also correlates with the performed kind of exercise. Therefore the aim of the study was to analyse in which way individuals react to sport concerning brain cortical activity, mood and cognitive performance and if these effects are based on the chosen exercise or depend on the individual itself. Methods The experiment took place during the MARS500 project initiated by the Institute of Biomedical Problems (IBMP) and the European Space Agency (ESA), where 6 male subjects (age 31,33±4,13) lived in confinement for 520 days, simulating a real mission to Mars. Every two weeks electrocortical activity (EEG), mood-parameters and cognitive performance parameters were recorded prior to and after one of six specified exercises (Active and Passive Running, Bicycle, Strength training, Expanders and Vibration). The measurement for mood parameters consisted of a self report on current psychological and physical state whereas cognitive performance was measured in form of commercially available brain games. Results A decrease of cortical brain activity in the prefrontal area was noticeable after all kinds of exercise; the effect was most pronounced after running and bicycling. The general cognitive performance was higher after sport for all kinds of exercise but also differed by a varying amount. The best results were reached after running and bicycling. Changes in mood regarding the exercises were more complex but always specific to sports. Discussion We could show that the effect on mood and cognitive performance depends on the performed exercise especially while comparing endurance training and strength training. Therefore it is proposed to regard personalised exercise during long term spaceflights as a possibility not only to counteract physiological but also neuro-psychological deconditioning in order to maintain and improve mission success and mission safety. ### **EXPLORING MEDIATORS OF ACCELEROMETER ASSESSED PHYSICAL ACTIVITY IN YOUNG ADOLESCENTS IN THE HEIA STUDY – A RANDOMIZED CONTROLLED TRIAL**

Bergh, I.H.1, van Stralen, M.M.2, Grydeland, M.1, Bjelland, M.3, Lien, N.3, Andersen, L.F.3, Ommundsen, Y.1

*1: Norwegian School of Sport Sciences, Norway, 2: VU University Medical Center, the Netherlands, 3: Faculty of Medicine, University of Oslo, Norway*

Introduction School-based interventions which include efforts to increase physical activity (PA) may promote a healthy weigh development in adolescents, but results are inconsistent (Brown et al., 2009). One possible explanation for low efficacy or effectiveness is limited evidence as to how interventions induce behaviour change (Baranowski et al., 2005). The purpose of this study was to examine whether personal, social and physical-environmental factors mediated intervention effect on PA and whether gender and weight status moderated mediated effects in the HEIA study – a school-based, randomized controlled trial to promote healthy weight development among young adolescents. Methods Accelerometer assessed PA (mean count per minute) and six potential mediators based on the social-ecological framework were assessed at baseline and post-intervention after 20 months. The product-of coefficient test was used to assess mediating effects. Results No mediating effect of any of the hypothesized mediators was identified. Gender and weight status did not moderate any mediated effects with the exception of weight status that moderated the mediated effect of enjoyment. Few intervention effects were seen on the mediators, except for a positive change in social support from teachers among girls ( $p<.05$ ) and the normal weight ( $p<.05$ ), and a negative effect on enjoyment ( $p<.05$ ) and self-efficacy among the overweight ( $p<.001$ ). However, change in enjoyment, self-efficacy, perceived social support from friends and environmental opportunities were associated with change in mean count per minute, and thus show evidence of being potential mediators of physical activity in adolescents. Discussion Even though no mediating effect on PA change could be observed, personal, social and physical-environmental factors were identified as potential mediators. Future studies should continue to examine mediating and moderation mechanisms in PA change in adolescents using a broad set of mediators. References Baranowski T, Jago R. (2005). ## COMPETENCIES OF THE PHYSICAL EDUCATION PROFESSIONAL TO PERFORM IN PRIMARY HEALTH CARE: THE DIMENSION OF SKILLS

Coutinho, S.S.1, Queiroga, M.R.1, Ferreira, S.A.1, Mishima, S.M.2, Pereira, M.J.B.2

1: UNICENTRO (Guarapuava, Brasil), 2: USP (Ribeirão Preto, Brasil) Research Support: CNPq, Brasil.

**Introduction** The physical education professional working in the areas of Primary Health Care (PHC) is recent in Brazil. There is still a lack of empirical research demonstrating the skills that these professionals may have to act in this context. The professional skills are studied from a concept that comprehends three linked dimensions: knowledge, skills and attitudes (Durand, 2000). This study aims to develop and analyze the competencies of the dimensions of skills that are required for the physical education professionals in the context of PHC. **Methods** For data collection, the Delphi technique with the performance of three rounds was used. The sample consisted of 31 subjects: 4 general coordinators, 12 sectional coordinators and 9 professors of physical activity programs developed in the public health system in six different Brazilian cities and 6 researchers. Results 36 competencies of the dimensions of skills divided into five indicators were developed: planning (13 competencies), communication (6), evaluation (4), incentive (3) and management (10). **Discussion** The results indicate two aspects. 1) Narrow technical skills: direct and diversify bodily practices; assess and prescribe exercise; organize events; develop programs and projects; report on the physiological adaptations and benefits caused by physical activity and raise awareness about the importance of regular physical activity. 2) Skills that show a broader view: plan actions knowing the mission for public health; and develop strategies for transformation of health practices based on the principles of continuing education; act in an interdisciplinary and multi-professional team, with possibilities of matrix support; establish link by listening; evaluate people and communities based on social and cultural context; favor community participation and empowerment of the user; develop bodily practices that enable the participation of all, starting from the needs and desires expressed by individual and collective ideas; obtain intersectoral articulation, understanding that health is the result of multiple factors; deal with unexpected events, discuss possibilities of intervention and use high technology to solve population health problems. As in studies with other health professionals, the results of this research show the need for the physical education professionals conduct their actions in view of the health-disease process which should not be restricted only to the biological aspects (Carvalho, 2005). **References** Carvalho YM. (2005). *Motrivência*. 17(24), 97-105. Durand T. (2000). *Rev Fr Gest*, 127, 84-102. Simões EJ, Hallal P, Pratt M, Ramos L, Munk M, Damascena W. (2009). *Am J Public Health*, 99 (1), 68-75.

## ADHERENCE TO A PROGRAM OF EXERCISE PHYSICIST IN PATIENTS WITH RISK CARDIOVASCULAR

Meseguer Zafra, M., Manzanares Serrano, A., Soler Torroja, M., Pérez Valero, I., Sesma Arnaiz, R., Fernández Garrido, D.  
*universidad catolica san antonio, medical centers Jesus Marín*

**Introduction** The program "ACTIVA" is an initiative conducted by Ministry of Health from Region of Murcia (Spain), with the objective to initiate the practice of physical activity in sedentary subjects with cardiovascular risk factors (CVRF). This study investigated the adherence of patients to the program "ACTIVA" in the municipality of Molina de Segura. **Method** The subjects in this study were 540 (35-65 years), patients of two medical centers, municipality of Molina de Segura (Spain). The criteria for inclusion in the program were the presence of two or more CVRF (hypertension, lipid disorders, overweight and smoking) and sedentary lifestyle. The subjects were included on the program for their family doctor or nurse. The program "ACTIVA" consisted of 30 sessions of training on strength, flexibility and aerobic endurance on 10 weeks. Results The 61% Of the 540 subjects involved on this study were women. The average of age was 50.8±8.8 years (men 49.8±9.4; women 51.4±8.3; p=0.04). From all subjects participating in the study the 40.9% suffered hypertension, 60.8% obesity, the 53.4% had lipid disorders and the 35.9% were smokers. 77.9% were derived by doctors and nurses 22.1%. From the total of the subjects that initiated the program (at least one session) 80.9% (437 subjects) (men 79% women 82%). With respect to the initiation of the program, we found significant differences according to the age: attended the 69.2% of under 45 years, the 82.7% between 45 to 55 years and 91% of older 56 (p<0.001). Also there were significant differences between subjects derived by medical centers (85% and 77.7% each) (p = 0.03). The average of attendance was the 64.6% (68.2% men and women 63.3%), with small differences depending the health center of source (67.3% and 62.3%). We found very significant differences in adherence to the program by age: older than 50 years had an average of 69.2% attendance and under 50 years old had 50.6% (p = 0, 003) **Discussion** In contrast to what would be expected, the study shows that with an exercise program with participation and close coordination with health professionals and graduates in sports science, high adhesion may be obtained in older patients, sedentary subjects with CVRF (over 60% obese), being higher still in patients over 50 years. In fact, the current perspective focused on health promotion through the physical activity puts increasingly greater degree the phenomenon of adherence as one of the essential pillars of it, because only if you practice physical activity on a regular basis can be able to obtain certain safeguards about their potential benefits (Marquez, 2004). **References** Márquez, S. (2004). Adherence to physical exercise: determinants, models and strategies of maintenance. *Domus*, 11-12, 93-112

## THE EFFECTS OF THREE MONTHS EXERCISE TRAINING ON IN VIVO AND EX VIVO MUSCLE ENERGY METABOLISM IN OBESE INDIVIDUALS

Ukropcova, B.1, Kurdiová, T.1, Valkovic, L.6, Baláz, M.1, Zemková, E.2, Srbecký, I.3, Kyselovicová, O.2, Belan, V.3, Jelok, I.4, Vician, M.5, Krssak, M.6, Trattnig, S.6, Ukropec, J.1

1: Inst Exp Endocrinology SAS, 2: FSPE, 3: UHB Comenius University, 4: NICD & 5: SMU (Bratislava, Slovakia), 6: Vienna GH (Vienna, Austria).

**Introduction** Obesity significantly increases the risk of metabolic disease, associated with perturbation of muscle energy metabolism. An ample evidence documents the beneficial effects of regular exercise on the whole body and muscle metabolism. The aim of this study was to measure in vivo and ex vivo muscle energy metabolism in obese individuals before and after exercise training. **Methods** Obese sedentary individuals (M/F 11/8; age 36±6yrs., BMI 32.1±3.5kg/m<sup>2</sup>) completed 3 months endurance or strength (n=11/8) training program, with 1 hour exercise session three times per week. Phosphorus magnetic resonance spectroscopy (31P-MRS) was used to measure the energetic status of muscle in vivo by measuring the intracellular phosphorus metabolites; i.e. phosphocreatine (PCr), ATP, inorganic phosphate (Pi) and maximal oxidative flux after either chemical or magnetic equilibrium perturbation. The samples of skeletal muscle were taken by muscle biopsy (vastus lateralis) before and after training. Ex vivo respiration (cytochrome C oxidase [COX] activity) of permeabilized muscle fibers was measured by oxymetry. Maximal aerobic capacity (VO<sub>2</sub>max) was measured by bicycle ergometry. Results Three months of exercise training increased physical fitness (VO<sub>2</sub>max, p=0.01) and in vivo muscle energy metabolism as assessed by 31P-MRS (maximal oxidative flux, p=0.03; initial recovery rate p=0.07), without a significant effect on ex vivo muscle COX activity (n=0.1). In vivo depletion of muscle PCr was negatively associated with muscle COX activity (p=0.004) and PCr recovery rate was also associated with calf muscle volume, and with parameters of physical fitness such as maximal heart rate (p=0.004) and VO<sub>2</sub>max

( $p=0,046$ ). In addition, extramyocellular lipid content was associated with the ATPase reaction rate ( $p=0,045$ ). Discussion Low physical fitness is one of the major risk factors of obesity and metabolic disease. Exercise training increased physical fitness as documented by an increase in  $VO_2\max$ , as well as in vivo muscle energy metabolism, measured by  $^31P$ -MRS. It has been shown that mitochondrial respiration increases with training, the lack of the training effect on COX activity in our study might be attributed to the limited size of the study population. The association of in vivo energy metabolism with ex vivo muscle respiration, muscle mass and extramyocellular lipid content points at the complexity of regulatory processes associated with muscle training. In conclusion, 3 months training is sufficient to increase both cardiorespiratory and muscle fitness in obese individuals. Grant support: EFSD & Lilly Fellowship

### **ANNUAL MEDICATION COSTS NEGATIVELY CORRELATE WITH FUNCTIONAL FITNESS, MOOD STATES AND SF-36 SCORES IN ELDERLY WOMEN.**

Teixeira, A.M., Marques, J., Martins, R.

*University of Coimbra*

**Introduction** The importance of physical activity in the maintenance of the well-being and quality of life in the elderly is unquestionable. The aim of this cross-sectional study was to analyze the effects of a multicomponent exercise on functional fitness, mood states, mucosal immunity, quality of life and annual cost of medication in elderly women. **Methods** The sample study consisted of 41 women, 20 who had been engaged in a multicomponent exercise protocol in the last year (68,5+6,5 years old, 154,8+6,1m stature and 65,5+9,0 Kg body mass) and 21 that were sedentary (72,7+8,0 years old, 152,3+5,2m stature and 71,13+10,6Kg body mass). Written informed consent was obtained from all the participants. Functional fitness was assessed using the Senior Fitness Battery Tests. Mood states and quality of life were evaluated using the POMS-SF and the SF-36 questionnaires respectively. Anthropometric, hemodynamic and metabolic parameters, salivary IgA concentration and secretion rate were also analyzed. The annual cost of medication was calculated by recording for each participant the amount and commercial name of the medicines taken regularly on a daily basis. Statistical analysis was done using the independent samples T-test for differences between groups and the bivariate Pearson's correlation for the association between variables. The significance level was set at  $p<0.05$ . **Results** Anthropometric measures showed that the elderly women engaged in exercise had lower BMI, waist, hip and abdominal circumferences, waist-hip ratio and percentage of fat mass. Functional fitness components including lower and upper body strength, lower and upper body flexibility, speed, agility and balance and aerobic endurance were also better for the exercising group. More favourable values on the POMS and SF-36 questionnaires were also found for this group. Differences between the two groups were also found for the annual medication costs ( $p=0.003$ ). No differences between groups were found for systolic and diastolic blood pressure, resting heart rate, lipid profile, glucose, haemoglobin, HbA1c and salivary IgA levels or saliva flow rate. The annual cost of medicines negatively correlated with age, functional fitness, depression, anger, fatigue, tension, the different SF-36 components, total SF-36 scores ( $r=-0.575$ ,  $p=0.0001$ ) and log saliva flow rate. **Discussion** This study shows that elderly women that practice regular exercise have lower annual costs with medication than their sedentary counterparts. Financially exercise seems to be a good investment as it promotes quality of life in latter years and reduces the amount of medicines regularly taken cutting costs at the individual and public levels.

#### **DYNAMIC AND MULTIDIMENSIONAL NATURE OF HANDBALL PLAYER**

Massuca, L.1,2,3, Fragoso, I.3

*1: UL-FEFD (Portugal); 2: ICPOL-ISCPSP (Portugal); 3: FMH-UTL (Portugal)*

**Introduction** Research on expertise or in talent identification has tended to be mono-disciplinary (Phillips et al., 2010) or focused in the inter relationships between morphologic and fitness profiles. In accordance, this study aims to identify the inter-relationships correlation between the morphologic, fitness, handball-specific skill (HBskill), psychological and biosocial profiles in handball players (HB). **Methods** A sample of male HB ( $n=225$ ) were evaluated in five dimensions: morphologic, fitness, handball-specific skill, psychological and biosocial. Predicted probabilities of each category were calculated using Massuca, Fragoso and Teles (in review) logistic regression models. Taking into account these scores, Pearson correlation analysis was performed to study the relation between profiles. **Results** Significant correlations were found between fitness profile and all the other dimensions considered in this study. Significant positive correlations were also found between the morphologic profile and: (1) "biosocial" ( $r=.450$ ,  $P<.001$ ); and (2) HBskill ( $r=.248$ ,  $P=.004$ ) profiles. The "biosocial" and HBskill profiles were significantly correlated with each other ( $r=.223$ ,  $P<.013$ ). **Discussion** The literature often focuses on the physical characteristics and/or physiological attributes to succeed in handball. However, this study showed that both dimensions were significantly correlated to each other ( $r=.669$ ,  $P<.001$ ). Moreover, they significantly correlate with HBskill (morphologic:  $r=.248$ ,  $P=.004$ ; fitness:  $r=.359$ ,  $P<.001$ ) and biosocial (morphologic:  $r=.450$ ; fitness:  $r=.550$ ; both  $P<.001$ ). According to literature, expert performers accumulate more minutes of sport-specific practice than non-expert performers (Baker et al., 2003; Helsen et al., 2000; Massuca & Fragoso, 2011). In fact, the amount of practice time seems to be associated with the time "needed" to learn and to improve technical and tactical skills. This may explain the positive correlation between the "biosocial" and handball-specific skills profiles ( $r=.223$ ,  $P<.05$ ). Nevertheless, all these findings underline the dynamic and multidimensional nature of HB. **References** Baker J, Côté J, Abernathy B (2003). ## WORK IS A MORE RELIABLE ESTIMATOR THAN HEIGHT OF COUNTERMOVEMENT JUMP PERFORMANCE

Dias, P., Amaro, N., Matos, R., Morouco, P.

*Polytechnic Institute of Leiria*

**Introduction** Since the early 80s that 'Bosco Tests' are commonly used all over the world. Indeed, most coaches rely on the countermovement jump (CMJ) to evaluate muscular power of the lower limbs. This is acceptable because in short activity patterns muscular power plays a major role. In fact, it is assumed that there is a good correlation between lower limb maximum power and maximum jump height. Results of CMJ are usually expressed in height, i.e., the vertical displacement of the centre of mass. However, this parameter does not take into account the mass of the subject. Thus, the purpose of the present study was to analyze the possible relationships between height and work of the CMJ and power in Squat. **Methods** Forty-two national level swimmers (22 male and 20 female; age:  $15.6 \pm 1.8$  years; body mass:  $57.4 \pm 9.5$  kg; height:  $1.68 \pm 0.13$  m) volunteered as subjects. The height in the CMJ was obtained using the jump fly time (ErgojumpTM, Italy). Work was calculated according to  $W = m \cdot g \cdot \Delta h$ . Using a dynamic measurement system (T-Force System, Ergotech, Spain), each participant executed *n* incremental repetitions (5 min rest) in Squat to assess average propulsive power. After Shapiro-Wilk normality test, Pearson's correlation coefficient (*r*) was used to establish relationships between variables. The level of statistical significance was set at  $p < 0.05$ . **Results** The height assessed in the CMJ was  $0.34 \pm 0.09$  m, being calculated the correspondent work of  $209.5 \pm 36.6$  J. Maximum value of average propulsive power was  $355.33 \pm 56.4$  W. Significant correlations were observed between power in squat with CMJ height ( $r = 0.64$ ,  $p < 0.05$ ) and work ( $r = 0.92$ ,  $p < 0.001$ ). **Discussion** The high correlation between height and work ( $r = 0.88$ ,  $p < 0.001$ ) in CMJ can induce that both variables are good estimators for performance. Moreover, the generally used equipments to evaluate CMJ provide the height of jump immediately. However, not taking into account the mass of the subject does not seem the most accurate procedure. Indeed, power presented higher correlation with work than with height, inducing a more reliable estimator for performance in the gym exercise. These data corroborate the findings of Morouço et al. (2011), which reported higher correlations between work and swimming performance parameters, than with height. Coaches evaluating CMJ should take in account the mass that the subject must overcome, with the aim of having a more trustworthy estimator of muscular power. **References** Morouço P, Neiva H, González-Badillo J, Garrido N, Marinho D, Marques M. (2011). *J Hum Kinet*, SI, 105-112.

## EFFECTS OF SPECIFIC PREPARATION PHASE TRAINING TO THE PERFORMANCE CHARACTERISTICS IN FEMALE HANDBALL PLAYERS

Kale, M.

*Anadolu University*

**Introduction:** The aim of this study was to examine effects of specific preparation training to the performance in women handball players. **Methods:** Fourteen women handball players (age/year)= $20.2 \pm 1.9$ , height(cm)= $170.7 \pm 5.5$ , body weight(kg)= $65.8 \pm 8.3$ ) from Turkish Women Handball Super League were voluntarily participated. Body fat percent(BF%), somatotype, sprint variables (10m, 20m, 30m), anaerobic power(AP), anaerobic capacity(AC), squat jump(SJ), countermovement jump(CMJ), lactate threshold(LT), maximal oxygen consumption(VO2max), maximal heart rate (MHR) were tested at pre and post specific preparation phases. LT, VO2max, MHR were determined from Modified Shuttle-Run Test(MSRT) (Hazır, 2000). Subjects'FBLLs(fixed blood lactate levels) were determined from the MSRT. MSRT was started at velocity of 8km.h<sup>-1</sup> and in every 3min velocity was increased 1km.h<sup>-1</sup> until the exhaustion, with 1min rest intervals for blood sampling from earlobe. Third degree polynomial fit was used to estimate mean running velocities, heart rates, oxygen consumptions of FBLLs at 2mM.L-1, 3mM.L-1, 4mM.L-1, 5mM.L-1 respectively. The players were trained 2 mesocycles training (sprint, strength and power, endurance, and technical-tactical training) for the specific preparation. Each mesocycle included 5 day training period in a week for 3 weeks. The training period included endurance running at FBLLs, weight training, sport-specific strength, sprint running, training, and competition game. Wilcoxin test was used to determine the effects of specific preparation phase training to the performance characteristics. **Results:** The results show that there were no significant differences between pre and post specific preparation training for AP, AC, BF%, endomorphy, and mezomorphy but woman handball players increased their some performance characteristics. Ectomorphy, 10m-20m-30m sprint variables, SJ, CMJ, VO2max, running velocities, heart rate, and oxygen consumption at FBLLs were significant differences ( $p < 0.05$ ). **Discussion:** Specific preparation training resulted in significant increases in sprint variables, squat and countermovement jumps, VO2max, running velocities, heart rate, and oxygen consumption at FBLLs. Such performance characteristics as strength, speed, and endurance that increases have been found in woman handball players (Granados et al, 2007; Gorostiaga et al, 2006). It is concluded that such increases in specific preparation training are likely to be considered advantages to women handball players because these biomotor characteristics give the forceful muscle contractions and also endurance for required in some handball game actions, such as sprinting, throwing, blocking, jumping, pushing. **References:** Granados C, Izquierdo M, Ibanez J, Bonnabau H, Gorostiaga EM. ## THE SCORING SKILLS WHICH DISCRIMINATE RESULT , ACCORDING SET NUMBER IN WORLD CHAMPIONSHIP VOLLEYBALL 2010

Joao, P.V., Silva, M., Lacerda, D., Vaz, L.

*IResearch Center for Sports Sciences, Health and Human Development (CIDESD) UTAD - Vila Real, Portugal.*

**Introduction** The study of the knowledge of the match isn't a recent concern, since one of the biggest challenges of the investigation has been, for a long time, the concern for the interpretation and understanding of the development of the specific knowledge in team sports. The aim of the present study intends to identify the actions of the game which discriminate the result (win/lose), according set number. **Methods** The sample of this study has been taken from the World Championship of Volleyball Male Seniors – Italy 2010. Were analyzed *n*=24 games, 3 were played in 5 sets, 12 in 4 sets and 9 in 3 sets which outcomes the result of 90 sets played throughout the 3rd round, which are the elite matches until the present study. These correspond to 24670 actions, in which 4083 services, 3434 receptions, 4906 attacks (3030 attacks after reception, 1876 attacks in transition), 2109 blocks, 1933 digs and 3299 sets. The Data Volley software was used in this research. To the data analysis was used the discriminating function (AD) in order to identify, throughout canonical structuring coefficient (CCE), the indicators which contribute the most to establish the maximum difference between the victories and defeats. We consider as relevant to the interpretation of the linear composite the  $|CCE| \geq 0,30$  (Tabachnick & Fidell, 1996). The level of significance was established in 5%. The calculation of the results was made by the software SPSS version 17.0. **Results** Regarding the total amount of the sample, the results suggest that the service point, the reception error and the block error were discriminating variables to the final out-

come of the match. Only in the matches of 4 sets occurred significant differences in the actions of serve point, side out error, service error and attack error, contributing to the result of the match. Discussion Regarding the results obtained throughout the positioning of the setter (defense zone and attack zone), the discriminating variables were service point, service error, excellent pass, pass error, excellent defense, side out error, counter attack point, attack point, excellent reception, side out point and reception error. We can say the action service point, it's possible associate to the success (win). It's very important training the efficacy of this action according the final outcome.

### **SPRINT VS INTERMITTENT TRAINING IN YOUNG BASKETBALL PLAYERS**

Padulo, J.1, Attene, G.2, Bramani, S.3, Pizzolato, F.4

1: University of "Tor Vergata" (Rome ITALY), 2: University (Cagliari ITALY), 3: Rehab. Institute (Como ITALY), 4: University (Verona ITALY).

Introduction In young basketball players, it is not known whether sprint or intermittent training fulfils the criterion of effective training to improve sprint vs endurance. The aim of this study was to compare the effects of intermittent training and repeated sprint ability training (Ferrari Bravo et al.; 2008) on physiological variables in female basketball players. Methods Sixteen participants were randomly assigned to either the intermittent training group (YYIRG, n= 8) or repeated-sprint training group (RSAG, n= 8). The following outcomes were measured at baseline and after 6 weeks of training: Yo-Yo IRT (YYRT) and RSA tests (Castagna et al.; A-B 2008). The YYIRG performed at the 80% of the maximal speed (YYIRT) 3 sets of 5' of shuttle running (16.47±0.61m - total time 20"), with 20" of recovery and 3' between sets. The RSAG performed (15+15m) with repeated sprint training: 3 sets of six maximal sprint with 20" of recovery and 4' between sets. Result The main effect of training type for all the variables investigated was never significant. In the RSA, best time (BT) was found a significant main effect of time (pre vs post) ( $p < 0.0001$ ), and the interaction training type x time ( $p < 0.03$ ). The RSAG showed a decrease in the BT by 3.1% ( $p < 0.005$ ) and the YYIRG showed a decrease by 6.2% ( $p < 0.0001$ ). Significant main effect of time in the worst time, with a decrement of 5.36%; in the total time, with a decrement of 5.08%; in blood lactate with a decrement of 24.02%. In the YYIRT significant main effect of time in the distance with an increment of 26.9%. Significant main effect of time in the final speed with an increment of 1.23%. Discussion These findings suggest that the two training protocols used in this study can be an effective training strategy for inducing anaerobic and basket-specific training adaptations. Therefore, even weather the YYIRG training is not done at very high speed, it can more increase the maximum speed of the RSAG. Moreover, given that the two trainings are different in terms of volume of work, we can suggest choosing the RSA training in team sports when we want to reduce the volume of work without compromising the anaerobic fitness. ### **PHYSIOLOGICAL PERFORMANCE IN MALE HANDBALL PLAYERS ACCORDING TO AGE AND PLAYING POSITION.**

Torres-Ronda, L., Gerona, T., González-Badillo, J.J.

*Fútbol Club Barcelona*

Torres-Ronda, L.1, Gerona, T.1, González-Badillo, J.J.2 1: F.C. Barcelona (Spain), 2:UPO (Seville, Spain) Introduction Few studies have evaluated specific physiological performance measures in male handball players (Ziv & Lidor, 2009). The aim of the present study was to analyze physiological characteristics of men's handball players according to age group and specific positional roles. Methods Eighty players from F.C. Barcelona handball teams volunteered to take part in this study (Senior-b:n=15;Under-18:n=16;Under-16a:n=17;Under-16b:n=16;Under-14:n=16). Players were measured for anthropometry, horizontal explosive power (5J), agility (T-test), throw speed and repeated sprint (6 x 12.5 m) and CMJ sequences. Results Results showed the experience of age in fitness performance in handball players. Differences were evident in mean and best result of 5JT, jumping, standing and sitting throw and T-test ( $P < 0.001$ ). For the repeated sprint and jump sequences mean, best and % decrease in CMJ was significantly different between age groups ( $P < 0.05$ ), but not for sprint sequences. No differences between play positions (goalkeepers, playmarkers, backs, pivots and wings) were found. Finally, weight and height showed significant correlation between all performance measures ( $P < 0.05$ ) irrespective of age group. Discussion The results indicate that age and years of training handball players aged 14 and over 20 years is an important determinant of performance in specific actions in the game, but not the relative endurance and the degree of fatigue reached when performing repeated sprints of the same distance. The fact that a significant correlation remains between weight and height and performance variables analyzed, independently of age, indicates that the weight and height are key variables in handball performance, which means that these variables are determinants of performance even when players have completed their biological and technical development (Mohamed, et al., 2009). These results suggest that there should be some difference in the testing analyzed between the different play positions, given the characteristics of height and weight between players. The lack of differences between play positions within each age could be explained by the small number of players within each team in various positions (Chaouachi, et al., 2009). ### **THE COMPARISON OF THE VISUAL REACTION TIME AND SPRINT TIME PARAMETERS OF MALE SOCCER AND BASKETBALL REFEREES**

Gurol, B.1, Okcu, M.1, Kale, M.1

*anadolu university health sciences institution*

THE COMPARISON OF THE VISUAL REACTION TIME AND SPRINT TIME PARAMETERS OF MALE SOCCER AND BASKETBALL REFEREES Gurol, B.1, Okcu, M.1, Kale, M.1 1: School of Physical Education and Sports, Anadolu University, Turkey Introduction The purpose of the study was to evaluate visaul reaction time and sprint time parameters of amateur leauge soccer and basketball referees. Methods In this study, 11 male soccer referees (age: 26,00±3,03 year), and 7 male basketball referees (age: 24,86±3,67 year) volunteered to the study. Visual reaction time (5s, 10s, 15s), and sprint time (5m, 10m, 15m, 20m) were tested. Subjects performed 1 attempt, and 2 visual reaction time test at each duration. Each referee performed 2 sprint conditions for each distance. Visual reaction time test, and sprint time test performed via Sport Expert MPS 501 (Turner Electronic, Ankara, Turkey) system. Results Average, minimum and maximum visual reaction time (5 sec)

of the soccer referees was  $0.512 \pm 0.064$  sec.,  $0.457 \pm 0.058$  sec., and  $0.561 \pm 0.084$  sec. respectively. Average, minimum and maximum visual reaction time (5 sec) of the basketball referees was  $0.519 \pm 0.054$  sec.,  $0.490 \pm 0.055$  sec., and  $0.599 \pm 0.031$  sec. respectively. 5m, 10m, 15m, and 20m sprint time of the soccer referees was  $1.061 \pm 0.063$  sec,  $1.852 \pm 0.082$  sec,  $2.557 \pm 0.107$  sec,  $3.267 \pm 0.119$  sec respectively. 5m, 10m, 15m, and 20m sprint time of the basketball referees was  $1.060 \pm 0.106$  sec,  $1.846 \pm 0.182$  sec,  $2.550 \pm 0.226$  sec,  $3.199 \pm 0.300$  sec respectively. Discussion It is concluded that visual reaction time and sprint time parameters can be analyzed in male soccer and basketball referees. In this way, the speciality of different branches' refereeing can be identified. Because of doing the similar training and sprint distances of soccer and basketball referees, results are close to each other. In conclusion, there was no statistical differences for visual reaction time and sprint time parameters between soccer and basketball referees ( $p > 0.05$ ). ### DOES PLAYING VENUE AFFECT FREE TESTOSTERONE CONCENTRATIONS IN ELITE BASKETBALL PLAYERS?

Moreira, A., Arruda, A.F.S., Aoki, M.S., Freitas, C.G., Drago, G., Oliveira, R., Crewther, B.T.

*University of São Paulo, Swansea University, EC. Pinheiros*

DOES PLAYING VENUE AFFECT FREE TESTOSTERONE CONCENTRATIONS IN ELITE BASKETBALL PLAYERS? Moreira, A.1, Arruda, A.F.S.1, Aoki, M.S.2, Freitas, C.G.1, Drago, G.5, Oliveira, R.1, Crewther, B.T. 3,4 1: School of Physical Education and Sport, USP (São Paulo, Brazil), 2: School of Arts, Sciences and Humanities, USP (São Paulo, Brazil), 3: Hamlyn Centre, Imperial College (London, UK), 4: Health and Sport Portfolio, College of Engineering, Swansea University (Swansea, UK), 5: CIIA- EC. Pinheiros (São Paulo, Brazil), Introduction The home advantage has been documented in some team sport competitions (Nevill and Holder, 1999). Pre-game increases in testosterone (T) levels have been reported with sports teams playing in their own home stadium, versus an opponent's venue (Carré, 2009) which could be related to the concept of territoriality. However, we are unaware of any studies taking a dyadic approach to the assessment of playing venue and using basketball teams of similar rankings. Thus, this study examined the influence of playing venue on free T concentrations in elite basketball players of similar abilities. Method 18 male athletes from 2 basketball teams were monitored during 2 competitive matches that were played against each other on a home and away basis. The teams were ranked first and second in the State championship during the monitoring period. Salivary free T was measured before and after each match and a session ratings of perceived exertion (RPE) was taken post-game. Results Playing at home was accompanied by elevated pre-game free T concentrations compared to playing away ( $p < 0.05$ ). The home teams also won their games. The T responses to competition were similarly elevated (% change from pre to post) when playing at home and away. No differences in session-RPE were noted across the playing venues. Discussion Playing at one's home venue resulted in elevated pre-match free T concentrations during competitive basketball games and these games were also won. The higher T concentrations at home might be related to the concept of territoriality and could be applicable to other team sports. Moreover, the territoriality and its association with dominance, aggressiveness and status emerges as a possible candidate to explain the perceived advantages of a sports team playing at their home venue, relative to playing at another venue (Archer, 2006). Interestingly, playing venue did not affect the free hormonal responses to competition, nor the perceived effort of athletes during these matches suggesting that perceived effort is independent of the playing venue and the corresponding outcomes of wins and losses. ##### NEURAL CONTROL OF BOUNCING GAITS ON DIFFERENT STIFFNESS SURFACES

Marquez, G., Morenilla, L., Fernandez-del-Olmo, M.

*Catholic University San Antonio*

Neural Control of Bouncing Gaits on Different Stiffness Surfaces. Gonzalo Márquez 1, 2, Luis Morenilla 2, Miguel Fernandez-del-Olmo 2. 1. Biomechanics Laboratory of Catholic University San Antonio (Murcia) Spain. 2. Motor Control and Learning Group of the University of A Coruña. Spain. Introduction. When we walk, run or jump, our musculoskeletal system needs to adapt its stiffness according to the physical features of the surfaces. Although, it has been suggested that the stretch reflex could play a role in adjusting joint stiffness during running on different surfaces stiffness (1), more studies are required in order to address this hypothesis. The aim of the present study was to explore the contribution of different neural pathways during repetitive vertical jumps (hopping) in different stiffness surfaces. Methods. Ten healthy subjects (173cm, 72.3Kg, 25.3yr) participated in this study. Subjects were instructed to hopping at 2.2 Hz on a stiff and elastic surfaces. Stiff surface consist on a force plate (~35.000 kN/m) and elastic surface was a sprung surface mounted over the force plate (60 kN/m). These two different experimental conditions were carried on a counterbalanced order at the same session. Transcranial Magnetic Stimulation (TMS) was applied in the contralateral primary motor cortex (M1) of the leg area using a double cone coil secured to the head through a custom made helmet (90% RMT intensity). H-Wave of the soleus was obtained by electrical stimulation (intensity of 20% and 50% of the Mmax) on the posterior tibial nerve. Motor evoked potentials (MEP) by TMS, H-wave and background EMG (EMG) of the soleus of the right leg was recorded during hopping at distinct intervals after ground contact: SLR (45ms), MLR (70ms) and LLR2 (120ms). In addition, leg stiffness (Kleg), contact and flight times during the jumps were calculated. Two way ANOVA was performed for the mentioned parameters. Results. Kleg was statistically higher during hopping on the elastic than on the stiff surface without differences in contact and flight times. Cortical excitability during jumps on the elastic surface was statistically higher than on the stiff surface, in all stimulation intervals. H-waves were significant higher during hopping on the stiff surface than on the elastic surface at SLR, and lower at LLR2, without differences at MLR. No differences were found on EMG nor M-waves. Discussion. The higher cortical excitability during jumps on the elastic surface suggests an increased supraspinal control of leg mechanics during the stance phase, since subjects need to couple with the displacement of the surface. In addition, the change in the pattern of discharge of Ia afferents across surfaces highlights the importance of this pathway in the accommodation of leg stiffness to the new surface. References: 1. ## ELECTRICALLY ASSISTED BICYCLE ALTERS MUSCLE ACTIVATION PATTERNS

Morio, C., Louis, J., Androuet, P., Temprado, J.J., Barla, C.

*Oxylane Research*

**ELECTRICALLY ASSISTED BICYCLE ALTERS MUSCLE ACTIVATION PATTERNS** Morio, C.1, Louis, J.2, Androuet, P.1, Temprado, J.J.2, Barla, C.1 1: Oxylane Research (Lille, France), 2: CNRS6233 (Marseille, France) Introduction Commuter cycling is a growing activity in modern cities and it is a good means to do sport and improve health (Oja et al., 2011). But exercise intensity of commuter cycling can lead to dropout for less fit and motivated people (Engbers et al., 2010). Thus, electrically assisted bicycle (EAB) represents an alternative means for such people. The EAB has been recently found to be a sufficient activity to meet the physical activity guidelines for untrained people (Simons et al., 2009). A recent study made by our group (Louis et al.) shows a reduction in gross efficiency while pedalling on EAB. The aim of the present study is to highlight changes in muscle activation in order to explain the impaired gross efficiency previously observed. Methods 19 subjects participated in this study. A single session of exercise on EAB on a home-trainer consisted in pedalling at 3 different speeds (16km/h, 21km/h, freely chosen) with 3 different electrical support modes (NO: without, S1: light and S4: high support). Surface EMG of 6 of the main lower limb muscles (VL, RF, BF, TA, GAL, SOL) were recorded. Average activity of each muscle was calculated for both pushing and pulling phase. Onset and offset of the main EMG burst were calculated in degrees referred to the crank angle. Metabolic and mechanical parameters were also recorded during the pedalling on EAB. ANOVA with repeated measures (3 speeds x 3 supports) were performed on every parameter. Results ANOVA analyses show speed and support effects on power output, energy expenditure (EE), gross efficiency and EMG parameters. The electrical support induces 20% and 60% power output reduction and 12% and 35% EE reduction for the light and high support, respectively. The EMG analysis do not corroborate this reduction with reduced EMG activity of the VL, RF, BF and SOL muscles while the TA and GAL muscle activation increased. Changes in the timing of muscle activation have been found for the RF and BF muscles. Discussion The higher reduction in power output compared to EE is confirmed by the impaired gross efficiency with electrical support during cycling (Louis et al., submitted). The changes observed in EMG activities and the muscle timing activations supposed that pedalling skills is alter while electrical support is provided to the cyclist. This modified pedalling technique might explain the impaired gross efficiency. This should be further confirmed by a reduction in pedalling efficacy index. ## GROWTH-INDUCED INCREASE IN THE ACHILLES TENDON MOMENT ARM DOES NOT COINCIDE WITH THOSE IN THE SELECTED BODY DIMENSIONS : A CROSS-SECTIONAL STUDY

Hashizume, S.1, Iwanuma, S.1, Kanehisa, H.2, Kawakami, Y.1, Yanai, T.1

1: *Waseda University*, 2: *National Institute of Fitness and Sports in KANOYA*

**Introduction** It is well established that, as body height and mass increase with growth, his or her capacity for muscle performances increases. Muscular strength, measured often as a muscle torque, is determined by the muscle force and the moment arm. Age-related increase in the moment of a tendon force, therefore, may be affected by an increase in muscle force and/or moment arm. Whereas growth-related difference in muscle strength has been studied extensively, growth trend of moment arm over the rapid growing phase have not been studied. The purpose of this study, therefore, was to examine the age-related difference in the Achilles tendon moment arm during growth stage, in relation with the changes selected body dimensions. **Methods** Five students in lower grades (LE, age:  $8.2 \pm 0.8$  years) and six students in upper grades (UE, age:  $11.3 \pm 0.6$  years) of elementary school, 10 junior high school students (JH, age:  $13.0 \pm 0.8$  years) and 12 adults (AD, age:  $25.4 \pm 1.8$  years) participated in this study. A magnetic resonance imaging system was used to record a series of coronal images of the right ankle at  $10^\circ$  dorsiflexion, anatomical position and  $10^\circ$  plantarflexion. The line of action of the Achilles tendon force was projected to the orthogonal plane of the talocrural joint axis, and the shortest distance between the projected line and the talocrural joint axis was determined as the Achilles tendon moment arm at anatomical position (Hashizume et al., 2012). Body height, body mass, lower limb length and foot length were measured for each subject. A one-way analysis of variance with Bonferroni's post hoc test was conducted to test the differences in the measured variables among the four age groups ( $p < 0.05$ ). **Results** The AD group had significantly greater Achilles tendon moment arm (40 mm) than the other groups (25 - 31 mm). However, there are no significant age-related differences in the Achilles tendon moment arm between LE (25 mm) and UE groups (29 mm) and between UE and JH groups (31 mm). In all pairs of age groups, significant differences were found in body height and mass. On the other hand, the lower limb length did not show significant effect of age between UE (351 mm) and JH (368 mm) and between JH and AD groups (383 mm). The foot length significantly differed among the four groups except for UE (239 mm) and JH groups (240 mm). **Discussion** The present results suggested that the Achilles tendon moment arm rapidly increase between AD and JH groups, whereas body dimensions increase between each groups. The results found in the present study indicate that the growth trend in the Achilles tendon moment arm is different from those in whole body and limb length. It was concluded that the age-related difference in the Achilles tendon moment arm differ from that in the selected body dimensions. **References** Hashizume S, Iwanuma S, Akagi R, Kanehisa H, Kawakami Y, Yanai T. ## THE EFFECT OF KNEE ANGLE DURING ISOMETRIC TRAINING ON MAXIMAL FORCE AND MUSCLE SIZE

Noorkoiv, M., Nosaka, K., Blazevich, A.J.

*Edith Cowan University*

**Introduction** It is known that increases in force production in response to exercise training typically occur at or around the training angle. However, the mechanisms underpinning this angle specificity are not known. The purpose of this study was to investigate the mechanisms underlying the angle-specific strength change after isometric training at short and long muscle lengths. **Methods** One group ( $n=8$ ) of young healthy men performed 6 weeks of isometric knee extension training in a flexed position (kneeFlex) corresponding to 80% of their maximal force-angle relationship value ( $38 \pm 4^\circ$ ,  $0^\circ$ =full knee extension). Force was calculated as torque per moment arm (measured using x-ray imaging). Another group ( $n=8$ ) trained at the corresponding force level in an extended knee position (kneeExt;  $88 \pm 6^\circ$ ). Subjects trained 3 times a week, 5 sets of 5 repetitions (5 contractions, 5 s rest, 1 min inter-set rest). Maximum torque and the EMG:M-wave ratio were measured at 8 knee angles ( $30$ - $100^\circ$ ) at 0, 3 and 6 weeks of training. Vastus lateralis (VL) fascicle length was measured with ultrasound and muscle cross-sectional area (CSA) was assessed with MRI at 0 and 6 weeks. **Results** In kneeExt force increased after 3 wk at  $40$  and  $50^\circ$  (7.6-6.2%), and after 6 weeks at  $30$ ,  $40$  and  $50$  deg (9.0-12.2%). In kneeFlex, force increased only from 0 to 6 wk at  $30$ ,  $40$

and 50° (5.7-11.5%). The changes in EMG:M-wave ratio were minimal in both groups, and these changes were not clearly correlated with changes in angle-specific force. Rectus femoris (RF), VL and vastus medialis (VM) CSA increased in a kneeFlex only. Correlation analysis revealed that subjects whose VM and RF CSA increased in distal regions tended to increase force production at short muscle lengths, whereas those who increased in middle and proximal regions of VL tended to increase force at long muscle lengths. Fascicle length increase was variable in both groups and, unexpectedly, only increased significantly in kneeExt (P=0.01). Interestingly, there was a negative correlation between the fascicle length at 0 wk and the change in fascicle length with training (P=0.02). Discussion The results that there is a clear specificity when isometric training has been performed at kneeExt and it is more variable with kneeFlex, are in agreement with the findings from others (Thepaut-Mathieu et al. 1988; Kubo et al., 2005). The mechanisms of angle specificity seem to be a complex interaction amongst many factors, however, variability in kneeFlex appears to be related to region of selective hypertrophy. Further analysis of fascicle length and other factors is needed. References Thepaut-Mathieu C, Van Hoecke J, Maton B (1988). *J Appl Physiol*, 64(4), 1500-1505. ### **DETERMINING THE LOAD FOR RESISTED SPRINT TRAINING WITH SLED TOWING IN SOCCER PLAYERS. A PILOT STUDY**

Cánovas, J.F.1, Martínez-Valencia, M.A.2, Marín-Pagán, C.1, González-Zaragoza, M.1, Alcaraz, P.E.1

1: UCAM (Murcia, Spain), 2: UCLM (Toledo, Spain)

**INTRODUCTION** Sled towing is one of most used training methods to improve specific strength and power during sprinting. Unfortunately, there are no studies about this type of training on soccer players specifically. Two studies (Alcaraz et al., 2009; Lockie et al., 2003), with sprinters and field-sport athletes proposed a regression equation to determine the load for sprint training with sled towing. These equations were based on percentage of athlete's body mass (Bm). The purpose of this study was to develop an equation that accurately describes the relationship between towing loads and speed in the acceleration phase of sprinting in soccer players. **METHODS** Fourteen male semi-professional soccer players (23.07 ± 3.29 years; height 1.77 ± 0.07 m; weight 75.43 ± 6.38 kg) were recruited for the study. The tests were performed on a natural grass surface. After a specific warm-up, subjects completed 10 × 20-m sprints, an unloaded sprint and nine ones with different loads according to Bm. Maximum velocity (Vmax) of each sprint was measured with a radar gun with a record data frequency of 33 Hz. The order for the trials was randomized and a five-minute rest period was allocated to remove the effects of fatigue. A regression analysis was used to determine the relationships between load (as a percentage of Bm) and velocity (as a percentage of Vmax over 20-m, established in the unloaded sprint). **RESULTS** The regression analysis showed the following regression equation:  $y = -0.995x + 101.67$ , with a value of  $R^2 = 0.8299$ . In this equation, "y" represents the percentage of load, and "x" is the required training velocity, as a percentage of Vmax. The  $R^2$  value reflects a highly significant lineal relationship among these variables ( $p < 0.001$ ). **DISCUSSION** As expected, an increase in time and a reduction of speed was observed when the load raised. However, the regression equation, behaves differently when compare with other equations published (Alcaraz et al., 2009; Lockie et al., 2003). It seems that a higher slope (m) may reflect a higher level of maximum strength, and therefore, a better performance with high loads. In this study, "m" had a value of -0.995, greater than slope calculated with athletes  $m = -0.867$  (Alcaraz et al., 2009) but less than sport-field athlete's slope, where  $m = -1.96$  (Lockie et al., 2003). These data may indicate that depending on different variables such as sport modality, strength characteristics, etc. athletes should use a different equation. This study aims to provide a new tool that allows coaches to determine the optimal load for training with soccer players. **REFERENCES** Alcaraz PE, Palao JM, Elvira JLL (2009). *J Strength Cond Res*, 23(2), 480-485. ### **TENDON STIFFNESS FOLLOWING YEARS OF SYSTEMATIC STRETCHING**

Moltubakk, M., Eriksrud, O., Paulsen, G., Seynnes, O., Bojsen-Møller, J.

*Norwegian school of sport sciences*

**Introduction** Stretching is commonly used as a means of improving sports performance, reducing injury risk, and in rehabilitation (Doucette and Goble, 1992, Wilson et al., 1992, Woods et al., 2007), while evidence of such effects at best is limited. Habitual stretching is assumed to reduce the stiffness of force transmitting tissues (Taylor et al., 1990), but stretching intervention studies of up to 8 wks have failed to provide a clear understanding of musculotendinous adaptations to this type of training (Weppler and Magnusson, 2010). We had the opportunity to examine a unique group of elite gymnasts; thus the purpose of the present study was to examine whether the large stretching component of these athletes' training routine would affect patellar tendon mechanical properties. **Methods** Twenty two national team rhythmic gymnasts (GYM) were compared to 16 control subjects (CON). This abstract includes preliminary data from 6 GYM and 5 CON. GYM (17±2 yrs) had performed systematic stretching of their quadriceps for 9±2 years, while CON (20±3 yrs) had been active in sports for 13±2 years, without systematic stretching. Patellar tendon force was determined during voluntary isometric knee extension ramp contraction at a knee joint angle of 90°. Corresponding tendon elongation was obtained by ultrasonography. Tendon stiffness was determined between 2250 and 2500 N, reflecting the lowest common force interval between subjects. Results Maximal tendon force and stiffness did not differ significantly between groups (GYM 3591±533 N; CON 3717±615 N;  $p=0.75$ , and GYM 1640±222 N/mm; CON 1991±791 N/mm;  $p=0.16$ , respectively). **Discussion** The present results suggest that years of systematic stretching, as performed during the training routine of female elite gymnasts, do not reduce tendon stiffness. These findings are in agreement with previous studies (Kubo et al., 2002 and Mahieu et al., 2007) reporting unaltered Achilles tendon stiffness after 3 to 6 wks of static stretching. It is possible that rigorous stretching imposes mechanical loads similar to those of strength training, with corresponding tendinous adaptations (Seynnes et al., 2009), or that an eventual reduction in tendon stiffness due to stretching is counteracted by the other components of the athletes' training routine. **References** Doucette SA, Goble E (1992). *Am J Sports Med*, 20 Kubo K, Kanehisa H, Fukunaga T (2002). *J.Appl.Physiol*, 92 Mahieu NN et al. ### **MECHANICAL PROPERTIES OF THE PATELLAR TENDON IN ELITE VOLLEYBALL PLAYERS WITH AND WITHOUT PATELLAR TENDINOPATHY**

Helland, C., Bojsen-Møller, J., Raastad, T., Seynnes, O.R., Moltubakk, M.M.H., Jakobsen, V., Visnes, H., Bahr, R.

*Norwegian School of Sport Sciences*

**Introduction** Patellar tendinopathy (PT) has an estimated prevalence of 40-50 % among elite volleyball players (Lian, Engebretsen & Bahr, 2005). The risk factors and functional consequences of this overuse injury are not fully understood. The aims of the present study were to

determine whether PT affects tendon mechanical properties in elite volleyball players, and whether potential changes in these properties impair jumping performance. Methods 20 healthy and 20 male volleyball players with PT were identified from a 5-year prospective cohort study on junior elite volleyball players. Subjects were evaluated with respect to maximal vertical jump performance and patellar tendon mechanical properties were examined using Ultrasonography (US) and Magnetic Resonance Imaging (MRI). An unpaired t-test was applied to evaluate group differences with an alpha level of 0.05. Results Preliminary results indicate that the PT group jumped significantly higher than controls in counter movement jumps (CMJ) and spike jump (SPJ) compared to the control group, PT:  $44.0 \pm 4.6$  cm and  $81.5 \pm 6.1$  cm vs. control:  $39.1 \pm 4.3$  cm and  $75.2 \pm 7.1$  cm, respectively ( $p < 0.05$ ,  $n = 24$ ). CMJ-SJ ratio was greater in PT compared to the control group;  $4.0 \pm 2.1$  vs.  $1.6 \pm 1.9$  ( $p < 0.05$ ). No differences were found in patellar tendon stiffness between the two groups ( $n = 14$ ). No differences were found in patellar tendon length between the two groups. Discussion Although mechanical properties were similar between groups, it may be speculated that differences exist in material properties (decreased Young's modulus in PT) as a result of the increased cross-sectional area (CSA) of the injured tendon. The differences in jump performance between the groups seem to correspond to earlier findings linking PT prevalence to higher jumping performance and therefore greater loading and/or more intense jump training (Lian, Refsnæs, Engebretsen, & Bahr, 2003; Visnes & Bahr, 2012). Importantly, these results indicate that jumping performance in elite volleyball players with PT is not impaired beyond the level of a matched control group. References Lian, O., Refsnæs, P. ### INTRAMUSCULAR DIFFERENCES IN FASCICLE LENGTH, FIBER LENGTH AND SERIES SARCOMERE NUMBER OF THE HUMAN TRICEPS SURAE: A CADAVER STUDY

Hirata, K.1, Komatsu, T.2, Ema, R.1, Fukutani, A.1, Hashizume, S.1, Iwanuma, S.1, Miyamoto, N.1, Wakahara, T.1, Kanehisa, H.3, Kawakami, Y.1

1: Waseda University (Tokorozawa, Japan), 2: Osaka University (Toyonaka, Japan), 3: National Institute of Fitness and Sports in Kanoya (Kanoya, Japan)

Introduction Skeletal muscle architecture has considerable effects on muscle force and power generation. Especially, muscle fiber length (LFiber) and series sarcomere number (SN) are important parameters that influence the length-force-velocity relationships of a muscle. Available data on the muscle- architectural parameters suggest existence of regional differences within a muscle, but few studies have clarified this over the whole muscle. Therefore, we aimed to examine in a cadaver study intramuscular differences in fascicle length (LFascicle), LFiber, and SN of the three muscles of the human triceps surae (medial gastrocnemius: MG, lateral gastrocnemius: LG, soleus: SOL). Methods The triceps surae was dissected from both legs of a cadaver (sex: male, body height: 153 cm, body mass: 59.6 kg). The lengths of fascicles removed from nine sites of MG and LG (proximal, central, and distal positions of medial, midsagittal, and lateral regions, respectively), 16 sites of SOL (3 sites [proximal, central and distal positions] of the anterior compartment and 13 sites [proximal and central positions of medial and lateral regions and in between, and distal positions of medial, midsagittal, and lateral regions] of the posterior compartment) were determined by a caliper. The lengths of fibers isolated from fascicles under a microscope were measured. For each fiber, sarcomere lengths were calculated at five positions (0%, 25%, 50%, 75% and 100% LFiber) by taking the inverse of the centroid frequency of the first-order peak obtained from microscopic image of the fiber by using the fast Fourier transformation. The SN was calculated from the LFiber divided by the average of five sarcomere lengths. Results & Discussion LFascicle, LFiber, and SN of each muscle ranged from 37.4 - 51.3 mm, 35.1 - 48.2 mm and 16160 - 22434 in MG, 31.0 - 53.9 mm, 33.0 - 47.1 mm and 16328 - 21001 in LG, and 20.7 - 37.3 mm, 20.4 - 32.4 mm and 11896 - 17374 in SOL, respectively. The LFascicle showed tendencies to increase from proximal to distal, and medial to lateral directions in MG, from distal to proximal, and lateral to medial directions in LG and from distal to proximal direction in SOL. Similar tendencies were observed also for LFiber and SN showing intramuscular differences. There was no substantial variation in the SN per LFiber among the sites of each muscle. These results indicate that there are intramuscular differences in length-related parameters of each muscle of the human triceps surae. These regional differences are attributable to those of SNs within fibers.

### CHANGES IN MUSCLE ARCHITECTURE AND TENDON COMPLIANCE AFTER A BOUT OF ECCENTRIC CONTRACTIONS

Vieillevoye, S., Boucher, C., Duchateau, J., Carpentier, A.

Université Libre de Bruxelles

Introduction Unaccustomed eccentric exercise induces muscle soreness and alterations in muscle cellular structure (Ishikawa et al., 2006). The aim of the present study was to investigate the changes in muscle architecture and tendon compliance during muscle contraction and passive stretching after eccentric contractions. Methods Ten male subjects performed a training session with the right calf muscles, consisting in 10 sets of 10 eccentric contractions at 120% of 1RM. Subjects were tested at baseline and immediately, 2 hours (H+2), 2 days (D+2), 4 days (D+4) and 7 days after the session. Muscle architecture and tendon compliance were investigated using ultrasonography (Abellaneda et al., 2009; Chen et al., 2006). Fascicle length (FL) and pennation angle (PA) of the Gastrocnemius Medialis muscle and Achilles tendon elongation (TE) were recorded, respectively, during passive stretching and muscle contraction at different torque levels. During passive stretching, the ankle joint was moved from  $-10^\circ$  to  $+30^\circ$  of dorsiflexion. Isometric contractions of the plantarflexor muscles were performed with the ankle joint in neutral position ( $90^\circ$ ). Results Isometric torque during MVC was reduced ( $22 \pm 9\%$ ;  $P < 0.001$ ) immediately after the eccentric contractions. Maximal torque was still significantly ( $P < 0.001$ ) depressed at H+2 ( $18 \pm 10\%$ ) and D+2 ( $13 \pm 10\%$ ). During contraction, FL shortened and PA increased progressively with the increase in target torque and reached, respectively,  $-51.8 \pm 3.8\%$  and  $+82.7 \pm 14.0\%$  of initial values at MVC. FL increased and PA decreased significantly during MVC after the session and remained enhanced until D+4. Distal TE during MVC decreased immediately after the session ( $-20.6 \pm 23.1\%$ ;  $P < 0.01$ ) and recovered its initial value at H+2. After the training session, passive torque recorded during stretching increased for ankle angle of  $25^\circ$  ( $+35.3 \pm 38.7\%$ ;  $P < 0.01$ ) and  $30^\circ$  ( $+27.2 \pm 34.9\%$ ;  $P < 0.01$ ). Passive torque values returned to baseline at H+2, but re-increased at D+4. No significant changes were recorded after the session for FL, PA and TE. Discussion The new finding is that the drop in MVC torque after eccentric contractions is associated with an increase in FL and a decrease in PA and TE, whereas the enhancement in passive torque during stretching is not associated with changes in muscle architecture and tendon elongation. In conclusion, a session of eccentric contractions did influence the components associated with muscle contraction but did not affect the passive components of the muscle-tendon unit. ### LONG-RANGE CORRELATIONS IN STRIDE INTERVAL OF THREE SIDEWARD GAIT PATTERNS

Yamashita, D.1,2, Yoshii, H.1, Fujii, K.1,2, Kouzaki, M.1

1: *Kyoto University (Kyoto, Japan)*, 2: *Japan Society for the Promotion of Science (Japan)*

**Introduction** Side stepping is often performed in daily life and various sports. Our preliminary study showed that there are three different gait patterns in side stepping; walk-like, run-like, and gallop-like gait patterns. Kinematic analyses revealed that gait patterns are dependent on side stepping speed. However, decision factor for these sideward gait patterns is still unknown. It is well known that, in case of forward walking and running, gait patterns are generated by neural networks referred to as central pattern generators (CPGs). CPGs produce not white-noise like (i.e., random) but pink-noise like fluctuations in their gait cycles (Hausdorff et al., 1995). If sideward gait patterns are also governed by CPGs, long-range correlations should be found in the sideward gait. Thus, we aimed to investigate the strength of long-range correlations for sideward gait patterns using detrended fluctuation analysis (DFA). **Methods** Six healthy male participants were required to step sideward on a treadmill. Participants sufficiently practiced in advance three gait patterns and each preferred speed was determined based on each subject's report. They performed each gait pattern for 8-10 minutes at each preferred speed. The data of 512 stride intervals were extracted. The strength of long-range correlations of stride intervals was assessed by "α" values in DFA (Hausdorff et al., 1995): white noise corresponds to an α of 0.5 whereas pink noise corresponds to an α of 1. An α value between 0.5 and 1 indicates long-range correlations such that any given stride interval is dependent on a stride interval at remote previous times. **Results** The preferred speed in walk ( $2.00 \pm 0.15$  km/h) was significantly slower than in gallop ( $3.95 \pm 0.14$  km/h) and run ( $4.01 \pm 0.20$  km/h), but not different between in gallop and in run. The exponent scale α was  $0.77 \pm 0.08$  in walk,  $0.88 \pm 0.10$  in gallop, and  $0.98 \pm 0.09$  in run. The exponent α in run was significantly higher than in walk ( $p = 0.008$ ) and tended to be higher than in gallop ( $p = 0.077$ ). **Discussion** We found the presence of long-range correlations in the stride interval during all the three sideward gait patterns in similar to the forward gait patterns, would be suggesting that these patterns are controlled by CPGs activities. It is also noteworthy that the high exponent scale α in run was close to 1. Our results suggest that the gallop mode is more well-coordinated gait pattern compared to the run mode in case of human sideward locomotion because the α value that is close to 1 reflects immature gait dynamics (Ashkenazy et al., 2002). **Reference** Hausdorff et al. (1995). *J Appl Physiol*, 80, 349-358 Ashkenazy et al. (2002). *Physica A*, 316, 662-670

### THE NET ACTION DIRECTION OF MUSCLES SPANNING KNEE AND HIP JOINTS IN COMPLICATED ACTIVITIES WITH VARIOUS DIRECTIONS

Hagio, S., Kouzaki, M.

*Kyoto University*

**Introduction** Appropriate electromyogram (EMG) processing makes it possible to estimate muscle activities producing the joint torques. To assess the movements more particularly, however, it is significant to estimate a net action direction of muscles: the force traces produced in the direction are actually correlated to EMG traces of a muscle. The purpose of the present study was to examine the net action direction of muscles spanning knee and hip joints in complicated activities with multi-directions. **Methods** Six subjects were seated comfortably in a chair with the hip and knee flexed at 90° from full extension. Then, the tri-axial force transducer was attached to the right ankle, and two force vectors in the medial-lateral, and anterior-posterior directions on the horizontal plane around the ankle joint were measured. Isometric endpoint forces for 20-s were produced in 12 different directions on the horizontal plane and at two different magnitudes (10 N and 20 N). For each trial, the subjects viewed the desired force as a target on the visual display. Surface EMGs were recorded from the twelve muscles around the knee and hip joints. Raw EMG traces were first rectified and averaged across the steady period. Then, the EMG activity was represented by polar plots as a function of task direction. Cross-correlation was calculated between surface EMG and the simultaneously recorded two force components. Then, EWA (EMG weighted averaging) direction was determined from peak correlation coefficient (Kutch et al., 2010), which indicates the net action direction of the muscle. The EWA directions for all tasks were represented by polar histograms. **Results** All muscles had wide active ranges, while the EWA directions of almost all the muscles denoted the roughly specific net action directions. For example, semitendinosus muscle was active mainly in the lower quarter plane of horizontal plane, while its EWA direction was approximately 255°. **Discussion** Present results demonstrated that some muscles (e.g. semitendinosus muscle) had roughly specific action directions. In others (e.g. sartorius muscle), however, the EWA directions were variable: no specific action directions. It was considered that the formers mainly produced the desired forces, and the latters were also involved in position stabilization. Additionally, the variability of the EWA directions gave suggestions that the action directions were dependent on the direction of muscular fascicle (Vieira et al., 2011). **References** Kutch JJ, Kuo AD, and Rymer WZ (2010). *J Neurophysiol*, 103, 3535-3546. ### MOTOR LEARNING BY OBSERVING BIOLOGICAL AND NON-BIOLOGICAL MOTION: CONTRIBUTING SENSORIMOTOR AND HIGHER-LEVEL PROCESSES

Roberts, J.W.1, Bennett, S.J.1, Elliott, D.1,2, Hayes, S.J.1

1: *Liverpool John Moores University*; 2: *McMaster University*

**Motor learning by observing biological and non-biological motion: Contributing Sensorimotor and Higher-level Processes** Roberts, J. W.1, Bennett, S. J.1, Elliott, D.1, 2, & Hayes, S. J.1 1: *Liverpool John Moores University*; 2: *McMaster University* **Introduction** Motor learning via observation is the result of the action-observation network coding biological motion. The following study aimed to examine the preferential motion information coded during action-observation for motor learning and thereby the processes involved. **Method** EXP1 tested the biological specificity of action-observation. Participants were randomly assigned to one of four groups: biological motion (BM), non-biological motion (NBM), end-state (END) and control. Attempts were made to perform a novel manual timing sequence in a pre- and post-test design. Prior to post-test the experimental groups observed a model featuring specialised trajectory information: expert performance (BM), computer-generated constant velocity (NBM), end-state information with no trajectory (END). EXP2 and EXP3 tested the processes involved during action-observation. The pre-test phase was withdrawn to withhold task objectives. We incorporated a recognition test after motor performance. Participants viewed a previously observed model and novel models followed by rating the certainty of recognition. In addition, EXP2 featured two sets of instructions designed to bias beliefs surrounding the origins of the model: human-generated cue, computer-generated cue. EXP3 featured an additional cognitive task (tone counting), which was treated as the primary task objective. **Results** The relative timing error revealed both BM and NBM groups learned ( $p < 0.05$ ) (EXP1). Incorporating a human- and computer-generated cue had no significant effect on timing performance, although the human cue combined with BM resulted in a greater rating of uncertainty than its computer counter-part ( $p < 0.05$ ) (EXP2). Furthermore, there was a significant negative correlation

between relative timing error and rating of certainty for the same group ( $r = -.61$   $p < 0.05$ ). The addition of a cognitively demanding task significantly attenuated learning ( $p > 0.05$ ). Discussion The similar learning effects of BM and NBM groups contrast suggestions that the learning system is biologically specific. Moreover, the learning advantage of these groups compared to controls indicates that trajectory information is essential during action-observation. Instructional cues influenced how participants processed the trajectory models. This is consistent with observation of biological motion combined with a human belief leading to an implicit representation associated with sensorimotor processes. The detrimental effect of the cognitively demanding task shows implicit motor learning through observation is not independent of cognitive processes. These findings support the view of a combined sensorimotor and higher-level system contributing to motor learning through observation.

#### MOMENTUM AND KINETIC ENERGY DURING THE TACKLE IN RUGBY UNION

Hendricks, S., Karpul, D., Lambert, M.I.

*University of Cape Town*

**Introduction** The tackle in rugby union is a dynamic and high impact contact situation that occurs frequently during matches and exposes players to a high risk of injury and muscle damage. Large differences in momentum and kinetic energy between the ball-carrier (BC) and tackler (T) have been identified as risk factors for injury and may contribute to the outcome of the tackle. Given the importance of the tackle in rugby union, little is known about the physical components of the tackle in real match situations. **Aim** The purpose of this study was to firstly quantify momentum and kinetic energy before contact in the tackle during real match situations in 3 competitions (Super 14, Varsity Cup and Under 19 Currie Cup) for the ball-carrier and tackler. Next, the study explored the relationship between these physical components and the outcome of the tackle. **Methods** Using a two-dimensional scaled version of the field, the velocity of the ball-carrier and tackler were measured 0.5s before contact. Players' weights were obtained from player profiles either from their National Union, Super 14 franchise or Provincial Union. Accordingly, momentum and kinetic was determined. Thereafter, the outcome of the tackle, and tackle location was identified. **Results** BC momentum in both types of tackles (front-on  $505 \pm 209$  kg.m/s; side-on  $500 \pm 186$  kg.m/s) was not significantly different to T momentum (front-on  $536 \pm 217$  kg.m/s; side-on  $458 \pm 183$  kg.m/s). Similarly, BC kinetic energy in both types of tackles (front-on  $1443 \pm 1407$  Joules (J); side-on  $1741 \pm 1262$  J) was not significantly different to T momentum (front-on  $1422 \pm 1009$  J; side-on  $1294 \pm 1043$  J). In isolation, the odds of a player succeeding in the tackle is increased by 50% (Odds Ratio (OR) 1.49, 95%CI 0.51-4.39) when the player enters the contact at a higher P or KE than the opponent. However, considering level of play, type of tackle, player position and distance from set piece, this odds ratio decreased to OR 0.92, 95CI% 0.25-3.38. **Discussion** This is the first study to quantify momentum and kinetic energy before contact in the tackle during real match situations for the ball-carrier and tackler. The lack of differences between level of competition and tackle types may indicate the dynamic nature of the tackle. As expected, the player with the higher momentum or kinetic energy was more likely to succeed in contact. However, when level of competition, type of tackle, player position and distance from set piece were considered, this odds ratio decreased. Using this study as a basis, it is recommended that future studies focus on the relationship between these physical components and the technical characteristics of the ball-carrier and tackler. Also, studying the impact dynamics of the tackle situation and its association with injury is proposed.

#### THE EFFECTS OF VARIOUS ANGLES IN SCULLING ON HUMAN BODY LIFT AND DRAG

LEE, H.T., KIM, Y.J.

*Department of Physical Education, Graduate School of Pukyong National University, Busan, Korea.*

**INTRODUCTION** This study analyses the effects of various angles in sculling on human body lift and drag by means of computational fluid dynamics, discusses the importance of sculling and provides a basis for the development of future water safety education programmes. **METHODS** Study subjects were based on the mean data collected from males in the age of 20s from a survey on the anthropometric dimensions of the Koreans. Moreover, lift, drag as well as coefficient values, all of which were governed by the angle of the palm, were calculated using 3-dimensional modelling produced by computational fluid dynamics programmes i.e. CFD. Interpretations were performed via general k- $\epsilon$  turbulence modelling in order to determine lift, drag and coefficient values. Turbulence intensity was set to one per cent as per the figures from preceding research papers and 3-dimensional simulations were performed for a total of five different angles 0°, 15°, 30°, 45° and 60°. **RESULTS** The drag and lift values for the differing angles of the hands during sculling movement are as follows. The lift and drag values gradually increased with the increasing angle of the palm, however, the magnitude of increase for drag started to predominate lift from 45° and lift gradually decreased from 60°. **DISCUSSION** Overall, it is concluded that the optimal efficiency of sculling can be achieved at the angles 15° and 30°, and it is anticipated that greater safety and informative education can be ensured for Life saving trainees if the results were to be applied to practical settings. However, as the study was conducted using simulation programmes which performed analyses on the collected anthropometric dimension, the obtained results cannot be made universal, which warrants further studies involving varied study subjects with actual measurements taken in water. **REFERENCES** Barry Bixler, Scott Riewald.(2002). ## LARGE POSTURAL FLUCTUATION BUT UNCHANGED POSTURAL SWAY DYNAMICS DURING TIPTOE STANDING IN COMPARISON WITH QUIET STANDING

Tanabe, H.1, Fujii, K.1, Kouzaki, M.1

*1:Kyoto University*

LARGE POSTURAL FLUCTUATION BUT UNCHANGED POSTURAL SWAY DYNAMICS DURING TIPTOE STANDING IN COMPARISON WITH QUIET STANDING Tanabe, H.1, Fujii, K.1, Kouzaki, M.1 1: Kyoto University (Kyoto, Japan) Introduction Tiptoe standing (TS) is used frequently by humans. Maintaining TS seems to require more complex control dynamics than quiet standing (QS). Although postural maintenance during TS represents a significant component of human movement, surprisingly few studies have revealed postural control dynamics during TS. Therefore, the purpose of this study was to examine the postural control dynamics during TS in comparison with QS. Methods Eight healthy male subjects were asked to perform two QS or TS on a force platform for approximately 40 s. During QS and TS, the orientation of the center of pressure (COP) was measured, and a surface electromyogram (EMG) was recorded from the soleus (SOL) and flexor hallucis brevis (FHB) muscles. To assess the postural sway amplitude, the path length and rectangular area of COP trajectory were calculated. In addition, to examine the dynamics of the neuromuscular mechanisms underlying balance control, we computed COP stabilogram-diffusion (SD) plots (Collins and De Luca, 1993). Moreover, we analyzed the power spectral density of the COP sway to examine the frequency domain characteristics of postural sway under different standing conditions. Finally, to investigate the relationship between COP and the activity of each muscle in the frequency domain, we adopted the squared coherence spectrum. Results and Discussion The path length and rectangular area were significantly larger during TS than during QS. In addition, the power spectral density (PSD) of the COP sway up to 6-7 Hz was significantly larger during TS than during QS. This might happen because (1) the feedback of somatosensory information from sole of the foot decreased (Diener, 1982); (2) relatively small muscle which contributes to TS requires muscle activity in higher frequency compared with QS (Kouzaki, 2012). On the other hand, there was no difference in the scaling coefficients from SD analysis between QS and TS. The scaling coefficient represents the probability that the COP will move efferently or afferently and reflects the control by central nervous system. In fact, the coherence spectrum between the COP and EMG from the SOL and FHB muscles showed statistically significant levels during TS at frequencies up to 17 Hz, while that of QS only showed significant level below 1 Hz. Therefore, our results suggested that large fluctuations during TS was compensated by the activities of the SOL and FHB muscles to enhance the postural control and the postural control dynamics during TS was consistent with that during QS.

## JUMPING PERFORMANCE DIFFERENCES AMONG COMPETING ELITE FEMALE HANDBALL PLAYERS WITH OR WITHOUT PREVIOUS ACL RECONSTRUCTION

Setuain, I., Millor, N., Alfaro, J., Gorostiaga, E., Izquierdo, M.

*1Research, Studies and Sport Medicine Center, Government of Navarre, Spain*

JUMPING PERFORMANCE DIFFERENCES AMONG COMPETING ELITE FEMALE HANDBALL PLAYERS WITH OR WITHOUT PREVIOUS ACL RECONSTRUCTION Igor Setuain<sup>1</sup>, Nora Millor<sup>1</sup>, Jesús Alfaro<sup>2</sup>, Esteban Gorostiaga<sup>1</sup>, Mikel Izquierdo<sup>3</sup>. <sup>1</sup>Research, Studies and Sport Medicine Center, Government of Navarre, Spain <sup>2</sup> San Miguel Clinic, Traumatology service, Pamplona, Spain <sup>3</sup>Public University of Navarre, Department of Health Sciences, Spain Female handball players are one of the most exposed athletes to the ACL injury. Persisting strength and neuromuscular control deficits may be observed among the athletes who had suffered this injury, despite having complete the rehabilitation process due to inadequate or incomplete rehabilitation. This factor could be one of the explaining reasons for the ACL reinjury rates among this population. Measuring jumping performance such as stance phase contact times or jump height during the rehabilitation process would help to minimize high-cost reinjury rate among female handball elite athletes. PURPOSE: To describe jumping performance among a group of 20 female handball elite athletes using a previously validated jump test battery. Secondly, to identify possible differences between injured and uninjured extremities, in jump height, stance phase contact time, and reached distance obtained. We hypothesized that previously injured extremities would show deficits in jumping performance despite the injured athletes have completed their rehabilitation process and being competing at the maximum level. METHODS: 20 female elite athletes (6 previously injured and reconstructed and 14 uninjured subjects) were evaluated performing a previously validated jump test battery that includes bilateral drop jump, unilateral drop jump, unilateral countermovement jump, unilateral triple jump for distance and the cross over hop for distance. Height (m), flight time (s), stance phase contact time (s) and distance (m) were obtained in each jump test performed. For the unilateral jump tests, comparison was made between reconstructed legs and the dominant ones of the uninjured subjects. For the bilateral drop jump test, comparison was made between reconstructed and uninjured subjects. RESULTS: Previously ACL reconstructed athletes demonstrated significantly lower bilateral drop jump flight time (0,393 vs 0,541 s;  $P < 0.001$ ) and less distance reached in triple leg hop for distance (0,382 vs 0,435 m;  $P < 0.05$ ) on their reconstructed leg compared with the healthy legs of the uninjured subjects. No significant differences were observed in the other variables recorded CONCLUSION: Previously ACL reconstructed athletes may cope with some functional deficits once returning to competition, potentially increasing their reinjury risk. Restoration of these deficits would help to decrease the reinjury rates among this population. REFERENCE: 1. Hewett TE, Myer GD, Ford KR. *University of Liege*

INFLUENCE OF FATIGUE ON THE STRIDE CHARACTERISTICS DURING AN INTENSE ENDURANCE RUNTEST. Jidovtseff, B, Rodriguez de la Cruz, C, Croisier, JL, Maquet, D, Bury T, Deflandre, D ULG (Liège, Belgium) Introduction The analysis of the stride and its variation during endurance running has been investigated in different studies (Slawinski et al, 2008). Most of them were achieved in laboratory and/or with heavy and complex equipment. Very recently, a small and practical device, adapted to field testing has been developed to analyze stride characteristics: the Myotest Run. This accelerometer allows the measurement of thirteen biomechanical parameters of the running stride. Therefore, the aim of the study was to investigate the influence of fatigue on stride mechanics during an exhaustive endurance test with Myotest Run. Methods Twenty male subjects (16-36 yrs) were involved in the study divided into two sessions: 1) a treadmill progressive VO<sub>2</sub>max test; 2) a field test at 90% of the VvO<sub>2</sub>max until exhaustion. Mechanical parameters (e.g. step frequency, step distance, contact time, distance on the contact time, stiffness) were recorded with the Myotest Run at each velocity during the treadmill test and at each lap in the 90% exhaustive test. Based on these two tests, three investigations have been conducted: 1) the influence of velocity on stride characteristics; 2) treadmill vs. field running characteristics 3) influence of fatigue on stride mechanics. A reproducibility analysis was also

performed with standardized running recordings achieved before the field test. Results The results show an excellent reproducibility of the Myotest Run values, except for the asymmetry of the race ( $CV > 5\%$ ). The stride on treadmill was not significantly different in comparison with the one on track, except for the hip angle at touchdown ( $p < 0,05$ ). Myotest analysis at different speed during the treadmill test showed that all biomechanical parameters changed with running speed ( $p < 0,05$ ). Surprisingly, classical statistics revealed only few significant changes in the stride with fatigue (decrease in CM vertical movement and in reactivity;  $p < 0,05$ ). However, an individual analysis allowed us to put forward four different changes of the stride with fatigue: 1) increase in stride length; 2) decrease in stride length and in CM vertical movement 3) decrease in stride length contact time; 4) no change in stride characteristics. These observations were partly observed by different authors (Avogadro et al, 2003). Conclusion This study confirmed that Myotest Run is a useful device in the stride analysis. The impact of fatigue on running pattern could be different according to subject characteristics. More researches are needed to elucidate how programs should be individualized. ## KINEMATIC ANALYSIS OF TREADMILL WALKING IN HEALTHY ADULTS ACCORDING TO PHYSICAL PERFORMANCE

Annoni, I.1,2, Cirasella, M.3, Mapelli, A.1, Sidequersky, F.V.1, Sforza, C.1, Galvani, C.2

1Università degli Studi di Milano; 2,3Università Cattolica del Sacro Cuore di Milano

Introduction Modified joint range of motion (ROM) and spatio-temporal gait parameters in elderly or obese healthy subjects have been found. Authors have hypothesized that these alterations may be due to a reduction in physical performance, especially for strength and flexibility (Daley, 2000; Wearing, 2006; Wert, 2010), but quantitative studies measuring the influence of physical performance on gait pattern are scanty. The aim of this study was to analyse the kinematics of treadmill walking of healthy adults to understand if strength and flexibility could affect gait parameters. Methods 20 healthy adults (age,  $26.9 \pm 4.7$  yr; BMI,  $22 \pm 1.9$  kg/m<sup>2</sup>; iMVC,  $1458 \pm 458$  N; Flexibility,  $34.8 \pm 13.6$  cm; PWS,  $5.5 \pm 0.5$  km/h) were recruited in the study. Isometric maximal voluntary contraction (iMVC) was measured by two force plates (Twin Plates, Globus, Italy) which were fixed onto the foot platform of a horizontal leg press (Technogym SpA, Gambettola, Italy). Flexibility was assessed by the V-sit and reach test. The preferred walking speed (PWS) was determined on a 50-m section of athletics track. A kinematic analysis was performed with an optoelectronic system (SMART-E, BTS, Italy) during a 10-min bout of treadmill walking at 5.5 km/h. The following parameters were computed: step length and width (m), step frequency (step/min), stance and swing phase durations (% cycle), double support time (% cycle), hip and knee extension (°) and hip and knee ROM (°). Results Significant associations, adjusted for age, height and weight, were identified between iMVC and step width ( $r = 0.501$ ,  $F = 6.04$ ,  $p = 0.024$ ), stance ( $r = 0.537$ ) and swing ( $r = -0.537$ ) phase durations ( $F = 7.28$ ,  $p = 0.015$ ), double support time ( $r = 0.639$ ,  $F = 12.43$ ,  $p = 0.002$ ), and between Flexibility and step length ( $r = -0.547$ ,  $F = 7.68$ ,  $p = 0.013$ ). Discussion Our data indicate that lower limb maximal strength and hamstring flexibility influence step length and width, stance and swing phase durations and double support time of treadmill walking, suggesting the necessity to attain and maintain adequate levels of both strength and flexibility even in a healthy adult population. ## BOOT FORCE AND ACCELERATIONS ARE SIMILAR FOR SLALOM AND GIANT SLALOM ALPINE SKI RACING

Kipp, R.W.1, Scheiber, P.2, Müller, E.2, Seifert, J.G.3

1: USA (Park City, USA) 2: CDL – Biomechanics in Skiing (Salzburg, AUT) 3: MSU (Bozeman, USA)

Introduction Slalom (SL) and giant slalom (GS) are very different skiing disciplines. This can be exemplified by the fact that on the men's World Cup there are only six ski racers that are found in both SL and GS top 30 World Cup point lists (FIS, 2012). This would lead one to believe that the two events are more different than alike. Determining differences in SL and GS kinetics would be valuable information for the preparation of competitive athletes. The purpose of this study was to determine if force and acceleration could be used to differentiate between SL and GS. Methods After IRB was accepted and consents forms signed, 3 male and 5 female collegiate ski racers [FIS SL pts. =  $75.53$  (29.11), GS pts. =  $71.02$  (28.95)] skied a warm up run, then completed 1 run of SL set at 10.2 m vertical distance and 4 m horizontal offset, and 1 run of GS set at 20.4 m vertical distance and 6 m offset on SL and GS skis (2010/11 FIS ski specifications), respectively. The 94m vertical run was groomed prior to data collection. Data from each of the 6 middle turns were averaged and used. Unidirectional force was measured with force insoles (Pedar, Novel Electronics) (100 Hz sampling frequency) and with triaxial accelerometry (Pendant G Data Logger) (50 Hz sampling frequency) attached to the lower ski boot. Sagittal (x), frontal (y) and vertical (z) were recorded. The inner and outer ski relationship during the turn was used to determine percent contribution for force between the SL and GS skis and for acceleration comparison. Data are listed as mean (+/-SD). Alpha level of significance was  $p < 0.05$ . Results Mean total force per turn in SL was  $943.71$  (291.24) and GS  $937.03$  (225.03) N,  $p = .45$ ,  $r = .87$ . When adjusted for body weight SL was  $1.323$  (.26) and GS  $1.324$  (.24) N/kg,  $p = .44$ ,  $r = .73$ . The inner SL ski accounted for  $33.51$  (6.84) and the inner GS ski  $31.16$  (7.84) %,  $p = .12$ ,  $r = .75$ . Mean acceleration (m/s<sup>2</sup>) for the outer ski: SLx  $-6.37$  (2.53), GSx  $5.46$  (3.84)  $p = .20$ ; Sly  $-0.67$  (2.17), GSy  $0.24$  (3.51)  $p = .24$ ; SLz  $11.96$  (1.55), GSz  $10.85$  (2.87)  $p = .06$ . For the inner ski: SLx  $-6.64$  (3.51), GSx  $-5.94$  (4.22)  $p = .20$ ; Sly  $-0.25$  (2.58), GSy  $-0.68$  (3.06)  $p = .35$ ; SLz  $12.64$  (2.02), GSz  $10.17$  (4.50)  $p = .07$ . Discussion There were no significant difference in absolute and relative mean forces between SL and GS. The inside ski accounted for about 1/3 of the total force in both SL and GS for a none significant difference. Accelerations were also non significant for both the inner and outer ski for SL and GS for all measurements. This would lead one to conclude that SL and GS with respect to mean force and acceleration measured at the boot, under these test parameters, are similar, and the differences found in race results must lie elsewhere.

## COMPARISON OF THE KNEE ANGULAR VELOCITY DURING SINGLE-LEG LANDING BETWEEN BASKETBALL AND VOLLEYBALL COLLEGE PLAYERS: DESCRIPTION BY QUATERNIONS REPRESENTATION

Domingos, M.B.1, Cunha, S.A.1, Spanó, N.V.1, Santiago, P.R.P.1

1: USP-EFERP (Ribeirão Preto, Brazil), 2: UNICAMP-LIB (Campinas, Brazil)

Introduction Knee joint movement analysis during the single-leg drop landing task has been used in studies of sports-related anterior cruciate ligament injury mechanism. Quaternions have a mathematical advantage, compared to Euler angles, since gimbal lock does not happen. However, this technique defines only one axis of rotation and, for that reason, there is no correspondence to the anatomical axes. On the other hand, Euler angles are dependent on the sequence of rotation chosen by the researcher, different from quaternions. Even with the possibility of standardizing the sequence of rotation as proposed by International Society of Biomechanics, differences will be found when angular velocities are calculated. Therefore, in situations of applied biomechanics, angular velocity is calculated in only one way when using quaternions. Objective The aim of the present study was to use the quaternions rotational representation to com-

pare the knee angular velocity during the single-leg drop landing task between basketball and volleyball college players. Methods Ten male college players (five basketball and five volleyball) without prior lower limb injuries and pain participated in this study. They performed ten single-leg drop landings from a platform with a height of 0.5 m. Six passive markers (three on the thigh and three on the shank) were used to obtain the 3D kinematics. Routines written in the Matlab software were used to smooth the raw data with the cubic splines function, and to create coordinate systems of the thigh and shank to extract the unit quaternions from the knee joint observed in the task. Then the scalar portion of the unit quaternion was used to calculate the angular velocity in degrees per second (°/s). Comparisons between groups were done using the boxplots (median and the confidence interval  $p < 0.05$ ) of the maximum angular velocity. Results The results indicate significant differences between the two groups (volleyball = 385.5 °/s [362.8 - 408.2] and basketball = 313.0 °/s [272.5 - 353.5]). Discussion The results of the current study showed that the maximum angular velocity of the volleyball players was higher than that of the basketball players. In general, it was observed that the volleyball players performed higher amplitudes of movements of the knee in the single-leg landing task compared to basketball players. This may occur due to the specificity of this movement in each sport. Acknowledgments: This work received financial support by the Research Foundation of the State of Sao Paulo (FAPESP - process number: 2010/20538-7), and (PIC/USP/CNPq - process number: 124719/2010-4).

### MOVEMENTS NECESSARY FOR INCREASING SPEED IN ROLLER SKIING WITH A DIAGONAL STRIDE

Nakai, A., Ito, A.

*Kinki Welfare University*

Movements necessary for increasing speed in roller skiing with a diagonal stride Nakai, A.1, Ito, A.2 1: Kinki Welfare University (Hyogo, Japan), 2: Osaka University of Health and Sport Sciences (Osaka, Japan) Introduction In roller skiing, the centre of mass of the total body of the athlete is positioned on the roller ski in contact with the ground and moves forward all the time. Roller skiing speed (RS), which was calculated from mean horizontal velocity of the total-body centre of mass, was expected to depend on horizontal velocity of roller skis. Thus, the purpose of this study was to examine the relationship between RS and movements of roller skis during diagonal roller skiing to understand the movements necessary for an increase in RS. Methods Two-dimensional kinematics were recorded using a digital video camera in seven male collegiate cross-country ski athletes who roller skied with a diagonal stride at the paced speeds of 1.67, 2.50, 3.33, 4.16 and 5.00 m/s on a level track. The duration of the single-support phase (SS), the double-support phase (DS) and the transition phase (TR) and cycle time (CT) were computed from the video images over one cycle. Additionally, horizontal velocity of the total-body centre of mass, maximal horizontal velocity of the roller ski (Vmax) and mean acceleration of the roller ski during DS were calculated. Results RS had negative correlations with the duration of SS, DS and TR ( $r = -0.465$ ,  $p < 0.01$ ;  $r = -0.396$ ,  $p < 0.05$ ;  $r = -0.920$ ,  $p < 0.001$ , respectively) and also CT ( $r = -0.900$ ,  $p < 0.001$ ). A highly positive correlation was found between RS and Vmax ( $r = 0.988$ ,  $p < 0.001$ ). Vmax negatively correlated with the duration of DS and TR and the mean acceleration of the roller ski during DS ( $r = -0.407$ ,  $p < 0.05$ ;  $r = -0.915$ ,  $p < 0.001$ ;  $r = -0.908$ ,  $p < 0.001$ , respectively). Discussion Vmax, which occurs at the beginning of the ground contact of the roller ski, was significantly associated with RS. The duration of DS and TR and the mean acceleration of the roller ski during DS decreased with an increase in RS. Therefore, reducing the duration of DS and TR and the mean acceleration of the roller ski during DS would result in higher Vmax, hence increasing RS more. CT and the duration of each phase decreased with increasing RS. The duration of TR showed a remarkably strong correlation with RS compared to that of the other phases. These facts indicate that shorter duration of the individual phases, particularly that of TR, would lead to increasing RS. Consequently, greater deceleration of the roller ski before kicking and more rapid movements of kicking and transition to the opposite roller ski would cause effective acceleration of RS. Moreover, it is suggested that the above movements for shorter duration are required to increase RS.

### ACUTE AND DELAYED SSC FATIGUE EFFECTS ON TREADMILL RUNNING: INFLUENCE OF FOOTWEAR VISCOELASTICITY

MORIO, C., BARLA, C., BERTON, E., NICOL, C.

*Oxylane Research*

ACUTE AND DELAYED SSC FATIGUE EFFECTS ON TREADMILL RUNNING: INFLUENCE OF FOOTWEAR VISCOELASTICITY Morio, C.1, Barla, C.1, Berton, E.2, Nicol, C.2 1: Oxylane Research (Lille, France), 2: UMR6233 (Marseille, France) Introduction Endurance running is a typical stretch-shortening cycle type exercise (SSC), which is well known for inducing acute (<2 hours post-exercise) and delayed (up to 8 days) functional defects (Nicol & Komi, 2011). Although various studies investigated the potential footwear capacity to reduce suspected risk factors (Jenkins & Cauthon, 2011), influence of footwear characteristics on the locomotor adjustments to fatigue remain unexplored. This study examined in both acute and delayed SSC recovery phases the influence of footwear visco-elasticity on neuro-mechanical changes of the running pattern. Methods An exhaustive SSC exercise was performed on a sledge apparatus by 8 healthy male subjects who repeated series of 25 bilateral jumps, with inter-series rests of 3 min. Rebound height was set at 80% of maximal performance. Functional fatigue effects were quantified before (PRE), after (POST) and two days (D2) later in a maximal drop jump test. Each testing session included also two submaximal treadmill runs of 3 min duration performed randomly with viscous (V) and elastic (E) type shoes. Footwear influence on the neuro-mechanical adjustments to fatigue were examined for the last 15 seconds of each run using 3D kinematics and electromyography of 8 major muscles of the right lower limb. Appropriate two-way ANOVA analyses (V-E vs. PRE-POST-D2) were performed with a significance level set at 0.05. Correlation coefficients were used to compare the V vs. E shoe influence. Results Delayed onset muscle soreness (DOMS) was reported in all lower limb extensors at D2. Drop jump performance decreased at both POST (-7±4%) and D2 (-8±8%). Treadmill run was mostly affected at D2, showing 8±9% increased lower limb stiffness, 7±13% reduced knee flexion and 32±38% increased ankle eversion ( $p < 0.05$ ). Emphasizing the similarity of the changes observed with both shoes, significant correlations were found for most neuromechanical parameters ( $0.51 < r <= "" p="" > </r$

### TALENT TRANSFER IN SPORT: EXPERT COACHES' INSIGHTS

Dickinson, R.K.1, Mallett, C.J.1,2, Gulbin, J.2, Weissensteiner, J.2

1: *University of Queensland, Australia*, 2: *Australian Institute of Sport, Australia*

Introduction Talent transfer (TT) is a relatively newly discussed term appearing in academic literature (e.g., Vaeyens et al., 2009), referring to the idea of athletes "swapping" sports, or being "recycled" within a sport system. As such, TT as a distinct phenomenon is relatively under-researched in either theoretical or empirical published literature compared to many other approaches to sport talent identification and development (TID&D). Despite little research, the strategy has been used on a systematic level by a number of countries. The current study aimed to understand TT in more depth through rigorously gathering the expert knowledge of coaches who have undertaken the

"transferring" of athletes within the Australian sport system. Method 13 expert coaches (10 male) experienced in attempting to "transfer" athletes participated in semi-structured interviews regarding their background, involvement, processes, and experiences in TT. Interviews were conducted face-to-face (11), and by telephone (2), averaging 92 mins. Interviews were audio recorded and transcribed, member-checked, and coded using Nvivo9 software, checking for inter-coder agreement amongst researchers. Data were organised into meaning units, higher and lower order themes, as per qualitative research methodology published by Côté et al (e.g., 1993), and also represented in the form of a model. Results There were conceptually varied definitions of TT within the sample. Coaches gave insights from their experiences into broad themes such as: transferable and non-transferable elements between sports, barriers and facilitators, coach skills and qualities, athlete qualities, possibilities and limits of TT, necessary support, and important considerations for TT. Considerations such as: the differences between sport cultures and environments, athletes' personal characteristics, squad dynamics, the importance of a clear and well structured program of training with realistic goals and expectations, respect for athletes' backgrounds, and adequate access to resources were key factors suggested for successful TT. Discussion A multi-dimensional model of successful TT, including physical, mental, environmental, interpersonal, and structural considerations is proposed. Results are discussed in relation to conceptions of TT, implications for coaching practice and talent management by individual coaches and national sport systems, and the wider context of TID&D research. Limitations of the current study and future research areas are also discussed. References Côté, J., et al. (1993). ## THE EFFECT OF STRENGTH VS. POWER TRAINING ON THROWING PERFORMANCE

Zaras, N., Spengos, K., Methenitis, S., Papadopoulos, C., Karampatsos, G., Georgiadis, G., Stasinaki, A., Manta, P., Terzis, G.

*University of Athens*

Introduction Shot put is a power demanding activity (Zatsiorsky et al., 1981). Recently it was shown that strength training enhances muscle mass and shot put performance, in novice throwers (Terzis et al., 2008) but the effect of power training on shot put performance remains unexplored. Aim of this study was to investigate the effects of 6 weeks strength vs. power training on shot put performance. Methods Seventeen participants were divided into Strength (N = 9) or Power (N = 8) groups. Training was performed 3/week for 6 weeks with 3 resistance exercises: leg press, bench press and semi-squat. For the Strength group, the load was set at 6RM while the Power group trained with ballistic exercises with 30% of 1RM (Kyröläinen et al., 2005). The following tests were performed before and after the training period: shot put throws, counter movement jumps (CMJ), Wingate, 1RM strength and ballistic throws tests. Vastus lateralis thickness, pennation angles and fascicle lengths were examined with ultrasonography, while fiber type composition and cross sectional area (fCSA) measured on histochemically stained muscle samples. Results Shot put performance increased significantly but similarly after strength and power training (7-13.5% vs. 6-11.5%, respectively). Leg press 1RM increased more after strength than after power training. Power training induced an increase in CMJ by 8.5% (p=0.006), and in ballistic throws by 9-26% (p<0.05), while strength training did not alter performance in these tests. Peak power during the Wingate test increased similarly in both groups. Muscle thickness increased only after strength training (10%, p=0.004). Muscle fCSA increased in all fiber types after strength training by 17-25% (p<0.05), while only type IIx fibers hypertrophied significantly after power training. Type IIx fibers (%) decreased after strength but not after power training. Discussion The results of the present study suggest that shot put throwing performance can be increased similarly after 6 weeks of strength or power training, in novice throwers. Improvements in shot put performance after strength training could be attributed mainly to muscle hypertrophy while improvements after power training might be attributed to adaptations in type IIx muscle fibers, although neural adaptations might have contributed also. It appears that ballistic power training might be used effectively during the last weeks before competition, when the strength training load is usually reduced, in order to increase muscle power and shot put performance in novice throwers. #### BIKING 2770 KM IN 14 DAYS: EFFECT ON MAXIMAL FAT OXIDATION

Morville, T., Rosenkilde, M., Munch-Andersen, T., Andersen, P.R., Kjær, K., Rasmussen, H.K., Mattsson, N., Grau, A.G., Dela, F., Helge, J.W.

*Xlab, Center for Healthy Aging*

Introduction Endurance training increases maximal fat oxidation and very prolonged exercise has been shown to markedly increase fat utilization during exercise. However, the limiting steps of fat oxidation are still subject to some discussion. This study examined the effects of 13 days repeated prolonged exercise on maximal fat oxidation and substrate stores as well as the primary steps regulating transport and oxidation of fat in skeletal muscle. Methods Data were obtained from 6 males completing a 13-day bike ride, covering 2770 km (age: 61 ± 4 yrs; cycling VO<sub>2</sub>-max: 48 ± 2 mL kg<sup>-1</sup> min<sup>-1</sup>). Before and 2 days after the bike ride a blood sample and a muscle biopsy (m. vastus lateralis) was obtained at rest overnight fasted. Body composition was determined using skinfold and bioimpedance techniques and respiratory gasses were sampled during a fat-max test and a VO<sub>2</sub>max test. Continuous heart rate sampling was performed throughout the 13 days in order to estimate the intensity and duration of exercise. The intensity was estimated as the average of 10 minutes intervals of heart rate recording from which the percentage of VO<sub>2</sub> max was then calculated. Results Maximal fat oxidation decreased from 0.63 ± 0.05 to 0.43 ± 0.07 g/min (P < 0.01). Plasma FFA concentration decreased from 500 ± 77 to 160 ± 38 μmol/L (P < 0.002). VO<sub>2</sub>max decreased from 48 ± 2 to 45 ± 2 mL/(kg min) (P < 0.04). The exercise intensity that elicits maximal fat oxidation was not significantly changed (59 ± 2 to 54 ± 5 % of VO<sub>2</sub>-max). Plasma glucose (5.9 ± 0.2 to 6.0 ± 0.3 mmol/L) and plasma triacylglycerol (0.9 ± 0.1 to 1.0 ± 0.2 mmol/L) as well as muscle glycogen (602±78 to 639±59 mmol/kg d.w.) and triacylglycerol (71±15 to 66±5 mmol/kg d.w.) all remained unchanged, pre and post, respectively. There were no changes in muscle CS- or HAD-activity. Average daily duration of exercise

was  $580 \pm 30$  min and the mean intensity was  $53 \pm 1$  % of  $VO_{2max}$ . Body weight and composition remained unchanged ( $77.4 \pm 4.6$  to  $77.7 \pm 4.8$  kg and  $21 \pm 1$  to  $20 \pm 3$  %, pre and post respectively). Discussion Maximal fat oxidation as well as aerobic fitness decreased. Very low plasma FFA at rest suggests low exogenous FFA delivery during exercise and along with the decreased aerobic fitness this could account for the decrease in maximal fat oxidation. Thus, in this study, the probable attenuation of exogenous FFA availability during exercise induced by the repeated prolonged exercise is likely to be the limiting factor for maximal fat oxidation.

### **SPRINT EXERCISE-INDUCED PDH ACTIVATION: ROLE OF FIO<sub>2</sub> AND FREE RADICALS.**

Morales-Álamo, D.1, Guerra, B.1, Guerrero, M.2, Cadefau, J.A.2, Cussó, R.2, Ponce-González, J.G.1, Guadalupe Grau, A.1, Rodríguez-García, L.1, Dorado, C.1, Calbet, J.A.1

1. 1. Dep. Educación Física, Universidad de Las Palmas de Gran Canaria, Spain. 2. 2. Unitat de Bioquímica, Facultat de Medicina, Universitat de Barcelona, Spain

Anaerobic glycolysis is strongly activated by sprint exercise and hypoxia ( $FIO_2=0.10$ ). It has been reported that free radicals (FR) may slow the kinetics of the oxidative metabolism in a pyruvate dehydrogenase (PDH) dependent manner. Since hypoxia increases free radicals levels, sprint exercise in hypoxia may result in greater dephosphorylation (activation) of PDH. Purpose. To determine if FR are implicated in the sprint exercise-induced PDH de-phosphorylation. To this purpose we determined PDH phosphorylation levels in response to a sprint exercise in normoxia (N,  $FIO_2=0.21$ ) and hypoxia (H,  $FIO_2=0.10$ ) in two conditions placebo (P) after the ingestion of antioxidants (A. The antioxidant cocktail was compound by 300 mg of alpha-lipoic acid, 500 mg vitamin C, and 200 IU vitamin E, and was administered to 2 h and 1.5 h before the sprints). Methods: Nine males (age:  $25 \pm 5$  yrs;  $VO_{2max}$ :  $51 \pm 6$  ml.kg<sup>-1</sup>.min<sup>-1</sup>; means  $\pm$  SD) performed on separate days in random order four 30s-isokinetic Wingate tests at 100 rpm in NP, HP, NA, and HA. Immediately before the start, at the end, and at 30 and 120 min into the recovery period, muscles biopsies were taken and PDH phosphorylations determined by Western blot and pyruvate concentration by spectrofluorometry. Results: Mean power output (MPO) and mean  $VO_2$  were, respectively, 6% and 37% lower in HP than in NP ( $P < 0.05$ ). Compared to NA, mean  $VO_2$  was decreased by 31% in HA, respectively ( $P < 0.05$ ). Peak blood lactate was similarly increased after the sprints. Muscle pyruvate concentration was increased by 104% immediately after the sprints, without significant differences between conditions. Ser293-PDH-1Ealpha and Ser300-PDH-1Ealpha phosphorylation were decreased by 65% and 88%, respectively, returning to near baseline values within 30 minutes of recovery ( $P < 0.05$ ). Conclusion: PDH dephosphorylation (activation) in response to sprint exercise is not influenced by the  $FIO_2$  or the ingestion of antioxidants. These findings indicate that free radical production during sprint exercise do not appear to play a major role in inducing PDH dephosphorylation. Supported by Ministerio de Educación y Ciencia, (DEP2009-11638) and (DEP2010-21866).

### **SOFTWARE FOR THE RAPID AND AUTOMATIC CALCULATION OF PHYSIOLOGICAL PARAMETERS CORRESPONDING TO THE MAXIMUM CONSUMPTION OF LIPIDS DURING EXERCISE**

Vittori, L.N., Manners, D.N., Maietta, P., Tentoni, C.

University of Bologna

Introduction Numerous studies have described the relationship between exercise intensity and fat oxidation, but few have assessed this relation at different exercise intensities. Most exercise programs for obese patients and resistance training for athletes, have been evaluated for their respiratory and cardiovascular benefits and increased oxidative capacity in skeletal muscle. The study of fat metabolism, induced by training during exercise, has received less attention, although its importance has been recognized both in performance sports and for its impact on health [1-4]. It is therefore imperative to precisely define rigorous standardization procedures (feeding, pre-test activities, test protocol, etc.) that allow a reliable determination of the maximum consumption of lipids (FatMax). In addition, for routine use such procedures should be integrated with an appropriate software to automatically determine parameters of physiological interest, related to the FatMax, in a robust and operator-independent manner. Methods Our group has developed an automatic procedure for determining FatMax, both in terms of load applied and in terms of parameters such as heart rate and RER. The program uses a robust curve fitting procedure for reliable results. The initial application for this procedure is the determination of exercise prescription for overweight subjects, with the aim of maximizing fat loss for a given exercise duration. In the study currently underway, we have recruited 16 subjects (14 female, age 40-54 years, BMI 23-34), who have undergone an initial incremental test to determine their individual FatMax, followed by twice weekly sessions lasting 1 hour, during which the subjects exercise on bike, steps and treadmill for 20 minutes each. During the session a heart rate monitor is used to hit the target heart rate prescribed, and a respirometer to check that the target RER is achieved. At the end of the study period a final incremental test will be performed to ascertain whether relevant physiological parameters have been altered by the training. Results The study is currently underway. The latest results will be presented, emphasizing the design and use of the software that we have developed, and aim to make freely available. References 1. ### **COMPARATIVE STUDY OF TRADITIONAL AEROBIC EXERCISE V/S SPRINT INTERVAL TRAINING WITH RESPECT TO PULMONARY FUNCTION TESTS & PHYSICAL FITNESS INDEX IN YOUNG SEDENTARY MALES: A RANDOMIZED CONTROLLED TRIAL**

Badaam, K.M., Khan, S.T., Munibuddin, A., Chaudhari, S.P., Doiphode, R.S.

Government Medical College, Aurangabad

Introduction: Physical inactivity and sedentary living are now a global 'non-communicable' disease. [1] Exercise is known to prevent various diseases and promote health. [2] However, for exercise guidelines to yield a health benefit for the individual, not only should the regime reliably modify key disease risk factors, it must also be plausible to implement. SIT is an exercise strategy that is intended to improve performance and health with short training sessions. [2] Methods: The trial registered with W.H.O: UIN: U1111-1126-7019 and in CTRI as CTRI/2011/12/002312. 14 Young sedentary healthy males age 18-25 years with normal baseline ECG, were enrolled & randomly allocated to either group to undergo an intervention for 3 weeks. Group I: AE: Subjects ran at low intensity like jogging for 30 minutes a day for 5 days a week. Group II: SIT: 60 seconds intense exercise followed by 90 seconds rest, repeated for 4 cycles, making a total of 10 minutes thrice per week. Pulmonary function test parameters (FVC, MVV) and Physical Fitness Index were measured at beginning and 2 days after 3 weeks intervention. Results: The improvement in FVC in litres in Group I was  $0.31 \pm 0.11$  and in Group II was  $0.48 \pm 0.17$ . The improvement in MVV in litres in Group I was  $21.5 \pm 11.6$  and in Group II was  $27.77 \pm 7.03$ . Thus, SIT showed better improvement in FVC &

MVV although difference in improvement was statistically not significant with p value of 0.09 & 0.29. Also, the improvement in Physical Fitness Index was more in Sprint interval training group and the difference was statistically significant. Discussion: Survival in asymptomatic adults without chronic respiratory diagnoses or persistent respiratory symptoms is associated with Forced Vital Capacity and not with airway obstruction as measured by the FEV1/FVC ratio. [3] Maintaining or improving fitness is associated with a lower risk of all-cause and Cardiovascular Disease mortality in men. Preventing age-associated fitness loss is important for longevity regardless of Body Mass Index change. [4] SIT showed better improvement in FVC, MVV and Physical Fitness Index compared to traditional aerobic exercise. References: 1. Gordon O M, et al. ### COMPARISON BETWEEN SUPINATED AND NEUTRAL WRIST POSITIONS ON ECCENTRIC CONTRACTION-INDUCED MUSCLE DAMAGE OF THE ELBOW FLEXORS

Lau, W.Y., Blazeovich, A., Newton, M., Nosaka, K.

*Edith Cowan University (Australia)*

COMPARISON BETWEEN SUPINATED AND NEUTRAL WRIST POSITIONS ON ECCENTRIC CONTRACTION-INDUCED MUSCLE DAMAGE OF THE ELBOW FLEXORS Lau, W.Y., Blazeovich, A., Newton, M., Nosaka, K. ECU (Australia) Introduction Eccentric contraction-induced muscle damage (EIMD) is characterised by delayed onset of muscle soreness, loss of muscle strength and increases in muscle proteins such as creatine kinase (CK) in the blood (1). Previous studies (e.g. 2) investigated EIMD of the elbow flexors in a supinated position; however, it seems likely that the wrist position would affect the magnitude of EIMD. No previous studies have systematically compared between supinated and neutral wrist positions on EIMD. The present study tested the hypothesis that eccentric contractions of the elbow flexors in a neutral position would induce less EIMD than those in a supinated position. Methods Ten non-resistance trained men (21-39 y) performed two exercise bouts consisting of 10 sets of 6 maximal isokinetic (60°s<sup>-1</sup>) eccentric contractions of the elbow flexors in a different wrist position (supinated vs neutral) for each arm separated by 4 weeks in a randomised, counterbalanced order. During the eccentric contractions, the elbow joint was forcibly extended from a flexed (60°) to a fully extended position (0°). The movements of the biceps brachii aponeurosis were recorded by B-mode ultrasonography (Aloka SSD-α10, Japan), and the movement distance of the aponeurosis origin from the beginning to the end of each contraction was calculated, and the average change in a set was obtained. Maximal voluntary isometric contraction strength (MVC), range of motion (ROM), muscle soreness and serum CK activity were assessed before, immediately after and 1-7 days following each exercise bout. Changes in these variables over time and changes in aponeurosis elongation over sets were compared between supinated and neutral wrist conditions by a two-way repeated measure ANOVA. Results Peak torque produced during eccentric contractions was similar between conditions. The aponeurosis origin was extended during eccentric contractions, and the average aponeurosis elongation increased ( $P < 0.05$ ) from the 1st set ( $8.0 \pm 2.0$  mm) to the 10th set ( $15.8 \pm 1.9$  mm) for the supinated condition; however, no significant increases were found in the neutral condition (1st set:  $5.1 \pm 1.0$  mm, 10th set:  $5.0 \pm 0.8$  mm). Compared with the supinated condition, changes in MVC, ROM, muscle soreness and serum CK activity following exercise were smaller ( $P < 0.05$ ) for the neutral condition. Discussion These results suggest that EIMD is less for the neutral than the supinated position, and this is likely associated with the smaller strain to muscle fibres and surrounding connective tissue in the neutral than the supinated condition. It is concluded that the wrist position affects the magnitude of elbow flexor muscle damage. ### REMOVAL OF STRATUM CORNEUM ENHANCES LOCAL SWEATING RATE

Ler, H.Y., Thompson, M.W., Ruell, P.

*University of Malaya*

REMOVAL OF STRATUM CORNEUM ENHANCES LOCAL SWEATING RATE Ler, H.Y. 1, 2, 3 Thompson, M.W.1 Ruell, P.1 1: University of Sydney (Australia); 2: University of Malaya (Malaysia); 3: Tunku Abdul Rahman College (Malaysia) The vapour pressure at the skin surface and the surrounding ambient vapour pressure determine the extent of skin wettedness and ultimately the effect on sweating efficiency (Candas, 1983). It has been suggested that prolonged skin wettedness might cause the stratum corneum to swell, thus causing a mechanical obstruction of the sweat duct (Randall, 1957). The present study investigated the effect of skin wettedness on local sweating rate with the removal of the stratum corneum. 8 healthy males (age:  $34.0 \pm 7.7$  yr; height:  $175.0 \pm 5.8$  cm; weight:  $68.3 \pm 7.2$  kg; body fat:  $9.7 \pm 3.9\%$ ) completed 2 sessions of a walking protocol ( $5.5 \text{ km} \cdot \text{hr}^{-1}$ , 4% inclination) for 90 min in hot, humid conditions ( $37^\circ\text{C}$ , 60% rh) on two separate days. A marked area at ventral upper-arm was stripped sequentially 5 times and stratum corneum was removed using an acrylic adhesive film (OPSITE™ Flexigrid). Colorimetric method was used to determine the amount of stratum corneum removed. Local sweating rate (SR), skin blood flow (SkBF), local skin temperature (Tsk) were measured continuously at both stripped and unstripped sites. Sweat samples were collected every 30 min and electrolyte concentrations of Na, K, Cl and Ca were analysed. The removal of stratum corneum layers on the stripped site was similar between trials ( $18.27 \pm 6.97$  vs.  $17.18 \pm 5.36 \mu\text{g}$ ;  $p = 0.79$ ). Local SR increased progressively but at the stripped site was significantly higher than at the unstripped site from 6-min ( $0.22 \pm 0.18$  vs.  $0.18 \pm 0.14$ ;  $p = 0.03$ ) to the subsequent measures:  $0.78 \pm 0.20$  vs.  $0.66 \pm 0.18$  at 25-min,  $p = 0.006$ ;  $0.86 \pm 0.13$  vs.  $0.71 \pm 0.12$  at 55-min,  $p = 0.013$ ;  $0.91 \pm 0.14$  vs.  $0.77 \pm 0.17$  mg.min<sup>-1</sup>.cm<sup>2</sup> at 85-min,  $p = 0.022$ . SkBF and local Tsk at both sites remained stable over time after the initial 10 min of walking. Local SR was significantly correlated with SkBF ( $r = 0.741$  vs.  $r = 0.734$ ;  $p < 0.01$ ) and local Tsk ( $r = 0.609$  vs.  $r = 0.374$ ;  $p < 0.01$ ) at stripped and unstripped sites respectively. Similar results were observed for sweat [Na], [K], [Ca] and [Cl] between sites. To our knowledge this is the first investigation to report a relationship between the removal of stratum corneum and local SR. Local SR was ~14.3% higher at the stripped site compared with the unstripped site. This implies that the removal of stratum corneum has a significant effect in lowering the skin wettedness level with a reduction of water reabsorption into the skin. However, the removal of stratum corneum did not affect Tsk, SkBF measures and mineral concentrations. In conclusion, the removal of stratum corneum using a stripping method enhances local SR during exercise in hot and humid conditions. Candas, V. et al (1983). *Eur J Appl Physiol*. 50, 223-234. ### PSEUDOEPHEDRINE AND ENDURANCE PERFORMANCE: A DOSE RESPONSE?

Pritchard-Peschek, K.1, Jenkins, D.1, Osborne, M.2, Slater, G.3, Taaffe, D.4

1: UQ (Brisbane, Australia), 2: QAS (Brisbane, Australia), 3: USC (Maroochydore, Australia), 4: UN (Ourimbah, Australia)

**Introduction** Previous research examining the influence of pseudoephedrine on exercise performance has found that ingesting doses  $\geq 180$  mg of pseudoephedrine elicits performance improvements of 5.1% in  $\sim 30$  min cycling time trials,<sup>1</sup> power output in a 30 s Wingate test by 2.8%,<sup>2</sup> and 1500 m run time by 5.8 s.<sup>3</sup> These findings collectively support the contention that only pseudoephedrine taken in doses of  $\geq 180$  mg is likely to improve exercise performance. The purpose of the present study was to examine a possible dose-response between pre-exercise pseudoephedrine intake and cycling time trial performance. **Methods** Ten trained male endurance cyclists ( $26.5 \pm 6.2$  years,  $75.1 \pm 5.9$  kg,  $70.6 \pm 6.8$  ml/kg/min) undertook three cycling time trials in which a fixed amount of work (7 kJ/kg body mass) was completed in the shortest possible time. Sixty minutes before the start of exercise, subjects orally ingested either 2.3 mg/kg or 2.8 mg/kg body mass of pseudoephedrine or a placebo in a randomized, double-blind manner. Following ingestion, subjects then consumed a standardized pre-exercise meal providing 2 g/kg body mass of carbohydrate. Venous blood was sampled at baseline, pre- and post-warm up and post-exercise for the analysis of pH and lactate, glucose, plasma catecholamine and plasma pseudoephedrine concentrations. **Results** Neither dose of 2.3 mg/kg nor 2.8 mg/kg body mass of pseudoephedrine significantly improved cycling time trial performance of  $\sim 30$  min duration. Plasma pseudoephedrine concentration increased from pre-warm up to post-exercise in both treatment conditions, with the 2.8 mg/kg body mass dose eliciting the highest concentration at both time points ( $p < 0.001$ ). There was large individual variation in plasma pseudoephedrine concentration both pre- and post-exercise between subjects following supplementation. **Discussion** The considerable variation in plasma pseudoephedrine was unexpected, and clearly indicates that a number of factors influence pseudoephedrine's uptake and appearance in the blood which are not yet fully understood. Peak plasma pseudoephedrine concentrations following pseudoephedrine supplementation also did not appear to coincide with the start of the performance trials. Combined with the differences in plasma pseudoephedrine between individuals, this may partially explain the lack of a performance benefit in the present study, and also the inconsistencies in performance following pseudoephedrine supplementation in previous investigations. **References** 1. ### THE EFFECT OF PHYSICAL INACTIVITY ON EXERCISE-INDUCED IL-6 RELEASE FROM THE LEG

Reihmane, D., Hansen, A.V., Gram, M., Olsen, A.B., Helge, J.W., Dela, F.

*University of Copenhagen*

**Introduction** Data on interleukin-6 (IL-6) release during acute exercise from working legs are not conclusive and lack information about the impact of training status. Some studies have shown an increase (Febbraio et al., 2003) whereas others report no changes (Steensberg et al., 2002) in IL-6 release during the first hour of exercise. In this study our aim was to investigate leg IL-6 release during moderate intensity exercise, and to test if there were differences in IL-6 release between an immobilized (IM) and a control (C) leg. **Methods** To examine our hypothesis, eleven healthy male subjects (age  $23 \pm 1$  (mean  $\pm$  SEM) yrs; BMI  $23.6 \pm 0.8$  kg m<sup>-2</sup>; VO<sub>2</sub>max  $43.2 \pm 1.2$  ml kg<sup>-1</sup> min<sup>-1</sup>) performed 45 min of two leg dynamic knee-extensor exercise (absolute leg workload  $18.1 \pm 0.6$  watts; relative workload for C  $52 \pm 3\%$ , for IM  $62 \pm 5\%$  of the leg maximal workload) after wearing a donjoy cast for 14 days. Arterial (A) and femoral venous blood samples from C and IM legs were collected every 15 minutes during exercise. Femoral blood flow was measured by ultrasound Doppler. **Results** There was an increase in average arterial plasma IL-6 concentrations during exercise comparing pre- and post-exercise levels (A:  $1.1 \pm 0.1$  vs.  $3.0 \pm 0.3$  pg ml<sup>-1</sup>, respectively,  $P < 0.05$ ). The IL-6 release was increased from rest to after 15 min of the exercise in both legs (C:  $0.35 \pm 0.10$  vs.  $0.73 \pm 0.03$  ng min<sup>-1</sup>; IM:  $0.38 \pm 0.07$  vs.  $0.79 \pm 0.17$  ng min<sup>-1</sup>; rest and exercise, respectively,  $P < 0.05$ ) where after it remained constant until the end of exercise. The IL-6 release did not differ between C and IM leg during rest or exercise. **Discussion** The present study for the first time shows that the immobilization for 14 days had no effect on leg IL-6 release during submaximal exercise. The immobilization resulted in a higher relative workload for IM leg, but this did not lead to an intensity induced increase in leg IL-6 release (Helge et al., 2003). In agreement with a prior study (Febbraio et al., 2003) leg IL-6 release was increased already 15 min after onset of exercise with this experimental model. **Reference List** Febbraio MA, Steensberg A, Starkie RL, McConnell GK & Kingwell BA (2003). *Metabolism* 52, 939-944. ### THERMAL AND PERCEPTUAL RESPONSES INDUCED BY ROWING IN COLD AND MODERATELY WARM CONDITIONS

Fournet, D.1,2, Williams, M.1, Redortier, B.2, Havenith, G.1

1. *Environmental Ergonomics Research Centre (Loughborough University, UK)* 2. *Oxylane Research (Villeneuve d'Ascq, France)*

**Introduction** The range of environmental conditions in which athletes are expected to perform may vary greatly between seasons. Though a multitude of studies have looked at cycling and running in this context, no investigations have focused on the influence of low temperatures on perceived exertion and thermal responses during rowing, an exercise type using different muscle groups. The aim of this study was therefore to evaluate the thermal strain associated with a fixed rowing exercise at two ambient conditions (10 and 20°C). **Methods** Eight active males exercised minimally clothed on a rowing ergometer at 55%VO<sub>2</sub>max in a cold (C) and moderately warm (W) environment. Rectal temperature and heart rate were monitored throughout the protocol. Skin temperature (T<sub>sk</sub>) was recorded by whole-body infrared thermography before and after 40 minutes of rowing (T40). A bodymapping technique was used to obtain population-averaged T<sub>sk</sub> maps (Fournet et al. 2011). Thermal sensation was assessed at each stage as well as rating of perceived exertion (RPE) using the 6-20 Borg scale. Sweat loss was calculated from body mass loss and water intake. Body fat percentage was deduced from skinfold thickness (7 sites). **Results** Rectal temperature and heart rate were similar in the C and W conditions. Sweat loss was significantly higher in W compared to C ( $225 \pm 88$  vs  $126 \pm 29$  g/m<sup>2</sup>/h,  $p < 0.01$ ). Mean T<sub>sk</sub> and local T<sub>sk</sub> were consistently higher in W (4°C on average) while the range of T<sub>sk</sub> over the body was larger in C. Interestingly, T<sub>sk</sub> body maps revealed similar patterns of T<sub>sk</sub> distribution in C and W with warmer upper back and arms than other segments. Only in C, significant correlations were found between mean T<sub>sk</sub> and BF% ( $r = -0.86$ ), local T<sub>sk</sub> and local skinfold thickness. Thermal sensation was warmer in W and RPE-T40 reached a higher value in W ( $12.0 \pm 1.2$  vs  $11.0 \pm 1.1$ ,  $p < 0.05$ ). **Discussion** At the same workload, the effort perception was less intense in C than W. This was associated with the same core temperature dynamics but a 4°C colder mean T<sub>sk</sub> in C, inducing a "slightly cool" sensation. This contribution of peripheral (vs central) inputs to RPE has also been shown elsewhere (Maw et al. 1993). Evaporative sweat loss contributed more to temperature

regulation in W compared to a larger dry heat loss (skin-air temperature gradient) in C. Larger local insulation provided by body fat directly influenced Tsk only in C where vasoconstriction was more pronounced. Rowing-specific patterns of whole-body Tsk distribution were produced for the first time which highlighted warmer Tsk over the rowing-specific active muscles. References Fournet D et al. (2011) ECSS Proceedings: 132 Maw JG et al. (1993) Eur J Appl Physiol 67:174-179

### EFFECT OF TRAINING SURFACE ON ACUTE PHYSIOLOGICAL RESPONSES FOLLOWING INTERVAL TRAINING

Binnie, M., Peeling, P., Pinnington, H., Landers, G., Dawson, B.

*University of Western Australia*

This study compared the effect of sand and grass training surfaces during a common pre-season interval training session in well-trained team sport athletes (n=10). Participants initially completed a preliminary testing session to gather baseline (BASE) performance data for vertical jump (VJ), repeated sprint ability (RSA) and a 3 km running time trial (RTT). Three days subsequent to BASE, all athletes completed the first interval training session, which was followed by a repeat of the BASE performance tests the following day (24 h post-exercise). Seven days later, the same interval training session was completed on the opposing surface, and was again followed 24 h later by the BASE performance tests. During each session, blood lactate (BLa), ratings of perceived exertion (RPE) and heart rate (HR) were recorded. Additionally, venous blood was collected pre-, post-, and 24 h post-exercise, and analysed for serum concentrations of Myoglobin (Mb), Creatine Kinase (CK), Haptoglobin (HP) and C-Reactive Protein (CRP). Results showed significantly higher BLa and HR responses experienced during the SAND session ( $p < 0.05$ ), with no differences observed between surfaces for the blood markers of muscle damage, inflammation and hemolysis ( $p > 0.05$ ). Twenty-four hours later, the RTT was performed significantly faster following the SAND session compared to GRASS ( $p = 0.001$ ). These results suggest that performing interval training on a sand (versus grass) surface can result in a greater physiological response, and less decrement in next day endurance performance.

### WEARING AN ICE VEST IMPROVES CYCLING CAPACITY IN THE HEAT

Cuttell, S., Victor, K., Tyler, C.

*Moulton College, Roehampton University.*

Institutions: 1 Moulton College, Moulton, NN3 7RR, UK. 2 Roehampton University, Whitelands College, Holybourne Avenue, London, SW15 4JD, UK. Introduction: Increased core body temperatures are widely accepted as a limitation of exercising in the heat (Armstrong et al., 1995). Interventions such as acclimation and cooling have been shown to attenuate the reduction in exercise performance and capacity observed. Most of the literature has focused on pre-cooling; however, such approaches are often impractical. Practical cooling of the neck during exercise has been shown to enhance running capacity in the heat (Tyler and Sunderland, 2011) but the torso covers a much larger area of the body's surface and so theoretically may be a more effective site to cool than the neck. The aim of study was to investigate the effects of ice vest cooling on cycling capacity in the heat. Methods: Twelve untrained, healthy, unacclimatised males ( $24 \pm 3.7$  years,  $83.1 \pm 12.1$  kg mass,  $1.82 \pm 0.08$  cm stature) completed an incremental cycle test to determine maximum power output ( $W_{max}$ :  $240 \pm 25$  W). Following this test and a full familiarisation participants completed two experimental cycle capacity tests; one with (VC) and one without (CG) an ice vest. During the familiarisation and main trials the participants cycled in a hot environment ( $35.0 \pm 0.1^\circ\text{C}$ ;  $50 \pm 1\%$  rh) to volitional exhaustion at 60%  $W_{max}$ . Physiological (HR, body mass, rectal and skin temp) and perceptual (RPE, feeling scale, thermal sensation of torso and skin) variables were measured at 5 minute intervals. Significance was set at the  $P < 0.05$  level. Results: Mean cycling capacity was longer in VC ( $28.91 \pm 10.48$  min) compared to CG ( $23.54 \pm 8.86$  min) ( $P = .024$ ;  $d = 0.46$ ). There was a significant difference between trials and temperature at the torso (CG:  $36.26 \pm .80$   $^\circ\text{C}$ ; VC:  $31.15 \pm 1.50$   $^\circ\text{C}$ ;  $P = .001$   $d = 3.63$ ). There was no effect between any other physiological variables ( $p = 0.05$ ). There was a significant difference between CG and IV for skin temperature at the torso (CG:  $36.26 \pm .80$   $^\circ\text{C}$ ; IV:  $31.15 \pm 1.50$   $^\circ\text{C}$ ;  $P = 0.01$ ) and thermal sensation of the torso (CG:  $6.74 \pm .992$ ; IV:  $4.62 \pm .881$ ;  $P = 0.001$ ). Other perceptual variables reported no significant differences between conditions CG and IV ( $p = 0.05$ ). Discussion: The present study indicates that the use of an ice vest can have a beneficial effect while exercising in the heat. Cardiovascular measures appear not to be effected, thus the study points towards thermal sensation of the torso having sufficient effect to enhance performance in the heat. ### REDUCTION IN THERMAL SENSITIVITY TO COLD DURING EXERCISE AND POST-EXERCISE RECOVERY

Ouzzahra, Y.1, Havenith, G.1, Redortier, B.2, Voelcker, T.2

*(1) Loughborough University; (2) Oxylane Research (FRANCE)*

Introduction A low skin temperature (Tsk) at the onset of exercise has been shown to improve performance (Schlader et al., 2011). Pre-exercise skin cooling is however limited by cold and uncomfortable perceptions resulting from a reduced Tsk. According to the concept of thermal alliesthesia (Cabanac, 1972), light exercise during skin cooling may improve thermal comfort associated with a low Tsk. Therefore, the aim of the present study was to compare thermal sensation and thermal comfort before, during, and after exercise, while cooling the skin in one body segment. Methods Using a customised liquid cooling garment, the whole chest of eight male participants ( $22.0 \pm 3.6$  y;  $181.8 \pm 2.3$  cm;  $78.3 \pm 5.7$  kg) was continuously cooled during three consecutive conditions: 30 min rest, 15 min exercise (cycling at 30%  $\text{VO}_2\text{max}$ ) and 15 min post-exercise recovery. Thermal sensation from 0 ("neutral") to -10 ("extremely cold") and thermal comfort from +5 (very comfortable) to -5 (very uncomfortable) were scored at 5 min intervals. Core temperature ( $T_c$ ) and chest Tsk (4 sites) were recorded throughout the experiment. Results Cooling caused a chest mean Tsk decrease from  $33.0 \pm 0.6^\circ\text{C}$  to  $28.1 \pm 0.9^\circ\text{C}$  in the resting period, resulting in a local thermal sensation of  $-6.9 \pm 1.6$  and a local thermal comfort of  $-3.4 \pm 1.1$ . Despite a further decrease in Tsk to  $27.8 \pm 0.9^\circ\text{C}$  during the exercise period, thermal sensation and thermal comfort both increased, respectively to  $-1.8 \pm 1.8$  ( $p < 0.05$ ) and  $1.0 \pm 2.1$  ( $p < 0.05$ ). This was accompanied by a minimal increase in  $T_c$  ( $0.1 \pm 0.1^\circ\text{C}$ ). During the recovery period, Tsk further decreased to  $26.6 \pm 1.0^\circ\text{C}$ , while thermal sensation and thermal comfort decreased to  $-4.9 \pm 1.1$  ( $p < 0.05$ ) and  $-2.0 \pm 0.9$  ( $p < 0.05$ ), respectively. Discussion The improvement in thermal comfort is in line with the concept of thermal alliesthesia. However, the mechanisms behind the decrease in thermal cold sensation despite a lower Tsk remain unclear, but may be related to the activation of stress-induced analgesia during exercise (Koltyn, 2000). The present results suggest the possibility of reducing discomfort and cold sensation by the incorporation of light exercise in pre-performance cooling strategies. ##### **THE EFFECT OF TWO WEEKS OF IMMOBILIZATION AND 6 WEEKS OF SUBSEQUENT AEROBIC TRAINING ON MITOCHONDRIAL RESPIRATION IN YOUNG HEALTHY MEN**

Gram, M., Hansen, A.V., Olsen, A.B., Reihmane, D., Helge, J.W., Dela, F., Hey-Mogensen, M.

*Faculty of Health Sciences*

**Introduction** Mitochondrial dysfunction has been related to lifestyle conditions such as obesity and type-2 diabetes. It is well known that these conditions are strongly affected by physical inactivity. Even so there is limited information on the effect of physical inactivity on mitochondrial function in human subjects. Thus, the aim of the present study is to investigate whether 2 weeks of unilateral immobilization and 6 weeks of aerobic retraining affect mitochondrial respiration in young healthy men. Also, we wanted to investigate if the inactive or trained state affects the mitochondrial ability to respond to acute exercise. **Methods** We recruited 12 young healthy recreationally active males. Subjects had one leg randomly immobilized with a DonJoy knee brace for 2 weeks. After the immobilization period subjects performed 6 weeks of supervised cycle ergometer training (20 sessions of 55 min). After immobilization and after the retraining period, subjects performed acute exercise for 45 min on a kicking ergometer. Muscle biopsies were taken before and after immobilization and after the retraining period, and before and after acute exercise in the immobilized and retrained state. Mitochondrial function was determined as respiration in saponin-permeabilized muscle fibers. Furthermore maximal voluntary contraction; VO<sub>2</sub>max and leg lean mass were measured. **Results** Maximal voluntary contraction and leg lean mass decreased from baseline to immobilization and increased to baseline again after retraining in the immobilized leg with no change in the control leg. VO<sub>2</sub>max was reduced after immobilization and was significantly higher than basal level after retraining. Immobilization resulted in a significant decrease in the ratio between succinate and glutamate supported respiration. This ratio returned to basal values after retraining. Furthermore, retraining caused an increase in succinate supported respiration and State 4<sub>o</sub>. Acute exercise resulted in a decreased state 2 and antimycin A inhibited respiration in the non-immobilized leg with no change in the immobilized leg. **Discussion** The major finding of the present study was that immobilization caused intrinsic changes in mitochondrial function, shown as a significant decrease in the substrate control ratio (succinate vs. glutamate supported respiration). Acute exercise altered the mitochondrial function in the control leg but this was not present in the immobilized leg. Based on these results we hypothesize that the acute exercise induced increase in oxidative stress, caused a mitochondrial adaptation resulting in a lower mitochondrial free radical production in the control leg; an adaptation which was blunted in the immobilized leg.

##### **INFLUENCE OF LOCALISED COOLING ON MUSCLE OXYGENATION AND BLOOD VOLUME CHANGES FOLLOWING INTENSE EXERCISE**

Ihsan, M., Abbiss, C.R., Lipski, M., Watson, G.

*Edith Cowan University*

**INFLUENCE OF LOCALISED COOLING ON MUSCLE OXYGENATION AND BLOOD VOLUME CHANGES FOLLOWING INTENSE EXERCISE** Ihsan, M.1, Abbiss, C.R.1, Lipski, M.2, Watson, G.1,3. 1: ECU (Joondalup, Australia), 2: GSU (Cologne, Germany), 3: UTAS (Tasmania, Australia) **Introduction** Post exercise cold water immersion (CWI) may enhance the rate of recovery following endurance exercise (Vaile et al., 2008). However, vasoconstriction induced by cooling is likely to suppress local blood flow and oxygen (O<sub>2</sub>) supply. We are currently unaware of any study that has examined changes in tissue oxygenation and blood volume during post-exercise CWI. Therefore, the purpose of this study was to investigate the effect of post exercise CWI on tissue oxygenation and blood volume changes. **Methods** Nine physically active males performed 30 min of continuous running (CR) at 70% of their maximal aerobic running speed (MAS), followed by 10 bouts of intermittent running (INT) at 100% of MAS. Following exercise, one of the participants' limbs was immersed in a cold water bath (10°C; COOL) to the level of their gluteal fold for 15 min. The contra-lateral remained outside the water bath and served as a control (CON). Vastus lateralis (VL) skin temperature (T<sub>sk-VL</sub>), VL tissue oxygenation (tissue oxygenation index, TOI) and blood volume changes (total haemoglobin volume, tHb = oxygenated Hb (O<sub>2</sub>Hb) + de-oxygenated Hb (HHb)) were monitored continuously throughout exercise and CWI using near infrared spectroscopy (NIRS). **Results** T<sub>sk-VL</sub>, TOI and tHb parameters were not significantly different between CON and COOL during CR and INT respectively. In contrast, T<sub>sk-VL</sub> was significantly lower in COOL compared to CON throughout CWI with peak differences occurring at the end of CWI (CON: 35.1 ± 0.6 vs COOL: 16.9 ± 1.7°C). Beyond 3 minutes of cooling, tHb was significantly lower during COOL compared with CON, with peak differences of ~ 20% evident at the end of the 15 min CWI. TOI was significantly higher in COOL, compared with CON, with peak differences of ~ 21% evident at the 12th min of CWI. Compared with pre-immersion values, TOI was higher throughout the CWI in the COOL condition however, at the end of CWI, TOI in CON was not significantly different from pre-immersion values. **Discussion** Post exercise elevations in muscle blood flow and O<sub>2</sub> consumption facilitates recovery by replenishing muscle O<sub>2</sub> stores and facilitating glycogen resynthesis (Tuominen et al., 1997). The present data indicates that blood supply (tHb) and muscle O<sub>2</sub> demand are lower following CWI and as such may be detrimental to the initial recovery process. **References** Vaile J, Halson S, Gill N, Dawson B. ##### **EFFECT OF PRECOOLING AND ACCLIMATION ON REPEAT SPRINT PERFORMANCE IN HEAT**

Brade, C., Dawson, B., Wallman, K.

*University of Western Australia*

**Introduction** To reduce the potential negative effects of heat on exercise performance, practises such as acclimation and the more acute method of precooling have both been used and reported to enhance performance. Acclimation is likely the more powerful of the two

methods, but it has yet to be established whether an acclimated individual would perform better if precooling was also done. Therefore, the aim of this study was to determine if precooling would have an additive effect on performance of an acclimated individual during repeat sprint exercise in the heat. Methods Ten physically active males completed three experimental trials; a Pre Acclimation (Pre Acc) trial and two post acclimation trials, one with precooling (Post Acc + PC) and another without (Post Acc). These trials consisted of a 30 min baseline period followed by a 70 min repeat sprint cycling protocol performed in the heat (~35.0°C and 60% RH) comprising 2 x 30 min periods of exercise and a 10 min half time period. Each half comprised 30 x 4 s maximal sprints interspersed with exercise at varying intensities. Precooling (ice slushy and cooling jacket) was administered during the baseline and half time periods. Separating the pre and post trials were five acclimation sessions (spread over 10 days) involving repeated (increasing from 8 to 12 by the last session) 3 min cycling efforts performed at 80% maximum power output with 1 min of passive rest between. Physiological measures included core (TC) and mean skin temperature (TSk), heart rate (HR), sweat loss, rating of perceived (RPE) exertion and thermal sensation (TS). Performance measures obtained were peak and mean power and work done. Results Moderate effect sizes suggested a greater amount of work per kg BM ( $J \cdot kg^{-1}$ ) was done in Post Acc (1st Half,  $1606 \pm 102$ ; 2nd Half,  $1605 \pm 71$ ) compared to Pre Acc (1st Half,  $1533 \pm 153$ ; 2nd Half,  $1538 \pm 109$ ). Furthermore, several (possible, likely and very likely) smallest worthwhile effects were found between these conditions, suggesting benefits in Post Acc. Post Acc + PC performance was not different to either Pre Acc or Post Acc. Moderate to strong effect sizes also suggested lower TC (0.2-0.3°C) in the Post Acc + PC and Post Acc compared to the Pre Acc, particularly over the second half of exercise. Sweat Loss was significantly higher ( $p < 0.05$ : 23.1%) in Post Acc + PC compared to the other two conditions. No significant differences were observed for TSk, HR, RPE or TS. Discussion Here, a short term (partial) heat acclimation protocol was beneficial for repeat sprint performance in the heat. Greater improvement may have been seen if full acclimation was undertaken. In addition, no further enhancement of performance was seen as a result of acclimated individuals precooling prior to performance, but this did produce a higher sweat loss.

### BEVERAGE TEMPERATURE, MUSCLE ACTIVATION AND FATIGUE AT ELEVATED CORE BODY TEMPERATURES

Burdon, C.1, Schmidt, C.1, Johnson, N.1, Chapman, P.2, O'Connor, H.1

1 USyd (Sydney, Australia), 2: ACU (Sydney, Australia).

Introduction: Cold receptor stimulation (through the use of ice slushy, menthol or cold neck collar) has recently been shown to elicit performance benefits during exercise tests in the heat [1, 2, 3]. However the contribution of peripheral and central fatigue reduction to this benefit is unclear. This study aimed to measure the effect of ice slushy versus thermoneutral beverage ingestion on maximal voluntary isometric contraction (MVIC) performance using active and inactive muscles and to measure peripheral and central fatigue at elevated core body temperatures. Method: Eight active participants (5M, 3F) performed three 45s MVICs of the elbow flexors and knee extensors in a reclined position (hips, knees & elbow at 90°) at ~37.5°C, 38.5°C and 39.5°C. Two carbon rubber electrodes were placed over the quadriceps and biceps brachii for percutaneous electrical muscle stimulation 5s before and at 15, 30 and 44s during the MVIC. To increase rectal temperature ( $T_r$ ) participants cycled in 40°C and 50% relative humidity at 60% Work Max. Immediately prior to each MVIC, participants consumed 50g of ice slushy (-1°C, ICE) or thermoneutral drink (38°C, CON) made from 7.4% carbohydrate beverage. Participants consumed water (19°C) during exercise to maintain body mass. Maximal force production ( $F_{max}$ ) was established at a familiarisation trial using 3s MVICs. Results: Participants cycled for  $22 \pm 5$  and  $20 \pm 7$  min to reach 38.5°C and 39.5°C respectively. Weight change was minimal (~400g) but similar between ICE and CON ( $p = 0.24$ ). Quadriceps mean force decreased from  $302 \pm 180$ N to  $232 \pm 151$ N at 39.5°C ( $p < 0.001$ ). Quadriceps % $F_{max}$  decreased at high  $T_r$  ( $14.6 \pm 13.1\%$ ,  $p = 0.05$ ). Quadriceps peripheral fatigue increased by  $4.0 \pm 7.6\%$  ( $p = 0.02$ ) and central fatigue increased by  $10.6 \pm 11.7\%$  ( $p = 0.06$ ) when  $T_r$  was elevated to 39.5°C. Biceps mean force decreased from  $179 \pm 67$ N to  $148 \pm 65$ N at 39.5°C ( $p < 0.001$ ). Peripheral and central fatigue were not significantly increased at 39.5°C ( $6.9 \pm 8.3\%$   $p = 0.92$  &  $1.9 \pm 22.3\%$   $p = 0.17$  respectively). No variable was significantly different between ICE and CON trials. Discussion: The MVIC caused significant peripheral and central fatigue and mean force output decreased with elevated  $T_r$  for both muscle groups. However, only the active (quadriceps) (not inactive biceps) showed decreased  $F_{max}$  when  $T_r$  was elevated. Therefore, increases in peripheral and central fatigue with elevated  $T_r$  was observed only with the active muscle group. Ice slushy ingestion failed to ameliorate the possibly overwhelming effect of heat on central fatigue and muscle force production. References: 1 Siegel, R, et al. ### ONE HOUR VARIABLE POWER CYCLING IMPAIRS SUBSEQUENT RUN PERFORMANCE

Etzebarria, N.

Loughborough University - University of Canberra

Etzebarria, N.1,2, Anson, JM.2, Pyne, DB.2,3 and Ferguson, RA.1 1: Loughborough University, UK, 2: University of Canberra, Australia, 3: Australian Institute of Sport, Australia. Introduction The cycle section in triathlon is influenced by race tactics, terrain and course-technicality often resulting in a pattern of highly variable power output. The extent to which these factors affect the subsequent running performance is unclear. We aimed to determine how a 1 h triathlon-specific cycling trial (with a highly variable power distribution) affects subsequent run performance and how an individual's cycling power profile relates to any decrement in run performance after variable power cycling. Methods After ethical approval was obtained, twelve well-trained male triathletes (age  $28 \pm 5$  y; peak  $4.9 \pm 0.5$  L.min<sup>-1</sup>; body mass  $73.5 \pm 7.7$  kg, mean  $\pm$  SD) performed an initial incremental cycle ergometer test to determine their maximal aerobic power (MAP). Subjects also completed a series of six maximal effort cycling intervals (6 s, 15 s, 30 s, 1 min, 4 min, and 10 min) to establish their power/duration relationship (power profile). Subsequently, each subject performed two experimental 1 h cycle-run trials on different days at either triathlon-specific variable (VAR) or constant (CON) power (both equivalent to 65% of MAP) followed by a 9.3 km run at race-pace (four laps of a road course). Subjects also completed a control 9.3 km run with no preceding exercise (NO-EX). Blood lactate (BLa), rating of perceived exertion (RPE) and heart rate (HR) were measured at 20, 40 and 60 min during the cycle trials. The split and total times for the 9.3 km run were also recorded. Results The overall 9.3 km run time was substantially slower ( $42 \pm 37$  s, mean  $\pm$  90% confidence limits (CL); standardised difference  $0.21 \pm 0.19$ ) after VAR ( $35:39 \pm 3:19$  min:s, mean  $\pm$  SD) compared with CON ( $34:57 \pm 2:50$  min:s). The decrement after VAR appeared primarily in the early stages of the run ( $35 \pm 20$  s, mean  $\pm$  90% CL slower after 2 laps). Both runs after the cycle exercise were substantially slower than NO-EX ( $33:49 \pm 2:33$  min:s). During the 1 h cycling mean BLa ( $8.2 \pm 2.6$  vs.  $3.3 \pm 1.5$  mM), HR ( $159 \pm 15$  vs.  $155 \pm 13$  bpm) and RPE ( $6.9 \pm 1.1$  vs.  $6.2 \pm 1.5$  units) were substantially higher after VAR compared with CON. Subjects with higher peak power output during the 6 and 15 s efforts, and higher mean power in the 1 and 4 min efforts, had the lowest reduction ( $0.32-0.39 \pm \sim 0.45$ ,  $r$ -value  $\pm$  90% CL) in run time after VAR. Discussion Cycling courses with a variable power profile are likely to result in an impaired ability to maintain performance during a subsequent run. Triathletes should aim to improve short-term peak power and medium length

mean power to minimise the impact of variable power cycling, and limit the decrease in running ability during the early stages of the subsequent run at race-pace.

### THE EFFECT OF PACING STRATEGY ON MUSCLE FATIGUE AND TECHNIQUE IN 1500M SPEED SKATING AND CYCLING

Stoter, I.K.1, MacIntosh, B.R.3, Fletcher, J.R.3, Pootz, S.3, Zijdewind, I.2, Hettinga, F.J.1

*University of Groningen*

The effect of pacing strategy on muscle fatigue and technique in 1500m speed skating and cycling Stoter, I.K. (1), MacIntosh B.R. (3), Fletcher J.R. (3), Pootz S. (3), Zijdewind I. (2) and Hettinga F.J. (1) 1) Center of Human Movement Sciences 2) Department of Neuroscience, University Medical Center of the University of Groningen, the Netherlands 3) Human Performance Laboratory, Faculty of Kinesiology, University of Calgary, Calgary, Canada Objective Theoretically, faster end times are expected when performing a fast start in a 1500m time trial in speed skating as well as in cycling. In practice this appears to be particularly true in cycling, but not as much in speed skating. A variable crouched position requiring isometric contraction distinguishes speed skating from cycling and may impact optimal pacing strategy. This study investigates differences in pacing strategy between speed skating and cycling when a faster start is instructed and whether these differences can be explained by underlying mechanisms of fatigue and technique. Method Nine well trained male speed skaters and nine well trained male cyclists performed two 1500m time trials in their sport of expertise. Athletes were instructed to start faster (FS) or slower (SS) than they were accustomed to. Velocity (V) per 100m was measured during each trial. Before and after the trial, maximal voluntary contraction (MVC), voluntary activation (VA) and rest twitch (RT) were measured to get insight into the central and peripheral contribution to muscle fatigue. Knee and trunk angles per 200m were measured in speed skating only to track changes in technique and aerodynamics. Results The SS trials showed similar pacing strategies in both sports. In the FS trials cyclists performed a more explosive 300m-start (V-mean 45.68 km/h, SD 3.30) than speed skaters (V-mean 42.31 km/h, SD 1.18) resulting in different pacing patterns. Though these starts were indeed faster than the instructed slower starts no difference in end times was found within sports. Both sports showed a significant decrease in MVC (12.6%) and RT (27.4%), but only cycling showed a decrease in VA (5.4%). In speed skating, knee angles were similar in both trials, but higher trunk angles were found in the FS trial. Conclusion Similar pacing instructions resulted in different pacing strategies in the FS trial of both sports. Cyclists start faster, resulting in central and peripheral contribution to muscle fatigue, where in speed skating peripheral contribution seems to be dominant. Speed skaters seem to attribute part of their energy resources to maintain knee angles and thereby their technical ability. This might be the cause of the different pacing strategies in speed skating and in cycling and might afford interesting possibilities to study regulation systems. References 1) Hettinga, F. J. et al. (2012). *Br J Sports Med*, 46(1), 30-35. 2) Hettinga, F. J. et al. (2011). *Br J Sports Med*, 45(1), 30-35.

### ORAL CONTRACEPTION AND ENERGY INTAKE IN WOMEN: IMPACT ON SUBSTRATE OXIDATION DURING EXERCISE

Isacco, L., Thivel, D., Meddahi Pelle, A., Zouhal, H., Duclos, M., Duche, P., Boisseau, N.

*Blaise Pascal University*

Oral contraception and energy intake in women: impact on substrate oxidation during exercise Isacco L1, Thivel D1, Meddahi Pelle A2, Zouhal H3, Duclos M4, Duche P1, Boisseau N1 1: University Blaise Pascal (Clermont-Ferrand, France), 2: INSERM unit (Paris, France), 3: Rennes University (Rennes, France), 4: Auvergne University, INRA, CHU (Clermont-Ferrand, France). Introduction Separately, oral contraception (OC) and energy intake (EI) may play a role in fuel selection during exercise in women (Bonen et al., 1991; Bemben et al., 1992; Jeukendrup et al., 2003). However no study dealt with the potential interaction of OC and EI in women during exercise. The aim of this study was to investigate the effect of OC in fed and fast conditions on substrate oxidation, metabolic and hormonal responses in normal weight women during exercise. Methods Substrate oxidation (Respiratory Exchange Ratio, fat and carbohydrate oxidation rates), metabolic (glycerol, free fatty acids, glucose) and hormonal (insulin, adrenaline and noradrenaline) responses were determined in 21 women: 10 regularly menstruating women (OC-) and 11 women using OC (OC+: low dose monophasic pill; ethinyl estradiol  $\leq 30 \mu\text{g}$ ) during a 45min exercise (65% of  $\text{VO}_2\text{max}$ ) in fast and postprandial states. Results At rest, OC+ women presented higher LDL-C, total cholesterol and triglyceride concentrations as compared to OC- ones. OC status had no influence on substrate oxidation, metabolic and hormonal responses during exercise. In fast state, whatever the OC status, women exhibited greater reliance on fat than in postprandial condition. This occurred in presence of lower plasma insulin concentrations and higher plasma FFA and glycerol levels. Discussion The results indicated that the use of low dose monophasic OC did not modify fuel selection, metabolic and hormonal responses to exercise in women. Bonen et al. (1991) found an increase in CHO oxidation during exercise in OC- as compared to OC+, and Casazza et al. underlined an increase in lipid mobilization in OC+ subjects. These discrepancies between our study and those results may arise from different protocol designs, OC formulations and exercise modalities. Fast condition, compared to fed one, decreased CHO oxidation during exercise leading to a greater lipid mobilization and utilization whatever the OC status. Thus, in women, fed or fast condition had a greater impact on substrate oxidation during exercise than OC status. This study also showed that regarding basal lipid profile, OC+ presented an higher atherogenic profile than OC-. A prospective study comparing pre and post treatment in a same female group could allow us to conclude to OC effects on lipid and glycaemic profiles. References Bonen A, Haynes F, Graham T. ### PHYSIOLOGICAL AND BIOMECHANICAL DIFFERENCES IN NORTH AFRICAN AND EUROPEAN HIGH LEVEL ENDURANCE RUNNERS AT DIFFERENT VELOCITIES

Santos-Concejero, J.1,2, Granados, C.1, Irazusta, J.2, Bidaurrazaga-Letona, I.1, Zabala-Lili, J.1, Gil, S.M.1

*University of the Basque Country*

Introduction Studies aimed at clarifying the superior performance of African runners have only been undertaken on athletes of East and South African origin (1, 2). The physiological responses to exercise in North African athletes remain poorly understood; therefore, the purpose of the current study was to investigate the physiological responses in North African and European Caucasian runners at different velocities. Methods Eight North African ( $29.9 \pm 6.6$  years and  $31.2 \pm 1.1$  min 10-km race time) and fourteen European ( $27.8 \pm 6.4$  years and  $31.7 \pm 1.4$  min) middle- and long-distance high level runners participated in this study. All subjects completed a maximal incremental running test at 1% slope on a treadmill, starting at 9 km/h without previous warm up. The velocity increased by 1.5 km/h every 4 minutes until exhaustion, with 1 minute of recovery between stages. During the test, physiological and biomechanical parameters and rating of perceived exertion (RPE) were assessed. Results North African runners presented lower values in the respiratory exchange ratio at 16.5

km/h and 18 km/h and also a lower RPE at 18 km/h ( $P < 0.05$ ). However, European runners showed a lower oxygen uptake and a higher propulsive subphase during the stance phase of the gait cycle at 19.5 km/h ( $P < 0.05$ ). Discussion The present study provides evidence that North African athletes have an enhanced fat oxidation capacity and a lower perceived exertion compared to European runners, which implies an advantage for long distance running (2, 3). On the other hand, European athletes displayed a lower energy cost of running probably due to their better biomechanical running pattern. Thus, the observed differences would be compensated, explaining why both groups were of the same athletic level despite the observed physiological and psychological advantages of North African runners. ### **GENDER DIFFERENCES IN MAXIMAL STRENGTH IMPROVEMENT AND MUSCLE FIBER CHARACTERISTICS AFTER 8 WEEKS OF RESISTANCE TRAINING.**

Moro, T., Pacelli, F.Q., Toniolo, L., Canato, M., Cancellara, P., Miotti, D., Reggiani, C., Paoli, A.

*University of Padova*

Introduction It is well known that heavy resistance training (RT) promotes skeletal muscle hypertrophy (Andersen & Aagaard 2010). In particular, some studies have shown that this kind of training tends to decrease the expression of MHC IIx and MHC I and, at the same time, increase the expression of MHC IIa. But gender differences in such kind of changes are not known. The aim of this study was to analyse the differences in gender response after two months of RT. Furthermore, we wanted to compare the changes in latissimus dorsi muscle fibres characteristics with the mechanical measurement of fibres. Methods Eighteen healthy volunteers participated in 8-week progressive resistance training for upper limbs muscles. One repetition maximal test was performed and mechanical and myosin characterization (Pietrangelo et al. 2009) of latissimus dorsi muscle fibres were analysed pre and post-training. We used a fine needle biopsy technique that allowed us to obtain about 4 mg of muscle sample (Paoli et al. 2010). Results The increase in 1RM after 8-weeks of training was significantly greater in women (+24%) compared to men (+13%). The electrophoretic analysis of muscle fibers showed some changes in MHC expression. We observed an increase in MHC IIa (male +13% and female +33%) and a decrease in MHC IIx (male -8% and female -26%) while the MHC I expression in male tends to decrease (-5%) and in female tends to increase (+6%). Interestingly, the two-way ANOVA analysis (time x gender) showed a gender significant difference for female only in MHC IIa expression. The mechanical analysis of single fibres showed that training increased significantly the cross sectional area (CSA) and fibre strength in male and muscle fibre tension both in male and female. Discussion The greater increase of 1RM performance with a substantial unchanged fibre CSA in female subjects could be explained by an improved motor units recruitment whilst males response to training seems oriented to hypertrophy. Moreover, also myosin changes showed a gender related difference. Taken together our results suggest that resistance training effects on muscle are gender specific and more work is needed to explain this difference. ### **THE EFFECT OF DIFFERENT TIME REST PERIODS AFTER WARM-UP ON RUNNING PERFORMANCE AT 110% OF VO<sub>2</sub>MAX TO EXHAUSTION.**

Skaugen, M.

*Norwegian School Of Sports Sciences*

The effect of different time rest periods after warm-up on running performance at 110% of VO<sub>2</sub>max to exhaustion. Skaugen, M & Ingjer, F. Norwegian School of Sport Sciences Introduction Active warm up normally improves physiological performance and exercise capacity mainly because of an increase in core and muscle temperature, and also an increase in perfusion of oxygen. Less attention has been focused on the time between the end of warming up and start of training or competition with the aim to improve performance. To improve performance, according to Bishop et al., (2003) that recovery period should be less than ~5 min. Only a few previous existing studies have examined the effect of different rest intervals after warm-up on subsequent high intensity performance. The aim of this study was to utilize a new intervention protocol that identifies important selected physiological variables that effect performance by using a warm-up protocol that may be incorporated in sports training. Methods Six endurance trained athletes (mean±SD: 26 ±4 yrs, VO<sub>2</sub>max of 72.6 ±6.67 l.min<sup>-1</sup>.kg<sup>-1</sup>) performed an initial VO<sub>2</sub>max test followed by 3 randomized tests of 20 min treadmill warm-up at a moderate intensity. After the warm up, the subjects rested for either 30s, 3, or 10 min before starting an all out run to exhaustion at a speed representing 110% of VO<sub>2</sub>max. The subjects also performed an identical criterion test but without the warm-up. The following physiological variables were measured: oxygen uptake (VO<sub>2</sub>), heart rate (HR), blood lactate concentration (LA), minute ventilation (VE), respiratory exchange ratio (RER), indirect oximetry (SaO<sub>2</sub>), and rectal temperature (Tr) were measured in all the performance tests. Results Time to exhaustion increased significantly ( $P < 0.05$ ) when using a warm-up following a rest interval of 30s (190±46.5s), 3 min (188±52.2s) and 10 min (190±44.1s) compared to no warm-up (122±37.4s). No statistical difference in time to exhaustion was observed between the tests using the 3 rest periods ( $P > 0.6$ ). Tr decreased significantly by -0.12°C and -0.28°C when subjects rested for 3 and 10 min ( $P < 0.05$ ). There was also significant difference for RER ( $P < 0.05$ ) between no warm-up and 3 and 10 min rest interval tests. No significant difference was observed in peak values for VO<sub>2</sub>, HR, VE, LA, and SaO<sub>2</sub> in performance tests using the 3 rest periods. Discussion Although a significant decrease in Tr was observed during various rest periods, the minor decreases in Tr resulting from 3 and 10 min tests seem not to have influenced the performance negatively. In practice, the importance of relatively short rest periods (<5 min) to enhance performance are likely not as relevant as previously suggested in the literature. Further studies are needed to elucidate the results of this and other studies. References: Bishop, D. (2003). Warm Up II: performance changes following active warm up and how to structure the warm up. *Sports medicine*, 33(7), 483-498.

**HEAD-TO-HEAD COMPARISON BETWEEN ACTIGRAPH 7164 AND GTIM ACCELEROMETERS IN ADOLESCENTS**

Tanha, T., Tornberg, A.B., Wollmer, P., Dencker, M.

*Clinical Sciences*

Head-to-head comparison between Actigraph 7164 and GTIM accelerometers in adolescents Tina Tanha 1, Åsa B Tornberg 1,2,3, Per Wollmer 1, Magnus Dencker 1 1) Dept of Clinical Sciences, Unit of Clinical Physiology and Nuclear Medicine, Skåne University Hospital, Malmö, Sweden. 2) Department of Health Sciences, Division of Physiotherapy, Lund University, Sweden. 3) Department of Clinical Sciences, Genetic & Molecular Epidemiology Unit, Lund University Diabetes Center, Skåne University Hospital, Malmö, Sweden Corresponding author: Tina Tanha, MD Dept of Clinical Sciences, Malmö Clinical Physiology and Nuclear Medicine unit Skåne University Hospital 205 02 Malmö, Sweden E-mail: tina.tanha@skane.se Phone: +46 40-338701 Fax +46 40-338768 Introduction: We compared, head-to-head, the old generation Actigraph model 7164 with the new generation Actigraph GTIM accelerometer. Methods: A total of 15 randomly selected teenagers (8 girls and 7 boys) were investigated. They performed a treadmill test wearing the two kinds of accelerometers around the waist simultaneously. The treadmill test consisted of three different levels of speed 4, 6 and 8 km/h for four consecutive minutes. Results: Accelerometer counts for the Actigraph GTIM vs. the Actigraph 7164 were at 4 km/h 21.6±12.9 vs. 26.5±11.5 counts, at 6 km/h 56.0±23.2 vs. 62.9±25.6 counts and at 8 km/h 142.6±37.2 vs. 156.4±34.9 counts (p<0.01 for all levels of speed). Discussion: Data from the old generation Actigraph 7164 and the new generation Actigraph GTIM accelerometers differ, where the Actigraph GTIM generates 10-23% lower values. These results need to be taken into consideration when using these devices.

**CONTRIBUTION OF ORGANS AND TISSUE OF FAT-FREE MASS ON RESTING ENERGY EXPENDITURE IN COLLEGE MALE ATHLETES**

Oshima, S.1, Miyauchi, S.1, Asaka, M.1, Kawano, H.2, Taguchi, M.2, Torii, S.2, Higuchi, M.2

*Waseda University*

Introduction Fat-free mass (FFM) is often utilized to estimate resting energy expenditure (REE) for athletes, however the validity of using FFM to estimate REE has not been fully investigated. Our previous study showed that the consistency of REE/FFM for male athletes in spite of different FFM was due to the steadiness of % contribution of the organ-tissue compartments to FFM (1). At the same time, FFM contains various internal organs with relatively high metabolic rates. Therefore, the purpose of this study was to evaluate the contribution of organs and tissue of FFM on REE in college male athletes. Methods There were thirty-two college male American football players participated in this study. REE was measured (REEm) by indirect calorimetry, and % body fat and bone mineral content were measured by dual x-ray absorptiometry. Mass of brain, liver, and kidney were obtained by MRI technique and mass of heart was estimated based on the measurements taken by echocardiography. REE was estimated (REEe) based on the two models, one using the four organ-tissue compartments and the other using seven organs and tissue. The specific metabolic rates of these organs and tissue were taken from the literatures (2, 3) Results and Discussion The average body weight and FFM were 80.8 ± 11.9 kg (Range: 63.7 to 106.0 kg) and 67.3 ± 7.8 kg (56.9 to 84.2 kg), respectively. The average REEm was 1841 ± 228 kcal and the REE/FFM was 27.4 ± 1.6 kcal/kg/day. There was no association found between REE/FFM and FFM. The mass of liver, kidney, and heart significantly positively correlated with FFM, on the other hand, brain did not. Consequently, the % contribution of brain mass to FFM was negatively correlated with FFM (r=-0.80, p<0.001), although the % contribution of liver, kidney, and heart mass did not have any correlation with FFM. However, since the % residual mass which include all the internal organs to FFM was consistent, the influence of reduction in % brain/FFM on REE was expected to be small. There were no significant difference between the REEm and REEe using either of the estimation models. In conclusion, the REE/FFM was steady regardless of FFM due to the consistency of percentage contribution of organs and tissue mass to FFM, and thus FFM was the reliable measurement to estimate REE for athletes. **14:45 - 15:45****Poster presentations****PP-PM11 Physiology 3****DONATION OF 450 ML BLOOD AND TEMPORARY IMPACT ON PHYSICAL PERFORMANCE IN PHYSICALLY ACTIVE MEN**

Kraag Ziegler, A., Grand, J., Magnussen, K., Dela, F., Helge, J.W.

*Copenhagen University*

Donation of 450 ml blood and temporary impact on physical performance in men Ziegler A. K.1, Grand J.1, Magnussen K.2, Dela F.1, Helge J. W.1 1: University of Copenhagen, Center of Healthy Aging (Denmark), 2: Dept. of Clinical Immunology, and Blood Centre Rigshospitalet/Hvidovre (Denmark) Introduction: It is well accepted that donation of blood negatively affects maximal oxygen consumption (VO2max) and endurance, with endurance being reduced the most. Only few studies have investigated the impact of a standard 450 ml blood donation on physical performance and hemoglobin (hgb) conc. and the recovery of physical performance shows considerable variation from 3-28 days. Therefore this study aimed to measure the temporary impact of blood donation on physical performance, measured as VO2max and time trial (TT) performance in physically active men, while also observing time until normalization of hematological parameters. Method: 16 male blood donors were included. To determine VO2max a standard incremental bicycle ergometer VO2max test was performed. Pulmonary respiration was measured using an automated online system (Jaeger Oxycon Pro). After a 30 minute break endurance was tested using a self paced 3 km all out TT. Subjects were verbally encouraged to ensure an all out run. To assess baseline physical performance, subjects were tested 2 times prior to blood donation, and the highest scored values were used as baseline performance. Subjects were then tested 3, 7, 14, and 28 days after blood donation. At baseline, day 3, 7, 14, 21, 28, 42, blood samples were taken to analyze hgb, iron status (ferritin) and hematologic profile. Results: VO2max declined by 6.7 % from 48.9±2.1 ml O2 /kg/min (mean±SEM) to 45.6±2.1 ml O2 /kg/min at day 3 compared to baseline. Subsequently VO2max gradually increased to 48.8±2.2 ml O2 /kg/min, at day 28 after bloodletting, thereby returning to baseline. The 3 km TT performance declined by 5.6 % from 13:55±00:46

minutes at baseline to  $14:42 \pm 01:12$  minutes at day 3. At day 14 TT performance was  $13:52 \pm 00:59$  minutes and not different from baseline. B-hgb was reduced by 9 % from  $9.6 \text{ mM} \pm 0.17$  at control to  $8.8 \pm 0.14 \text{ mM}$  at day 3. After this B-hgb increased gradually, but was not at baseline even at day 42 ( $9.4 \pm 0.17 \text{ mM} - 2.1 \%$  below baseline). P-Ferritin declined 54 % from  $61.5 \pm 7.8 \mu\text{g/l}$  at baseline to  $28.3 \pm 3.7 \mu\text{g/l}$  at day 14 and remained reduced below baseline throughout the study. Discussion: In the present study TT performance was back to baseline at day 14 and  $\text{VO}_2\text{max}$  at day 28, even though B-hgb and P-ferritin conc. remained below baseline for the duration of the entire study. It is apparent that the plasma volume expansion after blood donation and the concomitant increase in B-hgb conc. from day 3 and onwards were sufficient to restore endurance TT performance already after 14 days and  $\text{VO}_2\text{max}$  after 28 days. In conclusion we provide a time course for the recovery of physical capacity after blood donation and reveal a dissociation in the recovery time of endurance performance,  $\text{VO}_2\text{max}$  and B-hgb.

### CORRELATION OF INCREASED MYOCARD VOLUME AND IMPROVED EXERCISE PERFORMANCE IN MICE AFTER TREADMILL TRAINING

Rieger, G.1, Gubser, M.1, Klohs, J.2, Hoppeler, H.1, Vogel, J.2, Baum, O.1

*1 Institute of Anatomy, University of Bern, Switzerland; 2 Institute of Veterinary Physiology, University of Zürich, Switzerland*

**Introduction** In human, physiologic cardiac hypertrophy is a well-established phenomenon in response to endurance exercise. Due to the limitation in resolution of imaging techniques the relationship between heart size and exercise performance in mice has not been documented so far. **Methods** Eight C57BL/6-mice (12 weeks old) were subjected to a 3-week period of treadmill exercise, consisting of five 45-min units per week. The training program was initiated at a speed of 16 m/min and an incline of 5-degrees of the treadmill. The velocity and the incline were then increased on a weekly basis to maximum values of 20 m/min and 9-degrees. Two performance tests were conducted before and after the training to determine peak power outcome (PPO) and time-to-exhaustion (TTE) of the mice in response to the training. To monitor the sizes of the hearts *in vivo*, the mice were subjected to magnetic resonance imaging (MRI) in a small animal MR system Bruker PharmaScan 47/16 (Bruker, BioSpin MRI, Ettlingen, Germany) operating at 200 MHz before and after the training period. In anesthetized mice, a cine FLASH sequence of the mediastinum was recorded using the self-gating technique IntraGate (ParaVision 5.0, Bruker BioSpin MRI) with TE/TR = 1.8/57 ms and a RF pulse angle of 10 degrees. Eight serial sections of the hearts with 1 mm thickness were acquired in horizontal orientation (image size: 2.5 x 2.5 cm, matrix size: 256 x 256 resulting in a pixel resolution of 98 x 98  $\mu\text{m}^2$ ). One section of the cine FLASH sequence from the middle part of the heart was used to identify the time points of maximal and minimal ventricular expansion. At these time points the area of the left ventricle and the left myocardium was measured on the eight MRI sections. By multiplying the sum of the heart areas in these MRI sections with the thickness of slices (Cavalieri-approach) to obtain the volumes of the left ventricle and left myocardium were calculated. The myocardium volume was defined as the average calculated from the end-diastolic and end-diastolic volume (EDV and ESV). Results Treadmill training induced a significant ( $P \leq 0.05$ ) increase in PPO (+9%) and TTE (+91%) of the mice. Myocardium volume was significantly ( $P \leq 0.05$ ) increased (+10%), while EDV (-0.1%) and ESV (+0.4%), stroke volume (+0.2%) and ejection volume (+0.1%) were only non-significantly ( $P > 0.05$ ) altered in the mice after the training. TTE and myocardium volume were significantly ( $P \leq 0.05$ ) correlated ( $r = 0.94$ ). **Discussion** The increases in TTE were significantly correlated to the changes in myocardium volume. Thus, combining the results from the exercise test and the high-resolution small animal MRI represents a sufficient approach e.g. to quantify the impact of substances on cardiac hypertrophy in mice. GR and MG as well as JV and OB contributed equally to this study

### EVALUATION OF TRAINING LOAD WITH HEART RATE VARIABILITY: A NOVEL INDEX FOR FIELD USE

Saboul, D., Balducci, P., Pialoux, V., Hautier, C.

*université Lyon 1*

**EVALUATION OF TRAINING LOAD WITH HEART RATE VARIABILITY: A NOVEL INDEX FOR FIELD USE** Saboul, D.1-2, Balducci, P.1, Pialoux, V.1, Hautier, C.1 1: CRIS- Université Lyon 1 (Lyon, France), 2: Almerys (Clermont-Ferrand, France) **Introduction** Evaluation of training load (TL) is an important actual topic for coaches. In practice, methods proposed by Banister (TRIMP) or Foster (RPE) are commonly used although both methods present advantages and disadvantages (Borresen et al., 2009). Recent studies reported relationship between post-exercise heart rate variability (HRV) recovery and TL (Kaikkonen et al., 2011). The aim of this study was to observe dynamic of post-exercise HRV recovery after different training sessions (TS). The final objective was to validate a novel HRV index that may be used by coaches and athletes to assess TL. **Methods** Eight healthy male runners performed randomly 4 TS of different duration and intensity. TL is evaluated using Foster and Banister methods. In addition, HRV measurements were performed respectively 5 minutes before TS, 5 and 30 minutes after TS. We calculated a new HRV index (TLHRV) based on ratio between the HRV decrease during TS and HRV increase during recovery. Correlations between TLHRV, Banister and Foster TL indexes were tested. Results HRV significantly decreased 5 minutes after exercise whatever the TS. Conversely, HRV significantly re-increased during the 30 minutes of the recovery phase. There were no significant differences between HRV measured before each TS. By contrast, there were significant differences between HRV measured immediately and 30 minutes after TS. The TL estimates were significantly different between TS whatever the calculation method. In addition, TLHRV was significantly correlated with Foster ( $R=0.61; p=0.0002$ ) and Banister ( $R=0.48; p=0.005$ ) methods. Moreover, Foster and Banister methods were also correlated ( $R=0.46; p=0.009$ ). **Discussion** This study confirms that immediately post-exercise HRV responded according to exercise intensity (Kaikkonen et al., 2011). In addition, we can hypothesize that HRV 30 minutes after TS provides information on fatigue induced by exercise. Consequently, TLHRV formula likely takes into account the dynamics of HRV recovery with both the disturbance and the return to homeostasis balance. Significant relationships between this new TLHRV method and the validated Foster and Banister methods suggest that this tool may provide a strongly objective TL index incorporating physiological and psychological impact of training session. **References** Borresen J, and Lambert MI. ### BRAIN BLOOD FLOW DURING MORNING AND AFTERNOON ROWING PERFORMANCE

Faull, O.K., Cotter, J.D., Lucas, S.J.E.

*University of Otago*

**Introduction** Regulating brain blood flow acutely and chronically has important implications for exercise performance. Despite evidence of circadian rhythms in cerebral blood flow (CBF), blood pressure (BP), cerebrovascular responsiveness to carbon dioxide ( $\text{CO}_2$ ) and cerebrovascular autoregulation, all of which peak in the afternoon, the combined influence of these underlying circadian rhythms for exercise

performance is yet to be explored, despite performances in several sports being reported to peak in the early evening. We aimed to compare the CBF responses to rowing exercise at different times of day, since rowing has large haemodynamic effects and it is performed at opposing ends of a day. We hypothesised that a higher CBF and improved regulation in the afternoon would be positively related to maximal rowing performance. Methods Twelve trained male rowers completed an incremental rowing exercise protocol and a 2000-m maximal rowing ergometer test in the morning (7 am) and afternoon (4 pm), one week apart. Middle cerebral artery velocity blood flow (MCAv) and cerebral (prefrontal) and muscular (vastus lateralis) tissue oxygenation were recorded continuously using Transcranial Doppler sonography and Near Infrared Spectroscopy (NIRS), respectively. Heart rate and partial pressure of end-tidal carbon dioxide (PETCO<sub>2</sub>) were also measured throughout. Results Maximal rowing ergometer time trial performance was faster (3.4 s; 95% CI 0.9-5.8 s) in the afternoon; however MCAv remained consistent between the two trials during maximal exercise (~1 cm/s difference;  $p = 0.60$ ). Resting MCAv and BP also showed no time of day differences (~1 cm/s and 1.1 mm Hg differences;  $p > 0.05$ ), and neither did prefrontal haemodynamics during time trials. MCAv increased from rest ( $68 \pm 12$  cm/s (SD)) during all intensities of exercise ( $80 \pm 11$ ;  $81 \pm 12$ ;  $80 \pm 11$ ;  $84 \pm 13$  cm/s for 50%, 75%, 2000-m max and 30 s max, respectively), despite significant decreases in PETCO<sub>2</sub> ( $42 \pm 2$ ;  $40 \pm 2$ ;  $34 \pm 2$ ,  $36 \pm 3$  mm Hg, respectively) from rest (40 mm Hg). Prefrontal oxygenated haemoglobin decreased consistently across 2000 m at both times of day (morning:  $208 \pm 117 \mu\text{M}\cdot\text{cm}$  in the morning; afternoon  $276 \pm 177 \mu\text{M}\cdot\text{cm}$ ;  $p = 0.11$ ), whereas in the muscle it dropped more in the afternoon ( $238 \pm 96$  vs  $137 \pm 66 \mu\text{M}\cdot\text{cm}$ ;  $p < 0.01$ ). Conclusion 2000-m rowing ergometer performance was better in the afternoon, but this was not in conjunction with any differences in MCAv or cerebral oxygenation at rest or during maximal exercise. We suggest that changes in peripheral metabolism and contraction velocities, due to possible circadian increases in muscle temperature, contributed to the better afternoon performance. In addition, rowing performance did not produce the inverted-U profile of brain blood flow with exercise intensity that is observed in other sports.

### EXERCISE FOR FATTY LIVER DISEASE: IMPACT ON MICROVASCULAR HEALTH

Pugh, C.J.A., Cuthbertson, D.J., Sprung, V.S., Kemp, G.J., Green, D.J., Cable, N.T., Jones, H.I

*Liverpool John Moores University*

**INTRODUCTION** Although non-alcoholic fatty liver disease (NAFLD) is associated with liver-related pathology, the leading causes of mortality and morbidity relate to macro- and micro-vascular disease. Cutaneous microvascular function is a surrogate index of preclinical microvascular disease, but has not been previously examined in NAFLD patients. We hypothesised that nitric oxide (NO)-mediated cutaneous vasodilator function would be impaired in obese NAFLD patients, compared with obese matched controls, and that exercise training would induce a greater improvement in cutaneous vasodilator function than clinical conventional care. **METHODS** NO-mediated vasodilation in cutaneous microvessels was examined in 13 NAFLD patients (7 males, 6 females,  $50 \pm 3y, 31 \pm 1\text{kg}/\text{m}^2$ ) and 7 matched controls (3 males, 4 females,  $48 \pm 4y, 30 \pm 2\text{kg}/\text{m}^2$ ) using laser Doppler flowmetry combined with intra-dermal microdialysis of L-NG-monomethyl arginine to assay the NO dilator system response to forearm heating. Magnetic resonance imaging and <sup>1</sup>H spectroscopy quantified abdominal visceral and hepatic fat respectively and cardiorespiratory fitness was also assessed. NAFLD patients ( $n=11$ ) were then randomly assigned to 16-weeks of supervised moderate intensity exercise training ( $n=6$ ) or conventional care ( $n=5$ ). Baseline characteristics between groups were compared using independent t-tests. The effects of exercise were compared using analysis of covariance. Cutaneous blood flow data is presented as %CVCmax and data are reported as mean $\pm$ SE. **RESULTS** Hepatic ( $28.8 \pm 5.3$  vs.  $3.6 \pm 0.7\%$ ;  $P=0.0004$ ) and abdominal visceral ( $4.8 \pm 0.4$  vs.  $3.8 \pm 0.7$ ;  $P=0.05$ ) fat were elevated in NAFLD patients compared with controls. The NO contribution to cutaneous blood flow in response to heating was not different between NAFLD patients and controls ( $P=0.47$ ). Cardiorespiratory fitness was significantly greater following exercise training compared with conventional care, as was the contribution of NO to cutaneous blood flow at rest ( $3.3 \pm 2.5$  vs.  $-5.8 \pm 2.7\%$ CVCmax;  $P=0.04$ ) and in response to heating ( $42^\circ\text{C}$ ) ( $22.5 \pm 9.7$  vs.  $-18.0 \pm 8.1\%$ CVCmax;  $P=0.05$ ). There was no difference in BMI or fat deposition ( $P>0.05$ ) between interventions. **DISCUSSION** This is the first study to demonstrate that exercise training improves microvascular function via upregulation of the anti-atherogenic molecule NO in NAFLD patients. The benefit of supervised exercise training compared with conventional care, strongly supports a role for exercise in the prevention of CVD in NAFLD.

### MACRO- AND MICROVASCULAR ADAPTATIONS IN RESPONSE TO RESISTANCE TRAINING

Cocks, M.I, Shepherd, S.I, Tipton, K.D.2, Shaw, C.S.1, Wagenmakers, A.J.M.1

*1University of Birmingham, 2University of Stirling*

Resistance training (RT) has recently been added to physical activity guidelines due to its effects on muscular strength and insulin sensitivity, promoting and maintaining health and independence. However its effect on the vasculature is understudied. The few studies to investigate RT's effect on vascular health suggest that it has either no or a negative effect. It has been suggested that the effect of training may differ between the micro- and macrovasculature. As a result we aimed to use an integrative approach to investigate both micro- and macrovascular adaptations following 6 weeks RT. Eight previously sedentary males (age  $20 \pm 0.4y$ , BMI  $24.5 \pm 0.9 \text{kg}\cdot\text{m}^{-2}$ ) completed 6 weeks of whole body progressive RT 3 times per week. Insulin sensitivity was measured using an OGTT. Central and peripheral pulse wave velocity (PWV) and systemic wave reflections (augmentation index @75 bpm) were measured using applanation tonometry (SphygmoCor®). Filtration capacity was assessed using plethysmography. Finally muscle biopsies were taken from the vastus lateralis and eNOS content, phosphorylation (eNOS Ser1177) and NOX2 content were assessed in the muscle microvascular endothelium and sarcolemma (NOX2 only) using quantitative immunofluorescence microscopy. High eNOS content is seen in lean healthy and fit individuals, while NOX2 is high in obesity, cardiovascular disease and metabolic syndrome. Capillary density was also determined using immunofluorescence microscopy. Muscular strength assessed using 1RM and insulin sensitivity were increased following training ( $P < 0.05$ ). In addition, RT significantly reduced resting blood pressure and augmentation index @75 bpm ( $P < 0.05$ ). No difference was seen in central ( $P = 0.934$ ) or peripheral PWV ( $P = 0.708$ ). All measures of capillarization (capillary density  $P = 0.715$ ; capillary contact  $P = 0.716$ ) and filtration capacity ( $P = 0.333$ ) did not change following RT. Skeletal muscle microvascular eNOS content ( $P = 0.091$ ) and basal eNOS phosphorylation ( $P = 0.075$ ) did not change. Finally both endothelial ( $P = 0.319$ ) and membrane ( $P = 0.164$ ) NOX2 contents did not change. As previously documented RT was effective at increasing muscular strength and insulin sensitivity. In addition RT also improved blood pressure and systemic wave reflection. However, unlike endurance and high intensity intermittent training RT had no effect on central artery stiffness, skeletal muscle capillarization or skeletal muscle microvascular eNOS content. In conclusion RT is an effective method of improving insulin sensitivity and muscular strength, but is not effective to improve micro- and macrovascular function and health.

## ALTERED LV MECHANICS DURING EXERCISE ACROSS THE MENSTRUAL CYCLE

Nio, A.Q.X.1, Stöhr, E.J.1, Meah, V.1, Stemberge, M.1, Gaze, D.2, Shave, R.1

1: Cardiff Metropolitan University, UK; 2: St George's Healthcare NHS Trust, UK

**Introduction** Changes in estradiol across the menstrual cycle influence vascular function, but the impact on cardiac function at rest is still unclear. Even less is known about its effects on cardiac function during exercise. The purpose of this study was to examine left ventricular (LV) function and the underlying LV twist mechanics during the early-follicular (EF; low estradiol) and late-follicular (LF; high estradiol) phases of the menstrual cycle. **Methods** Seven healthy females (mean±SD; age 25±3 years; height 164.9±6.2 cm; body mass 62.3±5.0 kg), with regular menstrual cycles (25–32 days) performed 70% supine cycling exercise (116±31 W) during EF (Day 3–5) and LF (Day 10–14). Plasma volume was calculated using haemoglobin concentration and haematocrit. Serum estradiol and progesterone concentrations were analysed by automated immunoassay. Systolic blood pressure (SBP; FinometerPRO), cardiac output, heart rate, stroke volume, ejection fraction, LV volumes, basal and apical rotation and rotation velocity, twist and twisting velocity (2D speckle tracking echocardiography) were assessed at rest and during exercise. T-tests were used to compare EF and LF at rest and 70% exercise. Alpha was set at 0.1. **Results** Plasma volume did not change between EF and LF (-2±12%Δ). Estradiol concentration was higher during LF than EF (179.2±51.4 vs. 42.2±18.0 pg/mL; p<0.01). Progesterone concentration was similar between phases (EF 0.3±0.0 vs. LF 3.7±5.4 ng/mL; p=0.18). At rest, SBP (116±12 vs. 126±9 mmHg; p=0.03), cardiac output (3.32±0.71 vs. 3.59±0.76 L; p=0.08), end-diastolic volume (97±15 vs. 102±16 mL; p=0.04) and peak untwisting velocity (-87±32 vs. -110±19 deg/s; p=0.06) were lower during LF than EF. In contrast, resting heart rate, stroke volume, ejection fraction, end-systolic volume, basal and apical rotation and rotation velocity, twist and twisting velocity were not different between phases. During exercise, the resting differences in SBP, LV function and LV twist mechanics were not present. However, exercise-induced increases in SBP (53±19 vs. 40±19 mmHg; p=0.07) and peak apical systolic rotation velocity (69.1±42.2 vs. 27.9±44.8 deg/s; p=0.03) were greater during LF than EF. **Discussion** This is the first study to compare LV function and the underlying LV twist mechanics at rest and during exercise between the EF and LF phases of the menstrual cycle. Reduced SBP, cardiac output and end-diastolic volume at rest during LF may reflect the vasodilatory effect of elevated estradiol. Interestingly, with exercise, baseline differences were no longer apparent. In order to meet the metabolic demands of exercise and mitigate the resting differences observed between phases, apical rotation velocity may have increased to enhance systolic function.

## REPEATED SUPRA-MAXIMAL SPRINT CYCLING INDUCES ENDOTHELIAL STRESS IN HEALTHY YOUNG MALES

Kirk, R.J., Peart, D.J., Madden, L.A., Vince, R.V.

University of Hull

**Introduction** Endothelial microparticles (EMP), analysed with specific antibodies by flow cytometry provide information on the state of the endothelium (1). EMP are released either through cellular activation, injury, stress, or during apoptosis or necrosis (1). Importantly, EMP are found in the plasma of healthy subjects, being constantly shed into the circulation, as well as in various pathological conditions (2). Few studies have investigated the exercise-induced stress response on EMP release. The aim of this study was to quantify changes in biomarkers of vascular endothelium as a result of high intensity sprint cycling exercise in young healthy subjects. **Methods** Seven active males volunteered for the study (22 ± 3 years, 1.82 ± 0.06 m, 81.3 ± 8.4 kg, Peak Power Output (PPO) 300 ± 22 W) and performed high intensity cycling on 3 separate visits. A PPO test and familiarisation was completed in visit 1, while sessions 2 and 3 were randomised exercise trials performed under placebo (sodium chloride (PLAC); capsules containing 0.045g.kg.BW-1 NaCl) or experimental (sodium bicarbonate (BICARB); capsules containing 0.03g.kg.BW-1 NaHCO<sub>3</sub>) conditions. Subjects completed 10 sets of 15-sec cycle sprints at 120% PPO, each separated by 45-sec of active recovery. Endothelial function was assessed by EMP using CD-105+MP and vascular cell adhesion molecule (VCAM-1+MP) as biological markers at rest (T0) and immediately (TEND), 90-min (T90) and 180-min (T180) post-exercise. **Results** A significant increase in both markers was evident for each cycling condition from TEND to T90 (p<0.05) with no significant differences between conditions. There was a trend for EMP to return to basal levels at 180-min, with significance in CD-105+MP BICARB group, and VCAM-1+MP PLAC group (p<0.05). Data was combined regardless of condition, displaying a significant time effect for markers (p<0.001). **Discussion** Repeated supra-maximal exercise was capable of increasing the concentration of EMP when compared with those levels at rest. Additionally, the levels of EMP had returned to resting values after 180-min of recovery. The significant increase in CD-105+MP and VCAM-1+MP may be caused by increased oxidative and endothelial shear stress (3). However, the endothelium activation appears to resolve rapidly in recovery. An additional finding was no attenuation in the EMP response following NaHCO<sub>3</sub> ingestion, suggesting EMP release is not particularly sensitive to any alterations in blood pH. **References** 1. ## HEART RATE RESPONSES DURING FOUR DIFFERENT EXERCISE PROTOCOLS IN PATIENTS WITH CORONARY ARTERY DISEASE

Currie, K.D., McKelvie, R.S., MacDonald, M.J.

McMaster University

**HEART RATE RESPONSES DURING FOUR DIFFERENT EXERCISE PROTOCOLS IN PATIENTS WITH CORONARY ARTERY DISEASE** Currie, K.D.1, McKelvie, R.S.1-3, MacDonald, M.J.1 1: Department of Kinesiology, McMaster University (Hamilton, Canada), 2: Department of Medicine, McMaster University (Hamilton, Canada), 3: Hamilton Health Sciences (Hamilton, Canada) **Introduction** Cardiac rehabilitation programs typically prescribe moderate-intensity endurance exercise (END) given its proven ability to improve the health of patients with coronary artery disease (CAD) (Hansen et al., 2012). Interval exercise has emerged as an alternative prescription for cardiac rehabilitation (Cornish et al., 2011); however, there is no consensus on the optimal duration and intensity of the intervals. This study examined the acute heart rate responses to 4 different exercise protocols in order to compare their respective cardiovascular stimulation in patients with CAD. **Methods** Nine men and one woman with documented CAD participated in 4 testing sessions. Heart rate was measured continuously during each exercise protocol using a single-lead ECG, and mean and peak heart rates were determined from 5-second averages. The 4 exercise protocols included END, aerobic-interval exercise (AIE), sprint-interval exercise (SIE), and high-intensity interval exercise (HIE). END involved 30 minutes of continuous cycling at 55% peak power output (PPO). AIE involved 4 x 4-minute intervals at 80% PPO interspersed with 3.5-minute intervals at 35% PPO. SIE involved 4 x 30-second intervals at 95% PPO separated by 3-minute intervals at 10% PPO. HIE involved 10 x 1-minute intervals at 80% PPO separated by 1-minute intervals at 10% PPO. **Results** Peak heart rates were significantly different between exercise protocols (p=0.003). SIE elicited the lowest peak heart rate (115 ± 24 bpm) and AIE elicited the highest peak heart rate (136 ± 27 bpm), compared to END (130 ± 26 bpm) and HIE (126 ± 26 bpm). Mean heart rates were also different between

groups ( $p=0.0001$ ), with AIE ( $120 \pm 22$  bpm) and END ( $117 \pm 22$ ) eliciting the highest means, followed by HIE ( $111 \pm 20$  bpm), then SIE ( $100 \pm 22$  bpm). All 10 participants completed the SIE and HIE protocols. Only 50% of participants were capable of completing the AIE protocol, and 80% completed the END protocol. Failure to complete the exercise protocol was due to volitional fatigue. Discussion As anticipated, different exercise intensities and durations elicited different heart rate responses. While the peak and mean heart rate results suggest AIE provides the greatest cardiovascular load, the feasibility of the exercise protocol is questionable due to the increased rate of failure to complete the protocol. Future investigations of the acute and chronic effects of different interval exercise protocols are needed to decipher the optimal exercise prescription for patients with CAD. ### CARDIAC AUTONOMIC FUNCTION IN RESPONSE TO SHORT-TIME HIGH-INTENSITY INTERVAL TRAINING

Kiviniemi, A.M.1, Hannukainen, J.C.2, Savolainen, A.2, Eskelinen, J.J.2, Virtanen, K.A.2, Tulppo, M.P.1, Kalliokoski, K.K.2

1: *Verve Research (Oulu, Finland)*, 2: *Turku PET Centre, University of Turku (Turku, Finland)*

**Introduction** High-intensity, short-time anaerobic interval training (HIT, 4 – 6 x 30 s all-out cycling efforts) has been shown to improve aerobic fitness within two weeks similarly to aerobic exercise training. However, the effects of HIT on cardiac autonomic function are unclear. Recent findings suggest that anaerobic exercise, such as HIT, impairs the acute post-exercise vagal reactivation compared to aerobic exercise that may suggest HIT causing larger strain on autonomic nervous system. The aim of the present study was to assess the autonomic adaptations to HIT and the relationship between the improvement in aerobic fitness and tolerance of autonomic nervous system to HIT exercises. **Methods** Nine healthy men (age:  $48 \pm 5$  years, BMI:  $26 \pm 3$ ,  $VO_{2max}$ :  $33.9 \pm 3.8$  mL/kg/min) underwent two-week progressive (from 4 to 6 bouts per session) HIT program including six training sessions. Maximal oxygen consumption ( $VO_{2max}$ ) was measured at pre and post training conditions by bicycle ergometer test. The subjects recorded R-R intervals (RS800, Polar Electro, Kempele, Finland) at supine (5 min) and standing position (5 min) every morning during the intervention at home (from  $\geq 2$  days before first to 3 days after last HIT session). Mean heart rate (HR) and vagal HR variability (SD1 from Poincaré plot) were analyzed for both position and their responses to standing were also calculated. The values of pre and post training days were averaged to evaluate training adaptations. Secondly, the acute responses to each HIT exercise (the change from training day to post training day) were calculated and averaged within each subject. Results  $VO_{2max}$  improved from  $2.81 \pm 0.37$  to  $2.92 \pm 0.34$  L/min ( $p < 0.05$ , range of response:  $-0.13 - +0.25$  L/min). After HIT intervention, no changes occurred in HR and SD1 at either position or in their responses to standing (e.g. for supine position  $57 \pm 7$  vs.  $55 \pm 7$  bpm and  $25 \pm 11$  vs.  $31 \pm 19$  ms, respectively,  $p = ns$  for both). Also, these measures did not change significantly from training day to post training day averaged over all sessions for each subject. The HR response to standing was  $19 \pm 6$  and  $18 \pm 7$  bpm for training and post training day, respectively ( $p = ns$ ). The change in HR response to standing from training to post training day correlated with the change in  $VO_{2max}$  ( $r = -0.95$ ,  $p < 0.01$ ). Those subjects whose HR response to standing increased after HIT session showed impaired training response in  $VO_{2max}$ . **Discussion** Short-time high-intensity interval training over two weeks seems not to cause adaptations in cardiac autonomic function. However, the change in the orthostatic response of HR from training day to post training day seems to be associated with the training response in aerobic fitness. The change in orthostatic HR response after training day may identify subjects who gain larger benefits from short-time high-intensity interval training.

### NIGHT AND POST-EXERCISE CARDIAC AUTONOMIC CONTROL IN FUNCTIONAL OVERREACHING.

Dupuy, O., Bherer, L., Audiffren, M., Bosquet, L.

*Université de Poitiers*

**Night and post-exercise cardiac autonomic control in functional overreaching.** Olivier Dupuy<sup>1,2</sup>, Louis Bherer<sup>3,4</sup>, Michel Audiffren<sup>1,2</sup> & Laurent Bosquet<sup>1,4</sup> <sup>1</sup>Faculté des Sciences du Sport. Université de Poitiers. <sup>2</sup>Centre de Recherche sur la Cognition et l'Apprentissage, CNRS. Université de Poitiers. <sup>3</sup>Département de Psychologie. Université du Québec à Montréal. <sup>4</sup>Centre de recherche - Institut universitaire de gériatrie de Montréal. **Introduction** Peak performance in sport requires training loads that will occasionally push human body adaptation possibilities to their limits. Overtraining syndrome (OTS) is an important menace on performances and health in athletes. OTS results when appears an imbalance between the training and/or not training stress and sufficient recovery, which could lead to an unexplained underperformance. Functional Overreaching (FOR) and Non Functional Overreaching (NFOR) are physical states reached just before OTS on the continuum, but the line between the two is very thin. It is therefore very important to validate markers to prevent the development of NFOR. Heart rate variability and/or heart rate recovery could be such a marker. The primary purpose of this study was to evaluate the effect of a two-week overload period immediately followed by a one-week taper period on the autonomic control of heart rate during the night or after exercise cessation **Methods** Eleven male endurance athletes increased their usual training volume by 100% for two weeks (overload), and decreased it by 50% for 1 week (taper). A maximal graded exercise test and a constant speed test at 85% of peak treadmill speed both followed by a 10-min passive recovery period were performed at baseline and after each period. Heart rate variability was also measured during the overall night or during slow wave sleep **Results** All participants were considered as overreached based on performance, physiological and psychological criteria. We found a decrease of cardiac parasympathetic control during slow wave sleep ( $HFnu = 61.3 \pm 11.7$  vs  $50.0 \pm 10.1\%$ ,  $p < 0.05$ ) but not during the overall night period (4h period after the bed time), as well as a faster heart rate recovery following the maximal graded exercise test ( $\tau = 61.8 \pm 14.5$  vs  $54.7 \pm 9.0$  s,  $p < 0.05$ ), but not after the constant speed test, after the overload period. There was a return to baseline for both measures after the taper period. **Conclusion** These findings clearly underscore the relevance of monitoring cardiac autonomic control in the follow-up of athletes, but also that care should be taken in selecting the most sensitive measures, since cardiac autonomic control is not affected uniformly by overload training.

**POST- EXERCISE COLD WATER IMMERSION: EFFECT ON CORE TEMPERATURE AND MELATONIN RESPONSES**

Robey, E., Dawson, B., Halson, S., Goodman, C., Gregson, W., Eastwood, P.

*The University of Western Australia*

Post- exercise cold water immersion: effect on core temperature and melatonin responses Robey, E.1, Dawson, B.1, Halson, S.2, Goodman, C.3, Gregson, W.4 and Eastwood, P.5 1: SSEH UWA (Perth, Australia) 2: AIS (Canberra, Australia) 3: WAIS (Perth, Australia) 4: RISES LJMU (Liverpool, United Kingdom) 5: CSS UWA (Perth, Australia) Introduction Many athletes regularly complete training sessions in the early evening, followed by cold water immersion (CWI), which can be beneficial to subsequent (24-48 h) performance (Vaile et al., 2008). Most studies that have investigated CWI have shown that core temperature markedly decreases after CWI (Gregson et al., 2011; Sramek et al., 2000; Vaile et al., 2008). Core body temperature and melatonin levels also vary with normal daily circadian rhythms (Weinert and Waterhouse, 2007). It is possible that CWI completed after evening exercise affects this normal circadian rhythm of melatonin secretion and core temperature. Methods 10 male cyclists completed two evening (~1800 h) fatiguing cycling trials followed by a 15 min CWI (14°C) or thermoneutral water immersion (TWI; 34°C), and were then monitored for 90 min post-immersion. Cycling involved 15 min at 75% peak power, followed by a 15 min time trial. Core (rectal) temperature, heart rate and salivary melatonin were measured over this period. Results Core temperature was not different between the two conditions pre-exercise (~37.4°C), post-exercise (~39°C) or immediately post-immersion (~37.7°C). Core temperatures in both conditions were significantly ( $p<0.05$ ) below pre-exercise levels at 60 and 90 min post-immersion. However, core temperature was significantly lower after CWI than TWI from 30 min ( $36.84 \pm 0.24$  vs  $37.42 \pm 0.40^\circ\text{C}$ ,  $p<0.05$ ) until 90 min ( $36.64 \pm 0.24$  vs  $36.95 \pm 0.43^\circ\text{C}$ ,  $p<0.05$ ) post-immersion. Salivary melatonin levels significantly increased ( $p<0.05$ ) from post-exercise (~5 pM) to 90 min post-immersion (~8.3 pM), but were not different between conditions. At 30 and 90 min post-immersion heart rate was significantly lower (~5-10 bpm,  $p<0.01$ ) after CWI than TWI. Discussion These results show that undertaking either CWI or TWI post-exercise in the evening lowers core temperature below baseline for at least 90 min, however the magnitude of decrease is significantly greater following CWI. The usual evening increase in melatonin is unaffected by exercise or post-exercise water immersion undertaken between ~1800 and ~2000h. **NEUROMUSCULAR ELECTRICAL STIMULATION INCREASES MUSCLE PROTEIN SYNTHESIS RATES IN TYPE 2 DIABETIC MEN**

Burd, N.A., Wall, B.T., Dirks, M.L., Verdijk, L.B., Snijders, T., Hansen, D., Senden, J.M., Vranckx, P., Dendale, P., van Loon, L.J.C.

*Maastricht University*

Introduction Neuromuscular electrical stimulation (NMES) is suggested to serve as viable substitute to physical activity during compromised conditions that impose muscle disuse (illness or injury). However, limited information is available on whether NMES affects acute molecular and cellular responses involved in the regulation of muscle mass. Thus, we aimed to determine the influence of NMES on mixed muscle protein synthesis rates and gene expression of key proteins involved in the regulation of muscle protein turnover. Methods Six sedentary, type 2 diabetic men (age:  $70 \pm 1$  y, BMI:  $26.5 \pm 1.0$  kg·m<sup>-2</sup>) received a primed, constant infusion of L-[ring-<sup>13</sup>C<sub>6</sub>]phenylalanine and 60 min of one legged NMES. Biopsies of the vastus lateralis were obtained at 0, 2, and 4 h after NMES to measure mixed muscle protein synthesis rates and muscle mRNA responses in the unstimulated (CON) and stimulated (STIM) leg. The NMES protocol consisted of a pulse duration of 500  $\mu\text{s}$ , pulse frequency of 60 Hz, and a 3 sec contraction – 3 sec relaxation time. Results Muscle protein synthesis rates were increased by 21% and 64% above CON at 0-2 h and 2-4 h in the STIM leg, respectively (both  $P<0.05$ ). Similarly, the cumulative MPS response (0-4 h) was greater ( $P=0.02$ ) in the STIM leg ( $0.049 \pm 0.008$  %·h<sup>-1</sup>) as compared to CON leg ( $0.039 \pm 0.008$  %·h<sup>-1</sup>). There were no differences in muscle mRNA responses of mTOR, p70S6K, FAK, FOXO1, MAFBx, MuRF1, or myogenin in the CON or STIM conditions. Myostatin mRNA demonstrated a biphasic pattern of expression in the STIM condition with a 3-fold increase at 2 h and a decline at 4 h as compared to the CON condition. Conversely, muscle MyoD expression trended to decrease immediately at 0 h and trended to increase at 4 h in the STIM leg as opposed to the CON leg (both,  $P<0.10$ ). Summary Our data demonstrate that NMES stimulates mixed muscle protein synthesis rates and inhibits muscle myostatin expression in human skeletal muscle. This work provides insight into the capacity of NMES to stimulate acute anabolic responses that allow net muscle protein accretion. These data lend credence to the use of NMES to attenuate muscle protein loss during periods of muscle disuse.

**FAT OXIDATION KINETICS DURING EXERCISE IN OBESE INDIVIDUALS**

Lanzi, S., Codecasa, F., Cornacchia, M., Maestrini, S., Salvadori, A., Malatesta, D.

*ISSUL, University of Lausanne, CH, Istituto Auxologico Italiano, Verbania, I*

Introduction An impaired ability to oxidize fat may be a factor in the obesity's aetiology (3). Moreover, the exercise intensity (Fatmax) eliciting the maximal fat oxidation rate (MFO) was lower in obese (O) compared with lean (L) individuals (4). However, difference in fat oxidation rate (FOR) during exercise between O and L remains equivocal and little is known about FORs during high intensities (>60% V'O<sub>2</sub>peak) in O compared with L. This study aimed to characterize fat oxidation kinetics over a large range of intensities in L and O. Methods 12 healthy L [body mass index (BMI):  $22.8 \pm 0.4$ ] and 16 healthy O men [BMI:  $38.9 \pm 1.4$ ] performed submaximal incremental test (Incr) to determine whole-body fat oxidation kinetics using indirect calorimetry. After a 15-min resting period (Rest) and 10-min warm-up at 20% of maximal power output (MPO, determined by a maximal incremental test), the power output was increased by 7.5% MPO every 6-min until respiratory exchange ratio reached 1.0. Venous lactate and glucose and plasma concentration of epinephrine (E), norepinephrine

(NE), insulin and non-esterified fatty acid (NEFA) were assessed at each step. A mathematical model (SIN) (1), including three variables (dilatation, symmetry, translation), was used to characterize fat oxidation (normalized by fat-free mass) kinetics and to determine Fatmax and MFO. Results FOR at Rest and MFO were not significantly different between groups ( $p \geq 0.1$ ). FORs were similar from 20-60%  $\dot{V}O_2$  peak ( $p \geq 0.1$ ) and significantly lower from 65-85%  $\dot{V}O_2$  peak in O than in L ( $p \leq 0.04$ ). Fatmax was significantly lower in O than in L ( $46.5 \pm 2.5$  vs  $56.7 \pm 1.9$  %  $\dot{V}O_2$  peak respectively;  $p = 0.005$ ). Fat oxidation kinetics was characterized by similar translation ( $p = 0.2$ ), significantly lower dilatation ( $p = 0.001$ ) and tended to a left-shift symmetry in O compared with L ( $p = 0.09$ ). Plasma E, insulin and NEFA were significantly higher in L compared to O ( $p \leq 0.04$ ). There were no significant differences in glucose, lactate and plasma NE between groups ( $p \geq 0.2$ ). Conclusion The study showed that O presented a lower Fatmax and a lower reliance on fat oxidation at high, but not at moderate, intensities. This may be linked to a: i) higher levels of insulin and lower E concentrations in O, which may induce blunted lipolysis; ii) higher percentage of type II and a lower percentage of type I fibres (5), and iii) decreased mitochondrial content (2), which may reduce FORs at high intensities and Fatmax. These findings may have implications for an appropriate exercise intensity prescription for optimize fat oxidation in O. References 1. Chenevire et al. *Med Sci Sports Exerc.* 2009 2. ### SPRINT TRAINING IN HYPOXIA PROMOTES AEROBIC CAPACITY AND PHOSPHOFRUCTOKINASE ACTIVITY.

Puype, J.

*KULeuven*

Joke Puype<sup>1</sup>, Karen Van Proeyen<sup>1</sup>, Bert Ackaert<sup>1</sup>, Jean-marc Raymackers<sup>2</sup>, Karolina Szlufcik<sup>1</sup>, Louise Deldicque<sup>1</sup>, Monique Ramaekers<sup>1</sup> and Peter Hespel<sup>1</sup>. <sup>1</sup> Research Centre for Exercise and Health, KU Leuven, Belgium; <sup>2</sup> Institute of Neuroscience, U. C. Louvain, Louvain-la-Neuve, Belgium. Introduction Contradictory findings are reported regarding whether exercise training in hypoxia may further stimulate training-induced adaptations compared with similar training in normoxia. Although there are different possibilities to profit from the hypoxic stimulus, the strategy of "live low-train high" or so called "intermittent hypoxic training" is receiving major attention (Vogt et al., 2001). In this study we compared the effects of 6 weeks sprint interval training (SIT) in normoxia or in hypoxia on exercise performance. Muscle glycolytic and oxidative capacity were analysed as well. Methods Healthy male volunteers (19-36yrs) performed SIT (3d/week, 4-9 x 30-s sprints) under either hypoxic (3000m;  $FiO_2$  14.5%  $O_2$ ; HYP, n=10) or normoxic (0m;  $FiO_2$  ~ 20.9%  $O_2$ ; NOR, n=9) conditions. The control group did not train (CON, n=10). Before and after the training period the subjects performed a maximal incremental exercise test followed by a 10' time trial in normoxia and hypoxia, in addition a needle biopsy was taken from the m.vastus lateralis Results Compared with CON, maximal power output was enhanced in HYP (+5-7%,  $P < 0.05$ ), but not in NOR, as measured at sea level as well as at moderate altitude. Moreover, HYP increased the workload corresponding with the onset of blood lactate accumulation in normoxia compared with NOR ( $P < 0.05$ ) and CON ( $P < 0.01$ ). Nevertheless, HYP and NOR produced similar improvements (~5%) in both 10-min time trial performance and mean power output in a 30-s sprint. Interestingly, muscle phosphofructokinase activity was stimulated by 60% in HYP and was higher than NOR following SIT ( $P < 0.05$ ). The activity of citrate synthase was not differently affected by NOR and HYP. Discussion Our data demonstrates that intermittent sprint training in hypoxia is an effective strategy to increase whole-body oxidative capacity at sea level and at altitude as well as to enhance glycolytic enzyme activity in skeletal muscle. The increase in PFK activity may be caused by a HIF-1 $\alpha$  dependent mechanism because HIF-1 $\alpha$  triggers PFK transcription (Wenger, 2002). Vogt M., Hoppeler H. (2010). Progress in cardiovascular diseases 52: 525-533. Wenger R. H. (2002). *FASEB J.* 16:1151-1162.

### INTRA- AND INTER-MUSCLE DIFFERENCES IN ARCHITECTURAL CHANGES OF THE QUADRICEPS FEMORIS INDUCED BY RESISTANCE TRAINING

Ema, R.1, Wakahara, T.1, Miyamoto, N.1, Kanehisa, H.2, Yanai, T.1, Kawakami, Y.1

*1: Waseda University (Tokorozawa, Japan), 2: National Institute of Fitness and Sports in KANOYA (Kanoya, Japan)*

Introduction Muscle architecture is the property of skeletal muscles that determines muscle functions. Architectural parameters such as muscle thickness and pennation angle change as a result of resistance training, but findings are not consistent among studies for the quadriceps femoris. This might be due to intra- and intermuscular differences in the training-induced changes in architectural profiles. We tested this by comparing the resistance training-induced changes in muscle architecture among the four muscles and between different regions within each muscle of the quadriceps femoris. Methods Eleven healthy men completed a resistance training program of unilateral knee extensions for 12 weeks (3 days / week, 8 reps x 5 sets / day at 80% of 1RM). Before and after the training period, muscle thicknesses, fascicle lengths, and pennation angles of the four muscles (2 - 4 regions per each muscle) were measured using ultrasonography. Anatomical cross-sectional areas (ACSAs) at the same positions as the ultrasound measurements were also determined from magnetic resonance images. Results Relative increases in the ACSAs of the vastus lateralis and the rectus femoris and in the muscle thickness of the rectus femoris in the distal region were significantly higher than those in the proximal region (e.g. for ACSA, vastus lateralis:  $12 \pm 8\%$  vs.  $9 \pm 7\%$ , rectus femoris:  $28 \pm 14\%$  vs.  $19 \pm 7\%$ ). Relative increases in the muscle thickness and pennation angle of the vastus intermedius in the medial region were significantly higher than those in the lateral region. Relative increases in the ACSA, muscle thickness, and pennation angle of the rectus femoris were significantly higher than those of the vasti. Discussion The present study shows that intra- and inter-muscle differences exist in the architectural changes of the quadriceps femoris induced by resistance training. This might be attributable to the regional differences in muscle activation during exercise, because Wakahara et al. (in press) indicated that those corresponded to the regional differences of muscle hypertrophy of the triceps brachii. The inter-muscle difference in the increase in pennation angle matched with that of muscle hypertrophy. This could influence force-producing capacity of the muscles after training. Our results indicate that the training-induced changes in the muscle architecture of the quadriceps femoris should be assessed by taking into consideration inter- as well as intramuscular differences. ### LONG-RANGE CORRELATIONS IN MOTOR UNIT DISCHARGE VARIABILITY REVEALED BY FRACTAL ANALYSIS

Yoshii, H., Nagata, K., Kouzaki, M.

*Kyoto University*

Introduction During muscle activity, motor unit (MU) discharge is not periodically constant but irregularly fluctuates. This MU discharge variability may reflect not only force or movement production but also force or movement fluctuations. Since the MU discharge variability is non-stationary, it is difficult to quantify the time-correlation of MU discharge variability. Thus, MU discharge variability has not been

thoroughly quantified, and the physiological mechanisms behind it remain as yet unknown. Therefore, the purpose of the present study is to examine the time-correlation of MU discharge variability by using fractal analysis. Methods Six healthy male participants were required to perform sustained planter flexion for 10 minutes. The target force was ~5% of MVC. A bipolar fine-wire electrode was inserted into lateral and medial soleus to record motor unit action potential (MUAP). MU discharge rate time series was discriminated from recorded MUAP time series (Kouzaki et al. 2012). The strength of long-range correlation of MU discharge interval was assessed by 'α' values in detrended fluctuation analysis (DFA) (Peng et al. 1994): white noise corresponds to an α of 0.5 whereas pink noise corresponds to an α of 1. An α value between 0.5 and 1 indicates long-range correlations such that any given MU discharge interval is dependent on a MU discharge interval at remote previous times. Results and Discussion From DFA results, a value was about  $0.80 \pm 0.09$ , indicating that the time characteristic of MU discharge has long-range correlations. When a time series has long-range correlations, the fluctuations of it indicate the anti-persistent behavior. Thus, present result suggests that the forces or movements produced by MU discharge are maintained at a certain level. In conclusion, DFA revealed the existence of feedback control in motor activity by the determining the quantity of MU discharge rate variability. ### THE INFLUENCE OF SEX, AGE AND HERITABILITY ON HUMAN SKELETAL MUSCLE CARNOSINE CONTENT

Baguet, A., Everaert, I., Achten, E., Thomis, M., Derave, W.

*University Ghent*

**Introduction** The dipeptide carnosine is found in high concentrations in human skeletal muscle and shows large inter-individual differences. Sex and age are determining factors, however systematic studies investigating the sex effects on muscle carnosine content throughout the human lifespan are lacking. Despite the large inter-individual variation, the intra-individual variation is limited. The question may be asked whether the carnosine content is a muscle characteristic, which may be largely genetically determined. **Methods** A total of 263 healthy male and female subjects of 9-83 y were divided into 5 different age groups; Prepubertal Children (PC), Adolescents (A), Young Adults (YA), Middle Adults (MA) and Elderly (E). We included 25 monozygotic and 22 dizygotic twin pairs among the entire study population to study heritability. The carnosine content was measured non-invasively in the gastrocnemius medialis and soleus by proton magnetic resonance spectroscopy (1H-MRS). **Results** In boys, carnosine content was significantly higher (gastrocnemius: 22.9 %; soleus: 44.6 %) in A compared to PC, while it did not differ in girls. A decrease (~16 %) was observed both in males and females from YA to MA. However, elderly did not have lower carnosine levels in comparison with MA. Higher correlations were found in monozygotic ( $r=0.86$ ) compared to dizygotic ( $r=0.51$ ) twins, in soleus muscle, but not in gastrocnemius. **Conclusion** In conclusion, this study found an effect of puberty on muscle carnosine content in males, but not in females. Muscle carnosine decreased mainly during early adulthood and hardly from adulthood to elderly. High intra-twin correlations were observed, but muscle-dependent differences preclude clear conclusions towards heritability. **References** Baguet A, Reyngoudt H, Poltier A, Everaert I, Callens S, Achten E, Derave W (2009). ### PROLONGED EXERCISE COMBINED WITH CALORIC RESTRICTION: GLOBAL INCREASE OF MUSCULAR MAXIMAL FAT OXIDATION AND BASAL AMPK PHOSPHORYLATION MOSTLY MEDIATED BY NEUROENDOCRINE EFFECTS.

Ponce-Gonzales, J.G.1, Losa-Reyna, J.I, Rodriguez-García, L.I, Guadalupe-Grau, A.1, Santana, A.1, Holmberg, H.C.2, Calbet, J.A.L.1

1.- *University of Las Palmas de Gran Canaria.* 2.- *SWSRC, Mid Sweden University.*

Skeletal muscle AMPK (AMP-activated protein kinase) stimulates glucose uptake and fatty acid oxidation. It is activated by events that increase the AMP/ATP ratio as exercise, fasting or caloric restriction. Caloric restriction, likely through PGC-1α and SIRT1, induces mitochondrial biogenesis, which in turn facilitates fat oxidation. **Aim:** To determine the mechanisms responsible for the increase in muscle fat oxidation capacity when prolonged exercise (PE) and caloric restriction (CR) are combined and, more specifically, to determine the role played by locally exercise-triggered and global neuroendocrine mechanisms. **Methods:** Basal AMPK phosphorylation, PGC-1α, SIRT1 and SIRT3 protein expression were determined by Western blot before (PRE), after four days of PE+CR and after three days of control diet and reduced exercise (10,000 steps/day; CD), in 15 overweight healthy volunteers. Muscle biopsies were obtained from both deltoideus muscles and one of the vastus lateralis. During PE+CR, subjects combined CR with 45 min of one-arm cranking (at 15% of their maximal intensity) followed by 8h walking at 3.5 km/h (30-35 km) each day. Subjects were randomly assigned to a Protein group (n=8) or Sucrose group (n=7), attending to the ingestion of 0.8 g per kg of body weight of either whey protein or sucrose per day, respectively. **Results:** Maximal muscle fat oxidation was increased in all muscles, but more in the legs than in the arms (P<0.05). AMPK phosphorylation was increased in all muscles after PE+CR (P<0.05), and remained elevated after CD (P<0.05). No changes were observed in SIRT1. In contrast, SIRT3 protein expression was reduced after PE+CR and CD (both, P<0.05). PGC-1α was reduced after CD (P<0.05 vs PRE). The level of AMPK phosphorylation was greater in the arm than in the leg muscles, however, PGC-1α and SIRT3 protein expression was higher in the leg than in the arm muscles. Insulin and leptin sensitivity were dramatically improved. No significant differences in signaling were observed among supplementation groups or between muscles. **Conclusion:** Neuroendocrine factors predominate over local muscle activity to induce the elevation of basal AMPK phosphorylation and the reduction of PGC-1α and SIRT3 protein expression, in response to PE+CR. An elevation of PGC1α protein expression is not required to increase muscle fat oxidation capacity in response to caloric restriction combined with exercise in humans. The increase in AMPK phosphorylation could explain part of the improvement in leptin and insulin sensitivity. *Granted by DEP2010-21866.*

### EXPRESSION OF CATALASE AND IMPROVED MITOCHONDRIAL FUNCTION, METABOLISM OF GLUCOSE AND FATTY ACIDS IN MUSCLE CELLS RESISTANT TO INSULIN

Barbosa, M.R., Alberici, L.C., Kettelhut, I.C., Sampaio, I.H., Silveira, L.R.

*UNIVERSIDADE FEDERAL DE SÃO CARLOS*

Reactive oxygen species (ROS) are involved in various physiological processes in skeletal muscle. However, the high availability of fatty acids (FAs) induces insulin resistance. The pathogenesis of insulin resistance involves disorders of lipid metabolism. Although the mecha-

nism is still unclear, high levels of ROS are involved in the condition of insulin resistance. Therefore, we examined whether the reduction of mitochondrial capacity and the insulin response imposed by the high availability of fatty acids are associated with an increase of intracellular hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>). METHODS The skeletal muscle cells were isolated from quadriceps muscle from Wistar rats and cultured in DMEM medium. The cells were transfected with pcDNA3 plasmid in medium containing Lipofectamine (1:4). After differentiation, the cells were exposed to the palmitic acid (700µM) during 72h. After this period, the cells were collected and the CAT content and mRNA were determined as a control experiment. In addition, the citrate synthase activity (CS) and the mRNA level of PGC1α were examined as mitochondrial biogenesis factors. Protein content of insulin receptor (IR) and Akt defined by the Western Blotting. The extracellular ROS production were determined by Amplex fluorescent probe. Whereas the oxygen consumption was measured at presence of glucose (5.6 mM) with or without insulin (0.1U) using a Clark-type electrode. In addition, glucose uptake and fatty acids oxidation determined by radioactive method. The catalase transfection was successfully transfected as indicated by catalase mRNA and content (p<0.05). The palmitic acid treatment markedly reduced the citrate synthase activity as well as the mRNA levels of PGC1α (p<0.05). This effect was accompanied by an elevated production of H<sub>2</sub>O<sub>2</sub> but reduction of oxygen consumption, glucose uptake and fatty acid oxidation (p<0.05). In addition, the levels of PGC1α, PPARβ, phosphorylated Akt and citrate lyase were markedly reduced. However, the catalase transfection was observed to attenuate this effect (p<0.05). Our results showed that elevated fatty acid availability reduces mitochondrial oxygen consumption favoring ROS production and insulin resistance. The improvement in the oxidative capacity of the cells by CAT overexpression improved mitochondrial biogenesis, oxygen consumption, as well as glucose uptake, suggesting that the control of intracellular ROS is an important therapeutic target in protecting against type 2 diabetes in muscle cells. ### DOES CARDIORESPIRATORY FITNESS MODIFY THE ASSOCIATION OF LOW BIRTH WEIGHT WITH INSULIN RESISTANCE?

Aoyama, T.1, Tsushita, K.2, Miyatake, N.3, Numata, T.4, Miyachi, M.5, Tabata, I.5,6, Cao, Z.B.1, Sakamoto, S.1, Higuchi, M.1  
1: Waseda University, 2: Aichi Comprehensive Health Science Center, 3: Kagawa University, 4: Okayama Health Foundation, 5: National Institute of Health and Nutrition, 6: Ritsumeikan University

Introduction Low birth weight, a proxy for fetal underdevelopment, has been established as an important risk factor for insulin resistance later in life (Hales et al., 2001). Recently, high level of cardiorespiratory fitness (CRF) has been recognized as an important factor in the prevention of insulin resistance. However, few studies investigated whether CRF could attenuate the insulin resistance associated with low birth weight (Laaksonen et al., 2003). The aim of this study was to examine the association of birth weight with insulin resistance, and how the association is influenced by CRF. Methods Subjects included 336 Japanese aged 20 to 59 years (males, 129 and females, 237). They had participated in our previous research, in which maximal oxygen uptake (VO<sub>2</sub>max), insulin resistance, and potential confounders such as abdominal circumference, blood pressure, triglycerides, HDL cholesterol, blood glucose, and smoking status were measured. Insulin resistance was assessed by the homeostasis model assessment of insulin resistance (HOMA-R), which is calculated according to the following: Fasting glucose (mg/dL) × fasting insulin (µU/mL) / 405. In this study, birth weight was obtained by mail-survey. A questionnaire was sent to participant using reply-paid envelopes. They were asked to provide their birth weights, either through Maternal and Child Health Notebook records or their mother's memory. The reply rate of this survey was 41% and the completed questionnaires of subjects were 336. Results Birth weight was inversely correlated with HOMA-R (P < 0.01) in the partial correlation analysis controlling for sex and age. Multiple linear regression analysis revealed that birth weight was associated with HOMA-R (β = -0.15, P < 0.01) even after adjustment for abdominal circumference, blood pressure, triglycerides, HDL cholesterol, and smoking status. Further adjustments for VO<sub>2</sub>max did not attenuate the relationship between birth weight and HOMA-R (β = -0.16, P < 0.001), although VO<sub>2</sub>max (β = -0.29, P < 0.001) was a stronger predictor of HOMA-R than birth weight. Discussion Insulin resistance is the major metabolic disorder in the early stages of development of type 2 diabetes or metabolic syndrome. This study indicates that low birth weight is associated with increased insulin resistance in Japanese adults, suggesting that low birth weight may be a cause of diabetes or metabolic syndrome later in life. Our study also suggests that lifelong influence of low birth weight on insulin resistance could not be offset by lifestyle modification such as increasing CRF. However, increase in CRF may improve insulin resistance independently of their low birth weight. References Hales CN, Barker DJ. (2001). Br Med Bull, 60, 5-20. #### SALIVARY SECRETORY IMMUNOGLOBULIN A INCREASES AFTER YOGA EXERCISE

Eda, N., Shimizu, K., Suzuki, S., Tanabe, Y., Lee, E., Akama, T.

Waseda University

Objective Salivary secretory immunoglobulin A (SIgA) is useful as an immunological indicator of the risk of upper respiratory tract infection and a stress marker. It was reported that relaxation, such as watching a humorous video and listening to classical music, increased salivary SIgA secretion. We hypothesized that yoga exercise aimed at relaxation might enhance SIgA secretion. The aim of this study was to determine the effects of yoga exercise on mucosal immune function by estimating salivary SIgA. Methods 29 healthy adults (59.7 ± 12.1 yr; 2 males, 27 females) participated in this study. Each of them was at rest for 90 min on the first day, and performed yoga exercise for 90 min on the second day. During yoga exercise, they first massaged their legs and pressed acupressure points for 20 min. Then, they held yoga poses (Warrior Pose, Extended Triangle Pose, Downward-Facing Dog etc.) for 65 min, and finally lay supine (Corpse Pose) for 5min. Saliva samples stimulated by chewing a sterile cotton at a frequency of 60/60s were collected. SIgA concentration was measured using enzyme-linked immunosorbent assay (ELISA), and SIgA secretion rate was calculated by multiplying SIgA concentration by saliva flow rate. Mental states were assessed using the Profile of Mood States (POMS) - Brief Form. Measurements were carried out before and after rest and yoga exercise. Results Saliva flow rate showed no significant change by rest and yoga exercise. SIgA concentration (before

yoga;  $27.8 \pm 11.9$   $\mu\text{g/ml}$ , after yoga;  $32.8 \pm 14.2$   $\mu\text{g/ml}$ ) and SIgA secretion rate (before yoga;  $39.2 \pm 29.8$   $\mu\text{g/min}$ , after yoga;  $49.8 \pm 36.9$   $\mu\text{g/min}$ ) significantly increased after yoga exercise ( $p < 0.05$ ). The mood scores of Tension-Anxiety (T-A), Depression-Dejection (D), and Anger-Hostility (A-H) were significantly lower after yoga exercise (T-A;  $36.6 \pm 3.4$ , D;  $41.1 \pm 3.8$ , A-H;  $37.7 \pm 1.8$ ) than before that (T-A;  $39.1 \pm 5.5$ , D;  $42.9 \pm 5.4$ , A-H;  $39.7 \pm 5.1$ ;  $p < 0.05$ ). Discussion In this study, salivary SIgA concentration and SIgA secretion rate significantly increased after yoga exercise. It has been reported that salivary SIgA decreased after high-intensity exercise, but showed no significant difference after low-intensity exercise. The mood scores of T-A, D, and A-H improved after yoga exercise, and these results agreed with previous studies. Therefore, in this study, it is possible that the effect of relaxation increased salivary SIgA concentration and SIgA secretion rate after yoga exercise. Conclusion In summary, we conclude that yoga exercise aimed at relaxation might improve the mood states and enhance mucosal immune function.

### ORAL-RESPIRATORY MUCOSAL IMMUNE RESPONSES DURING A MULTI-STAGE ULTRA-MARATHON COMPETITION IN HOT AMBIENT CONDITIONS.

Gill, S.1, Barrett, E.1, Freeth, E.1, Waterman, J.1, Marczak, S.1, Teixeira, A.3, Rama, L.3, Costa, R.J.S.1,2

Coventry University, UK; Coimbra University, Portugal.

Introduction: Endurance running has previously been linked with disturbances to mucosal immunity. The aim was to determine the effects of a multi-stage, ultra-marathon (MSUM) competition conducted over five consecutive days totalling 230km in hot ambient conditions ( $T_{\text{max}} 36.8 \pm 3.6^\circ\text{C}$ , RH 35%) on oral-respiratory mucosal immune responses. Methods: On each of the 5 stage days, unstimulated saliva and whole blood samples of ultra-endurance runners (UER  $n=37$ ; Control (CON)  $n=13$ ) were collected pre-stage, immediately post-stage and during recovery. Illness symptoms were monitored during and four weeks after competition. Salivary immunoglobulin A (IgA),  $\alpha$ -amylase, lysozyme and cortisol were determined by ELISA. Plasma osmolality (Posm) was determined by freeze-point osmometry. Data were analysed using a repeated measures ANOVA with post hoc HSD. Results: Saliva flow rate (SFR) was lower on pre-Stage 5 compared with pre-Stage 1 ( $p < 0.01$ ). Post-stage decreases in SFR were only observed on Stage 2 ( $p < 0.01$  vs. pre-stage). Post-stage decreases in salivary IgA concentration were observed on Stage 5 only ( $p < 0.01$  vs. pre), while salivary IgA secretion rate decreased post-Stage 2 and 5 ( $p < 0.01$  vs. pre). Salivary  $\alpha$ -amylase concentration and secretion rate increased post-Stage 1 to 3 (additionally Stage 5 for secretion rate;  $p < 0.01$  vs. pre). Salivary lysozyme concentration increased post-Stage 2 and 4 ( $p < 0.05$  vs. pre), while salivary lysozyme secretion rate increased post-Stage 5 only ( $p < 0.01$  vs. pre). Salivary cortisol concentration was lower pre-Stage 5 compared with pre-Stage 1 ( $p < 0.01$ ), and lower post-Stage 2, 3 and 5 compared with post-Stage 1 ( $p < 0.01$ ). Increases in Posm were observed post-stage throughout all stages ( $p < 0.01$  vs. pre), but remained within normal physiological range throughout MSUM (except for post-Stage 4, 298mOsmol/kg). UER presented higher SFR, salivary IgA and amylase secretion rates during Stage 3 recovery compared with CON ( $p < 0.05$ ). Additionally, higher salivary cortisol levels pre-Stage 1 and 3 were observed ( $p < 0.05$  vs. CON). Conclusion: Both neuroendocrine activity and hydration status may have contributed to fluctuations in SFR observed. Prevention of any substantial depressions in salivary IgA,  $\alpha$ -amylase and lysozyme responses pre-stage, post-stage, and during recovery along the MUSM competition may have adequately protected the oral-respiratory mucosal tract, as reflected by the low prevalence of illness symptoms reported ( $n=1$ ) during and the month following MSUM competition.

### SALIVARY HORMONES, IGA AND PERFORMANCE DURING INTENSE TRAINING AND TAPERING IN JUDO ATHLETES

Papacosta, E.1, Gleeson, M.1, Nassis, G.P.2

1: Loughborough University, UK, 2: Faculty of Physical Education and Sport Science, National and Kapodistrian University of Athens, Greece

Introduction Judo is a demanding combat sport that incorporates periods of intensified training in order to be able to optimise performance. Therefore, the need for tapering periods during the lead up to competition is essential. The aims of this study were to identify the time-course of change of selected salivary hormones, mucosal immunity, mood state and performance capacity during a 2-week taper in judo athletes, and to examine the diurnal variation in salivary testosterone (sT), cortisol (sC) and IgA (SIgA). Methods Eleven male judo athletes (mean $\pm$ SD: age  $20 \pm 6$  years;  $\text{VO}_2\text{max}$   $57.2 \pm 7.2$   $\text{ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ ; training experience  $8.5 \pm 4.7$  years) completed 5 weeks of training: 1 week of normal training (NORM), 2 weeks of intensified training (INT) and 2 weeks of exponential tapering (TAPER). Five times in total during the study period, subjects completed once per week a vertical and horizontal countermovement jump tests, a grip strength test, a Special Judo fitness test (SJFT), a multistage fitness test (MSFT) and a 3x300-m run test and anthropometric measurement. During this time, subjects also completed questionnaires to assess mood state and muscle soreness. Two daily saliva samples (at 07:00 and 19:00) were collected at the end of each week during NORM and INT and every day during TAPER. Results TAPER resulted in increased morning sT, decreased evening sC, lower muscle soreness and enhanced mood state (all  $p < 0.05$ ). A significant 7.0% improvement in 3x300-m performance time and 6.9% improvement in the vertical countermovement jump were also observed during TAPER. No significant changes were found in the SJFT and MSFT. Enhancements in 3x300-m and vertical jump performance were accompanied by an increased evening sT/C ratio and morning and evening SIgA secretion rate (all  $p < 0.01$ ). A diurnal variation in salivary markers was evident, with the higher values of sT, sC and SIgA absolute concentrations and secretion rate in the morning. Discussion This study has identified that TAPER increased sT, reduced sC and muscle soreness and enhanced mood state in trained judo athletes, and these results are similar to the findings of tapering in cyclists (Zehsaz et al., 2011). The improvements in anaerobic performance and power of lower extremities were concomitant with increased sT/C ratio and enhanced mucosal immunity. This study indicates that changes in salivary hormones, muscle soreness and mood state precede the improvements in performance and mucosal immunity. Furthermore, this study has shown that responses of sT, sC and SIgA absolute concentrations and secretion rate display a diurnal variation with the higher values in the morning, which are in agreement with previous studies in endurance athletes (Gleeson et al., 2001; Dimitriou et al., 2002) References Zehsaz F, Azarbaijani MA, Farhangimaleki N, Tiidus P. ## FUNCTIONAL ANALYSIS OF TFE3, THE ENERGY METABOLISM RELATED TRANSCRIPTION FACTOR, IN SKELETAL MUSCLES.

Naka, A.1, Iida, K.2, Iwasaki, H.1, Nakagawa, Y.1, Yamada, N.1, Shimano, H.1

1. University of Tsukuba, 2. Ochanomizu University

**Introduction** TFE3 is a basic helix-loop-helix transcription factor that has been recently noticed as a regulator of metabolic genes. Adenovirus-mediated expression of TFE3 in liver led to metabolic consequences, such as upregulation of metabolic genes, activation of various insulin signaling molecules and enhancement of glycogen synthesis (Nakagawa et al.). However, action mechanisms of TFE3 in other organ have not been clarified yet. Skeletal muscle is another important organ for energy metabolism which is related to energy production for exercise. Therefore, in this study, we investigated the effects that TFE3 brings on skeletal muscles. **Methods** To accomplish the objective of this study, we generated mice overexpressing muscle-specific TFE3. We compared the metabolic changes, gene expressions, histological findings and exercise capacity in this transgenic mice (Tg) with those in Wild type mice. Results Hk2 (hexokinase 2), Glut4 (glucose transporter 4) and Gys1 (glycogen synthase 1) expression significantly increased in Tg mice muscles. Concomitant with the enhancement of these genes expression, muscle glycogen stores were increased and exercise endurance capacity was enhanced in Tg mice. Expression of genes, such as Hk2, Glut4 and Gys1 were further enhanced in Tg muscles after 4 weeks of training. Consequently, insulin sensitivity was enhanced in Tg mice, and exhibited better improvement after 4 weeks of exercise training. Tg mice also exhibited enhanced expression of genes involved in insulin signaling and its downstream actions as Irs-2 (insulin receptor substrate-2) and Insig-1 (insulin-induced gene-1). **Conclusions** The findings in the present study suggest that TFE3 is a potential transcriptional regulator of muscle glucose metabolism. This potential role of TFE3 suggests that it may be used for treating metabolic diseases, as well as increasing endurance in sport. **References** 1. ## MATRIX METALLOPROTEINASE GENES ON CHROMOSOME 11Q22 AND RANGE OF MOTION

Burger, M., O'Connell, K., Raleigh, S.M., Posthumus, M., Collins, M.

University of Cape Town

**Matrix Metalloproteinase Genes on Chromosome 11q22 and Range of Motion** Burger, MC.1, O'Connell, K.1, Raleigh, SM.3, Posthumus, M.1, Collins, M.2,1 1: MRC/UCT Research Unit for Exercise Science & Sports Medicine, University of Cape Town, 2: South African Medical Research Council, Cape Town, South Africa, 3: Division of Health & Life Sciences, University of Northampton, UK **INTRODUCTION** A recent heritability study has demonstrated that human range of motion (ROM) has a substantial genetic component [1]. Furthermore, the COL5A1 BstUI RFLP has now been identified as the first gene variant to be associated with human ROM [2]. Other musculoskeletal soft tissue coding and/or signalling genes may also associate with ROM measurements. Therefore the aim of this study was to investigate the association between these four MMP gene variants and ROM measurements, including sit-and-reach (SR), straight leg raise (SLR) and total rotation of the shoulder (ShTR) in physically active individuals. **METHODS** Three hundred and thirty-four physically active Caucasians were included in this study. All participants were genotyped, using a Taqman assay, for the MMP1 1G/2G rs1799750, MMP3 A/G rs679620, MMP10 C/T rs486055 and MMP12 A/G rs2276109 variants. SR, SLR and ShTR ROM tests were performed on all participants and investigated for genotype effects. Significance was accepted  $p < 0.05$ . **RESULTS** There were no significant differences between the MMP1 (SR, mm: 1G1G 267±110, n=79; 1G2G 265±116, n=170; 2G2G 282±110, n=64;  $p=0.507$ ), MMP3 (SR, mm: AA 265±114, n=81; AG 277±102, n=160; GG 257±120, n=88;  $p=0.078$ ), MMP10 (SR, mm: CC 267±114mm, n=222; CT 273±102, n=70; TT 252±125, n=16;  $p=0.923$ ), MMP12 (SR, mm: AA 265±110, n=147; AG 270±110, n=61; GG 331±61, n=7;  $p=0.321$ ) genotypes and the SR ROM measures. In addition there were no significant genotype effects on SLR and ShTR. No haplotype- or age-genotype interaction with ROM was observed. It was interesting to note that individuals with the minor MMP12 rs2276109 GG genotype seemed to be much more flexible for all measurements (SR, mm: GG 331±61, n=7; AA+AG 266±110, n=308;  $p=0.135$ ), however, due to the sample size, this finding was not significant. **CONCLUSION** The MMP1, MMP3, MMP10 and MMP12 genes were not associated with ROM in this study. Due to the observed trends and rarity of the MMP12 GG genotype, a further analysis with a larger sample size is required. **REFERENCES** 1. ## EFFECTS OF ACUTE ENDURANCE EXERCISE ON GENE EXPRESSION IN SKELETAL MUSCLE: SEARCH FOR PUTATIVE MYOKINES

Catoire, M., Mensink, M., Boekschoten, M.V., Müller, M., Schrauwen, P., Kersten, S.

Wageningen University

**Background:** Exercise is known to be a powerful way to prevent and treat type 2 diabetes mellitus. Skeletal muscle is the predominant organ impacted by exercise but many of the metabolic changes induced by exercise may involve the liver. An important question is how exercise- or better skeletal muscle contraction - can alter hepatic function and insulin action. It is hypothesized that myokines play an important role in the cross-talk between skeletal muscle and liver. Since only a few myokines are known so far, identifying unknown myokines might provide valuable information for future research on the pathogenesis and treatment of type 2 diabetes mellitus. The aim of this study was to investigate the effect of acute endurance exercise on gene expression in skeletal muscle, with a focus on potential myokines, and to assess the importance of local and systemic effects of exercise on gene expression in skeletal muscle. **Methods:** Nine healthy, male subjects (40-60 years) cycled for one hour with one leg at a submaximal rate. The passive leg served as control. Before and after exercising, muscle biopsies were taken from both legs and analyzed with microarray to determine which genes changed in response to exercise. **Results:** One-legged cycling induced a significant change in 761 genes ( $p < 0.01$ ), of which 594 were significantly upregulated and 167 genes were downregulated. In contrast, in the control leg only 235 genes changed significantly ( $p < 0.01$ ; 165 upregulated, 70 downregulated). There was an overlap of 63 genes between both legs. In the exercising leg the top 3 regulated genes all belonged to the NR4A transcription factor family, with a highest fold change of 25 (NR4A2). In the non-exercising leg the top 3 consisted of ANGPTL4, PDK4 and ZNF750, with the highest fold change of 2.1 for ANGPTL4. Genes coding for potentially secreted proteins were (amongst others): ANGPTL4, THBS1 (both legs), CYR61, MCP-1, VEGFA and CX3CL1 (exercising leg). **Conclusion:** Exercise-induced gene expression changes are the result of both systemic and local stimuli. The NR4A transcription factor family are potential regulators of the

adaptive processes that take place in skeletal muscle during and after exercise. Several putative myokines are identified that are involved in processes such as angiogenesis, growth, insulin signaling and lipid metabolism.

### ACE I/D POLYMORPHISM AND ACTN3 R577X POLYMORPHISM AFFECTS MUSCULAR STRENGTH AND FUNCTIONAL CAPACITY IN RESPONSE TO HIGH-SPEED POWER TRAINING IN OLDER CAUCASIAN WOMEN

Pereira, A., Silva, A., Costa, A., Bastos, E., Marques, M.

UNIVERSIDADE DE TRAS OS MONTES

**Introduction** The angiotensin-converting enzyme (ACE) and the alpha-actinin-3 (ACTN3) gene have been associated with power phenotypes and have been suggested to influence skeletal muscle function in response to strength training (Lima et al. 2010). There is a paucity of research data concerning exercise training-induced adaptations in older population. The purpose of this study was to investigate the possible associations between ACE I/D and ACTN3 (R/X) polymorphisms and maximum strength, power and muscle function in older Caucasian women and their adaptation during 12-weeks of high speed power training. **Methods** Older women (n=139; age= 62.5+/-8.1; ID:n=52; DD:n=52; II:n=35 and RX:n=54; RR:n=52; XX:n=33) realized a period of intervention consisted of 40% of one repetition maximum (1RM) to 75% and 3 sets 4-12 reps in countermovement jump (CMJ) (Pereira et al., 2012). Strength was measured dynamically in leg extension exercise (1RMLE), power was evaluated by CMJ and functional capacity was recorded by sit to stand test (STS). ACE I/D and ACTN3 R/X polymorphisms were determined by polymerase chain reaction. Significant differences were performed by ANOVA (means±SD). The trainingxgenotype effects were analyzed by repeated-measures ANOVA. Results Whole body was independent of ACE and ACTN3 genotypes. At baseline no significant effects of both ACE and ACTN-3 genotype were found for all considered strength parameters. Genotype effect for ACE showed no statistically difference only in 1RMLE (P=0.187). But subjects with genotype DD had higher maximal strength than others after the high-speed power training. Although, genotype effect for ACTN3 showed significant effects for all measures: 1RMLE (p=0.011), CMJ (p=0.050) and STS (p=0.033). RR genotype exhibited a positive and a prevalence of strength (1RMLE: 33.1±6.4), power (CMJ: 0.164±0.02) and functional capacity (31.3±4.7) comparing to RX and XX genotypes. The combined influence of ACE DD+ACTN3 RR vs. ACE II+ACTN3 XX polymorphisms was also studied. In response to high-speed power training, the results showed that the D-allele carriers and R-allele combination seems to induce significant increases but only for 1RMLE. **Discussion** These data suggest that ACE genotype is not associated with muscle strength adaptation to high-speed power training. On the other hand, strength training response seems to be significantly affected by the presence of the ACTN-3 RR genotype alone or in combination with the ACE DD genotype in older Caucasian women's. The results provide a novel insight that these genetic variations may interact to determine muscle performance in older women. Lima, R. M., Leite, T. K., Pereira, R. W., Rabelo, H. T., Roth, S. M., & Oliveira, R. J. (2010). ACE and ACTN3 Genotypes in Older Women: Muscular Phenotypes. *Int J Sports Med*, 31, 1-7 Pereira A, Izquierdo M, Silva AJ, Costa AM, Bastos E, González-Badillo JJ, Marques MC. (2012). Effects of high-speed power training on functional capacity and muscle performance in older women. *Exp. Gerontol.* (2012) (accepted). doi:10.1016/j.exger.2011.12.010

### DIFFERENCES IN NATURAL KILLER CELL NUMBERS BETWEEN ELITE KAYAKERS AND NON-ATHLETES

Borges, G.F.1,4, Rama, L.1, Rosado, F.1, Alves, F.2, Santos, A.1, Gomes, B.1, Massart, A.1, Pedreiro, S.3, Paiva, A.3, Teixeira, A.M.2

1: FCDEF-UC (Coimbra-Portugal), 2: FMH-UTL (Lisbon, Portugal), 3: HC (Coimbra, Portugal), 4: ISB-UFAM (Brazil).

**Introduction** Prolonged strenuous exercise has been associated with a depression of immune function. At rest immune function in athletes compared with non-athletes has more similarities than disparities. However, there is a need for more studies that specify subsets and relates to specific times of the training. **Aim** The objective of this study was to see if chronic training was able to produce sustained differences in the peripheral blood cells in leukocytes subpopulations (WBC, granulocytes, monocytes, total lymphocytes, B and T lymphocytes, CD4+ and CD8+ T cells and NK cells) of athletes (kayakers) after a rest period of 6 weeks when compared to non-athletes. **Methods** The sample comprised 13 elite male kayakers, 20±3 years old, 75.0±7.9kg weight and 177.3±7.1cm stature. Their VO2max was 58.3±7.8 mL.kg.min<sup>-1</sup>. The non-athlete group comprised 7 healthy males, aged 18±1 years old, 81.3± 13.8 kg of weigh and 171.9±4.5cm stature. The athlete blood samples were collected at the beginning of the training season, after an off period of six weeks of training. To verify the differences between the athlete and non-athlete groups the Mann-Whitney U Test was used, and significance was set at P<0.05. **Results** No differences between the trained kayakers and the non-athletes were found at rest except for the total number and percentage of NK cells, namely in the CD3-CD56+CD8+ subset whose values were lower in the athletes. **Discussion** Our results seem to confirm that a reduction in NK cell numbers, especially in CD56+CD8+ subset even for longer periods of time. During exercise the number of circulating NK cells in the peripheral blood increases after one to two hours and then reduce to values that may be below the baseline (Del Giacco et al., 2001). The reduction in NK cell counts has been reported to persisted for up to seven days following exercise (Shek et al., 1994). The lower peripheral blood NK cell counts, especially CD3-CD56+CD8+ subset, in elite athletes may relate to reduced cellular production and cytotoxicity. On the other hand, this finding may reflect a chronic adaptation to training, suggesting that a decrease in the number of CD3-CD56+CD8+ cells could mean a lower risk of lysing autologous cells and decrease the inflammation status together with a redistribution of the NK cells into tissues for immune surveillance. **References** Del Giacco SR, et al. (2001). *Allergy* 56:215-223. Shek PN, et al. (1994). *France: CRSSA* : 121-137.

### THE AGT AND AGTR1 POLYMORPHISMS AND THEIR CONTRIBUTION TO PERFORMANCE-RELATED PHENOTYPES

Gineviciene, V., Jakaitienė, A., Milasius, K., Tubelis, L., Kucinskas, V.

Vilnius University

**Introduction** Among the individual components of renin-angiotensin system (RAS), the genes encoding angiotensinogen (AGT) and angiotensin-II receptor type1 (AGTR1) together with environmental factors play important role in physiological process. The significance of AGT C/T (C704T, Tre235Met) and AGTR1 A/C (3'UTR A1166C) polymorphisms is unknown in physical performance, anthropometric features, and for body composition in a population of athletes participating in different disciplines. **Methods** A total of 164 Lithuanian elite athletes (77endurance-oriented, 38power-oriented, 49"mixed group") and 240 healthy unrelated citizens (controls) were genotyped (PCR-RFLP). Vertical jump (counter-movement) test was used for the estimation of the short-term explosive muscle power (STEMP). Anaerobic alactic maximum power (AAMP) was estimated by the stair climbing test. Aerobic capacity function was determined using the maximum oxygen consumption (VO2max). Anthropometric measures were also estimated. **Results** There were no significant allele or genotype frequency differences between the athletes groups and the controls. The height, weight, muscle mass, handgrip strength and indices of functional

capacity STEMP, AAMP and VO<sub>2</sub>max were significantly different with respect to gender ( $p < 0.05$ ). Regression analysis for total athletes group showed that gender, fat mass and muscle mass have significant impact on AAMP ( $R^2 = 0.575$ ). The high muscle mass and low fat mass of an athlete lead to improved AAMP. There as STEMP and muscle mass (positive) are important describing AGTR1 A/C genotype ( $R^2 = 0.421$ ). High STEMP was observed of AGTR1 A/A genotype for men and of AGTR1 A/C genotype for women in speed/power-oriented sports. VO<sub>2</sub>max of athletes with AGTR1 A/A genotype was higher than of those carrying AGTR1 A/C and C/C genotypes ( $p < 0.05$ ). Discussion Reports on the RAS polymorphisms have to date focused on the AGT T allele and AGTR1 C allele, and its association with pathological events (cardiovascular complications). In the study, we employ an alternative way where the significance of AGT(C/T) and AGTR1(A/C) is accessed via their physiological effects in athletes. Statistical significance was reached for AGTR1(A/C) but not for AGT(C/T) polymorphism. We found that the influence of AGTR1 polymorphism on the physical capacity phenotype is different depending on gender and associated with a complex phenotypic characteristic. The athletes, carriers of the AGTR1 A/A genotypes, typically have better VO<sub>2</sub>max (aerobic capacity) as well as have better ability to achieve high muscle capacity indices when exercising short-term explosive muscle power tasks. Summarizing the results we conclude that in the Lithuanian athletes the AGTR1 genotypes show unique characteristics and the A allele of the AGTR1 might influence general sporting prowess.

##### WHAT PHYSICAL AND PERFORMANCE QUALITIES CHARACTERISE ELITE RUGBY SEVENS PLAYERS?

Higham, D.G.1,2,3, Pyne, D.B.1,2, Anson, J.M.2

1: Australian Institute of Sport (Canberra, Australia), 2: University of Canberra (Canberra, Australia), 3: Australian Rugby Union (Sydney, Australia)

Introduction Rugby sevens is a format of rugby union that has increased in popularity in recent years and will be contested at the Olympic Games from 2016. Marked differences in the specific demands of competition between 15-player rugby union and rugby sevens suggest the characteristics of high-level players in each format may also differ (Higham et al., 2011). Although the characteristics of 15-a-side rugby union players have been well defined, little information exists on rugby sevens players. We profiled the anthropometric, physiological and performance qualities of elite-level rugby sevens players, and quantified relationships between these characteristics. Methods Eighteen male international rugby sevens players undertook anthropometric (body mass, stature, sum of seven skinfolds, lean mass index), acceleration and speed (40-m sprint), muscular power (vertical jump), repeated-sprint ability (6 x 30-m sprint) and endurance (Yo-Yo intermittent recovery level 1 test and treadmill VO<sub>2</sub>max) testing. Associations between measurements were assessed by correlation analysis. Results Rugby sevens players had anthropometric characteristics (body mass  $89.7 \pm 7.6$  kg, stature  $1.83 \pm 0.06$  m, sum of skinfolds  $52.2 \pm 11.5$  mm; mean  $\pm$  SD) similar to backs in international 15-player rugby union. Acceleration and speed (40-m sprint  $5.11 \pm 0.15$  s), muscular power (vertical jump  $66 \pm 7$  cm), and endurance (VO<sub>2</sub>max  $53.8 \pm 3.4$  mL/kg/min) qualities were similar to, or better than, professional 15-a-side players. Coefficients of variation ranged from 2.5 to 22%. Relative VO<sub>2</sub>max was largely correlated with Yo-Yo distance ( $r = 0.60, 0.21$  to  $0.82$ ; 90% confidence interval) and moderately correlated with 40-m sprint time ( $r = -0.46, -0.75$  to  $-0.02$ ) and repeated-sprint ability ( $r = -0.38, -0.72$  to  $0.09$ ). A very large correlation was observed between velocity at VO<sub>2</sub>max and Yo-Yo distance ( $r = 0.89, 0.74$  to  $0.96$ ). Discussion Our findings provide an important first step toward the development of physical performance standards for players training to compete at the international level. International rugby sevens players require highly-developed speed, power and endurance to tolerate the demands of competition. The small between-athlete variability of characteristics in rugby sevens players highlights the need for relatively uniform physical and performance standards in contrast with 15-a-side teams. Simple field-based measures may be employed to assess training adaptations and prescribe velocity thresholds for performance monitoring in place of time-consuming and expensive laboratory-based tests. ##### STEROID HORMONE RESPONSE TO RUNNING AND CIRCUIT TRAINING EXERCISE IN TRAINED MEN UTILISING ELISA AND MASS SPECTROMETRY

Tanner, A.V., Nielsen, B.V., Allgrove, J.E.

University of Greenwich

Steroid hormone response to running and circuit training exercise in trained men utilising ELISA and mass spectrometry Tanner, A.V1; Nielsen B.V2 and Allgrove, J.E2 1: University of Hertfordshire, United Kingdom 2: University of Greenwich, United Kingdom Introduction Cortisol (C) and testosterone (T) are important biomarkers of acute and chronic stress (Urhausen et al., 1995). However, it is unclear how different forms of training affect the response of these hormones. Additionally mass spectrometry (MS) is currently widely used in pharmaceutical and health industries to measure small biomarkers; however use in sports research is limited. The purpose of this study was to examine the effect of various training sessions on salivary and plasma C and T in male runners and test the validity of MS to measure salivary stress hormones in exercise research. Methods 10 male runners completed the study. Four trials were completed: a) 30 min tempo run at lactate threshold (TEMP); b) 30 mins running alternating 3.5 mins at 90% and 2 mins at 30% VO<sub>2</sub>max (INT); c) 30 mins circuit training with 3x10 exercises of 30 secs with 30 secs recovery between exercises (CIR) and d) 30 mins rest (REST). Saliva and plasma samples were collected pre exercise and at 0, 15, 30 and 60 mins post exercise and rating of perceived exertion (RPE) and heart rate (HR) were recorded. Plasma and saliva samples were analysed for C and T with ELISA and saliva samples also with MS. Results Mean HR ( $\pm$ SD) was:  $161 \pm 7, 159 \pm 14, 130 \pm 12$  and  $63 \pm 1$  beats per minute for TEMP, INT, CIR and REST respectively with INT and TEMP higher than REST. Peak HR was higher in INT compared to CIR ( $p = 0.021$ ) and TEMP ( $p = 0.004$ ). Salivary C was higher in INT than REST ( $p = 0.004$ ) and remained elevated at 60 mins post exercise. Salivary T was higher than REST immediately post exercise in INT, TEMP and CIR ( $p < 0.05$ ). Overall, TEMP was higher than REST ( $p = 0.05$ ). Plasma and salivary measures were correlated in C ( $r = 0.813$ ) and T ( $r = 0.568$ ) with peaks occurring simultaneously. There was a strong correlation for salivary C measured with MS and ELISA ( $r = 0.934, p < 0.05$ ). Discussion This study found that an INT session elicited an increase in salivary C which is in agreement with previous research (Vuorimaa et al., 2008;

Hough et al., 2011). The study implied peak HR may indicate salivary C levels and could be a useful tool to assess training stress. Moreover, MS was revealed as a valid technique to measure the salivary C response to exercise and routine use in the exercise arena pursued. Further method development is required to reliably measure T with MS due to low assay sensitivity; however MS remains the gold standard in hospital and pharmaceutical analysis. ### REPEATED SPRINT ABILITY TASK DEPENDENCY: THE EFFECT OF RUGBY UNION SPECIFIC TASKS

Morel, B.1, Hautier, C.1, Rouffet, D.2

*Université Claude Bernard Lyon 1*

1: CRIS (Lyon, France), 2: ISEAL (Victoria, Australia) Introduction The ability of team sport players to repeat maximal efforts, referred as Repeated Sprint Ability (RSA), strongly influences both individual and team performances. It has been shown that RSA is task dependent but it is still mainly studied using cycling or running protocols (Girard and al., 2010). This study proposes to investigate RSA of rugby players during specific rugby tasks as running sprints (RU) but also mauling (MA) and scrummaging (SC) which are repeated all over the game. Methods 8 rugby players performed three RSA tests interspersed by at least 48h. We used RSA test consisting in 5 repetitions of 5s maximal exertion interspersed with a 20s passive recovery. Three tasks were investigated: RU monitoring average speed, SC using a yoke with a force sensor to measure the average force production over the 5s repetitions and MA assessed with a moving yoke (on wheels) recording the distance of displacement to evaluate the average speed on 5s. To complete the performance data obtained, blood lactate accumulation, EMG recordings of the Vastus Lateralis and Rate of Perceived Exertion (RPE Borg scale) were recorded for each task. Results The repetition of RU, MA and SC induced a decrease in the performance associated of respectively 23%, 13% and 7%. Furthermore, an EMG level decrease was observed only during MA (21%) and SC (13%) while blood lactate accumulation was significant just for RU (9.2 mmol/L) and MA (8.8 mmol/L). Average RPE was higher during the repetition of SC (7.8) compared to MA (7.2) and RU (7.1). Discussion RSA induced performance decrease for the three tasks tested but the decrease was more important for scrummaging compared to running sprints. Mauling is intermediate as it didn't differ from both others situations. Furthermore it is interesting to observe that EMG loss is present only for scrummaging and mauling tasks while blood lactate accumulation was significant just for the dynamic tasks. These results are in line with previous studies which demonstrated that voluntary activation failure occurred during the repetition of isometric contractions while the repetition of concentric contraction leads fatigue from peripheral perturbation (Babault and al., 2006). Mauling (slow dynamic task) seems to be intermediate with scrummaging (static) and running sprints (fast dynamic). The three tasks tested on the same RSA test causes different level of fatigue and seem to be linked to different fatigue causes. Thus RSA seems to be task dependent for rugby activity which tends to indicate that specific tests have to be developed and used depending on the players role. ### EVOLUTION OF SKIN TEMPERATURE AFTER AEROBIC TRAINING

Fernández-Cuevas, I.1, Sillero Quintana, M.1, García-Concepción, M.A.1, Gómez Carmona, P.1, Marins, J.2

*Technical University of Madrid (Universidad Politécnica de Madrid)*

Introduction Thermal response of skin temperature has been studied during exercise and immediately after (Merla, 2010). However, more studies about the influence of exercise on skin temperature through the time are required in order to better understand the impact of physical activity on thermoregulatory system and metabolism. The aim of this study was to evaluate the thermal response of skin temperature during and after aerobic exercise. Methods 15 physically active males (mean  $\pm$  SD: age, 22  $\pm$  3,34 yr; height, 178  $\pm$  0,04 cm; weight, 73,03  $\pm$  7,3 Kg) performed 45' of running on treadmill at a moderate intensity (60-75% HR). Skin temperatures were recorded before the exercise, immediately after, and 1, 2, 4 and 8 hours after the test by infrared camera (FLIR T335) in a standardised room, with controlled temperature (20,64  $\pm$  0,70C and 44  $\pm$  3% humidity), following the patterns set by Gómez Carmona et al. (2010) patented protocol. Skin temperatures from over 72 Region of Interest (ROI) were obtained using termotracker® software. An ANOVA analysis and post hoc Tukey analysis were carried out on the averaged temperatures by the moment of the measurement. RESULTS: The effects of the resistance training were different according to the considered area. In the upper limb, there were not found significant differences ( $p = 0.08$ ) within the 8 hours after the season training. Temperatures did not increase immediately after the training season (from 31.5  $\pm$  0.7  $^{\circ}$ C to 31.5  $\pm$  1.7  $^{\circ}$ C) but increased only 0,5  $^{\circ}$ C (32.0  $\pm$  0.7  $^{\circ}$ C) one hour after. Those values remained constant 8 hours after the training season (32.2  $\pm$  0.5  $^{\circ}$ C). In the lower limb, the averaged values increased significantly ( $p < 0,05$ ) immediately after the training season (from 30.1  $\pm$  0.9  $^{\circ}$ C to 31.1  $\pm$  0.9  $^{\circ}$ C), keeping similar values after one hour of recovery (31.1  $\pm$  0.7  $^{\circ}$ C), and then progressively reducing their values up to temperatures not significantly different from baseline 8 hours after the training. The abdominal area significantly ( $p < 0,05$ ) reduced his initial temperature after the training (from 32.7  $\pm$  1.04  $^{\circ}$ C to 31.4  $\pm$  1.7  $^{\circ}$ C), increasing significantly ( $p < 0,05$ ) the temperature after one hour of recovery (33.4  $\pm$  0.8  $^{\circ}$ C), and keeping significantly higher values ( $p < 0,05$ ) even 8 hours after the training season (33.8  $\pm$  0.7  $^{\circ}$ C). DISCUSSION: Ring (2000) suggested that the influence of exercise on skin temperature is up to 6 hours. However our results show that after 8 hours, skin temperature is still affected by exercise. It could be a relation with metabolism, and as Knab (2011) described, metabolism is affected by exercise up to 14 hours after, in that case, skin temperature could be also a metabolic indicator. Further investigation are required in order to go deeper on that topic References Gómez Carmona, P. M. (2010). Spain Patent No. P201031080 Merla, A (2010) *Ann Biomed Eng*, 38(1), 158-163. Ring, E., & Ammer, K. (2000) *Thermology International*, 10(1), 7-14. Knab, A. M. (2011) *Med Sci Sports Exerc*, 43(9), 1643-1648.

### COMPARISON OF PHYSIOLOGICAL RESPONSES IN INLINE-SPEEDSKATING TO RUNNING AND CYCLING. A SIMPLIFICATION OF EXERCISE TESTING?

Hildebrand, C., Mierau, J., Joisten, F., Strüder, H.K.

*German Sports University*

Introduction: Exercise testing is the basis for an individual targeted training and therefore indispensable in high performance sport. For optimal results, athletes are tested in a sport specific mode. However a specific inline-speedskating test poses some practical and methodological problems. Laboratory testing requires a special ergometer whereas field testing is only possible on a special skating track. Therefore, it was the aim of the study to investigate if results from more traditional exercise test in running or cycling can be transferred to

inline-speedskating. Methods: For this reason we examined five male athletes ( $29 \pm 3.9$  years,  $172.2 \pm 5.9$  cm and  $69.3 \pm 7.5$  kg) of the top national level. The subjects performed three incremental exhaustive tests (ergometer cycling (EC), field running (FR), field inline-speedskating (FIS)) in randomized order. The protocols were designed so that step duration and intensity increase were comparable. Oxygen uptake (VO<sub>2</sub>, absolute [l·min<sup>-1</sup>] and relative [ml·kg<sup>-1</sup>·min<sup>-1</sup>]), heart rate (HF [b·min<sup>-1</sup>]) and blood lactate concentration (LA [mmol/l]) were measured during each trial through a portable spirometry system (MetaMax 3B, Cortex, Germany). Results: Maximal values for absolute VO<sub>2</sub> ( $p=0.06$ ), LA ( $p=0.49$ ) and HF ( $p=0.63$ ) were not significantly different for all three exercise modes. Only the relative VO<sub>2</sub>max differed significantly ( $p=0.02$ ) between inline-speedskating (67.23) and cycling (82.04). At workloads corresponding to 2 and 4 mmol/l lactate no significant differences ( $p > 0.05$ ) could be revealed for HF or VO<sub>2</sub>. Even for HF and LA at respiratory thresholds (ventilator threshold, respiratory compensation point) no significant differences ( $p > 0.05$ ) could be detected. Conclusion: The results indicate that a cycling and running test revealed comparable physiological responses to an inline-speedskating test. Therefore we conclude that both a cycling and a running exercise test with the applied test protocol are a qualified alternative for an elaborate inline-speedskating test.

## EVALUATING THE CYCLIST'S VIBRATIONAL COMFORT DURING OUTDOOR FIELD TESTING

Vanwalleghem, J., Mortier, F., De Baere, I., Loccufier, M., Van Paepegem, W.  
Ghent University

Evaluating the cyclist's vibrational comfort during outdoor field testing Vanwalleghem J. (1), Mortier F. (1), De Baere I. (1), Loccufier M. (2), Van Paepegem W. (1) (1): DMSE (UGent, Belgium), (2): EESA (UGent, Belgium) Introduction The effect of vibrational exposure to sports activities has shown to have a negative influence on the performance of sportsmen. This superimposed vibration cannot be neglected during cycling, especially when cycling a cobblestones pavement. Because human comfort to vibrations is rather subjective, two methods exist to evaluate and quantify the vibrational comfort. The aim of this study is to set up an experimental test procedure for quantifying vibrational comfort and to find out which method is most appropriate for measuring comfort during cycling. Vibrational comfort and bicycle instrumentation The first evaluation method is written down in whole-body and hand-arm vibration standards (BS6841:1987), at which the acceleration level measured at the contact points between the cyclist and the bicycle is used for vibrational comfort evaluation. The second method is called 'absorbed power', which is a measure for the power lost by the human body due to vibrational exposure. Absorbed power is defined in terms of contact velocity and contact force at the contact points between the cyclist and the bicycle. The racing bicycle used for testing is equipped with acceleration and force sensors, each measuring the contact acceleration and contact force at the handlebar and the saddle in two orthogonal directions in plane of the bicycle. The contact velocity then results from integrating the acceleration signal. The entire data acquisition and storage system is packed in a backpack which is carried by the cyclist. Results The outdoor tests were performed with a Museeuw Flax 5 racing bicycle and a cycling speed of 30km/h is maintained over a 180m distance at both an asphalted and cobblestones pavement road (Mortier, 2011). The results were analysed using both evaluation methods and both show less comfort when cycling on cobblestones. If the cyclist is asked to handle the bicycle in such a way that his vibrational exposure decreases subjectively, this subjective feeling of increased comfort is also found in the results from the absorbed power method whereas the whole-body vibration method yields contrary findings. Another advantage of the absorbed power method is that power loss is expressed in Watt, which may be related to cycling performance. These initial tests have shown that the bicycle instrumentation is successful and future work can lead to conclusions on how comfort is related to e.g. tyre pressure, bicycle frame material, cycling position, etc. References BS 6841:1987, Guide to measurement and evaluation of human exposure to whole-body mechanical vibration and repeated shock. ## THE USE OF FREEPOWER® TO PREDICT 1RM

Comotto, S.1, Varalda, C.1, Di Muzio, D.1, Picerno, P.2, Piacentini, M.F.1  
1:University of Rome

THE USE OF FREEPOWER® TO PREDICT 1RM Comotto, S.1, Varalda, C.1, Di Muzio, D.1, Picerno, P.2 Piacentini, M.F.1 1:DISMUS (University Foro Italico, Italy) 2:SENSORIZE S.r.l., Rome, Italy Introduction To correctly prescribe a strength training program, it is essential to assess an individual's maximal strength (1RM). Determination of 1RM can be done directly and indirectly by prediction equations. The aim of the present study was to evaluate the validity and the reliability of the prediction of 1RM assessed with an inertial measurement unit during 4 different trials. Methods Six males ( $23 \pm 2$  yrs;  $76 \pm 11$  kg;  $177 \pm 6$  cm), all trained from different sports, with no experience in weight lifting, were recruited for the present study. The participants performed 4 trials (T1, T2, T3 and T4) for the upper (UL) and lower (LL) limbs, with a rest of minimum 2 days. The 1RM for UL was conducted at the chest press (Technogym, Gambettola, Italy) whereas the LL 1RM on a horizontal leg press (Technogym Gambettola, Italy). Each trial consisted in a direct measurement (1RM) and an indirect measurement for UL and LL. Tests on the same trial were randomized. The direct measurement was performed with an incremental test arriving at the load that participants could lift only once. The prediction of 1RM was assessed using FreePower (Sensorize S.r.l., Italy), a software that inputs acceleration data measured by a wireless inertial measurement unit fixed to the weight stack of the machine through a magnetic pocket. The software estimates 1RM by using a mathematical relationship between force, power and velocity measured in correspondence of at least three increasing loads. Repeated measures ANOVA ( $p < 0.05$ ) was used to evaluate differences between trials and between direct and indirect measurements. Intraclass correlation coefficients (ICC) were used to evaluate reliability. Retest correlation was measured by Pearson correlation coefficient ( $p < 0.05$ ). Results Differences emerged for 1RM between T1 and T2 ( $p < 0.05$ ) and T3 and T4, in both direct and indirect measurements for UL and LL. Thus, to evaluate the ICC only T3 and T4 were considered. A high ICC (range 0.973–0.998) were found for UL and LL in both direct and indirect measurements. In addition, the retest correlation was  $> 0.95$ . No differences emerged between direct and indirect measurements. Discussion Determination of 1RM is fundamental to prescribe correct resistance training programs in different sports. Direct 1RM measurement is time consuming, and may lead to muscle soreness as well as temporary deterioration of the function of the tested muscles. Differences founded for T1 and T2 demonstrate that a familiarization session is needed both for direct and indirect measurements. Since no differences emerged between direct and indirect measurements, results of this study demonstrated that FreePower is a reliable and useful device to determine 1RM. ## RELATIONSHIPS BETWEEN MAXIMUM STRENGTH, SPRINT ABILITY AND RATE OF INCREASE IN SPRINT TIME IN 20-M SLED TOWING

Martínez-Valencia, M.A.1, Cánovas, J.F.2, Romero-Arenas, S.2, Linthorne, N.P.3, González-Ravé, J.M.1, Alcaraz, P.E.2

Introduction Towing sled is one of many methods that have been implicated in the development of running speed, in this sense, it has been suggested that resisted sprint towing increases athlete's strength (Alcaraz et al., 2008). In this training method the load is adjusted to set the intensity of the exercise, and this weight is often set to a percentage of the athlete's body mass (Bm). Other authors (Murray et al., 2005) suggested that the athlete's sprint time increased linearly with increasing sled mass, but we hypothesized that the effect of the sled mass on athlete's sprint ability depends on strength or power variables. According to this suggestion, previous study (Murray et al., 2005) proposed assigning loads as a proportion of strength. In this respect, the aim of the study was to determine the relationship between maximum strength, sprint ability and rate of increase in sprint time. Methods Nine men active competitive athletes specialized in sprinting were recruited for the study ( $22.6 \pm 4.0$  years,  $1.83 \pm 0.04$  m, and  $72.4 \pm 8.0$  kg). The participants performed two tests in two days. The first day, 1-RM from a half-squat position, the last acceptable single repetition with the highest possible load was recorded. This load was also normalized by dividing by the participant's Bm. 48 hours after, seven 20-m sprints (unloaded sprints and sprints pulling resistances of 5, 10, 15, 20, 25 and 30% of Bm) from a standing start were done. The participants were placed 1-m behind the starting line. The resisted sprint trials were performed using a weighted sled attached to each athlete by a 2.7-m cord and waist harness, and an unlimited rest period was given between trials to minimize the effects of fatigue. The participant's unloaded and loaded sprint time were plotted against the load (%Bm), obtaining a straight line ( $y = mx + c$ ), the gradient of the line of best fit (m) was taken as the rate of increase in sprint time. Results A Pearson's Product moment correlation coefficient showed that there was no significant association ( $p \leq 0.05$ ) between 1 RM, also 1 RM/Bm, and rate of increase ( $1.80 \pm 0.36$  seconds per body mass). However, a significant correlation was found between unloaded sprint time and rate of increase ( $r = -0.74$ ). Discussion The lack of correlation to 1 RM may be explained by the stage of the season, the test was conducted at the end of the season. The effects of the sled-towing exercises on athlete's velocity profile may be due to the athlete's sprint ability in 20-m, suggesting that sled mass may be applied taking into account the individual sprint level of the athlete. Introduction Muscle soreness and weakness accompany intense or prolonged physical activity. Within 48 hours of injury, studies show that the majority of cells infiltrating muscle were macrophages (Clarkson and Sayers, 1999 & Fielding et al., 1993) and can therefore provide baseline comparisons for studying the effect of massage and its ability to modify muscle inflammation, weakness, and damage. In this study we extend our previous work by comparing the effect of immediate vs. delayed application of massage on peak torque recovery following intense eccentric exercise (EEX). Methods Eighteen skeletally mature New Zealand White rabbits were instrumented with peroneal nerve cuffs for stimulation of hindlimb tibialis anterior muscles. Following a bout of EEX, rabbits were assigned to a protocol of 0.5Hz, 10N, 15min massage applied immediately post exercise, 0.5Hz, 10N, 15min massage applied 48 hours post exercise, or exercised, non-massaged control. Using this design, six rabbits were tested under each of the three protocols. A torque-angle relationship was obtained for 21 tibiotarsal joint angles pre and post EEX and post four consecutive days of massage. Results EEX produced an average 49% ( $\pm 13\%$ ) decrease in peak isometric torque output ( $n=18$  hindlimbs; 6 immediate, 6 delay, and 6 exercised, non-massaged). Both immediate and delayed application of massage showed significant improvement of recovery of peak torque as compared to the exercised, non-massaged control ( $p=0.0005$  and  $p=0.0135$ , respectively). Immediate application of massage produced a significant 79% increase in peak torque recovery as compared to the exercised, non-massaged control ( $p=0.0005$ ). However, 48 hour delay of massage onset produced a significant 47% reduction of peak torque recovery compared to recovery produced by immediate application ( $p=0.0115$ ). Discussion While there is clinical significance of both immediate and delayed massage producing enhanced recovery compared to non-massaged control animals, massage beginning 48 hours post EEX had a significantly diminished effect in restoring function of EEX muscle compared to immediate massage. These data provide a starting point for linking the mechanical properties of skeletal muscle with physical therapies, and may shed light on the design and optimization of therapeutic massage based therapies for recovery from EEX in humans. ## DOSE-DEPENDENCY OF MASSAGE ON RECOVERY OF MUSCLE ACTIVE PROPERTIES FROM ECCENTRIC EXERCISE

Best, T.1, Butterfield, T.A.2, Zhao, Y.1, Zhang, X.1, Jarjoura, D.1, Haas, C.1

1: The Ohio State University (Columbus, Ohio, USA), 2: University of Kentucky (Lexington, Kentucky, USA)

Introduction Minimizing the symptoms of acute and chronic skeletal muscle pain and weakness is critical due muscle dysfunction causing high exercise attrition rates and the economic burden of physical inactivity (Macera et al., 2003 & Pratt et al., 2000). Treatment with alternative approaches (massage) has become increasingly common to mitigate exercise associated muscle pain and dysfunction. However, the mechanisms of action and optimal strategies have not been conclusively demonstrated (Cherkin et al., 2003 & Gordon et al., 2006). This study explored the effects of three massage parameters (frequency, magnitude and duration) on recovery of peak torque output following eccentric exercise (EEX). Methods Twenty four skeletally mature New Zealand White rabbits were instrumented with peroneal nerve cuffs for stimulation of hindlimb tibialis anterior muscles. Following a bout of EEX, rabbits were assigned to a massage protocol with frequency of 0.25 or 0.5 Hz at 5 or 10N for 15 or 30min. The contralateral hindlimb served as the EEX, non-massaged control. Using this design, three rabbits were tested under each of the eight protocols, which provided  $n=12$  rabbits for comparison of the high and low condition of each parameter. A torque-angle relationship was obtained for 21 tibiotarsal joint angles pre and post EEX and post four consecutive days of massage. Massage was performed via a customized device that allowed quantifiable, repeatable loading (Zeng et al., 2008). Results EEX produced an average 62% ( $\pm 13\%$ ) decrease in peak isometric torque ( $n=45$  hindlimbs; 24 massage, 21 exercised, non-massaged). There were differences on torque recovery between the two magnitudes ( $p=0.004$ ) and the two frequencies

( $p=0.012$ ), but no difference for the two durations. The 0.5Hz, 10N, 15min protocol produced greatest peak torque recovery, values approximately equal to pre-EEX. Discussion There were no significant interactions between or among the parameters, showing no dependence on the effect of these three parameters on torque recovery. This is the first evidence of a dose-response effect for magnitude and frequency of massage on recovery of in vivo active muscle properties following EEX. These results may help to explain the variability in human studies evaluating the efficacy of massage on recovery from EEX. References Butterfield, TA, et al. (2008) *Med. Sci. ### CHARACTERISTICS OF AGING AT THE GOLF SWING IN SIMILAR SCORE AMATEUR GOLFERS

Chikara, N., Tatsuya, U., Daisuke, Y., Akira, I.

*Osaka University of Health and Sports Sciences*

**Introduction** Physical fitness (e.g. muscle strength) decreases with aging. However, the golf score does not depend on the physical fitness and age, because senior golfers the contribution of the golf skill can be important for improving the golf score. Therefore, the purpose of this study was to examine the characteristics of golf swing for the adult amateur golfers with different age and similar golf score players. **Methods** A total of 15 male adult golfers (age: 36–74 years, average score:  $85.7 \pm 3.6$ ) were participated in this study. They performed a maximal swing with three clubs (a 1W, a 7I, a SW). They also performed 5 approach swings with a sand wedge assuming 10, 30, and 50 yards shot. The body and golf club position data were obtained by 3D motion capture system (Vicon. Vicon Motion Systems), and analyzed kinematic parameters of golf swing motion. Pearson's product-moment correlation coefficient was used to clarify the relation between the age and kinematic parameters. One-way analysis of variance (ANOVA) was used to consider the differences of kinematic parameters among the four age groups (aged: 36–45, 46–55, 56–65, and 66–75 years). Results Impact in the maximal swing, the club head speed at was negatively-correlated to age to all clubs (1W:  $r = -0.761$ ,  $p < 0.001$ , 7I:  $r = -0.699$ ,  $p < 0.01$ ; SW:  $r = -0.679$ ,  $p < 0.01$ ). Especially, the left hip rotation angle at impact was decreased with aging for the 1W ( $r = 0.601$ ,  $p < 0.05$ ). In the approach shot trials, the head speed at impact did not show any difference between age groups. Moreover, the coefficient of variation of head speed at impact was similar among all age. Discussion In general, the decrease in the head speed indicates the decrease in flying distance. Therefore, the result suggests that the flying distance in maximal shot was also decreased with aging. Moreover, the flying distance is considered to a first advantage to the golf score. However, the subjects in this study have a similar golf score in spite of a wide age group. Considering that the stability of flying distance at approach shot was not decreased with aging, we suggest that the skill to compensate for the decrease in the flying distance was the stability of distance and direction (e.g. maximal shot, approach shot and putting).

#### CYTOKINE LEVELS ARE MODULATED AFTER ACUTE EXERCISE PERFORMANCE IN HYPOXIA

Lira, F.S., Machado, P.P., Santos, S.A., Silva, E.T., Caris, A., Oller do Nascimento, C.M., Oyama, L.M., Tufik, S., Santos, R.V.T., de Mello, M.T.

*Unifesp*

**Introduction** Cytokine, mainly interleukin 6 (IL-6), interleukin 10 (IL-10), and interleukin 1 receptor antagonist (IL-1ra) play a key role in the immune system and metabolism during periods of stress and rest. It is known that, during and after exercise cytokine levels are modulated. However, the concentration of these cytokines during and after exercise in the hypoxia exposure is unknown. Our hypothesis is that exercise performance in the hypoxia exposure may impair cytokine levels. **Methods** Eight male subjects were exposed to normobaric hypoxic exposure at 4,200 m or sea level and performance treadmill exercise for 1 hour (~ 50%  $VO_{2peak}$ ). Plasma levels of cytokine (IL-6, TNF- $\alpha$ , IL-10 and IL-1ra) were determined at rest, and immediately and 1 h after exercise bouts. Results No differences were found in performance parameters (heart rate, oxymetric, rating of perceived exertion). IL-6 levels were increased immediately and 1 hour after exercise than rest in both altitudes ( $p < 0.001$ ). Interestingly, increased levels of TNF- $\alpha$  and IL-10 immediately after exercise, as compared as rest and 1 hour after exercise, were observed only in the sea level ( $p < 0.05$ ). We also found that, IL-1ra levels were increased 1 hour after exercise in relation to rest and immediately after exercise in both altitudes ( $p < 0.05$ ). Discussion The inflammatory markers increased in serum, skeletal muscle and adipose tissue following exhaustive exercise is well-established (Petersen and Pedersen 2005, Rosa et al 2011). There is no data in the literature about the effect of the performance exercise in hypoxic exposure at 4,200 m upon cytokine levels. Our exercise sea level data are according with the literature, showing that cytokine levels are increased after acute exercise. However, the usual condition is impairing when exercise is performance in hypoxic exposure at 4,200 m. These alterations may, at least in part, contribute to the immunosuppression state. These findings can help to better knowing upon effects the hypoxic exercise regimen on immune system response. 3 DAYS OF HEAT ACCLIMATION ATTENUATES THE MONOCYTE HSP70 RESPONSE FOLLOWING ACUTE HYPOXIC EXPOSURE IN HUMANS. Lee, B.I, Emery, E.2, Hussain, A.1, James, R.1, Mackenzie, R.2; Thake, D.1 1: Coventry University (Coventry, UK), 2: University of Westminster

(London, UK). Introduction Research has shown that adaptation to one environmental stressor can induce protective characteristics for exposure to a second, new stressor. This occurs via activation of common protective pathways, such as the cytoprotective heat shock protein family (HSP70) and is termed cross acclimation (Horowitz et al., 2007). To date no research has investigated cross-acclimation responses between heat and hypoxia in whole body humans. Thus the aim of this study was to determine whether the initial phase of heat acclimation could confer increased cellular tolerance to an acute hypoxic exposure in humans. Method 16 males were separated into two matched groups. Group A (mean  $\pm$  SD; Age  $21 \pm 2.7$  yrs; height  $1.85 \pm 0.08$  m; mass  $75.7 \pm 8.2$  kg; PPO  $289 \pm 52$  Watts; VO<sub>2</sub>peak;  $46.15 \pm 10$  ml.kg.min<sup>-1</sup>) completed 3 days of exercise heat acclimation; 60 minutes cycling at 50%VO<sub>2</sub>peak (Castle et al., 2011) in 40°C 20% RH. Group B (Age  $20 \pm 1.3$  yrs, height  $1.75 \pm 0.05$  m, mass  $76 \pm 10$  kg; PPO  $284 \pm 34$  Watts; VO<sub>2</sub>peak  $46.26 \pm 8$  ml.kg.min<sup>-1</sup>) completed 3 days of exercise training in 20°C, 40%RH. Each group completed a hypoxic stress test (HST; 15 minutes rest, 60 minutes cycling at 50%VO<sub>2</sub>peak at 3000m above sea level) one week before, and 48 hours following the final day of acclimation. Venous blood samples were collected pre and post each HST and pre and post acclimation on days 1 and 3 for determination of intracellular monocyte HSP70 concentrations via flow cytometry. Results There was no significant difference between group A and B in the percentage change from rest in HSP70 concentrations following the first HST ( $129 \pm 59$  Vs  $130 \pm 52\%$ ,  $p = 0.97$ ). Heat acclimation produced a significant increase in basal HSP70 in group A ( $p = 0.03$ ), with no change in group B ( $p = .218$ ). The percent change in HSP70 from rest following the second HST was significantly lower in group A Vs group B ( $100.1 \pm 13$  Vs  $133 \pm 33\%$ ,  $p = 0.02$ ). Discussion The 3-day acclimation period induced a significant increase in basal HSP70 in group A, with no change in group B. The HSP70 response following HST2 was attenuated for group A, possibly indicating improved tolerance and ability to cope with the hypoxic insult via increased reserves of HSP70. This may be due to increased cytoprotection via pathways up-regulated by adaptation to heat stress, and shared by hypoxia. Work examining the shared pathways involved, and how improved cytoprotection impacts on whole body human performance is ongoing in our laboratory. ### EFFECT OF PROLONGED EXERCISE ON ORAL AND BLOOD NEUTROPHIL FUNCTION

Davison, G.I, Jones, A.W.2

1: University of Kent (UK); 2: Aberystwyth University (UK)

Introduction The response of blood neutrophils to prolonged and/or strenuous exercise has been extensively studied but there is very little research on subpopulations other than peripheral blood neutrophils. In one previous study (Müns, 1994) neutrophils were obtained from nasal lavage following a 20 km run, in which a significant post-exercise increase in neutrophil number and a significant post-exercise decrease in phagocytic activity was observed. Neutrophils obtained in this way may represent a more appropriate subpopulation to study in relation to upper respiratory illness in athletes but there is limited research in this area. Such studies are widespread in dentistry research, in which strong associations have been observed between oral neutrophil functions and oral infection. The aim of this study was to determine the effects of prolonged exercise on the number and function of neutrophils obtained from the oral cavity. Methods Nine healthy men participated in a prolonged exercise bout (2.5 h at ~55% maximal oxygen uptake). Oral neutrophils were obtained with methods modified from Lukac et al. (2003). Briefly, 20 ml saline was swilled in the mouth for 2 mins before expectoration. This was then concentrated 15 times by gentle centrifugation ( $450 \times g$ ) and replacing the supernatant with a smaller volume of buffer (HBSS). Saliva samples were also obtained and screened for blood contamination and any subject ( $n = 2$ ) with a positive sample was removed from the analysis giving  $n = 7$ . Blood samples were obtained pre- and post-exercise and both samples (blood and concentrated oral rinse) were used for determination of PMA-stimulated oxidative burst (OBA) by chemiluminescence assay. Results Blood neutrophil count was increased ~3-fold post-exercise ( $P < 0.001$ ) but there was no change in the oral samples ( $P = 0.164$ ). Mean oral neutrophil OBA did not decrease significantly post-exercise ( $15 \pm 37\%$  decrease,  $P = 0.167$ ) whereas the post-exercise decrease in blood neutrophil OBA was significant ( $30 \pm 19\%$  decrease,  $P = 0.003$ ). Moreover, an actual post-exercise decrease in oral neutrophil OBA was only evident in 4 of the 7 participants compared to the clear decrease of blood neutrophil OBA evident for all 7 participants. Discussion A significant post-exercise decrease was only evident in blood neutrophil stimulated OBA. These findings suggest that there is poor agreement between the oral and blood neutrophil responses to prolonged exercise. This highlights the importance of studying other subpopulations of immune cells (other than peripheral blood) in relation to illness and infection risk in athletes and further research is required. ### LEUKOCYTE AND PLATELET COUNTS ELEVATED DUE TO ACUTE EXERCISE IN YOUNG SUBJECTS.

Alis, R.1, Romagnoli, M.1, Ibanez, S.1, Vaya, A.2

Universidad Catolica de Valencia

Leukocyte and platelet counts elevated due to acute exercise in young subjects. Alis, R.1; Romagnoli M.1; Ibañez, S.1, Vaya, A.2 1 Catholic University Valencia (Valencia, Spain). 2 La Fe University Hospital (Valencia, Spain) Introduction: Acute exercise causes transient ischaemia [1] especially in the muscle tissue being activate, resulting in local inflammation and leukocyte activation [2]. This study investigates the changes in leukocyte and platelet counts due to acute exercise in young subjects. Methods: The exercise protocol consists of a maximal incremental treadmill test (1 male 9 female,  $13,90 \pm 1,60$  years,) in fasting conditions. Blood samples were collected before and just after exercise from antecubital vein. Samples were analyzed in the first hour after extraction. Basic haematological parameters, white cell count, platelet count and red cell indices, including mean cell volume (MCV), mean haemoglobin concentration (MCH) and mean corpuscular haemoglobin concentration (MCHC) were measured in a Sysmex ME 8000 autoanalyser (TOA Medical Electronics, Japan). Fibrinogen content was measured using coagulometric techniques on an ACL-7000 autoanalyser (Instrumentation Laboratory, Italy). Differences between pre and post measures were assessed using multiple analyses of variance (MANOVA). Pearson's correlation coefficient was used to investigate relationships between variables. When data weren't normally distributed non parametric tests were used.  $p$  values  $< 0.05$  were considered as statistically significant. All values as mean  $\pm$  sd. Results: Platelet count augmented with exercise (pre:  $261,80 \pm 45,92$ , post:  $284,50 \pm 55,01$ ,  $p < 0,05$ ) leukocytes augmented as well (pre:  $6,41 \pm 1,19$   $10^3/\mu$ l, post:  $8,38 \pm 2,41$   $10^3/\mu$ l,  $p < 0,05$ ). We found a positive significant correlation between leukocyte and platelet count increment with exercise ( $r = 0,685$   $p = 0,029$ ). MCV augmented (pre:  $86,92 \pm 4,24$  fl, post:  $87,78 \pm 4,17$  fl,  $p < 0,05$ ) and MCHC decreased with exercise (pre:  $33,69 \pm 32,86$  g/dl, post:  $32,86 \pm 0,67$  g/dl,  $p < 0,05$ ). We found a positive correlation between the increase in leukocyte count and the decrease in MCHC ( $r = 0,635$   $p = 0,049$ ). Fibrinogen content decreased but not significantly with exercise. Change in fibrinogen was correlated with the rise in leukocyte count ( $r = 0,674$   $p = 0,033$ ) and platelet count ( $r = 0,740$   $p = 0,014$ ). Discussion As seen before leukocyte count [2] and platelet count [3] increases with exercise. The results points to an immune and inflammatory response to acute exercise in young subjects References 1. Camus, G., et al., Are

similar inflammatory factors involved in strenuous exercise and sepsis? *Intensive Care Medicine*, 1994. 20(8): p. 602-610. 2. ### THE EFFECT OF ANTIOXIDANT SUPPLEMENTS ON THE HEAT SHOCK PROTEIN RESPONSE TO STRENGTH TRAINING

Sorstrom, A.N., Cumming, K.T., Paulsen, G., Raastad, T.

*Norwegian School of Sport Sciences*

**Background:** The heat shock protein (HSP) response to strength training is considered as an important adaptation to maintain homeostasis in muscle fibres, by preventing damage and restoring structures. Strength training has previously been shown to increase HSP content (Gjovaag & Dahl, 2006, Paulsen et al., 2011). Antioxidant supplements, typically used by athletes, may however blunt or abolish the heat shock protein response, as seen after endurance exercise (Jackson et al., 2004, Khassaf et al., 2003). The purpose of this study was to investigate the effect antioxidant supplementation (vitamin C and E) on HSP70 and AlphaB-crystallin content, after strength training in recreationally trained subjects. **Methods:** 25 recreationally trained subjects completed 10 weeks of strength training with either vitamin C (1000mg/day) and E (235mg/day) or placebo supplements in a randomised double blinded fashion. The subjects trained their knee-extensor muscles 2 times a week; 2-3 x 7-10RM per exercise (squat, knee-extension, leg press and lunges). Muscle biopsies were obtained from m. vastus lateralis before, 6 weeks in, and after the training period. The protein levels of HSP70 and AlphaB-crystallin were analysed by western blotting. **Results:** HSP70 and AlphaB-crystallin content changed in neither the placebo group nor the antioxidant group, after 6 or 10 weeks of strength training, and there were no significant changes between the groups ( $p \geq 0.05$ ). We are currently running analyses of samples from additional subjects. **Conclusion:** These preliminary data indicate that vitamin C and E supplementation have no effect on HSP70 and AlphaB-crystallin protein levels in muscles exposed to 10 weeks of strength training. The lack of HSP response to strength training contradicts previous studies. This might be related to the fact that the subjects recruited to this study were familiar with this mode of exercise. **References** Gjovaag (2006). *Eur J Appl Physiol*, 98:310-22. ### ACUTE AND LONG TERM HEAT SHOCK PROTEIN RESPONSES TO BLOOD FLOW RESTRICTED RESISTANCE TRAINING AND HEAVY LOAD STRENGTH TRAINING IN UNTRAINED FEMALE SUBJECTS

Cumming, K.T., Rønnestad, B.R., Ellefsen, S., Ugelstad, I., Raastad, T.

*1 Norwegian School of Sport Sciences, 2 Lillehammer University College*

**Introduction** Heat shock proteins (HSP) have cytoprotective properties, and respond to different cellular stress. The muscular HSP content increase after strenuous exercise, and the magnitude of the response is related to the type of stress put on the exercised muscle (1);2). Heavy load strength training (HLS) induces a high-mechanical stress, and increase HSP levels (3). However, little is known about the HSP response to blood flow restricted resistance training (BFR), which is characterised by low-loads (low mechanical stress), and high metabolic stress. The aim of this study was to compare the acute and long term HSP response to HLS and BFR in untrained women. **Methods** Nine untrained female subjects performed 12 weeks unilateral knee-extension training twice a week. One leg was exercised with partial BFR induced by a pressure cuff (90-100 mmHg), 5 sets to failure at 30 % of 1 RM (45s rest). The other leg exercised 3x 10-6 RM of HLS (90s rest). Muscle biopsies were sampled before and 1h after the first training bout and before and 1h after the last training bout for both legs and exercise protocols. Muscle biopsies were homogenised and extracted into cytosolic- and cytoskeletal fractions. Homogenates were analysed for  $\alpha$ -B-crystallin ( $\alpha$ Bc) and HSP70 by western blotting. **Results** Resting levels of cytosolic  $\alpha$ Bc and HSP70 was unchanged after 12 weeks of training, whereas cytoskeletal HSP70 levels increased by 102 $\pm$ 111% in the BFR trained leg. In the untrained state (after the first exercise bout) cytosolic  $\alpha$ Bc levels were acutely reduced by 36 $\pm$ 24 and 40 $\pm$ 31 % for HLS and BFR, respectively, with a concomitant increase in cytoskeletal fraction of 8 $\pm$ 6 and 19 $\pm$ 19% for HLS and BFR, respectively. HSP70 was unchanged 1h after the first exercise bout for both exercises and fractions. After 12 weeks of training the acute  $\alpha$ Bc response was abolished whereas an acute cytosolic HSP70 response was manifested as a 58 $\pm$ 69 % increase in the BFR leg and a 51 $\pm$ 25 % increase in the cytoskeletal fraction in the HLS leg 1 h after exercise. BFR and HLS increased 1RM knee-extension to similar extend (12 $\pm$ 7 and 12 $\pm$ 7 %, respectively) **Conclusion** In the untrained state, both exercise protocols induced an acute response of small heat shock proteins, probably reflecting acute protection of stressed myofibrillar proteins. This stress response was, however, abolished in the trained state, indicating increased exercise tolerability. After 12 weeks of training an increase was only found in the cytoskeletal HSP70 levels after BFR. **Reference list** 1) Folkesson (2008). *Acta Physiol*, 194:215-222 2) Paulsen (2009). *J Appl Physiol*, 107:570-582 3) Paulsen (2011). *Eur J Appl Physiol*, Epub ahead of print

### DIVERGENCE OF INTRACELLULAR AND EXTRACELLULAR HSP72 IN TYPE 2 DIABETES: DOES FAT MATTER?

Rodrigues-Krause, J.1,2, Krause, M.1,2, O'Hagan, C.3, De Vito, G.3, Boreham, C.3, Newsholme, P.2,5, Murphy, C.1, Colleran, G.1

*(1) ITT Dublin, Ireland; (2) UCD Conway Institute and (3) Institute for Sport and Health UCD; (5) Curtin University, Perth, Western Australia*

**Introduction:** Recent evidence indicates that Extracellular Heat Shock Protein 72kDa (eHSP72) is increased in both Type 1 and Type 2 Diabetes (T2DM), although the physiological role of this protein in the blood is still unknown. However, levels of intracellular HSP72 (iHSP72) are reduced in diabetic patients, which has been related to insulin resistance in skeletal muscle. Therefore, the aim of this preliminary study was to compare the levels of eHSP72 and iHSP72 in obese and non-obese individuals with and without T2DM. **Methods:** Fifteen sedentary male participants (7 obese controls (C) vs. 5 obese and 3 non-obese T2DM; age 54 $\pm$ 9 years) were selected according to their BMI (30kg/m<sup>2</sup> for obese and 23-27kg/m<sup>2</sup> for non-obese participants) and evaluated for fasted values of blood lipid profile, serum CRP (C-reactive protein), plasma eHSP72 and skeletal muscle iHSP72 and heat shock factor 1 (HSF-1). Body composition was measured by whole body DEXA and muscle biopsy (vastus lateralis) was performed via a micro biopsy. **Results:** As expected, fasting glucose and HbA1c (C=6 $\pm$ 0.2 vs. T2DM=7.3 $\pm$ 0.5%) were higher in T2DM. Body fat percentage was lower in the non-obese group (21.9 $\pm$ 3.1%) compared with obese controls (34.1 $\pm$ 4.1%) and obese T2DM (39.6 $\pm$ 3.6%). Insulin resistance was lower in non-obese T2DM when compared with the obese T2DM group as indicated by HOMA-IR results. In obese T2DM a higher level of eHSP70 was observed (0.227 $\pm$ 0.03ng/mL) compared with obese controls (0.13 $\pm$ 0.04ng/mL) and non-obese T2DM (0.154 $\pm$ 0.05ng/mL). Skeletal muscle iHSP72 and HSF-1 levels were reduced in T2DM, but non-obese subjects were associated with a smaller decrease than the obese T2DM. **Conclusion:** Obese diabetic participants were associated with higher eHSP70 compared to non-obese T2DM and obese control participants. The level of iHSP72 was

lower in obese T2DM, which was associated with a reduction of HSF-1. Since elevations of eHSP70 are linked with cardiovascular and pro-inflammatory complications, lower eHSP70 found in non-obese T2DM could indicate better control of the disease. Moreover, iHSP70 and HSF-1 levels were reduced in obese T2DM, and to a lesser extent in non-obese. These results indicate eHSP70 elevations and iHSP72/HSF-1 decrements in diabetic participants could be related to obesity and its complications, rather than with diabetes alone. Our data also suggest that eHSP72 may be a potential biomarker for diabetes control.

### THE INFLUENCE OF DAILY PHYSICAL ACTIVITY IN TOTAL ANTIOXIDANT CAPACITY AND OXIDATIVE DNA DAMAGE, IN HUMAN LYMPHOCYTES

Soares, J.P.1, Bento, T.2, Joao, P.1, Oliveira, M.M.3, Peixoto, F.4, Gaivao, I.5, Mota, M.P.1

**INTRODUCTION** The study of physical exercise benefits in health is well documented in the literature. Some of the proposed mechanisms that explain organism function enhancement are related with bioenergetics and mitochondria improvement, associated with decrease in ROS production and increase e antioxidant capacity. As a consequence, oxidative damage tends to decrease as an adaptation to chronic exercise. Despite this explanation, results are inconsistent and might be explained due to methodological issues. One of the main problems might be related with the lack of daily physical activity control. Indeed, considering the inclusion in a group of physical exercise may be insufficient to discriminate active and sedentary people. So, we aimed to estimate the influence of total daily physical activity (TDPA) in oxidative stress related variables (total antioxidant capacity and oxidative DNA damage).  
**METHODS** Thirty health men, nonsmokers, above 40 years old, integrated this study. 15 of these subjects had a moderate to vigorous daily physical activity and the remaining ones had sedentary to lower daily physical activity, according to the levels proposed by the ACSM (1). Daily physical activity was measured during at least 4 days to 7 days with an accelerometer (ActiGraph); total antioxidant capacity was measured in plasma with ABTS Assay; and oxidative DNA damage was quantified by comet assay with FPG enzyme formamidopyrimidine DNA glycosylase sites (FPG sites, oxidized purine bases). Independent-Samples T-test was used to analyze differences between groups, and significant level was set at  $p < 0.05$ .  
**RESULTS AND DISCUSSION** Our results revealed that the most active subjects tend to evidence higher antioxidant capacity, suggesting the importance of an active lifestyle in the increasing antioxidant protection. This could mean that the most active individuals are more capable to resist against oxidative stress. One of the possible consequences of oxidative stress is the DNA damage of various cells. Our results showed that the most active subjects tend to have less DNA damage, which seem in accordance to the results of the total antioxidant capacity.

### MUSCLE FATIGUE EXPERIENCED DURING MAXIMAL ECCENTRIC EXERCISE IS PREDICTIVE OF THE PLASMA CREATINE KINASE RESPONSE

Hody, S.1, Rogister, B.1, Leprince, P.1, Wang, F.2, Croisier, J.L.3

*University of Liège*

**Introduction** Unaccustomed eccentric exercise may cause skeletal muscle damage leading to an increase in plasma creatine kinase (CK) activity. A wide variability among individuals in CK response to standardized lengthening contractions has been well described (Clarkson and Ebbeling, 1988). However, the reasons underlying this phenomenon have not yet been understood. Therefore, this study investigated a possible correlation between the changes in muscle damage indirect markers after an eccentric exercise and the decline in muscle performance during the exercise. **Methods** Healthy untrained male subjects ( $n=27$ ) performed an unilateral eccentric protocol consisting of three sets of 30 maximal isokinetic eccentric contractions of the knee extensor muscles, separated by a 30s rest phase. The muscular work was recorded using a Cybex Norm dynamometer to assess muscle fatigue by means of various fatigue indices. Markers of exercise-induced muscle damage (EIMD) including plasma CK activity, muscle soreness, and stiffness were measured before (pre) and 24hours after (post) exercise. Pearson's correlation coefficient was used to examine relationships between measured parameters. Results Large inter-subject variability was evident for both muscular work during exercise and changes in all markers of EIMD. In accordance with the conclusions of Chapman et al. (2008), we found that the cumulative work developed during the eccentric exercise session was not associated with changes in the markers of EIMD. More interestingly, the log (CKpost/CKpre) and muscle stiffness appeared to be closely correlated with the relative work decrease during the 3 sets of eccentric contractions ( $r=0.84$  and  $r=0.75$ , respectively). **Discussion** This is the first study to propose that the muscle fatigue profile during maximal eccentric protocol could predict the magnitude of the symptoms associated with muscle damage in humans. This original finding could be useful for researchers who apply intense eccentric protocols to immediately detect subjects having a higher risk of suffering from severe breakdown of muscle tissue, a condition known as rhabdomyolysis. In addition, the present data provide a valuable basis for mechanistic studies investigating the etiology of the large inter-subject variability to eccentric exercise. **References** Chapman DW, Newton MJ, Zainuddin Z, Sacco P, Nosaka K. (2008). *Br J Sports Med*, 42(7): 585-591. Clarkson PM, Ebbeling C. (1988). *Clin Sci (Lond)*, 75(3): 257-261.

### INFLUENCE OF HIGH TEMPERATURE AND INTENSE SELF-PACING CYCLING ON IMMUNE CELLS

Gomes, E.C.1,2, Oliveira, G.G.A.1, Nunes-Silva, A.2, Maia-Lima, A.1, Ramos, G.P.1, Pacheco, D.A.S.1, Goulart, K.N.O.1, Nunes-leite, M.M.S.1, Silami-Garcia, E.1, Teixeira, M.M.2

*Federal University of Minas Gerais*

High intensity exercise in a warm environment might elicit a higher physiological stress and, thus, mobilize a higher number of neutrophils and lymphocytes to the blood. The aim of this study was to investigate the effect of a warm environment on performance and total and differential blood cell count. **Methods:** 8 male cyclists (mean $\pm$ SD: 59 $\pm$ 9 mL O<sub>2</sub>/kg/min) performed, in a randomized order, two 30km time trials in an environmental chamber set at two different temperatures: warm trial (WT) 35°C and thermoneutral trial (TT) 25°C. Both environments had an average relative humidity of 68%. Blood samples were collected pre, post and 1h post-exercise. These samples were used to assess hematocrit, haemoglobin, total cell count, neutrophils and lymphocytes. The athletes' core temperature, heart rate (HR) and RPE were measured throughout the exercise protocol and they were allowed water ad libitum. Data related to the athletes' performance was analysed using 2-Sample t-test; all other data was analysed using General Linear Model ANOVA with Tukey's post-hoc

test (Minitab 15). Results: Athletes' performance was significantly impaired in the heat (mean, SD: WT 55.9±3.9 min; TT 61.0±3.8 min); nevertheless, the average HR was similar in both trials. The athletes initiated trials with a similar core temperature; however, in the heat, a significant increase in their core temperature was observed from km 14 onwards compared with the thermoneutral environment. Their core temperature at the end of the exercise was 39.4±0.6 (WT) compared to 38.6±0.4 (TT). The athletes did not finish the exercise dehydrated and there were no differences between trials: percentage of body weight loss 1.16% (TT) x 1.26% (WT). 1h post-exercise a significant increase in total cell count (TT 428±191 x 10<sup>5</sup>/ml, WT 464±181 x 10<sup>5</sup>/ml) and neutrophil (TT 272±110 x 10<sup>5</sup>/ml, WT 310±137 x 10<sup>5</sup>/ml) was observed compared with pre-exercise values (total cell count TT 262±79 x 10<sup>5</sup>/ml, WT 281±90 x 10<sup>5</sup>/ml; neutrophils TT 152±55 x 10<sup>5</sup>/ml; WT 148±38 x 10<sup>5</sup>/ml). Temperature did not affect these variables. Conclusions: Athletes' internal temperature was significantly higher during the trial in the hot environment, and this affected performance significantly. Nevertheless, the warm temperature did not interfere with the shift pattern of the immune cells analysed.

##### ACUTE EFFECTS OF BRISK WALKING ON CHOCOLATE CRAVING AND VISUAL ATTENTIONAL BIAS AMONG NORMAL AND OVERWEIGHT REGULAR CHOCOLATE EATERS AFTER DIFFERENT ABSTINENT PERIODS

Oh, H., Taylor, A.H.

*University of Exeter*

**Introduction** Despite good intentions failure to self-regulate snacking is a common problem, leading to weight gain. A 15 min brisk walk reduces self-reported chocolate craving (Taylor & Oliver, 2009) and consumption (Oh & Taylor, 2012). The mechanisms are less clear but cues may trigger attentional bias (AB) to chocolate images, and exercise may acutely reduce AB. We were also interested in if the effects differ among normal and overweight people, and for short and long-term abstinence from snacking. **Methods** Twenty normal (BMI 22.4 ± 1.9 kg/m<sup>2</sup>) and 21 overweight (30.6 ± 4.4 kg/m<sup>2</sup>) abstaining regular chocolate eaters (>100 gms per day), and 17 females (22.7 ± 2.9 kg/m<sup>2</sup>) abstaining during Lent (for at least 1 week) were randomly assigned in a cross-over design to a 15 min-brisk walk or rest (on separate days) condition. AB was assessed pre and post-treatment using an adapted visual dot probe task, with chocolate/neutral images presented for 200ms (initial AB; IAB) or 1000ms (maintained AB; MAB) using e-prime. Reaction time (RT) to probes replacing neutral and chocolate-related images was used to calculate IAB and MAB. Subjective craving on a 100-mm Visual Analogue Scale (Smeets et al., 2009) was assessed at pre-, during-, immediately after, and 10 mins after treatment. Results A 3-way mixed ANOVA revealed no moderating effect of BMI status or abstinence status. Fully repeated 2-way ANOVAS revealed significant condition x time interactions for IAB (F(1, 57) = 6.4, p < 0.05). Post hoc paired t-tests showed that at post-treatment IAB (t(57) = 2.8, p < 0.01, ESd = 0.42) after the exercise condition was significantly lower than after the rest condition. A fully repeated 2-way ANOVA revealed a significant condition x time interaction (F(2.09, 118.94) = 14.62, p < 0.001) for chocolate craving. Post hoc t tests (with Bonferroni correction) revealed that the craving was significantly lower than the rest condition immediately after (t(57) = 3.67) and 10 mins after exercise (t(57) = 4.15), p < 0.001). **Discussion** A short bout of moderate intensity exercise reduced cravings and AB to chocolate cues, regardless of BMI and abstinence period. Physical activity appears to help self-control capacity and self-regulation, in the presence of salient cues and similar inhibitory effects have been shown among smokers, heavy alcohol drinkers and among addicted animals. Sedentary behaviour may be a risk factor for self-regulation of mood enhancing and rewarding behaviours. **References** Avena, N. M., Rada, P., & Hoebel, B. G. ##### THE QUIET EYE: PRE-PROGRAMMING OR ONLINE CONTROL?

Vine, S.J., Lee, D., Moore, L.J., Wilson, M.R.

*University of Exeter*

**Introduction:** The Quiet Eye (QE; Vickers, 1996); a fixation that starts prior to the initiation of a movement and remains steady during the execution of the movement, underpins the accuracy and resilience of visuomotor skills. However, it is unclear whether the early (pre-programming of movement), or late (sensory feedback for the online control of movement) phase of the QE is most important for successful performance. The aim of this study was to examine if the proportion of the QE responsible for pre-programming and online control, varied during successful and unsuccessful putts under pressure. **Methods:** 55 expert golfers (mean handicap = 2.72, SD = 1.95) were asked to hole as many 5 ft putts as possible, until they missed. Anxiety was manipulated via financial incentives and non-contingent feedback, allowing for changes in QE to be assessed at the point of failure (the final, missed putt). Gaze was recorded using an ASL mobile eye tracker. Total QE (TQE), pre-programming QE (PPQE; duration of QE until fore-swing of the club) and online control QE (OCQE; duration of QE from initiation of fore-swing until contact) were calculated for the first, penultimate and final putts. Data were subjected to one-way repeated measures ANOVA. Significant effects were followed up with pair-wise comparison t-tests. **Results:** TQE was significantly shorter (both p < .001) for the final missed putt (M = 1564, SD = 802ms) compared to the first (M = 2245, SD = 976ms) and penultimate (M = 2175, SD = 819ms) putts. There was no main effect for PPQE (p = .21) suggesting that the duration of PPQE was consistent across all putts (M = 1443.42, SD = 786.48). OCQE was significantly shorter (both p < .001) for the final missed putt (M = 158, SD = 159ms) when compared to both the first (M = 310, SD = 108ms) and penultimate (M = 278, SD = 92ms) putts. **Conclusion:** The results suggest that the QE in golf putting provides late sensory information to support the online control of movement, potentially leading to a more precise contact between putter and ball. The association between reduced OCQE and performance failure supports previous research showing that QE fixation is 'cut short' under pressure (Vine & Wilson, 2010). Findings may shed light upon the debate surrounding the optimal timing of information pick-up in motor skills (Oudejans et al., 2002) and have implications for understanding the mechanisms that underpin the QE. **References:** Vickers, J.N. ## **ANALYSIS OF THE INCIDENTS REPORTED TO THE HOTLINE FOR SEXUAL HARASSMENT IN SPORT IN THE NETHERLANDS**

Vertommen, T., Schipper van Veldhoven, N., Van Den Eede, F., Sabbe, B.

*University of Antwerp*

**Background** The prevention policy of the Netherlands Olympic Committee\**Netherlands Sports Confederation (NOC\*NSF)* against sexual harassment in sports has been crucial for the social safety in the last decade. Rules of conduct were formulated for coaches and the NOC\*NSF hotline was installed. Victims and perpetrators of sexual harassment but also other (indirect involved) athletes, parents, coaches, board members of clubs and federations can reach this emergency telephone 24/7 for support, first relief and report on incidents. More support or advice, when necessary, is given by counselors for victims, sport organizations and (supposed) perpetrators. **Aim** The aim of this study is to analyze information on age, sex and position of victim and accused, form of harassment, circumstances and duration of the incidents, as reported in the registration forms to the hotline for sexual harassment in sport. **Method** In the decade 2001-2010, 601 reports of sexual harassment in sport are collected by the Project Sexual Harassment. The 601 registration forms have been analyzed and recoded into a dataset containing at least 323 actual incidents of sexual harassment. **Results** First results show that victims are in 48 per cent of the incidents younger than 16 years old and in 74 per cent younger than 20. Almost all of them (90%) are athletes, performing at all different levels. There is a variety of 46 different sport disciplines in the 323 incidents. The results also show that sexual harassments appears in many different forms, going from light verbal intimidation and unwanted functional touching to more severe forms as sexual abuse and rape. Correlation with other forms of non-sexual integrity violations is demonstrated. **Conclusion** The hierarchical relation between coaches and athletes is proven to be a risk factor for the onset and continuation of sexual harassment in any sport type. These results show the relevance of a diffuse set of prevention measures and will guide future policy.

## **CONTEXTUAL FACTORS IN MARTIAL ARTS AMONG YOUTH**

Vertonghen, J., Theeboom, M.

*Vrije Universiteit Brussel*

**Introduction** Although contrasting results are found regarding the presumed positive or negative effects of martial arts involvement among youth, little is known about the underlying conditions that give rise to these presumed effects. Many studies on the social-psychological outcomes of martial arts can be described as a "black box" testing approach, which means that the measurement of the outcomes of martial arts involvement is emphasised, while the context and actual processes that take place are not examined and remain somewhat mysterious. The aim of the present study was to analyse contextual factors that might influence social-psychological outcomes of martial arts as practised by youngsters. Based on the literature, the contextual factors in this study were defined as the type of guidance, structural qualities of martial arts, social context and participants' characteristics (Coalter, 2007; Holt, 2008; Mahoney & Stattin, 2000; Petitpas et al., 2005). **Methods** Youngsters practising aikido, judo, karate or kick-/Thai boxing (N=477, age=13.98±2.13years) as well as their parents (N=307) were assessed in terms of their goal orientations, physical aggressiveness, participation motives, psychosocial behaviour and social background. Next to this quantitative methodology, also a qualitative research design was set-up to take the type of guidance into account. In total, 20 aikido, karate or kick-/Thai boxing teachers were interviewed and observed in order to analyse different teaching approaches. **Results** Based on the results of the present study, it was found that depending on the type of martial art being practised, differences exist in several contextual factors: -Characteristics of participants: youngsters practising kick-/Thai boxing show more physical aggression and behavioural problems than judoka, aikidoka and karateka involved in this study. -Social context: kick-/Thai boxers are from a lower social class than the other martial artists involved in this study. -Type of guidance: differences were found in the teaching approach used by teachers of different martial arts as well as within one martial art. **Discussion** This study has provided a better understanding of several contextual factors that might influence social-psychological outcomes of martial arts involvement by young participants. Although further research would be relevant to explore interrelationships between the four contextual factors examined in this doctoral research and possible other factors, this study indicated that in order to formulate statements regarding outcomes of martial arts practice by young participants, the structural qualities of martial arts, type of guidance, participants' characteristics and social context have to be taken into consideration. **References** Coalter F (2007) *A wider social role for sport*. ## **USING ATHLETES' WORLD RANKINGS TO ASSESS PERFORMANCE OF COUNTRIES**

Malcata, R.M.1,2, Vandenbogaerde, T.J.1, Hopkins, W.G.2

*Auckland University of Technology*

**Introduction** There is a need for valid and objective methods to track the sporting performance of countries. Using the sport of swimming, we have developed a method in which athletes' world rankings are combined into a country score. **Methods** Top 150 rankings in the 32 Olympic swimming events were downloaded for 1990 to 2011. Each rank was assigned an importance score based on the number of athletes on each rank who ever achieved the top rank. The score was the proportion of such athletes predicted with a logistic model relating rank to proportion, and the modelled proportion was closely approximated by 1/rank. Scores for each country's individual athletes were then summed over all events to determine a country's performance score, representing predicted number of athletes ever achieving top rank. The method was validated by correlating country scores with country medal counts at major competitions (World Championships and Olympics). Other measures of country performance were derived using proportions of athletes achieving any top-three rank and winning gold at major competitions. **Results** The mean correlation over the 22 years between medal count and country score based on 1/rank was 0.93. For scores based on logistically modelled top rank, top-three rank and gold, the correlations were 0.94, 0.92 and 0.95 respectively. With score-estimates based on 1/rank, the three countries with the highest scores in 2011 were USA (a score of 41 athletes in the 32 events), China (21) and Japan (18). In the Olympic year 2008, the top three countries were USA (45), Australia (23) and Japan (17), while China was fifth (9). Although USA was always ranked first over the 22 years, the gap between first and second has become much smaller (a difference of 37 in 1990 vs 20 in 2011). **Conclusion** We have successfully developed a valid and practical method for tracking the performance of a country in sports that have an annual or seasonal published list of individual world rankings. This meth-

od includes performances of athletes not winning medals and therefore allows for more comprehensive performance assessment than methods based on medal counts. The method will allow tracking and comparison of performance within and between countries and sports.

### CAREER PERFORMANCE TRAJECTORIES OF OLYMPIC SWIMMERS

Allen, S.V., Hopkins, W.G., Vandenberghe, T.J.

AUCKLAND UNIVERSITY OF TECHNOLOGY

**INTRODUCTION:** Assessing the progression of a swimmer's competitive performance against benchmarks is a key element in talent identification and development, but information about changes in performance of elite swimmers during their formative years is needed to inform these benchmarks. Here we report the effects of age on performance and estimates of performance progression required to attain peak performance at the elite level. **METHODS:** The swimmers were the top 16 in each event of the 2008 Olympics. Their age at the Olympics was  $21.5 \pm 3.5$  y and  $23.9 \pm 2.9$  y for females and males respectively (mean  $\pm$  SD). We searched the Web for annual best times of each swimmer from their earliest available competitive performance through to 2011 (4285 times in the 13 stroke and distance combinations for each sex, for 391 swimmers, over  $9.8 \pm 2.9$  y). Times were log-transformed for analysis of changes in performance as percentages using a mixed linear model that included an effect for better performance in Olympic years, an effect for the use of new-generation swimsuits in 2009, and the effect of age on each swimmer's times modelled as individual quadratic trajectories. The trajectories were used to estimate age of peak performance and progression of performance leading to the peak. **RESULTS:** Olympic years and swimsuits accounted for additional performance enhancements in all events of  $1.2 \pm 0.3$  % and  $1.1 \pm 0.5$  % respectively (mean  $\pm$  between-event SD). After adjustment for these effects, the trajectories for females and males predicted peak performance occurring at ages  $23.2 \pm 2.1$  y and  $24.7 \pm 2.3$  y respectively (mean  $\pm$  SD). Peak performance occurred at later ages for the shorter distances, with a difference of  $\sim 3$  y between the shortest and longest distances. Both sexes showed similar progressions to peak performance: over ten years  $11.6 \pm 6.4$  %, and over five years  $3.0 \pm 1.6$  %. **DISCUSSION:** The improvement off their trend that swimmers showed at the Olympics could be due to better preparation and higher motivation for this pinnacle event, but swimsuits probably also contributed in 2008, as they did in 2009. The surprising finding that peak performance occurred a year or two after the Olympics could be due to Olympic selection of athletes who are still seen to be improving. The range in age of peak performance for different distances presumably reflects different maturation of aerobic and anaerobic capacities and should be considered in event selection. The progression over ten years shows too much between-swimmer variability to allow identification of potential Olympic swimmers, but around five years out from an Olympics our progression data should be useful for talent identification.

### PSYCHOLOGICAL WORK WITHIN A HANDBALL TEAM

Keczei, D.

*Sport School of Debrecen*

**PSYCHOLOGICAL WORK WITHIN A HANDBALL TEAM** Keczei, D. 1, Rathonyi-Odor, K. 2, Borbely, A. 3 1: Sport School in Debrecen (Debrecen, Hungary) 2,3: University of Debrecen, (Debrecen, Hungary) Introduction In professional sports just one thing counts really, which is performance. For this reason, the development of performance is constantly needed, which can be realized if we harmonize physical, psychic and social attitudes. Several factors must cling together for a sportsman to gain success. The aim of this paper is to present the function, structure, dynamics and goals of a men handball team, and to demonstrate a three-month-long therapy and its results. **Methods** The object of the therapy was to clear up the situation, handling and solution of problems and achievement of ambitions. The therapy was divided into 3 parts: before playoff (team work, fill in some tests, personal therapy, feedback of results), during playoff (team work, personal therapy) and at the end of the season. The team filled in the following tests: self-made sociometrics questionnaire, then self-made questionnaire about roles, tasks and responsibility in the team and relationship with the coach and finally the Pierre-test. Results The work was successful because the team has been building, developing self-awareness and better understanding of each other. Our belief strengthened that each team would need psychological preparation for sport because in professional sport building up the personality of psychic functions, properties is very important, and the regulation of these factors. On the basis of the self-assessment test results we were able to show for the team the importance of faith, the attitude to a match, since if only two aspects, motivation and self-confidence are highlighted, even then the difference is very marked. We also drew attention to the fact that after winning or losing the game we can quantify what happens to their self-esteem, confidence and other psychological factors, depending on whether they are satisfied or dissatisfied with their performance. **Discussion** The players recognized the professionalism and competence of the coaches, problems inherent in human relations have also improved. The team understood that it is very important to focus on the desired task. Great progress was that the new leader nominated by the players was helped by us to adapt to the new role. According to the measurement of Pierre-test we developed the team's medium-low attention with Autogenic Training. In carrying out the exercises, due to the number of errors committed, and social situations occupied in the team, individual therapies have led to progress. ### IS THERE AN ASSOCIATION BETWEEN SOCIAL ACTIVITIES AND PHYSICAL FUNCTIONS IN OLDER JAPANESE ADULTS?

Tsunoda, K., Kitano, N., Mitsuishi, Y., Tsuji, T., Yoon, J.Y., Yoon, J., Saghadzadeh, M., Monma, T., Takeda, F., Okura, T.

*University of Tsukuba*

**Introduction** Although exercise helps maintain an older person's physical functions (PFs), little is known about the association between their social activities and their PFs. This cross-sectional study investigated associations of habitual exercise and social activities with the PFs of older adults. **Methods** Our study included 261 community-dwelling older Japanese adults ( $73.5 \pm 5.5$  years old) recruited in 2010 from a cohort study in Kasama City, Japan. We used seven items to assess exercise and social activities: 1) exercise, 2) visiting relatives' or friends' houses, 3) recreational activity except exercise, 4) learning activity, 5) visiting temples or shrines, 6) paid work, and 7) unpaid work. We divided responses for 1) and 2) into low frequency ('once a year or less' and 'several times a year'), middle frequency ('several times a month'), and high frequency activities ('several times a week' and 'every day or almost every day'). For responses 3) to 7), low frequency was 'once a year or less', middle frequency was 'several times a year', and high frequency was all other responses. For PFs, we measured grip strength, sit and reach (SR), functional reach (FR), timed up and go (TUG), manipulating pegs (PEG), and choice stepping reaction

time (CSRT). We divided participants into two equal groups based on each PF score. We used logistic regressions, controlling for age, gender, education, and income. Results Middle and high levels of exercise were significantly associated with high scores in FR (ORs= 3.22 and 1.87), TUG (ORs=2.45 and 1.91), and CSRT (ORs=2.50 and 3.46). A middle level of visiting relatives' or friends' houses was associated with FR (OR=1.90), and a high level was associated with CSRT (OR=2.92). Middle and high levels of learning activity were associated with CSRT (ORs=2.07 and 2.61). A middle level of learning activity was also associated with FR (OR=1.85), and a high level was associated with SR (OR= 2.77) and PEG (OR=2.52). Only a high level of paid work was associated with CSRT (OR=2.23), while middle and high levels of unpaid work were associated with CSRT (ORs=2.28 and 4.83). Discussion CSRT was associated with four of six social activities. Krueger et al. (2009) reported that social activity was strongly associated with cognitive function. CSRT is known to reflect not only PF, but also cognitive function (Pijnappels et al., 2010), which we observed with our associations. Our data suggests that social activities, as well as habitual exercise, are important for maintaining PFs in older adults. References Pijnappels M, Delbaere K, Sturnieks DL, Lord SR. (2010). ## **RUNNING IN BEIJING – AN EXISTENTIAL INVESTIGATION OF CHALLENGED RUNNER IDENTITIES**

Ronkainen, N.1, Harrison, M.2, Ryba, T.V.1

1: Aarhus University, 2: University of Jyväskylä

Running in Beijing – an existential investigation of challenged runner identities Ronkainen, N, Harrison, M. and Ryba, T.V. Introduction Transnational migration is a growing phenomenon. While there is a growing body of research on migration in professional sports (Maguire and Falcous 2010), there is little work exploring non-professional athletes' migration experiences. In this research, we investigate non-elite Western runners' identity negotiations in their migration to Beijing, China. We examine the runner identity from historical and cultural perspectives, and discuss the contemporary running culture. Endurance running is a modernist pursuit with the emphasis on measured achievement (Chalmers 2006); Beijing with its heavy traffic and poor air quality is not favorable environment for these practices. Theory and method With existential psychology as our theoretical orientation, we explore the experiences in the light of fundamental existential questions such as, freedom, authenticity, loneliness and choice (Nesti 2004) and seek to understand how runner identity is negotiated when the everyday running practices are challenged. The ethnographic data was collected in two phases in 2011 and 2012 and includes participant observation, interviewing and first author's autoethnographic writing. Analysis In the first author's autoethnographic account two main themes emerged - the loss of control and isolation. Preliminary analyses on the interviews of other runners in Beijing revealed themes of realignment of meaning in running practices, running as a transnational culture and the great importance of local runner community. Some runners had found new positive dimensions from the challenge, while others talked about Beijing as solely a limitation. Discussion Our findings have several implications for sport psychology practitioners. First, all athletes encounter difficult times when they lose control over their sporting practices, such as injuries, transitions and burnout. Existential psychology is a suitable approach when working with athletes in these situations – it acknowledges isolation and questioning of meaning as fundamentals for human life, not pathology, and sees the encounter with hardship as potential for personal growth and authenticity. Second, knowledge of the discursive field of a specific sport sub-culture may enable practitioners to better understand the identity tensions athletes encounter. Third, based on the first author's autoethnography, we acknowledge the benefits of diary writing for athletes as a means of reflecting and understanding the boundary situations they encounter in their careers. ## **PRE-SEASON PLANNING STRATEGIES OF ITALIAN SERIE A CLUBS DURING 2009/10-2011/12 SOCCER SEASONS**

Francioni, F.

University of Rome

Introduction: In soccer, pre-season period is a fundamental phase of the entire annual periodization however there is a lack of information about how clubs plan it (Cadwell & Peters, 2009). Thus, the aim of present study was to analyze the pre-season planning of Italian Serie A (First League) clubs during three consecutive soccer seasons (2009/10; 2010/11; 2011/12). Methods: For each season investigated clubs were divided in three groups, according to the official ranking of the previous season: 1) 1-6 ranked (R1-6); 2) 7-17 ranked (R7-17); 3) the 3 clubs up-graded from Serie B (SB). Furthermore, clubs were divided in two geographical groups (i.e., northern and southern). A descriptive analysis was applied to investigate the following parameters: OS, duration of the off-season period (i.e., from the last official match of previous season to the first pre-season training); PP, overall duration of pre-season period (i.e., from the first training to the first official match); TC, number of days of the pre-season period spent in training camp; TP, duration of transition phase (i.e., from the last official match of previous season to the first one; FM, number of friendly matches played during the pre-season period. Results: In relation to the clubs' rank of the three seasons data showed a lower SD for TC and PP, which had a mean of 20±2 days (range: 18-21 days), 39±2 days (range: 38-41 days), respectively. Conversely, a higher SD was registered for TP and OS, which had a mean of 84±7 days (range: 77-91 days), 45±6 days (range: 39-50 days), respectively. Furthermore FM showed a mean of 6 matches. The same trend of data was showed also according to the geographical groups analysis. Discussion: These findings suggest that, independently by clubs' rank and geographical groups, clubs adopted very similar pre-season planning strategies for TC, PP and FM. This aspect can be explained by the training strategies (i.e. necessity and choices of coaches) and the economical support that each clubs receive (i.e. sponsors, paid camps, etc.). Conversely, the TP and OS gaps can be explained by the prestige (i.e. level of national and international competition) of clubs and the calendar constriction. References: Cadwell B.P & Peters D.M. **EFFECTS OF SLOW AND FAST STANDING BALANCE PERTURBATIONS ON H-REFLEX RESPONSE IN YOUNG AND ELDERLY MALES**

Piiirainen, J.M., Linnamo, V., Avela, J.

*University of Jyväskylä*

**INTRODUCTION** Synaptic transmission efficiency (H-reflex) between Ia afferent and motoneuron during static postural sway has been shown to decrease during ageing (Koceja et al. 1995). In addition, modulation of the H-reflex response seems to depend on the sway position and direction (Tokuno et al. 2008). However, it is not known how H-reflex is modulated during specific balance perturbations and if these modulations are age-related. Thus, the purpose of this study was to examine H-reflex response at different time points after sudden standing balance perturbation induced with two different accelerations in young and elderly males. **METHODS** Nine young (YOUNG, 27±3 years) and ten elderly (OLD, 68±3 years) males participated in this study. Standing balance perturbation was measured using custom build balance measurement device in SLOW (amplitude: 7.5cm, acceleration: 0.3m/s<sup>2</sup>, velocity 15cm/s) and FAST (amplitude: 7.5cm, acceleration: 4.0m/s<sup>2</sup>, velocity 25cm/s) conditions in anterior and posterior direction. H/M20% was measured and analysed 10ms, 30ms and 90ms after the onset of each perturbation in SLOW and FAST conditions. **RESULTS** During SLOW perturbation H/M20% was higher 10ms after the posterior (94%, p<.05) perturbation and 90ms after anterior (87%, p<.05) perturbation in YOUNG than in OLD. YOUNG had also slightly higher (n.s) H/M20% in four other time points. In FAST perturbations the differences were larger and YOUNG showed significantly higher H/M20% ratio 10ms and 30ms after both posterior and anterior perturbations (102-109%, p<.05). YOUNG had higher H/M20% in 30ms after the anterior (12%, p<.05) and posterior (23%, p<.05) perturbation in FAST than in SLOW, while no significant differences were observed in OLD. Both groups showed significantly reduced (YOUNG 91-92%, p<.01-.001 and OLD 75-84%, p<.01-.001) H/M20% 90ms after FAST anterior perturbation. **DISCUSSION** Elderly group had lower H-reflex response during both perturbation velocities. For young subjects H-reflex response was higher after the FAST perturbations than after SLOW ones, which was not observed in the elderly subjects. These differences might be due to age-related adaptability of the Ia-afferent pathway; for example higher pre-synaptic inhibition in elderly subjects (Morita et al. 1995). In any case, the mechanisms related to this phenomenon may impair balance control during sudden balance perturbations in elderly. **REFERENCES** 1. **DOES LOWER LIMB STRENGTH IS ASSOCIATED WITH MUSCLES RECRUITMENT DURING THE GAIT?**

Goncalves, M.

*São Paulo State University*

**Introduction** Lower limb strength declines with aging and it should be associated with an impaired functional performance during daily activities, such as, walking. In line of this, our study investigated the association between lower limb strength and the electromyographic (EMG) activation of trunk and lower limb muscles during walking. **Methods** Data of thirty seven older adult women were considered for this study. In the first visit in the data collect environment, hip, knee and ankle maximal voluntary joint torques were recorded. During the second visit in the data collect environment, volunteers were familiarized with the gait on treadmill at self-selected speed and were recorded 1-minute of gait on preferred treadmill walking speed. EMG signals were recorded at sample frequency of 2000 Hz on the muscles: internal oblique (IO), multifidus (MU), gluteus maximus (GM), biceps femoris (BF), rectus femoris (RF), tibialis anterior (TA) and gastrocnemius lateralis (GL). Strength was measured isokinetically at 120°/sec with five maximal repetitions and the concentric/concentric peak torque of hip, knee and ankle movement on sagittal plane was normalized by the mass of each volunteer. EMG signal was processed using full-wave rectification and a low pass filter (4th order and cut-off of 10 Hz) at the initial and final stance phase of ten first consecutive strides. Then, the linear envelop values were normalized by the mean of each muscle activation. We computed the Pearson and Spearman correlation coefficients to quantify the association between lower limb strength and EMG activation (significant level was set at p<0.05). **Results** Hip abduction strength were associated with TA activation during initial stance (p=0.02 and r=0.36) and with GM and MU activation at final stance (p=0.04 and r=-0.33; and p=0.01 and r=-0.4, respectively). Knee extensor strength is associated with RF activation at initial stance final stance (p=0.00 and r=-0.45; and p=0.02 and r=-0.37, respectively). Hip extensor strength was associated with RF activation at final stance (p=0.02 and r=-0.36). **Discussion** In older women a poor strength at knee extensor was associated with diminished recruitment of RF activation at initial stance which could reflect an impaired stability to reduce the anterior displacement of center of mass. The positive association between lower hip abduction strength and TA activation in initial stance could reflect a compensatory mechanism to maintain the stability. Therefore, older women with low knee extensor and hip abduction strength require higher levels of RF, MU and GM activation to push forward the center of mass at final stance. **Conclusion** The most novel aspect of this study is that older women with hip and knee impaired strength have changes in trunk, hip, knee and ankle muscles activation during walking. These changes in muscles recruitment could be related with a reduced stability during initial stance and an impaired capacity to move forward at the final stance and it could reduce the functional performance during walking.

**REACTION TIME ANALYSIS IN VISUAL RESPONSE USING ELECTROMYOGRAPHY AND ELECTROENCEPHALOGRAPHY**

Yotani, K.1, Tamaki, H.2, Nakamoto, H.1, Shibano, K.1, Yuki, A.3, Kirimoto, H.2, Kitada, K.4, Ogita, F.1, Mori, S.1

1: National Institute of Fitness and Sports, 2: Niigata University of Health and Welfare, 3: Aichi University of Education, 4: Ishikawa National College of Technology

**Introduction:** Visuo-motor related time (VMRT) can be calculated by subtracting the latency of motor-evoked potentials (MEPs) from pre-motor time (PMT) measured by electromyography (EMG) for simple reaction tasks (Yotani et al., 2011) and reflects the time elapsed from visual stimulation to the motor cortex through the visual cortex. Moreover, the peak latency in event-related potentials (ERPs) reflects the speed of information processing in the brain and can be recorded using electroencephalography (EEG). We assessed the relationship

between VMRT and the latency of ERP components (P300 [P3] and visual evoked potentials [VEP]) to visual stimulation. Method: Seven healthy male subjects (mean age, 24±3 yrs) were asked to flex the right thumb as quickly as possible in response to a visual signal. EEG was recorded on the scalp at Fz, Cz, Pz and Oz during the task, and EMG was recorded from the right flexor pollicis braevis muscle simultaneously with production of the light signal. MEP latency was measured from the flexor pollicis braevis muscle using transcranial magnetic stimulation (TMS). P3 latency was measured at Fz, Cz and Pz. Three VEP component latencies (P1, N1 and P2) were measured at Oz. In addition, VMRT was calculated as PMT minus MEP latency. Results: Significant positive correlations were observed between Fz-, Pz-P3 latency and VMRT ( $r=0.77-0.85$ ,  $P<0.05$ ), and no significant correlations were observed with the Cz-P3 latency. In the VEP, significant negative correlations were observed only between the Oz-P2 latency and VMRT ( $r=-0.76$ ,  $P<0.05$ ). Discussion/Conclusion: The ERP latencies of Fz-P3, Pz-P3 and Oz-P2 reflect the higher order brain processes. (Numata et al., 1998; Mehta et al., 2000). The results of the present study suggest that the VMRT is affected by those processing speed. References: Yotani K, Tamaki H, Yuki A, Kirimoto H, Kitada K, Ogita F, Takekura H. (2011). ### MUSCLE ACTIVATION UNDER DIFFERENT LOADING CONDITIONS DURING THE POWER CLEAN EXERCISE

Psycharakis, S., Dryburgh, I.

*Edinburgh Napier University*

**Introduction** The power clean is a component of the clean and jerk Olympic lift and is also commonly utilised as a training exercise in the training programs for several sports and individual athletes. However, no studies have explored the electromyographical (EMG) activation of the major muscles that are used during this exercise. The aim of the present study was to examine muscle activation during different loading conditions of the power clean exercise for the following muscles: gastrocnemius (GS), vastus lateralis (VL), transversus abdominus (TA), multifidus (MU), erector spinae (ES) and trapezius (TR). **Methods** Eight experienced lifters performed five maximal voluntary contraction (MVC) exercises followed by three sets of three power clean repetitions at 70%, 80% and 90% of their 1 repetition maximum, in randomised order. The peak and mean values for each load were calculated and normalised to the highest EMG value recorded during the power clean or the MVC exercise. **Results** There was a significant increase with load for the peak EMG values of the ES ( $p=0.002$ ) and the mean EMG values for the GS ( $p=0.002$ ) and VL ( $p=0.049$ ). There was a trend for increasing EMG with load for the other muscles, but no other comparisons reached significance. Interestingly, peak EMG values were significantly greater during the power clean than the maximal voluntary contraction in the MU and ES muscles. **Discussion** The findings suggest that when athletes attempt to increase lifting loads from 70 to 90%, performance can be improved if activation of the ES, GL and VL is increased. The relative contribution of each muscle group in the force generation required for the lift is, however, not known, and it cannot be suggested that these muscles are prioritised over others in training. Indeed, there was a trend of increase in muscle activation with load for all muscles, which suggests that performance could potentially be improved if activation of all six muscles tested in the present study increases. The peak EMG values recorded during the power clean exceeded in many cases those of the MVC exercise, a phenomenon previously noted by other researchers (e.g. Soderberg and Knutsen, 2000). This finding suggests that if the power clean exercise is used in training programmes it could have positive effects in muscle activation and, therefore, force development of the muscles tested in the present study. The findings also suggest that the power clean could be used as an MVC exercise for the MU and ES in future EMG studies. **References** Soderberg, GL, Knutsen, LM. (2000). *Phys Ther*, 80: 485-498.

### COMPARISON OF RECRUITMENT PATTERNS DURING ON-WATER AND ON-ERGOMETER ROWING.

Fleming, N., Donne, B.

*Trinity College Dublin*

**Introduction** The development of dynamic rowing ergometers which more accurately simulate on-water biomechanics have led to their increased use in training. While electromyographic (EMG) and kinematic analysis of rowing ergometer designs has been performed (Nowicky et al., 2005); a direct comparison to the on-water scenario is necessary. This study assessed recruitment patterns during on-ergometer and on-water rowing to validate task specificity of rowing ergometry. **Methods** Male rowers ( $n=10$ ; age  $21\pm 2$  yr, height  $1.90\pm 0.05$  m, body mass  $83.3\pm 4.8$  kg) performed 3 by 3 min exercise bouts at heart and stroke rates equivalent to 75, 85 and 95%  $VO_{2max}$  on both dynamic and stationary rowing ergometers and on-water. During exercise, surface EMG data were recorded (Mega ME6000) from Rectus Femoris (RF), Vastus Medialis (VM), Biceps Femoris (BF) and Erector Spinae (ES). Video recording at 50 Hz with audio triggers pre- and post-exercise facilitated data synchronisation. EMG data from 10 consecutive stroke cycles in the latter stage of each bout were amplitude processed via root mean squaring and normalised relative to pre-trial maximal sprints. Overall muscle activity within cycle was quantified via integration (iEMG) of rmsEMG data. Mean data for 10% interval of stroke cycle were compared using repeated measures ANOVA, Tukey post-hoc tests quantified significant differences ( $P<0.05$ ). **Results** iEMG activity significantly increased in RF (75 vs. 95%;  $118\pm 17$  vs.  $130\pm 20$   $\mu v.s$ ,  $P<0.01$ ) and VM (75 vs. 95%;  $195\pm 28$  vs.  $249\pm 29$   $\mu v.s$ ,  $P<0.01$ ) as exercise intensity increased. No intensity related differences were observed in BF or ES. Comparing rmsEMG data across rowing conditions revealed significant differences at discrete 10% intervals of stroke cycle in RF and VM. On-water RF activity was significantly greater than dynamic ergometry at the 10 and 20% interval ( $P<0.01$ ). On-water RF activity was also significantly greater than both rowing ergometer conditions at 60 ( $P<0.01$ ) and 70% ( $P<0.001$ ) intervals. During the drive phase (10, 20 and 30%) mean VM activity was significantly greater on-water vs. on-ergometer; these differences were most pronounced at 95%  $VO_{2max}$ . While on-water ES activity at the 20% interval was significantly greater than on-ergometer ( $P<0.05$ ) during exercise at 75%  $VO_{2max}$ , significant differences were not observed at 85 and 95%  $VO_{2max}$ . No significant differences in BF activity were observed across condition at any exercise intensity. **Discussion** Results suggest that significant difference exist comparing recruitment patterns during on-water and on-ergometer rowing. These differences may be due to altered acceleration and deceleration of moving masses on-ergometer which do not perfectly simulate the on-water scenario. **References** Nowicky A, Burdett R, Horne S (2005) *J Sports Sci Med* 4, 18-28.

## SYNERGETIC AND ANTAGONIST MUSCLE STRENGTH AND ACTIVITY RELATIONSHIPS IN WOMEN WITH KNEE OSTEO-ARTHRITIS

Patsika, G., Katis, A., Amiridis, I.G., Kellis, E.

*Neuromechanics Lab, Aristotle University of Thessaloniki*

Synergetic and antagonist muscle strength and activity relationships in women with knee osteoarthritis Patsika G. 1, Katis A. 1, Amiridis I.G. 1 and Kellis E. 1 1. Laboratory of Neuromechanics, Department of Physical Education and Sports Sciences, Aristotle University of Thessaloniki, Greece Abstract Introduction Osteoarthritis (OA) is the most common form of arthritis (Guccione et al., 1994) and the leading cause of chronic functional disability (O'Reilly et al. 1998). People with knee OA display limitations in daily activities (Hortobagyi et al., 2005) and a lower quality of their life (Baker & McAlindon, 2000), due to increased pain (Dekker et al. 1992; O'Reilly et al., 1998) and muscle weakness (O'Reilly et al., 1998). The purpose of this study was to investigate the differences in strength balance and muscle co-activity during an isokinetic test between women with knee OA and typical individuals. Method Twelve females with knee OA (age  $60.33 \pm 6.66$  yr, height  $1.61 \pm 0.05$  m, mass  $\pm 77.08 \pm 9.2$  kg) and eleven controls (age  $56.54 \pm 5.46$  yr, height  $1.64 \pm 0.05$ , mass  $\pm 77.36 \pm 13.34$  kg) volunteered to participate in this study. Subjects performed maximal isokinetic knee extension and flexion strength at  $60^\circ/s$ ,  $120^\circ/s$  and  $150^\circ/s$  was measured. Surface, electromyography (EMG) from the biceps femoris (BF), vastus lateralis (VL) and vastus medialis (VM) was recorded during all tests. Functional and conventional ratios and synergetic (Aagaard et al., 1995; Kellis & Katis, 2007) and co-activation ratios were calculated. Analysis of variance was used for the statistical analysis. Results During isokinetic protocol people with knee OA demonstrated higher moment ratios during isokinetic tests. Moreover, people with knee OA have shown higher VM to VL ratio during extension and knee flexion and lower co-activation ratio during knee flexion. Discussion People with knee OA might demonstrate different synergetic and antagonist muscle strength and activity in order to stabilize the knee joint during maximum contractions. Concentric and eccentric forms of exercise can be used in decreasing muscle weakness in the knee joint region and also can impede the disease progression, in order to perform the knee joint muscles more efficient. Key words: arthritis, quadriceps, hamstrings, co – activation, strength testing, conventional ratio, functional ratio Bibliography Aagaard P, Simonsen EB, Trolle M, Bangsbo J, Klausen K. ## NORMALIZATION OF MUSCLE HARDNESS FOR LOWER LIMB MUSCLES BY CONSIDERING INDIVIDUAL MUSCLE THICKNESS

Murayama, M.

*Keio University*

NORMALIZATION OF MUSCLE HARDNESS FOR LOWER LIMB MUSCLES BY CONSIDERING INDIVIDUAL MUSCLE THICKNESS Murayama, M.1, Kuwada, K.2, Uchiyama, T.2, Yoneda, T.3 1 Institute of Physical Education, Keio University, 2 Faculty Science & technology, Keio University, 3 School of Health & Sports Science, Juntendo University (Japan) Introduction Changes in muscle hardness are commonly evaluated for medical rehabilitation and conditioning in sports medicine. Horikawa et al. (1993) non-invasively evaluated muscle hardness using a two-layered spring model with a pressure device. Recently, we proposed a modification to this method that considers individual muscle thickness (MT) (Murayama et al. 2008). In brief, we compared the hardness values calculated from 5–30% MT and concluded that muscle hardness should be calculated from a range of approximately 15% MT in the elbow flexor muscle. However, the feasibility of using this normalization for other muscles has not been established. The purpose of the present study was to identify a relevant range of distortion for evaluating muscle hardness in the human quadriceps muscle and triceps surae muscle by considering individual MT. Methods This study included 157 college students who volunteered to participate. The subjects were instructed to assume a standing position, with their back and legs against a wall (for evaluating muscle hardness in the quadriceps muscle) or with their shin leaning against a supporting device such as a shin guard (for evaluating muscle hardness in the triceps surae muscle). We measured the MT and the subcutaneous tissue thickness (ST) by ultrasonography. We used a muscle hardness meter, which was attached to a stage controller system. The muscle hardness meter could be shuffled linearly for approximately 25 mm at 40 mm/s by the stage controller system. Results & Discussion In most of the subjects, muscle hardness values (E) for both muscles were calculated by responded force data against distortion in the range of 5–25% MT. However, in some subjects, the final depth of distortion did not reach 25% MT. Therefore, the calculation of E from long-range MT was not always possible. Further, strong correlations were observed among muscle hardness values in the range of 5–25% E. Furthermore, significant correlations were observed between muscle hardness values and ST. In particular, the correlation coefficient (r) was larger for short-range MT than for long-range MT (i.e., r for 5% E > r for 25% E). Therefore, the calculation of E from short-range MT was strongly influenced by individual ST. From these results, we concluded that muscle hardness calculated from a range of 15% MT is adequate, because measurement in this range had the least number of disadvantages. References. ## ELECTRICALLY ASSISTED BICYCLE ALTERS INDEX OF EFFECTIVENESS AND MUSCLES COORDINATION

Androuet, P.

*Oxylane*

ELECTRICALLY ASSISTED BICYCLE ALTERS INDEX OF EFFECTIVENESS AND MUSCLES COORDINATION Androuet, P.1, Morio, C.1, Barla, C.1 1: Oxylane Research (Lille, France) Introduction Electrically assisted bicycle (EAB) is a novel tool for meeting the physical activity guidelines in terms of intensity and is sufficiently high to contribute to the moderate-intensity standard (3–6 MET) of the physical activity for adults (Simons et al., 2009). This was confirmed by Louis et al. (submitted) that the energy expenditure in electrically assisted cycling, in every support conditions, was sufficiently high to contribute to the ACSM standards for moderate-intensity health-enhancing physical activity for adults. Furthermore, this study show that with electrical support for same speed the power output decrease and for high support the gross efficiency (GE) decrease too. The more the electrical support was, the less the organism was efficient to move. The present study aim to explain GE reduction by analysing the Index of Effectiveness (IE) and the muscular coordination in normal condition and at different support level on EAB. Methods 12 subjects participated in this study. A single session of exercise on EAB on a home trainer consisted in 5 sequences of pedalling for the duration of 3 minutes. Two levels of support (S2 and S4) and one level without support (NO) was tested for

a pedalling cadence of 75rpm. Finally, 2 sequences of pedalling were carried out without support at power recorded at S2 and S4 (NOS2 and NOS4, respectively). Data were recorded for the final 30s of each ride. IE was measured by the Powertec pedal force system. Surface EMG of 6 lower limb muscles (VL, RF, BF, TA, GAL, SOL) were recorded. Average activity of each muscle was calculated for 30 cycles of pedalling. Onset and offset of the main EMG burst were calculated in degrees referred to the crank angle (Dorel et al., 2008). ANOVA with repeated measures (2 supports x 2 powers) were performed on every parameter. Results Statistics analyses showed no significant support effect on IE but presented an increased variability on IE and pedalling rate for S4. EMG analyses showed that support have no significant effect on EMG burst. However, EMG burst reduce significantly with power decrease. Interaction between power and support showed that this reduction is limited by support for the VL, RF, BF and GL muscles. Discussion Our hypothesis was that electrical support altered IE and muscles coordination. IE value was not modify modified by the support but the maximal support increased variability between cycle of pedalling. It's supposed that subject can't keep a stabilized pedalling rate while using the maximal electrical support. EMG analyses support this finding with EMG burst reduction. ### WAVELET SCALOGRAM ANALYSIS OF GASTROCNEMIUS SEMG DURING THE COUNTER MOVEMENT JUMP

Baeyens, J.P.1,2, Pintens, S.2, Aerenhouts, D.1, Vissers, D.2,3, Clijisen, R.1,2

1: VUB (Brussels, Belgium), 2: University College Thim van der Laan (Landquart, Switzerland), 3: UA (Antwerp, Belgium)

**Introduction** The wavelet transformation provides combined time appended information concerning the amplitude-frequency domain of sEMG, furthermore its is applicable to a non-stationary sEMG signal. **Methods** Raw sEMG data obtained with a Megawin device on the right gastrocnemius of 40 male sprint athletes (14,7 yrs  $\pm$  1,9) performing a counter movement jump, were pre-amplified, downsampled to 1KHz, band pass filtered to 20-500Hz, normalized to maximal voluntary contraction (MVC) and (complex Morlet) wavelet transformed to a time/frequency/amplitude combined scalogram output. For analysis, the scalogram was divided in different levels of amplitude (0: 0%-10% MVC ; 1: -20% ; 2: -30% ; 3: -40% ; 4: -50% ; 5: -60% ; 6: -70% ; 7: -80% ; 8: -90% ; 9: -100% ; 10: >100%). Within the different amplitude levels, 'areas of activity' were defined by boundary detection on the time and frequency variable. based on a capturing of 90% of the activity along the time axis and 90% along the frequency axis, starting from the frequency or time variable's centroid of activity. The output variables were time onset/offset; frequency lower/higher bound, area of activity, and for the levels 8-10 the frequency centroid. Repeated measurement ANOVA was used in SPSS19 (significance level 5%) for the factor 'amplitude level'. Results Post hoc significancies between the different amplitude levels were: • Increased mean 'frequency lower bound' from level 1 (27.1Hz) to 10 (46.3Hz); decreased mean 'frequency higher bound' from level 1 (340.2Hz) to level 10 (189.1Hz). • Decreased mean 'area of activity' from level 1 (14968.8) to 10 ((level 7: 592.3, level 8: 394.8, level 9: 240.8, level 10: 833.4). • The mean time interval (time offset – time onset) decreased from level 1(2702.3 msec) to 10 (531.5 msec). The 95% confidence interval for the frequency centroid on the levels 8-10 was between 67.4 and 97.1 Hz. **Discussion** Gastrocnemius sEMG activity during the counter motion jump presented with a spread out of activity in time and borderline activity over a broad frequency bandwidth for the low amplitude levels evolving in sEMG activity for the highest amplitude levels concentrated over a small time interval and a small frequency bandwidth. Following the conclusions from Schiaffino et al. (2011), the sEMG activity of the highest amplitude level of gastrocnemius activity within this study suggest dominant contribution of fast twitch muscle fibers. #### RELATION BETWEEN ANTHROPOMETRIC CHARACTERISTICS, HANDGRIP STRENGTH AND BALL-HANDLING PERFORMANCE IN YOUNG BASKETBALL PLAYERS

Apostolidis, N., Zacharakis, E., Kostopoulos, N., Bolatoglou, T.

UNIVERSITY OF ATHENS

**RELATION BETWEEN ANTHROPOMETRIC CHARACTERISTICS, HANDGRIP STRENGTH AND BALL-HANDLING PERFORMANCE IN YOUNG BASKETBALL PLAYERS** Apostolidis, N.1, Zacharakis, E.1, Kostopoulos, N.1, Bolatoglou, T.1 1: Faculty of Physical Education and Sport Science, Dpt of Games and Sports, University of Athens **Introduction:** In basketball game the anthropometric characteristics and especially arms' and hands' length can define handgrip strength. Furthermore, the anthropometric characteristics can define the performance of the young basketball players (Visnapuu & Jurimae, 2007). The aim of the present study was to investigate the relation between arms' and forearms' length and hand surface with the handgrip strength, as well as between handgrip strength and the basketball handling as it is expressed by shooting and dribbling skill (A.A.H.P.E.R., 1984). **Methods:** A sample of 105 young basketball players (aged 13.5 years) volunteered to participate in the following measurements and tests: (a) Anthropometric measurements of body high, length of arms, forearms and fingers, as well as hand surface and (b) handgrip strength, shooting and dribbling skill tests (I). For the statistical analyses were conducted: (a) Pearson correlation for the initial exploration of the relation between all of the measured variables and (b) six separate stepwise regression analyses in order to confirm the predictability of the anthropometric characteristics against handgrip strength, and of the handgrip strength against dribbling and shooting skills. Statistical significance was accepted at  $p < 0.05$  level. **Results:** Strong correlations were revealed among handgrip strength and all of the measured variables. The results of the regression analyses revealed significant predictability of the anthropometric characteristics against handgrip strength and also of the handgrip strength against dribbling and shooting skills. **Discussion:** The results of the study are in accordance with the recent literature, namely, the anthropometric characteristics of body high, arms and forearms length, as well as the hand surface are clear predictors of the handgrip strength. Regarding the second part of the study, handgrip strength is also clear predictor of shooting and mostly dribbling abilities. Conclusively, the longer of the arms and hands, the stronger of the handgrip, and the stronger of the handgrip, the better of the basketball handling. **References:** American Alliance for Health, Physical Education, Recreation and Dance, (1984). ### QUANTITATIVE ANALYSIS OF REAL MADRID OFFENSIVE PROCESSES

Barbosa, A.1, Sarmiento, H.2, Anzano, A.1, Campanico, J.2

*Institut Nacional d'Educació Física de Catalunya*1 *University of Trás-os-Montes e Alto Douro, Vila Real, Portugal* 2

**Introduction** The purpose of this study was to characterize the offensive process of the teams of Real Madrid. We analyzed the different styles of play (Counterattack (Ca), Fast Attack (F.A.) and Positional Attack (P.A.)) by accessing the interaction contexts in Real Madrid (R.M.) 2010/2011. **Methods** The sample consisted of 12 football games of domestic competitions that were analyzed by systematic observation. The design used in the present study was descriptive and was based on an observational methodology applied to the acquisition of data (Anguera et al., 2000). The matches were analyzed through systematic observation by using a specific instrument to observe the offensive process (Sarmiento et al. 2010). The study of the data reliability was calculated by the intra and inter observer agreement, and values above 0.90 for all criteria were achieved. Chi-square test to compare the differences between the team concerning the styles of play and descriptive analyses for all variables was done with the statistics software SPSS.19.0. **Results** R.M. plays more through the P.A. (39,2%), followed by the F.A. (34,39%) and the offensive style less performed is the Ca. (29.1%). Regarding to the sector where the possession of the ball is recovered, the lateral corridors of the defensive midfielder zones are more often used to recover the ball, zones 4 and 6 in F.A. and P.A., and in the Ca. are the zones 7 and 9. The recovery of ball possession generally occurs in interaction contexts of relative numeric superiority. In terms of orientation, the zones more often used for the last pass are the two left-hand (P.A., 29%; C.A., 36.4%; and F.A.,40%). The central zone (Z11) characterizes the end of the offensive process (P.A., 45.7%; C.A., 45.4% and F.A., 42.3%). We can analyze that the most frequent behaviors regarding the end of the offensive process were the shot and the recovery of the ball possession by the opponent. Concerning the goals scored, the RM team scored more goals (14) through the F.A. When compared with the goals scored by Ca. (10) or by the P.A. (5). The type of attack that presented more efficiency was F.A. with 9.2%. **Discussion** We believe that there exist an attacking style that seems more efficient but more important than efficiency is identifying a set of principles that predict a style of play. The success of the offensive process is directly related to the players of a team awareness and their ability to adapt behavior according to the opposing team's defensive model. **References** Sarmiento, H., Anguera, T.; Campanico, J.& Leirão, J. (2010). Development and Validation of a Notational System to Study the Offensive Process in Football. *Medicina(Kaunas)*, 46(6), 401-407.

### T-PATTERNS REGARDING GOAL SITUATIONS OR EMINENT SCORING SITUATIONS

Barbosa, A.1, Sarmiento, H.2, Anzano, A.1, Campanico, J.2

*Institut Nacional d'Educació Física de Catalunya*1, *Espanha*; 2 *University of Trás-os-Montes e Alto Douro, Vila Real, Portugal*

**Introduction** This study intends to identify the significant repeated and regular behaviors, emerging from the diversity of game actions. It intends to determine the behavioral variables regarding Goal situations or eminent scoring situations, in two teams that share the same coach and the same technical staff. The selected football teams are Real Madrid (RM 2010/2011) and International Milan (MI 2009/2010). **Methods** To collect data, we used the instrument developed and validated by Sarmiento et al. (2010). This instrument consists in a specific notation analysis to study the offensive process and its variables. Several offensive sequences were coded through the observation of 24 games of Inter Milan and Real Madrid, 12 per each team. In order to verify pattern occurrence, we used the software THÈME 5.0, which is a professional system for detecting and analyzing hidden behavioral patterns. The reliability of the data was calculated by the intra observer agreement, and values above 0.95 were achieved for all the variables. For pattern detection, we only considered the ones that were repeated 3 times, and the significance level was set at 0.005. **Results** We detected 3 complete t-patterns, referring to the whole process, from ball possession recovery until successfully completing the offensive process (OP). The same standard repeated with the finishing zone with scoring being the frontal part of the goalpost. We have identified three patterns that repeated five times each. The data collected complements previous research. The area of ball possession recovery is located in the defensive midfield sector, with prevalence in the side wing. In the analyzed patterns we found the prevalence of zone 4. When recovering the ball there is a relative numerical superiority by intercepting the pass. The second analyzed action takes place in zone 8 which seems to prove the direct style of the offensive game. Patterns end with an eminent scoring situation in the central area of the goalpost (Z11). One of the patterns we analyzed ends in relative numerical inferiority. **Discussion** We believe that although the coach's plan suffers some adjustments, according to the characteristics and type of championship, the central idea that manages an offensive game model has the same principles and sub-principles in spite of the team change, championship and players. **References** Sarmiento, H., Anguera, T.; Campanico, J.& Leirão, J. (2010). Development and Validation of a Notational System to Study the Offensive Process in Football. *Medicina(Kaunas)*, 46(6), 401-407.

### TIME SPENT CYCLING IS THE MOST PREDICTIVE FACTOR IN ORDER TO BE SUCCESSFUL IN A OFF-ROAD TRIATHLON RACE.

Caria, A., Massidda, M.

*University of Cagliari*

**Introduction** Race result prediction is one of the most interesting aspects for sports scientists. Triathlon is a 3-event endurance sport (swimming, cycling and running) that are generally completed in succession and are separated each other by a transition periods of only a few seconds (Suriano et al., 2010). A scarce number of studies have examined the Triathlon in its entirety, particularly as far as the relationships between overall and single event competition times and positioning during an official off-road race. **Purpose** The purpose of this study was to identify the most important event in order to be successful in a off-road Triathlon race. **Methods** Two-hundred-ninety-seven athletes were studied (n=260 males, n=37 females) during a world stage of the 'X TERRA World Championship'. All athletes have completed the World's off-road Triathlon race (1.5 km, 30 km, 10 km). The Swim Time (S), the Bike Time (B), the Run Time (R), the Transition Time between S and T (T1) and Transition Time between the T and R (T2) were recorded for each athlete using the SYNOPSIS GPS system (T4 model). The analysis was computed for each gender separately, considering the final standings as dependent variables and the S, B, R, T1 and the T2 as independent variables. **Results** For males, the 99.4% of the final standings variability was explained by the B ( $R^2_{adj}=.9940$ ,  $F=43098.82$ ,  $df=1$ ,  $p<0.01$ ). The second most important variable (even if with a less significant level with respect to B) was the R ( $R^2_{adj}=.9943$ ,  $F=22777.01$ ,  $df=2$ ,  $p<0.01$ ), followed by the T2 ( $R^2_{adj}=.9945$ ,  $F=15652.47$ ,  $df=3$ ,  $p<0.01$ ) and by the T1 ( $R^2_{adj}=.9946$ ,  $F=11971.65$ ,  $df=4$ ,  $p<0.01$ ). For females, the only significant variable entered in the regression equation in predicting the variability of the final standing was the B ( $R^2_{adj}=.9951$ ,  $F=7259.37$ ,  $df=1$ ,  $p<0.01$ ). **Discussion** Our results suggest that the time spent cycling during off-

road Triathlon competition was the best predictor of the final positioning in both sex. However, the time spent running and the transition times were correlated to the final standing in males but not in females. Finally, swimming time was not significantly related to the final positioning in both gender. This result agrees with those of previous researches on Triple Iron Triathlon (11.6 km swimming, 540 km cycling and 126.6 km running) that showed the low importance of swimming performance in order to be successful during competition (Knechtle and Kohler, 2009). In conclusion, Triathlon is more than the sum of its parts, but it is "one sport, three disciplines and two transitions" (Millet and Vleck, 2000). References Knechtle B, Kohler G. (2009). *Br J Sports Med*, 43(6):437-441. Millet GP, Vleck VE. (2000). *Br J Sports Med*, 34, 384-390. Suriano R, Bishop D. (2010) *J Sci Med Sport*, 13,340-347.

### EFFECTS OF A TRAINING PROGRAM ON MEDICINE BALL THROWING PERFORMANCE IN YOUNG VOLLEYBALL PLAYERS

Battaglia, G.1,2, Bellafiore, M.1,2, Proia, P.1, Palma, A.1,2

*School of Sports Science, University of Palermo*

**Introduction** It is often recommended that off-season training programs aim to develop muscular strength and power in volleyball players (Marques et al., 2008). However, improvements in performance may be possible with a well-designed training regimen. The purpose of this case report is to study the effects of a specific training program to improve explosive power of upper limbs in young female volleyball players. **Methods** In the present study were included twenty one short-limbed girls (Scelic Index  $\geq 54.6$ ) of which 11 age-matched control sedentary subjects [SS] (age: 15.00 $\pm$ 0.52 years, BMI: 21.10 $\pm$ 2.09, SI: 55.45 $\pm$ 1.45) and 10 volleyball players [VP] (age: 14.50 $\pm$ 0.97 years, BMI: 22.17 $\pm$ 1.87, SI: 55.29 $\pm$ 2.12). SS did not perform any physical activity during the 4-week experimental period. Instead, VP completed 3 training sessions per week, which included specific exercises to improve explosive power of upper limbs and technical-tactical exercises. Over the 4-weeks, athletes performed 2-4 sets of 4-12 repetitions for resistance exercises during each training session (~55 minutes). All sessions were supervised by one of the investigators as well as by the team head coach. Muscular strength and power were assessed before and after the 4-week training program by seated backward overhead ball throw (SBOBT) and seated chest pass throw (SCPT) using a 3-kg rubber medicine ball. All tests were performed for three times but only the best performance was considered. **Results** We did not show any significant differences in SS' performances during SBOBT and SCPT after 4-weeks. Instead, we found that this specific training program can improve throwing performance in young female volleyball players. Indeed, we showed that VP increased the distance both in SBOBT ( $P < 0.001$ ) and SCPT ( $P < 0.001$ ) after 4-weeks of a specific training program. **Discussion** The current findings suggest that this specific training program can improve VP' explosive power during the pre-competition season by implementing a well-designed training program. However, in agreement with Ha'kkinen et al. (1993) we suggest that in order to maintain the explosive strength, the magnitude of both strength and explosive training stimuli should be given careful attention during the entire course of the competitive season. **References:** Marques MC, Tillaar R, Vescovi JD, González-Badillo JJ. (2008). *J Strength Cond Res*, 22(4), 1147-55. Ha'kkinen, K. (1993). *J Sports Med Phys Fitness*, 33(3), 223-32.

### THE INFLUENCE OF LIFE COMMITMENTS AND EMOTION REGULATION ON COACHING EFFECTIVENESS

Davis, P., Davis, L., Dinning, S.

*Northumbria University*

**Introduction:** Sport coaches are often volunteers with numerous life commitments (e.g., jobs, family) outside of the domain of sport. The influence of life commitments and associated stress on athletes' performance has been shown to be significant; however, coaching effectiveness has not been examined in relation to coaches' personal responsibilities. Therefore, the aim of this study was to analyse the influence of life commitments, perceived stress and emotion regulation on coaching effectiveness. **Methods:** Thirty level three (UKCC) coaches from the United Kingdom completed questionnaires measuring perceived stress, coaching effectiveness and emotion regulation. Additionally, coaches completed a qualitative writing task exploring their perceptions of the influence of life commitments on their coaching effectiveness. Linguistic analyses were conducted on the writing transcripts to investigate participants' expressions of emotions and indicators of cognitive processes (e.g., insight, causation). **Results:** Coaches reported experiencing a range of life commitments (e.g., education, relationships) and a variety of emotions (e.g., joy, anger, sadness) associated with personal responsibilities outside of the domain of sport. Coaches perceived their life commitments to be both positive (e.g., financially enabling sport participation) and negative (e.g., causing fatigue) influences on their coaching effectiveness. In particular coaches who reported high levels of perceived stress reported that life commitments were more detrimental to their coaching effectiveness. Linguistic analyses revealed that coaches felt that they largely understood the influence of life commitments on their emotions and coaching effectiveness. Coaches' attempts to cope with perceived stress also emerged as a theme in the qualitative analyses. **Discussion:** Coaches' perceived effectiveness can be influenced by the life commitments they experience outside of sport. The regulation of coaches' emotions and the ability to manage perceived stress can reduce the detrimental effects of personal responsibilities on coaching effectiveness. The implications of life commitments on coaching effectiveness have received limited research attention; interventions aimed at developing effective emotion regulation may help coaches cope with perceived stress, enhance coaching effectiveness and prevent burnout.

### ANTHROPOMETRIC PARAMETERS AND FIELD TEST RESULTS OF YOUNG ATHLETES ON A FOLLOW-UP STUDY

Petridis, L.

*University of Debrecen*

**Introduction** The purpose of this study was to examine the effect that, body height and body weight changes can have on physical tests performance in pre-pubertal and pubertal athletes. Improvement of conditioning abilities at that age can vary according to the athletes' age period, their sport and their gender. **Methods** A total of 79 athletes were measured (40 boys and 39 girls) practicing in either basketball or handball. The subjects were divided into two age groups ( $n = 42$  of 11-12 years old and  $n = 37$  of 13-14 years old). Data were obtained in two separate measurements, in spring of 2010 and in autumn of 2011, thus the changes of data were recorded within a 16 month period. Body height (BH), body weight (BW), vertical jump (VJ), 30 m sprint run and 2800 m run were measured at the two time periods. Regression analysis was used to analyze the effect of the body parameters and grouping factor on the physical tests performance. **Results** BH changed 4.6 $\pm$ 2.44%, BW 13.0 $\pm$ 9.95%, 30m 6.12 $\pm$ 11.72%, VJ 16.93 $\pm$ 23.37% and 2800m 5.93 $\pm$ 11.04%. In both age groups (11-12 & 13-14 years) boys basketball players had a faster growth in BH and in BW, however in all three physical tests had lower improvement compared to handball players. Among body parameters BH had a significant effect on the 30m run ( $\beta = 0.39$ ;  $t = 2.78$ ;  $p < 0.05$ ), while the BW, sex, age group and sport didn't show to effect 30m run performance. On vertical jump BH showed significant effect ( $\beta = 0.42$ ;  $t = 3.23$ ;  $p < 0.05$ ), BW had a negative, but not significant effect. Between boys and girls, there was a slight, but not significant

difference, with boys performing higher. 2800m run, didn't seem to be effected by any parameter. Discussion It seems that among the three physical tests, at the pre-pubertal age BH can be important only in 30m run, which has a logical explanation, while there is no difference in the improvement pace between boys and girls, as also between basketball and handball players. In many aspects a similarity between the two sports conditional requirements and between the training patterns can explain the lack of any improvement alterations in this age group.

### **THE IMPORTANCE OF THE OBSERVATION IN FOOTBALL. QUALITATIVE STUDY WITH PORTUGUESE FIRST LEAGUE COACHES**

Sarmiento, H.1,3, Pereira, A.2, Anguera, M.T.3, Campanico, J.1,2, Leitao, J.1,2

1- UTAD, CIDESD (Vila Real, Portugal); 2-IPV (Viseu, Portugal); UB (Barcelona, Spain)

Qualitative analysis is the primary method used to improve human movement. Several professional soccer coaches rely on qualitative analysis for improving the performance of their teams (Knudson & Morrison, 2002). This study aims to understand how do these coaches makes the diagnostic decisions that affect the team's performance. The participants were 8 experienced Portuguese First League coaches (14,9±8,6 years of experience). Semi-structured interviews (Creswell, 2006) were carried out and the data were analyzed through the technique of content analysis (Bardin, 1977). The elaboration of the categories had been defined à posteriori. The software QSR NVivo 9 was used in coding the transcripts of the interviews. The analysis of the data allowed to establish a model of qualitative analysis consisting of four dimensions: preparation; observation; diagnostic/evaluation; intervention. Coaches considered that the most important aspect in the preparation of an observation is the knowledge of the game, through both the identification of critical characteristics as the knowledge of the individual characteristics of players. Regarding the observation task, they consider that the most important aspects to observe in the game are: the 4 moments of the game (offensive and defensive organization, and transition defense/attack and attack/defense); tactical schemes (corners, free kicks, etc.); individual characteristics of players; random aspects of the game. Coaches have the perception that over the years his observation became more effective and they value different aspects in the game. However, perceive that the quality of his observation is influenced by factors such as the expectations, the environment, the referee's errors and by its position in the field. These coaches evaluate the teams in a general way focusing mainly on strengths and weaknesses and they follow a specific logic of prioritization for the evaluation of these aspects. The intervention is done mainly through the adaptation of the training exercises, but also through visual strategies (movies, photos, etc.) and meetings (individual, by sector or in group). They have a great concern with appropriate intervention (body language, appropriate feedback, etc.). To communicate with players during the game, they provide immediate feedback or use target players that serve to convey the message, but consider that the half time is the privileged time to talk with the players. ### **ANALYSIS OF THE SAILING BOAT TRACK IN A VIRTUAL SIMULATOR WITH DIFFERENT LEVEL SKILL SAILOR.**

Manzanares Serrano, A., Segado Segado, F., Menayo Antúñez, R.

*Universidad Católica de San Antonio Murcia*

Introduction Physical attitude, speed of the boat and tactical intelligence are the main elements of the competitive movement in dinghy sailing (Spurway, Legg & Hale, 2007). The aim of this research has been analyze and compare the boat track by sailors of different levels and related them with the success they got at the start. Methods The participants of this study have been six Optimist class sailors from Murcia (Spain), between the ages of 12 to 15. The level of the sailors is determined by the position they have in the ranking. Two of them are on the top of the classification, another two are on the middle positions and the last two are on the lower positions of the ranking. The registry of the boat track by the sailors was carried out with the sailing simulator VSail-Trainer®. Research variables were the boat track and the speed of the boat on second 0,0. The boat race consisted of a simulated start, with stable conditions of wind, opponent and sea. The simulated start presented the same conditions that can be found in a real start. Result The results show that expert sailors do a better performance of boat track, due to the fact that they reach the second 0.0 in a closer position to the start line and at a better speed than sailors with less experience. It must be highlighted that the rest of the sailors of the middle positions of the ranking perform a boat track different than the rest, even surpassing the start line before the 0.0. Beginners perform the less stable boat track and are the last ones to surpass the start line. Discussion Expert sailors show the best behaviour, which consists on reaching the 0.0 second as close as possible to the start without surpassing it. This can be due to a major capacity to assimilate environmental changes and adapt to them that expert sailors have in relation to beginners (Rocha, Araujo & Serpa, 1995). The differences shown by those sailors in the middle positions of the ranking in relation to those of the lower positions can be due to the capacity to look for a better strategy, which is developed as one gains experience (Walls, Bertrand, Gale y Saunders, 1998). **GENDER, AGE AND PERCEPTION OF IMPORTANT LEADERSHIP OF MONITORS WORKING IN ADAPTED PHYSICAL ACTIVITY PROGRAMS IN SPAIN**

Campos, A.I., González, M.D.2

*1: Polytechnic University of Madrid (Madrid, Spain), 2: Alcalá University (Madrid, Spain)*

**Introduction** The importance of human resources programs that develop physical activity and sport is essential for safe and effective implementation and to ensure the benefits of physical activity and sport as well as the influence of its leadership (Madella, 2003; Campos, 2010). The objective is study of gender, age and the perceptions of the importance of leadership in the work of the monitors physical activity and sport of adapted physical activity programs in Spain and their analysis by gender and age. **Methods** The quantitative methodology consisted of a cross-sectional survey. Cluster sampling was used. The final sample size was 241 monitors. Data were collected through structured questionnaires with face-to-face interview between January and November 2011. All the statistical analyses were done using the SPSS/Windows 19.0 statistical software. The inferential analysis with Cronbach's was .802. Signification levels were set at  $p < 0.05$ . Results 64,3% of monitors are men and 35,7% women. By age, 31,5% of monitors are under 30 years, 57,2% of monitors are 30 to 50 years and 11,3% monitors are over 50 years. 14,1% of the monitors perceive that leadership is not important, 17,8% important and 68,1% very important. By gender, 13,6% of men believe that leadership is not important, 17,4% important and 69% very important; and 15,1% of women perceive that leadership is not important, 18,6% important and 66,3% very important. By age, 18,4% of monitors under 30 years believe that leadership is not important, 17,1% important and 64,5% very important; 13% of monitors 30 to 50 years perceive that leadership is not important, 18,8% important and 68,2% very important; and 7,4% monitors over 50 years believe that leadership is not important, 11,1% important and 81,5% very important. **Discussion** Most monitors are men and under 35 years. Most monitors programs working in adapted physical activity programs in Spain perceived that the leadership in their very important job, men more than women and as age increases perceived leadership is more important. The human resources are very important in efficient development of physical activity and sport and the influence of its leadership (Camy, Chantelat y Le Roux, 1999; Campos, 2010) **References** Campos A. (2010). Dirección de recursos humanos en las organizaciones de actividad física y del deporte. Síntesis, Madrid. Camy J, Chantelat P, Le Roux N. (1999). Sport et emploi en Europe. **GENERAL CHARACTERISTICS OF PHYSICAL ACTIVITY PROGRAMMES FOR ELDERLY PEOPLE: RESULTS OF A CLUSTER ANALYSIS**

Marques, A.I., Rosa, M.J., Amorim, M., Oliveira-Tavares, A., Santos, R., Mota, J., Carvalho, J.

*CIAFEL*

**Background:** Despite the recommendations for an active lifestyle, most of the elderly European citizens are not physically active. The role of community-based interventions in promoting physical activity (PA) and the positive effects of participation in PA programmes have been closely studied and publicized. It is widely accepted that the benefits of such programmes depend on adherence to exercise regimes, which is influenced by degree of enjoyment and satisfaction. Moreover, one of the most important factors in customer satisfaction is quality of service. Thus, quality is an important issue when designing a PA programme for older people. **Aims:** 1) to distinguish groups of PA programmes according to the implementation of the quality management practices (QMP), and 2) to identify the general characteristics of the cluster with the best results in quality practices, concerning the profile of the programmes' coordinators and the programmes' features. **Methods:** A methodological triangulation was conducted in 26 PA programmes using questionnaire surveys, semi-structured interviews and document analysis. Cluster analysis using Ward's method of agglomeration with squared-Euclidean distance measures was used to identify subgroups of PA programmes based on the results of the QMP associated with the EFQM's criteria. The significant differences in categorical variables and continuous variables among subgroups types were compared with the chi-square test and the Kruskal-Wallis test, respectively. **Results:** We identified four clusters of PA programmes: "Beginners - results neglected", "Committed - process focus", "Committed - society focus", and "Beginners - customer oriented". They differ essentially in degree of implementation of each EFQM's criterion and scope of all criteria. No significant differences were found between clusters for their general characteristics, except for the number of facilities managed by the programme ( $p \leq 0.05$ ). **Conclusions:** Clustering identified four subgroups of PA programmes. The number of facilities is significantly associated with the created clusters. The cluster with the best results in quality practices – the "Committed - process focus" – is the one whose programme coordinators have a bachelor in physical education, whose programmes have run for a longer period of time, which have the largest number of customers and facilities and which are mostly free of charge and led by women. Since the quality of a service increases customer satisfaction, the continuous improvement of the PA programmes should be implemented to increase elderly satisfaction and adherence.

**DESIGNING MODEL OF STAKEHOLDER- ORIENTED WITH EMPHASIZING ORGANIZATIONAL LEGITIMACY IN SPORT ORGANIZATIONS**

Goharrostami, H., Kozechian, H., Amiry, M., Honari, H.

*Tarbiat Modares University*

**Introduction** Organizational legitimacy is obtained through provision of stakeholders' interests. Also, According to Sotiriadou (2008), many stakeholders are actively involved in national sport (Sotiriadou et al., 2008). Hence, this study is intended to identify factors that affect provision of stakeholders' interests in ministry of sport and youth of I.R.IRAN emphasizing organizational legitimacy. **Method** The participants of this study include 366 stakeholders of ministry of sport and youth of I.R.IRAN. For data gathering purposes, literature review, structured interview and questionnaire were used. In the interview session, the conceptual model, the variables and the relationships

among them were discussed with 22 managers and experts, and later on the conceptual model, based on the data from questionnaires, was tested with Amos16. Results Based on the fit indices, the model hypothesized in this study was fit (GFI=.924, AGFI=.900, CFI=.970, NFI=.930, RMSEA=.043). The results of study showed that there was a significance relationship between stakeholders' capability of management and providing of stakeholders' interests ( $p=0.000$ , Regression weight=1.307). Adaptive culture also influenced on providing stakeholders' interests ( $p=0.000$ , Regression weight=-.484). However, there was not a significance relationship between organic structure and provision of stakeholders' interest ( $p=.298$ , Regression weight=.074) Contextual factors (adaptive culture ( $p=0.000$ , Regression weight=.734), organic structure ( $p=.048$ , Regression weight=.157)) influenced on stakeholders' capability of management, moreover, another significance relationship between provision of stakeholders' interest and organizational legitimacy was found ( $p=0.000$ , Regression weight=.846). Discussion and conclusion In fact, national sport organizations such as ministry of sport and youth need to provide stakeholders' interests at national level to survive in its environment and increase organizational legitimacy. The increase of organizational legitimacy results in more political and social support by stakeholders. Consequently, achieving organizational goals is easier (Koen et al., 2007). Hence, all of these issues are dependent on the development of an effective sport system in which stakeholders' needs and demands are satisfied. References Sotiriadou, K. (2009). ## COOPERATION MODELLING IN THE CONTEXT OF GLOBALIZATION: PARTNERING COMPETENCES PERSPECTIVE

Valantiene, I., Krikstaponytė, I., Tilindienė, I., Staskeviciūtė, I.

*Lithuanian Academy of Physical Education*

Introduction Globalization is altering the world economic landscape in fundamental ways. Besides others, it creates important new opportunities—wider markets for trade, an expanding array of tradable, larger private capital inflows, improved access to technology. Prior researches on partnering and globalization also suggests that as the speed of knowledge generation and innovation has increased dramatically, organizations need to engage in partnering to optimize their innovation efforts and management efficiency and that the degree of organizations innovation success via cooperation is positively correlated with its level of partnering capability and competences needed for it. The following research methods are used in this paper: comparative analysis of scientific literature, systematization and generalization, authors work experience in the fields of partnering/alliances management and competence. The novelty of this paper. The theoretical aspects of the scientific literature on managerial competences as well as their development are widely researched (Boyatzis, 1982; Krogh, Roos, 1996; Wallace, Hunt, 1996; Magarinos, 2002). Prior research suggests that the degree of a organization's success via cooperation is positively correlated with its level of partnering and managerial competences. Based on a grounded theory approach, we have developed a conceptual framework of partnering competences, which also provides some testable ground for further research and managerial practice. Conclusions 1. In order to have successful partnering, organizations will have to enter into partnering more aggressively in the future cause of the reasons to learn; to take advantage of partners' specialization advantages; to leverage resources; to create linkages; to leap over existing constraints; and to 'lock out' the competition. 3. The concept of competence is used for the wide spectrum of skills and abilities which are close with experience: specialization, intelligence, problem solving, talent. The degree of organizations innovation success via cooperation is positively correlated with its level of partnering capability and competences needed for it. 4. Partnering competencies can be grouped into three categories: managerial, generic and technical. 5. The main task of partnering competence development for cooperative success is to grow organization to that level that it could survive the challenges of competition and globalization. ## LEGISLATIVE CREEP: UNPACKING LEX OLYMPICA

Osborn, G., James, M.

*University of Westminster; Salford University*

At Atlanta 1996 many commentators argued that the value of the official sponsorship agreements was undermined by rival brands and the look and feel of the Games diluted by unregulated clutter. Following this, and since the Sydney 2000 Games, the International Olympic Committee has required specific legislation, via the Host City Contract, to protect the commercial and intellectual property rights associated with each edition of the Games. In terms of the evolution and scope of the legislation and regulatory measures each host uses, this 'law' tends to be iterative in that it uses the previous legislation as the starting point from which it enacts measures based on the assumed successes and perceived shortcomings of what has gone before. This 'horizontal legislative creep' has seen host governments enact ever more draconian restrictions on the ability of local businesses to trade effectively during the Games period in order to fulfil the requirement of the Host City Contract but without ever pausing to contemplate whether or not such legislation is necessary or appropriate. However, in addition to this there is a related form of creep that needs to be evaluated. Here we see the practices and approaches developed for the Olympic Games adopted and utilised across sporting mega events in a form of 'vertical creep'. This paper analyses these instances of creep, and locates it within the debate around the need for, and scope of, 'Olympic Law', or what, in a nod to the debates on the emergence, existence, scope and desirability of *lex sportiva*, we have contentiously termed 'Lex Olympica'. Mark is a Reader in Law and Head Salford Law School. He has published widely sports law in the UK and is the author of *Sports Law* (Palgrave). Guy is Professor of Law at Westminster University and is one of the UK's leading authorities on law and popular culture. Over the past two years, Mark and Guy have been examining the development and scope of 'Olympic Law' and in particular its impact on advertising and trading around London 2012 venues. Their publications include: 2012 'The Olympic Laws and the tensions and contradictions of promoting and preserving the Olympic Ideal' with G Osborn in V Girginov (Ed), *The 2012 London Olympic and Paralympic Games: Vol. 1 Bidding, Delivering and Engaging with the Olympics*, (Routledge, forthcoming June 2012) ch.6. 2012 'The Olympics, the law and the contradictions of Olympism' with S Greenfield and G Osborn in H Lenskyj and S Wagg (Eds), *Handbook of Olympic Studies*, (Palgrave, forthcoming March 2012) pp304-318. 2011 'London 2012 and the impact of the UK's Olympic and Paralympic legislation: protecting commerce or preserving culture?' with G Osborn, 74(3) *Modern Law Review* 410-429, 0026-7961. 2010 'Consuming the Olympics: the fan, the rights holder and the law' with G Osborn, commissioned piece for the British Library's Olympic Legacy website, 'Sport and Society: The Summer Olympics Through the Lens of Social Science' available at: <http://www.bl.uk/sportandsociety/exploresocsci/parlaw/law/law.html>.

## IS OF HUMAN RESOURCES MANAGEMENT IN THE SPORT OF LOCAL PUBLIC ADMINISTRATIONS

Pérez, E., Martínez, G., Pablos, C., Mestre, J., Campos, A.

*Catholic University of Valencia*

**Introduction** 45% of citizens in 1990 and 63% in 2010 recognizes the local governing bodies as entities of public administration to be contacted for sports, according to the survey of sports habits in Spain (García Ferrando & Llopis, 2010). Our research analyzes the profile of local public administrators who carry out their work in the field of sports and physical activity. **Methods** This research has followed a descriptive quantitative methodology of survey procedures, all of this based on the design and methodological application of the study of Campos (2005). Questions and reflections on the responses could be produced; the selection of places and people that was necessary to obtain information have been previously analyzed and applied. The study population is finite (10,000 workers in the region under study). The size of the sample obtained by applying the formula for finite populations (Campos, 2001) is 588 people. The realization of standardized interview (questionnaire), registration of information and data collection were carried out by author of the research. **Results** The profile of people working in roles of physical activity and sports for local government responds to: A man older than 30 years, born in the same region where he works; bachelor, without a major in physical education or sports, has attended courses in the last 4 years. He has several functions, primarily teaching, along with other tasks not related to sports. He has experience working in other areas of physical activity. He is satisfied with his current tasks, which are performed in different populations. He has participated in Federated competitions. He obtained his job based on his biography and/or curriculum vitae. He has a full-time temporary contract. He has been working in this field for over 4 years and has previous work experience in other fields. He does not consider his job to be temporary Work and is not aware of his employment rights. He wants to have a life-long career in an occupation related to physical activity and sports. He thinks that more staff needs to be employed in the institution where he works. **Discussion** It confirms the lack of human resources and specialized training in physical activity and sports of the local professional public administrators in this region of Spain. **References** García M, Llopis R. (2011). Survey of sports habits in Spain 2010. CSD – CIS, Madrid, Spain. Campos, A, Pablos, C. & Mestre, J.A. (2006). ## CONTROLLING HEART RATE RESPONSE ON BICYCLE ERGOMETER

Lefever, J., Hias, J., Berckmans, D., Aerts, J.M.

*Katholieke Universiteit Leuven*

**Introduction** An optimal training pace is necessary to reach substantial health benefits and will help to avoid under- and overtraining. Knowledge of the actual exercise intensity is essential to optimise the training. Power output can be used as a direct indicator of exercise intensity (Jeukendrup et al., 1998). This technology is still quite expensive, so heart rate is more often used as an indicator for exercise intensity and to prescribe essential training zones. A possible way for effective fitness training is through monitoring and controlling the heart rate of the individual. Heart rate controllers have already been developed for running, using nonlinear modelling techniques (Cheng, 2008). The goal of this study was to explore if model predictive control (MPC) allows controlling heart rate for cycling applications by making use of compact, dynamic, linear data-based model structures. **Methods** Six amateur male road cyclists ( $22 \pm 1$  years;  $75.3 \pm 7.2$  kg;  $182.0 \pm 5.6$  cm) participated in this study. Sixteen datasets were collected to develop a MPC heart rate controller based on single-input, single-output discrete-time transfer function models describing the dynamic responses of heart rate to variations in exercise intensity. These model structures were re-estimated every thirty seconds and allowed updating the MPC algorithm for an optimal heart rate control. The experiments lasted seventeen minutes and the target heart trajectory varied between 115 and 178 bpm. **Results** The RT2 between the wanted and the controlled heart rates was 0.77 (std = 0.055) using the MPC control algorithm. The heart rate varied from the predetermined value by 5 bpm. **Discussion** A MPC control based on compact dynamic model structures was developed to control the cyclist's individual heart rate response during cycling ergometer training. The results indicate that the a simple algorithm gives comparable results as the more complex and nonlinear controlling techniques ( $\pm 5$  bpm). This technique can be used to optimise the cycling training by keeping the heart rate in the optimal training zone. **References** Cheng, T.E. (2008). ## ESTIMATING LACTATE THRESHOLD BASED ON SUBMAXIMAL CYCLING TESTS

Lefever, J., Berckmans, D., Aerts, J.M.

*Katholieke Universiteit Leuven*

**Introduction** During cycling, an optimal training pace is necessary to avoid overtraining. Knowledge of the exercise intensity and the physical condition is essential to optimise the training. The power output can be used as a direct indicator of exercise intensity (Jeukendrup et al., 1998) and the lactate threshold (LT) is a measure of the cyclists condition. However, a strenuous and invasive test protocol is used to calculate the LT. This means that test protocol cannot be performed daily to avoid overtraining. Since the heart rate recuperation speed is a measure of someone's condition, we hypothesised that the heart rate dynamics during a submaximal cycling test could serve as a non-invasive estimation of the LT. So, the objective of this study was to find a significant relationship between the heart rate dynamics during a submaximal cycling test and the LT. **Methods** Nine healthy students ( $21 \pm 1$  years) participated in this study. All the participants performed an incremental step test until exhaustion on a Tunturi T8 ergometer (Tunturi, Turku, Finland) for determination of their LT. On a different day, they performed a submaximal test to determine their heart rate dynamics. The heart rate dynamics were estimated with a multi variable dynamic transfer function approach making use of an instrumental variable parameter estimation method (RIVBJ, Taylor et al., 2007). Exercise intensity was defined as the input and heart rate as the output of the considered system. A linear regression analysis method was used to describe the relationship between the quantified heart rate dynamics and the LT. **Results** The heart rate dynamics were described by the parameters of a second order RIVBJ model structure and yielded model fits between 0.38 and 0.99 with a coefficient of determination (RT2) of  $0.88 \pm 0.10$  ( $n = 9$ ). A significant ( $P < 0.0001$ ) relationship between the heart rate dynamics (quantified based on the denominator parameters of the RIVBJ model structure) and the heart rate at LT ( $r = 0.97$ ) was found. **Discussion** A non-invasive submaximal cycling test was developed, based on the relationship between the heart rate dynamics and the heart rate at LT. This test could be incorporated into the warming up protocol to calculate the daily condition. In a next step, this could allow altering predefined training protocols and training intensities, based on the daily estimated condition instead of using the condition

measured based on an invasive maximal heart rate test. References Jeukendrup, A.E. & Van Diemen, A. (1998). Heart Rate Monitoring During Training and Competition in Cyclists. *Journal of Sports Sciences*, 16, 91-99. Taylor, C. J., Pedregal, D. J., Young, P. C., & Tych, W. (2007). ### IS IT CANNABIS REAL PROBLEM IN BASKETBALL?

Andjelkovic, M.1, Dikic, N.1,2, Vukasinovic Vesic, M.1, Vajagic, B.1, Radivojevic, N.1, Antic, T.1, Curcic, D.1, Baralic, I.1, Djordjevic, B.1, Turner, R.2, Heinz, G.2

*Sports Medicine Association of Serbia 1, FIBA Europe 2*

Introduction According to the WADA statistics Cannabinoids are on the second place in 2009 with 7,8% (399/5084) and on the third place with 9,6% (533/5546) in 2010 of all reported positive findings. Percentage of Cannabinoids of total tests performed in 2009 has been 0,14% (399/ 277,928) and 0,2 % (533/258,267) in 2010. There is the opinion that basketball is the sport with the most of the Cannabinoids users. Methods In order to check that, we have performed two studies. First was analysis of the statistics of 34 National Antidoping Agencies (NADO) for 2009 and 2010. In second study, we have performed anonymous testing of the urine of 8 national teams during U20 European Championship Men 2011-Division B. We have done testing on 96 players on social drugs: Cannabis, Cocaine, Opiates with the morphine structure, Amphetamine Methylenedioxymethamphetamine or Ecstasy. Results Basketball doping positive cases have been reported by 12 NADO (35%) in 2009 and 15 NADO (44%) in 2010. Cannabinoids have been reported by 9 (26%) NADO in 2009 and 8 (24%) NADO in 2010. That was 72.22% and 39.29 % of all reported positive findings, which is 0.53% and 0.39% of all test performed in 2009 and 2010, respectively. In second study, one sample has been positive on cannabis of 96 tested samples, which is 1.04%. Discussion Our first research has showed that Cannabinoids are presented in much more then world average (up to 3 times) in basketball and that they are the most frequently used substance among basketball players. Second study has just confirmed that Cannabinoids are present in very high numbers, up to 5 times more than world average. We might conclude that Cannabinoids are real problem in basketball and that basketball governing bodies should implement new educational policy and couple with problems on the way to convince basketball players to change habits and stop consider Cannabinoids as necessary recreational drug.

#### MICROSOFT KINECT AS MOTION ANALYSIS DEVICE FOR DIDACTIC PURPOSES: PROCESSING KINECT MOTION DATA ACCORDING TO MOTION ANALYSIS PROTOCOLS TO OBTAIN HIGH-ACCURACY PARAMETERS WHEN DEVELOPING EXERGAMES

Di Tore, S., Aiello, P., Corona, F., Baldassarre, G., Gomez, F., Sibilio, M.

*University of Studies of Salerno*

Introduction Microsoft Kinect is an accessory to the Xbox 360 capable of tracking a user's body segment positions and orientations in 3D, in real time. Goal of this research is obtaining an evaluation of Microsoft Kinect's motion data accuracy, in order to use specific range of parameters when projecting and developing Kinect-based exergames and in order to assess whether Kinect is suitable as a motion analysis device in educational context. Exergaming is the use of video games in an exercise activity (Sinclair, Hingston, et al. 2007). "We now need high-quality randomized, controlled trials to evaluate the effectiveness and sustainability of exergaming, as well as its clinical relevance" (Daley, 2009). Methods Methodology involves the comparison of data traced via Kinect with data traced via both optical based system from BTS BioEngineering and inertial-magnetic system from XSenS and processed with same software and same protocol. Motion data obtained with Kinect will be processed against an ad-hoc developed protocol and compared with data obtained with other motion capture technologies, both stereo optical and inertial/magnetic ones, in order measure the gap between technologies and have a secure basis when projecting exergames, and in order to evaluating the feasibility of using Kinect as a motion analysis device in an educational context. Results This work describes the development of a software module to acquire motion data from Kinect, calculate position of additional points required by the protocol and convert them in a format readable by stereophotogrammetry-based BTS bioengineering Smart Analyzer Software. The Kinect SDK takes data coming from the Kinect camera and performs a process called "skeletonization". It detects individual users who are within view of the camera and then tracks the positions of their bodies as a series of joints in space. As far as outputting data to file for later analysis, the Kinect SDK doesn't provide functionality to save this data. The output EMT ASCII format contains only 3D position of points (and not segments). Discussion The expected results are: an estimate of the accuracy and reliability of Kinect to know what degree of accuracy is implementable in the development of exergames and evaluation the opportunity of using Kinect in an integrated system of motion analysis for use in educational context. #### CONVERTING DATA FROM MOTION ANALYSIS SYSTEMS BASED ON INERTIAL AND MAGNETIC SENSORS TO MOTION ANALYSIS SYSTEMS BASED ON STEREPHOTOGRAMMETRY

Di Tore, A., Vastola, R., Prospero, R., Raiola, G., Sibilio, M.

*University of Studies of Salerno*

Introduction Kinematic motion analysis techniques can vary by their input methods; there are two primary input methods: magnetic systems based on inertial and magnetic sensors, and optical systems based on stereophotogrammetry The use of instrumentation based on stereophotogrammetry requires the measurement to be carried out in a laboratory This implies problems relative to dimension of a laboratory and to measuring in artificial environment The Inertial and Magnetic Measurement Systems (IMMSs) allow the user to

execute and acquire the movement in laboratory-free settings (Cutti, Ferrari et al. 2010), but actually there is a lack of protocols to process the data acquired by IMMs. Furthermore, methodological differences make it difficult to compare results obtained with different protocols, and a standardization is difficult to implement. This pilot work is part of a global project that aims at determining the accuracy of a motion inertial measurement system. Methods In order to compare data acquired via IMMs with data acquired via an optical video based system, and to process them according to same protocol, the work describes the development of a software module able to create an interchange data format, converting the joint kinematics data from Xsens IMMs Moven to a format compatible with Smart Analyzer Software. Results The software parses the non-well-formed MVNX, an Xml file format of Xsens, calculate the position of additional points not considered in MVNX file and required by chosen protocol, and convert the data in EMT, a file format used by BTS bioengineering Smart Analyzer Software. The MVNX (Moven Open XML format) files contains 3D position and 3D orientation of each segment (not the sensors) in XML format (Roetenberg, Luinge et al. 2009). The section defines all positions of connecting joints and anatomical landmarks with respect to origin of that segment, and the section contains the actual motion capture data. Each time frame consists of one row, containing 23 segments with 7 channels per segment (4 quaternion, 3 position) = 161 columns of data. The output EMT ASCII format contains only frame-per-frame 3D position of points (and not segments). Conclusions The software is released under GNU/GPL license and a web-based version is available at Unisa Laboratorio H website. References Cutti, A. G., A. Ferrari, et al. (2010). ### MOTION ANALYSIS IN DIDACTIC EXERGAMES DESIGN

Di Tore, S., D'Elia, F., Raiola, G., Palumbo, C., Sibilio, M.

*University of Studies of Salerno*

Introduction Exergaming is the use of video games in an exercise activity (Sinclair, Hingston, et al. 2007). In this work we considered the history of exergaming and the current state of research in this field, pointing out that research has focused on exergames bioenergetic side, while a few papers consider the kinematic side. This is attributable to the fact that, while the history of exergames is relatively old, accessible markerless devices able to detect motion are relatively recent. "We now need high-quality randomized, controlled trials to evaluate the effectiveness and sustainability of exergaming" (Daley, 2009). A device that looks set to change significantly design and fruition of exergames (and videogames) is Microsoft's Kinect. The Microsoft Kinect device detects the gestures of the user and uses them to control a game, but also measures the 3D world, can measure surfaces, track motion and even put a skeleton on real-time analysis. This pilot work is part of a larger project aimed at evaluating the different technologies that can capture the movement in order to determine which are best suited in the design of exergames accessible in educational contexts. This work focuses on Microsoft Kinect Methods The selected method has involved the design and development of a pilot educational exergame, described below, which uses Kinect both as an interface and as players performance analysis device. Results The exergame, for now tested on a small number (< 20 students, 9 years aged) of participants, seems to show that kinect is suitable for capturing the movement of the body in relation to space and time and to recognize and evaluate trajectories, distances, paces, and executive succession timing of motor actions Discussion Exergames capable of recording and evaluating performance in connection with the kinematics seems to have great potential in education and rehabilitation, also considering the possible lack of precision of devices such as Kinect. Performance improvement is a relative concept: for elite athlete could be measured in hundredths of a second, while in didactics or rehabilitation the tolerance threshold is much wider References Sinclair, J., P. Hingston, et al. (2007). Considerations for the design of exergames, ACM. Daley, A. J. (2009). 'Can exergaming contribute to improving physical activity levels and health outcomes in children?' *Pediatrics* 124(2): 763-771.

### SINGLE-GENDER GAMEPLAY IN PHYSICAL EDUCATION: EFFECTS ON PERCEIVED COMPETENCE, MOTIVATION AND PHYSICAL ACTIVITY IN GIRLS

Slingerland, M., Barmiento, H.

*Fontys University of Applied Sciences*

Introduction Creating physical education environments that foster perceived competence, autonomous motivation and high levels of physical activity during coeducational physical education (PE) lessons is a challenge in adolescent girls, especially during games lessons. This study aimed at increasing perceived competence, autonomous motivation and in-class physical activity in adolescent girls by applying a single-gender grouping strategy during gameplay sessions within a coeducational setting. Methods Four-hundred-and-sixty-three students (252 girls: 54%) agreed to participate in the study. During their PE lesson participants played two similar 30-minute gameplay sessions with one week in between sessions. One session consisted of mixed-gender gameplay while the other session was played in single-gender groups (girls versus girls / boys versus boys). Participants played one of three sports: volleyball (n = 55), football (n = 74) or indoor hockey (n = 155). Students wore heart rate monitors for the duration of the gameplay session and filled out a situational motivation scale and perceived competence scale after each session had ended. Three separate repeated measures ANOVA's were employed with perceived competence, motivation and physical activity as the dependent variables, gameplay condition (single-gender grouping versus mixed-gender grouping) as the within-subjects factor and gender and lesson subject as between-subjects factors. Results Valid data was provided by 265 students (142 girls: 54%). Interaction effects (condition x gender) indicated that perceived competence (F (1, 249) = 12.84, p < .001) and percentage of lesson time in MVPA (F (1, 259) = 8.57, p < .01) increased in girls in the single-gender condition. However, a significant interaction effect of condition x gender x sport for perceived competence (F (2, 249) = 3.46, p < .05) showed that increases in competence only occurred in girls in the single-gender condition when football was the lesson subject. Furthermore, the interaction of condition x sport for MVPA indicated that, irrespective of gender, MVPA was highest during football (F (2, 259) = 4.44, p < .05). No changes in motivation were observed. Conclusion Single-gender grouping within a coeducational setting can be an effective strategy for PE teachers who aim at increasing perceived competence and in-class physical activity in female students during PE. However, the effectiveness might vary depending on the subject being taught. Furthermore, since one gameplay session might not be sufficient to bring about changes in motivation, future studies should investigate if a longer period of gameplay in single-gender groups results in increased autonomous motivation in adolescent girls.

## THE RELATIONSHIP BETWEEN ACHIEVEMENT GOALS AND SELF-TALK IN PHYSICAL EDUCATION

Argyropoulou, E., Zourbanos, N., Papaioannou, A.

*University of Thessaly, Trikala*

**Introduction** Self-talk in sport has been claimed to facilitate the learning of new skills and the enhancement of sport performance. Hardy, Oliver, and Tod (2009) proposed a conceptual model for self-talk in sport postulating that one of the personal antecedents that influences individual's self-talk are Achievement Goal Orientations (AGT). AGT is often used by researchers and sport psychologists to investigate and to understand why some individuals seem to be more motivated than others in sport and physical activity (e.g., Roberts, Treasure, & Conroy, 2007). The main objective of the present research was to bridge the gap between positive and negative self-talk and achievement goals by examining students' thoughts in PE during play with high and low sport achievers. **Methods** Participants were 628 students (325 females and 303 males) with a mean age of 14.49 years (SD = .50). **Measures** Self-Talk in PE. An adapted version of the Automatic Self-Talk Questionnaire for Sports - ASTQS (Zourbanos et al., 2009) in PE was administered to assess students' self-talk. Achievement goals in PE. The Task and Ego Orientation in Physical Education Questionnaire (TEOPEQ; Duda & Nicholls, 1992) was administered to assess students' achievement goals. **Results** Dependent t-tests revealed significant differences for the negative self-talk dimensions revealing that students experience higher negative self-talk referring to worry, disengagement, somatic fatigue and irrelevant thoughts when they play against the best student than when they play against the worst student. Non-significant differences were observed for positive self-talk referring to instruction and anxiety control, but significant differences were observed for self-talk referring to psych up and confidence showing that students exhibit more positive self-talk when they play against the best student than when they play against the worst student. **Discussion** The present findings suggest that students' achievement goals may impact students' self-talk. Taking into account the significant role of thoughts on performance, this line of research may contribute to subsequent explorations into the antecedents of students' self-talk. **References** Duda JL, & Nicholls JG. (1992). Dimensions of achievement motivation in schoolwork and sport. *J Educ Psychol*, 84(3), 290-299. Hardy J, Oliver E, & Tod D. (2009). ## THE PHENOMENON OF TEENAGERS' SPORT DROPOUT

Mondoni, M.

*Università Cattolica Sacro Cuore*

**The phenomenon of teenagers' sport dropout** Mondoni M.1, A. Superti, A. Ajani.1, L. Bottini 1Faculty of Science Education: degree in physical educations and sports-Catholic University of Sacred Heart of Milan **Introduction** Teenagers are abandoning sports at an increasingly worrisome rate. The phenomenon of dropout has reached levels whose consequences should not be ignored. Indeed, the consequent sedentary lifestyle and unbalanced nutrition patterns are the cause of hypo kinetic diseases, i.e. obesity, cardiovascular diseases and 2 diabetes. **Objectives** This study aims to shed light on the phenomenon of sports dropout, in all its aspects, causes and potential consequences on the social life and health of the youngsters. By investigating and understanding the reasons that lead teenagers to abandon any sportive activity, we intend to outline possible interventions that could limit and, eventually, reverse this phenomenon. **Methodology** The data was collected in form of anonymous surveys, through the cooperation of P. E. teachers. We surveyed the entire population of 12165 students attending high schools in the province of Cremona (Italy). The questions refer to the sport practiced (i.e. reasons for the choice, beginning age, frequency of training, etc) and the dropout (i.e. causes etc). **Results** As expected soccer is the most practiced sport with 36.10% of the students identifying it as their main sportive activity, followed by volleyball 17.52% and basketball. These are also the sports with the highest dropout rates, but interestingly other sports such as swimming and gymnastics suffer in their survival rate, with relative high dropout and low average practice rate-only few students seem to practice them at an older age. Furthermore, despite the dropout phenomenon, more than one third of the students who are practicing a sport are committed to more than 2 trainings per week (32%). The reasons that drive the choice of a sport are mainly personal and peer-related around 75%, on the other hand, health experts or PE teachers seem to have an insignificant role. Finally, the decision of abandoning the sport is identified by the students in their change of taste and in the decision of investing their time in some other activities. Also in this case, the decision seems to be taken quite autonomously. **Conclusions** The fact that the majority of the teenagers choose the sport at a very young age, before 7 years old, and that this decision-making process is rarely supported by PE experts, may produce an inefficient matching between physical predisposition, skills and sport chosen. It is evident how this could lead to a higher rate of dropout in older ages, especially in those sports where the physical characteristics represent a determinant limitation to a competitive practice. Therefore, the introduction of a figure of sport consultant in elementary school system could help children to combine their personal attitude with their physical potential for a more successful and satisfying sportive experience in older ages.

## THE EFFECT OF AN INTEGRATED SCHOOL CURRICULUM Pedometer INTERVENTION TO ENHANCE PHYSICAL ACTIVITY AND REDUCE WEIGHT STATUS IN CHILDREN

Duncan, M.J., Birch, S.L.

*Coventry University*

**Introduction** Integrating physical activity through the school day using an integrated curriculum model has been suggested as one means to increase total daily PA in an attempt to reverse the decline in PA and halt increases in overweight and obesity seen in young people worldwide (Oliver et al., 2006). Few studies have examined whether this is the case. The aim of this study was to examine the effect of an integrated school curriculum pedometer intervention on physical activity and weight status in children. **Methods** Following ethics approval and informed consent, 59 children (22 boys, 27 girls, aged 10-11) from a primary school in central England completed a 4-week integrated physical activity intervention based on virtually walking from John O'Groats to Lands End. Habitual physical activity (via pedometer) and weight status (Body mass index) were determined pre and 4 weeks post intervention using pedometer. Steps/day were also calculated during the intervention period, plotted on individual maps of the journey the length of the UK and used as an open-loop feedback tool to encourage physical activity. Focus group interviews were utilised to examine the children's experiences of the intervention. **Results** Results indicated that average steps/day were significantly higher (P = .0001) during and post the intervention compared to

baseline and children classified as normal weight were significantly more active than those classified as overweight/obese ( $P = .003$ ). Body mass index was not significantly different across the measurement period ( $P < .05$ ). Qualitative data indicated that the children thought the intervention was interesting and could help in making them, and their wider family group, more active. The children also reported that the use of the step count data in school lessons made them think more and understand more about physical activity because they could engage with the data collected differently than during normal school teaching. Discussion These results support prior claims that using a pedometer led integrated curriculum model can increase children's PA (Oliver et al., 2006) and that pedometers can be effective open loop feedback tools in providing a goal based approach to increasing PA (Lubans et al., 2009). The use of a 4-week integrated curriculum pedometer intervention in school is therefore feasible and results in increases in school day physical activity both in the wider school curriculum and during leisure time. ### **THE RELATIONSHIP BETWEEN YEAR GROUP, GENDER AND WEIGHT STATUS ON THE MASTERY LEVEL OF FUNDAMENTAL MOVEMENT SKILLS.**

Bryant, E.S., Duncan, M.J.1, Birch, S.L.1, Oxford, S.  
*Coventry University*

Introduction: Fundamental Movement Skills (FMS) are the underpinning skills of sporting and physical activities (Cowely et al., 2010). In schools children are excluded from games due to their lack of skill (Ignico, 1990), thus decreasing participation levels in physical activity. Research has therefore predicted that mastery in these FMS will result in an increase of physical activity levels progressing from childhood to adulthood (Okley et al., 2004). However, there is a lack of research in this area in England and therefore the aim of this study is to identify the effects that age, gender and weight status have on the mastery level of FMS. Method: 292 children in years 2-6 from a school in central England completed the research. Each child performed 8 FMS (run, hop, gallop, jump, balance, kick, throw and catch) 3 times in front of a camera. This was then analysed using Quintic Biomechanics software and the process orient checklist (objective measurement). Height and weight were measured to calculate body mass index (BMI) and used to determine weight status using Cole et al. (2000) criteria. Ethical approval and informed consent were gained prior to research commencing. Results: Using SPSS results from a 2(gender) by 2(weight status) by 5(year group) ways analysis of variance indicated; that weight status of the children significantly affected the mastery level of the jump ( $P < 0.05$ ). Gender significantly affected the mastery level of kick, catch, throw and balance ( $P < 0.05$ ). Boys had a higher mastery of kick, catch and throw, whilst girls had a higher mastery of balance. Each year progressively has a higher percentage mastery of the skills ( $P < 0.05$ ). Discussion: Weight status having a negative effect on the jump is consistent with the findings from Okley et al. (2004). The male gender had a higher mastery level of the object control skills, whereas the female gender had a higher mastery of a static skill. This supports previous research from Hardy et al. 2010. Blatchford et al. (2003) suggests this is because boys are more likely to engage in ball games compared to girls and thus increasing mastery of object control skills. Year group, gender and weight status all had an effect on the mastery of FMS and therefore can influence physical activity levels in life and highlighting the importance of the mastery of FMS. ### **IDENTIFYING THE COMPETENCIES OF THE PHYSICAL EDUCATION PROFESSIONAL TO PERFORM IN PRIMARY CARE: A DELPHI STUDY**

Coutinho, S.S.1, Queiroga, M.R.1, Volski, V.1, Santana, C.S.2, Mishima, S.M.2, Pereira, M.J.B.2  
*1: UNICENTRO (Guarapuava, Brasil), 2: USP (Ribeirão Preto, Brasil). Research Support: CNPq, Brasil.*

Introduction In Brazil, it is observed that numerous programs and initiatives to promote health which are developed in the Unified Health System (SUS) and related to the Primary Health Care (PHC) have included the physical education professional as one of the professions that should make up the interdisciplinary health team (Malta et al., 2009). In this sense, this research aimed to create a list of general and specific skills that can give support to the physical education professional practice in the context of PHC. Methods The research subjects are physical education professionals who work in programs for the promotion of bodily practices/physical activities, linked to the Primary Health Care for of the SUS and also researchers who study physical education and SUS. For data collection and organization, the Delphi technique was used to perform three rounds. Results The answers to the first round of questions generated a list of 135 general skills and 88 specific skills. After the first sending, a content analysis of the listed skills was accomplished, resulting in 21 general skills and 19 specific skills. After the 2nd and 3rd round, skills were analyzed using descriptive statistics, which resulted in the following general skills: bond, communication, creativity and flexibility, humanization, leadership, planning, adaptation and strategic vision, evaluation, prevention, encouraging empowerment, teamwork and respect to differences, knowledge about the Brazilian Unified Health System (SUS), epidemiology and strategies for permanent and continuous learning. And in the following specific skills: individual and group evaluation, broad view of the body, body-oriented practices, knowledge about public health policies and their relationship with physical education, knowledge of diversified body practices beyond the narrow focus on biomechanics and the spend of calories, planning and prescription of physical activities, including special groups, conception of first aid, awareness about the importance of regular physical activity practice, development of programs and projects, and knowledge in anatomy, kinesiology, biomechanics, human physiology and exercise. Discussion The listed skills point to the possibility of having a professional who has a broaden view of health not restricted only to the biological aspects. ### PP-SH07 Sport Psychology

#### A QUALITATIVE INVESTIGATION OF THE TACIT KNOWLEDGE OF JAPANESE OLYMPIC SPRINTER

Kitamura, K.

*Tohoku University*

**Introduction** In learning process of sport movements, full use of body movement is emphasized to transfer coaches' explicit knowledge within the athletes. However, the tacit knowledge approach emphasizes understanding the kinds of knowledge that athletes create their own movement by themselves. But how tacit knowledge affects sport learning other than explicit knowledge has not been sufficiently elucidated (Ikuta & Kitamura, 2011). In the present study, we focused on the application of the action directed learning through sharing the feelings. Action directed learning is defined as the learning process to focus on the tacit knowledge to pursuit the ideal feeling which leads an ideal movement, not to acquire the skills. Using a qualitative analysis of experiences of elite sprinter, we aimed to demonstrate (1) how action directed learning was seen, and (2) what the factors are that promote or inhibit action directed learning. **Methods** One Olympic medalist in short-distance run was selected as participant of this study. In depth, semi-structured, open-ended interviews were used to analyze the action directed learning of the participant. Immediately after the interviews the speech data were transcribed, and the meaning was analyzed using the transcriptions. Data were analyzed based on the qualitative data analysis method of Patton (2002), and hierarchical categories were created through discussions with co-researchers. **Results** As a result of inductive analysis, 94 meaning units were finally identified as subjects of analysis for this study. These units were divided into a total of 3 categories, devotion, commitment, and investigation with 10 subcategories. The following three points were demonstrated from the results of the study. First, the elite sprinter experienced many kinds of body movements which brought him a sensibility. Second, he directed himself to commit to deliberate practice as a way of monitoring his movements. Third, the elite sprinter intentionally reflects his feeling which he got during movement. In addition to reflection in action, other frequent behavior including reflecting the sense of action was reported. **Discussion** Participant monitored his behavior in such a way that he tried to find the proper expressions of tacit knowledge for his learning setting. In short, it was found that action consciousness is frequently influenced by many factors, and strongly shaped by a tacit instructional behavior which leads the participant to create his ideal action. **References** Kumiko Ikuta and Katsuro Kitamura. (2011). *Practical Art Language: Action directed learning through sharing the feelings*, Tokyo Japan, Keio University Press.

#### SINGLE AND COMPOSED CONFIGURATION OF PERCEPTUAL CUES ON THE ANTICIPATION OF TENNIS SERVES

Zawadzki, P., Roca, J.

*Barcelona University*

**Introduction** Players are common required to fit their responses under a variety of strokes of different opponents. On the tennis serve devolution this becomes evident because of anticipation requirement (Farrow and Abernethy, 2002). During association of perceptual cues to response, two functional ways can be establish: constancy between elements or configuration between values of elements (Roca, 2006). The aim of this study was compare the analyses of two single cases approximating the concepts of Model Field Theory to Statistical Correlation Theory to verify the existence of both cases. **Methods** One female and one male tennis professionals were recorded during an official match, kinematics method were used to digitise polar coordinates of four perceptual cues (position, ball toss, knee bend and racket arm). Pearson Correlation (r) and Canonical Correlation Analysis (Rc) were performed between perceptual cues and bounce result. **Results** On the female case a single perceptual cue were founded, significant results shows the height of ball toss correlated to serve depth ( $r=0.887$ ,  $p<0.01$ ). On the male case significant results were found but with no power ( $r<0.5$ ) of prediction on the single cues, however, composed cues presented values of  $Rc=0.9098$  ( $p=0.0104$ ) presenting similar weights for position ( $cv=0.1601$ ) and ball toss ( $cv=-0.1365$ ) however with different directions on the relationship. No results were found about constancy on perceptual cues. **Discussion** Associations between values of elements were found, the power related serve as evidence to support perceptive configuration theory. Nonetheless, results also suggest two ways of configuration, one established by the relationship of just two variables or cues, called here as single configuration and another established by the relationship between one cue with a group or between two groups of cues, called here as composed configuration. Ventura (2004) demonstrated that a reduction of performance is observed when the grade of variability increase; what could propose that during player development a technique disguise occurs and through that more than one cue must be perceived by his opponent. In any case, the Opponent Study in Sport reveals itself as field plenty of opportunities to help players to fit better their responses. **References** Farrow, D., and Abernethy, B. (2002). #### RELATIONSHIP BETWEEN ATTITUDES TOWARDS DOPING AND SELF-ESTEEM IN PARTICIPANTS OF A POPULAR LONG-DISTANCE ROAD CYCLING EVENT

Morente-Sánchez, J.1, Freire, C.1, Ramírez-Lechuga, J.2, Zabala, M.1,3

*1 Faculty of Sport Sciences, University of Granada (Spain); 2 Faculty of Sport, University Pablo Olavide (Seville-Spain); 3 Spanish Cycling Federation, Madrid (Spain)*

**Introduction** In view of the lack of scientific literature investigating the association between attitudes towards doping and other factors, the purpose of this study was to know the relationship between the attitudes towards doping and the self-esteem of participants in a popular long-distance road cycling event. **Methods** The sample was composed by 2022 amateur cyclists ( $40.95\pm 9.42$  years) who participated in a long-distance (205 km) Spanish road cyclist event called "Quebrantahuesos" (UCI Golden Bike). Descriptive design was carried out by means of two validated questionnaires: Performance Enhancement Attitude Scale -PEAS- (Petroczi & Aidman, 2009) and Rosenberg Self-Esteem Scale -PSES- (Fleming & Courtney, 1984; Rosenberg, 1965). The PEAS has 17 questions using a Likert scale from 1 (Strongly Disa-

gree) to 6 (Strongly Agree) for different statements that supported the use of doping in sport. In other hand, Rosenberg's scale - 4-point scale ranging from 1 (strongly disagree) to 4 (strongly agree)- was originally developed as a Guttman scale scored dichotomously (yes/no). The correlation coefficient of Spearman was used to analyze the relationship between Self-Esteem and attitudes towards doping. Results The correlation coefficient of Spearman showed a negative value of  $r = -0.140$ ;  $p < 0.001$ -. Consequently, the higher score in "Performance Enhancement Attitude Scale", the lower score in "Rosenberg Self-Esteem Scale". Discussion According to Van Amsterdam et al. (2010), the typical banned drugs abuser is a male poly-substance user who has a low self-esteem due to a poor body image. In our study, unsurprisingly, a relation between attitudes towards doping and self-esteem existed, but despite of the fact that there were significant differences, the relationship between both factors was very weak. It could be because this type of sample (amateur cyclists) looked for other aims such as performance improvement instead of changing their body image. In this way, we recommend further research in this field because there is a significant dearth in this matter. References 1. Petroczi, A., Aidman, E. (2009). ### **CHALLENGE OF THE GAME – ATHLETES' SKILLS: THE ROLE OF FLOW THEORY ORTHOGONAL MODEL IN ULTRA MARATHON ATHLETES**

Stavrou, N.A., Bagios, I., Noutsos, K., Psychountaki, M.

*National & Kapodistrian University of Athens*

**Introduction** The concept of flow has been described as an optimal subjective mental state. A central issue of flow theory is that whether or not an athlete is in flow depends on his/her perception of the existing challenges and the nature of his/her skills (Csikszentmihalyi, 1982). When the challenges and skills are perceived as being in balance, in a high level, the athlete experiences flow. When the skills outperform the challenge, there is relaxation, whereas when the skills and challenges are below average, there is apathy, and, finally, when the challenges outweigh the skills, there will be anxiety (Csikszentmihalyi, 1982). The purpose of the study was to examine the role of subjective estimation of challenge of the competition and athlete's skills in the quality of their experience. **Methods** One hundred and fifteen athletes participate in the present study, ranging in age from 26 to 66 years ( $M = 40.31$ ,  $SD = 7.98$ ). Just after the competition, the athletes completed the Flow State Scale – Short Form (FSS-SF; Jackson, Martin, & Eklund, 2008), and five 11point Likert type scales measuring (a) challenge of the game, (b) athlete's skills, (c) stress, (d) activation and (e) subjective estimation of performance. The race length was 44 km, the higher altitude 2800m and the mean duration of the competition was approximately 7 hours. Results The results indicated significantly higher correlations between athletes' skills and FSS-SF subscales compared to the value of the correlations of perceived challenge of the game. The athletes in the flow and relaxation quadrants revealed higher values of flow experience compared to the athletes of the other two states, sustaining significant differences among the four states (Wilks'  $\Lambda = .629$ ,  $F_{3,100} = 1.719$ ,  $p < .05$ ,  $\eta^2_p = .143$ ). Significant correlations revealed among activation and flow experience. Finally, no significant differences revealed in athletes' performance among the four states. **Discussion** Athletes' quality of experience is differentiated among the quadrants of the orthogonal model. Specifically, the results suggest that the perception of skillfulness is essential for the athlete to experience positive mental states, compared to the perception of challenge. The importance of athletes' skills on the quality of their experience is further supported by the significantly higher correlations between the FSS-SF factors and the perceived skills, suggesting a close relationship, compared to the correlations between the FSS factors and perceived challenges. Finally, activation appears as an important factor for flow experience. References Csikszentmihalyi, M. (1982). *Annual review of personality and social psychology* (Vol. 3, pp. 13-36). ### **COMPETITIVE AGGRESSIVENESS AND ANGER TEMPORAL TREND APPROACHING TO A WATER-POLO MATCH.**

Ferri, I.

*University of Padua*

**Introduction** Wide part of educational value of sport results from healthy, genuine and equilibrate emotional experiences. Emotions can widely influence sport performances: the IZOF model and the directional perception approach show the great subjectivity that characterizes emotions effects and explain how personal perception determines intensity and facilitative or dysfunctional direction of each emotions. Contact sport, more than others, can stimulate and carry aggressive and violent behaviors but very different levels of aggression acceptance exists (Kerr, 2002). The aim of this study was to examine temporal trend of competitive aggressiveness and anger in two different dimensions, intensity and direction, approaching to a match in a water-polo team. **Methods** Participants were a sample of Italian young male athletes ( $N = 15$ , mean age 15.9 years,  $SD \pm 0.7$ ) of a water-polo team, regularly involved in a national championship. They had on average 5.4 years of experience ( $SD \pm 1.3$ ). Written informed consent was signed by all players parents. An adapted version of the CAAS (Competitive Aggressiveness and Anger Scale, Maxwell et al., 2007) was used to define a 'state' assessment (48, 24, 2 hours before and 48 hours after the match). The score of each items ranges from 1 to 5 for intensity and from -4 to 4 for direction dimensions. Results Aggressiveness and Anger mean scores were analyzed. Before the match aggressiveness intensity has been proved significantly lower rather than 48 hours after the match ( $p < .01$ ) and results quite facilitative just before the match ( $t = 4.2$ ,  $p < .01$ ). Anger intensity before the match can be overlapped to the levels reached after the game and after the match anger direction resulted significantly higher compared with the value obtained 48 hours before the match ( $t = -9.2$ ,  $p < .01$ ). **Discussion** Results confirmed that aggressiveness and anger temporal trend changes according to the IZOF model and the directional perception perspective. Further investigations are needed to better understand how manage aggressiveness and anger levels to improve athletes performances. Anticipating athletes intentions and perceptions could represent a great challenge to reduce violent behavior in sportive competitions (Russell, 1993). References Kerr J. (2002). *The Sport Psych*, 16, 68-78. Maxwell JP, Moores E. (2007). *Psychol of Sport and Exe*, 8, 179-193. Russell GW. (1993). *The social psychology of sport*. NY: Springer.

## EXECUTIVE FUNCTIONS IN VOLLEYBALL- AND BADMINTON PLAYERS

Schmitz, G., Effenberg, A.O.

*University of Hannover*

**Introduction** Motor control and cognitive executive control are interrelated, but the underlying mechanisms are largely unknown. 10 weeks of table tennis training can improve executive control in children with developmental coordination disorder (Tsai, 2009). A similar effect was reported for healthy adults after two years of baseball- but not tennis-training, suggesting that cognitive improvements are based on sport-specific demands (Kida et al., 2005). The aim of the present study was to investigate (1.) whether experts from different sports have different executive abilities and (2.) if sport-specific training has acute effects on executive functions. **Methods** 47 athletes participated in the study (aged 24.9 ±5.2 years, 18 female). 19 were volleyball-players (expertise: 14.8 ±2.8 years) and 8 Badminton-Players (expertise: 13.8 ±8.3 years). 20 subjects from various sports (expertise: 8.0 ±5.7 years) served as control-group. Executive functions were assessed with Tower of London (ToL), Stroop-Test (ST), Trail Making Test (TMT), FAIR II Test (FT) and a Maze Test (MT), latter including a reference trail (rMT) as screening tool for visuomotor control. All tests were applied before and in a modified version 50 minutes after sport-specific training or social activity (control-group). Results were submitted to repeated measure ANOVAs and significant effects were decomposed with Fisher's LSD test. For clarity only p-levels are reported here. **Results** (1.) Volleyball-players performed better in rMT than badminton-players and the control-group (both  $p < 0.01$ ). Badminton-players were better than the other groups in MT (both  $p < 0.05$ ) and better than volleyball-players in ToL ( $p < 0.05$ ). Expertise correlated negatively with performance in TMT across all subjects ( $r = -0.44$ ,  $p < 0.01$ ). (2.) All groups significantly enhanced their performance from pre- to post-test in FT ( $p < 0.001$ ), MT ( $p < 0.001$ ), TMT ( $p < 0.05$ ), ST ( $p < 0.001$ ) and ToL ( $p < 0.05$ ) but not in rMT ( $p > 0.05$ ). Rates of enhancement did not differ significantly between groups ( $p > 0.05$ ). **Discussion** (1.) Results confirm that executive and probably sensorimotor abilities differ between experts of various disciplines. Higher performance of badminton-players in MT and ToL might be based on more effective planning and decision-making, since those functions are addresses by both tests. The negative correlation of TMT and expertise might indicate a detrimental effect of long-term sport-specific training on cognitive flexibility. (2.) Enhancements from pre- to post-test can be explained by repeated measures effects. Therefore no acute effect of sport-specific training was found. **References** Kida N, Oda S, Matsumura M (2005). *Cog Brain Res*, 22(2), 257-264. ## IS PERFECTIONISM ASSOCIATED WITH BURNOUT OF UNIVERSITY BASEBALL ATHLETES? -DEVELOPMENT OF PERFECTIONISM SCALE AND BURNOUT SCALE FOR BASEBALL ATHLETES-

Shimizu, Y., Miyazaki, M.

*International Christian University and J.F. Oberlin University*

**Introduction** Baseball is one of the most popular club sports from elementary to college level in Japan. College baseball athletes' maladjustment to college baseball teams and dropout from athletic clubs has become one of the prevalent problems. The purpose of this study was to develop Perfectionism Scale for Baseball Athletes (PSBA) and Burnout Scale for Baseball Athletes (BSBA) and to examine the relationship between the subscales of PSBA and BSBA. **Methods** The subjects of 203 baseball athletes (mean age=19.43, SD=0.86, mean baseball experience=11.33, SD=2.12) in four official university baseball teams were asked to answer a questionnaire composed of question items on socio-demographic background and 42 baseball athletes' perfectionism evaluation question items and 30 baseball athletes' burnout evaluation question items both of which were developed from our preliminary survey in 2010. Exploratory factor analyses, confirmatory factor analyses and reliability analyses were conducted to develop PSBA and BSBA. Multiple regression analyses were employed to examine the relationship between PSBA and BSBA. **Results** The results of exploratory factor analyses yielded for PSBA a 8-factor model with 39 items ("Social Norm," "Teammates," "Practice," "Performance," "Goal Setting," "Coaching," "Competition," "Managing") and for BSBA a 4-factor model with 30 items ("Emotional Exhaustion," "Maladjustment to Clubs," "Depersonalization," "Lack of Personal Accomplishment"). Confirmatory factor analyses and Reliability analyses confirmed that each scale had acceptable structural validity and satisfactory Cronbach's alpha reliability. The results of multiple regression analyses showed that the sub-scales "Social Norm" and "Performance" of PSBA had significantly positive association with the sub-scales of BSBA and the sub-scales "Competition" and "Coaching" of PSBA had significantly negative association with the sub-scales of BSBA. **Discussion** The findings above support the use of PSBA and BSBA in assessing perfectionism burnout tendency of baseball athletes respectively and suggest that baseball athletes with high perfectionism in competition and coaching have a high risk of burnout. This implies that appropriate psychological intervention from baseball managers and coaches may prevent athletes' burnout. Future research with a larger sample size and longitudinal design will be needed in order to explore effective psychological coaching intervention methods. **References** Midori SAWAGUCHI, Yasuo Shimizu (2011) Development of Perfectionism Scale for University Athletes. *Kyusyu Journal of Sport Psychology*. 23:28-29.

## IMAGERY TYPES OF ATHLETES IN DIFFERENT SPORTS

Kizildag, E., Tiryaki, M.S.

*Mersin Universitesi*

**Introduction:** The main purpose of this study was to compare the imagery use of elite male and female athletes in different sport types. Imagery has been defined as; "creation or re-creation of an experience generated from memorial information, involving quasi-sensorial, quasi-perceptual and quasi-affective characteristics, which is under the volitional control of imager, and it may occur in the absence of the real stimulus antecedents normally associated with the actual experience" (Morris etc. 2005). Hall etc. (1998) developed the Sport Imagery Questionnaire (SIQ) to assess the frequency with which athletes use these imagery functions. These functions are: cognitive specific-CS, cognitive general-CG, motivational specific-MS, motivational general-arousal-MG-A, motivational general-mastery-MG-M. **Methods:** 186 athletes (122 male and 64 female) from 6 various sports (volleyball, basketball, soccer, track and field, tennis, swimming), aged between 15 to 33 years (Mage= 21. 25± 3. 42) participated in the study. We used SIQ (Hall, etc., 1998). SIQ consists of 5 subscales (CS, CG, MS, MG-A, MG-M) and 30 items. In Turkish version of SIQ has supported the Questionnaire's 4 factor structure and 21 items. To determine if there was a difference between male and female athletes we used to data Kruskal Wallis. **Results:** Results of this study there was a significant difference in MS subscale ( $p < .05$ ). To determine the source of the difference we used Mann-Whitney U test. In this test result female volleyball and female basketball players had significantly higher score than tennis players in MS (Uvolleyball-tennis= 34.5,  $p < .05$ ; U basketball-tennis= 19.0,  $p < .05$ ). It was also found that male volleyball players had higher scores than soccer players in CI (Uvolleyball-soccer= 188.0,  $p < .01$ ), male swimmers had significantly scores than male basketball players in MG-A (Uswimming-basketball= 59.5,  $p < .05$ ). **Discussion:** In literature review we were not run across imagery studies that compare gender. Generally in

compare sport types male- female distinction didn't find. Male volleyball players had higher scores than soccer players in CI. The reason of this difference the soccer player more amateur group than volleyball players in our study. Salmon etc. (1994) found elite soccer players used imagery more than novice and found they used motivational dimension more than cognitive. Isaac, Marks (1994) and Gammage etc. (2000) studies showed there were imagery differences existed based on gender and type of activity. References Gammage, KL. Hall CR. Rodger WM. (2000). *Sp Psychologist*, 14,348-359. Hall C. Mack D. Paivio A. Hausenblas H. (1998). *Int J of Sp Psy*, 29, 73- 89. Isaac AR. Marks DF. (1994). *Bri. J Psy*, 85, 479- 500. Morris T. Spittle M. #### PREVENTING INJURIES IN BASKETBALL

Klein, C., Luig, P., Henke, T.

*Ruhr-University Bochum*

**Introduction** Approximately 1.7 million citizens within the EU-27 area play basketball regularly. Recent research shows an injury incidence of 3-6 injuries/1000h. Thus, one has to expect at least 720,000 basketball-related injuries a year causing direct medical costs of 500 million. The purpose of this study, which is part of the EU funded project "Safety in Sports", is to illustrate smart ways how to prevent basketball injuries in a sustainable manner. **Methods** A structured literature search for relevant publications of the period 1990-2009 was performed. The identified sources were furthermore graded by a panel of basketball injury prevention experts (n=20) in terms of their effectivity, applicability and acceptance. This evaluation process led to a number of encouraging recommendations which were adapted to the national demands and have been pilot implemented into two national basketball associations within the FIBA-Europe. **Results** 70 sources dealing with 108 preventive recommendations were identified and divided into four categories – (1) Training/Physical Preparation, (2) Technical/Political Approaches, (3) Equipment/Facilities and (4) Medical/Non-medical Support. The great majority (47 %) is focusing on the first category, which is also judged most valuable by the expert panel. These preventive measures focus on basic physical preparation, structured warm-up routines, basic and advanced technique training and neuromuscular training. Further important preventive measures are given in the category Equipment/Facilities. These recommendations focus on ankle injury prevention via external ankle stabilisation as well as custom-made mouth guards to reduce dental injuries. **Discussion** Basketball associations and clubs should follow a pro-active strategy as to the risk of injury and communicate with members and the general public openly about risks involved and necessary measures to be taken by clubs and individuals. Players should be provided with educational materials presenting basic exercises. It is recommended to have all national associations to include an injury prevention module in their trainer education curriculums and to designate an official staff member as 'safety promotion ambassador' of the federation. Such a pro-active approach will also contribute to the positive image of the game and will help to attract new members.

#### COOLING HYPERTHERMIC INDIVIDUALS WITH ICE SLUSHY VERSUS ICE PACKS

Burdon, C.1, Schmidt, C.1, Johnson, N.1, Chapman, P.2, O'Connor, H.1

*1 USyd (Sydney, Australia), 2: ACU (Sydney, Australia).*

**Introduction:** During endurance exercise in hot environments core body temperature ( $T_{tr}$ ) is elevated, which can lead to heat exhaustion and heat stroke. Cooling hyperthermic individuals as quickly as possible is recommended (1). In field situations, immersion in ice/cold water is often impractical so the application of cold towels and ice packs to the neck, axilla and groin is typically used as an alternative (1). Recently, the use of an ice slushy bolus has been demonstrated as an effective pre-cooling technique (2). The aim of this study was to compare the efficacy of ice packs (IP) against ice slushy consumption (SC) for reduction in  $T_{tr}$  and management of hyperthermia. **Methods:** The study was a randomised cross-over trial. Eight active participants (5M, 3F) heated to a  $T_{tr}$  of  $\sim 39.5^{\circ}\text{C}$  by cycling in a climate chamber ( $40^{\circ}\text{C}$ , 50% relative humidity). Water ( $19^{\circ}\text{C}$ ) was consumed to prevent dehydration with intake matched between trials. Upon reaching  $T_{tr}$   $39.5^{\circ}\text{C}$ , exercise was terminated and participants were removed to a cool room ( $22^{\circ}\text{C}$ ) with a fan ( $2.2\text{ m.s}^{-1}$ ) and reclined supine until  $T_{tr}$  dropped by  $1^{\circ}\text{C}$ . In IP, ice packs (n=4; 300g ice each) were placed bilaterally on the axilla and groin. In SC, participants consumed 400g of ice slushy ( $-1^{\circ}\text{C}$ ) in two 200g boluses. **Results:** Participants cycled for  $42\pm 11$  min to reach  $39.3\pm 0.2^{\circ}\text{C}$  and were cooled to  $38.3\pm 0.2^{\circ}\text{C}$ . No difference in cycling time, peak  $T_{tr}$  and end- $T_{tr}$  was observed between conditions ( $p=0.57$ ,  $p=0.19$  &  $p=0.17$  respectively).  $T_{tr}$  decreased  $1^{\circ}\text{C}$  in  $12\pm 2.8$  min with SC versus  $15\pm 2.1$  min with IP ( $p=0.02$ ). Rate of  $T_{tr}$  change was  $0.09\pm 0.04^{\circ}\text{C.min}^{-1}$  for SC and  $0.06\pm 0.01^{\circ}\text{C.min}^{-1}$  for IP ( $p=0.05$ ). Some participants experienced a transient  $T_{tr}$  increase with IP before cooling. **Discussion:** Cooling after exercise-induced hyperthermia was significantly faster with 400g ice slushy consumption than a traditional method of ice packs placed over the neck, axilla and groin. The superior rate of decrease with SC is considered important as rapid cooling ensures the best outcome following hyperthermia (1). Use of cold air and ice packs is associated with a decrease in skin temperature which would reduce skin blood flow and likely lead to shunting of blood internally, temporarily increasing  $T_{tr}$ . In contrast, we propose that the more effective cooling with ice slushy consumption is a result of concurrent internal and external cooling via heat sink, evaporation and convection. Cooling with SC also restores fluid balance after prolonged exercise in the heat. This method (SC) may be useful as an alternate or complimentary strategy to ice packs when individuals are able to ingest fluid and immersion baths are not available. **References:** 1. ### RECURRENT CHILDHOOD WHEEZING AND EXERCISE INDUCED ASTHMA IN LATER LIFE

Rosenhagen, A., Vogt, L., Thiel, C., Bernhoerster, M., Banzer, W.

*Goethe University*

Aim Exercise induced asthma (EIA) common in endurance and other athletes limits physical activity. Although a correlation between recurrent childhood bronchitis and the development of asthma has been reported, its relation to EIA in adult athletes has not been assessed. The study evaluates the EIA risk after recurrent childhood wheezing (RCW) and its aggravating influence on the known risk factors. Methods To evaluate the effect of RCW on EIA, 570 multiple choice questionnaires were evaluated, assessing the history of RCW and the EIA occurrence. The latter was defined either according to physician-derived diagnosis, by typical symptoms or by decrease of the 1-second forced expiratory volume after a 6-minute running test. Contingency tables and a logistic regression model were worked out to describe referring parameters of EIA incidence. Result Almost one quarter of the athletes with RCW were attributed positive for EIA. Contingency calculations revealed a 2.6 times higher chance of symptoms of EIA after RCW. Outdoor sports performed on a professional level further increased this risk. Long lasting sport participation, exercising in cold weather, self-limiting of symptoms within 30 min are revealed as predicting factors for a higher risk of EIA. The Nagelkerke R<sup>2</sup> of .596 for this model explains almost 60% of the variance. Summary These results suggest an effect of recurrent affections of the respiratory tract in childhood to EIA in adults. For safe sports participation, the athlete, as well as involved caregivers (parents, coach) should have an adequate knowledge of EIA and prevention/intervention strategies like warming up or the use of inhalers.

### NO DIFFERENCE IN EFFECTIVENESS BETWEEN FOCUSED SHOCKWAVE THERAPY AND RADIAL SHOCKWAVE THERAPY FOR TREATING PATELLAR TENDINOPATHY. THE TOPSHOCK STUDY: A RANDOMIZED CONTROLLED TRIAL.

Van der Worp, H., Zwerver, J., Hamstra, M., Van den Akker-Scheek, I., Diercks, R.L.

*center for sports medicine*

Introduction Patellar tendinopathy is a chronic knee injury that is often therapy resistant. Conservative and surgical treatment of patellar tendinopathy are not always successful, hence new treatment options are being developed (Gaida & Cook, 2011). One of these treatments is Extracorporeal Shockwave Therapy (ESWT). Two ESWT technologies are available: focused shockwave therapy (FSWT) and radial shockwave therapy (RSWT). These two technologies generate therapeutic waves with different characteristics. The aim of the study was therefore to compare the effectiveness of FSWT and RSWT for treating patellar tendinopathy both in combination with eccentric training. Methods Patients were randomized into two groups (van der Worp et al., 2011). One group received three sessions of FSWT whereas the other group received three sessions of RSWT. Both groups also received an eccentric training program. Follow-up measurements took place 1, 4, 7 and 14 weeks after the final shockwave treatment. The primary outcome measure was the VISA-P questionnaire which measures pain, function and sports participation. Secondary outcome measures were pain during ADL, sports activities and the decline squat. Results 43 subjects (57 tendons) were included in the study. 21 subjects (31 tendons) received FSWT whereas 22 subjects (26 tendons) received RSWT. Both groups improved significantly on the VISA-P score, but there were no differences in improvement between the FSWT group (15.0 points on the VISA-P) and the RSWT group (9.6 points,  $p=.30$ ). This was also the case for the secondary outcome measures. Discussion Despite the technological differences, there were no differences in the effectiveness between FSWT and RSWT. Based on this it is not possible to recommend one treatment over the other on grounds of outcome. Both groups improved significantly although it is questionable whether this difference is clinically relevant. References Gaida JE, Cook J. ### STRUCTURAL DEFORMATION OF LONGITUDINAL ARCH DURING RUNNING FOR MEDIAL TIBIAL STRESS SYNDROME

Noh, B., Masunari, A., Miyakawa, S.

*University of Tsukuba*

Introduction Medial tibial stress syndrome (MTSS) is one of the most common exercise induced leg injuries. But the literature regarding MTSS which was analyzed dynamically is not seen. In recent years, using fluoroscopy to perform motion analysis as well as to evaluate the biomechanics of the connective tissues during gait and running has received increased attention. Therefore, The aim of this study was to examine sagittal plane motion of the medial longitudinal arch (MLA) and the lateral longitudinal arch (LLA) as well as the kinematics of the arch during running for medial tibial stress syndrome. Methods A total of 10 individuals with 5 MTSS and 5 non-injured controls volunteered. Fluoroscopic imaging was used to investigate the movement of the bones during running of the right foot. The data were analyzed using a template method. Sagittal motion was defined the translational motion of the 1st metatarsal (M1), 5th metatarsal (M5) and d1, d2(d1 and d2 which is distance of the M1 and M5 for the calcaneus.). Results Regarding translational motion, the motion MLA and LLA of the MTSS had significantly larger anterior displacement and inferior displacement of the M1, M5 than non-injured controls ( $p<.05$ ). With regard to the d1 and d2 displacement, MTSS had significantly larger anterior displacement of the d1 and d2 than non-injured controls ( $p<.05$ ). Discussion In both M1, M5 translational motion was displaced anteroinferiorly. The relationship with MTSS between increased tension of the tibialis anterior and tibialis posterior found in the present study (Mannoji T., 2001). And the inferior displacement has a relationship with shock absorption insufficient of contact and to muscle fatigue which is insertion in metatarsals (Japan Sports Assoc., 2007). If the movement of the metatarsals was extreme, Early occurrence of muscle fatigue which has been inserted in the metatarsals and increased tension of that muscle. Oida (2011) reported that foot arch decreased with the output incompleteness of intrinsic muscles of the foot. Because of that d1 and d2 had anterior displacement. This kind of things in traction the periosteum of the tibia related possible MTSS. This study suggested that it is possible risk factor for MTSS not only excessive decrease of MLA but excessive decrease of LLA. References Mannoji T. (2001). Shin-splint, 286-289. Ishiyaku Publishers, Inc. Japan Sports Assoc. (2007). Text for the Athletic Trainer, 122-128. Bunkoudo. Oida T. (2011). Tokai Hokuriku Jpn Phys Ther Assoc., 27, 128.

## EYE INJURIES IN SPORTS – LATEST FIGURES

Jendrusch, G.1, Katlun, T.2, Schnell, D.2, Schulz, D.3, Henke, T.1, Platen, P.1

1: Ruhr-Universität Bochum (Bochum, Germany), 2: Ressort Sports Ophthalmology (BVA) (Germany), 3: ARAG Sports Insurance (Düsseldorf, Germany)

Introduction According to Schnell (2000) about 3 % of all eye injuries happen during sports activities. A good quarter of these eye injuries are so severe that they need ophthalmic treatment. Roughly 10 % of all eye injuries during sports activities lead to blindness. In those circumstances latest figures of eye injuries in sports will be presented. Furthermore, the risk of eye injuries during diverse sports disciplines will be pointed out. Methods 1.830 eye injuries were evaluated on the basis of 180.218 sports injuries (club sports) that have been recorded by the database of sports accidents of the ARAG Sports Insurance and the Ruhr-Universität Bochum between 1988 and 2008. In order to calculate the sports discipline related risk of eye injuries the frequency of eye injuries in one sports discipline has been qualified with regard to the frequency of all sports injuries that have been recorded in this sports discipline. Essential results The average age of the 1.830 eye injured – this equals 1.02 % of all sports injuries – was  $31.6 \pm 16.3$  (age range: 3 - 85 years). 78.2 % of the injured persons were male, whereas 21.8 % were female. On average the men were  $31.8 \pm 16.0$  years old (age range: 3 - 85 years) and the women were  $30.5 \pm 17.2$  years old (age range: 3 - 82 years). In the summarily relatively rare eye injuries in sports, blunt trauma, e.g. contusions, are dominant with over 50 %. These are often injuries caused by balls (e.g. in tennis or squash), rackets (e.g. in squash or ice hockey) or hand and elbow hits during tackles/tacklings (e.g. in handball or soccer). Correspondingly, especially sports disciplines like squash, badminton, tennis, but also water polo, which involves swimming and grasping movements above the surface of the water at eye level, contain a significantly higher risk of eye injuries than other sports disciplines. Conclusion Due to the special risk of eye injuries in squash the use of protective (sports) goggles (polycarbonate lens eye guards) is clearly recommended from an ophthalmological point of view (already for a long time) [Schnell, 2000; Jendrusch et al., 2002]. For one-eyed athletes or sports persons with monocular defective vision protective sports goggles should be obligatory in order to protect the remaining healthy eye. ## COLD WATER IMMERSION RECOVERY PROTOCOLS: DO THEY CAUSE CARDIAC ARRHYTHMIAS AND REPRESENT A CARDIOVASCULAR RISK?

George, K.P., Dolman, G.M., Gregson, W., Somauroo, J., Jones, H.

Liverpool John Moores University

Background: In contemporary sporting environments athletes have adopted whole limb cold water immersion (CWI) as a strategy to aid recovery. Little attention has been paid to the cardiovascular risk associated with CWI despite evidence from "work-physiology" studies of substantial numbers of cardiac arrhythmias being induced with water immersion. The aim of this initial study was to evaluate the effect of CWI (8 and 22oC) at rest on heart rate (HR), blood pressure (BP) and cardiac electrical activity (ECG). Methods: Ten healthy male subjects (mean age  $25 \pm 5$ ; height  $1.79 \pm 0.04$  m; body mass  $79.5 \pm 4.6$  kg) completed two experimental trials consisting of; 30 min supine rest, 10 min CWI and 10 min supine recovery in a stable laboratory environment (22oC, 50% RH). CWI was to the level of the iliac crest and was performed, in a random order, at water temperatures of 8oC and 22oC. HR, BP and both prolonged single lead rhythm and 12 lead ECG data were collected continuously via finger photo-plethysmography, PowerLab and SpaceLabs ECG machines. ECG data were read by a consultant cardiologist. HR and BP were averaged over 1 min intervals across the last 10 min of supine rest, CWI and recovery. Results: HR and mean arterial pressure (MAP) did not significantly changes across the 22oC CWI trial. In the 8oC trial HR increased marginally but MAP was significantly increased during immersion (Rest:  $79 \pm 7$  mmHg; Immersion:  $98 \pm 12$  mmHg,  $P < 0.05$ ) and then returned to baseline during recovery. Sinus arrhythmia and sinus bradycardia were common. There were 2 cases of a low atrial rhythm (1 throughout all phases and another developing in recovery); 1 case with a premature ventricular complex and 2 cases with atrial ectopic beats during baseline or recovery. There was no ST depression but new T-wave inversion in inferior leads occurred in 2 cases during immersion which normalised in recovery. There were no significant time-by-trial interactions for P wave duration and axis, PR duration, QRS duration and axis, QT, QTc, T wave axis and  $sV1+rV5$  voltage. Conclusion: Ten minutes of CWI (at 8oC) resulted in a minor but statistically significant pressor response. Few cardiac arrhythmias were detected and these were not consistently mediated by temperature, trial phase and presented no immediate clinical concern. T wave changes were seen in one athlete, but as to whether this represents a benign phenomenon or an increase in cardiovascular risk is undetermined.

## INCIDENCE OF SPORT INJURIES IN JAPANESE BLIND FOOTBALL PLAYERS: A 1-YEAR PROSPECTIVE STUDY

Kinoshita, H.

Tsukuba University of Technology

INCIDENCE OF SPORT INJURIES IN JAPANESE BLIND FOOTBALL PLAYERS: A 1-YEAR PROSPECTIVE STUDY Hiroaki Kinoshita, Kazushige Ishizuka, Yasuko Kohda, Yoshiki Fukunaga Tsukuba University of Technology (Tsukuba, Japan) Introduction: Blind football is an adaptation of football 5-a-side (futsal), one of Paralympic games, played with modified FIFA (Fédération Internationale de Football Association) rules, for athletes with visual impairments including blindness. Players are assigned to one of sport classes based on their level of visual impairment. Class B1 players are totally or almost totally blind, and Class B2 /3 are partially sighted. For Class B1 games, teams are consisting of 4 field players with visual impairments, using eye shades to ensure fairness, and one goalkeeper may be sighted. The ball is equipped with a noise-making device inside to allow players to locate it by sound. During the game, players have to say clearly and audibly the word "voy" or "go", or any other similar word, when approaching the opponent with a ball to avoid collision between players. As little research has been performed on the athletes with disabilities relative to sports injuries, especially in blind football players, the objective of this study is to find the features of sports injuries in blind football. Methods: In this 1-year prospective study, 11 male Japanese national team blind football players (all Class B1, mean (SD) age  $31.5$  (6.5) years) were interviewed and recorded the incidence of injuries, from July of 2010 to June of 2011. This study documented injury type and location caused by football, according to the FIFA standardized injury report form. An injury is defined as an absence from training or game for at least a week followed by diagnosis of anatomic tissue damage and medical treatment. Results: During the investigation period, there were five total injuries among four players. The body parts injured were head / neck (40%) and lower extremity (60%). The injuries were diagnosed as fracture (20%), sprain (60%) and laceration / abrasion (20%). Discussion: According to many studies of sport injuries in football, major locations of injuries are lower extremities, espe-

cially in thigh, ankle, knee and lower leg. In this study, head / neck injuries were relatively high rate compared to many studies of football-related sports injuries. Head / neck injuries were predominantly caused by collisions between players. As players are completely blinded during the game, they have to say clearly and audibly the words like "voy" approaching the opponent with a ball. Collisions often happen when they could not say the words properly by mistake. Overall, it is indicated that incidence of sport injuries in Japanese blind football was low and there was no catastrophic injury such as fatal or causing permanent severe functional disability. ### THE RELATIONSHIP BETWEEN PHYSICAL ACTIVITY AND BONE HEALTH OF PREMENOPAUSAL WOMEN USING DEPOT-MEDROXYPROGESTERONE ACETATE

Babatunde, O.

*Staffordshire University*

The relationship between physical activity and bone health of premenopausal women using Depot-medroxyprogesterone acetate (DMPA) Babatunde, O.O.1., Forsyth, J.J.1 1: Staffordshire University (UK) Introduction Progesterone-only contraception, such as Depot-Medroxyprogesterone Acetate (DMPA), has been associated with decrease in bone health. Physical activity, particularly of a high-impact nature, is known to be beneficial for enhancing bone health and has been advocated for women in the hope of offsetting this contraceptive hormone-related loss in bone mineral density (WHO,2007;Committee on Safety of Medicine,2004); however, little is known about whether exercise is actually helpful for DMPA users. The aim of this study was to examine the relationship between physical activity and bone health of premenopausal DMPA users. Methods Bone health of 45 DMPA users (23 ±3.7yrs) was assessed using calcaneal broadband ultrasound attenuation (BUA). Recent bone-loading exercise (specific to the hip and spine) was assessed using a bone loading history questionnaire. Results The duration of DMPA use ranged from 6 to 132 months. There was a significant but negative correlation between BUA (mean of 62.8 ±10.8 dB/MHz) and recent hip ( $r = -0.499$ ,  $p=0.001$ ), and spine exercise ( $r = -0.642$ ;  $0.001$ ). In a regression analysis, 63% ( $p=0.001$ ) of the variation in BUA was explained by recent hip and spine exercise ( $BUA = 66.3 + 1.82$  (recent hip exercise) –  $2.398$  (recent spine exercise)). Discussion The findings of this study corroborate those of previous research, suggesting that in a hypo-oestrogenic state, as induced by DMPA, a relative increase in mechanical strain could impair bone health (Ehrlich,2002). A cycle of prolonged DMPA use and concurrent engagement in high-impact physical activity may result in a compromise of bone's structural integrity and consequently bone strength. It is suggested that the lack of oestrogen may counteract the effects of physical activity by inhibiting bone formation in response to mechanical bone loading. References 1. ### TRAINING CHARACTERISTICS IN DIFFERENT SPORT CATEGORIES AND THEIR RELATIONSHIP WITH NON-CONTACT INJURIES

Malisoux, L.1, Frisch, A.1, Urhausen, A.1,2, Seil, R.1,2, Theisen, D.1

1: *Sports Medicine Research Laboratory, CRP-Santé, Luxembourg*; 2: *Centre de l'Appareil Locomoteur, de Médecine du Sport et de Prévention du Centre Hospitalier de Luxembourg, Luxembourg*

Introduction Training characteristics in high-level sports require careful modulation to optimize performance. However, inappropriate training load could be a risk factor for sport injuries, especially non-contact injuries (NCI). The aim of this study was to compare training characteristics in different sport categories and to investigate their relationship with NCI. Methods Young (12-19 years) high-level athletes ( $n=154$ ) from a regional sport school were followed during the school season 2010-2011 (41 weeks) regarding training characteristics and sport injuries. The 15 represented sport disciplines were classified into 3 categories: racket, team, and individual sports. Practice volume and intensity were used to determine weekly volume, load, monotony and strain for each athlete (Foster et al. 2001). Sport injuries were considered in case of time-loss >3 days and subdivided into contact injuries and NCI. The effect of age, gender, sport category, and injury status (no injury, contact injury or NCI) on training characteristics was tested using analyses of covariance. A repeated measures analysis of covariance was used to study changes of training characteristics prior to NCI, taking into account significant factors from the previous analyses. Results NCI represented 66 % of the 126 injuries recorded and concerned 65 athletes. Across sport categories, differences were found for mean weekly volume ( $p<0.001$ ), load ( $p<0.001$ ), monotony ( $p<0.05$ ) and strain ( $p<0.001$ ), while age was related to weekly load ( $p<0.05$ ) and strain ( $p<0.05$ ). However, no relationship was found between training characteristics and injury status. Controlling for sport category and age, we found no significant difference between mean training characteristics 7 days prior to NCI and those 2-5 weeks prior to NCI. Discussion The method used here to characterize training behavior was sensitive to discriminate between different sport categories and highlight age-related differences. Injury status seems to be unrelated to average training characteristics. Furthermore, NCI do not seem to be coupled to short-term modulation of training behavior. The relationship between training behavior and injury, especially NCI, should be further studied. References Foster, C., J. A. Florhaug, J. Franklin, et al. (2001). ### UPPER LIMB INJURIES DURING THE MEN'S FIELD HOCKEY JUNIOR WORLD CUP 2009

Mukherjee, S.

*National Institute of Education, Nanyang Technological University, Singapore*

UPPER LIMB INJURIES DURING THE MEN'S FIELD HOCKEY JUNIOR WORLD CUP 2009 Mukherjee S Nanyang Technological University, Singapore Introduction Field hockey players are at risk of upper limb injuries and the use of protective gear is uncommon in the sport. Despite the suggestive evidence, there are no reports on hand and upper limb injuries in elite youth hockey players during major international tournaments. The objective of this study was to provide a descriptive epidemiological account of upper limb injuries in elite youth male field hockey players during the Men's Junior World Cup 2009. Methods A total of 324 players were observed during 58 matches in the tournament. The injury reporting system was based on that used in team sports during international tournaments. All injury documentation was done by direct on-location observation by a trained sports medicine physician followed by confirmation from the team doctors or physiotherapists. Results A total of 28 hand and upper limb injuries were documented in the 58 matches observed. The overall

injury frequency rate was 19 per 1000 match hours and 22 per 1000 player matches. Most injuries (50%) were due to the ball striking the body part with hand being the commonest site (61%) and contusion being the commonest type (82%) of injury. The left hand and wrist was more commonly injured than the right side. The incidence of injuries was higher in the second-half (64%) than the first half. Fifty-four of the 324 athletes observed wore gloves on either left or both hands. Nineteen of the 20 hand/wrist injuries were in athletes not wearing gloves. Discussion Male elite youth hockey players are at a high risk of upper limb especially hand and wrist injuries during major international tournaments. The injuries can lead to both short and long-term player time loss in the tournament matches. With the hand being the most commonly injured part of the upper limb, use of protective gloves can provide significant protection against hand and wrist injuries in the sport and the players should be educated on the evidence of injury risks and consequences and encouraged to adopt safe practices in the field hockey. ### **APPROPRIATE SODIUM SUPPLEMENTATION INCREASES SERUM SODIUM LEVELS IN ELITE ATHLETES WHICH ARE MAINTAINED DURING EXTREME EXERCISE – IMPLICATIONS FOR EXERCISE ASSOCIATED HYPONATRAEMIA.**

WEATHERALL, L., JUTLEY, R.S., BLOW, A., NANJIAH, P., VOYSEY, V.

#### *PRECISION HYDRATION*

Appropriate Sodium Supplementation Increases Serum Sodium Levels in Elite Athletes Which Are Maintained During Extreme Exercise – Implications for Exercise Associated Hyponatraemia. Weatherall et al. Introduction Exercise Associated Hyponatraemia (EAH) results from overhydration with low-sodium drinks or water in the face of high sweat losses. EAH causes problems ranging from poor coordination, confusion and muscle weakness to seizures and death. There is little evidence linking sweat sodium losses to EAH. As net sodium losses can vary 13-fold amongst athletes training in the same session, it is important to collate such evidence(1). This study evaluates whether sodium supplementation based on individual sweat sodium levels can protect against EAH during extreme exercise compared to water alone. Methods Randomised crossover study comparing H2ProHydrate (500, 1000 or 1500 mg/l sodium) to Evian water (5mg/L sodium) in 7 elite male athletes. Pre-trial all underwent the Precision Hydration pilocarpine-induced sweat sodium analysis. Randomisation was to water or H2Pro allowing ad libitum drinking for 72 hrs pre-trial while maintaining standard diet. Cross-over was undertaken 2 weeks later. Athletes were subjected to extreme exercise consisting of maintaining 70% VO<sub>2</sub> max in a climate chamber at 28C, 55% humidity for 60 min followed by a 15-min blinded performance time trial(TT). Ad libitum drinking was allowed throughout. End-points were baseline serum sodium sampling (pre-trial), post-chamber exposure and post-TT exposure and drink volumes. Results Mean sweat sodium concentration was 1043mg/L (range 430-1640). One athlete failed to complete the trial on water due to nausea and dizziness and was therefore excluded. Mean serum sodium levels were higher in all athletes on H2Pro pre-trial, following the 60-min chamber exposure and following the TT. Baseline mean(mmol/L):H2Pro 141.2;water 138.5 Post-chamber mean(mmol/L):H2Pro 141.7;water 138.2 Post-TT mean(mmol/L):H2Pro 141.5;water 138.7 Analysis showed that 'high sodium sweaters' (>1380 mg/L or 60 mmol/L,n=3) increased their serum sodium by the highest margin(138 mmol/L on water vs.142 mmol/L on H2Pro). The remaining group show a modest rise(139 mmol/L on water vs.141 mmol/L). Ave. volume of drink consumed: 1758 ml ( H2Pro), 1505 ml (water) Conclusion Appropriate sodium pre-loading allows higher serum sodium levels which are maintained during extreme exercise. The greatest increases are seen in high sodium excretors who would typically have the highest sodium losses during exercise. Increased voluntary drinking of H2Pro indicates greater palatability which may help prevent hyponatraemia. The lower water intake compared to H2Pro could explain why serum sodium levels while on water did not decrease to dangerous levels. These findings have implications on understanding the onset of EAH. Introduction To the best of our knowledge, there is no study regarding the effect of exercise order manipulation during concurrent training in the water-based exercises on the neuromuscular and cardiorespiratory adaptations in young women. Therefore, the aim of the study was to compare the effects of different intra-session exercise orders in the neuromuscular and cardiorespiratory adaptations induced by concurrent water-based exercise training in young women. Methods Twenty-six healthy young women (25.12±2.94years) were randomly placed into two concurrent training groups: resistance training prior to (RA, n=13) or after (AR, n=13) aerobic training. Subjects trained resistance and aerobic training in water environment 2 times per week performing both exercise types in the same training session. The peak oxygen uptake (VO<sub>2</sub>peak), oxygen uptake corresponding to the first and second ventilatory thresholds (VO<sub>2</sub>VT1 and VO<sub>2</sub>VT2) was evaluated during a maximal incremental test on a treadmill before and after the training. Moreover, maximal dynamic strength (one repetition maximum test) of the knee extensors and elbow flexors were evaluated and the quadriceps femoris muscle thickness was determined by ultrasonography. Results There were significant modifications after training in the VO<sub>2</sub>peak (p<0.001), VO<sub>2</sub>VT1 (p=0.001) and VO<sub>2</sub>VT2 (p=0.002) in both groups. Between the groups RA and AR there was no significant difference in the relative gains for all cardiorespiratory variables (VO<sub>2</sub>peak: p=0.219; VO<sub>2</sub>VT1: p=0.321; VO<sub>2</sub>VT2: p=0.939). For maximal dynamic strength (1RM) of the knee extensors (p<0.001) and elbow flexors (p<0.001) there were significant increments after training in both groups. Between the groups RA and AR there was no significant difference in the relative gain for the 1RM of the elbow flexors (p=0.946). However, the RA group present-

ed greater relative gain compared to AR for the 1RM of the knee extensors ( $27.72 \pm 16.81$  vs  $43.58 \pm 14.00\%$ , respectively,  $p=0.015$ ). The quadriceps femoris muscle thickness ( $p<0.001$ ) presented modifications after training in both groups. The RA group presented greater relative gain compared to AR for the quadriceps femoris muscle thickness ( $5.76 \pm 1.88$  vs  $10.24 \pm 3.11\%$ , respectively,  $p<0.001$ ). Discussion The intra-session sequence in water-based exercises influence the strength and hypertrophy gains to concurrent training, as observed greater relative changes on strength of knee flexors and quadriceps femoris muscle thickness was found when the resistance training was performed prior to aerobic training. In summary, to optimize the strength and hypertrophic gains in the young women, the concurrent training prescription in water-based exercises should include an intra-session order of resistance training prior to aerobic training.

### **INFLUENCE OF COMPRESSION STOCKINGS ON CALF MUSCLE-PUMP CAPACITY**

Meyer, H., Meurer, R., Bulling, B., Lötzerich, H.

*German Sports University Cologne*

Influence of compression stockings on calf muscle-pump capacity Meyer, H. 1, Meurer, R. 1, Bulling, B. 2, Lötzerich, H. 1 1: German Sports University Cologne, Institute of Outdoor Sports and Environmental Science 2. Practice for Vascular Diseases, Cologne Introduction: It is well known that compression garments (CG) improve venous pooling or blood flow parameters such as deep venous velocity (Lawrence 1980). However, whether or not there is an enhancement of venous return parameters during physical exercise, is still unclear. The aim of our study is to quantify the influence of CG on calf muscle-pump capacity during physical exertion. Methods: 43 subjects, 21 male (age:  $22.8 \pm 5.5$  years; height:  $185.2 \pm 5.7$  cm; weight:  $77.8 \pm 12.2$ kg) and 22 female subjects (age:  $21.3 \pm 2.6$  years; height:  $169.6 \pm 5.2$  cm; weight:  $58.4 \pm 5.9$ kg) completed 2 randomized testing sessions. In the course of one session, the subjects wore compression socks (?Running Compression Socks?, CEP, Bayreuth (Germany), 24-18mmHg ), during the second, they did not. At each session, every subject had to execute three times twelve tiptoestandings to the pulse of a metronome. The muscle pump capacity was measured by 2-channel-venous-occlusion-plethysmography (Compactus 712, Gutmann MD GmbH, Geretsried, Germany) Results: The calf muscle-pump capacity increased significantly ( $p<0.05$ ) whilst executing the tiptoestandings. The mean improvement ranges from  $1.15 \pm 0.66$ ml/100ml without to  $1.56 \pm 0.59$ ml/100ml with compression stockings. Through compression stockings, all subjects could enhance the capacity under compression conditions, females from  $1.04 \pm 0.64$ ml/100ml to  $1.36 \pm 0.61$ ml/100ml, males from  $1.26 \pm 0.69$ ml/100ml to  $1.76 \pm 0.49$ ml/100ml. Discussion: The present study shows a significant performance enhancement for the function of calf muscle-pump achieved by wearing CG. Previous studies have shown inconsistent results; whilst some promise performance improvement by using CG in sports (Kemmler 2009, Chatard 2004), others do not agree on those findings (Scanlan 2008, Sperlich 2010). For the positive results of wearing CG, the present study may be a statement of grounds. References: Sperlich B, Haegele M, Achtzehn S et al. ### **INFLUENCE OF A NINE WEEK BALANCE TRAINING PROGRAM ON ONE LEG STAND PERFORMANCE**

Roos, L., Maeder, U., Wyss, T.

*Swiss Federal Institute of Sports Magglingen*

Introduction Balance is crucial in everyday activities such as walking or climbing stairs. In military basic training balance is even more important since recruits have to perform a large number of physical activities on uneven surfaces often while carrying heavy loads. Research suggests that a specific training can improve balance performance [1]. Therefore, the objective of this study was to investigate the improvement of the balance ability over a 9 week training program. Methods In this study 406 male recruits of the infantry training camp in Aarau, Switzerland volunteered during their basic training. Thereof, 243 recruits were chosen to participate in a 9 week balance training program. A 30 minutes program was included into the army sports training of 180 minutes per week. The 163 recruits of the control group participated in the normal army sports training comprised of endurance runs, strength and coordination training and sports. To test the recruits' balance abilities a one leg stand [2] was performed in week 1 and week 11 of basic training. Results Control and intervention group showed a significant increase of the one leg stand duration over the 11 weeks of basic training,  $9.06 \pm 13.46$  s and  $12.71 \pm 15.40$  s respectively. However, the difference in performance enhancement between the groups was significant ( $p=0.014$ ). There was no significant difference in total duration of sport ( $140.21 \pm 76.96$  vs.  $145.24 \pm 27.80$  minutes per week), amount of trainings per week ( $1.73 \pm 0.63$  vs.  $1.86 \pm 0.35$ ) or self reported intensity ( $2.26 \pm 0.23$  vs.  $2.35 \pm 0.39$  on a scale of 1 to 3) between control and intervention group. Discussion Both groups increased the total duration of one leg stand suggesting that the activities executed during daily military training already increase the recruits' balance abilities to a certain degree. The most common military actions such as lifting, carrying loads while marching, climbing, crawling, jumping, digging [3] require good balance and core strength to succeed. However, the intervention group had a significantly higher performance increase. A balance training as deployed here, therefore, could be useful for injury prevention during military basic training [1]. References 1. McGuine, T.A. and J.S. ### **ADAPTATION TO ENDURANCE TRAINING IN TEAM SPORTS – THE INFLUENCE OF TRAINING STATUS**

Franke, J.1,2, Hinrichs, T.2, Platen, P.2

*1Saarland University, 2Ruhr-University Bochum*

Introduction: It is known that training status and training intensity significantly influence endurance enhancement in endurance sport athletes. The aim of this study was to investigate the influence of pre-training level of performance on endurance enhancement in team sport athletes when using sport specific training versus classical endurance training modes. Methods: 93 elite players (62 male, 31 female) from 4 team sports were investigated. They completed a VO<sub>2</sub>max-Test on a treadmill and a field test for calculating running velocity at 4 mmol/l lactate (v4). Each team was randomly divided into two training groups according to the individual endurance capacities.

Group one performed a high intensity interval run training (HIT, 4x4 min at 95% of their maximal heart rate (HRmax)) using sport specific running tracks, while group two performed an extensive run training (ET, 45min at 75% of v4). Both groups followed this regime 3x per week for 4 weeks in addition to the equal team training. To examine the influence of training status on endurance enhancement a median (md) split was applied for baseline parameters considering endurance performance. Men (m) and women (w) were analysed separately. Results: Training methods had no sig. effect on performance enhancement for any of the measured parameters. v4 increased sig. from pre to post training in m and w. VO2max did not change sig. while max. running velocity during the VO2max test increased. ANOVA for pre to post differences in v4 of the two md split groups showed a sig. influence of training status on performance enhancement in men (md: 3.8 m/s, mean value below md: 3.6±0.3 m/s, difference pre to post testing (pre/post): 0.2±0.2 m/s; mean value above md: 4.1±0.1 m/s, difference pre/post: 0.1±0.2 m/s) while in women the influence of training status on performance enhancement was not sig. (md: 3.1 m/s, mean value below md: 2.9±0.2 m/s, difference pre/post: 0.3±0.1 m/s; mean value above md: 3.4±0.2 m/s, difference pre/post: 0.2±0.2 m/s; p=0.63). Changes in VO2max were independent of training status in m and w. Considering training method, HIT was analysed to be more effective for improving v4 in men with a lower training status than ET while there was no influence of training method in women (p=0.70). Discussion and Conclusion: In this group of elite team sport athletes we could show an influence of training status on performance enhancement in m while this was not visible for w. It can not be ruled out that the difference in gender is masked by the generally lower performance level in women. Maybe their level of performance was not high enough to induce and analyze different ways of endurance improvements.

## ACOUSTIC FEEDBACK IN HIGH PERFORMANCE ROWING TRAINING

Schaffert, N.1, Mattes, K.1, Effenberg, A.O.2

1 University of Hamburg, 2 Leibniz University Hannover

Introduction Using sonification as acoustic feedback (AF) has effects on perception accuracy and regulation of movement patterns (Effenberg, 2005). Thus, it has become increasingly interesting in motor control and learning. To examine effects of AF on the mean boat velocity (vB), it was provided in technique training of elite rowers during the direct preparation phase for the World Championships. The investigation aimed at optimizing the boat run in on-water training. Methods The German National Rowing Team (N=47) (juniors and seniors) was examined with the AF-system Sofirow in 12 boats (small and big boats). The boat acceleration (aB) was measured as effect variable with a MEMS-acceleration sensor (up to 125Hz, 1% measuring accuracy, ±2g measuring range). The aB-time trace was sonified (Parameter Mapping) and transmitted to athletes and coaches time synchronously during on-water training. Statistical analysis considered a minimum of 3 training sessions per boat in which AF was presented in blocks (with and without AF alternately). Standardized questionnaires examined AF's functionality and the athletes' perception of it. Results The analysis of variance showed a significant increase of the mean vB with AF compared to the reference section without AF for all boats (F2=15.85; p=0.00; η2p=0.45) and a significant interaction between the boats (F3=16.88; p=0.00; η2p=0.73). Intra-cyclical structure of the aB-time trace changed qualitatively. Replying to the questionnaires, AF was perceived as functional and supportive for the movement execution by providing a guiding function. Discussion The results show the immediacy of AF to affect the mean vB in on-water rowing training of elite athletes as well as the potential to display characteristic phases of the rowing cycle (rc) by affecting its time-structure. AF drew athletes' attention to the time-dynamic structure of rc which enables them to regulate its critical phases more precisely and supported the feeling for the movement execution. Moreover, synchronization and coordination among the athletes was improved. AF offers new possibilities to assist the technique training of elite rowers by providing feedback information via the sense of hearing and thus, to facilitate the development for a feeling of the rhythm in racing boats. AF has been integrated into the technique training of elite athletes in preparation for the Olympic Games. References Effenberg, A.O. (2005). ## GRIP STRENGTH: ARE DINAMOMETERS EQUIVALENT? JAMAR VS E-LINK

Tomás, M.T., Fernandes, M.B.

Lisbon Higher School of Health Technologies

Introduction Levels of risk for future disability can be assessed with grip strength. This assessment is of fundamental importance for establishing prevention strategies. It also allows verifying relationships with functional capacity of individuals. Most studies on grip strength use the JAMAR Hydraulic dynamometer that provides the value of isometric force obtained during the performance of grip movement and is considered the "gold standard" for measurement of grip strength (Mathiowetz, 2002). However, there are different dynamometers available commercially, such as portable computerized dynamometer E-Link (Biometrics), which provides the value of maximum force (peak force) in addition to other variables as the rate of fatigue for hand strength, among others. Of our knowledge, there are no studies that allow us to accept or not and compare values obtained with both devices and perhaps use them interchangeably. The aim of this study was to evaluate the absolute agreement between the measurements of grip strength (peak force or maximum force in kg) obtained from two different devices (portable dynamometers): a computerized (E-Link, Biometrics) and one hydraulic (JAMAR). Methods 41 subjects (15M, 26F, 20 ± 2 years, 23.8 ± 4.5 kg/m2) were assessed at the same time of day on two consecutive days. Test position chosen was the one recommended by the American Association of Occupational Therapists. We considered the best result from three attempts for the dominant hand. Statistical analysis included correlation (Spearman coefficient) between values obtained on both equipments; Bland-Altman analysis to assess agreement between the two measurements and intraclass correlation coefficient (ICC) to assess the absolute agreement. Results Values for grip strength were 41.0±9.9 kg on JAMAR and 40.6±10.5 kg on E-Link showing that differences between both dynamometers ranging from -9.1kg to 4.1kg (0.4±2.9, mean±sd). E-Link slightly underestimate grip strength, without statistical significance. The correlation coefficient between the two measurements was strong (rs =0.962, p <0.001) and Bland & Altman analysis of the values obtained were all, except one, within the range of mean±2SD. ICC was excellent (0.961; p<0.001). Discussion Data indicate that the two measurements were equivalent, revealing that the tested dynamometers can be comparable in different studies with young adults or in different clinical settings. It seems these two dynamometers can be used interchangeably however one must not forget that the same dynamometer should be used in consecutive measurements in the same study and in clinical settings or validity could be compromised. ### THE ACUTE EFFECTS OF STRENGTH TRAINING ON RUNNING PERFORMANCE OVER TWO CONSECUTIVE DAYS

Doma, K., Deakin, G.B.

*James Cook University*

**THE ACUTE EFFECTS OF STRENGTH TRAINING ON RUNNING PERFORMANCE OVER TWO CONSECUTIVE DAYS** Doma, K.1, Deakin, G.B.1 1: JCU (Cairns, Australia) Introduction Strength training (ST) has been shown to impair running economy with an 8-hour recovery period (Palmer et al., 2001). Accordingly, ST may interfere with endurance adaptations by causing acute detrimental effects on endurance training stimuli. However, to determine whether there are cumulative effects of strength training on endurance training stimulus, it is essential to examine the acute effect of strength training on endurance performance over consecutive days. Subsequently, the purpose of this study was to examine the acute effects of strength training on running performance over two consecutive days. Methods Six male and four female moderately trained runners undertook two running performance tests (RP1 and RP2) 10- and 24 hours following a strength training session, respectively. A baseline running performance test (Base RP) was conducted at least two days before the ST session. Maximal voluntary contractions of the knee extensors were collected prior to and following the ST session and RP1 and RP2. The running performance test was a three stage discontinuous test with the first two stages set at 70- and 90% of ventilatory threshold (VT), respectively, for 10 minutes. The last stage was set at 110% of VT in order to record time-to-exhaustion (TTE). There were two minutes rest between each stage with oxygen cost (CR) and blood lactate (BL) collected during and after the running performance test, respectively. The exercises during the ST session were performed in the order of incline leg press, leg extension and leg curls. All ST exercises were performed at six repetitions maximum with six sets for the incline leg press and four sets for the leg extension and leg curls, respectively, with three minutes rest between each set and exercise. A one way repeated measures analysis of variance was used to determine differences in performance variables. Results The TTE was significantly less during RP 1 and RP2 compared to Base RP ( $P < 0.05$ ). In addition, MVC following the ST session and prior to and following RP 1 and RP2 were significantly less than the MVC prior to the ST session ( $P < 0.05$ ). There were no significant differences in CR and BL between Base RP, RP 1 and RP2. Discussion The attenuation in running performance at maximum effort (i.e. TTE) over 2 consecutive days indicates that cumulative effects of fatigue may be induced as a result of performing one ST session. Such findings may be due to impaired muscular contractility as the knee extensor muscles did not recovery to baseline (i.e. MVC prior to the ST session). The comparable CR between Base RP, RP 1 and 2 shows that strength training does not cause cumulative effects on running performance at sub-maximal levels. Subsequently, caution should be taken when generating training programs that consists of strength and endurance training sessions. References Palmer CD, Sleivert GG. (2001). *J Sci Med Sport*, 4, 447-459.

### SEEKING EQUIVALENCE OF THE ACUTE RESPONSES TO CONTINUOUS AND INTERVAL AEROBIC EXERCISE

Hughes, M.G., Birdsey, L.

*Cardiff Metropolitan University*

**Introduction** A diverse range of training protocols has previously been used to address the issue of how interval training adaptations differ to those obtained from continuous exercise. However, a weakness of these studies is that training duration, mean relative exercise intensity or both of these factors are not fixed at the same values during training. For this reason, it is difficult to be conclusive about the relative merits of these training types. In the present study we sought to identify which variation of a standard interval training protocol would elicit equivalent acute responses to a bout of continuous exercise using sessions of the same training duration. **Methods** Nine healthy, active participants (mean  $\text{VO}_2\text{peak}$  44.5ml/kg/min) performed a maximal test, followed by four 42-min cycle ergometry bouts of either continuous (70 % $\text{VO}_2\text{peak}$ ), or interval exercise. The three interval exercise sessions were variations of the methods used by Helgerud et al. (2007) and comprised six repetitions of 4min all at 85 % $\text{VO}_2\text{peak}$ , interspersed by 3 min of relative recovery at either low, medium or high intensities (45, 60 and 75% of  $\text{VO}_2\text{peak}$ ; i.e., LOW, MEDIUM, HIGH, respectively). Heart rate (HR), Oxygen consumption ( $\text{VO}_2$ ) and blood lactate concentration (BLa) were assessed through the four bouts. **Results** The relative exercise intensities were different between sessions. Specifically, mean BLa was higher in all interval sessions and % $\text{VO}_2\text{peak}$  was lower in the continuous and LOW conditions than in the MEDIUM and HIGH conditions ( $74 \pm 3$  and  $70 \pm 4$  % $\text{VO}_2\text{peak}$  vs.  $77 \pm 4$  and  $83 \pm 4$  % $\text{VO}_2\text{peak}$ , respectively). It was calculated that an interval-recovery intensity of 52 % $\text{VO}_2\text{peak}$  for both the mean  $\text{VO}_2$  and HR data would elicit the same mean response as continuous work at 70 % $\text{VO}_2\text{peak}$ . However, inspection of individual data showed a high variability of results, such that a recovery intensity of between 42 and 66 % $\text{VO}_2\text{peak}$  would elicit the same  $\text{VO}_2$  as the continuous bout in different individuals. The equivalent range for matching the HR responses was between 35 to 61 % $\text{VO}_2\text{peak}$ . **Discussion** For the group mean data, adopting the interval training procedures used in the present study with a recovery intensity of around 52 % $\text{VO}_2\text{peak}$  should elicit equivalent mean  $\text{VO}_2$  and HR responses to continuous exercise at 70 % $\text{VO}_2\text{peak}$ . These findings may be useful for future studies where the physiological benefits of continuous vs. interval exercise are to be compared using matched duration and relative intensity. However, the extent of variation observed in the present study suggests that the individual responses to the contrasting exercise types should be considered if the acute physiological stresses in training are to be controlled for. ### CHANGE IN UNDERGRADUATES' SELF-ASSESSED KNOWLEDGE AFTER LACTATE INQUIRY-BASED LEARNING EXPERIENCE

Gabel, K.A.

*Montana State University Billings*

**CHANGE IN UNDERGRADUATES' SELF-ASSESSED KNOWLEDGE AFTER LACTATE INQUIRY-BASED LEARNING EXPERIENCE** Gabel, K.A., Montana State University Billings, USA **Introduction** In the influential BIO 2010 report (NRC-NAS, 2003), recommendations highlighted the need for science students to be taught to think independently, answer realistic scientific questions and work cooperatively in groups. Therefore, the aim of this project was to evaluate changes in self-assessed knowledge within an inquiry-based learning experience designed for teams of Health and Human Performance (HHP) undergraduate students. **Methods** Students ( $n = 30$ ) enrolled in a junior-senior level Exercise Physiology course worked in teams to pilot-test relationships among blood lactate and glucose levels, heart rate, and ratings of perceived exertion during an incremental submaximal cycling exercise. Questionnaires were given to students before and after the experience to evaluate changes in lactate knowledge, previous research experience, major in school, and level of interest in HHP research. Students self-assessed knowledge on a 6 point scale from 1 representing No knowledge to 6 being Very high knowledge. Statistical analyses were completed using SPSS (Version 18), i.e. descriptive and nonparametric tests (Wilcoxon). **Results** Changes occurred in all self-assessed knowledge areas: concept of lactate (Pre Mdn=3.5, Post Mdn=5.0,  $z = -4.4$ ,  $r = -.56$ ), lactate metabolism (Pre Mdn=3.0, Post

Mdn=5.5,  $z=-4.7$ ,  $r=-.61$ ), lactate research (Pre Mdn= 3.0, Post Mdn=5.0,  $z=-4.7$ ,  $r=-.60$ ), hematological research methods (Pre Mdn=3.0, Post Mdn=5.0,  $z=-4.5$ ,  $r=-.57$ ), and research methods related to exercise (Pre Mdn=3.0, Post Mdn=5.0,  $z=-4.3$ ,  $r=-.56$ ),  $p<.05$ . Overall, self-assessed ratings of knowledge changed from Low (rating of 3.0) to High (rating of 5.0). Interest in HHP research remained at the Moderate level (Pre Mdn=4.0, Post Mdn=4.0,  $z=.151$ ,  $r=.02$ ). Discussion Exercise physiology undergraduate students are known to have misconceptions about lactate (Morton, et al, 2008). In the present study, lactate knowledge increased two levels (from low to high) after the inquiry-based learning experience. This type of teaching model can enable exercise physiology instructors to stimulate undergraduate students' cognitive development of exercise physiology concepts (Kolkhorst, et al. 2001). Integration of research into teaching may also enable instructors to try new research ideas (Robertson, 2007). This project provides groundwork for a series of lactate-glucose research questions to be answered by future exercise physiology students. #### STUDY OF REPRODUCIBILITY AND VALIDITY OF THE METHOD TO MEASURE BRIDGING FORCE BY USING A SCALE

Madokoro, K., Takei, K., Murata, S., Ihara, T., Kai, Y.

*Technical School of Medical and Welfare Ryokuseikan*

Study of reproducibility and validity of the method to measure bridging force by using a scale Madokoro,K.1,Takei,K.1,Murata,S.2,Ihara,T.3,Kai,Y.1 1: Technical School of Medical and Welfare Ryokuseikan(Saga,Japan),2:Faculty of Rehabilitation Science,Nishikyusyu University,3:Department of Rehabilitation,Hiramathu Hospital Introduction It is important to evaluate physical functions of elderly people from the viewpoint of fall prevention as well as to prevent them from being bedridden. Clinical usefulness of 30-sec chair-stand test (CS-30), etc. has been reported in the past as a simple method to measure the lower extremity muscle strength of elderly people. However, it is often difficult to use these tests on frail elderly people, considering physical burdens. In this study, therefore, we designed a quantitative evaluation of lower extremity functions of elderly people who have difficulty in standing by measuring their strength to push the floor with the bottom of their feet at the time of making the bridging motion (bridging force) and investigated the reproducibility and validity. Subjects and method The subjects were 19 community-dwelling frail elderly females (average age:  $84.7 \pm 6.4$  years old; average weight:  $49.9 \pm 7.5$ kg). In addition to bridging force, functional reach test (FRT), CS-30 and timed up and go test (TUG) were also conducted for measurement. To measure bridging force, the bridging motion was taken in the supine position, a scale set up on the bottom of the feet was pushed to the floor with maximum effort, and the bending position of the hip joint and the intermediate position of the ankle joint were maintained during measurement. Measurements were taken twice, and the average was adopted as the representative value. For statistical processing, the intraclass correlation coefficient (ICC) was obtained for reproducibility and Pearson's coefficient was obtained for validity for review purposes. The level of significance less than 5% was determined as significantly different. Results ICC in the measurement of bridging force was 0.964 (95% CI: 0.925-0.983). Significant correlation with bridging force was observed in FRT ( $r=0.486$ ,  $p<0.05$ ) only. No significant correlation was observed between other measurement values and bridging force. Discussion Based on the results of the study, extremely high reproducibility (ICC=0.964) was recognized in the measurement of bridging force. The possibility to safely and simply predict physical functions of elderly people with difficulty in standing or walking was also indicated as we recognized a significant correlation with FRT which is considered as the index of physical functions.

#### EFFECTS OF INTRA-SESSION EXERCISE ORDER IN THE NEUROMUSCULAR ADAPTATIONS TO CONCURRENT TRAINING IN THE ELDERLY

Cadore, E.L., Izquierdo, M., Pinto, S.S., Conceicao, M., Alberton, C.L., Pinto, R.S., Baroni, B., Vaz, M.A., Lanferdini, F., Radaelli, R., González-Izal, M., Bottaro, M., Trindade, G., Krueel, L.F.

*Federal University of Rio Grande do Sul*

Background A limited number of studies have explored the neuromuscular adaptations related to concurrent strength and cardiovascular intervention in elderly populations and there are no data regarding the effect of exercise order manipulation during concurrent training on the neuromuscular adaptations in elderly subjects. Objective The aim of this study was investigate the effects of different intra-session exercise orders in the neuromuscular adaptations induced by concurrent training in elderly. Methods Twenty-six healthy elderly men ( $64.7 \pm 4.1$  years), were placed into two concurrent training groups: strength prior to (SE,  $n=13$ ) or after (ES,  $n=13$ ) endurance training. Subjects trained strength and endurance training during 12 weeks, three times per week performing both exercise types in the same training session. Upper and lower body one maximum repetition test (1RM) were evaluated as strength parameters. Upper and lower body muscle thickness (MT) were determined by ultrasonography. Lower-body maximal surface electromyographic activity of vastus lateralis and rectus femoris muscles [maximal electromyographic (EMG) amplitude] were determined during a maximal voluntary contraction. Results Both SE and ES groups increased the upper and lower-body 1RM, but the lower-body 1RM increases observed in the SE was significant higher than ES ( $35.1 \pm 12.8$  vs.  $21.9 \pm 10.6\%$ , respectively,  $P<0.01$ ). Both SE and ES showed MT increases in all muscles evaluated, with no differences between groups. In addition, there were significant increases in the maximal EMG in the muscles evaluated in both SE and ES. Discussion The intra-session exercise sequence had an influence on strength adaptations, as observed in the greater strength increases when strength training was performed prior to endurance training. Nevertheless, in the elderly, it is important to point out that the intra-session concurrent exercise sequence had no influence on muscle hypertrophy. From a practical point of view, to optimize the strength gains in the elderly, the concurrent training prescription should include an intra-session exercise order of strength training prior to endurance training.

## EFFECTS OF COMBINED STRENGTH AND POWER TRAINING ON LOWER EXTREMITY MUSCLE FUNCTION IN YOUNGER AND OLDER MIDDLE-AGED MALES

Nakatani, T., Terada, K., Nadamoto, M., Murakami, K., Shiraishi, A.

*Dept. Health and Human Performance*

**Introduction** Regular exercise has many positive health benefits and can prevent age-related loss of skeletal muscle mass and muscular function. Muscle strength decreases with advancing age and there is a steep decline after the age of 50 years (Murray et al., 1980; Hakkinen and Hakkinen, 1991). Few studies have examined the effects of combined strength and power training on middle-aged adults. The purpose of the study was to compare lower extremity muscle function adaptations in younger and older middle-aged males in response to a 12-week combined strength and power training program. **Methods** Twenty-six healthy males (aged 40–68 yrs) were divided into a younger middle-aged (YM) group ( $41 \pm 1.5$  yrs,  $n = 8$ ) and an older middle-aged (OM) group ( $54.7 \pm 6.9$  yrs,  $n = 18$ ). Training was performed once every 2 weeks at each subject's work place and 2-3 times/week at home for 12 weeks. The program included lower limb resistance training as well as plyometric, agility, and muscular endurance exercises. The training intensity was individualized and based on active muscle rating of perceived exertion during multiple sets. The outcome measures, determined pre- and post-training, were vertical jump (VJ) height, rebound jump (RJ) index (jumping height/contact time), anaerobic power during maximum bicycle pedalling (AP), 30-second chair-stand (CS-30), and 2-minute step. **Results** After 12 weeks of training, the RJ Index was significantly different between the YM and OM groups. The RJ index decreased by 14.2% in the YM group but increased by 14.3% ( $P < 0.05$ ) in the OM group. VJ height and power increased significantly by 18.5% and 7.2% ( $P < 0.05$ ) in YM and 20.2% and 9.1% ( $P < 0.05$ ) in OM. The CS-30 increased by 21.5% ( $P < 0.05$ ) in YM and 11.7% ( $P < 0.05$ ) in OM. There were no differences in the mean and maximum AP outputs and the 2-minute step for either group. **Discussion** The main finding of this study was that a 12-week combined strength and power training program was effective in improving the rebound jump performance of OM males. The results suggest that combined strength and power training may have limited effects on lower extremity muscle function in older middle-aged men. **References** Hakkinen K and Hakkinen A (1991). ## COMPARISON OF VENTILATORY AND METABOLIC RESPONSES FIXED BY THE TOLERANCE TIME IN FOUR INTENSITIES ON RESISTANCE EXERCISE BETWEEN YOUNG AND ELDERLY.

Arakelian, V.M.1, Sousa, N.M.F.1, Ferraresi, C.2, Rodrigues, M.F.C.2, Togashi, G.B.1, Gatto, C.D.V.G.1, Perez, S.E.A.2, Baldisera, V.1,2, Borghi-Silva, A.1,2

*1Universidade de São Paulo, – Interunidades em Bioengenharia (EESC/IQSC/FMRP), Brazil, 2Federal University of São Carlos, Brazil.*

**Introduction:** The resistance training has been strongly encouraged, providing favorable effects (Taylor, Dodd et al. 2005); however, little is known about adjustments in the in this type of exercise in different intensities (Kraemer et al. 2002), as well as, the safety for aging people (Visser et al. 2005). So, the aims of the study were to evaluate and compare the ventilatory and metabolic changes during resistance exercise in Leg Press 45°(LP) at different intensities between young and elderly. **Methods:** Two groups were evaluated: 1)- 15 young subjects, (age:  $23 \pm 2.5$  years) and 2)- 13 elderly subjects (age:  $69 \pm 4$  years). All volunteers performed one test for determining the maximum load (1RM) in exercise of LP, and four tests at different intensities of 1RM - 30%, 60%, 75% and 90%. For all intensities the subjects performed flexion and knee extension for 3 seconds on each repetition of movement. The exercise was continued until the time limit of tolerance (Tlim). During the exercises, ventilation (VE), oxygen consumption (VO2) and blood samples for blood lactate determination [La] were collected. Two-way ANOVA were used to test the interaction effect for: VE, VO2 and [La], with Tukey post hoc test, for all comparisons between the groups in each intensity ( $p < 0.05$ ). **Results:** Comparing VE and VO2, we observed significant differences between the rest and exercise in both groups ( $p < 0.0001$ ) for all intensities. Values of VE (group 1:  $45.3 \pm 1.3$  l/min at 30%;  $40.9 \pm 2.7$  l/min at 60%;  $38.7 \pm 5$  l/min at 75% and  $24.9 \pm 3.6$  l/min at 90% - group 2:  $35.7 \pm 1.2$  l/min at 30%;  $31.8 \pm 1.8$  l/min at 60%;  $26.2 \pm 4.2$  l/min at 75% and  $21.9 \pm 2.1$  l/min at 90%) were significant higher for the younger group in all intensities ( $p < 0.05$ ), the values of VO2 were significant higher for de group 1 at 30% (group 1:  $1.7 \pm 0.05$  l/min and group 2:  $1.30 \pm 0.06$  l/min) and 60% (group 1:  $1.51 \pm 0.11$  l/min and group 2:  $1.05 \pm 0.10$ ) ( $p < 0.05$ ). The [La] was a significant increase in post-exercise comparing pre exercise ( $p < 0.0001$ ). Comparing each intensity between young and older subjects, significant differences were found, with a greater accumulation of lactate in the young group for all intensities ( $p < 0.05$ ). **Discussion:** Significant differences were reported with respect to the ventilatory and metabolic parameters in the intensity of exercise performed, and that aging was shown to be crucial for a reduction in the relative values of aerobic capacity and pulmonary function (Fleg & Lakatta, 1988; Fleg et al. 1995; Evans et al. 1992). These results can provide objective evidence of ventilatory and metabolic responses to programs aimed at implementing strength training or muscle endurance-based understanding of such physiological adjustments to resistance exercise. **References:** Taylor, et al. ## RELATIVE AGE EFFECT IN OLYMPIC SPORTS – A COMPARISON OF BEIJING 2008 AND SINGAPORE 2010

Hoffmann, A., Wulff, J., Büsch, D., Sandner, H.

*Institute for Applied Training Science*

**Introduction** The Relative Age Effect (RAE) refers to a biased distribution of birth-dates within an age-grouped cohort. During the last three decades, RAE has been widely studied in sport science. Results vary depending on sports, age-group, sex, and level of performance (Delorme, Boiché & Raspaud, 2010; Williams, 2010). Most of the studies were conducted in game sports and specific samples (e. g. professional leagues). To draw consequences for strategies of talent identification and talent development, a closely examination of RAE among participants of most important international competitions is needed. This study investigates the existence of RAE in Olympic Games 2008 (OG) and Youth Olympic Games 2010 (YOG). **Method** Birth-dates of 4983 participants of the OG in Beijing (2782 male) and 3508 participants of the YOG in Singapore (1826 male) were classified in quartiles. Chi-square analyses, differentiated by sex, sports and success, were used to determine if the frequency distributions were statistically different from expected equal distribution. **Results** For the sample of YOG, an RAE emerged both for male and female, whereas in OG, only for male an over-representation of relative younger athletes could be shown. RAE exists in YOG for male in more sports and with larger effect sizes than for female. In OG, in contrast to male, for none of the female subsamples an asymmetry in birth-date distributions could be demonstrated. Only for male and in sports determined dominantly by speed and endurance, RAE could be proven both in YOG and OG. There was no difference in distribution of

birth-dates for successful and less successful athletes. When RAE occurs, effect sizes are small to medium ( $0,14 < w < 0,34$ ). Discussion Results and possible implications are discussed against the background of the state of the art. Present data corroborate former studies suggesting a nuanced consideration of RAE. Until now, most studies confine on the examination of the prevalence of RAE. To enlighten the causes of RAE and the relevance in long term athlete development, longitudinal tracking of asymmetries in birth-date distributions within an age-grouped cohort is needed. Furthermore, there is a demand of incorporating biological age. References Delorme, N., Boiché, J., & Raspaud, M. (2010). ### **VOLUNTARY MUSCLE FORCE INCREASED AFTER A 12-WEEK STRENGTH TRAINING WITH PULSED MAGNETIC FIELDS IN HEALTHY OLDER PEOPLE**

Creuznacher, U., Schulz, A., Köhling, R., Zschorlich, V.

*University of Rostock*

**Introduction** Keeping an active and independent life is a common interest of older people. Many health care programs aimed at saving and restoring physiological fitness, i.e. muscular strength. Compared to electrical stimulation pulsed magnetic fields elicit muscle contractions more painlessly, even at higher frequencies and intensities. Therefore peripheral applied magnetic stimulation could play a prospective role in strength training programs, especially in case of preventing age-related muscle atrophy. **Methods** Seven healthy subjects ( $72,6 \pm 5,8$  yrs;  $164,4 \pm 6,2$  cm;  $72,3 \pm 11,9$  kg) took part in a 12 week strength training program of the quadriceps femoris muscle. The unilateral stimulation training of the non-dominant leg was performed on two days per week. Each training session consisted of three sets of 30 magnetically induced muscle contractions (frequency: 50 Hz; duration: 500 ms, pulse width: 280  $\mu$ s, inter-pulse interval: 3 s) and a resting phase of three minutes between each set. The stimulation intensity was set to 50 % of the torque during maximal voluntary contraction. The elliptic magnetic coil RT 120-II (MagVenture, Denmark) was placed directly over the thigh. **Results** The maximal isometric voluntary torque (PTmax) was used for the determination of the training effect. In addition, the contralateral leg served as control. A two-sided paired t-test revealed a significant increase of PTmax of the trained leg from  $130,2 \pm 31,2$  Nm to  $166,8 \pm 39,9$  Nm ( $28,4 \pm 11,1$  %;  $p \leq .0006$ ). The contralateral leg showed a small increase which was not significant (pre:  $145,4 \pm 27,9$  Nm; post:  $149,9 \pm 27,3$  Nm;  $p \leq .1329$ ). **Discussion** The results suggest that peripheral applied pulsed magnetic fields are capable to mediate an enhancement of maximal voluntary torque in the elderly. Despite the fact that only a few studies focussed on strength training with electrical currents, no other studies examined the effect of pulsed magnetic fields on muscle strength in older people. Caggiano et al. (1994) observed a small increase of PTmax ( $8,5 \pm 10,3$  %) of the knee extensors in  $72 \pm 4$  years old males after a 4 week electrical stimulation training (EST) at a low intensity level of 36 % of individuals' maximal voluntary torque. In a recent study, Maggioni et al. (2010) examined a more obvious improve in maximal voluntary quadriceps strength of  $25,8 \pm 11,3$  % during a 6 week EST of hospitalized females of  $84,1 \pm 3,4$  years. References Caggiano, E., Emrey, T., Shirley, S., Craik, R.L. (1994). *J Orthop Sports Phys Ther*, 20, 1, 22-28. ### **EVALUATION OF THE REPEATABILITY AND VALIDITY OF MEASURING THE ABDUCTION-IN-FLEXION MUSCLE STRENGTH OF THE HIP JOINT IN ELDERLY FEMALE COMMUNITY RESIDENTS**

NORIHISA, M., SHIN, M., KOJI, N., KAZUMI, F.

*Takeo Nursing and Rehabilitation School*

**Objective:** The extension muscle strength of the knee joint as measured by Hand-Held Dynamometer (HHD) is often used as a value representing the lower extremity muscle strength. However, the measurement of the extension muscle strength of the knee is difficult when subjects have knee-joint diseases, or the posture in a sitting position is unstable. With this background, we invented a method to measure the abduction-in-flexion muscle strength of the hip joint to straightforwardly evaluate the lower extremity muscle strength, and examined its repeatability and validity. **Methods:** The subjects consisted of 33 elderly female community residents. The abduction-in-flexion muscle strength of the hip joint was measured in a supine position, with the hip and knee joints bent to 45- and 90-degree positions, respectively, and with the plantae being placed on the examination table. Two sensor pads of the HHD were placed outside the knees, fixed with belts, and the maximum isometric muscle strength was measured while abduction in flexion was performed. The extension muscle strength of the knee joint, one-leg standing time, and TUG were also measured. Each measurement was conducted twice, and the better value was regarded as representative. The repeatability of the abduction-in-flexion muscle strength of the hip joint was evaluated based on the ICC of each measurement. As for the validity of the abduction-in-flexion muscle strength of the hip joint, we performed correlation analysis between the measurements to evaluate the criterion-related validity. **Results:** As a result of evaluating the repeatability of the abduction-in-flexion muscle strength of the hip joint, the ICC was 0.851. The abduction-in-flexion muscle strength of the hip joint showed a significant correlation with the extension muscle strength of the knee joint ( $r=0.513$ ), one-leg standing time ( $r=0.399$ ), and TUG ( $r=-0.384$ ). **Conclusion:** The method to evaluate the abduction-in-flexion muscle strength of the hip joint showed marked repeatability, and validity. However, the subjects in this study consisted of healthy elderly citizens who were living independently in the community. It is now necessary to conduct an investigation involving elderly citizens dependent on care and those with physical disabilities, and determine whether or not the abduction-in-flexion muscle strength of the hip joint is an appropriate index of the lower extremity muscle strength.

### **A STRENGTH, MOVEMENT CONTROL AND BALANCE TRAINING PROGRAM TO PREVENT FALLING FOR OLD ADULTS AGES '61-65' YEARS**

Elnemr, A.1, Elkhateb, N.2, Elnemr, O.3

*Faculty of physical education / Helwan University 1: FPEM (Giza, Egypt), 2: FPEG (Giza, Egypt), 3: HU (Cairo, Egypt)*

**Introduction** Millions of older adults experience an injury due to falling, falls can result in hip fractures, head injuries or even death. Researchers have identified that among the most effective fall prevention programs is a specific physical activity which can target reduce fall risk by increasing balance, gait and total body strength. **Methods** Ten older men ages 61- 65 years participated in the study. Tests for determination lower and upper body 1 RM strength (leg press, chest press, abdominals and seated row) and balance (Tester stands with tandem and single leg stance with eyes open for 10 seconds then closed for 10 seconds in each position on the Posturomed with one brake released) were undertaken before and after 12 weeks of training. Participants learn eight body-movement exercises (with and

without Posturomed) during 1-hour classes and participated in a high-intensity strength training program (three sets of ten repetitions at 80% of 1 RM, 3d / wk for 12 wk). Results Strength variables increased with percentages between 42% - 47% and balance variables increased with percentages between 56% - 74%. Discussion Both strength variables and balance variables increased as a result of the training program, the results of the present study seem to correspond to what happens in experimental situations in the older adults submersed (Frontera et al., 1988 and Fuzhong et al., 2005). High-intensity strength training (80% of 1 RM for 12 weeks is safe for this population and produced significant increases in strength. The increase in strength was associated with an increase in balance. Using the Posturomed (a neuro-orthopaedic therapeutic device) is safe and enjoyable for this population and produced significant increases in balance. ### COMPARISON OF HOME AND LAB TESTING IN OLDER PEOPLE WITH AND WITHOUT KNEE OSTEOARTHRITIS.

van Leeuwen, D.M.1,2, de Ruiter, C.J.1, Lips, P.T.A.3, Deeg, D.J.H.3, de Haan, A.1,2

*Research Institute MOVE, VU University Amsterdam*

Comparison of home and lab testing in older people with and without knee osteoarthritis. D.M. van Leeuwen 1,2, C.J. de Ruiter 1, P.T.A. Lips 3, D.J.H. Deeg 3, A. de Haan 1,2 1 Research Institute MOVE, VU University Amsterdam, The Netherlands 2 Institute for Biomedical Research into Human Movement and Health, Manchester Metropolitan University, Manchester, UK 3 EMGO+ Institute, VU University medical center, Amsterdam, The Netherlands INTRODUCTION: Knee osteoarthritis (OA) is characterized by pain, loss of strength and limitations with activities such as walking and stair climbing. A battery of tests, such as the short physical performance battery, could assess function over a wide area, and is easy to administer in a home setting with limited space and time with elderly participants. However, more elaborate lab tests may be more sensitive to detect impairments. The aim of the present study is to investigate differences between lab tests and a performance battery that can be applied in a home setting, between subjects with and without knee OA, and how various performance tests are related. METHODS: From 64 participants (33 men, 31 women), aged  $70 \pm 5$  years, with or without radiographic knee OA (Kellgren and Lawrence grade 2-4 vs. 0-1) physical functioning was assessed with a 6-minute walk test (6MWT), a stair climb test (SCT) and measurement of maximal isometric knee extensor strength. These tests were compared with a battery of 3 tests consisting of a repeated chair stand test, a short (6m) walk test, and a balance test, which were summed to an overall performance score (range 0-12). Health-related quality of life was assessed with the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC). RESULTS: Overall physical performance was significantly lower in participants with OA (10 [8-11] vs. 8 [7-10],  $P < 0.05$ ), predominantly caused by a slower short walk test ( $5.4 \pm 0.9$  s vs.  $5.1 \pm 0.8$  s,  $P < 0.05$ ). In contrast to our expectations, no differences between participants with and without OA were observed in maximal strength, chair stand, 6MWT, SCT and WOMAC score. This may be explained by our finding that participants with OA had relatively high performance levels and very low impairments as shown by their values for 6MWT ( $546 \pm 82$  m), maximal strength ( $\sim 150$  Nm) and WOMAC (99 [93-100]). All lab tests (SCT, 6MWT and maximal strength) were significantly related to overall performance ( $|\rho|$  between 0.43 and 0.39,  $N=64$ ). The relationships between 6MWT, SCT, maximal strength and the short walk test were strong ( $\rho$  respectively -0.69, 0.76 and -0.52,  $P < 0.001$ ), but the relationships with balance and chair stand were low ( $|\rho|$  between 0.07 and 0.36). CONCLUSION: A short physical performance battery applicable in a home setting had reasonable relationships with physical performance tests in a lab setting. This suggests that home tests are a good alternative if time and space are limited, especially for less fit elderly having trouble to visit a lab.

### STRUCTURE AND FORCE GENERATION CAPACITY ON KNEE EXTENSION AND FLEXION MUSCLES IN AMATEUR JUNIOR WRESTLERS.

Hiratsuka, K.1, Ihara, Y.1, Teshima, T.1, Tanaka, S.1, Kumagawa, D.2, Tsunoda, N.1

*1:Kokushikan University, Japan. 2:Japan institute of Sports Science, Japan.*

Introduction Structural and functional characteristics of the skeletal muscle are directly affect to the athletic performance in amateur wrestlers. It is cleared that the characteristics of muscle structure and force generation capacity due to body size are important to planning for the training program. Therefore, the purpose of this study was to investigate characteristics of the muscle structure and function with body weight class in Japanese amateur junior wrestlers. Methods The subjects were 29 Japanese amateur junior wrestlers aged from 16 to 17 years old. These subjects were classified light body weight (<64kg: LG), middle body weight (65-75kg: MG) and heavy body weight (76kg<: HG). The whole and lower limb muscle volumes were measured by the body impedance analysis methods. Moreover, the relative value of lower limb muscle volume to the whole muscle volume was calculated in all the subjects. Isokinetic peak torques on knee extension and flexion as a muscle functional parameters were measured using isokinetic dynamometer (Biodex System 3). And also, isokinetic knee extension and flexion torques measurement with 30 repetitive maximal contractions as a muscle endurance index was measured in all the subjects. Results Significant differences of whole and lower limb muscle volume were obtained among the three groups. In HG, relative lower limb muscle volume to the whole muscle volume was significantly higher than that of LG and MG. The knee extension and flexion peak torques to the body weight in MG were showed highest value compared to the other groups. Significant difference of decrease ratio on knee extension with 30 repetitive maximal contractions was not observed among the three groups. However, significant group difference was observed in knee flexion contractions. Discussion The relative lower limb muscle volume to the whole muscle volume in HG showed higher than that of MG and LG. Muscle force generation capacities related to the peak torque of knee flexion in MG was significantly decreased compared to the other groups. From the results in this study, it seems that the states of the muscle size and function in amateur junior wrestlers are important factor for the planning of the fitness training program. **EFFECTS OF LOW-INTENSITY AEROBIC DANCE ON PHYSICAL FITNESS AND BODY COMPOSITION IN HEALTHY OLDER ADULTS**

Shimura, Y.1, Tanaka, K.2

*1: Osaka International University (Osaka, Japan), 2: University of Tsukuba (Ibaraki, Japan)*

Introduction: Older adults generally have reduced muscle mass, less muscle strength, less endurance, balance, and aerobic power than young adults. Numerous studies have found that exercise including resistance training, aerobic exercise and balance training might offer many significant physical benefits for older adults. Aerobic dance could be also an effective exercise to improve their aerobic power, lower muscle strength and endurance, flexibility, balance, and agility (Keogh et al., 2009). However there are few reports about the physical and mental benefits associated with aerobic dance for older adults. The purpose of this study was to investigate the intervention effects of low-intensity aerobic dance on physical fitness and body composition in healthy older adults. Methods: Participants were seventeen healthy older adults aged 62-81 years. Ten participants (Aerobic dance group: age  $72.2 \pm 5.1$  years) performed low-intensity aerobic dance program for 90 min, 1 day a week, for 16 weeks. Seven participants (Walking group: age  $67.1 \pm 3.4$  years) completed a walking program for 90 min, 1 day a week, for 16 weeks. Additionally, we advised them to perform their respective training programs in their daily life. Physical fitness (hand-grip strength, 10-m walking, timed up & go, 8-foot up & go, functional reach, single limb stance with eyes open, single limb stance with eyes closed, sit & reach, 30-sec chair stand, 30-sec arm curl, and stand-up from lying position) and muscle mass in forearms, upper arms, lower legs, thighs and trunk were measured 2 times (first day session, 4 months after the initial session) of all participants. Results: The baseline characteristics of the aerobic dance group were very similar to those of the walking group. Regarding physical fitness, the aerobic dance group had significant improvement in the 8-foot up & go (Pre:  $23.7 \pm 4.3$  sec, Post:  $19.7 \pm 2.5$  sec,  $P < 0.05$ ), timed up & go (Pre:  $6.1 \pm 1.4$  sec, Post:  $5.1 \pm 0.6$  sec,  $P < 0.05$ ), and 30-sec chair stand (Pre:  $21.3 \pm 6.1$  times, Post:  $26.8 \pm 7.1$  times,  $P < 0.05$ ). In contrast, the walking group had significant improvement only in the 8-foot up & go (Pre:  $23.4 \pm 2.9$  sec, Post:  $21.3 \pm 3.1$  sec,  $P < 0.05$ ). There were no significant changes in the muscle mass of all regions in both groups. Discussion: This study suggests that low-intensity aerobic dance has some beneficial effects to improve the mobility including lower muscle strength and endurance, agility and dynamic balance in healthy older adults. **ASSOCIATION BETWEEN MENTAL HEALTH AND PHYSICAL FITNESS IN JAPANESE MIDDLE-AGE AND OLDER ADULTS**

Takahashi, S., Suzuki, K., Masuko, T.

*Tohoku Gakuin University*

PURPOSE Physical activity programme improves mental health and physical fitness. Higher physical fitness level has been shown to be associated with higher levels of mental health in the older populations. We investigated the association between mental health and physical fitness in Japanese middle-age and elderly individuals using longitudinal data. METHODS Thirty-five women ( $58.5 \pm 8.1$  years) and ten men ( $64.9 \pm 5.7$  years) participated in a 12-week physical activity programme. The programme consisted of 12 training sessions; contents of the session were 20-min of warm-up, 20-min of walking, 40-min of resistance training with an elastic band and a balance ball, and 10-min cool-down. The frequency of training was once a week. Before and after the programme, mental health and physical fitness of the participants were measured. The mental health was measured using WHOQOL-BREF that is constructed by 4 domains (Physical, Psychological, Social, and Environmental QOL). Physical fitness was measured by grip strength, sit-ups, sit-and-reach, single-leg balance with eyes open, 10-m hurdle walk, and 6-min walk. The effect of the programme on mental health and physical fitness was tested by paired *t* test. Then, we analyzed the association between the change of mental health and the change of physical fitness using multi level modeling. RESULTS The results of paired *t* tests showed that 4 domains of mental health significantly improved after the programme ( $t(44) > 2.2$ ,  $p < 0.031$ ). All of physical fitness components also were significantly higher levels than the levels before training except sit-and-reach ( $t(44) = 1.9$ ,  $p = 0.061$ ). The multi level modeling revealed that there was no significant association between the changes of mental health domains and the changes of physical fitness components. CONCLUSIONS Physical activity programme can improve mental health and physical fitness level in middle and older Japanese adults, while the improvements of mental health and physical fitness are independent.

**THE MULTIDIMENSIONAL STRUCTURE OF THE GRONINGEN FRAILTY INDICATOR**

Bielderman, A.1, van der Schans, C.P.1, de Greef, M.H.G.1, Boersma, N.2, Krijnen, W.P.3, Steverink, N.4

*1: Hanze University of Applied Sciences Groningen, 2: University Medical Center Groningen, 3: Hanze University of Applied Sciences Groningen, 4: University Medical Center Groningen*

Introduction The Groningen Frailty Indicator (GFI) is a widely used self-report screening instrument to identify frail older adults. Frailty is suggested to be a dynamic and multidimensional construct. However, factor structure of the Groningen Frailty Indicator has not been examined yet. Aim of the study is to evaluate the factor structure and validity of the 15-item Groningen Frailty Indicator questionnaire. Methods Older adults aged 65 years and over ( $n=1401$ ) completed the GFI. A subsample of 120 older adults completed additional questionnaires (De Jong Gierveld Loneliness scale, Hospital Anxiety Depression Scale (HADS), RAND-36 physical functioning). Factor structure, internal consistency, construct validity and criterion-related validity of the scale were evaluated. Exploratory and confirmatory factor analyses were used to evaluate factor structure of the GFI. Results Factor structure of the GFI provided support for a three dimensional structure of the scale. The subscales Mobility, General health and Psychosocial functioning showed moderate to good internal consistency (respectively Cronbach's alpha's:  $\alpha=0.81$ , [95% CI=0.79-0.82];  $\alpha=0.60$ , [95% CI=0.56-0.63];  $\alpha=0.80$ , [95% CI=0.78-0.81]). Analyses of construct validity showed significantly higher GFI subscale scores in older age groups, female respondents and institutionalized living respondents than in respondents in younger age groups, male respondents and independently living respondents. Scores on the GFI

subscales correlated significantly with related scales: Mobility GFI with RAND36 physical functioning ( $r=0.61$ ); General health GFI with Rating of health ( $r=0.54$ ); Psychosocial functioning GFI with De Jong Gierveld scale ( $r=0.71$ ); Psychosocial functioning GFI with HADS ( $r=0.66$ ). Conclusion Present findings support a three dimensional factor structure of the Groningen Frailty Indicator. Three valid and reliable frailty subscales were established to identify frail older adults in different domains of functioning.

### ADHERENCE AND EFFECTS OF COGNITIVE-DEMAND PHYSICAL EXERCISE IN THE ELDERLY: A LONG-TERM OBSERVATIONAL STUDY

Shigematsu, R.1, Okura, T.2, Nakagaichi, M.3, Nakata, Y.4,5

1 Mie University, 2,4,5 University of Tsukuba, 3 Nagasaki University

**Introduction.** Exercises that encourage elderly persons to be physically active have been extensively developed. However, few have proved to exhibit method-effectiveness and use-effectiveness in a long-term setting. We recently developed square-stepping exercise (SSE), which demands cognitive and physical activity (Shigematsu et al., 2006 & 2008). SSE is similar to walking and can be easily performed indoors. Walking involves only forward-stepping movements, whereas SSE involves step movements in multiple directions. SSE is performed on a thin mat (100 × 250 cm) that is partitioned into 40 squares (each side = 25 cm). During the exercise, participants step on the mat and follow an instructor's demonstration. The process requires cognitive capacities: there are 200 stepping patterns, which the participants need to identify, based on the instructor's demonstrations, memorize, and mimic. Here, we assessed the effects of SSE in compliance and functional fitness among elderly persons in a long-term, observational setting. **Methods.** Sixty-three persons (SSE group,  $n = 32$ ; walking group,  $n = 31$ ) had participated in a 3-month intervention study. At the end of the intervention period, they were encouraged to continue the assigned exercise autonomously. We measured the adherence to the assigned exercise for a total of 4 years, and functional fitness after 1 and 4 years. The physical performance tests for functional fitness were adopted from our previous study and included the use of the following items: chair stands, stepping with both feet, grip strength, functional reach, walking around 2 cones, forward tandem walking, backward tandem walking, simple reaction time, and choice reaction time. Functional fitness at each point was compared with that at the 3-month intervention entry in terms of method-effectiveness (per-protocol based [PPB]) and use-effectiveness (intention-to-treat [ITT]). **Results.** At each time-point, 22 (69%) and 20 (63%) of the SSE group had continued the assigned exercise. These values were comparable to those of the walking group (65% and 65%). No adverse effects of SSE were reported. From the PPB and ITT analyses, we found that SSE was as effective—or more effective—than walking with regard to functional fitness. **Conclusions.** SSE is a good exercise choice that is highly recommended for the elderly on a long-term basis. **References.** Shigematsu R, Okura T. ### EFFECTIVENESS OF TWO LOWER LIMBS EXERCISES ON IMPROVEMENTS OF LOCOMOTIVE SYNDROME FOR OLDER ADULTS

OHKI, K., KIMURA, Y., YAMAZAKI, S., HISATOMI, M., NAKAGAWA, N.

Showa Women's University

**PURPOSE** Some impediment to locomotive organs is due to enfeebled bone, joints and muscles with ageing, which led moving capacity such as walking down. Active older adults have good status of locomotive organs than inactive ones of the same age. In this study, we focus on older adults who cannot stand up off the 50 cm high chair, and examine improvements on locomotive syndrome by two exercises during the short-term intervention. **METHODS** Subjects: Thirty-seven urban men ( $n=22$ ) and women ( $n=15$ ) volunteered to participate in the study (age=69 yr, body mass index=27 kg/m). **Experimental design:** Participants completed two exercises, one-leg standing exercise with eyes open one minute for each leg three times a day, squat exercise with fifteen repetitions once a day, every day for 12-wk. **Measurements:** Before and after the training, following items were measured. 1) locomotion check (a questionnaire for seven items) , 2) one-leg standing time with eyes open, 3) 10m walk time, 4) standing upright time off the chair for ten reps consecutively, 5) emotionally, geriatric depression scale (GDS). **RESULTS** After the training, all subjects cleared the locomotion check. One-leg standing time with eyes open increased significantly ( $60.7\pm 42.0$  sec  $\rightarrow$   $72.8\pm 45.2$  sec,  $p<0.05$ ). In 10m walk test, walking time reduced significantly ( $5.44\pm 0.63$  sec  $\rightarrow$   $4.76\pm 0.65$  sec,  $p<0.05$ ) and walking speed increased significantly ( $110.2\pm 16.1$  m/min  $\rightarrow$   $126.0\pm 20.3$  m/min,  $p<0.05$ ). Standing upright time off the chair reduced significantly ( $7.64\pm 0.87$  sec  $\rightarrow$   $5.57\pm 0.98$  sec,  $p<0.05$ ). GDS had a tendency to reduce (3.8 pts  $\rightarrow$  2.7 pts), but the change was not significant. **CONCLUSIONS** This shows that one-leg standing exercise and squat exercise reinforce balance abilities and muscle strengths, and contribute to improvements of locomotive syndrome. This study was supported by a grant from the Ministry of Education, Culture, Sports, Science and Technology of Japan (#22500702).

### RISK OF FUNCTIONAL MOBILITY LOSS IN ELDERLY

MATA, E., Vila-Maldonado, S., Moreno-Vecino, B., González-Morales, M., de la Llave, M.J., Aznar, S., Ara, I.

UNIVERSIDAD DE CASTILLA-LA MANCHA

**Introduction** Functional mobility (FM) is one of the most important factors for independent life in older life. Loss of FM can result in difficulties while performing everyday tasks and activities. Moreover, it is considered as a sign of the frailty syndrome (Searle et al., 2008). Accordingly, the aim of this study was to assess the prevalence of loss of FM and also to assess its association with health related quality of life and anthropometric variables in non-institutionalized people over 65 years old from Castilla-La Mancha region (Spain). **Methods** A cross-sectional study was carried out in a sample of 514 participants (82 males; 432 women) with ages ranging between 65 and 90 years old. The risk of functional independence loss was evaluated by using the "Senior Fitness Test" criterion performance scores (Rikli & Jones, 2001); self-reported health status was measured using EuroQol questionnaire (EQ-5D) (Brooks, 1996) and anthropometric measurements were obtained using standardized techniques and equipment (Gomez-Cabello et al., 2011). **Results** In total, 5.2% of the participants presented risk for functional dependence. There were no differences in the prevalence of risk by sex and the frequency of risk increased by age (65-74 years old: 2.9%; >74 years old: 10.6%;  $p=0.002$ ). Compared with their healthy counterparts, those at risk of losing their functionality, showed worse health status (EQ-D5 index: at risk  $0.57\pm 0.29$ ; pre-risk  $0.81\pm 0.22$ ; healthy  $0.88\pm 0.14$ ,  $p=0.001$ ) and health-related quality of life (EQ-D5 VAS: at risk  $6.66\pm 1.77$ ; pre-risk  $7.63\pm 1.98$ ; healthy  $8\pm 1.78$ ,  $p=.002$ ), worst scores in all five dimensions (mobility, self-care, usual activities, pain-discomfort, and anxiety-depression) of the EQ-5D (all  $p<0.001$ ), higher values in all anthropometric measures (body fat percentage, body mass index, waist circumference) (all  $p<0.001$ ) and higher prevalence of overweight-obesity and central obesity (all  $p<0.001$ ). **Discussion** Low functionality levels (i.e. reduced physical fitness levels) are associated with a reduced quality

of life as well as with overweight-obesity and central obesity. All of these factors can be facilitators for developing frailty syndrome in the elderly population, which is considered as a risk factor of mortality, disability and hospitalization (Fried et al., 2001). ### COMPLEX SYSTEM FOR THE MONITORING OF THE PREVENTIVE MEDICAL EFFICACY OF REGULAR EXERCISE IN MENO-PAUSE

Orbán, K.1, Kovács, T.1, Vári, B.1, Szilágyi, N.1, Kiss, B.1, Keresztes, N.1, Szablics, P.1, Molnár, A.1, Balogh, L.1, László, F.1,2, Varga, C.2

*University of Szeged*

**Introduction** Menopause changes the physique, the body shape, reduces the body's basic metabolic level appearing on the excess kilograms. In this age many women begin to improper body weight reduction cures, resulting in loss of bone mass which is further enhanced by oestrogen deficiency resulting in osteoporosis. The combination of obesity and oestrogen deficiency also significantly increases the risk of cardiovascular diseases, and the inactive way of life just enhances these problems (Vuksanović et al., 2008). **Methods** Women over the age of 50 were involved to the test (n=96; mean age: 57.64 years; age range: 50-76 years; BMI: 28.41±0.51) who did aerobic physical activity three times a week (mean HR: 115.74±2.91 bpm). Psychosomatic health status was analysed (survey method) in the beginning and at the end of the program. The intensity of training was followed by Polar system (pulse, calorie consumption). The changes in fitness status (step test), resting blood pressure and heart rate, just as body composition (InBody230) were measured every month. These results were completed with lab tests (glucose, LDL-, HDL-cholesterol, triglyceride, HbA1c) and plasma leptin and insulin; levels (ELISA). **Results** By the effect of regular physical activity, the fitness status of the tested women improved significantly, and their blood pressure, resting HR and exercise pulse decreased. The weight loss of participants was 1.79±0.41 kg in average after the four months program. They lost 2.39±0.40 kg fat mass, while their fat-free mass increased by 0.58±0.16 kg. Their mineral mass content increased by 30±0.01 g. The decrease of abdominal obesity degree was less pronounced than the obesity degree related to the whole body, which can be explained by the different impact of sexual steroids expressed in femoral-gluteal and abdominal areas (Kirchengast, 1998). Improvement can be detected also by analysing the hormone and bloodchemical laboratory results: the glucose level decreased, as well as the level of cholesterol and triglyceride. **Conclusion** Our results suggest that this combination of multidisciplinary methods is suitable for the investigation of the mechanism of the beneficial actions of physical exercise. **References** Kirchengast S. ### ACTN3 R577X POLYMORPHISM INFLUENCES THE TENDENCY FOR PHYSICAL ACTIVITIES IN ELDERLY JAPANESE WOMEN

Dai, U.1, Naoki, K.2, Inkwon, H.2

*1: Bunkyo University (Kanagawa, Japan), 2: Nippon Sport Science University (Tokyo, Japan)*

**Introduction** Several gene polymorphisms have recently been reported as determinants of (1) daily physical activities, (2) execution of exercises, or (3) continuance of physical training in individuals from the general population. Therefore, the aim of this study was to investigate whether the ACTN3 R577X polymorphism influences the fitness status and tendency for physical activities and exercise in elderly Japanese women. **Methods** The study included 101 female subjects (age, 65–90 years). All the subjects underwent battery tests for their fitness status. These tests evaluated the body composition, isometric strength during handgrip, back extension, plantar flexion and knee extension, stable standing time on a single leg, and walking speed on a 10-m obstacle course. They also filled a questionnaire on daily physical activities, exercise execution, and active daily living (ADL). Genotyping was performed for the ACTN3 (rs1815739) polymorphism by using TaqMan-based real-time polymerase chain reaction. **Results** The ACTN3 polymorphism of the subjects was in Hardy-Weinberg equilibrium. Significant differences were observed between the subjects with an active life (who answered "Yes" for the question "Do you regularly perform any exercises or physical training?") and contrastive subjects (who answered "No" for the same question) ( $\chi^2 = 7.88$ ,  $p = 0.019$ ) with respect to the presence of ACTN3. The results for back extension strength per BW ( $p < 0.01$ ), stable standing time on a single leg ( $p < 0.05$ ), walking speed on a 10-m obstacle course ( $p < 0.05$ ), and ADL score ( $p < 0.05$ ) were significantly better in the R allele-dominant model (RR and RX) group members who had an active life than in the XX group members who did not perform exercises regularly. **Discussion** The results suggest that the ACTN3 RR and R alleles also influence the fitness status and tendency for performing physical activities in elderly Japanese women, as roughly similar as angiotensin-converting enzyme genotype (Thompson et al., 2006) and aromatase gene polymorphism (Salmen, et al., 2003). **References** Salmen T, et al.: Relation of aromatase gene polymorphism and hormone replacement therapy to serum estradiol levels, bone mineral density, and fracture risk in early postmenopausal women. *Ann Med*, 35: 282-288, 2003. ### THE INFLUENCE OF TRAINING STATUS ON THE RELATIONSHIP BETWEEN URIC ACID LEVELS AND RISK FACTOR OF CARDIOVASCULAR DISEASE IN ELDERLY

Zago, A.S., Jacomini, A.M., Yoshimura, F.E., Trapé, A.A.

*Univ Estadual Paulista*

**Introduction** Physical exercise is strongly recommended to decrease risk factor of cardiovascular disease (RFCD). Uric acid (UA) is the final enzymatic and product of purine degradation and it has been associated with high BP due to the stimulus for the superoxide production and inhibition of vasodilatation. Therefore, the aim of this study was to investigate the relationship between RFCD and UA and whether this relationship may be mediated by the training status (TS). **Methods** All participants (n=126) performed the indirect maximal oxygen uptake ( $\text{Vo}_{2\text{max}}$ ) by 1 mile walk and AAHPERD Functional Fitness Battery Test (coordination, flexibility, muscular strength, agility and cardiovascular endurance tests) to assess TS. The general functional fitness index (GFFI) was calculated using the sum of the percentile score of each test as described by Zago et al (2003). For the assessment of RFCD, it was evaluated the resting systolic and diastolic blood pressure (SBP and DBP), total-cholesterol (CHOL), LDL-cholesterol (LDL-c), HDL-cholesterol (HDL-c), triglycerides (TG), glucose (GL), nitrite

(NOx), T-BARS and uric acid (UA) by blood sample collection (12h overnight fast). Data were analyzed by Pearson correlation coefficient and ANOVA one-way. The GFFI was considered as independent variable (G1 – regular GFFI; G2 – good GFFI; and G3 – very good GFFI). Results The main correlations were found between GFFI and CHOL ( $r=-0.4 / p<0.01$ ), TG ( $r=-0.5 / p<0.01$ ), UA ( $r=-0.3 / p<0.01$ ), NOx ( $r=-0.4 / p<0.01$ ), SBP ( $r=-0.4 / p<0.01$ ) and DBP ( $r=-0.4 / p<0.01$ ), and between UA and CHOL ( $r=-0.3 / p<0.01$ ), TG ( $r=-0.5 / p<0.01$ ), HDL-c ( $r=-0.4 / p<0.01$ ), SBP ( $r=-0.3 / p<0.01$ ) and DBP ( $r=-0.3 / p<0.01$ ). ANOVA revealed differences among groups, especially between G1 and G3 in Vo2max (22.1(8) and 36.9(5) ml/kg/min), CHOL (203.4(37) and 168.9(31) mg/dL), TG (157.7(59) and 94.2(39) mg/dL), UA (4.7(1.5) and 3.7(1.0) mg/dL), NOx (110.9(28) and 140.3(29)  $\mu$ M), SBP (129(14) and 114(12) mmHg) and DBP (83(14) and 74(8) mmHg). Discussion This finding strengthens the hypothesis that low values of UA are related with low BP and low RFCD. Moreover, the relationship among RFCD, BP and UA may be mediated by training status since the major variables evaluated in this study had better results in the group classified as very good GFFI (G3). **Introduction** We have reported on the importance of catecholamines on thermoregulation and exercise-induced fatigue both in human and animal studies (Roelands et al., 2008; Hasegawa et al., 2008). To investigate the relationship between body temperature regulation and hypothalamic catecholamines in the preoptic area and anterior hypothalamus (PO/AH) during incremental treadmill running in the rat using biotelemetry and brain microdialysis methods. **Methods** Ten male Wistar rats were used. A telemetry device was implanted into the peritoneal cavity and an intracerebral guide was implanted in the left PO/AH. After 2 h of baseline collections on the treadmill, the animals were exercised for one hour in a normal environment (23°C). Treadmill speed was increased every 20 min (10, 20, 26 m/min). During the experiment, body core temperature (Tcore), tail skin temperature (Ttail), (an index of heat loss), and oxygen consumption (VO2), (an index of heat production), were simultaneously measured. Brain microdialysis samples were collected every 10 min, and these samples were analyzed by HPLC for noradrenaline (NA), dopamine (DA) and serotonin (5HT). **Results** Tcore and VO2 significantly increased during treadmill and were exercise intensity dependent. After an initial drop Ttail increased significantly during exercise. Both NA and DA levels in the PO/AH increased significantly during exercise. There was no effect on serotonin release. Tcore, VO2 and Ttail were positively correlated with the levels of NA and DA. **Discussion** We employed in vivo brain microdialysis, biotelemetry, and metabolic measurements to perform continuous monitoring of brain neurotransmitters, core body temperature, and thermoregulatory responses, during incremental running in a rat model. Our data suggest that thermoregulatory responses are dependent on the intensity of the exercise and that these responses are associated with changes in NA and DA release, but not in 5-HT release in the PO/AH. These new findings also suggest that the running animal model may be useful for examining the neurotransmitter-governed mechanisms of thermoregulation and central fatigue during exercise (Nybo, 2008). **References** Hasegawa H, Piacentini MF, Sarre S, Michotte Y, Ishiwata T, Meeusen R (2008). #### EFFECT OF INGESTING SMALL AMOUNTS OF A CARBOHYDRATE ELECTROLYTE SOLUTION ON COGNITIVE PERFORMANCE IN THE HEAT

Fan, P.W.1, Yeo, Y.Y.W.2, Nolte, H.W.3, Lee, J.K.W.1,2

1. DSO National Laboratories, Republic of Singapore; 2. National University of Singapore, Republic of Singapore; 3. ERGOmics TECHNOlogies, Pretoria, South Africa

**Introduction** Carbohydrate electrolyte (CE) solutions have been extensively investigated and proven to enhance endurance performance (Coombes and Hamilton, 2000). In contrast, findings on the effect of carbohydrates on cognitive performance are divergent (Gibson, 2007). The primary aim of the study was to investigate the effect of ingesting small amounts of a commercially available CE solution on cognitive performance following exercise in the heat. The secondary aim was to determine if changes in body mass can be used as an accurate surrogate for changes in total body water. **Methods** Twelve healthy males aged 24 $\pm$ 2 (mean $\pm$ SD) years, with peak oxygen uptake of 59 $\pm$ 5 ml/min/kg participated in the study. Prior to the experimental trials, all participants underwent three practice sessions on the cognitive test battery - symbol digit matching, search and memory, digit span, choice reaction time and psychomotor vigilance tests; and a full familiarisation trial. They completed two experimental trials ingesting either the CE (sucrose: 48 g/L, glucose: 20 g/L, sodium: 18 $\pm$ 3 mmol/L, potassium: 3.3 $\pm$ 0.1 mmol/L) or placebo (P) drink (1 ml/kg body mass) before exercise, at 15 min intervals during the run and in between each cognitive test after exercise. Participants ran on a level treadmill at 70 $\pm$ 5% of their peak oxygen uptake for 75 min in the heat (dry bulb temperature: 30.2 $\pm$ 0.3°C, relative humidity: 70 $\pm$ 3%). Cognitive performance was assessed before and after the exercise. Body mass, body core temperature, mean skin temperature, heart rate, ratings of perceived exertion and blood glucose were measured. Total body water was measured by diluted isotope method. **Results** Body core temperature was elevated at the end of the trials (P: 39.5 $\pm$ 0.4°C, CE: 39.6 $\pm$ 0.5°C, P=0.41). Mean skin temperature (P: 35.3 $\pm$ 0.5°C, CE: 35.3 $\pm$ 0.5°C, P=0.53), heart rate (P: 171 $\pm$ 10 beats/min, CE: 171 $\pm$ 10 beats/min, P=0.97) and ratings of perceived exertion (P: 17 $\pm$ 2, CE: 16 $\pm$ 2, P=0.18) were similar between the trials. At the end of the run, blood glucose concentration was higher in the CE trial (Pre: 4.6 $\pm$ 0.2 mmol/L, Post: 6.4 $\pm$ 1.1 mmol/L) than in the P trial (Pre: 4.7 $\pm$ 0.2 mmol/L, Post: 6.0 $\pm$ 1.4 mmol/L, P<0.05). Maximum digit span was improved by 1 $\pm$ 2 units in the P trial (P<0.05) and degraded by 1 $\pm$ 1 unit in the CE trial (P<0.05). Ingestion of CE solution had no effects on other cognitive tests (P>0.05). No relationship (R<sup>2</sup>=0.11,

$P=0.15$ ) was found between change in body mass ( $-1.3\pm 0.4$  kg) and total body water ( $-1.9\pm 1.6$  kg). Conclusion These results suggest that the ingestion of small amounts of a CE solution can degrade short term memory after exercise in the heat. Acute changes in body mass do not accurately predict changes in total body water. References Coombes J.S. and Hamilton K.L. (2000). ### EFFECT OF PHYSICAL FITNESS ON THE CEREBRAL BLOOD FLOW IN ELDERLY WOMEN

Hirasawa, A., Sato, K., Ooue, A., Sadamoto, T.

*Japan Women's College of Physical Education*

**Introduction** The decline in the resting cerebral blood flow (CBF) occurs with ageing (Scheel et al. 2000), and the reduced CBF generally increases risk factors for cerebrovascular disease e.g., stroke and Alzheimer's disease in elderly people. Previous study suggested that fitter persons with higher maximal oxygen uptake have a higher the resting CBF in elderly man (Ainslie et al. 2008). However it has not yet been examined if other physical fitness components such as muscular strength and endurance, body flexibility and balance could also affect the resting CBF. We, therefore, studied the relationship between CBF indices and fitness score obtained in various components and compared the CBF indices between high fitness score group (FIT) and low fitness score group (UNFIT) in elderly women over 65 years old. **Methods** The subjects comprised 120 healthy elderly women between 65 and 89 years old. The resting blood flow in common carotid artery (CCA) was measured as CBF index in subjects in supine position by ultrasonography. Mean arterial blood pressure (MAP) was also measured with Finometer. As CBF index, the cerebrovascular resistance (CVR) was calculated from the ratio of MAP to CCA blood flow. Each score in 6 fitness tests (handgrip strength, trunk flexibility, 10-m walking and getting over obstacles, one-leg balance with eyes opened, 30-s upper body-raising, and walking distance for 6 min) were obtained and then added as total fitness score in individual subject. From the value of total fitness score, the subjects were divided into FIT ( $>$  the median in all subjects;  $n = 60$ ) and UNFIT ( $<$  the median in all subjects;  $n = 60$ ). **Results** The CCA blood flow and CVR were positively correlated to the total fitness score (CCA blood flow:  $r = 0.21$ ,  $p < 0.05$ ,  $n = 120$ ; CVR:  $r = -0.21$ ,  $p < 0.05$ ,  $n = 120$ ). The CCA blood flow was also significantly correlated to the score in trunk flexibility and 30-s upper body-raising (trunk flexibility:  $r = 0.21$ ,  $p < 0.05$ ,  $n = 120$ ; 30-s upper body-raising:  $r = 0.19$ ,  $p < 0.05$ ,  $n = 120$ ). The FIT showed a significantly higher CCA blood flow and a significantly lower CVR compared to UNFIT group (CCA blood flow:  $440 \pm 108$  vs.  $388 \pm 95$  ml/min,  $p < 0.01$ ; CVR:  $0.23 \pm 0.07$  vs.  $0.26 \pm 0.07$  mmHg/ml  $\cdot$  min $^{-1}$ ,  $p < 0.05$ ). **Discussion** This study found that CCA blood flow and CVR in elderly women showed a positive correlation to the total fitness score and the score in the trunk flexibility and 30-s upper body-raising. These findings suggest that not only cardiorespiratory fitness component but also other components such as body flexibility and muscular endurance affect the resting CBF and play an important role in preventing the age-related decline the resting CBF.

### ROLE OF FUNCTIONAL ASYMMETRY OF BRAIN HEMISPHERES IN SPORTS

Porozovs, J., Praulite, G., Spunde, A., Perepjolkina, V., Voita, D.

*Riga Teacher Training and Educational Management Academy*

**Introduction** Differences of behaviour between left-handers and right-handers are determined by functional asymmetry of brain hemispheres. Physiological processes in right and left human brain hemispheres realise in different ways. Asymmetry of brain hemispheres of left-handers is less explicit than right-handers. In some branches of sports (box, tennis, fencing) left-handers have advantages in comparison with right-handers. The statistical data show that 30 – 40 % of cases boxers left-handers win in significant competitions (Brooks et al., 2004). **Methods** Psycho-physiological parameters (velocity of movement, the level of nervous system strength and reactions in conflict situations) as well as exactness of basketball throws in the basket were observed for basketball players: right-handers and left-handers. Tapping test was used in order to observe the strength of nervous processes. Behaviour test of K. Tomass was used to determine typical reactions of basketball players in conflict situations: competition, cooperation, compromise, evasiveness and adaptation. The exactness of basketball throws in the basket was checked up for every observed person throwing with the right hand and with the left hand in 3 series dynamics (10 throws in every of series) and also after load (30 throws). **Results** The velocity of movement touches to surface during 40 seconds for basketball players – right-handers with leading right hand was higher than for basketball players – left-handers with leading left hand. Basketball players right-handers as well as left-handers had middle nervous system strength. Competition reaction for basketball players – right-handers was more typical in comparison with left-handers ( $p < 0,05$ ). Cooperation was a little more typical for left-handers in comparison with right-handers ( $0,05 < p < 0,1$ ). The exactness of basketball throws in the basket of left-handers with "leading" (left) hand (4,78 from 10 throws) was higher than right-handers with "leading" (right) hand (3,89 from 10 throws) ( $p < 0,05$ ). The exactness of basketball throws in the basket of left-handers with "passive" (right) hand was higher than right-handers with "passive" (left) hand before load and after load ( $p < 0,05$ ). **Discussion** The possibility of basketball players left-handers to do more exact basketball throws in the basket, probably, is connected with domination of right hemisphere which has significant role in providing of spatial orientation. For left-handers it is more accustomed to act with right hand than for right-handers to act with left hand. It is connected with that fact that many of tools and instruments are adapted for the work with right hand. It is recommendable for basketball players left-handers fully to put into use their advantages in the actions with "passive" hand. References 1. Brooks, R., Bussiere, L.F., Jennions, M.D., Hunt J. Sinister strategies succeed at the cricket World Cup. In: *Proc Biol Sci.*, Number 2, 2004, p.64–66.

### RELATIONSHIP BETWEEN SEROTONIN LEVELS IN THE VENTRAL TEGMENTAL AREA AND THERMOREGULATION IN FREELY MOVING RATS

Ishiwata, T., Takatsu, S., Hasegawa, H.

*Rikkyo University*

**RELATIONSHIP BETWEEN SEROTONIN LEVELS IN THE VENTRAL TEGMENTAL AREA AND THERMOREGULATION IN FREELY MOVING RATS** Takayuki Ishiwata<sup>1</sup>, Satomi Takatsu<sup>2</sup>, Hiroshi Hasegawa<sup>2</sup> 1:Dept. Sport & Wellness, Rikkyo Univ., Saitama, Japan 2:Grad. Sch. Integ. Arts & Sci., Hiroshima Univ., Hiroshima, Japan **Introduction** The relationship between exercise performance and thermoregulation is well documented. Several brain neurotransmitter systems, including the serotonergic system, are activated during exercise. Brain serotonin (5-HT) is an important monoaminergic neurotransmitter. The serotonergic system is involved in the regulation of physiological functions and behaviour, including thermoregulation. The 2 main sources of 5-HT innervation to the forebrain are the dorsal raphe nucleus (DRN) and median raphe nucleus (MRN). We have already reported that perfusion of tetrodotoxin into the DRN or MRN decreases body temperature (T<sub>b</sub>) (Ishiwata et al., 2001) by increasing heat loss, without changing heat production, in freely moving rats (Ishiwata et al., 2008). These results

suggested that heat loss is the primary effect of 5-HT projection from the DRN or MRN on thermoregulation. The ventral tegmental area (VTA) is an important area that regulates the heat loss response (Kanosue et al., 1998). The present study was designed to determine the relationship between 5-HT levels in the VTA and thermoregulation in freely moving rats by using microdialysis/biotelemetry techniques. Methods A telemetry device and a microdialysis probe were surgically implanted. We measured extracellular 5-HT levels in the VTA during cold and heat exposure (5 or 23°C) combined with on-line HPLC system. Furthermore, we perfused citalopram (5-HT reuptake inhibitors) into the VTA. We continuously measured  $T_b$  and heart rate (HR), indexes of heat production, by the telemetry technique. The tail temperature ( $T_{tail}$ ), an index of heat loss from the dorsal surface of the skin, was continuously measured at approximately 10 cm from the base of the tail using a mini temperature data logger. Results & Discussion During heat exposure,  $T_b$  increased by approximately 1.5°C, with an increase in  $T_{tail}$  and a decrease in HR, suggesting the activation of the heat loss response. 5-HT levels in the VTA increased after 1 hour of heat exposure. During cold exposure,  $T_b$  increased by approximately 0.8°C, with an increase in HR and a decrease in  $T_{tail}$ , suggesting the activation of the heat production response. 5-HT levels in the VTA did not change during cold exposure. Perfusion of citalopram increased 5-HT levels in the VTA, with a decrease in  $T_b$  by approximately 0.5°C and an increase in  $T_{tail}$ , but without a change in HR. Therefore, we concluded that the VTA plays an important role in the regulation of the heat loss response and 5-HT in the VTA is a key neurotransmitter. ### SHORTENING OF LONG-LATENCY SOMATOSENSORY EVOKED POTENTIALS IN BASEBALL PLAYERS

Yamashiro, K., Sato, D., Onishi, H., Maruyama, A.

*Niigata University of health and welfare*

Koya Yamashiro 1,2, Daisuke Sato1,2, Hideaki Onishi1,3, Atsuo Maruyama1,2 1Institute for Human Movement and Medical Sciences, Niigata 950-3198, Japan 2Department of Health and Sports, Niigata University of Health and Welfare, Niigata 950-3198, Japan; 3Department of Physical Therapy, Niigata University of Health and Welfare, Niigata 950-3198, Japan Introduction We investigated the neuro-plastic changes in baseball player using long-latency somatosensory evoked potentials (SEPs). In general, long-term training of athletes and musicians is known to induce neuro-plastic changes. The aim of this study is to clarify whether the long-term training affect the long-latency SEPs relating to information processing of stimulation in baseball players. Methods SEPs were recorded from two groups (baseball group and sports group) in fifteen subjects at Fz, Cz, Pz, C3, C4 stimulating index finger of right hand. The intensity of the stimulus was three times the sensory threshold, and was never reported as painful. The inter-trial interval was randomized between 5-8 s. In baseball group, seven subjects have played baseball over 7 years. While, other subjects have played various sports such as swimming, track and field and soccer. Long-latency SEPs were measured under passive (control) condition and reaction time condition (movement condition). In the passive condition, subjects relaxed and had no task. In the reaction time condition, they were instructed to prepare to push the button, and to push it as fast as they could when the stimulus was presented. Results P100 and N140 were elicited by two groups and conditions. The latency of P100 and N140 in baseball group was significantly shorter than in sports group. In addition, reaction time in baseball group was significantly shorter than in sports group. Moreover, the latency of P100 and reaction time were significantly positive correlation. Discussions Sensation of hands is more important for baseball player than for runner, swimmer and soccer player. Baseball players need sensation of hands in various situations such as throwing, batting and catching. Therefore, long-term training may induce neuro-plastic changes in hand area, and this phenomenon may play an important role to quick responses to required movements.

### CHANGES IN ASPECTS OF COGNITIVE FUNCTION IN RESPONSE TO PASSIVE AND ACTIVE MANIPULATION OF CORE AND SKIN TEMPERATURE

Watson, P., Bandelow, S., Maughan, R.J.

*Loughborough University*

Introduction Cognitive function has been reported to decline following strenuous exercise in the heat (Gopinathan et al. 1988; Cian et al. 2001). Dehydration does not explain this response, since task performance is restored following a period of rest (Cian et al. 2001), but hyperthermia, may contribute to the observed reduction in cognitive function. The aim of the present study was to determine the effect of passive and active means of raising core temperature on aspects of cognitive function. Methods Eight active males ( $22 \pm 2$  y,  $81.4 \pm 5.5$  kg,  $1.82 \pm 0.05$  m,  $4.7 \pm 0.4$  L/min) completed a preliminary trial, a familiarisation trial and 3 experimental trials (cool immersion/cool exercise (C/C), cool immersion/warm exercise (C/W) and warm immersion/warm exercise (W/W)). Volunteers were seated in a water bath maintained at a temperature of either 37.0°C or 39.5°C for 30 minutes before entering a cool (10°C, 60% rh) or warm (35°C, 60% rh) room to undertake cycle exercise at a workload corresponding to 60%  $\dot{V}O_{2peak}$  until volitional exhaustion. Cognitive function was assessed before and immediately after water immersion and after exhaustion, using a battery of computer-based tests. Core (rectal) and weighted mean skin temperature were recorded. Results Immersion in warm water increased core temperature from  $37.0 \pm 0.30$ °C to  $38.3 \pm 0.20$ °C ( $P < 0.001$ ), with no change after the cool immersion ( $P = 0.445$ ). Exercise time was  $83.5 \pm 9.0$  min in the C/C trial, with significantly shorter times when exercise was undertaken in the heat (C/W  $43.3 \pm 8.4$  min; W/W  $33.1 \pm 9.4$  min;  $P < 0.001$ ). At the end of exercise core temperature was  $38.4 \pm 0.30$ °C,  $38.8 \pm 0.50$ °C and  $39.2 \pm 0.40$ °C in the C/C, C/W and W/W trials respectively ( $P = 0.037$ ). Warm water immersion resulted in slower reaction times on the interference level of the Stroop test and on the high memory load condition of the Sternberg working memory test (both  $P < 0.05$ ), but not at the baseline level of each test ( $P > 0.05$ ). No such effect was apparent following exercise ( $P > 0.05$ ). Adding core and/or skin temperatures into the analysis did not explain this slowing better than the warm immersion condition itself. Discussion These data suggest that warm immersion can specifically impair response times in complex tasks involving executive function and working memory. This effect was not solely caused by core or skin temperature changes, but appears to involve additional factors present during passive, but not active, heating, possibly related to changes in brain blood flow resulting from warm water immersion. **DOES TDCS OVER THE PRIMARY MOTOR CORTEX HAVE AN EFFECT ON THE CONSOLIDATION OF MOTOR MEMORIES?**

Rroji, O., Pauwels, L., Bekkers, E., Wenderoth, N.

*KU Leuven*

Introduction: Transcranial direct current stimulation (tDCS)(1) is a non-invasive, painless cortical stimulation technique(2) that is well tolerated by healthy subjects and patients. Recent studies have demonstrated that non-invasive brain stimulation enhances memory formation and cortical plasticity for a variety of tasks including visuo-motor coordination(3), implicit motor learning and probabilistic classification learning in healthy volunteers. Here we tested whether tDCS affects also use-dependent plasticity, i.e. increase in neural and behavioral efficiency as a consequence of repeated practice. Methods: 14 healthy young volunteers (age 18 to 30, 6 females, 4 left handed) were involved. The subjects had to practice to flex their non-dominant thumb as fast as possible for 10 blocks, consisting of 20 movements each (1 mov every 3s). Between blocks there were 1min break to prevent fatigue, in total 20min. In half of the subjects, real tDCS was applied during the first training session with the anode mounted over the contralateral primary motor cortex(M1) and the cathode placed on the contralateral shoulder. Results: First analyses indicate that real tDCS enhanced retention performance 1 day and particularly 1 week after training, as indicated by a significant training x stimulation interaction ( $F(16,160)=4.09$ ,  $p<0.0001$ ) which was revealed by an analysis of variance for repeated measurements. In an ongoing experiment we are testing whether placement of tDCS electrodes and the amount of training will show a different result compared to the previous experiment. Discussion: Our data show for the first time that tDCS has a positive effect on use-dependent plasticity. Importantly, tDCS did not affect training performance per se but rather memory consolidation. Its beneficial effect seems to be enhanced when the motor memory is repeatedly reactivated even if reactivation occurs one day after the tDCS intervention. Our results might have important implications for increasing the efficiency of motor practice in healthy subjects and rehabilitation settings. References: 1.Paulus W. **EFFECT OF HEMODYNAMIC CHANGES CAUSED BY VALSALVA MANEUVER ON BRAIN NEAR-INFRARED SPECTROSCOPY MEASUREMENTS**

Tsubaki, A.1,2, Furusawa, A.A.2, Kojima, S.1,3, Onishi, H.1,2

*Niigata University of Health and Welfare*

Introduction Near-infrared spectroscopy (NIRS) is widely used to measure human brain activation on the basis of cerebral hemodynamic response. The advantage of NIRS over other methods is that it provides direct, real-time measurement of oxygenation in cortical tissue. However, a limitation of NIRS is that hemodynamic changes influence the measured signals. The purpose of this study was to clarify the relationship between NIRS signals and blood pressure during the Valsalva maneuver. Methods Four healthy volunteers participated in this study. All participants provided written informed consent after experimental procedures had been explained. The study was approved by the Ethics Committee of Niigata University of Health and Welfare (17157-100203). Subjects performed a 20-s Valsalva maneuver to change blood pressure. NIRS (OMM-3000, Shimadzu) optodes were set in a holder at a distance of 30 mm and stabilized by a crepe bandage around the head. Changes in oxyhemoglobin (O<sub>2</sub>Hb) concentration were calculated by using the modified Beer-Lambert law. Thirty-four channels with an inter-optode distance of 30 mm were used for deep-penetration measurements (deepO<sub>2</sub>Hb), and nine channels with an inter-optode distance of 15 mm were used for shallow-penetration measurements (shallowO<sub>2</sub>Hb). The difference value (diffO<sub>2</sub>Hb) of deepO<sub>2</sub>Hb and shallowO<sub>2</sub>Hb was calculated. Beat-to-beat mean arterial pressure (MAP) was recorded by volume clamping the finger pulse with a Finometer (Finapres Medical Systems BV) on the left side. A height reference sensor was used to remove confounds related to arm position. Skin blood flow changes were measured at the forehead by a laser Doppler blood flow meter (Omegaflow FLO-CI, OmegaWave, Inc). The relationships between deepO<sub>2</sub>Hb, shallowO<sub>2</sub>Hb, diffO<sub>2</sub>Hb, and MAP were assessed using Pearson's correlation coefficient with significance set at  $P<0.05$ . Results Pearson's correlation coefficient between deepO<sub>2</sub>Hb and MAP, shallowO<sub>2</sub>Hb and MAP, and diffO<sub>2</sub>Hb and MAP was 0.64–0.88 ( $P<0.01$ ), 0.64–0.89 ( $P<0.01$ ), and 0.45–0.67 ( $P<0.01$ ), respectively. Discussion Regional and systemic changes in the cardiovascular state strongly influence NIRS signals. Our observations, which revealed a significant relationship between O<sub>2</sub>Hb and MAP, demonstrate that not only are blood pressure changes influenced by deep and shallow-penetration NIRS signals, but also that diffO<sub>2</sub>Hb is suitable for measuring brain activation.

**SPONTANEOUS WHEEL RUNNING ALTERS BRAIN ACTIVITY RELATED TO MENTAL CONDITION IN OBESE ZUCKER RATS**

Yanagita, S., Kanemaru, J., Ochiai, H., Umezawa, M., Takeda, K.

*Tokyo University of Science*

Introduction Throughout the world, obesity has become an increasing health concern due to its being a risk factor of lifestyle disease. Physical exercise is strongly recommended for obese people because it helps to improve lipid metabolism and in turn prevent lifestyle disease. In general, however, it is thought that obese people tend to have a negative impression regarding the performance of physical exercise. It is thus suggested that physical exercise might be detrimental to the mental condition of obese people, in spite of its efficacy in improving physical health. It is well known that mental condition is integrated by brain activity in several regions of the brain. Therefore, it is possible that brain activity related to mental condition in obese people differs from that in the non-obese. In this study, we examined the effects of spontaneous wheel running on the activation of several brain regions related to mental condition in obese (fa/fa) and lean (wild type) Zucker rats. Materials and Methods Male Zucker rats were used in this study. The rats were housed individually in plastic cages with or without an attached running wheel and were randomly assigned to either physically active or sedentary conditions. Physically active rats were allowed voluntary access to their wheels for 2 weeks. Daily wheel revolutions were recorded digitally, and running distance was calculated by multiplying wheel circumference by the number of revolutions. We assessed the expression of c-Fos, the protein encoded by the immediate early gene c-fos, which is well known as a transcription factor and functional marker of neuronal activity. This assessment was performed using immunohistochemistry in various brain regions related to mental conditions, such as the prefrontal cortex, paraventricular nucleus of the hypothalamus, hippocampus, central nucleus of the amygdala, ventral tegmental area, dorsal raphe nucleus and locus coeruleus. Results Two weeks of spontaneous wheel running increased the expression number of c-Fos in all brain regions compared to sedentary conditions in both obese and lean rats. The number of c-Fos immunoreactive cells in specific brain regions was significantly lower in obese rats than that in lean rats. Discussion The results of the present study showed that spontaneous wheel running enhanced c-Fos expression in several brain regions related to mental conditions and that these effects were blunt-

ed in obese rats. The results of the present study, taken together with numerous studies that have shown that spontaneous wheel running has excellent effects on the maintenance of brain functions, suggest that it is necessary for obese people to have the ability to engage in spontaneous physical activity in their daily lives.

### REGULAR PHYSICAL ACTIVITY IMPROVES COGNITIVE PERFORMANCE DURING ODDBALL TASK IN YOUNG ADULTHOOD

Krell, J.1, Putze, F.1, Heger, D.1, Benzinger, S.1, Engelmann, J.1, Schultz, T.1, Bös, K.1, Stahn, A.2

*1 Karlsruhe Institute of Technology (Karlsruhe, Germany), 2 Charité, Center for Space Medicine (Berlin, Germany)*

**Introduction:** Physical activity has been associated with improved health across lifespan. There is also growing interest in the relationship between exercise and cognition. Physical activity has been linked to enhanced cognitive task performance and neurophysiologic measures such as event related brain potentials (ERP). However, most research has focused either on children or elderly. The purpose of this study was to determine the effects of regular exercise on central information processing during a modified oddball-task in a cross-sectional study with young adults. **Methods:** 119 university students who were regularly engaging in physical activity and 33 students who were physically inactive within at least one year prior to the study took part in it (age: 18 to 34 yrs). All participants performed cognitive testing as well as various physical performance tests to determine endurance, strength and gross motor skills. Reaction time (RT) and P3 components of ERP in an auditory oddball task at midline electrode sites (Fz, Cz, Pz) were used as dependent measures for data analysis. **Results:** Active subjects had a significantly lower body-fat percentage and higher VO<sub>2</sub>max, maximum strength as well as coordinative performance than inactive participants. In the oddball task, the active group revealed faster reaction times ( $F=7.20$ ,  $p<.01$ ,  $\eta^2=.052$ ) and larger P3 amplitudes over all electrode sites (Fz:  $F=4.67$ ,  $p<.05$ ,  $\eta^2=.044$ , Cz:  $F=6.04$ ,  $p<.05$ ,  $\eta^2=.056$ , Pz:  $F=7.15$ ,  $p<.01$ ,  $\eta^2=.065$ ) than compared to the inactive group. Coordinative performance, but not aerobic capacity or strength performance, had a significant effect on P3 amplitude ( $F=12.30$ ,  $p<.01$ ,  $\eta^2=.110$ ). **Discussion:** The results suggest that regular exercise increases cognitive information processing during an oddball tasks in young adults. Type of sport as well as type of physical performance may further play a crucial role underlying this relationship. Our results indicate that sports associated with high motor control might be particularly valuable in promoting cognition and brain health. However, in contrast to our hypothesis, no effect of aerobic capacity, amount of physical activity or exercise intensity on ERPs was found in this task. Moreover, an enhanced response speed as seen in the active group could also be explained by a better efficiency of peripheral motor processes. To clarify this problem it should be investigated whether there is still an effect on response speed in a task that does not require motor responses.

### THE RESPONSE OF CORTICAL ALPHA ACTIVITY TO PAIN AND NEUROMUSCULAR CHANGES CAUSED BY EXERCISE INDUCED MUSCLE DAMAGE

Plattner, K., Tam, N., Lambert, M.I., Baumeister, J.

*University of Cape Town and University of Paderborn*

**Introduction** It is known that exercise-induced-muscle-damage (EIMD) is characterized by pain, swelling and shortening of the muscle, increased serum creatine kinase (CK) activity, decreased force output (FO) and altered neuromuscular function. How these symptoms of EIMD affect brain function, in particular cortical activity has not been described. Therefore the aim of this study was to investigate the relationship between the symptoms of EIMD and cortical alpha ( $\alpha$ ) activity during a submaximal biceps movement. **Methods** 37 right-handed male participants were recruited for this study. Before the start of the study all participants were familiarized with the testing equipment and different test protocols. Subjects were divided into a control and experimental group with testing as follows: 12h pre-EIMD and 12h, 36h and 132h post-EIMD. Electroencephalography (EEG) was recorded on all subjects whilst performing a maximal voluntary contraction (MVC) and a self-paced submaximal flexion-extension movement. Data were collected continuously during the premovement, movement and rest phase and therefore represent the common state of the brain during the movement protocol. CK, biceps girth, resting elbow angle and a pain score were also measured at these times. **Results** At 12h neuromuscular functioning was already disturbed whilst the sensation of pain was perceived but not fully developed. Muscle pain scores in the experimental group peaked after 36h with lowest torque reported at 12h.  $\alpha$ -1 activity increased significantly in the motor and somatosensory (SS) area 12h post-EIMD while  $\alpha$ -2 activity increased in the contralateral fronto-central area. At 36h pain had further increased and neuromuscular function improved whilst  $\alpha$ -1 and  $\alpha$ -2 activities had decreased. **Discussion** Whilst it is not clear the cause of increase in  $\alpha$ -1 activity over the motor and SS area in the EIMD group we hypothesize that it may increase in order to counteract the loss of movement steadiness and force output whilst experiencing EIMD. Recording of  $\alpha$ -1 activity in this proximal location we assume it to be a top-down regulator of peripheral function. An increased  $\alpha$ -1 activity may be part of an upstream regulation of motor perception, activation and neuromuscular function. It seems  $\alpha$ -1 activity over the motor and SS cortex may compensatory increase in response to the changes in neuromuscular function during movement, whilst an increase in  $\alpha$ -2 activity is related to the suppression of pain experienced within the first 12h of an EIMD protocol. Mostly peripheral symptoms associated with EIMD have been studied but none have provided adequate explanations for the delayed pain response associated with EIMD. The novelty of this study explored the response of the brain's cortical  $\alpha$ -1 and  $\alpha$ -2 activities, peripheral symptoms and delayed pain response to EIMD. Evidence points towards these brain areas and frequencies may regulate the pain response acutely while experiencing the symptoms of EIMD during movement.

### IS-PM02 ACSM Exchange Symposium/Pacing : Who Got the Turtle's Running Shoes?

#### WHO GOT THE TURTLE'S RUNNING SHOES?

de Koning, J.J.1, Foster, C.2

*(1) VU University, Amsterdam and (2) University of Wisconsin-La Crosse, La Crosse*

Carl Foster, Ph.D., FACSM, University of Wisconsin-La Crosse Why Do they Do it that Way? In 1987, American author Ed Regis wrote a very engaging book 'Who Got Einstein's Office?'. Despite it's name, the book was not about the interfaculty squabbling over who inherited the office of the man who changed the course of physics, but over the interplay between the theoretical and experimental physics communities, and how their work is a complimentary necessity to progress in physics. In the early 1990's, independent interest in how humans distribute their energetic reserves during heavy exercise (pacing strategy) arose nearly simultaneously in Europe (Amsterdam) and the U.S.(Milwaukee). However, the initial approach to answering the question about why the turtle beat the hare was strikingly different, being more of a theoretical-first principles analysis in Europe (van Ingen Schenau and de Koning) and more pragmatic-descriptive in the U.S. (Foster). In this lecture we present a historical overview of how these two decidedly different approaches, which in some ways characterize more fundamental differences between the approach to problem solving in Europe and the U.S., worked in a complimentary fashion, and integrated themselves with approaches to the same problem from other laboratories, to allow progress relative to understanding how the cultural differences between Europe and the U.S. combine to provide insight into problem solving.

#### WHAT BRINGS FANS INTO THE STADIUM? QUESTIONNAIRE ABOUT THE MOTIVES FOR SOCCER ATTENDANCE IN BELGIUM AND IN PORTUGAL

de Carvalho, M.1,2, Sarmiento, J.2, Boen, F.1, Scheerder, J.1

*KU Leuven (België) & UP (Portugal)*

The motives that take people into the soccer stadium have been studied in diverse research domains including marketing, sociology, and psychology. Smith & Stewart(2007) collected 6 factors that moderate sport consumption behaviour: sport context, competition, physical environment, economic, promotional and social context. From a sociological perspective, Funk et al.(2009) provided a parsimonious measuring tool of 5 motives to explain sport event attendance (Socialization, Performance, Excitement, Esteem, and Diversion). From a psychological approach, team identification (Wann&Branscombe,1993) and place attachment (Theodorakis et al.,2010) have also been shown to predict attendance. Nevertheless, we still lack a common language and a model that can integrate all these angles. The aim of our study is to identify the motives that take soccer fans into the stadium or not, taking into account all the above mentioned perspectives. Therefore, a questionnaire was designed to conduct a cross-cultural comparison in Belgium and Portugal. Methods Based on a thorough scrutiny of the available literature, a 1st version of a questionnaire was elaborated in Dutch. A pilot study was conducted with a sample of 70 individuals. The questionnaire had several flaws, namely, in the extension, and organization. The corrected version in Dutch was translated to Portuguese and a pilot study was also performed, with a sample of 40 individuals. Minor changes were executed and a last version was accomplished. Results The final version of the questionnaire includes 3 parts: (i)the person as a soccer fan (including loyalty questions, team and place identification scales and social items) (ii)consumption habits, and choices (iii)socio-demographical items. We expect that for different clusters of individuals the relative weight of attendance predictors differs. We hypothesise that less attached fans will be more influenced by the service quality than more attached fans. Conclusion This questionnaire is being applied on-line in 2 studies reaching: (i) an intercultural wide-ranging population by means of the educational system from one Portuguese (i.e. Aveiro) and one Belgian city (i.e. Leuven), with a soccer club playing in the 1st league (Beira-Mar and OHL); (ii) an intercultural diverse

population by the means of internet. Data is being analysed and further results will be presented. References Funk D, Filo K, Beaton A & Pritchard M(2009). ### **ASSET SPECIFICITY IN SPORT – HOW CENTRALIZED SHOULD AN EFFICIENT PRODUCTION OF ELITE SPORTING SUCCESS BE?**

Flatau, J.

*University of the Saarland*

Research Problem Sporting success is a product of giftedness and training. Since the first can be assumed to be distributed equally and the latter causes costs it is not surprising that virtually all surveys on collective sporting success identify population size and gross income product (a proxy variable for financial power) as explaining variables. Hence, from an economic perspective, the productivity of the promotion of elite sport becomes the focus of attention. Theory Every production can be organized more or less hierarchically. According to Williamson (1985), the general comparative profitability of markets decline as the asset specificity of the product and therefore the market transaction costs increase. Applying this approach to collective sporting success, the question is whether its in many countries currently quite hierarchical promotion system could be decentralized without a decline in effectiveness but in costs. Our hypothesis is that asset specificity varies strongly across the different sport and that therefore this but also national characteristics ought to be taken into account for the design of an efficiency-optimized promotion system. State of Research For the field of the promotion of talent development, Emrich & Pierdzioch (2011) identified over-centralization with regard to productivity and Flatau & Emrich (2011) could prove the dependency of that lack of efficiency on the sport-related site and physical asset specificity as assumed above. Here, we present analogous analyses for the promotion of short-term sporting success. Method Using a questionnaire survey sample of 1,558 elite athletes, we compare the sporting success of those preparing for competition (i.e., training, medical/scientific services etc.) centralized at Olympic Training Centres with that of those preparing decentralized (in sport clubs etc.) and measure in how far this relation is intervened by asset specificity, the popularity and the degree of commercialization of the respective sport. Other than in preceding analyses we use metric parameters for site as well as for physical asset specificity basing on training site/facility density and cost measurement. Results and Discussion The results confirm the assumption that the comparative efficiency disadvantages of centralized production of sporting success decrease with increasing asset specificity. Hence, a cost-optimized production of sporting success ought to confine costly centralized promotion organizations to sport with high asset specificity. References Emrich, E, Pierdzioch, C (2011). ### **CONFIGURATIONS OF EUROPEAN NATIONAL SPORTS SYSTEMS: A SOCIO-ECONOMIC APPROACH.**

Camy, J.

*University of Lyon*

Introduction Is it possible to conceive of sport in Europe as contributing to "national sports systems"? Can we compare these various national sports systems and identify different configurations within them? Our intention here is to test a new, systematic and quantifiable socio-economic theoretical model, to enable us to respond to these questions. Theoretical framework Socio-economics does not consider economics as a distinct and autonomous system to which all other social phenomena must submit (Polanyi, 1944). Our analysis combines two resources; the first, "Economic "regulation theory" (Boyer, 1990) which states as its object, "the study of the transformation of social relations, which creates new forms- both economic and non-economic- organized in structures and reproducing a determined global structure" and the second "constructivist structuralism" which "views each activity including economic ones as 'total social facts' " (Bourdieu 2000). We consider sport as a sector (corresponding to group 93.1 of the NACE 2008 classification). Our basic premise is that the sector is made up of five components, which are all present in most E.U. countries. Each one of these offers specific sport services: professional sport, voluntary competitive sport, commercial sporting leisure, voluntary sporting leisure and public sport services. National sport systems are characterized by a particular combination of these components and by the type of intra- and inter-regulations which are in place. Methodology The characteristics of each of these components can be identified and measured by key indicators. We have tried out our theoretical model against various empirical researches conducted within the E.U. (Vocasport, Eurobarometers, Study on the private and public financing of sport, etc...), along with other sources of information. By making use of social and economic data we have been able to characterize the situation of sport in E.U. countries. Results On the basis of restricted number of key indicators, we have first of all clearly identified different types of national sports systems characterized by both the disparities in economic and social importance of their components and by the form of regulation existing between them. Following this first observation, we would propose a provisional typology of the national sports systems", settling upon four main "configurations" which we have called "entrepreneurial", "missionary", "bureaucratic" and "social". ### **PATHWAYS OF SCIENCE: FROM PHYSICAL EDUCATION AND PHYSIOTHERAPY TO RADIODIAGNOSTICS AND RADIOTHERAPY AT THE STATE UNIVERSITY IN GHENT, 1906-1936**

Delheye, P., Vangrunderbeek, H.

*K.U.Leuven - FaBeR*

Introduction The development of new scientific specializations is partially determined by the migration of researchers between and within universities. This case-study focuses on the complex triangular relationship between medicine, physiotherapy and physical education. As previous research has demonstrated, the first international congress on physiotherapy was organised in Belgium in 1905. Furthermore, the Belgian State was an international pioneer with the creation of the Higher Institute of Physical Education (HIPE) at the State University in Ghent in 1908 (Delheye 2005). Methods The study is based on research in the State Archives of Belgium and in the archives of Ghent

University. Institutional documents and correspondence of protagonists were analyzed. Results In 1908, the Belgian State appointed two physiatrists, Florent Gommaerts and Jules De Nobele, to the HIPE, which was attached to the Faculty of Medicine. During their academic career, Gommaerts and De Nobele profiled themselves almost exclusively within the new field of physiotherapy. As a consequence, research in physical education was hardly developed. As physiatrists (physicians-physiotherapists), Gommaerts and De Nobele struggled with an inferior academic and scientific status, as compared to their colleagues within the Faculty of Medicine. Territorial conflicts and power struggles manifested themselves in several areas. As a result of the succession of this first generation of physiatrists, however, physiotherapy was integrated fully into the Faculty of Medicine in the middle of the 1930s. At the same time, radiography, radiodiagnosics, and radiotherapy – which originally were considered sub-disciplines of physiotherapy – gained independence within the Faculty of Medicine. Discussion/Conclusion At the State University of Ghent, physical education was instrumental to the upwards scientific mobility of physiotherapy. Via the HIPE, indeed, physiatrists could migrate upwards to the Faculty of Medicine. Physical education, for its part, retained its inferior status after physicians-physiologists took over the leadership of the institutes for physical education from 1935 onwards. Further research is needed to demonstrate whether or not these early developments at the State University in Ghent occurred also internationally in a similar way. ### **SPORT AND IMMIGRATION IN FRANCE IN THE THIRTIES. SPORT PRACTICES OF POLISH MIGRANTS IN BURGUNDY, A MEAN OF INTEGRATION?**

Bretin-Maffioletti, K.

*Université de Bourgogne - Faculté des Sciences du Sport*

In multicultural societies, such as the French society, the integration of « foreigners » is of major interest (Noiriél, 1988). This is particularly true during economical and cultural crisis periods, when social cohesion is endangered. Since the eighties, sport practice is presented and used by politicians as a way to encourage integration (Gastaut, 2004). This vision of sport is inspired by the original thinking of the first English modern sport advocates. It is also built on the mythical and historical figures of great champions coming from the French colonies or from immigration (Gastaut, 2004). For example, Alfred Nakache (swimmer) and Alain Mimoun (runner), coming from Algeria, Alfredo Binda (cyclist), coming from Italy and of course Raymond Kopa and Michel Platini (soccer players), coming from Polish and Italian immigration. However, besides these extraordinary careers, the integrative role of sport for people who arrived in France all along the 20th century remains to be explored. This communication focuses on ordinary sport and leisure practices in a community of Polish migrants, who arrived in a mining region of Burgundy in the thirties. The aim is to determine the effects of sport practice on social integration and on the relationships with the local community. In the absence of archives, the study methodology consists of oral interviews of the first generation of migrants and their descendants. Data extraction is based on content analysis and discourse analysis. Sport appears as an essential aspect of migrants' everyday life, which facilitated their adaptation to new working and living conditions. On the contrary, Polish sport practices took place in community societies. These Polish organizations probably confirmed the distance between French workers and foreigners. Lastly, the accounts traduce identity switches, as revealed by changing competitive situations. The current study suggests that the integrative role of sport can be limited in History. Secondly, and more importantly, this analysis shows a complicated migrants' situation that can't be reduced to an integration/exclusion dialectic. GASTAUT, Y. (2004). "L'intégration par le sport, réalités et illusions". Cahiers français, n°320, Paris : La Documentation française, pp. 58-63. NOIRIEL, G. (1988). #### **PHYSICAL PRACTICE AT LOW INTENSITY AND ANTIOXIDANTS STATUS IN ELDERLY PEOPLE**

Bouزيد, M.A.1, Fabre, C.1

*University Lille 2*

Physical practice at low intensity and antioxidants status in elderly people Bouزيد, M-A.1 Fabre, C.1 1: Université de Lille 2, EA-4488: Activité Physique, Muscle Santé, France Introduction There is an imbalance between oxidants/antioxidants with age in favor of oxidants. Moderate or high chronic exercise can reverse this phenomenon. However the majority of elderly people prefer practice low intensity training exercise like gym maintenance. The aim of this study was to demonstrate the effects of low intensity training on both resting and exercise-induced antioxidant status in two groups: active vs sedentary subjects. Methods 10 active subjects whose practice gym maintenance at least since 2 years (Age:  $68.1 \pm 6.6$  years; High:  $1.64 \pm 0.08$  m; Weight:  $68.4 \pm 6.4$  Kg) and 10 sedentary subjects (Age:  $65.1 \pm 3.5$  years; High:  $1.62 \pm 0.15$  m; Weight:  $71.8 \pm 18.6$  Kg) performed an incremental exercise test on cyclo-ergometer. Blood samples were taken, by an intravenous catheter, at rest and at 20 minutes of recovery. The measured parameters were superoxide dismutase (SOD), glutathione peroxidase (GPX), glutathione reductase (GR),  $\alpha$ -tocopherol, and ascorbic acid. Results At rest, active subjects had higher value of SOD (+9,8%) compared to the sedentary subjects ( $p < 0.05$ ). At the recovery, plasma concentrations GR and GPX increased significantly above resting values for both the two groups ( $p < 0.01$ ). A significant increase at the recovery (+10%) was observed on  $\alpha$ -Tocopherol level only for the active group ( $p < 0.05$ ). Discussion Our data showed that active subjects present higher levels on some antioxidants at rest and at the recovery compared to the sedentary group. Many studies reported that physical training improves body's ability to fight against the deleterious effects of free radicals by increasing the effectiveness of the antioxidant system. Cabrera et al [1] demonstrated that reactive oxygen species (ROS) produced during physical training play an important role in the regulation of gene antioxidant expression. The increase of rate of these species produced during exercise activates MAPKs. This in turn activates the NF- $\kappa$ B pathway and consequently the expression of antioxidant enzymes associated with defense against ROS. References [1] Gomez-Cabrera M, Domenech E, Viña J. Moderate exercise is an antioxidant: Upregulation of antioxidant genes by training. Free Rad Bio & Med (2008) 126–131

## ASSESSMENT OF CARDIORESPIRATORY FITNESS IN EPIDEMIOLOGICAL STUDIES – RECOMMENDING STEP TEST OR CYCLING ERGOMETRY?

Trampisch, U.1, Winzen, M.2, Jensen, K.2, Franke, J.3, Platen, P.2

(1+2) Ruhr-University Bochum, (3) University of Saarland

**Introduction** Physical activity and cardiorespiratory fitness (CRF) are both inversely associated to e.g. risk of mortality, type 2 diabetes and coronary heart disease. The effect of CRF itself remains significant even after adjusting for physical activity. Consequently, CRF should be assessed in addition to physical activity as main exposure variable in epidemiological studies. This underlines the need for a valid and precise assessment of physical fitness to avoid the introduction of bias. The gold standard to assess CRF is a standardized maximal treadmill exercise test with direct measurement of maximal oxygen uptake (VO<sub>2</sub>max). But conducting this test for the entire population in epidemiological studies is seldom feasible. The applicability of conducting exercise tests under submaximal conditions is greater. Submaximal tests such as step test or cycling ergometry allow the prediction of VO<sub>2</sub>max. Unfortunately, little is known if these submaximal tests reflect the actual individual's fitness. The aim of the study was to 1) analyze the validity of two submaximal CRF tests, step test and cycling ergometer test, within a cohort of adults and 2) recommend either step test or cycling ergometer test for further application within epidemiological studies. **Methods** Participants were 24 women and 27 men, age 22–67 yr. VO<sub>2</sub>max was assessed by a maximal treadmill exercise test following the modified Bruce protocol. Results served as gold standard for the assessment of criterion validity of the submaximal tests. Step test was performed following the protocol of the modified Canadian Aerobic Fitness Test with slight modifications. Cycle ergometry was performed following the standardized WHO protocol. VO<sub>2</sub>max was predicted for both submaximal tests by regression equations. VO<sub>2</sub>max was correlated with the predicted VO<sub>2</sub>max obtained from step test and cycling ergometry by Intra-Class-Correlation (two-way mixed, consistency). **Results** Directly measured VO<sub>2</sub>max during treadmill test (reference) and predicted VO<sub>2</sub>max from step test were associated with ICC=0.78 (95%CI: 0.63; 0.87), and from cycling ergometry with ICC=0.79 (95%CI: 0.65; 0.87). Bland-Altman Plots did not show any systematic bias. **Discussion** Predicted VO<sub>2</sub>max of submaximal CRF tests, step test and cycling ergometry, showed both comparatively high association to the gold standard. Cycling ergometry turned out to be more feasible and standardisable for participants and study personnel compared to step test during examination. In order to assess CRF in epidemiological studies, we recommend submaximal cycling ergometer test.

## HIGH INTENSITY INTERVAL TRAINING DECREASES MYOCARDIAL GLUCOSE UPTAKE

Eskelinen, J.J.1, Hannukainen, J.1, Savolainen, A.1, Heinonen, I.1, Virtanen, K.1, Kapanen, J.3, Nuutila, P.1, Knutti, J.1, Kalliokoski, K.1

University of Turku

**Introduction** Aerobic exercise training (AET) induces eccentric cardiac hypertrophy with improved contractile function. These changes are associated with changes in cardiac metabolism towards increased glucose utilization and reduced fat utilization. Recent studies suggest that anaerobic high-intensity interval training (HIT) may provide the same health-enhancing effects as AET. However, it is largely unknown what kind of changes HIT induces in cardiac metabolism and function. Thus, the purpose of the present study was to investigate the effects of HIT on myocardial glucose and fatty acid uptake (GU and FFAU) using positron emission tomography (PET) and cardiac structure and function using magnetic resonance imaging (MRI). **Methods** Eighteen healthy sedentary middle-aged men were recruited into the study. They were randomly divided into HIT group (n=9) and AET group (n=9). Within two weeks, the subjects in HIT group finished six training sessions each consisting of 4 to 6 times 30-seconds "all out" sprints (Wingate-type) with 4 min rest between sprints. Correspondingly the subjects in AET group did six training sessions consisting of 40-60 min of cycling at the intensity of 60% of max workload in VO<sub>2</sub>max -test. Myocardial GU and FFAU were measured using PET and <sup>18</sup>F-FDG and <sup>18</sup>F-FTHA tracers before and after the exercise intervention. Structural and functional changes in heart were measured using MRI on second day after the last training session. VO<sub>2</sub>max-test until volitional exhaustion was performed before and after the last training session. **Results** Measurements and data analyses are still partly ongoing, but all the subjects in HIT group have completed the study. HIT enhanced VO<sub>2</sub>max by 5% (from 33.9 ± 3.8 ml/kg/min to 35.5 ± 3.7 ml/kg/min, p = 0.019) and the maximal workload by 8% (224 ± 31 W to 241 ± 31 W, p = 0.010) in the VO<sub>2</sub>max-test. Myocardial GU during euglycemic hyperinsulinemic clamp decreased in HIT group by 22% (34.9 ± 10.0 μmol/100 g/min to 27.3 ± 11.1 μmol/100 g/min, n = 7, p = 0.041), while whole-body glucose uptake increased non-significantly by 11% (p = 0.21). Myocardial FFAU and cardiac functional and structural data for both groups are under analysis. **Discussion** This partly incomplete data suggests that HIT induces different changes in cardiac metabolism (decreased glucose uptake) than previously reported for AET. Interestingly this is similar change as seen in heart failure patients and may suggest that extreme HIT training is not necessarily acutely so healthy for heart of sedentary middle-aged men without good preparation with increasing exercise intensities over longer period of time.

## THE MODERN RUGBY PLAYER: ARE WE BREEDING GIANTS AND WHAT ARE THE CONSEQUENCES?

De Ridder, J.H., Van den Berg, P.H.

North-West University

**Introduction** Although physique is not the only factor determining success in sport, the modern game of rugby union has become a sport in which the physique of the players is a very important predictor of success. Furthermore the economic, political and social drivers of sporting success will act to select body types which conform more and more to an ideal morphology (Olds, 2001). In rugby, the rates of increase in height and body mass appear to have outstripped secular trends in the population from which these athletes are drawn. Therefore, the aim of this presentation is to answer the question resulting from existing anthropometric data, on whether we are busy breeding giants to play rugby and also to demonstrate the consequences this will have in future. **Methods** The anthropometric data of the two most trendsetting studies on this topic were used. The first study was done on 1420 male rugby players drawn from 21 separate reports and communications between 1905 and 1999 on elite, national and state players (Olds, 2001). The second study was done on the national team of South Africa (Springboks). Data of 1349 rugby players between 1896 and 2004 were mapped (De Ridder & Meyer, 2007). **Results** In the study done by Olds (2001) the results suggest that the rates of increase of body mass and BMI are well above those of the general population of young males. The study by De Ridder & Meyer (2007), suggest major shifts in the body size and shape of the rugby players, with the players as a whole becoming taller and heavier. The data also suggests that the rates of increase of body mass and BMI in the Springboks are well above those of the general population of young males. **Discussion** Recognition of the importance of the demands of the game of rugby on the modern player's physique, has led to a tendency for coaches to favour increasingly taller and heavier players, even for backline positions. Taken into consideration that rugby has one of the highest injury rates when compared to

other team sports, this has the potential to result in a big increase in the incidence of injuries in rugby in the future. Conclusion The final rankings of the rugby teams at the recent 2011 World Cup in New Zealand, demonstrate that large body size is a significant predictor of success in rugby union. Rugby has become a fast-moving and high intensity gladiator sport, featuring big tackles and giant players. This could have a great impact on the game in the future and especially the players are going to feel the effects of injuries later in life. References Olds, T. (2001). The evolution of physique in male rugby union players in the twentieth century. *Journal of Sports Science*, 19, 253-262 De Ridder, J.H. & Meyer, E. (2007). ### **MODERATORS INFLUENCING THE IMPACT OF PHYSICAL EXERCISE ON FATIGUE IN PATIENTS UNDERGOING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION**

Vandenbergh, D.1, Bohus, M.2, Dreger, P.3, Schwerdfeger, R.4, Jäger, D.5, Ulrich, C.M.1, Kühl, R.1, Wiskemann, J.1,5  
1:Preventive Oncology, NCT/DKFZ, Heidelberg2:Central Institute of Mental Health, Mannheim; 3:University Clinic Heidelberg4:German Clinic for Diagnostics, Wiesbaden5:Medical Oncology, NCT Heidelberg

**Introduction** Allo-HSCT is a curative yet demanding treatment option in the field of hemato-oncology. In a recent randomized controlled trial (RCT) our group could show that a partly self-administered exercise program can improve cancer-related fatigue (CRF)(1). For a better understanding of these findings we are going to investigate possible moderators of this effect. **Methods** The data of 80 patients participating in a RCT were analyzed. Experimental group patients performed strength and aerobic exercise intervention and were compared to a social contact control group. The exact study design is described elsewhere (1). CRF was measured using the Multidimensional Fatigue Inventory (MFI) (subscales General Fatigue (GF), Physical Fatigue (PF)) and the fatigue scale of the Profile of Moods States (POMS-F) questionnaire. Moderator analysis is based on the findings of Baron and Kenny (2). Hypothesis As reported by Courneya et al. (3) we hypothesize that the effects of exercise on CRF is moderated by clinically relevant variables. According to their findings we selected five possible moderators: Age, Body Mass Index (BMI), Risk group, conditioning regime, Sense of Coherence (SOC). **Results** For all dependent fatigue variables (GF, PF, POMS-F), group allocation remained the only significant (all  $p < .05$ ) independent variable when controlled for possible moderators (all  $p > .168$ ). Results were different for SOC. Even though it isn't a moderator for any outcome, its contribution to the analysis of CRF's variance is as significant ( $\beta = -.382$ ,  $p < .0005$ ) as it is for group allocation ( $\beta = -.349$ ,  $p = .001$ ). **Discussion** Our results show that the effect of exercise on CRF in allo-HSCT patients is not moderated by clinically relevant variables. No matter what the patient's age, BMI, conditioning regime or risk group is, the intervention seems to be beneficial for all. This is an important finding because it supports the necessity of an accompanying exercise program for all allo-HSCT patients. **References** (1)Wiskemann J., et al., *Blood*. 2011;117:2604-2613 (2)Baron RM., et al., *J Pers Soc Psychol*. 1986;51(6):1173-82 (3)Courneya K., et al., *Cancer Epidemiol Biomarkers Prev*. 2009;18:2600-2607

#### **EFFECT OF COMBINED EXERCISE TRAINING ON PHYSICAL AND METABOLIC FITNESS IN ADULTS WITH INTELLECTUAL DISABILITY: A CONTROLLED TRIAL.**

Calders, P., Elmahgoub, S., de Mettelinge, T.R., Vandenbroeck, C., Dewandele, I., Rombaut, L., Vandeveldel, A., Cambier, D.

*Arteveldehogeschool / Universiteit Gent*

**INTRODUCTION:** The purpose of this study is to evaluate the effect of combined aerobic and strength training on metabolic and physical fitness in adults with intellectual disabilities compared to endurance training and no training. **METHODS:** This study is a controlled trial with patients receiving either combined (COM), endurance (END) or no training (C). Forty-five adults with intellectual disabilities (mean age: 42 (9,2), mean body mass index (BMI): 24 (3,9), mean IQ: 56 (5,6)) were recruited from two centres for intellectual disabilities (Sterrenhuis, Brasschaat and Emiliani, Lokeren, Belgium). Subjects received either combined aerobic and strength exercise training (n=15) or endurance training (n=15) twice a week for 70 minutes per session for 20 weeks or no training (n=15). Groups were matched for age, sex and intellectual disability. Before and after the training period lipid profile (triglycerides, HDL, LDL and total cholesterol), physical fitness (aerobic capacity, muscle strength); blood pressure (resting systolic and diastolic) and body composition (BMI, waist, fat mass and fat free mass) were evaluated. **RESULTS:** Compared to no training, combined exercise training has significant positive effects on total cholesterol levels, aerobic capacity, muscle strength and resting systolic blood pressure, while endurance exercise training has significant effects on aerobic capacity and resting systolic blood pressure. Compared to endurance training, combined exercise training resulted in a significant better evolution of total cholesterol (mean differences: -18 versus -3mg/dl), 1RM upper (+6 versus +1 kg) and lower limb (+25 versus +8kg) and abdominal muscles (+15 versus +1kg), hand grip strength (+9 versus +2kg), muscle fatigue resistance (+11 versus +5sec), sit-to-stand (+5 versus +2/30sec) and systolic blood pressure (-15 versus -10 mmHg). **CONCLUSION:** This study revealed a tendency towards more beneficial effects of combined exercise training in adults with intellectual disability.

#### **EFFECT OF AN EXERCISE INTERVENTION PROGRAM ON BALANCE, FLEXIBILITY AND MUSCLE ENDURANCE OF PERSONS WITH INTELLECTUAL DISABILITY**

Moss, S.J., Beukes, E., Oosthuizen, C.

*North-West University*

**Introduction:** Persons with intellectual disability are more prone to be inactive than the normal population (Fernhall et al., 1996). This increased level of inactivity may be associated with functional capacity decline with a further reduction in activity levels. The aim of this study was to investigate the effect of a physical exercise intervention program on balance, flexibility and muscle endurance in adults with

intellectual disability (ID). Methods: Participants with severe and profound ID ( $n = 33$ ) were recruited for participation in this study. Consent was obtained after the tests were demonstrated to the subjects. Balance (Biodex), flexibility (sit-and-reach test), and muscle endurance (upper body, lower body and abdominal endurance) were determined at baseline and end of the intervention period. A physical exercise intervention program was conducted four days a week for four consecutive weeks for 1 hour. Descriptive statistics (SPSS vers 15.0) were performed to determine the baseline characteristics of the subjects Independent t-tests were performed to determine differences between the males and females with dependent t-tests performed to determine changes from baseline to end for the variables. Results: The females presented with a BMI ( $31.2 \pm 5.1$  kg/m<sup>2</sup>) significantly higher than the males ( $26.6 \pm 6.5$  kg/m<sup>2</sup>). The females however reported higher values than the males for upper body muscle endurance, lower body muscle endurance, abdominal muscle endurance and flexibility. The males reported better total balance than the females. The results of the exercise intervention indicated that the adherence to the intervention was 64%. Improvements in all variables were reported, with a significant improvement in total balance ( $p=0.023$ ). Discussion: Persons with intellectual disabilities have been neglected with regards to participation in physical activity and exercise interventions. Previous research has found that regular exercise reduces risk factors for coronary heart disease in persons with intellectual disability (Moss, 2009). The major finding of this study is that an exercise intervention of four weeks aimed at functional fitness of persons with ID will improve balance, flexibility and muscle endurance. Improvement of functional fitness in persons with ID may improve self sufficiency in persons with ID. References: Fernhall B., Pitetti K.H., Rimmer J., McCubbin J.A., Rintala P., Millar L., et al. ### RELATIONSHIP BETWEEN METABOLIC SYNDROME RISK AND CARDIOVASCULAR FITNESS

Peinado, S., Romero, B., Morencos, E., Peinado, A.B., Butragueno, J., Cupeiro, R., Rojo-Tirado, M.A., Calderon, F.J., Benito, P.J.

*Facultad de Ciencias de la Actividad Física y del Deporte (INEF). Universidad Politécnica de Madrid.*

Introduction There are many epidemiological studies that determine the relationship between metabolic syndrome and cardiorespiratory fitness (1,2). These studies need to be concluded by using randomized controlled clinical trials. The aim of the present study is to determine if there is a correlation between cardiovascular fitness (CVF) and metabolic syndrome risk (MS risk)(3,4) after improving the the VO<sub>2</sub>max in overweight people. Methods Eighty-four overweight people (18–50 years; BMI>25 and <30 kg/m<sup>2</sup>) were randomized to one of the following groups: strength training (S;  $n=19$ ), aerobic training (E;  $n=25$ ), a combined S and E training (SE;  $n=22$ ), 3 times/wk for 24 wk, and diet and physical recommendations group (C;  $n=18$ ). All of them in combination with diet restriction. The measurements took place for all subjects before training at weeks 1 to 2, and after 22 weeks of training in weeks 23 to 24. All groups were evaluated for changes in blood concentrations for lipoprotein-lipids, cardiovascular fitness with an incremental test, body composition and dietary composition. Two-way ANOVA with repeated measures was used to determine differences between pre and post intervention in each training group. The Pearson's correlation coefficients were used to analyze the relationship between cardiovascular fitness and metabolic syndrome risk. The level of significance was set at  $\alpha=0.05$ . Results No significant correlations were found between cardiovascular fitness change and metabolic risk syndrome. S and SE obtained correlations trend toward significance (S:  $r=0.43$ ,  $p=0.06$ ; SE:  $r=0.37$ ,  $p=0.09$ ). Significant improvements in peak oxygen uptake (VO<sub>2</sub>peak) were obtained in all groups S (19%), E (19%), SE (17,76%) and C (19%). MS Risk decreased significantly in S and SE (S: -42,4%, SE: -31,1%,  $p<0,05$ ). Discussion The main finding of the present study was that the groups that improved significantly MS risk obtained correlations trend toward significance with CVF. A randomized controlled clinical trial using a larger sample size would presumably find significant correlations between MS risk and CVF, being able to prove what previous epidemiological studies have evidenced (1,2). ### LIFE QUALITY AND CARDIOVASCULAR RISK FACTORS IN PARTICIPANTS OF WORLD BIKE TOUR SP

Benetti, M., Sierra, A., Gabriel, E., Kiss, M.A.P.D., Cortez, J.A.A., Martini, J.S.C., Bastos, F.C.

*University of Sao Paulo*

Cardiovascular diseases are responsible for the largest amount of deaths resulting of coronary artery disease (CAD) and are the main cause of expenses in medical assistance. About 85-90% of the patients with CAD present many modifiable cardiovascular risk factors represented by hypertension, smoking, hypercholesterolemia, diabetes mellitus, sedentary lifestyle, and obesity, and no modifiable risk factors as advanced age, familiar history of sudden death. There are evidences that the atherosclerotic process begins in childhood and its severity is proportional to the cardiovascular risk factors (CRF) and life quality, with the cardiovascular prevention requiring primary and secondary interventions. The SF 36 questionnaire produces a health functioning profile based on psychometric measures. The components of life quality are divided into eight concepts: physical functioning (PF), role physical (RP), bodily pain (BP), general health (GH), vitality (VT), social functioning (SF), role emotional (RE) and mental health (MH). Thus, the objective of this research was to determine the life quality profile and the frequency of cardiovascular risk factors in participants of a bike ride called World Bike Tour São Paulo, as well as comparing these concepts according to the gender of the individual. Methods: the event had 8000 participants, 1300 of which , 889 male (68.38%) and 411 female (31.62%), aged between 12 and 80 years ( $34.9 \pm 9.9$  years), answered the SF 36 questionnaire, Portuguese version, and 8 questions about cardiovascular risk factors recommended by the American College of Sports Medicine. For the analysis, we established a raw scale (0-100) average and standard deviation (STDEV) for each concept and a frequency for the cardiovascular risk factors. We used t-Student test to compare the groups by gender. Results: average and STDEV for the general (G), men (M) and women (W) group MH – G  $76.74 \pm 15.88$ ; M  $77.36 \pm 15.45$ ; W  $75.37 \pm 16.70$ \* RE – G  $82.13 \pm 31.11$ ; M  $81.92 \pm 30.85$ ; W  $82.56 \pm 31.68$  SF – G  $86.64 \pm 17.05$ ; M  $87.06 \pm 16.75$ ; W  $85.73 \pm 17.65$  VT – G  $71.35 \pm 16.97$ ; M  $72.18 \pm 16.46$ ; W  $69.53 \pm 17.88$ \* GH – G  $81.41 \pm 14.75$ ; M  $80.83 \pm 14.74$ ; W  $82.64 \pm 14.68$ \* BP – G  $80.40 \pm 17.57$ ; M  $80.33 \pm 17.25$ ; W  $80.52 \pm 18.23$  RP – G  $86.15 \pm 25.14$ ; M  $85.54 \pm 25.09$ ; W  $87.46 \pm 25.20$  PF – G  $92.68 \pm 10.98$ ; M  $93.45 \pm 10.15$ ; W  $91 \pm 12.43$ \* Obesity – G 12.77%; M 13.9%; W 10.4% Sedentary lifestyle – G 27.64%; M 28.6%; W 25.5% Diabetes – G 2.7%; M 3%; W 2% Smoking – G 5.48%; M 7.1%; W 5.1% Hypertension – G 9.46%; M 11.1%; W 5.9%\* Hypercholesterolemia – G 14.26%; M 15.8%; W 10.8%\* Advanced Age – G 15.21%; M 19.3%; W 6.4% Familiar history – G 13.15%; M 13.1%; W 13.3% At least one CRF: G 57.7%; M 50.87%; W 50.77% At least one modifiable CRF: G 47.1%; M 49.09%; W 42.68% \* $P<0.05$  Conclusion: The concepts presented a statistical difference between the gender groups for VT, GH and PF, as well as for the risk factors hypertension and hypercholesterolemia; 57.7% of the general group has at least one CRF and 47.1% has at least on modifiable CRF.

## **EIGHT WEEKS OF ENDURANCE TRAINING BASED ON CRITICAL VELOCITY ASSOCIATED WITH GLUTAMINE SUPPLEMENTATION**

Fontana, K.E., Molina, G.E., Kobayashi, L., Rocco, G.F.

*University of Brasilia - UnB*

**Introduction** The individualized prescription of exercise intensity is critical for obtaining satisfactory results in endurance training. Many practitioners of physical activity are associated with the use of glutamine expecting even better aerobic performance. **Purpose:** Analyze the aerobic capacity and body composition of a supervised endurance-training program associated with glutamine supplementation and placebo. **Methods** Twenty-three physically active healthy young male ( $21.8 \pm 2.1$  years) volunteered to the study and underwent an endurance-training program based on critical velocity (CV) that consisted of three weekly sessions during eight weeks. CV was calculated by the slope of the linear regression between the time obtained through running tests of 400 and 2400 m (T400 e T2400). The peak oxygen output (VO<sub>2peak</sub>), oxygen uptake at anaerobic threshold (VO<sub>2AT</sub>) and at respiratory compensation point (VO<sub>2RCP</sub>) were determined by an incremental running treadmill test with breath by breath gas analyze. Blood lactate samples were used to determine the lactate threshold (LT) and the onset of blood lactate accumulation (OBLA). The experimental design was double blind controlled by placebo and the subjects were randomly assigned to two groups receiving either placebo (PLA, n=11) or glutamine (GLN, n=12) supplementation. Each oral supplement was given solved in a liquid sweetened vehicle once a day (0.003 g/kg). The tests were performed in random sequence, with a minimum interval of 48 hours between them. The training effect was compared by t-student test and the supplementation effect by ANOVA. **Results** Independently of supplementation, after the eight-week endurance training program there were differences on all the variables except VO<sub>2RCP</sub>, VOBLA. When the training effect was observed on supplemented groups (PLA and GLN), both groups differed on T400, T2400, VO<sub>2AT</sub>, CV, VAT and no differences were found on body mass, VO<sub>2RCP</sub>, VLT and VOBLA. Percent body fat, VO<sub>2peak</sub> and VRCP differed only in the PLA group. The VO<sub>2peak</sub> differed between PLA and GLN ( $p=0.027$ ) with higher values on the PLA group. CV was higher than other velocities measured in the study (VAT, VLT, VOBLA, VRCP). **Conclusions:** The critical velocity can be used as an aerobic performance measure, however does not replace the anaerobic threshold measured by direct methods. Moreover, glutamine supplementation did not show an ergogenic effect on aerobic output or on body composition in physically active young male after an eight-week endurance-training program.

## **EFFECTS OF A MODERATE ENDURANCE AND RESISTANCE TRAINING IN GERMAN FIREMEN**

Jaitner, T., Kusch, A.

*TU Dortmund University, University of Kaiserslautern*

**Introduction** Fire emergencies impose high levels of physical stress in hazardous environments (Myhre et al., 1997). A high physical fitness is mandatory for firemen (Williford et al., 1999), and especially endurance and resistance training should be integrated in their daily working routines. Therefore, a specific training program was designed with two restrictions. First, the working capability should not be limited considerably due to fatigue. Secondly, standard exercise tests could not be applied because reservations on physiological testing were reported for different reasons (e.g. restrictions in career opportunities or occupational aptitude). **Methods** 77 firemen participated in a 10 week training intervention with at least two sessions a week. The Borg scale was used to adjust the training load individually. For the endurance training, a standardized 10 min indoor cycling routine was repeated every two weeks, and heart rate, cadence and pedal resistance forces were measured. Progress in resistance training was monitored by dumbbell weight. Based on training frequency, subjects were posthoc divided into a regular training group (RT, >60% of all trainings sessions) and a non regular training group (NRT). ANOVA and non-parametric tests were applied to analyze the training effects of both groups. **Results** During the cycling routines subjects cycled at appr. 81 rpm and reached a heart rate of appr. 142 bps. For the RT group, pedal resistance forces ranged from 176N to 239N in mean and showed a linear increase over the whole intervention phase ( $p \leq 0.01$ ). Heart rate and cadence did not differ significantly. For the NRT group no significant changes in any parameter could be stated. According pedal forces, ANOVA revealed a significant effect of group and time ( $p=0.00$ ,  $F= 15.503$ ). Subjects of the RT groups also increased the weight of the dumbbell from beginning till end of the resistance training by 5,2 kg in mean ( $p \leq 0.01$ ). The NRT group showed a slight but not significant difference in training load. **Discussion** Firemen who trained regularly were afterwards able to master a higher training load while the perceived exertion as well as the corresponding physiological parameters remained constant. Although only moderate training loads were applied, the endurance and resistance training seems to substantially enhance their physical fitness. For specific professions as fire fighting such training regimes might be promising to keep the balance between working capabilities and demands on physical fitness and training during working time. **References** Myhre, L. #### **POSTPRANDIAL MYOFIBRILLAR PROTEIN SYNTHESIS RATES OF RESTED MUSCLE ARE MAXIMALLY STIMULATED BY INGESTING 20 GRAMS OF WHEY PROTEIN.**

Witard, O., Jackman, S., Breen, L., Smith, K., Selby, A., Tipton, K.

*University of Stirling*

**Introduction:** The dose-response of muscle protein synthesis (MPS) to the provision of free crystalline essential amino acids has been well documented in rested muscle of untrained individuals in the fasted state; however data examining the dose-response to more practical, intact sources of protein remain scarce. We aimed to characterise the dose-response relationship between postprandial myofibrillar-MPS

rates and the single-bolus ingestion of a range (0-40g) of intact whey protein (WP) doses in rested muscle of resistance-trained males. Methods: In this parallel research design, single-blind study, 48 resistance-trained males (age: 21±2y; body mass: 83±11kg; >12mo resistance training) were assigned to one of four groups, ingesting either 0 (WP-0), 10 (WP-10), 20 (WP-20) or 40 (WP-40) g of whey protein isolate ~3h 45min after consuming a standardised energy-rich (30kJ·kg<sup>-1</sup> BW), high protein (30 %Energy) breakfast. The fractional synthesis rate (FSR) of myofibrillar protein, and rates of whole body phenylalanine oxidation and urea production were determined over a 4h post-drink period by combining the continuous isotopic tracer infusion of L-[ring-<sup>13</sup>C<sub>6</sub>]-phenylalanine and <sup>15</sup>N<sub>2</sub> urea with the collection of muscle biopsies. Results: The AUC over 4h post-drink for concentrations of amino acids, insulin and urea increased in a curvilinear manner relative to the dose of ingested WP (40>20>10>0g, P<0.05). Myofibrillar FSR was ~25% higher in WP-10 (0.040±0.002 %·h<sup>-1</sup>) vs. WP-0 (0.032±0.003 %·h<sup>-1</sup>, P<0.05) and a further ~30% higher in WP-20 (0.052±0.005 %·h<sup>-1</sup>, P<0.05). However, no difference in myofibrillar FSR was observed between WP-20 and WP-40 (0.051±0.003 %·h<sup>-1</sup>, P>0.05). The response of MPS to WP ingestion, expressed as change in FSR relative to 0g / mean post-drink amino acid concentration was ~50% lower in WP-40 (0.000073±0.000011 %/nmol/mL) vs. WP-20 (0.000094±0.000004 %/nmol/mL, P<0.05). Conversely, the AUC for whole body phenylalanine oxidation and urea production rates in WP-40 (4.99±1.17 μmol phenylalanine×4h and 232.1±47.7 μmol urea×4h, respectively) was greater than WP-20 (0.12±4.14 μmol phenylalanine×4 h and 57.4±61.8 μmol urea×4 h, respectively, P<0.05). Conclusions: These data are the first to demonstrate that myofibrillar-MPS rates are dose-dependent on ingested intact protein, reaching a maximal stimulation with the ingestion of 20g of whey protein in rested muscle of trained men. Thus, in the postprandial state, ingesting a dose of intact whey protein isolate in excess of 20 g elicits no further stimulation of MPS and instead stimulates non-anabolic processes such as amino acid oxidation. Funded by GlaxoSmithKline Nutrition, Brentford, UK.

### IS THERE A CUMULATIVE EFFECT OF GRAPE POLYPHENOL SUPPLEMENTATION ASSOCIATED WITH TRAINING ON RATS METABOLISM FEED WITH HIGH FAT DIET ?

Lambert, K., Thomas, C., Cassan, C., Hokayem, M., Fabre, O., Mercier, J., Avignon, A.

*INSERM*

Introduction Polyphenols have been associated with improvement of insulin sensitivity both in rodent and obese human. Exercise training is also a well known therapeutic for insulin resistance. The purpose of our study was to investigate the association of grape polyphenol (PP) with exercise training on the mechanisms of insulin resistance in high fat diet fed rats. Methods 40 male Sprague-Dawley rats were used. During 4 weeks they were fed ad libitum with a high fat diet (HFD) (58%kcal from fat, D12330 Research Diet). Then rats continued the HFD for 8 weeks but they were included in one of 4 groups of 10 rats: HF rats with only the diet, PP rats with a supplementation of PP in drinking water (50mg/g body weight), EXO rats submitted to exercise training on treadmill (1h/day; 5days/week; 10% slope at 30m/min) and EXO+PP rats with exercise training and PP supplementation. Before randomization, all rats performed a maximal velocity test which was reproduced at the end of the study. Glucose tolerance tests were performed at rats' arrival, after the 4 weeks of HFD and after the 8 weeks of treatments. Results Compared to HF rats, exercised rats presented a significant decrease in body weight associated with a decrease in adiposity. However, there was no effect of PP on these parameters (no difference between HF and PP as EXO and EXO+PP) although EXO+PP rats presented the smaller values. Training induced a significant increase in maximal velocity compared to basal values without a better improvement in EXO+PP compared to EXO. On insulin sensitivity, HF rats presented a higher glycemia compared to trained rats with a significant increase at 90 minutes after glucose injection. Moreover, hepatic glycogen content was significantly increased in EXO+PP compared to HF. Discussion At this time of analysis, training is able to counteract the deleterious effect of a high fat diet with a small benefit of grape polyphenol supplementation on these alterations.

### DIETARY SUPPLEMENT USE, IMPACT ON MICRONUTRIENT INTAKE OF YOUNG GERMAN ATHLETES

Braun, H., Koehler, K., Geyer, H., Mester, J., Thevis, M., Schaenzer, W.

*German Sport University Cologne*

Introduction It is widely accepted, that the use of Dietary Supplements (DS) does not compensate for an inadequate diet and DS use in young athletes should be discouraged (IOC Statement 2011). In contrast studies have shown a high prevalence of DS use in young athletes (Braun et al. 2009). In most studies, the prevalence of use was assessed, but little is known about dosage and nutrient intake from DS. Therefore, the aim of this study is to evaluate dietary intake, DS use and its impact on total nutrient intake of young athletes. Methods & Subjects Between April and May 2011, 27 young athletes (age 13-18y) reported their diet using a validated 7-d food and activity record (Koehler et al. 2010). Energy intake and micronutrient intake was estimated based on the German food database (BLS II.3) using Ebispro Software. Athletes were asked to name all DS (e.g. company name, dosage pattern, frequency of use) used within the 7 days of food recording. Each DS was included into the food database to evaluate the diet with and without DS use. Results We found 12 athletes (44%) using 16 different DS (15x vitamins and/or minerals, 1x protein powder enriched with vitamins/minerals). None of these athletes had any experience with individual nutrition counseling so far. Assuming that dietary micronutrient intake should be 100% RDA, this level was reached by all athletes only for copper and vitamin K. At least half of the group did not reach the RDA for vitamin D (n=11 athletes), folic acid (n=11), iron, vitamin B12, pantothenic acid, and vitamin A (n=6 each). Micronutrient intake was improved above 100% RDA by DS use only for vitamin D (n=2), vitamin C (n=1) and iron (n=3). Furthermore, DS use increased micronutrient intake towards tolerable upper intake levels for iron (n=3), magnesium (n=3), zink (n=2), and vitamin B6 (n=1). Discussion In the present study, dietary intake of young athletes did not meet the RDA for selected micronutrients. Supplementation with vitamins and minerals did increase micronutrient intake (> 100% RDA) only for few athletes and nutrients. Some athletes took micronutrients leading to intakes higher than the suggested upper intake levels. Based on these preliminary data, the use of DS did not enhance micronutrient intake in young athletes substantially. Therefore, we suggest that young athletes need more information on optimizing their diet, but also more information on a wise use of dietary supplements. ### PROTEIN INGESTION PRIOR TO SLEEP IMPROVES POST-EXERCISE OVERNIGHT RECOVERY

Res, P.T.1, Groen, B.1, Pennings, B.1, Beelen, M.1, Wallis, G.A.2, Gijsen, A.P.3, Senden, J.M.G.3, Van Loon, L.J.C.1,3  
 1,3 Maastricht University, 2 GlaxoSmithKline Nutrition, UK

**Introduction** The role of nutrition in modulating post-exercise overnight recovery remains to be elucidated. We assessed the impact of protein ingestion immediately prior to sleep on digestion and absorption kinetics and protein metabolism during overnight recovery from a single bout of resistance type exercise. **Methods** 16 healthy young males performed a single bout of resistance type exercise in the evening (20:00 h) after a full day of dietary standardization. All subjects were provided with appropriate recovery nutrition (20 g protein, 60 g carbohydrate) immediately after exercise (21:00 h). Thereafter, 30 min prior to sleep (23:30 h) subjects ingested a beverage with (PRO) or without (PLA) 40 g specifically produced intrinsically [<sup>1-13</sup>C]phenylalanine labeled casein protein. Continuous intravenous infusions with [ring-2H5]phenylalanine and [ring-2H2]tyrosine were applied with blood and muscle samples collected to assess protein digestion and absorption kinetics, whole-body protein balance and mixed muscle protein synthesis rates throughout the night (7.5 h). **Results** During sleep casein protein was effectively digested and absorbed resulting in a rapid rise in circulating amino acid levels which were sustained throughout the remainder of the night. Protein ingestion prior to sleep increased whole-body protein synthesis rates (311±8 vs 246±9 μmol/kg/7.5 h) and improved net protein balance (61±5 vs -11±6 μmol/kg/7.5 h) in the PRO vs PLA experiment, respectively; P<0.01). Mixed muscle protein synthesis rates were ~22% higher in the PRO vs PLA experiment, which reached borderline significance (0.059±0.005 vs 0.048±0.004 %/h; P=0.05). **Conclusion** This is the first study to show that protein ingested immediately prior to sleep is effectively digested and absorbed, thereby stimulating muscle protein synthesis and improving whole-body protein balance during post-exercise, overnight recovery. Protein ingestion before sleep allows athletes to optimize recovery from resistance type exercise.

### HYDRATION STATUS OF FEMALE BASKETBALL PLAYERS BEFORE AND DURING TRAINING

Mertens, E., Aerenhouts, D., Deforche, B., Clarys, P.  
 Vrije Universiteit Brussel

**Introduction** Data on hydration status of female basketball players and basketball performance are scarce. Dehydration has negative consequences on health and sports performance. In this study we assessed the hydration status of female basketball players. The aim of the present study was to evaluate the pre-training hydration status and to study the influence of the pre-training hydration status on training intensity. **Methods** All 20 female basketball players (age 18,2 ± 3,8, height 167,8 ± 6,4) of a local competitive basketball club participated in this study. Urine specific gravity (PAL-10S refractometer) as an indicator of hydration status was measured before training. Body mass was measured before and after the training session in combination with fluid intake (assessed by weighing a personalized bottle of water before and after training) was used to calculate sweat loss. During training all players had to wear a SenseWear Armband, sampling at the highest rate (1/s), to estimate number of steps and total intensity. **Results** Pre-training urine specific gravity ranged from 1.004 to 1.027 g/ml. Eight out of 20 players started training dehydrated. The mean (± SD) sweat loss during training amounted to 655,4 ± 249,7 ml/h, and mean fluid intake was 446,9 ± 168,6 ml/h. There was a significant correlation between sweat loss and number of steps (6121,9 ± 610,1) during training (r=0.577, p=0.008), but no correlation between sweat loss and intensity (r=0.114, p=0.632). There was no significant difference between pre-training well hydrated and pre-training dehydrated players in number of steps (p=0.499) and intensity (p=0.631). **Discussion** It can be concluded the 40% of the players started the training dehydrated. The hydration status was not related with training intensity, as measured by number of steps and intensity.

### IMPACT OF A HIGH-DAIRY CALCIUM BREAKFAST ON SUBSTRATE METABOLISM DURING EXERCISE AND PERCEPTUAL APPETITE SENSATIONS

Gonzalez, J.T., Rumbold, P.L., Stevenson, E.J.  
 Northumbria University

The aim of this study was to assess the effects of a breakfast, high in dairy calcium on substrate oxidation and appetite regulation before and during exercise. **Methods** Nine recreationally active males completed two trials in a randomised crossover design separated by 7 d. In the control trial (CON), breakfast consisted of skimmed milk and cereal to provide 1.5 g•kg body mass<sup>-1</sup> carbohydrate and 3 mg•kg body mass<sup>-1</sup> of calcium. In the high-calcium trial (CAL) a calcium supplement, extracted from milk, was used to increase the calcium content to 9 mg•kg body mass<sup>-1</sup>. A 60 min treadmill run was performed at 60% VO<sub>2</sub>peak, 180 min after consumption of breakfast. Indirect calorimetry was used to estimate energy expenditure and substrate metabolism, and visual analogue scales were administered to determine subjective appetite sensations. Blood samples were taken in the fasted state, throughout the postprandial period following breakfast, and during and after exercise to determine non-esterified fatty acid (NEFA) concentrations. **Results** The total amount of lipid oxidised during exercise was not significantly different between trials (CON: 30.5 ± 7.6 g, CAL: 31.1 ± 9.2 g; P>0.05). The amount of carbohydrate oxidised during exercise was also similar between trials (CON: 100.4 ± 24 g, CAL: 99.7 ± 27.3 g; P>0.05), hence energy expenditure was not significantly different (P>0.05). There was no difference in serum NEFA concentrations at any timepoint (P>0.05). The time-averaged area under the curve for feelings of fullness was greater during the 180 min following the CAL breakfast (63 ± 17 mm) compared to the CON breakfast (59 ± 20 mm; P<0.05) breakfast, yet there was no significant difference in any of the other appetite ratings (hunger, satisfaction and prospective consumption, all P>0.05). **Discussion** Substrate metabolism was unaffected by the dairy calcium content of the pre-exercise meal. This supports previous findings in trained female runners (White et al., 2006) but conflicts with more recent studies in sedentary populations (Ping-Delfos and Soares, 2011). Differences in meal composition may play a role and warrant further investigation. This study also demonstrates that increasing the dairy calcium content of a meal can increase postprandial fullness. **References** White KM, Lyle RM, Flynn MG, Teegarden D, Donkin S (2006). *Int J Sport Nutr Exerc Metab*, 16, 565-579. **IS-SH02 It's Natural to Play: Promoting Psychomotor Development in Challenging Environments****WHAT CAN WE LEARN FROM THE STRIP BABY PROJECT?**

Sääkslahti, A.1

*1: University of Jyväskylä, 2: University of Turku*

Introduction Physical activity (PA) and sedentary behavior has been tracked from early childhood. To ensure a healthy lifestyle and support children's overall development, the Specific Turku Coronary Risk Factor Intervention Project (STRIP baby) was launched in 1990 with 1,062 seven-month-old children and their families enlisted. Methods From 1994 onwards, three- to four-year-old children (N = 228) were randomly selected and divided into the PA intervention (n = 116) and control (n = 112) groups. The four-year intervention program was based on Bandura's Social-Cognitive theory (1986), containing an intensive session (duration 1 h) with the parents once a year, printed material twice a year and a PA demonstration session by a physical education teacher once a year. Public media was also used for intervention purposes. Physical activity, motor skills, growth and health parameters were measured. Statistical analysis was performed with repeated measures of ANOVA and the MIXED procedure. Results The children in the PA intervention group spent more time playing outdoors and their play in the high-activity category increased with age, whereas no change occurred in the control group. The girls in the PA intervention group had weaker perceptual motor skills, but performed better in locomotor skills, than the girls in the control group. The boys in the PA intervention group had better perceptual motor skills and locomotor skills than the boys in the control group. Amongst all the girls, low-activity play was related to a higher BMI. At the age of six, high activity play was related to lower serum total cholesterol and triglyceride levels, and positively correlated to the HDL/total cholesterol ratio. Amongst all the boys, positive correlations between playing outdoors and both HDL levels and HDL/total cholesterol ratios were found at the age of four. Conclusions Family-based intervention showed that it was possible to affect positively the physical activity and motor skills of preschool-age children, as well as to promote health by increasing physical activity. For further interventions we suggest that the PA intervention targeted at young children's parents should help to activate parents, be voluntary, be based on a positive motivational climate; and should offer PA knowledge. In addition the PA intervention should include concrete PA models, consider individual differences, take into account possible gender preferences, and utilize public material and information in order to encourage the use of neighborhood play areas as well as the use of professional educators. **THREATS AND CHALLENGES OF NATURAL PLAY AMONG CHILDREN**

De Martelaer, K.

*Vrije Universiteit Brussel*

One of the three sessions in the invited workshop of G. Stratton: It's natural to play: Promoting psychomotor development in challenging environments In this presentation an overview will be given of actual threats and challenges among children during physical active natural play. International trends of family characteristics, outdoor play, environmental and didactical aspects will be presented. Based on own research data concerning movement skills of young children and the influences of home and school, the focus will be on possibilities for further research in the domain of natural play and psychomotor development of children.

**PHYSICALLY ACTIVE PLAY AND POLY-VOCALITY: PHYSICALLY ACTIVE PLAY INTERVENTIONS.**

Stratton, G., O' Dwyer, M., Taylor, S., Rosenberg, M.

*Swansea University*

This presentation will review the range of research in physically active play undertaken by the REACH group. We have redesigned school playgrounds and completed increasingly complex studies with parents and pre-school teachers and used multiple methodologies to demonstrate significant increases in physical activity and changes in pro-social behaviour that was maintained for 12 months. We have also found differential effects for girls and boys and for normal and overweight children. Further research work migrated into natural environments and we have found positive effects on active play when environmental and educational changes were implemented. Our collaborators in North Wales and West Australia have also developed interventions using affordable recycled equipment and social marketing. Their findings will also be reviewed. The journey through this research will include discussion using different research approaches, policies paradigms and principles.

## IS-BN05 Musculoskeletal Modelling for Problem Solving in Rehabilitation (\*)

**MAKING THE LINKS BETWEEN REHABILITATION AND MUSCULOSKELETAL MODELLING: REQUIREMENTS AND TOOLS**

Van Sint Jan, S.

*Université Libre de Bruxelles*

MAKING THE LINKS BETWEEN REHABILITATION AND MUSCULOSKELETAL MODELLING: REQUIREMENTS AND TOOLS Van Sint Jan, S<sup>1</sup>; Bontempi, G<sup>2</sup>; Van Summeren, S<sup>3</sup>. 1Lab. Anatomy, Biomechanics & Organogenesis (LABO). 2Machine Learning Group. 3Lab. Web and Information Technology (CoDE-WIT). Univ. Libre de Bruxelles, Belgium. Introduction Musculoskeletal modelling (MSM) showed major recent theoretical progresses including optimisation and prediction algorithms, and improved data visualisation. Despite these efforts, practical applications in daily Clinics remain rare because of a lack of extensive clinical validation. Integration of MSM tools to better understand complex pathologies also remains a challenge. This presentation reports the first results of a running effort of integration of MSM tools within a larger pipeline for the data handling of patients performed by the ICT4Rehab project ([www.ict4rehab.org](http://www.ict4rehab.org)). Methods The project is focuses on the development of an integrated system organised around several tools: - database allowing sharing of clinical data (anamnesis, clinical testing and functional), - biomechanical analysis (including MSM), - and data mining. As such, MSM is not the unique tool available from the overall ICT4Rehab pipeline. Indeed, while it is clear that MSM is useful as a supplementary source of patient's physiological parameters next to the "usual" clinical testing, it however cannot answer all questions arising from the handling of severe disorders such as spasticity. The above-described pipeline is under development in collaboration with several clinical centres that are closely involved in the project development thanks to an active communication channel. From an MSM perspective, models integrated in the analysis pipeline could appear simplistic compared to the literature in the MSM field. The ICT4Rehab models are limited to the study of joint amplitude, muscle excursion and muscle moment arms. On the other hand, such MSM modelling is easily understood by clinicians, and can be validated, for example using medical imaging. Model customization is also of importance. Results Although the project has recently started, the first results are promising at various levels. Even if it is not fully deployed yet, the entire clinical pipeline is now fully defined: - clinical data are stored in the database; - clinical data can be analyzed using modelling tools and biomechanical analysis; - and results are further analyzed in advanced data mining modules. Discussion In contrast to an isolated MSM tool that gives numerous, but often not properly validated results, we believe that the integrated approach taken by the ICT4Rehab project, focusing on the integration of MSM methods with complementary clinical tools, will be more attractive for clinicians. The project has therefore adopted as its main strategy to respect the daily work habits of clinicians by integrating their professional habits in a new work pipeline that is complemented by new and more advanced analysis tools. We believe that this is crucial for clinical acceptance.

**MUSCULOSKELETAL MODELS FOR GAIT ANALYSIS: WALKING THROUGH LIFE**

Kersting, U.

*Aalborg University*

Introduction Studies have compared walking gait of children to that of adults or between certain age groups, i.e., elderly versus younger adults (e.g., Bleyenheuff and Detrembleur, 2012). Comprehensive reference data bases are hampered by variable of marker sets and inter-tester variability being an inherent issue (McGinley et al., 2009). The purpose of this study was to provide a consistent database of healthy controls from childhood to the elderly. Secondly, results obtained from an established gait model were compared to an individually scaled musculoskeletal model. Methods A total of 195 subjects from 6 to 86 years were recruited. Gait was recorded by a Vicon system (612, 8 cameras, Vicon, Oxford, UK) in a gait laboratory. Six trials at preferred walking speed were recorded. The Vicon gait marker protocol was used and processed using the plug-in gait (PIG). Data were exported and processed in the AnyBody Modelling System (AnyBodyTech, Aalborg, DK) using an optimization and scaling algorithm. Age groups were compared by ANOVA and correlations with age and selected anthropometric parameters were performed. Results between models were compared by paired t-tests. Results No age dependency of selected kinematic parameters such as knee angle at TD or the amount of knee flexion during stance was found. Walking velocity did only vary minimally with age while cadence was increased in children compared to all adult age groups. Across all subjects, a significant correlation of leg length and cadence was observed. Integrated ankle joint power decreased with age while hip work increased with age. Model comparisons revealed off-sets between discrete kinematic parameters while ranges of motion were comparable. This also applies to net joint kinetic parameters. Obviously, individual muscle forces or work were not extracted from the PIG calculations. Discussion In summary, gait velocity was highly consistent despite the fact that subject chose their preferred walking speed. In healthy subjects, gait kinematics remain reasonably constant over a large age range. There are, however shifts in total joint work as described by Karamanidis & Arampatzis (2005). Musculoskeletal models allow for a more detailed analysis of changes in particular muscle groups which related well to previous results. It is therefore expected that the inclusion of individualized musculoskeletal models into standard clinical gait analysis will allow for enhanced understanding of alterations in gait function. **TECHNICAL ASPECTS IN SPEED SKATING**

Van der Helm, F.

*Delft University of Technology*

Speed skating requires high technical skills in order to transfer the power generated by the muscles to the propulsion of the skater. Many examples exists of skaters able to generate more power though resulting in less forward speed. Van Ingen Schenau and de Koning have developed a power balance model to analyse the generation and dissipation of power during skating [1,2]. Air friction and ice friction are the major causes of power loss. The skater generates power by shortening muscles, resulting in joint rotations of the lower limb, and finally in a translation of the Center-of-Mass with respect to the push-off at the skate. The push-off is necessarily side-wards from the

skate, though must have a forward component for positive propulsion. There is quite some loss of power in the left and right acceleration of the skater's mass, which does not benefit the forward motion in itself. The skater makes an S-curve over the ice, to go from one side of the lane to the other, necessary to allow a full push-off to generate the required power by stretching the leg. All these elements in the skater's motion are related to each other in the power generation. The goal of this study is to understand the relations between the motions, power generation and power losses. Accurate measurements have been performed to record the skater's motion over the ice, using the LPM system at the Thialf Ice Rink in Heerenveen. Also the forces involved have been recorded. We present a simple 2 dimensional model of speed skating on the straights which mimics observed kinematic and force data. The primary features of the model are: the skater is modeled as three point masses, only motions in the horizontal plane are considered, air drag forces which are quadratic in the forward velocity and coulomb type ice friction forces at the skates are included, and idealized contact of the skate on the ice is modeled by a holonomic constraint in the vertical direction and a nonholonomic constraint in the lateral direction. Using the measured leg extension coordination (kinematic data) we are able to predict reasonably well the forward speed, even if we do not fit for that. In the future, we plan to use the model for finding coordination patterns which results in optimal performance. [1] De Koning JJ, de Groot G, and van Ingen Schenau GJ. A power equation for the sprint in speed skating. *J Biomech* 25: 573 - 580, 1992 [2] de Koning JJ; Foster C; Lampen J; et al. Experimental evaluation of the power balance model of speed skating. *J. ##### DOWNHILL TURN TECHNIQUES AND PERFORMANCE IN CROSS-COUNTRY SKIING: ASSOCIATIONS WITH MECHANICAL AND PHYSICAL PARAMETERS

Bucher, S.1,3, Supej, M.2,3, Sandbakk, Ø.4, Holmberg, H.C.3

(1) Nord-Trøndelag University College, Norway, (2) University of Ljubljana, Slovenia, (3) Mid Sweden University, Sweden, (4) Norwegian University of Science and Technology, Norway

**INTRODUCTION:** Downhill turns in cross-country skiing are performed in widely varying conditions. In order to effectively utilize potential energy and accelerating forces, skiers adapt the entrance velocity, the trajectories throughout the turn and the employment of different techniques. The aim of this study was to characterize the main techniques utilized in downhill turns among elite cross-country skiers and to examine how downhill turn performance is influenced by technique distribution, mechanical parameters and the skiers' maximal power characteristics. **METHODS:** 12 female elite cross-country skiers performed six highly standardized subsequent turns using a freely chosen technique. The subjects were continuously monitored by a high-end real time kinematics GNSS and one camcorder. The measured trajectory was used for calculating total and intersection time, velocity and energy dissipation at each point of observation, and was linked to the use of technique. Additionally, maximal isometric squats and counter-movement jumps were performed to characterize the athletes' maximal strength and power. **RESULTS:** Three techniques with significantly different mechanical patterns were employed by the skiers: side stepping, skidding and ploughing. The typical technique distribution for the best skiers was a short phase of skidding at the beginning of the turn, followed by an early transition to and overall greater proportion of side stepping. An early transition between the decelerating and accelerating phase and high velocity at the transition point were strongly correlated to the performance variables (i.e., time and energy dissipation; all  $p < 0.05$ ). Furthermore, better skiers' turns are related both to higher velocities and shorter trajectories (all  $p < 0.01$ ). Peak force, time to peak force and rate of force development in absolute values were most strongly correlated with performance (all  $p < 0.05$ ). **CONCLUSIONS:** This study identified technique distribution and mechanical parameters linked to better downhill turn performance in cross-country skiing. Better skiers preferred skidding to ploughing and showed an earlier initiation and overall greater use of the side stepping technique. The athletes' absolute maximal power is linked to the ability to ski at a high velocity and with short trajectories throughout.

##### THE POLING THRUST IN SKI SKATING IS ACCOMPLISHED BY HIP AND KNEE FLEXION IN V2 BUT NOT IN V1

Hallén, J., Myklebust, H., Losnegard, T.

Norwegian School of Sport Sciences

**THE POLING THRUST IN SKI SKATING IS ACCOMPLISHED BY HIP AND KNEE FLEXION IN V2 BUT NOT IN V1** Hallén, J., Myklebust, H., Losnegard, T. Norwegian School of Sport Sciences, Norway Introduction Ski skating is a complex cyclic technique where both arms and legs are producing the propulsive forces. The main ski skating techniques are V1 and V2. Smith et al. (2009) showed that the leg/ski thrust in V1 and the arm/poling thrust in V2 contributed most to the propulsion. The present study will evaluate how lowering of the center of mass (COM), contribute to the poling thrust during V1 and V2 skate, evaluated by accelerometry. Methods Fourteen elite senior male cross country skiers ( $VO_{2max}$ : 76.2 (4.8)  $ml \cdot kg^{-1} \cdot min^{-1}$ ) volunteered and were all familiar with rollerski treadmill testing. After a warm up, the skiers did two 1-min trials with V1 and V2 skate at 4° inclination and 3  $m \cdot s^{-1}$ . One tri-axial accelerometer (pluX, Lisbon, Portugal) was mounted directly to the skin at the subject's lower back (hip). Hip displacement was calculated by double integration of the signal. Uni-axial accelerometers were attached to the poles and the ski-boots to detect poles and skis hits and lift-offs. Results The hip vertical displacement was 50% larger in V2 than V1 [0.12 (SD 0.02) vs 0.08 (0.02) m,  $p < 0.05$ ] even if the pattern of acceleration was similar. However, in the horizontal direction (for-aft), the patterns were different between techniques and maximal forward acceleration was 28% larger in V2 than V1 [3.7 (0.4) vs 2.9 (0.6)  $m \cdot s^{-2}$ ,  $p < 0.01$ ]. During V2, forward acceleration was linked to the pole thrust and lowering of the hip, while the largest forward acceleration in V1 occurs without pole ground contact. Furthermore, in V1 the hip was elevated during the poling thrust. Discussion Displacement of the hip in the vertical direction approximates change in the skier's potential energy. Hip acceleration in forward direction approximates the size of the propulsive forces. The present results indicate that the potential energy gained by extension of hip and knee joints during the first part of the ski thrust, is transferred to forward kinetic energy by the poling action in V2. Video analysis reveals that during the first 75% of the poling action in V2, only minor changes occur in the angles of the shoulder and the elbow joints. Hence, the poling action is actively performed by knee- and hip flexion more than dynamic action of the arm muscles. Contrary to V2, the reaction forces through the poles are partly used to elevate the hip in V1. Conclusion: The present data shows that the poling

thrust in V2 is accomplished to a large extent by the legs and trunk by first elevating the COM to gain potential energy before lowering COM by gravity and actively flexion of the hip and the knees during the pole thrust. Authors: Gantenbein C.1, Goepfert B.3, Hoppeler H.2, Vogt M.2. 1: Institute of Exercise and Health Sciences (University of Basel), 2: Institute of Anatomy (University of Bern), 3: Laboratory for Biomechanics and Biocalorimetry (University of Basel). Introduction: Insights into the biomechanical processes and muscle control in alpine skiing are of particular importance in order to improve the quality of the movement, to prevent injury, to sift talents or to optimize training recommendations (Turnbull, Kilding, & Keogh, 2009). Due to the lack of current data on muscle activity patterns in elite ski racers since the carving technology has been invented, the present study shows the relationship between the driving technique and muscle activity patterns that occur. Method: In the following pilot study, a Swiss elite athlete took part from the discipline Alpine Skiing (Junior World Champion 2009 in the combination). Hip and knee angles were recorded and EMG activity of 12 muscles was derived on the right side of the body during four giant slalom races in a medium steep terrain. For the EMG analysis, the wavelet method according to von Tscherner was used (von Tscherner, 2000). Results: The average hip and knee angle at the outer leg ( $44 \pm 2^\circ$ , respectively  $43 \pm 1^\circ$ ) is significantly smaller than the inner leg ( $65 \pm 2^\circ$ , respectively  $81 \pm 3^\circ$ , extended leg =  $0^\circ$ ). The average angular velocity at the outer leg at the knee is  $69 \pm 3^\circ / s$  during knee extension and at the inner leg  $84 \pm 8^\circ / s$  during knee flexion. The M. vastus lateralis and M. vastus medialis show activity during the swing phase on the outer leg and the M. rectus femoris is active while the inner leg phase. The M. biceps femoris shows activity during the outside leg phase and the M. semitendinosus while the inner leg phase. At the beginning of a turn, it shows a visible preactivation of the hamstrings compared to quadriceps muscles. Conclusion: During giant slalom races, knee angular velocities are rather low. Unilateral activation of the muscles M. vastus lateralis and M. vastus medialis at the outer leg and an activation of the M. rectus femoris at the inner leg indicate that the M. quadriceps is not activated synchronously in regular competitive skiing. Differences in activity patterns of the hamstrings show the great importance of the rotational stability of the lower extremity in competitive skiing. The results confirm the great importance of a function-specific training of knee extensors and flexors muscles in alpine ski racing. References: Turnbull, J., Kilding, A., & Keogh, J. (2009). ### IMPACT CHARACTERISTICS OF DIFFERENT ICE HOCKEY ARENA DASHER BOARDS DURING SIMULATED BODY CHECKS

Poutiainen, P., Peltonen, J., Isolehto, J., Avela, J.

*University of Jyväskylä*

Introduction Incidence and severity of ice hockey related concussions have increased during recent years (Biasca et al., 2002). Modifying and developing the playing environment may serve to reduce concussion rate by influencing impact characteristics during body checks. Thus, the aim of this study was to determine how ice hockey dasher board materials and structures affect impact characteristics and thereby concussion risk. Methods Measurements were divided into two parts; in the first part, the physiological characteristics of body checks were determined in real game measurements (five games of the Finnish National Hockey League and two playoff games of the second highest ice hockey league in Finland) and the second part consisted of simulation of body checks in the laboratory. Four different commercially available dasher boards were tested in body check simulations. High speed cameras and accelerometers were used to collect data and peak forces, stopping distances and stiffness values were subsequently defined. Results Dasher board materials and structures had a major effect on impact characteristics. Flexible protective shielding material (Acryl) resulted in 17 % and 16 % lower peak forces, 110 % and 136 % greater stopping distances and 62 % and 56 % lower stiffness values in the straight and the corner parts of the dasher board, respectively, compared to the reference dasher board (tempered glass). However, the dasher board with flexible protective shielding material including shielding supporting posts yielded inconsistent results, so this kind of dasher board cannot be classified as safe. The single-framed dasher board was found to be 29 % and 11 % more flexible than its dual-framed counterpart, and heavier protective shielding resulted in 33% and 19 % higher element stiffness in the straight and the corner parts of the dasher board, respectively. Discussion In light of the results and the epidemiology of concussions, it seems that the most safe dasher board would be single-framed with light and flexible protective shielding material, and would not include shielding supporting posts. ### DOUBLE AND TRIPLE LUTZ IN ARTISTIC ROLLER SKATING: KINEMATIC COMPARISON

Fantozzi, S., Di Michele, R., Ciacci, S., Giovanardi, A., Merni, F.

*University of Bologna*

DOUBLE AND TRIPLE LUTZ IN ARTISTIC ROLLER SKATING: KINEMATIC COMPARISON Fantozzi S. 1, Di Michele R. 2, Ciacci S. 2, Giovanardi, A. 2, Merni F. 2 1 DEIS (Bologna, Italy), 2 Faculty of Exercise and Sport Sciences (Bologna, Italy) Introduction Knowing the biomechanical key factors of each jump is fundamental for figure skating coaches in order to more effectively teach triple jumps to their athletes. Notwithstanding the number of studies on ice skating (King et al., 2004), no biomechanical jump analysis, to the knowledge of the present authors, was performed on roller skating. The purpose of the present study was to compare some kinematic characteristics of double and triple Lutz jumps in roller skating. Methods 5 elite male skaters performing a series of double and triple Lutz were acquired using 10 infrared cameras (Smart-D, BTS, Milan, Italy, 250 Hz). For the trunk, the upper limbs and the foot segments, markers were attached directly on specific anatomical landmarks. For the thigh and the shank segments, the calibrated anatomical system technique was exploited (Cappozzo et al., 1995). The resultant velocity angle was also considered. Five key events were identified for each jump: toe-pick (instant in which the toe-pick impacted the ground), end of gliding (last contact of the left foot), take-off (last contact of the right foot), maximum height (top of the flight phase), and landing (instant of contact with the ground). Results The hip and the knee were flexed at the toe-pick, whereas the flexion was clearly lower at the take-off. On the contrary, the ankle at toe-pick was in the neutral position, and plantarflexed at the take-off, but differently depending on the skater. The skaters' horizontal velocities at take-off for the triple Lutz (mean: 2.69 m/s) were lower than those for the double one (mean: 3.17 m/s). Vertical velocities at take-off showed slightly higher values for the triple (mean: 2.90 m/s) compared to the double (mean: 2.72 m/s) Lutz. The average resultant velocity angle in the 5 athletes was  $40^\circ$  in the

double and 47° in the triple Lutz, at the take-off. The greatest difference between the double and triple jumps was the rotational velocity during the flight estimated from the rotation of the pelvis segment. The pelvis rotation velocity was higher in the triple Lutz already during the toe pick (means: 0.84 rev/s for double and 1.75 rev/s for triple one). Jumping height and flight time were higher for the triple jump for three skaters. Discussion For the first time a biomechanical comparison between the double and the triple Lutz in roller skating was performed. Some of these findings were already roughly known to coaches and skaters, but only in the present study some specific descriptors of the jump were characterized and quantified. ### **SPEED AS AN INJURY RISK FACTOR IN COMPETITIVE ALPINE SKI RACING DEPENDS ON EVENTS**

Gilgien, M.1, Spörri, J.2, Kröll, J.2, Chardonnens, J.3, Boffi, G.4, Jahnel, R.2, Cabri, J.1, Müller, E.2

1 Norwegian School for Sport Sciences, 2 University of Salzburg, 3 Swiss Federal Institute of Technology Lausanne, 4 Swiss Federal Institute of Technology Zürich

Introduction It was postulated that speed is an important factor for the increased injury rate in competitive alpine speed events of downhill (DH) and super-giant slalom (SG) compared to giant slalom (GS) skiing (Florenes et al., 2009). The speed characteristics in World Cup racing is not well described in the literature. The aims of this study were to a) map the speed distribution in men's World Cup alpine skiing for the events of GS, SG and DH, and to b) elaborate on potential susceptibility to injuries as result of speed differences between the events. Method Forerunners speed was captured in 6 GS, 2 SG and 4 DH men's World Cup races with a Global Navigational Satellite System (GNSS). The differential GNSS Doppler signal was recorded at 50 Hz using the GPS/GLONASS (L1/L2) with an antenna G5Ant-2AT1 (Anticom, Torrance, CA, USA) affixed to the forerunners helmet and a receiver Alpha (Javad, San Jose, USA). The GNSS-captured speed pattern was time-normalized using the time difference between the winner and the GNSS-forerunner. The mean speed ( $s_{mean}$ ), max speed ( $s_{max}$ ) and the standard deviation ( $\pm SD$ ) were computed. The relative  $s_{mean}$  ratio between SG and GS and between DH and GS was calculated. Based on the  $s_{mean}$  we calculated the mean kinetic energy ( $E_{kin\_mean}$ ) for GS, SG and DH using skier's mass of 100kg (Neumayr et al., 2003). The  $E_{kin\_mean}$  ratio between the race events was computed in relation to the  $E_{kin\_mean}$  of GS. Results For GS:  $s_{mean} = 66$  km/h ( $\pm 13$  km/h) and  $s_{max} = 96$  km/h. For SG:  $s_{mean} = 86$  km/h ( $\pm 16$  km/h) and  $s_{max} = 121$  km/h. For DH:  $s_{mean} = 96$  km/h ( $\pm 20$  km/h) and  $s_{max} = 143$  km/h. The  $s_{mean}$  ratio for SG/GS was 1.31 and for DH/GS = 1.47.  $E_{kin\_mean}$  for GS was 17kJ ( $\pm 7$ kJ), for SG was 28kJ ( $\pm 12$ kJ) and for DH it was 36kJ ( $\pm 17$ kJ). The ratio for  $E_{kin\_mean}$  was 1.72 for SG/GS and 2.16 for DH/GS. Discussion Fifty % increase in  $s_{mean}$  from GS to DH results in doubling of kinetic energy. This is significant in regard to the forces that occur in racer's falls, since the force ratio between GS and DH are equal to the energy ratio. From our analysis, we postulate that the potential for injuries may be associated with the speed differences between the events. Future investigations may pinpoint more accurately the potential factors responsible for ski related injuries. References Florenes, T. W., Bere, T., Nordsletten, L., Heir, S., Bahr, R., (2009). ### OP-PM17 Training and Testing 2

#### **COMPARISON OF A TEAM SPORT GLOBAL POSITIONING SYSTEM AND A VIDEO BASED MOTION TRACKING SYSTEM IN AN ELITE COMPETITIVE FOOTBALL ENVIRONMENT**

Li, F.X., Dallaway, N., Daley, T.

*University of Birmingham,*

Introduction Professional football clubs are increasingly utilising GPS tracking systems to monitor players speed and distance run during training sessions in order to quantify the work load. Additionally, the video-based motion analysis system Prozone (PZ, Leeds, UK) tracks the players' movements in competitive matches. When both systems are used together they potentially provide a comprehensive account of the total distance and speeds covered by players in both training and competition. However, the relative accuracy of each system has not yet been evaluated. The aim of the study is to investigate the differences in the physical performance data from the PZ and GPS systems in an elite competitive football environment. Methods In a Barclay's premier league reserve team fixture (UK), ten outfield players wore GPSPORT (Fyshwick, Australia) SPI Pro X 15Hz GPS units and were tracked via the PZ motion camera system. Data for overall distance, sprint distance ( $> 7m.s^{-1}$ ) and high speed distance ( $> 5.5m.s^{-1}$ ) was compared between the 2 systems. Results In all cases GPS recorded lower distance and number of sprints than PZ. No significant difference was found for overall distance (GPS: 7717m  $\pm$  2389, PZ: 9341m  $\pm$  3288,  $p > .1$ ). However significant differences were found between the high speed running (241m  $\pm$  140 compared to 645m  $\pm$  252,  $p < .001$ ) and sprint distance (62m  $\pm$  50 compared to 248m  $\pm$  122,  $p < .001$ ) speed zones. Significant differences ( $p < .001$ ) were also found in the number of sprints between the 2 systems with GPS recording (4  $\pm$  3) and PZ (36  $\pm$  17). Discussion Although GPS and PZ recorded similar overall distance run, in the high intensity running zones and in the number of sprints these differences were significant. It is possible that the sampling frequency is the source of these differences. The GPS system only records sprints at 1Hz whereas the PZ system samples at 10 Hz. The accumulative distance of sprints shorter than 1s recorded by PZ accounts for the majority of the differences in this speed zone between the 2 systems. Due to the differences between the 2 systems care should be taken when using data from them interchangeably to log the total load on players, in particular, when the GPS system is used to monitor the work load of a player returning from injury. Future research should be conducted to determine a correction factor between the 2 systems to allow a direct comparison of the data.

## MATCH ANALYSIS OF ELITE FEMALE BASKETBALL DURING COMPETITION

Conte, D.1, Minganti, C.2, Tessitore, A.1

*1 Dpt. of Human Movement and Sport Sciences, University of Rome "Foro Italico*

Introduction Basketball, as team sport, has fascinated worldwide spectators with its dynamic play. However, how the time-motion is structured in a game is more known for male rather than for female competitions. Thus, the purpose of this study was to investigate the duration of live time (LT), and stoppage (ST) playing phases during official Italian female elite basketball games. Methods To this scope three First Division championship games were continuously recorded and analyzed by a very expert match analyst. The LT was considered the actual playing time, while ST was any stoppage in play. Both LT and ST durations were classified according to 5 classes of frequency (1-20; 21-40; 41-60; 61-80; and >80 seconds). The LT phases were further classified in those entirely played on a half court and those on total court, in order to register one or more transfer (TR) phases, using 5 classes of frequency ( $n=1; 2; 3; 4; >4$ ). Chi Square was applied to investigate differences among games, and classes of frequency. Furthermore, a descriptive statistic (frequency and percentage), and LT/ST ratio was calculated. Results No significant differences were found among matches for LT, ST and TR, while a difference was found for half court actions  $p<0.001$ . Moreover, significant differences were found among LT, ST and TR classes of frequency  $p<0.001$ . Descriptive analysis showed, both for LT and ST, higher frequency of occurrence for 1-20s ( $45.9\pm7.7$  and  $49.2\pm9$ , respectively) and 21-40s ( $29.3\pm3.4$  and  $31.7\pm1.5$  respectively). Furthermore, 36.2% and 63.8% of actions were played on half and total court, respectively. The TR analysis showed as 48.4% and 27.1% of TR actions were performed with 1 and 2 transfer phases, respectively. The LT/ST ratio was  $1.09\pm0.28$ . Discussion The findings of this study showed as most of the LT and ST phases lasted less than 40 seconds, with a 1:1 LT/ST ratio, and a reduced number of consecutive TR phases in actions, underlining the intermittent nature of female basketball (Matthew and Delextrat, 2009). These data could help female basketball coaches to set-up drills with a short duration and a reduced number of TR. References Matthew D, Delextrat A. (2009). *J. of Sports Sci*, 27(8), 813-821.

## MECHANICAL POWER MEASUREMENT DURING WALKING <4, 6 KM/H> AND RUNNING <8, 10, 12 KM/H> USING ACCELEROMETERS

Pluk, A.

*KU Leuven*

Mechanical power measurement during walking (4, 6 km/h) and running (8, 10, 12 km/h) using accelerometers Pluk, A.1, Berckmans, D.1, Jonkers, I.2 1: M3-BIORES (KU Leuven, Belgium), 2: FaBeR (KU Leuven, Belgium) Introduction Power and energy expenditure are investigated to determine training intensity in running. Most methods are based on force measurement and speed or segmental energy analysis, limiting these calculations to laboratory conditions. In this study, mechanical power is measured using wearable accelerometers. Methods Six male students between 21 and 23 years old walked and ran at 5 different speeds (4, 6, 8, 10 and 12 km/h). 3D kinematic data was measured using a two camera Krypton system (Nikon Metrology Instruments, Belgium) sampled at 100 Hz. 3D acceleration data from the ankles of the subjects was measured at 125 Hz using 2 Zephyr BioHarness BT accelerometers (Zephyr Technology, Annapolis, USA). 3D ground reaction forces (GRF) were measured using an instrumented, split-belt motorised treadmill (Forcelink, The Netherlands) at 1000 Hz. From the kinematics and GRF mechanical power was calculated. Individual strides were identified by detecting the heel-strike in the GRF data and GRF, acceleration and power were time normalised per stride to 0-100%. For each stride the minimum and maximum values of GRF, power and acceleration were calculated in each direction. Results The relation between acceleration data and power was analysed for each subject. Pearson correlation coefficients are calculated for minimum and maximum values in each direction, resulting in  $R^2=0.197$  and  $R^2=0.737$  for forward;  $R^2=0.004$  and  $R^2=0.118$  for upward;  $R^2=0.177$  and  $R^2=0.235$  for medio-lateral; and  $R^2=0.083$  and  $R^2=0.793$  for the resulting acceleration and power. Discussion A clear disruption in the relation can be seen between the walking speeds (4 and 6 km/h) and the running speeds (8, 10 and 12 km/h). Because only a small number of different velocities were tested, only a very limited number of data points per test subject were available. Therefore statistically sound individual analysis is not possible, where this could be very beneficial to study individually different running characteristics. Looking at the relation between acceleration and power, a moderate relation in maximum forward direction ( $R^2=0.737$ ) is observed, where in the total power a strong linear relation ( $R^2=0.793$ ) between the maximum total power and the maximum total acceleration is seen. Looking at the relation between power and acceleration for the individual subjects, a similar strong relation is present in each of the individual test subjects. Conclusion Triaxial accelerometers were used to measure mechanical power for different speeds. A strong linear relation was established between the total acceleration and total mechanical power, even for individual test subjects. This relation confirms the possible use of accelerometers as a portable technology to evaluate power expenditure during running.

## OPTIMISING TECHNICAL SKILLS AND PHYSICAL LOADING IN SMALL-SIDED BASKETBALL GAMES

Klusemann, M.J., Pyne, D.B., Foster, C., Drinkwater, E.J.

*Australian Institute Of Sport*

Introduction The organisational pattern of small-sided basketball games defines the balance between physical and physiological demands and technical practice needed for competitive success. Differences in technical, physiological and physical demands of small-sided basketball games related to the number of players, court size and work-to-rest ratios are not well characterised. Methods A controlled trial was conducted to compare the influence of number of players (2v2 / 4v4), court size (half / full court) and work-to-rest ratios (2x5 min / 4x2.5 min) on the demands of small-sided games. Sixteen elite male and female junior players (aged 15-19 years) completed eight variations (2 x 2 x 2) of a small-sided game in randomised order over a six week period. Technical elements (e.g. shots, rebounds and passes) and movement patterns were assessed by video analysis. Heart rate responses and rating of perceived exertion (RPE) were measured to assess the physiological load. Results There were ~60% more technical elements in 2v2 than 4v4 and ~20% more in half court than full court games. Heart rate ( $86 \pm 4\%$  v  $83 \pm 5\%$  of maximum; mean  $\pm$  SD) and RPE ( $8 \pm 2$  v  $6 \pm 2$ ; scale 1-10) were moderately higher in 2v2 than 4v4 small-sided games. The 2v2 format elicited substantially more sprints ( $36 \pm 12\%$ ; mean  $\pm 90\%$  confidence limits) and high intensity shuffling ( $75 \pm 17\%$ ) than 4v4. Full court games required substantially more jogging ( $9 \pm 6\%$ ) than half court games. Discussion This is the first study to systematically investigate the effect of the number of players, court size and work-to-rest ratios on the various demands of small-sided basketball games. The main finding is that the number of players has the largest influence on the technical, physiological and high intensity movement patterns in small-sided basketball games. Court size and work-to-rest ratios can influence the frequency of various movement patterns. Basketball coaches can manipulate different variables of basketball drills and small-

sided games to vary the technical, physiological and physical demands of their basketball practice. Applying these training concepts will help coaching staff meet specific training and conditioning goals.

##### **ULTRA-ENDURANCE EXERCISE IS ASSOCIATED WITH EXTENSIVE INFLAMMATORY CELL INFILTRATION IN HUMAN SKELETAL MUSCLE OF EXPERIENCED ATHLETES**

Wahlin-Larsson, B., Marklund, P., Mattsson, C.M., Ponsot, E., Lindvall, B., Lindvall, L., Ekblom, B., Kadi, F.

*University of Örebro*

ULTRA-ENDURANCE EXERCISE IS ASSOCIATED WITH EXTENSIVE INFLAMMATORY CELL INFILTRATION IN HUMAN SKELETAL MUSCLE OF EXPERIENCED ATHLETES Wahlin-Larsson, B.1, Marklund, P.1, Mattsson, C.M.2,3, Ponsot, E.1, Lindvall, B.4, Lindvall, L.4, Ekblom, B.2,3, Kadi, F.1. 1School of Health and Medical Sci. (Örebro university, Sweden), 2The Swedish School of Sport and Health Sci. (Stockholm, Sweden) 3Dep of Physiology and Pharmacology, Karolinska Institutet, (Stockholm, Sweden) 4 Dep of Neurology, University Hospital (Örebro, Sweden) Introduction As ultra-endurance exercises impose an extreme physiological stress reflected by high levels of systemic inflammatory markers (Kim et al., 2007; Kim et al., 2009), it is hypothesized that skeletal muscle can be the site of an important inflammatory reaction. To our knowledge, the effects of very prolonged endurance exercise on local skeletal muscle inflammation have not been examined. The aim of this study was to assess the effects of a single 24 h ultra-endurance exercise bout followed by a 28 h recovery period on local muscle and systemic inflammatory responses in well trained ultra-endurance athletes. Method Blood and muscle samples were collected before (PRE), immediately after the exercise (POST) and after 28h of recovery (POST28). CRP and several inflammatory cytokines were assessed together with the evaluation of the occurrence of inflammatory cells (CD3+, CD8+, CD68+) and the expression of major histocompatibility complex class-I (MHC class-I) in skeletal muscle. Result A major finding was the occurrence of an extensive inflammatory cell infiltration in skeletal muscle of all athletes and the number of CD3+, CD8+ and CD 68+ cells were 2-3 fold higher at POST28 compared to PRE (P<0.05). The inflammatory cell infiltration was associated with a significant increase in the expression of MHC class-I in muscle fibers. At POST, the levels of IL-6, IL-8 and CRP were significantly increased. At POST28, IL-8 and CRP continued to increase. There were no significant associations between the magnitude of the systemic and local muscle inflammatory reactions. Discussion In conclusion, an endurance activity at a low intensity (~60% VO2max) but sustained over a very prolonged period (24 h) induces an extensive infiltration of inflammatory cells in skeletal muscle of well-trained athletes 28 h after termination of the exercise bout. The concomitant systemic inflammation usually reported after such exercises (Neubauer et al., 2008; Suzuki et al., 2003), was not correlated with the amplitude of the local muscle inflammatory reaction. ##### **RACE CYCLING: BIOLOGICAL EVOLUTION**

Le Goff, C., Kaux, J.F., Goffaux, S., Couffignal, V., Coubard, R., Laurent, T., Melon, P., Fillet, M., Chapelle, J.P.

*University Hospital of Liège*

Introduction: The metabolic and cardiac impact of a cycling effort on blood biology is not very well described in the literature. We aimed to measure the concentration of different biomarkers (cardiac and metabolic) released during an international cycling race. Materials and methods: Venous blood samples of 15 young men (25.1 ± 6.4 y.o.) were collected just before (T1), just after (T2), 3 hours (T3) after an international cycling race of 179.6 kilometers in Belgium for the determination of cardiac and metabolic biomarkers: red blood cell (RBC), haemoglobin (Hgb), creatinin (Cr), highly sensitive troponin T (hsTnT), myoglobin (MYO) and NT-proBNP. All automated assays were performed according to the manufacturer's specifications. For the statistical analysis, an Anova calculated with the Statistica Software version 9.1 was used. Results and discussions: RBC and Hgb levels varied significantly between T0 and T3 (respectively p=0.0026, and p=0.002). Cr concentration also varied significantly between all times (T0-T1:p<0.0001, T1-T3:p=0.0326 and T0-T3 p=0.0001). These changes might be related to renal flow depletion during exercise. MYO increased significantly between T0 and T1 (p<0.0001), but quickly decreased between T1 and T3, however the T3 level stay higher than T0 (p=0.014). The stress delivered from the physical activity performed during the race induced a significant variation of hsTnT which increased significantly between T0 and T1 (p<0.0001) and stayed higher 3 hours after the end of the exercise (T0-T3: p<0.0001). The intense exercise delivery by the race induced a significant variation of NT-proBNP, that followed the same kinetic of hsTnT but in smaller proportion. We noticed variations statistically significant between T0 and T1 and between T0 and T3 for NT-proBNP. These increases of cardiac biomarkers were significant but reasonable and could not allow us to talk about cellular necrosis or irreversible injury. Conclusion: Our results show that stress generated by a cycling race could be the cause for the different metabolic variations observed. Troponin T stays without a doubt the most specific marker for stress related to myocardial tissue. Its increase can then be considered as being of interest.

##### **EFFECT OF AGE AND BIOLOGICAL SEX ON PERFORMANCE IN SPRINT, OLYMPIC, HALF-IRONMAN AND IRONMAN DISTANCE TRIATHLONS.**

Wu, S.S.X., Peiffer, J.J., Nosaka, K., Abbiss, C.R.

*Edith Cowan University*

Introduction A number of studies have examined the influence of biological sex and age on exercise performance [1]. However, little is known with regards to the interaction of differing modes of locomotion and exercise duration with these factors. The purpose of this study was to examine the interaction of biological sex and age on performance over the three disciplines of triathlon during events of varying

distance. Methods Time for each discipline (swimming, cycling, and running) and overall finishing times of the top 20% of male and female amateur triathletes performing in various age groups (i.e. decade of age >20y) of four standard distance triathlons were examined. The triathlon distances included a sprint (0.75 km swim, 20 km cycle, 5 km run, n=68) an Olympic (1.5 km swim, 40 km cycle, 10 km run, n=76), a half-Ironman (1.9 km swim, 90 km cycle, 21.1 km run, n=256), and an Ironman (3.8 km swim, 180 km cycle, 42.2 km run, n=234). Overall race data was obtained from official event websites. For each event and discipline, performance time of each triathlete was normalised to the fastest age group of the respective sex. Results An age related decline in overall performance during the half-Ironman was observed beyond 40 y for males (P=0.021) and females (P=0.001). Performance decline in the Ironman was observed from 40 y for males and 50 y in females (P=0.018). The age related decline in overall performance was not significantly different between males and females during the sprint and Olympic distance triathlons. Swimming performance of both males (P=0.011) and females (P=0.002) was significantly better in younger (20-29 y) compared with athletes 30 y and older in all events. Fastest cycling times for males was observed at age 30-39 y irrespective of race distance, while females were fastest at age 40-49 y in all events, except for the half-Ironman where 20-29 y were fastest (P=0.034). An age related decline in running performance was observed in the half-Ironman and Ironman > 40 y in males (P=0.009), > 40 y (P=0.001) and 50 y (P=0.012) in females, respectively. Discussion Results from the present study indicate that the age related decline in overall performance in both males and female athletes was more evident in the longer distances (Ironman and half-Ironman), compared with shorter events [2]. These differences appear to be closely associated with decreases in running performance. Further research is needed to understand the physiological factors responsible for age related declines in exercise performance of differing duration and locomotion. References 1. ### THE PHYSIOLOGY OF WORLD-CLASS SLEDGE ICE-HOCKEY PLAYERS

Sandbakk, Ø., Bucher, S., Skovereng, K., Welde, B., Ettema, G.

1) Norwegian University of Science and Technology, Norway, 2) North-Troendelag University College, Levanger, Norway

INTRODUCTION: Sledge ice-hockey is a modified version of regular ice hockey targeting athletes with a physical disability, typically affecting the lower body. An aluminum sledge is used as an adaptive device and each player carries two sticks for puck handling and player movement. Thus, the players rely solely on their upper body to propel themselves across the ice surface. An ice sledge hockey game is performed as 3 periods of 15 minutes on a 60 x 30-m ice rink, characterized by a constant alternation between short dashes, stopping actions and circle moves leading to multiple changes of work load and intensity. In order to better understand the demands of world-class sledge ice-hockey, the present study compared physical and technical abilities of world-class (WC) and national-class (NC) sledge ice-hockey players. METHODS: Six WC and six NC sledge ice-hockey players from the A and B Norwegian national team performed the following sport-specific tests on ice: 1) 30-m maximal sprint, 2) multiple sprints (eight 30-m sprints at 30 seconds intervals with active recovery) and 3) a time-trial technique test where the athletes controlled the puck through multiple turns. In the laboratory, a 3-min all out poling ergometer test was performed sitting in a modified poling machine to determine peak respiratory parameters, and 1 repetition maximal strength and peak power was assessed in the bench press (BPr), bench pull (BPu) and pull-down (PD) exercises. The athletes' training diaries over the last year were analyzed. RESULTS: WC players showed 10-13% faster times both for the single 30-m and throughout all eight sprints in the multiple sprint test, whereas the technique test was ~15% for the WC players (all P<0.05). In the ergometer test, WC players showed ~5% higher VO<sub>2</sub>peak in absolute values and significantly faster oxygen kinetics (both P<0.05). Furthermore, WC players showed 15-25% higher maximal strength and power in all exercises (all P<0.05). WC players trained ~15% higher total volume with 30% more sport-specific training on ice and twice as much low intensity endurance training (all P<0.05). CONCLUSIONS: The current results show that maximal sprint ability, upper-body maximal strength and power, and aerobic capacities differentiate world-class from national-class sledge ice-hockey players. It is therefore suggested that these physical capacities are important for reaching world-class level in this sport. In addition, also technical ability showed clear differences between performance levels. The current study also indicates that the combination of sport-specific training on ice and low-intensity endurance training are important in attaining an international level in sledge ice-hockey.

#### IS-PM08 Towards an Integrative Approach of Exercise-Induced Fatigue

##### CELLULAR MECHANISMS OF SKELETAL MUSCLE FATIGUE

Westerblad, H.

Karolinska Institutet, Stockholm

Intense, repeated activation of skeletal muscles causes a decline in performance known as muscle fatigue. The decline in performance includes reduced force production and slower contractions. Changes in many properties may be involved in fatigue development, including impaired neural activation of muscle cells (central fatigue) as well as impairments intrinsic to the muscle cells (peripheral fatigue). Peripheral fatigue may include defects in action potential propagation, sarcoplasmic reticulum (SR) Ca<sup>2+</sup> handling and/or the function of the contractile elements. A range of mechanisms have been identified which may contribute to the decline of performance and these include changes in ionic composition, metabolite concentration, phosphorylation status and production of reactive oxygen species. Many different types of exercise cause fatigue and an important challenge is to identify the relative importance of various mechanisms in different conditions. Most of the mechanistic studies of fatigue have been performed on isolated muscle and another major challenge is to use the knowledge generated in these studies to identify the mechanisms of fatigue in humans under normal conditions and in association with various diseases.

## CENTRAL MECHANISMS IN MUSCLE FATIGUE

Taylor, J.L.

*Neuroscience Research Australia and the University of New South Wales, Sydney*

In humans, muscle fatigue can be defined as an exercise-related decrease in maximal voluntary force or power of a muscle or muscle group. Some of this fall occurs because cellular mechanisms reduce the maximal output of the muscle fibres, and some occurs because of reduced drive from the central nervous system to the muscle. The relative muscular and neural contributions vary with different types of exercise (Taylor & Gandevia 2008). As each muscle fibre receives input from one motoneurone, and each action potential in a motoneurone generates an action potential in the muscle fibres it innervates, the firing rates of motoneurons are critical for the production of force. If they are too low, the muscle fibres will not produce all the force of which they are capable. When not fatigued, some people produce firing rates which drive some muscles fully on some occasions, but most do not. With fatigue, ability to drive the muscles is reduced. During fatiguing contractions, motoneurons become less responsive to synaptic input. Multiple mechanisms may contribute to this decrease. Responses to stimulation of the corticospinal axons decrease despite maximal voluntary effort (Butler et al. 2003), and removal of voluntary drive reveals that motoneurone excitability is profoundly depressed (McNeil et al. 2009, 2011). This depression is likely a consequence of repetitive firing of motoneurons. In addition, fatigue-sensitive small-diameter afferents can inhibit some motoneurone pools although they facilitate others (Martin et al. 2006). If motoneurons are harder to drive during fatigue, their firing rates will slow unless they receive extra input. Extra descending drive from the cortex is easily supplied during submaximal exercise to maintain task performance. During maximal efforts, force increments evoked by transcranial magnetic stimulation of the motor cortex increase, which implies that descending input becomes less able to drive the motoneurons and that there is cortical output untapped by the voluntary effort. However, it does not reveal if descending drive has increased or decreased in absolute terms. While the cause of insufficient descending drive remain unclear, it is exacerbated by firing of fatigue-sensitive small-diameter muscle afferents (Gandevia et al. 1996). In fatigue, motoneurone firing rates during maximal voluntary effort become too slow to drive the muscle fibres maximally. Changes in motoneurone excitability may be an important factor. ## BEYOND CENTRAL AND PERIPHERAL MECHANISMS IN MUSCLE FATIGUE

Enoka, R.M.

*University of Colorado, Boulder*

At least since the seminal work of Mosso (1894), physiologists have distinguished between central and peripheral mechanisms in the study of muscle fatigue. With this approach, muscle fatigue is quantified as the decline in an objective measure of muscle function and experiments are designed to identify the rate-limiting adjustments that contribute to the reduction in performance. These studies have informed us that muscle fatigue can be produced by a number of impairments, including such diverse mechanisms as the management of calcium by muscle fibers and the excitability of neural networks. The translational interpretation of such observations, however, remains challenging (Enoka, 2012). Three examples underscore the limitations of this traditional approach to the study of muscle fatigue. First, although the decrease in maximal voluntary contraction force (torque) is greater for old adults than young adults after performing a series of anisometric contractions (Baudry et al. 2007), old adults can sustain a submaximal isometric contraction for a longer duration than young adults (Hunter et al. 2004). These observations indicate that the relative fatigability of old adults, and presumably the underlying mechanisms, varies across tasks, but the findings provide no insight on the functional significance of the contrasting results. Second, the traditional approach to muscle fatigue does not accommodate the fatigue reported by clinical populations in the absence of physical activity. Persons with multiple sclerosis, for example, typically report fatigue as a major debilitating symptom, yet fatigability as measured on standardized performance tests often does not differ from healthy control subjects (Steens et al. 2012). Rather, self-reported levels of fatigue in multiple sclerosis and other neurological diseases are more related to psychological factors and the function of supraspinal networks (Morgante et al. 2011). Third, it is difficult to reconcile the traditional approach with the viewpoint that perceptions of fatigue can be related to the regulation of homeostatic factors required to maintain the energetic and physical integrity of the body (Swart et al. 2009). Given these limitations of the traditional approach to the study of muscle fatigue, it seems necessary to reiterate the perspective described by Mosso: "On an examination of what takes place in fatigue, two series of phenomena demand our attention. The first is the diminution of the muscular force. The second is fatigue as a sensation." A scheme will be described in which fatigue comprises two domains, one related to factors that influence fatigability (decrease in muscle force) and the other to factors that modulate perceptions of fatigue (sensation). #### THE IMPACT OF AN ALTERNATIVE SPORT-BASED EDUCATION CURRICULUM ON CONFIDENCE AND MOTIVATION.

McCann, B., Shaw, D.

*Robert Gordon University*

THE IMPACT OF AN ALTERNATIVE SPORT-BASED EDUCATION CURRICULUM ON CONFIDENCE AND MOTIVATION. McCann, B.1 & Shaw, D.J.1  
1 Robert Gordon University (Aberdeen, Scotland) Introduction The Scottish Executive estimates that each young person (aged 16-18 years) not currently engaged in education, employment or training (NEET) has an approximate per capita cost to society of £100,000. The innovative 'Alternate Academy' concept, a 12-week training programme jointly developed by Transition Extreme and Robert Gordon Universi-

ty, sought to provide opportunities for this group of young people to increase their confidence and motivation, whilst serving as a catalyst for re-engagement with education or training to assist participants in progressing to a positive destination. Alternative, adrenaline-based extreme sport (i.e., climbing, skateboarding, BMX and in-line skating) was the medium through which participants were to be re-engaged. Methods Ongoing evaluation data was gathered from five cohorts of participants (n=72; 66 male and 6 female) over an 18 month period, comprising of both qualitative and quantitative methods. These data were used to inform key themes for subsequent focus groups (to understand intra- and inter-cohort journeys) and individual interviews (to understand individual journeys), both of which explored pre-, during- and post-academy experiences. Results Analyses of evaluation data indicated a trend towards increased participant confidence and motivation. Focus group outcomes highlighted that participants were initially motivated to engage with the Alternative Academy through an interest in sport, but that the curriculum subsequently increased motivation to re-engage with education, employment or training. Participants qualitatively indicated increased confidence in situations other than sport. Interviews indicated that participants experienced increased levels of confidence and motivation at various stages during and following participation on the programme, with individual journeys demonstrating the impact of each. Discussion Quantitative and qualitative results indicated the positive impact of the Alternative Academy on participant confidence and motivation which were believed to have developed due to involvement in the training programme. Participants articulated that both were transferable to other aspects of their lives such as seeking employment or future training opportunities. Inter cohort comparisons indicated common themes related to the positive impact of sport in a wider context. The long lasting effect for participants was also demonstrated, some of whom had completed the programme 15 months prior to the focus groups and interviews being carried out. Sport, and in particular adrenaline-based and extreme sports, should continue to be researched in the future as possible mechanisms of not only addressing health and wellbeing concerns in young people, but also employability and personal development amongst the disengaged, NEET population.

### ANTI-DOPING COMPETENCE DEVELOPMENT AMONG STUDENTS OF SPORT SCIENCES

Bondarev, D.

*Lund University*

Introduction. Doping behavior may be explained both by individual predispositions (Sniehotta, Scholz & Schwarzer, 2005) and by underlying values and processes leading to this behavior, namely situational opportunities (Ajzen, 1985). The second one in many respect is influenced by norms and values promoted by surroundings of the athlete. Recent approaches in anti-doping initiatives target mostly athletes with little emphasis on coaches or medical practitioners. Relatively little has been done to target and adequately prepare students of sport sciences who considered being the main future figurants of sport and exercising world to deal with doping issues. Therefore, the aim of this study is to develop a model of anti-doping competence which could be incorporated to the curricula of sport sciences students. Methods. Data was obtained through questionnaires of 321 Sport Sciences students and during four focus group interviews with 40 students. Results. Results of the factor analysis identified three groups of variables. First group (68 % of the total variance) accounted following variables: intention to use doping (.76), attitude towards doping (.68), knowledge about doping (.67), motivation to comply (.66), self-efficacy to dope (.53), physical self-concept (.51). Second group (42 % of variance) consisted of such a variables as past use (.62), motivation to comply (.58), knowledge about doping (.55), subjective norms (.51). Third group (26 % of variance) and consists of the following variables: negative attitude towards doping (-.64), mastery goals (.52), self-efficacy to resist (.52), and motivation to comply (-.51). In addition transcriptions of focus group interviews had been analyzed to identify possible missing issues of questionnaires. Discussion. The results of the study show that it is possible to distinguish between three levels of anti-doping competence among sport science students. First level refers to potential doping users who accept doping use for their purpose, highly susceptible to complying with sport community norms and identifying themselves strictly with athletes, neglecting other parts of social life. At the second level of anti-doping competence are those who recognize that doping is illegal but may be used in exceptional situations. Under pressure of competition or influence of surroundings such athletes may rationalize an action that they had earlier categorized as being wrong. Third level of competence in anti-doping is related to those who are able to critically assess sport community norms and believe in their own ability to perform well. The results suggest that possible anti-doping interventions have to be suited to the level of anti-doping competence.

### INCREASING PHYSICAL OR SPORTS ACTIVITY LEVELS IN TRANSITION UNIVERSITY STUDENTS

Soares, A., Pereira, M., Canavarró, J.

*Universidade de Coimbra*

Soares, A.1, Pereira, M.1, Canavarró, J.1 1: FPCEUC (Coimbra, Portugal) Introduction: Health-compromising behaviors such as physical inactivity are difficult to change. Most social-cognitive theories assume that the intention to change is the best direct predictor of actual change, but people often do not behave in accordance with their intentions. The Health Action Process Approach (HAPA) suggests a distinction between (a) preintentional motivation processes that lead to a behavioral intention, and (b) postintentional volition processes that lead to the actual health behavior. Objective: The prediction model, as well as the effects of intervention, were examined in a study with University of Coimbra first-year-student sample who was enrolled in a health intervention project (N=224). Participants were assigned to one of the intervention groups (educational group and HAPA intenders/actors group) or to a control group. Main Outcome Measure: The study included 2 measurement points in time, covering a period of 2 months. Motivational variables, intentions, planning, coping, self-efficacy and physical or sports activity levels were assessed. Results: Structural equation modeling revealed that the model fit data sets well. Participants in the HAPA group did significantly more physical or sports activities than those in the other groups. Conclusions: HAPA volition variables were effective predictors of physical or sports activities adherence. Parsimonious interventions might contribute to health behavior change. ### STUDY INTO THE GENDER-SPECIFIC TRANSITIONS AND CHALLENGES FACED BY FEMALE ELITE ATHLETES.

Tekavc, J., Wylleman, P., Cecic-Erpic, S., Reints, A., Rosier, N.

*Vrije Universiteit Brussel*

STUDY INTO THE GENDER-SPECIFIC TRANSITIONS AND CHALLENGES FACED BY FEMALE ELITE ATHLETES. Tekavc, J.1/2, Wylleman, P.1, Cecic-Erpic, S.2, Reints, A.1, Rosier, N.1 1: Vrije Universiteit Brussel (Brussels, Belgium), 2: Univerza v Ljubljani (Ljubljana, Slovenia) Introduction Although researchers have examined how talented and elite athletes develop through (as well as after) their athletic career (Wylleman & Reints, 2010), and despite the increased participation of women in elite sport, most empirical data on the athletic career development is

related to male talented and elite athletes. Methods Taking into account the multi-level factors of influence on career development, the developmental lifespan model (Wylleman & Reints, 2010) was used as conceptual framework to conduct a preliminary study into the empirical data available on the development of female talented and elite athletes. Results Research shows that differences in biological determinants (e.g., pregnancy) may explain the existence of female-specific career transitions and why women may show a different career path than men. At athletic level, female athletes typically specialize, achieve their peak, and end their athletic careers one to two years earlier than male athletes in the same sports. At academic/vocational level, female athletes have been found to more often continue their studies into higher education than male athletes, to benefit less from having a university degree than male athletes and also get less often jobs in the sport system, like coach or manager. Discussion While recognizing gender differences in athletes' career development, no attempt has been made to develop gender-specific athlete career transition models. More research on the role of gender on multi-level challenges (e.g., transition into higher education, sponsorship, lifestyle) faced by female athletes is therefore warranted. This research should not only add to the development of athletic career transition models specific to elite female athletes, but extend and detail the knowledge base currently available on the gender-specific transitions faced by elite female athletes. References Wylleman P, Reints A (2010). *Scandinavian Journal of Medicine & Science in Sports* 20(2), 88–94.

### **STUDY INTO THE FACTORS CONTRIBUTING TO THE CONTINUED DEVELOPMENT OF TALENTED AND ELITE YOUTH ATHLETES INTO ELITE SENIOR LEVEL USING A DEVELOPMENTAL AND HOLISTIC PERSPECTIVE.**

Rosier, N.1, Wylleman, P.1, De Bosscher, V.1, Van Hoecke, J.1, Reints, A.1, Tekavc, J.2

1: *Vrije Universiteit Brussel (Brussels, Belgium)*, 2: *Univerza v Ljubljani (Ljubljana, Slovenia)*

Introduction Researchers have examined how talented athletes develop through (as well as after) their athletic career. While different normative challenges have been studied (e.g., initiation into competitive sport, dropout from competitive sport, retirement from elite sport), few empirical data is available on the challenges talented athletes face during as well as after making the junior-senior transition. Methods Taking into account the multi-level factors of influence on career development, the developmental lifespan model (Wylleman & Reints, 2010) was used as conceptual framework to conduct a preliminary study into the empirical data available on the junior-senior transition. Results At athletic development the junior-senior transition generally entails that first-year senior athletes will generally be at a lower end in terms of athletic prowess and/or achievement and that, on average, only one junior elite athlete in three actually makes a successful transition into senior elite ranks. In comparison to challenges faced at other levels of development (e.g., psychological, academic) this transition is also a 'point of no return' as athletes cannot return to an earlier period or point in their athletic career. As the junior-senior transition occurs during adolescence, talented athletes will face challenges at psychological level including developing an own identity, coping with unexpected situations, higher expectations and pressures, and developing higher self-initiated/self-regulated behaviors. At psychosocial level, it was found that at the onset of the junior-senior transition, coaches become more personally involved, emphasize more the technical proficiency, and expect from them progress through discipline and hard work; with first-year senior athletes, coaches were found to make them more responsible for the training and competitions, as well as placing great demands upon them. At academic level, talented athletes will in first instance face challenges as they make the transition out of secondary education; during and after the junior-senior transition those talented athletes who continue into higher education will in second instance be required as 'student-athletes' to cope with challenges that strongly differ from that at secondary education level. Discussion As past research has been restricted (e.g., retrospective, limited number of participants, restricted to characteristics at athletic level), a clear need exists for research allowing not only to understand the developmental (stage-like) process occurring during the junior-to-senior process but also to look beyond the individual athlete characteristics and take into account the (structural and organisational aspects) of the environment in which talents develop. References Wylleman P, Reints A (2010). *Scandinavian Journal of Medicine & Science in Sports* 20(2), 88–94.

### **CORNER REFEREES IN JUDO CONFORM TO THE HEAD REFEREE BECAUSE OF THE OPEN FEEDBACK SYSTEM**

Boen, F., Ginis, P., Smits, T.

*KU Leuven*

CORNER REFEREES IN JUDO CONFORM TO THE HEAD REFEREE BECAUSE OF THE OPEN FEEDBACK SYSTEM Boen, F. 1, Ginis, P. 1, Smits, T. 2 1: Department of Kinesiology (KU Leuven, Belgium), 2: Department of Communication Sciences (KU Leuven, Belgium) Introduction This experiment tested whether the conformism observed among panels of judges in aesthetic sports (Boen et al., 2006, 2008; Vanden Auweele et al., 2004) also occurs among referees in a combat sport. Similar to aesthetic sports, judo refereeing relies upon a form of open feedback. However, in judo this system is reactive (i.e., two corner referees have to publicly 'correct' the score given by the higher-status head referee), whereas it is active in aesthetic sports (i.e., judges with equal status report their score simultaneously and can use the feedback about the scores of their colleagues for evaluating later performances). In order to test whether such reactive open feedback system leads to conformism among referees in judo, we designed an experiment in which this feedback was manipulated. Methods Participants were twenty certified Flemish referees, who had to score two sets of 11 video-ambiguous fragments that are used during formation and training of judo referees: one set with feedback about the head referee's score, and one set without feedback. Results When participants knew the head referees' score, their scores were significantly more in line with this score than when they did not know this score. More specifically, for both sets of fragments at least 10% less deviations from the head referee were observed when participants were given feedback about the score of the head referee. Discussion These results suggest that preventable conformism can occur in typical judo refereeing, i.e. with reactive open feedback. Consequently, judo federations should contemplate eliminating the reactive open-feedback system to avoid conformism and facilitate divergent opinions by the corner referees. One possibility is to give all referees an electronic device with which they can input their score without seeing the score of the head referee. #### CARDIO-RESPIRATORY ORIGIN OF THE VO<sub>2</sub> DECREASE OBSERVED DURING A CONSTANT SUPRAMAXIMAL CYCLING EXERCISE.

Hanon, C.

*INSEP*

Cardio-respiratory origin of the VO<sub>2</sub> decrease observed during a constant supramaximal cycling exercise. Hanon C 1, Dorel S 1,2, Delfour-Pereyhton R 1,2, Leprêtre P-M 3, Bishop D.J. 5, Perrey S 4 and C. Thomas 1,6 1) INSEP, Paris, 2) Nantes, France, 3) Amiens, France, 4) Montpellier-1, France, 5) ISEAL Melbourne, Australia, 6) Evry Val d'Essonne, France. Introduction: A significant decrease in whole-body at the end of supra-maximal running exercise has previously been reported (1). This decrease was concomitant with a decrease in running velocity that could be considered as one of the possible explanations for this phenomenon. A strong correlation ( $P < 0.0001$ ) between the regrouped 400-, 800- and 1500-m tidal volume (VT) and responses has been observed in the last 100 m (1). It has also been reported that a reduction in systemic and locomotive skeletal muscle O<sub>2</sub> delivery limits aerobic capacity in trained humans (2). Therefore, the aims of this study were to confirm the occurrence of the decrease during severe, supra-maximal exercise without confounding influence of a decrease in power output, and to identify the primary factors that limit the ability to maintain in healthy, trained subjects. Methods: Eleven specifically trained male subjects volunteered for this testing protocol consisted of two sessions: 1) basal spirometric monitoring (volume and flow), a torque-velocity cycling test (muscular profile) and an incremental test (aerobic capacities) on calibrated cycle ergometer; 2) a constant-load supra-maximal cycle test performed until exhaustion. Ventilatory and cardiac responses were recorded continuously during the entire experimental session and arterialised capillary blood samples (85 µL) were taken at 0, 5 and 8 min of recovery. Results: The mean performance was  $51.4 \pm 6.9$  s with a mean power of  $640.5 \pm 50.8$  W corresponding to  $185 \pm 24$  % of MAP and  $49 \pm 3.8$  % of Pmax. A decrease in greater than 5% was observed in 6 of our 11 subjects with 5/6 subjects presenting also a decrease in stroke volume (SV). The magnitude of the decrease was correlated with SV decrease ( $R=0.75$ ,  $P < 0.01$ ), peak exercise end tidal O<sub>2</sub> partial pressure ( $R=0.80$ ,  $P < 0.005$ ) and rest forced expiratory volume in 1 s ( $R=0.72$ ,  $P < 0.05$ ), but with any metabolic variables. Discussion: Our results corroborate the relationship reported between SV and changes in intrathoracic pressure consecutively to voluntary lungs inflation and suggest that in those subjects with high levels of expiratory flow, greater positive expiratory intrathoracic pressure could increase the ventricular afterload and reduce the rate of ventricular filling during diastole (3). Therefore, the occurrence of decrease during a mild-acidosis strenuous exercise (pH = 7.21) results mainly from cardio-ventilatory factors. 1) Hanon C, Thomas C. *J Sports Sci*, 2011. 29(9): p. 905-12. 2) Gonzalez-Alonso J, Calbet JA. *Circulation*, 2003. 107(6): p. 824-30. 3) Amann M. *Experimental physiology*, accepted article. 2012

#### COMPARISON OF OBJECTIVE AND SUBJECTIVE RESISTANCE TRAINING QUANTIFICATION

Brown, N., Bubeck, D., Alt, W.

*University Stuttgart*

Introduction Quantification of training intensity in resistance training is difficult, since there are no valid objective methods to monitor how hard a subject is working during a training session (McGuigan et al., 2004). Therefore various authors recommend the use of the RPE-scale (Singh et al., 2007; McGuigan et al., 2004). Although recommended, it is unclear which objective biomechanic or physiologic parameters the RPE represents. Chen et al. (2002) compared RPE and different physiologic parameters. No significantly high correlations were found. The purpose of this study was to determine if RPE is related to objective mechanic parameters during training sessions and to analyse if a difference in RPE between two intensities can be found. Methods The subjects ( $n=13$ , 69% male, age=24.69 years) had at least one year of strength training experience and were randomly assigned to two groups (g1:  $n=8$ , g2:  $n=5$ ) providing a cross-over design for the different training protocols. Subjects performed 10 training sessions (5 hypertrophy 8-12RM (HYP), 5 strength 1-3RM protocol (MAX)) with 10 standard exercises. After each training session-RPE was measured 30 minutes after the end of the exercise. Training load, number of repetitions, contraction mode, RPE-AM (active muscle) and recovery times were protocolled for each set and exercise during the training session. Pearson correlation coefficients were calculated between RPE, objective protocolled training parameters and RPE-AM. A Wilcoxon signed rank test was used to determine differences in RPE between the two training protocols. Results No statistical significant correlations were found between RPE and the objective training parameters. Correlations between session RPE and RPE-AM were low ( $r=0.45$ - $-0.39$ ). A significant difference in session RPE between the two training protocols was found (HYP=  $6.30 \pm 1.74$ , MAX=  $4.47 \pm 2.17$ ,  $p < 0.01$ ). Discussion A correlation between an objective training parameter and subjective training quantification using RPE could not be found. Therefore a more complex interaction of objective training parameters is assumed. In agreement with the findings of Chen et al. (2002) the representational factor of the RPE remains unclear. In this study a difference between HYP and MAX-protocol was found to be consistent with the findings of Singh et al. (2007). However, in our study MAX produced lower RPE values than HYP, which is contrary to recent findings. Further research should focus on the development of a valid and reliable objective quantification method, since quantification of resistance exercise using subjective measurements is critical. #### NEUROMUSCULAR FATIGABILITY OF TRUNK EXTENSORS AND FLEXORS FOLLOWING 10 WEEKS OF SPECIFIC EXERCISE AT DEVICES

Alexander, N., Ullrich, B., Stening, J., Felder, H., Hökelmann, A.

*Universität Magdeburg and OSP Rheinland-Pfalz/Saarland*

Introduction A deficiency in lower back muscle endurance is a risk-factor for low-back pain (Demoulin et al, 2006). This study analyzed the effects of 10 weeks of endurance-oriented strength training for the major trunk muscles on maximum voluntary isometric capacity

(MVC) of the major trunk muscle groups and EMG estimated neuromuscular fatigability of the trunk extensors and flexors. Methods Adolescent regional athletes were separated into two groups: training group (n = 11) and control group (n = 10). The total duration of the experimental period was 13 weeks. The first two weeks were used as a control period. Thereafter, training subjects started a 10 weeks progressive strength training period for the trunk extensors, flexors, lateral flexors and rotators on training machines equipped with a biofeedback system. Testing was performed during the baseline (weeks -2, -1) and after 10 weeks of training. Measurements included MVC force measurements of the major trunk muscles and analysis of the neuromuscular fatigue resistance of specific trunk muscle groups. Surface EMG of m. erector spinae, m. latissimus dorsi, m. rectus abdominis and m. obliquus externus was collected during sustained isometric trunk extension and flexion contractions at 40% of pre-exercise MVC. Results No significant enhancement for any parameter was detected in controls. Significant increases in MVC of the major trunk muscle groups and endurance time during sustained isometric trunk extensions and flexions occurred following training. Normalized [% Max pre fatigue] EMG-RMS values of all analyzed muscle groups were higher during the fatiguing contractions at the first baseline compared to the second baseline measurement and the end-measurement. However, no significant differences in normalized EMG-RMS values during fatiguing trunk extensions occurred among the second baseline testing and the end-measurement. Contrary, significant lower normalized EMG-RMS values of the analyzed trunk flexor muscles were found after the training period compared to both baseline measurements. Discussion The present exercise increased the maximum voluntary isometric capacity and endurance-time during sustained isometric trunk extensions and flexions in adolescent athletes. EMG-RMS analysis during fatigue suggests a rapid learning effect, rather than training-induced alterations. Although without statistical significance, average EMG activity during fatigue was lower after training indicating some neuromuscular adaptations. The present results indicate that baseline variability in EMG traces has to be considered when neuromuscular fatigability is analyzed in training studies. ### **CUSHIONING AND STABILITY DURING TREADMILL RUNNING: EFFECTS OF TREADMILL AND FOOTWEAR**

Delattre, N., Roux, M.

*Oxylane*

Introduction Treadmills are increasingly used in both physical activity and research fields. However, treadmills can be made of various constructions and materials resulting in a wide range of mechanical behaviours. In shoe research field, the main studied features are cushioning and stability. Ferris and Farley (1997) reported an interaction between ground or shoes properties, and body stiffness, while Lafortune et al. (1992, 1996) highlighted the link between body stiffness and lower limb shock propagation. However, no study assessed how ground and shoe properties influence the shock propagated to the lower limb. On the other hand, Clarke et al. (1983) and De Wit et al. (1995) have studied the relationship between stability and shoe sole properties. However, no work had yet integrated the ground and shoes properties in stability assessment. This study aimed at assessing both ground and shoe sole properties on cushioning and stability during treadmill running. Methods Nine subjects ran at 3.5m/s on five treadmills (T1-T5: stiffness from 107 to 538 N/mm) with soft midsole shoes (40 AskerC, 88 N/mm), hard midsole shoes (65 AskerC, 119 N/mm) and barefoot. The analysed parameters were tibial acceleration (accelerometer), vertical ground reaction force (VGRF, custom-made force plate underneath each treadmill) and foot inv/eversion angle (gyroscope). Cushioning was assessed through peak tibial acceleration (PTA), acceleration slope (AS), and VGRF loading rate (LR). Stability was assessed through inv/eversion angle amplitude (IEAA), and angular velocity (IEAV). Results The analysis showed an effect of treadmill stiffness on PTA and AS, but not on LR, IEAA, and EIIV. AS was significantly lower for T1 (89±26 g/s), T2 (97±30 g/s) and T3 (119±30 g/s), than for T4 (186±82 g/s) and T5 (219±111 g/s). Barefoot induced significantly higher values of PTA, AS, and lower LR compared to shod conditions. No difference between soft, hard and barefoot conditions was found for PTA, AS and LR. EIIV was only affected by the footwear conditions: 406±145 °/s (soft), 513±170 °/s (hard), 615±192 °/s (barefoot). Discussion The results showed that, during treadmill running, 1) cushioning was affected by treadmill stiffness, not footwear; 2) stability was influenced by footwear, not treadmill stiffness. The results allowed to distinguish between two treadmill conceptions. These findings strongly influenced the conception of treadmills and indoor footwear running shoes. #### **STRENGTH AND BALANCE PERFORMANCE IN HEALTHY OLDER ADULTS: COMPARISON BETWEEN HIGH FREQUENCY VIBRATION, RESISTANCE AND POSTURAL SENSORIMOTOR TRAINING.**

Iodice, P., Bellomo, R.G., Di Pancrazio, L., Saggini, R.

*University of Chieti*

Introduction. Aging is characterized by a gradual decrease in muscle mass and muscle strength which contributes to a decline in physical functions, increase disability, frailty, and loss of independence. Age related loss of muscle mass is referred to as sarcopenia. The study have the purpose to compare three different methods of specific training for the sarcopenic elderly with the aims to obtain increase in strength and balance. Methods. 40 male volunteers diagnosed with sarcopenia (CDCP) (70,9±5,2yrs). The patients were randomly assigned to three different training programs for 12 wk, global sensorimotor training, high intensity focused vibrational program (intensity: 300hz) and resistance program (intensity:60-80% of maximum theoretical force, 10-12 repetitions for 3sets). Before and after the training programs the isometric lower limb force was measured by dynamometer. At the same time, stabilometric test and analysis of walk were performed. Results. All the training, in a different manner, shows an increase in muscular isometric strength. Both the sensorimotor and the vibrational training increase stability with a reduction of sway area and surface of ellipse (p<0.01). The analysis of walking shows a significant increase in the length of the half-step in all three groups (respectively 107%, p <0.01; 91% p < 0.01; 65% p <0.05;). Discussion. Our results suggest that all our training counteract sarcopenia progression and each of them are able to stimulate a specific effects.

Sensorimotor and vibrational training have better results against the instability associated with aging. A training program to strengthen muscles for elderly including a sensorimotor intervention can counteract sarcopenia and increase stability.

### THE IMPACT OF MORPHO-FUNCTIONAL PARAMETERS TO THE QUALITY OF LIFE FOR WOMEN AGED 55 – 65 OLD

Haxholli, S.1, Kacurri, A.1, Haxholli, K.2, Haxholli, M.2

*Albanian Agency of Sports Services*

Introduction Especially assessing the morpho – functional parameters and body composition are essential to determine the quality of life in this age. Therefore, developing intervention programs that focus restoring or optimizing physical and psycho-social capabilities has been one of the main efforts of this study. The main purpose of this study is to evaluate and discuss the changes or not in strength, flexibility, balance, and anthropometric parameters improved with training program. Methods Pre-test/Post-test control group design was used in this research. This design enables the evaluation of effectiveness of the intervention used in similar one from Alfieri et al 2010 as well model program plan has been rely on ACSM, 2006. Quality of life questioner (paper and pencil) was asked for both groups (intervention & control) to write their feelings and psycho-social status before starting and after intervention. According to the gain scores,  $D = Y_2 - Y_1$ , represent the dependent variable difference from pre-test to post-test assessment that were used in ANOVA comparisons. Results The circumference of waist is meliorating by 9.4% and the biceps by 9.8 %. Vvariables of gluteus and thigh couldn't meet the difference of 5 %, all other anthropometric variables as waist and weight are improved by 5.5 % and 8.8 %. So far and functional parameters have the same trend and even more stressed always in favour of intervention group like as: balance 22.68%, flexibility 38.4 % and strength 44.5%. Discussion Regular physical activity provides multitude benefits, adult who maintain a regular routine of physical activity that is of longer duration or of greater intensity are likely to derivate greater benefits. Systematic training can help individuals how to be efficient in daily life (Waneen W. Spiriduso, EdD, et al 2005). Implementing combined and planed programs of physical activity base on aerobic, strength and balance with moderate to vigorous intensity arranged per individuals to develop the morph functional parameters in broadly recommended and applied in the similar studies, intervention program shaped in period of 12 – 16 weeks (Dishman et al 2002), (Barbosa et al 2002) and to (Brill et al 2000), as well Cousins, S.O. (1998). References American College of Sports Medicine. (2006). ACSM's, seventh edition. Philadelphia: Lippincott, Williams & Wilkins. Bouchard C., PhD, Steven N Blair, PED, William L. ### BRISK WALKING PROGRAM IN POSTMENOPAUSAL WOMEN: EFFECTS ON PERCEIVED HEALTH, CARDIORESPIRATORY FITNESS AND LIPID-LIPOPROTEIN PROFILE TWO YEARS AFTER THE INTERVENTION

Garnier, S., Gaubert, I., Auneau, G., Mauriège, P.

*Université Paul Sabatier*

Introduction Walking being considered as the commonest and most feasible form of sustainable dynamic aerobic exercise for sedentary subjects (Lee and Buchner, 2008; Hamer and Chida, 2008), helps postmenopausal women to feel better (Lean and Lara, 2003) and improves their metabolic risk profile (Roussel et al., 2009). However, these beneficial effects at long term have not been fully investigated. Aims of the present study were thus to examine the effects of a brisk walking program on perceived health, cardiorespiratory fitness (CRF), body composition and selected metabolic risk factors, two years after the intervention. Methods 248 initially sedentary and overweight-to-obese (mean body mass index, BMI =  $30 \pm 4$  kg/m<sup>2</sup>) postmenopausal women ( $60 \pm 5$  yr-old) were recruited. 196 women were subjected to a 4-month endurance-training program walking (3 sessions of 45 min each/week at 60 % of their heart rate reserve) (exercise group) and 52 women did not exercise during the 4-month study period (control group). Following measurements were performed before and after the 4-month study-period as well as two years later: . perceived health estimated by a visual analogue scale (six questions) . CRF assessed by the 2-km walking test (Laukkanen et al., 1993) and estimated VO<sub>2</sub>max then calculated, . height, weight (BMI calculated) and waist circumference measured using standardized procedures, . fat mass and fat-free mass determined by bioelectrical impedance . lipid-lipoprotein profile measured for the exercise group, only Results Two years later, the decrease in body weight, fat mass, resting systolic and diastolic blood pressures as well as the increase in CRF ( $p < .001$ ) were maintained in the 91 women who completed the study. Changes in the lipid-lipoprotein profile and perceived health were maintained for five out of six items ( $p < .05$ ). Discussion The brisk walking program reduced body fatness, improved selected metabolic risk factors, CRF and perceived health of postmenopausal women. These improvements were sustainable two years later. References Hamer M, Chida Y. (2008). Br J Sports Med, 42, 238-43. Laukkanen RMT, Kukkonen-Harjula TK, Oja P, Pasanen ME, Vuori IM. (1993). Background: Ageing results in a progressive loss of functionality and mobility that decreases the quality of life and may lead to a high prevalence of falls (PF) among elderly population. "More Active Ageing" (MAA) is an exercise intervention implemented in the senior Portuguese community, focused on postural stability, balance and strength, aiming falls reduction and its severity. Purpose: A cross sectional study was designed to: 1) assess the baseline data of the MAA program on Health, Functional Fitness (FF) and Physical Activity; 2) identify which of those parameters can be correlated with falls in this group. Methods: 715 independent elderly ( $72.3 \pm 5.2$  y) were assessed by trained examiners who administered a fall & health questionnaire and a FF battery including U-G, C-5 and 2minStep tests from SFT2, items 4-7 of FAB Scale3, Calf Raise (CR) and Calf Stretch (CS) tests (in validation process). Spearman's Correlation Coefficient (SPSS) was used to analyze age, fear of falling (FoF) and medicine intake (Meds) influence on FF results inside groups of non-fallers (NF), fallers (F) and recurrent fallers (RF),  $p < 0.05$ . Discussion: All the FF results were correlated with FP (40.6%) for the entire sample. Age was negatively associated with FF tests results, especially in RF group. FoF was correlated with FF results in NF and F groups, but in the RF group only CR test was associated with this variable ( $r = -0.4$ ). Meds presented also a negative correlation with FAB6 and 2min tests in all groups (NF, F,

RF) and in the F group this variable also appears to affect the CR test results ( $r=-0.4$ ). Conclusions: FF tests showed to be relevant factors for falls and Age, Meds and FoF seems to influence negatively functional fitness status in this group. 1.Skelton, D. A. (2001). ### **MUCOSAL IMMUNE MARKERS AND FUNCTIONAL FITNESS IN MIDDLE AGED MEN UNDERGOING DIFFERENT LEVELS OF PHYSICAL ACTIVITY**

Teixeira, S.

*University of Coimbra*

Mucosal immune markers and functional fitness in middle aged men undergoing different levels of physical activity. Teixeira, S.I, Ferreira, J.P1., Teixeira, A.M1. 1 Research Centre for Sport and Physical Activity, Faculty of Sport Sciences and Physical Education, Coimbra University, Coimbra, Portugal. Introduction Medical care is improving and resulting on a longer life expectancy for us and for the future generations. The aim of this study was to see if there were differences in mucosal immunity between groups that have different levels of physical activity routines (sedentary, regular moderate exercise and regular athletics training and competition). Methods The study participants were 52 men age, divided into 3 groups: sedentary (74.5+/-10.2 years old, 1.7+/-0.1m stature and 77.1+7-11.0kg body mass), active (69.9+/-6.4 years old, 1.7+/-0.1m stature and 81,0+/-13.1kg body mass) and veteran athletes (62.5+/-5.6 years old, 1,7+/-0.1m stature and 76.6+/-7.3kg body mass). They all signed an informed consent form. Functional fitness was evaluated using the senior Fitness Test battery tests (1). Anthropometric measures (BMI and navel perimeter) were also assessed. Saliva samples were also collected and levels of IgA, alpha-amylase were determined by ELISA. Statistical analysis was done using the ANOVA one way for differences between groups and the bivariate Pearson's correlation for the association between variables. The significance level was set at  $p<0.05$ . Results As expected the veteran athletes (middle distance and marathon runners) showed the best results for the functional fitness tests with significant differences for lower and upper body strength, aerobic resistance and agility and balance between the sedentary and active groups and between the sedentary and veteran athletes groups. Differences in salivary alpha-amylase concentration, salivary IgA concentration and secretion rate were also found between the veteran and active groups, with higher values for the veteran athletes. No anthropometric differences were found between the 3 groups. Correlations were found between the navel perimeter and all the functional fitness tests analyzed. The navel perimeter also correlated with salivary flow rate. Discussion The veteran athletes show better mucosal immunity values than the elderly active, which could be due to their higher activity levels. Very prolonged exercise and periods of intensified training can lead to a decrease in salivary IgA values (2), which does not seem to be the case with our veteran athletes probably because their training load is not as heavy as expected (minimum 1h running, 3x week). In turn an increase in mucosal immunity seems to have occurred which is in accordance with studies showing improved salivary IgA and alpha-amylase levels in subjects undergoing regular moderate exercise. ### **ELDERLY PEOPLE IN OUTDOOR ACTIVITY PARKS**

Diketmüller, R., Kolb, B., Mayrhofer, R., Studer, H.

*University of Vienna*

Introduction The City of Vienna has recently constructed several outdoor activity parks to promote physical activity for elderly people. Although there is no evidence yet as to whether the target group is actually using these parks, politicians are intrigued to set up similar parks across the city. The project „Let's go outside!“ focuses on: who is using the existing parks in what manner, how elderly people evaluate the parks and what are the specific needs of elderly people to exercise in open spaces. The aim was to develop guidelines for planning and managing outdoor activity parks for the city. Methods Following McKenzie's System for Observing Play and Recreation in Communities an observation method was developed to qualitatively describe and quantitatively evaluate elderly's usage patterns of outdoor activity parks (n=246 hours). Five outdoor activity parks were systematically observed and analysed focusing on the target group (60+). A subgroup of elderly was invited to inspect the parks, assess and evaluate the equipment and the suitability of the infrastructure for their target group. Results The results show that elderly people (60+), for whom the parks were explicitly constructed, only seldom visit (5-21%) or use aphysically actively the outdoor activity parks (0,3 - 8%). The five analysed cases are very different and appeal to heterogeneous user groups. In order to encourage the use of the parks it is essential to consider the setting of the equipment, the material quality, physical activity instruction and programmes and accessibility. The outcomes of the park observations, interviews and focus group discussions provided the basis for the guidelines, which were developed in a participatory process with elderly people, park advisors, as well as social workers, planners and experts in the field of physical activity and sports. Discussion and conclusions The results illustrate the importance of the specific needs of the heterogeneous target group for the planning of new outdoor activity parks. Supervised physical activity programmes support elderly in their engagement in public open space. The integration of the results of the focus group into the urban planning guidelines have been a major contribution from a setting-based (health promotion) perspective. #### **DISTINCT AND ADDITIVE EFFECTS OF SODIUM BICARBONATE AND MILD HEAT STRESS ON A FIBER TYPE SHIFT VIA CALCINEURIN-NFAT PATHWAY IN HUMAN SKELETAL MYOBLASTS**

Tetsuo, Y.1, Naoshi, F.2

*National Hospital Organization Sagami Hospital*

**Introduction** Ingestion of sodium bicarbonate (NaHCO<sub>3</sub>) is known to enhance performance, probably via increased buffering of intracellular acidity. So far, little is known about direct effects of NaHCO<sub>3</sub> on myogenesis, especially in vitro. We have previously shown that continuous mild heat stress (CMHS) at 39°C induces a fast-to-slow fiber type shift of mammalian myoblasts. In this study, we examined the effects of NaHCO<sub>3</sub> and the combined effects of NaHCO<sub>3</sub> and CMHS on the differentiation of human skeletal muscle myoblasts (HSMMs) under culture conditions. **Methods** We used commercially available HSMMs of normal human skeletal muscle. Cells were seeded in the growth medium and incubated at 37°C until they reached 60-70% confluency. Then, the medium was changed to differentiation medium and supplemented with either 11, 22, or 33 mM NaHCO<sub>3</sub>. The cells were cultured at 37°C or 39°C for 7 d and harvested for Western blot analysis and real time PCR. We also performed loss- and gain-of-function experiments of individual NFATc isoforms. **Results** With increasing NaHCO<sub>3</sub> concentration, the mRNA levels of myosin heavy chain (MyHC) type I were increased, whereas those of MyHC IIx were unaltered. The NaHCO<sub>3</sub>-induced fast-to-slow shift was enhanced by CMHS. Likewise, intracellular calcium levels, the expression levels of NFATc2, NFATc4, and mitochondria related genes (PGC-1α, mtFA, and COX I) were upregulated with increasing NaHCO<sub>3</sub> concentration, which were additively enhanced by incubation at CMHS. Overexpression and knockdown experiments demonstrated that NFATc2 and NFATc4 regulate MyHC I expression. **Discussion** NaHCO<sub>3</sub> and/or CMHS induced a fast-to-slow fiber type shift, in which NFATc2 and NFATc4 acted as functional molecules. NaHCO<sub>3</sub> and/or CMHS also upregulated mitochondria related genes expression and membrane potential. From the viewpoint of cells under culture condition, we postulate that the supplementation of NaHCO<sub>3</sub> enhances mitochondrial function. NaHCO<sub>3</sub> and CMHS have an additive effect on a fast-to-slow fiber type shift and PGC-1α expression, which may provide insight into prevention of metabolic disease. **References** Yamaguchi, T., T. Suzuki, H. Arai, S. Tanabe, and Y. Atomi. 2010. Continuous mild heat stress induces differentiation of mammalian myoblasts, shifting fiber type from fast to slow. *Am J Physiol Cell Physiol* 298:C140-148.

#### **RECOMBINANT ERYTHROPOIETIN TREATMENT ENHANCES VO<sub>2</sub> MAX AND MYOGLOBIN CONCENTRATION IN HUMAN SKELETAL MUSCLE.**

Guadalupe Grau, A.1,3, Helbo, S.2, Plenge, U.4, Marianne Kristensen, M.3, Fago, A.2, Dela, F.3, Boushel, R.3,4, Belhage, B.4, Helge, J.W.3

*University of Las Palmas de Gran Canaria, University of Copenhagen, University of Aarhus*

Recombinant erythropoietin (rEPO) treatment has been shown to enhance endurance performance to a greater extent than what can be accounted for by increased blood oxygen carrying or diffusion capacity. This could be explained by peripheral adaptations in target tissues such as skeletal muscle, where EPO receptors are present, yet their function has not been elucidated. Moreover, mitochondrial oxidative capacity has been recently demonstrated to be higher after rEPO treatment. This led to our hypothesis that part of the ergogenic effect rEpo treatment resides in an effect on skeletal muscle myoglobin expression. **Methods.** Human EPO was administered by muscular injection (5000 IU IM once weekly) in 6 healthy volunteers over 8 weeks. One week of daily sub-cutaneous (SC) injections of 5000 IU of rEpo, followed by one week without treatment. Followed by one weekly SC injection for seven weeks, titrating the rEpo dosage to maintain haematocrit level at 50% IU. Oral iron (100 mg) supplementation was also given daily. Body composition was measured by DXA. Subjects performed a graded cycle ergometer exercise test where VO<sub>2</sub>max was measured. Capillarization was measured by immunohistochemical staining, whereas the concentration of myoglobin (Mb) was measured spectrophotometrically. VEGF protein expression was measured by Western Blot. **Results.** As expected, rEPO significantly increased blood haematocrit by 51%, and VO<sub>2</sub>max (from 54±3 to 58±3 ml.kg<sup>-1</sup>.min<sup>-1</sup>, P<0.05) without any exercise intervention. In the muscle myoglobin expression was higher after rEPO treatment (from 5.75 ± 0.70 to 6.89 ± 0.90 mg/g; P<0.05), whereas both the skeletal muscle capillarisation (from 4.89 ± 0.26 to 4.68 ± 0.49 Cap. per fiber) and the VEGF to tubulin α protein expression (from 3.8 ± 1.0 to 5.3 ± 3.9 a.u. P=0.3) remained unchanged. **Conclusion.** Higher myoglobin concentration was found in human skeletal muscle after rEpo treatment. The higher muscle oxygen transport capacity supports the presence of higher VO<sub>2</sub>max and may also be beneficial during endurance exercise. **Acknowledgements** This study was supported by grants from the ULPGC, Manuel Morales Foundation.

#### **DOWN-REGULATION OF INTERLEUKIN-1 RECEPTOR AND TOLL-LIKE RECEPTOR PATHWAYS IN NEUTROPHILS FOLLOWING PROLONGED, INTENSE EXERCISE**

Neubauer, O.1,2, Sabapathy, S.2, Lazarus, R.3,5, Ashton, K.4, Desbrow, B.2, Jowett, J.3, Cameron-Smith, D.6, Haseler, L.2, Wagner, K.H.1,2, Bulmer, A.2

**Introduction** Prolonged, strenuous exercise induces a systemic inflammatory response that is followed by counter-regulatory and anti-inflammatory responses during the recovery period (Neubauer et al., 2008). Neutrophils play an essential role in these responses, and they are critical for tissue repair, remodelling, growth (Walsh et al., 2011), and the resolution of inflammation (Theilgaard-Mönch et al., 2006). Evidence is emerging that the underlying mechanisms in neutrophils are regulated by highly coordinated transcriptional programs (Radom-Aizik et al., 2008). **Aim** This study aimed to investigate the gene expression changes in circulating neutrophils following an experimental exercise trial (EXTR1) consisting of two hours (h) of intense, continuous cycling and running. We hypothesised that gene expression responses in neutrophils during recovery reflect the regulation of pathways involved in the systemic inflammatory response, and in sub-

sequent counter-regulatory mechanisms. Methods Eight healthy, endurance-trained, male subjects (age:  $25.0 \pm 4.1$  years;  $VO_2$  peak:  $56.3 \pm 6.7$  mL.kg<sup>-1</sup>.min<sup>-1</sup>) participated. Skeletal muscle and blood samples were taken one week before the EXTRI (baseline), and 3 h, 48 h, and 96 h post-EXTRI under standardized conditions. Microarray analysis was performed using the Illumina iScan platform. Differential expression in a paired design was tested using lumi and limma from Bioconductor. Gene set enrichment analysis (GSEA) was used to identify enriched molecular signatures chosen from the Molecular Signatures Database. Differential expression of selected genes was confirmed via RT-qPCR. Results Circulatory neutrophil counts increased 3 h post-EXTRI ( $P < 0.001$ ) and returned to baseline 48 h post-EXTRI. Genes associated with neutrophil activation (eg., CAMP), viability (eg., SOD2, MCL1), and tissue damage (eg., S100A12) were up-regulated 3 h post-EXTRI ( $P < 0.05$ ). GSEA indicated an up-regulation of the interleukin (IL)-1 receptor (IL1R) and toll-like receptor (TLR) pathways 3 h post-EXTRI (FWER  $p$ -value  $< 0.05$ ). Up-regulated genes that are associated with these pathways included IL1RN (encoding the anti-inflammatory cytokine IL-1 receptor antagonist), IRAK3 (a negative regulator of IL1R-/TLR-signalling), IL1R1, TLR6, and FADD (a regulator of TLR-mediated apoptosis, and a negative regulator of innate immune signalling). Discussion The transcriptional regulation of IL1R- and TLR-pathways indicates the acute activation of innate immune cellular activity in response to exercise. The up-regulation of IL1RN, IRAK3, and FADD appear to contribute to an early counter-regulation of these pathways. These data suggest a novel mechanism, by which neutrophils negatively regulate the innate immune response to exercise to avoid overshooting inflammation. References Neubauer O. et al. ### MORNING-TYPES ARE PREVALENT IN ATHLETES PARTICIPATING IN INDIVIDUAL SPORTS

Rae, D.E., Kunorozva, L., Stephenson, K.J., Roden, L.C.

*University of Cape Town*

Introduction Recently, a link between an individual's diurnal preference (i.e. chronotype) and a variable number tandem repeat (VNTR) polymorphism in the Period 3 gene (PER3) has been demonstrated. The longer PER35 and shorter PER34 alleles have been associated with a preference for mornings and evenings respectively. The extent to which this chronotype-genotype relationship exists in athletic populations has not been determined. Methods Caucasian, male cyclists (CYC,  $n=125$ ,  $37.2 \pm 7.1$  years old,  $9.5 \pm 7.1$  years training), runners (RUN,  $n=120$ ,  $35.6 \pm 7.1$  years old,  $9.4 \pm 7.1$  years training), Ironman triathletes (IM,  $n=287$ ,  $36.8 \pm 6.5$  years old,  $2.2 \pm 1.8$  years training) and a control population of active, non-competitive individuals (CON,  $n=96$ ,  $32.9 \pm 8.1$  years old,  $6.1 \pm 6$  years of training) participated in this study. The chronotypes of all CYC, RUN and CON participants and a sub-sample of the IM group ( $n=49$ ) were assessed using the Horne-Östberg Morningness-Eveningness Personality Questionnaire. The PER3 VNTR genotype for each participant was determined by a PCR-based test using DNA extracted from buccal or blood samples. Results The CYC, RUN and IM groups contained more morning-type individuals (CYC: 79%; RUN: 72%; IM: 65%) than the control group (42%,  $p < 0.001$ ). Furthermore, the athletic populations contained more individuals genotyped as PER35/5 – i.e. homozygous for the "morning-type" allele – (CYC: 41%; RUN: 23%; IM: 28%) than the control group (9%,  $p < 0.001$ ). The prevalence of the PER35 allele was greater in the athlete groups (CYC: 61%, RUN: 58%, IM: 56%,  $p < 0.001$ ) than the control group (38%,  $p < 0.001$ ), and differed from reported frequencies in other populations world-wide. When the data from all four groups were pooled, a strong relationship between chronotype and PER3 VNTR genotype was observed ( $p < 0.001$ ). Finally, the time of day at which the athletes preferred to train was related to their chronotype ( $p < 0.001$ ). Of all the morning-types in this study 77% reported preferring to train in the morning. Similarly, 79% of the evening-types preferred to train in the evenings. Discussion This is the first study to demonstrate the chronotype-PER3 VNTR genotype association in an athletic population. Based on our data, Caucasian males participating in individual endurance sports with early start times in South Africa are more likely to be morning-type individuals. Furthermore, the PER3 VNTR may be one of the factors contributing to this observation. Future investigation into the relationships between chronotype, genotype, performance and efficacy of training time of day is warranted.

### INVOLVEMENT OF INFLAMMATORY TRANSCRIPTION FACTORS IN THE RESPONSE OF ELDERLY WEIGHT LIFTERS AND SEDENTARY CONTROLS TO A SINGLE BOUT OF RESISTANCE EXERCISE

Wessner, B.1, Gryadunov-Masutti, L.1, Ferunaj, P.2, Erindi, A.2, Ploder, M.3, Tschan, H.1, Bachl, N.1

1: *University of Vienna, Centre for Sport Science an University Sports, Austria*, 2: *Academy of Physical Education and Sport "Vojo Kushi", Tirana, Albania*, 3: *Medical University of Vienna, Austria*

Introduction: Ageing is associated with progressive loss of muscle mass and function. It is known that resistance exercise training provides an effective measure to counteract this process even at a very old age (ACSM et al., 2009). However, intense resistance exercise has been shown to cause a significant inflammatory response by transiently activating nuclear factor- $\kappa$ B (NF- $\kappa$ B) signalling in human skeletal muscle of young subjects during the first few hours post exercise (Velle et al., 2011). It is not clear whether this holds true for trained and untrained elderly subjects. The aims of the current study were to evaluate whether the NF $\kappa$ B signalling pathway would be activated and differentially regulated between elderly elite weight lifters and sedentary age-matched controls after a single bout of resistance exercise. Methods: Eight elderly ( $61 \pm 9$  y) still active master weight lifters (WL) and 8 ( $61 \pm 8$  y) sedentary controls (SED) were recruited from the Tirana (Albania) area. At least 2 d after assessment of 1-RM, a unilateral leg extension exercise session was applied (3 sets, 70-75% of the 1-RM until voluntary fatigue, 2-min rest between the sets). Three hours after termination of the exercise, skeletal muscle biopsies were taken from m. vastus lateralis of the exercised leg (EX) as well as the control leg (CO). Tissues were immediately stored in RNAlater solution and frozen until analyses. After extraction of RNA and cDNA synthesis, PCR arrays (RT<sup>2</sup> Profiler™ PCR Array Human NF $\kappa$ B Signaling Pathway, SABiosciences) were applied on pooled samples. Up-regulation of genes was confirmed on the individual samples using real-time PCR and GAPDH as endogenous control. Results: The groups did not differ in age, BMI, height, and weight. As expected the relative 1-RM was significantly higher ( $+24\%$ ,  $p < 0.05$ ) in WL than in SC. The PCR array provided evidence that EGR1, FOS, and JUN would probably be up-regulated due to resistance exercise whereas none of the tested genes was identified to be differentially regulated between SC and WL. This was confirmed by the evaluation study showing a 13.6- ( $p=0.003$ ), 3.2- ( $p=0.043$ ), and 2.7-fold ( $p=0.036$ ) increase in EGR1, FOS, and JUN mRNA due to resistance exercise but no differences between SED and WL. Conclusion: We could show that a single bout of exercise is able to affect inflammatory transcription factors in trained as well as in untrained elderly individuals. Interestingly, EGR1 was highly up-regulated due to resistance training. Although the exact role of EGR1 is unclear up to now, there is a link to SIRT1 which is involved in the regulation of factors involved in differentiation, survival, apoptosis, inflammation and stress response. ## CO-INGESTION OF CARBOHYDRATE AND WHEY PROTEIN ISOLATES ENHANCE PGC-1A MRNA EXPRESSION IN TRAINED ATHLETES

Hill, K., Stathis, C., Grinfeld, E., Hayes, A., McAinch, A.

*Victoria University*

**Introduction** Adaptations with endurance training induce improvements in muscle oxidative energy capacity and mitochondrial biogenesis. The regulation of protein synthesis involves several signalling pathways which are influenced by amino acids, insulin and mechanical stimulation. PGC-1 $\alpha$  plays a vital role in regulating mitochondrial biogenesis by co-activating a number of transcription factors involved in the adaptation process. Limited research exists on the benefits of protein supplementation for endurance athletes, in particular the effects of co-ingestion of whey protein isolates and carbohydrate on endurance training adaptations. The aim of the present study is to therefore, investigate the effects of 2 weeks of co-ingestion of whey protein isolate and carbohydrate supplementation on endurance recovery processes. **Method** Six endurance trained male cyclists and triathletes (age  $29 \pm 4$  years, weight  $74 \pm 2$  kg,  $VO_2$  max  $63 \pm 3$  ml oxygen. kg<sup>-1</sup>. min, height  $183 \pm 5$  cm; mean  $\pm$  SEM) were randomly assigned to one of two dietary interventions in a single blind cross over design; carbohydrate (CHO) or carbohydrate and whey protein isolates (CHO+WPI). Each dietary intervention was followed for 16 days which included 2 days having increased CHO content, re-presenting a loading phase. The dietary interventions were iso-caloric and carbohydrate content matched. Participants then performed a controlled exercise bout, followed by time trial to exhaustion. Blood samples and muscle biopsies were taken at various time points. **Results** Plasma insulin was significantly increased in the recovery period at 180 mins ( $P < 0.05$ ) and PGC-1 $\alpha$  mRNA expression was significantly up regulated in the CHO+WPI group at the end of 6 hours of recovery ( $P < 0.05$ ), compared to CHO group. Muscle glycogen concentration were comparable at rest, decreased ( $P < 0.05$ ) following exercise and increased at the end of 6 h recovery. **Conclusion** The results suggest co-ingestion of CHO+WPI supplementation benefits recovery and adaptations to endurance exercise. Protein supplementation with adequate carbohydrate availability during training did not influence pre and post muscle glycogen levels. However, increases in plasma insulin content and muscle PGC-1 $\alpha$  mRNA expression, indicates a response in metabolism for improved adaptations to training.

### IS-SH01 Intervention Development Using Social, Environmental and Psychological Approaches

## PSYCHOLOGICAL AND ENVIRONMENTAL DETERMINANTS OF BEHAVIOUR CHANGE FOR PHYSICAL ACTIVITY AND SEDENTARY BEHAVIOUR

Brug, J.

*VU University Medical Center*

**Introduction** Lack of physical activity (PA) is an important determinant of avoidable burden of disease. Planned promotion of PA requires insights into important and changeable determinants of behaviour change. The modest effects of health education have induced a shift in focus from personal to environmental correlates of PA. **Methods** This presentation will use results from systematic reviews, mediation analyses and original observational studies conducted within the European Commission FP7 projects HOPE and ENERGY to provide an overview of recent evidence regarding the importance of psychological and environmental factors as potential determinants of PA. **Results** The series of reviews indicate that there is still lack of consistent evidence for the importance of contextual factors as determinants of PA. This lack of evidence for association should not be interpreted as evidence for lack of associations because the reviews made clear that few studies had been replicated, many studies used weak research designs and non-validated measures, were restricted to micro-environmental factors, and failed to apply multilevel analyses. Furthermore, the evidence shows that perceived environments may be more important correlates of behaviour than objective environmental characteristics, and the relative importance of environments may differ substantially according to the specific PA studied. Additionally, socio-cultural environments may be more important than physical or build environmental factors. Further mediation analyses suggest that the influence of environmental factors is often mediated by individual level, social cognitive factors, such as attitudes, beliefs and intentions. **Discussion** The available intervention studies confirm that interventions that focus on trying to change individual level and environmental determinants, i.e. that try to improve motivation, abilities and opportunities for PA, are more likely to be successful. **References** Brug J, Te Velde SJ, Chinapaw MJ et al. ## DEVELOPING, EVALUATING AND IMPLEMENTING A COMMUNITY PHYSICAL ACTIVITY INTERVENTION: FROM 10,000 STEPS GHENT TO 10,000 STEPS FLANDERS

De Bourdeaudhuij, I.1, De Cocker, K.1, Van Acker, R.1, Brown, W.2, Cardon, G.1

*Ghent University*

**Introduction** Previous studies showed the potential of multi-strategy community-based approaches to changing physical activity. The first aim of this presentation is to describe the effectiveness of the physical activity promotion project '10,000 Steps Ghent' after 1 year and after 4 years of intervention. The second aim is to report on the wide-scale dissemination of this effective whole-community program in Flanders using the RE-AIM framework. **Methods** A multi-strategy community-based intervention was implemented in Ghent (about 240.000 inhabitants) in 2005 with 1 year follow-up measurements in 2006 (n=866) and 4 year follow-up measurements in 2009 (n=420). A local media campaign, environmental approaches, the sale and loan of pedometers, and several local physical activity projects were concurrently implemented. Based on the positive results in this pilot study, this evidence-based intervention was disseminated in Flanders (about

6 million inhabitants), a large region in Belgium from 2009 onwards. Dissemination included media strategies and peer networks of specific professional organizations, such as local health promotion services. Two consecutive evaluation moments were executed, one in 2010 and one in 2011 including organizations that disseminated the program and citizens living in the work area of these organizations. Measures were structured according to the RE AIM dimensions (reach, effectiveness, adoption, implementation, maintenance). Results The multi-strategy community-based intervention proved to be effective after one year with an increase of 8% in the number of people reaching the 10,000 steps standard, and with an average increase in daily steps with about 900 in the intervention community (Ghent), compared to no increase in the comparison community. After four years, a slight increase in steps was still visible in the intervention community compared to a decrease in the comparison community. The dissemination and wide-scale implementation of the program was found to be effective with 90% of all organizations being aware of the 10,000 Steps program, and with an increase of 9,2% of the population meeting the 10,000 Steps recommendation between the pilot baseline measurement in 2005 and the follow-up measurement in 2011. Discussion The multi-strategy '10,000 Steps' program shows potential for wide-scale dissemination but a supportive linkage system seems recommended to encourage adoption levels and high quality implementation.

### **MAKE YOURSELF COMFORTABLE – STAND UP! THE DEVELOPMENT OF AN INTERVENTION TO REDUCE SEDENTARY BEHAVIOUR IN YOUNG ADULTS AT RISK OF TYPE 2 DIABETES**

Biddle, S.

*Loughborough University*

Sedentary behaviour has become a popular area of research with evidence building for significant deleterious effects of prolonged sitting. The rising prevalence of Type 2 Diabetes Mellitus (T2DM) is a major public health problem and sedentary behaviour has been identified as a risk factor for diabetes, often independent of the time spent in moderate-to-vigorous physical activity. Project STAND (Sedentary Time ANd Diabetes) aims to reduce sedentary behaviour in younger adults at high risk of T2DM. A reduction in sedentary time is targeted using theory driven group structured education and participants are encouraged to self-monitor and self-regulate their behaviour. The intervention is being assessed in a randomised controlled trial with 12 month follow up. Inclusion criteria are a) aged 18-40 years with a BMI in the obese range; b) 18-40 years with a BMI in the overweight range plus an additional risk factor for T2DM. Participants are randomised to intervention or control arms. The primary outcome is a reduction in sedentary behaviour at 12 months as measured by an accelerometer (count <100/min). Secondary outcomes include physical activity, sitting/lying time using the ActivPAL posture monitor, fasting and 2h oral glucose tolerance test, lipids, inflammatory biomarkers, body weight, waist circumference, blood pressure, illness perceptions, and efficacy beliefs for behaviour change. This presentation will describe the rationale for the study of sedentary behaviour and outline the principles behind the intervention.

### **OP-PM22 Training and Testing: Youth population**

#### **PHYSICAL RESPONSES OF DIFFERENT SMALL-SIDED GAME FORMATS IN ELITE YOUTH SOCCER PLAYERS**

Brandes, M.1, Heitmann, A.2, Müller, L.2

*1 University Oldenburg, 2 University of Bremen*

Introduction A major use of small-sided games (SSGs) in soccer training is the concomitant development of game-specific aerobic fitness (Hill-Haas et al., 2008). We hypothesize that the SSG formats of 2 vs. 2, 3 vs. 3, and 4 vs. 4 players reveal game-like intensities and therefore are most adequate to increase game-specific aerobic fitness. Methods Heart rate (HR), percentage of maximum heart rate (HRmax), blood lactate concentration (La), and time-motion characteristics of 17 elite male youth soccer players (aged 14.9 ± 0.7 years, VO2max 61.4 ± 4.5 ml/kg/min, HRmax 199.6 ± 7.3 beats/min) were collected by global positioning systems while performing the SSG formats. Play time (2 vs. 2: 3 x 4 min, 3 vs. 3: 3 x 5 min, 4 vs. 4: 3 x 6min) was interrupted by 1.5 minutes of passive rest. Grid area was adjusted to keep a constant grid area per player at 1:150. Repeated-measures analysis of variance and effect sizes according to Batterham & Hopkins (2006) were calculated to demonstrate the differences between SSG formats. Results Highest physiological responses were obtained in 2 vs. 2 (HR: 186±7 beats/min, HRmax: 93.3 ± 4.2%, La: 5.5 ± 2.4 mmol/l) followed by 3 vs. 3 (HR: 184 ± 8 beats/min, HRmax: 91.5 ± 3.3%, La: 4.3 ± 1.7 mmol/l) and 4 vs. 4 (HR: 179 ± 7 beats/min, HRmax 89.7 ± 3.4%, La: 4.4 ± 1.9 mmol/l). Time spent with an intensity above 90% or between 85-89% of HRmax did not differ significantly between 2 vs. 2 and 3 vs. 3, but was less prominent in 4 vs. 4. Pronounced differences were found for time spent in the speed zones "walking" (<5.3 km/h), "moderate-speed running" (10.3–13.9 km/h), and "maximum sprinting" (>26.8 km/h). Discussion The findings suggest that all the formats reveal game-like intensities and are suitable for aerobic fitness improvements. The time-motion characteristics of the SSG formats tested indicate a shift towards higher velocities if the grid and the number of players increases, suggesting that the players make use of the larger pitch and off-the-ball movements. However, we found pronounced demands on the anaerobic energy supply in 2 vs. 2, whereas 3 vs. 3 and 4 vs. 4 remain predominantly on an aerobic level. As the effect sizes demonstrate a higher heart rate response in 3 vs. 3 compared to 4 vs. 4, we suggest using 3 vs. 3 for soccer-specific aerobic fitness training. If higher loads with extended anaerobic demands are aimed for, soccer coached might prefer 2 vs. 2. References Hill-Haas S, Coutts A, Rowsell G, Dawson B. (2008) J Sci Med Spo 11, 487-90. ## EVALUATION OF AN EYE-HAND COORDINATION TEST FOR TALENT IDENTIFICATION IN TABLE TENNIS; A VALIDITY AND REPRODUCIBILITY STUDY

Faber, I.R., Nijhuis-van der Sanden, M.W.G., Oosterveld, F.G.J.

*Saxion University of Applied Science*

**Introduction** Talent identification programs (TID) in sports can provide an optimal advise to connect personal preferences, talents and choices in sports. As a result, both elite sports and sports on amateur level benefit from these programs. TID often contain tests to assess specific sport skills in athletes which are considered to be key-predictors for success (Régnier et al., 1993). In this context, valid and reliable tests are essential to obtain trustworthy results. In this study, an eye-hand coordination test was evaluated, which could be used in a test battery for motor skills for TID in table tennis. Good eye-hand coordination is suggested to be a necessary trait to excel in table tennis (Rodrigues et al., 2002) but also in other racket sports, hockey, volleyball or basketball. **Methods** In total 43 youth table-tennis athletes (age 7-12 years) from national (n=13), regional (n=11) and local training-level (n=19) were tested. The children were instructed to throw a ball to a vertical positioned table tennis table with one hand and to catch the ball correctly with the other hand as frequently as possible in 30 seconds. The best of two attempts was registered as final score. The test consisted of four subtests in which the distance to the table tennis table (1 or 2 m) and the ball (table tennis or tennis ball) were varied. 10 children did a retest after 4 weeks to calculate reproducibility. For validity a one-way ANOVA was used to test whether the test could discriminate between the children from different training-levels. Mean differences for test-retest were used to present results of reproducibility (Bland-Altman plot). Results Subtest-means (SD) ranged from 15-29 (SD 5-7) for the national level, 15-26 (SD 3-5) for regional level and 8-17 (SD 5-7) for local level. All subtests were able to discriminate between national and local level and between regional and local training level ( $p < 0.05$ ). However, there was no significant difference between the national and regional training level. Reproducibility seems sufficient for all subtests; mean differences for test-retest were between -2.7 and 0.2 (SD 2.9-4.5). **Discussion** This eye-hand coordination test appears to be a valid and reproducible tool and implementation in a test battery for motor skills in TID for table tennis seems legitimate. Further research is desirable to obtain evidence for the use of the test in other sports. **References** Régnier G, Salmela JH, and Russell SJ (1993). ## THE RELATIONSHIP BETWEEN AGILITY AND LINEAR SPRINT PERFORMANCE IN YOUNG ELITE SOCCER PLAYERS

Stöcker, F., Herdener, L., Oberhoffer, R., Schulz, T.

*Technische Universität München*

**Introduction** The diversity of sprint ability is an integral part in soccer and has often game-winning relevance. Sprint actions represent approx. 11% of the total covered distance in a soccer match (Little & Williams, 2005). Detailed researches show: About 50% of sprint actions in professional soccer are finished after 10m. Nearly 40% of these actions have one or more changes in direction (Rehagel, 2011). Therefore the ability to change running direction while moving with high speed is very important in soccer. As a result, agility sprint ability is crucial for soccer-specific performance (Svensson & Drust, 2005). This study aims to investigate the relative loss of time (RLT) while performing an agility sprint protocol (AS) in comparison to a linear sprint (LS). **Methods** 142 elite youth soccer players participated in this study; they were divided into three groups (G1: 11-12j, n=52; G2: 13-14j, n=63; G3: 15-16j, n=26). LS consisted of a 30m linear sprint with 1m flying start. The course of the AS is also 30m long and has the same starting conditions but is arranged in a triangled shape. Section lengths (5m-4m-1m-1m-4m-1m-1m-4m-5m) and angles of the turns (135°-45°-90°-45°-90°-45°-90°-45°-135°) in AS were designed matching soccer-specific changes in directions and running distances (Rehagel, 2011). All persons performed both the AS (once in both directions) and the LS with full recovery period in between. The results of AS for each direction were summarized (AS<sub>total</sub>). The RLT (%) was calculated as followed:  $(AS_{total} - (2 \times LS)) / LS \times 100$ . Statistical analysis were using Pearson's correlation coefficient. Normal distribution was not granted for LS in G2, therefore Spearman's rank coefficient was calculated. Results AS<sub>total</sub> and LS had a significant correlation in all groups (G1: 0.752,  $p < 0.001$ ; G2: 0.591,  $p < 0.001$ ; G3: 0.536,  $p = 0.002$ ). Also RLT and LS were correlated at high levels of significance (G1: -0.461,  $p < 0.001$ ; G2: -0.643,  $p < 0.001$ ; G3: -0.636,  $p < 0.001$ ). **Discussion** Although agility sprint performance is significantly positively correlated with linear sprint performance in young elite soccer players, these findings suggest, the better the linear sprint ability, the bigger gets the relative loss of time. In conclusion the LS seems to be a reasonable test to predict the agility sprint performance. In higher level of sprint performance testing designs should include both linear and multidirectional tests. **References** Little, T., & Williams, A. G. (2005). Specificity of acceleration, maximum speed, and agility in professional soccer players. ## A MULTIDISCIPLINARY APPROACH TO SELECT JUNIOR HANDBALL PLAYERS: GENERAL MODEL

Massuca, L.1,2,3, Fragoso, I.3

1: UL-FEFD (Portugal); 2: ICPOL-ISCPSP (Portugal); 3: FMH-UTL (Portugal)

**Introduction** Research on expertise or in talento identification has tended to be mono-disciplinary (Phillips et al., 2010) or focused in the inter relationships between morphologic and fitness profiles. In accordance, this study aims to evaluate: (1) the contribution of morphologic, fitness, handball-specific skill, psychological and biosocial profiles to the prediction of handball players' success; and (2) the applicability of said model to the prediction of success in junior handball players. **Methods** A sample of male handball players (HB; n=225) were divided into three groups: (1) top elite (n=41); (2) non-top elite (n=126); and (3) junior elite (n=58). Morphologic, fitness, handball-specific skill, psychological and biosocial profiles were determined according to Massuca, Fragoso and Teles (in review). One logistic regression (Forward: LR) was performed, with success as dependent variable (Success=1, if the HB is a top elite athlete; Success=0, if the HB is a non-top elite athlete) and each category as predictors. Results When the entire sample was considered, logistic regression revealed that the fitness ( $b=3.828$ ,  $X^2_{Wald}(1)=17.180$ ,  $P < .001$ ,  $OR=45.978$ ), the psychological ( $b=-20.343$ ,  $X^2_{Wald}(1)=37.484$ ,  $P < .001$ ,  $OR=0.000$ ) and the "biosocial" profiles ( $b=2.011$ ,  $X^2_{Wald}(1)=4.986$ ,  $P < .05$ ,  $OR=7.471$ ) have a significantly contribute to the prediction of success ( $G^2(3)=106.802$ ,  $P < .001$ ; correct class. = 91.1%). This multidisciplinary model allowed us to identify 4 HB junior athletes with more than a 50% of probability of success. **Discussion** It seems that fitness profile plays an important role and contributes to a great extent to high performance in handball. However, it seems that only an ideal fitness profile is not sufficient to be successful in handball. In fact, this study also showed that "biosocial" profile is also associated with handball players' success (see Massuca & Fragoso, 2010). Given the complexity of handball, it is understandable that a degree of scepticism exists as to the relevance of talent selection but, the present

study investigated the relationship of a 5 categories of variables with success at a senior elite level. Furthermore, athletes are target for inclusion in development squads at a junior level therefore it is appropriate that investigations are carried out with these age groups. Moreover, our findings may provide a useful contribution to a first examination of the "Long Term Athlete Development Model" (Ford et al., 2011) in handball players. Study of Portuguese handball players of different playing status. A morphological and biosocial perspective. *Biology of Sport*, 28(1), 37-44.

### THE D-TEST: A NEW TOOL FOR ASSESSING THE AGILITY OF YOUNG SOCCER PLAYERS IN PRE-FORMATION CATEGORIES

Segui, R., Dellal, A., Pialoux, V., Hautier, C.

*UFR-STAPS*

**Introduction** The development of the agility is essential in young soccer players, and it constitutes the aim of the training in the process of pre-formation. However, the majority of agility test is destined for the talent identification or adult players. Therefore, it appears that there is a lack of specific tool to test the agility and motricity especially in pre-formation categories. Consequently, the aim of this study was to examine the interest of a new tool, the D-Test, and to show if this test discriminate the agility skills in soccer either by category or the playing positions in youth players of pre-formation. **Methods** 60 young elite players from the pre-formation categories of the same club (Olympique Lyonnais FC) participated in this study: U13(n=19, height: 151.4±7.8 cm, body mass: 42.1±6.4 kg), U14 (n=21, height: 163.7±7.6 cm, body mass: 52.32±7.8 kg) and U15 (n=20, height: 167.7±8.2 cm, body mass: 54.2±9.2 kg) including in whole categories 6 goalkeepers, 7 central defenders, 14 full-backs, 13 axial midfielders, 13 external midfielders and 7 forwards. All players performed 3 times the D-Test (2 trials) in 3 different period of the competitive season 2011-2012. The conditions were standardized with the application of the test on a new-generation artificial turf in the same of the day and the performances were measured using photocell (Polifemo® Microgate, Bolzano-Bozen, Italy) placed at hip height. Practically, the D-Test consisted by the combination of the following sequence (on 20m): rolling start, lateral motricity (3m + 3m), ground reaction footwork with a rhythm hurdle (4x40cm), three short acceleration short (3x4m) interspaced by two 180° changes of directions with an alternance of the leg used (one time with the right leg and the other time with the left leg). **Results** A significant difference between age group (F= 6-60, p<0.01) was found. The U13 had significantly slower performance in the D-Test compared to U14 (p<0.01) and U15 (p<0.01). Moreover, the inter group analysis showed no significant difference between playing positions (p<0, 05), whereas a significant difference were observed in U13 and U14 with greater performance of external midfielders and forwards (p<0.05). **Discussion** The major findings of the present study demonstrated that the D-Test is an interesting assessment tool in the determination of the agility skills of young soccer players according to the playing position, allowing to direct the specific method of individual training.

### IS-PM07 Exercise to Reduce Musculoskeletal Pain (\*)

#### STRENGTH, ENDURANCE, AND BALANCE TRAINING TO CONQUER WORK RELATED MUSCULOSKELETAL PAIN

Sogaard, K.

*Institute of Sports Science and Clinical Biomechanics*

Physical exercise has been shown to be effective in the prevention and treatment of work-related musculoskeletal disorders (2), with most evidence obtained from interventions targeting sedentary jobs (8) and by use of intense strength training (1). Physical exercise may also benefit employees with physically heavy work and MSD. Probably, to optimize a health enhancing effect the content of the suggested physical exercise training program should be modified, when implemented among employers with physically heavy jobs (4). A number of Danish RCTs have used the concept Intelligent Physical Exercise Training, tailoring an exercise intervention to work exposure, employee health status and physical capacity (4). The recent interventions are among jobs with highly different exposure profiles i.e. lab technicians, cleaners, health care, pilots, and construction workers (3,5,6,7,8,9). The interventions use a broad variety of available types of training to tailor the health enhancing physical activity. The interventions are in general successful in obtaining an acute effect, such as improved musculoskeletal health, muscle strength, balance, aerobic fitness, and body weight. Therefore, the workplace as an important arena for general health promotion are supported across job with different exposure profiles. In contrast there was no consistent findings or major improvements in long term effect such as productivity, work ability and sick leave. Therefore, it is suggested that future studies should consider implementation strategies and how to introduce sustainable behavioural changes. Possibly, multi dimensional interventions, a participatory approach, and introducing individual preference in the physical activity program could optimize a long term effect. 1) Andersen LL et al. 2008;59(1): 84-91 2) Blangsted A.K. et al. *Scand J Work Environ Health*. 2008;34(1):55-65 3) Christensen JR et al. *BMC Public Health* 2011;11:671. 4) Holtermann A. et al. *BMC Musculoskeletal Health*. *BMC Public Health* 2010;10:120 5) Jorgensen, et al. *BMC Public Health* 2011;11:776. 6) Jørgensen MB et al. *BMC Public Health* 2011;11:840. 7) Lange B, et al. *Clin J Pain* 2012 (in press) 8) Zebis MK, et al *BMC Musc Dis*. 2011;12:205. 9) Gram, B et al *Scand J of Work, Environ & Health* (E-pub).

#### MECHANISMS OF SHOULDER MUSCLE PAIN AND ACTIVATION DURING EXERCISES

Madeleine, P., Vangsgaard, S., Samani, A.

*Aalborg University*

**Introduction** Shoulder injuries are frequent in relation to physical activity in sports and at work with both overhead and repetitive arm movements (Madeleine 2011). Low load movement are also found to be associated with neck-shoulder disorders. These disorders are often accompanied by pain located in deep structures of the shoulder girdle. Despite important scientific effort, our knowledge about pathophysiology of these disorders is still scarce. Moreover, these disorders have consequences for muscle function and overall perfor-

mance. The aim of this presentation is to review muscular activation in the neck-shoulder girdle in relation to various pain stages, i.e. acute, sub-acute and chronic pain. Methods Experimentally induced pain (exogenous, e.g. injection of hypertonic saline and endogenous: high level eccentric exercise inducing delayed onset muscle soreness) and clinical pain were studied. Pain intensity as well as pressure pain thresholds were assessed. Surface electromyography (bipolar and high-density) from the upper, middle and lower trapezius muscle were recorded during both static and dynamic contractions. Analyses consisted of computing pressure pain mapping and temporal and spatial changes in muscular activation. Focus will be given to a newly developed method to assess functional connectivity among muscles, i.e. normalized mutual information (Madeleine et al., 2011). Results Pressure pain mapping enabled to study the extent of hyperalgesia induced by high level eccentric exercise. We found that mechanical sensitivity is heterogeneously distributed over the trapezius prior and during DOMS (Binderup et al. 2010, Kawczynski et al., 2011) in agreement with clinical findings. Both experimental and clinical pain changed the activation profile of the trapezius sub-divisions during static and dynamic contractions (Samani et al., 2010; Madeleine 2011). The normalized mutual information among upper-middle trapezius sub-divisions increased in presence of delayed onset muscle soreness (Madeleine et al., 2011). Discussion The various extent of hyperalgesia as well as the spatial reorganization of the trapezius muscle activity in response to experimental and clinical pain during shoulder functional movement provided new information about the sensory-motor interactions. Our results provide new evidence of sensory and neuromuscular partitioning in the shoulder girdle. References Binderup AT, Arendt-Nielsen L, Madeleine P. (2010). *Eur J Pain*, 14, 705-712. ### EXERCISE AND RHEUMATOID ARTHRITIS: MOVE TO IMPROVE

Häkkinen, A.

*University of Jyväskylä*

Rheumatoid arthritis (RA) is characterized by a chronic poly-arthritis, synovial hyperplasia and erosive synovitis, progressive cartilage and bone destruction and an accelerated loss of muscle mass (rheumatoid cachexia). RA is responsible for considerable amount of disability and in turn decreases in physical activity (PA). In a large multicenter study the majority (80%) of the RA patients were physically inactive. RA patients have been found to have a 25-70% reduction in muscle strength. However, only quite a small number of studies are reporting the effects of strength training in RA. Most of these studies have expectedly reported increases from 14% to 75%, in muscle strength when the training period has been from 3 weeks up to 2 years. One study reported increased muscle mass (5.5%) after 6-month training and one positive but small effect of exercise on bone mineral density. In RA patients have also lowered cardiorespiratory fitness and higher risk of cardiovascular diseases. There are seven randomized aerobic exercise studies with RA patients. In those studies, intervention has lasted 8-12 weeks, with intensity of 50-85% of maximal heart rate and frequency of 2-5x/week. Four of these studies reported significant increase in aerobic capacity or exercise tolerance, while in 3 studies no changes were observed. Both in strength and aerobic training studies physical function and walking speed have improved and only occasional adverse effects were found (e.g. increase in pain or number of tender joints). Exercise is safe treatment for adults with RA. From all the subjects (N=590) included in 9 strength training studies, only 2 discontinued due to increased joint pain. Most of the studies reported no changes in disease activity and none of them reported progression of joint damage. However, exercise may have detrimental effect on large joints in patients with an extensive pre-existent large joint damage. Overall physical activity as well as specific exercise can be recommended as non-pharmacological treatment of RA due their generic and local health benefits. Regular exercise in RA is associated with significant reductions in morbidity and mortality and increase in health related quality of life and functional capacity. Physical activity and exercise should be a regular life-style. Therefore motivation and barriers to exercise, and beliefs about its benefits and risks, should be discussed with the patient to improve long-term adherence. References: 1. #### OP-PM23 Cardiovascular Physiology

### REGIONAL DIFFERENCES IN LEFT VENTRICULAR CONTRACTILE BEHAVIOUR FACILITATE A PROGRESSIVE RISE IN KINETIC ENERGY DURING INCREMENTAL EXERCISE

Stöhr, E.1,2, González-Alonso, J.2, Shave, R.1,2

*1 Cardiff Metropolitan University, 2 Brunel University West London*

Introduction Whilst the linear relationship between heart rate and exercise intensity is widely accepted, the response of regional (base vs. apex) LV contractile rate to incremental exercise has never been examined. Furthermore, differences in the contribution from circumferential and radial planes of motion at the LV base and apex may limit the rise in LV kinetic energy (EK) required for enhanced ejection at progressively increasing exercise intensities. We hypothesised that during incremental exercise, 1) the rise in contractile rate would significantly differ across LV regions and 2) despite an enhanced contractile rate, the increase in absolute Ek produced during each contraction would be limited by the progressively shortened systolic duration. Methods Nine healthy men (age: 26±4 yrs, peak heart rate: 173±14 bpm) performed continuous and discontinuous incremental exercise on a supine cycle ergometer. At rest and throughout exercise, we measured strain rate (SR, index of contractile rate) in the circumferential and radial planes of motion at the LV base and apex, respectively. Data were collected using novel 2D speckle tracking ultrasound. LV mass was estimated as myocardial area multiplied by the specific gravity of muscle (1.05g/m<sup>2</sup>). Total systolic Ek per beat was calculated as the integral of (1/2 regional mass)•(regional strain rate<sup>2</sup>) over the systolic ejection time. Results During continuous incremental exercise, circumferential and radial SR increased progressively from rest to 90% of maximal exercise capacity (r<sup>2</sup>= .82 to .98, P≤0.01). The regional rise in SR was significantly greater for circumferential SR at the apex (P<0.0001). Despite a significant shortening of systolic ejection time (P<0.001), systolic Ek increased continuously at both the LV base

and apex ( $r^2 = .86$  to  $.99$ ,  $P < 0.01$ ). However, the rise in systolic  $E_k$  was achieved with a progressively greater contribution from radial function at the LV base and circumferential function at the LV apex. Responses were confirmed during discontinuous exercise, despite significantly different heart rates compared with the continuous exercise test ( $P < 0.001$ ). Conclusions In accordance with our first hypothesis, the rise in peak LV contractile rate during incremental exercise is non-uniform across the LV. However, in contrast to our second hypothesis,  $E_k$  increases progressively at the LV base and apex during incremental exercise. This uniform rise in  $E_k$  is achieved by region-specific contributions of LV circumferential and radial function at the base and apex, respectively. Exploration of these novel findings in other populations could provide important insight into cardiac function in health and disease.

### LEFT VENTRICULAR TWIST MECHANICS FOLLOWING EXERCISE TRAINING IN POST-MYOCARDIAL INFARCTION PATIENTS

McGregor, G.S.1,2, Stohr, E.1, Oxborough, D.3, Shave, R.E.

1Cardiff Metropolitan University, Cardiff, UK. 2University Hospital, Coventry, UK. 3University of Leeds, Leeds, UK

**INTRODUCTION:** Endurance exercise training has been shown to reduce left ventricular (LV) end diastolic and end systolic volumes in patients with myocardial infarction (MI). Whilst these structural changes are reasonably well characterised, the effects of exercise training on LV function are less well understood. The development of novel echocardiographic techniques such as speckle tracking imaging (STI) has enabled a more detailed study of global LV function. LV systolic twist, the net difference between basal and apical rotation, is a key component of efficient LV systolic contraction. The effect of exercise training on LV twist mechanics in post MI patients has not been previously reported. **PURPOSE:** To determine the effect of exercise training on resting LV twist mechanics in post MI patients following successful percutaneous coronary intervention (PCI). **METHODS:** Cardiopulmonary exercise testing (CPET) and resting echocardiography were performed on 33 male ( $56 \pm 9$  yrs) clinically stable post MI patients at baseline ( $34 \pm 7$  days post MI) and 10 weeks later. Patients were assigned to either supervised exercise training ( $n=21$ ) or control ( $n=12$ ). Supervised exercise training consisted of mixed modality (treadmill, cycle, rower, cross-trainer) exercise training for 30-40 minutes twice weekly at 60-80% of  $V_{O2}$  peak. Controls received standard general physical activity advice. **RESULTS:** The exercise training group showed significant improvements in peak  $V_{O2}$  ( $3.2 \pm 3.1$  ml.kg<sup>-1</sup>.min<sup>-1</sup>,  $P < 0.001$ ) and ejection fraction (EF) ( $2.0 \pm 4.4\%$ ,  $P < 0.05$ ) and significant reductions in EDV ( $-6.1 \pm 6.7$ ml,  $P < 0.001$ ) and ESV ( $-4.3 \pm 5.6$ ml,  $P < 0.001$ ). In contrast, peak  $V_{O2}$  ( $-0.6 \pm 3.4$  ml.kg<sup>-1</sup>.min<sup>-1</sup>,  $P > 0.05$ ), EDV ( $0.4 \pm 7.2$ ml,  $P > 0.05$ ), ESV ( $1.0 \pm 5.4$ ml,  $P > 0.05$ ) and EF ( $-1.0 \pm 4.7\%$ ,  $P > 0.05$ ) were unchanged in the control group. LV twist mechanics in the exercise training group were characterised by a reduction in apical rotation ( $-2.3 \pm 4.6^\circ$ ,  $P < 0.05$ ), unchanged basal rotation ( $-1.1 \pm 3.5^\circ$ ,  $P < 0.05$ ) and a resultant reduction in peak LV twist ( $-3.4 \pm 5.3^\circ$ ,  $P < 0.01$ ). Conversely, controls demonstrated an increase in peak LV twist ( $4.1 \pm 4.2^\circ$ ,  $P < 0.01$ ) secondary to an increased basal rotation ( $2.0 \pm 2.5^\circ$ ,  $P < 0.05$ ) and unchanged apical rotation ( $1.6 \pm 3.2^\circ$ ,  $P > 0.05$ ). **CONCLUSION:** Consistent with findings in previous studies, exercise training improves  $V_{O2}$  peak and facilitates favourable change in EDV, ESV and EF in post MI patients. Furthermore, LV systolic twist mechanics appear to be influenced by exercise training in these patients. These data offer a valuable insight into the effects of exercise training on LV function in post MI patients.

### POST-REVASCULARISATION EXERCISE TRAINING FOR PERIPHERAL ARTERIAL DISEASE

Askew, C.D., Stefanovic, B., Russell, F.D., Green, S., Walker, P.J.

Queensland University of Technology

**POST-REVASCULARISATION EXERCISE TRAINING FOR PERIPHERAL ARTERIAL DISEASE** Askew, CD. 1,2; Stefanovic, B. 2; Russell FD. 2; Green, S. 3; Walker, PJ. 4. 1: Institute of Health and Biomedical Innovation, Queensland University of Technology, 2: University of the Sunshine Coast, 3: University of Western Sydney, 4: School of Medicine, Discipline of Surgery and Centre for Clinical Research, University of Queensland (Australia). **Introduction** Peripheral arterial disease (PAD) is an atherosclerotic disease characterised by blockages in the arteries of the lower limbs. Although supervised exercise training is recommended for patients with early stage PAD and claudication, the effects of exercise training in patients who have undergone revascularisation are not clear. This study aimed to determine the effect of post-revascularisation exercise training on walking tolerance, muscle fatigue and lower limb blood flow in patients with PAD. **Methods** Fifteen patients who had recently (<6 weeks) undergone surgical or percutaneous revascularisation for PAD were randomised to either supervised exercise training (SET;  $n = 8$ , age =  $61 \pm 6$  y) or standard care (CON;  $n=7$ , age =  $65 \pm 10$  y). Patients in SET attended three training sessions per week for six weeks, and completed interval treadmill walking and progressive plantar flexion resistance exercises. Before and after the intervention period, walking capacity was determined with a six-minute walk test. Maximum voluntary contraction (MVC) force, muscle endurance, and fatigue of the calf muscles were assessed using an isometric plantar flexion dynamometer in both the revascularised and non-revascularised legs. Blood flow was assessed at rest and during exercise using strain gauge plethysmography. **Results** Six-minute walk distance increased with SET (pre  $405 \pm 89$ ; post  $452 \pm 94$  m) compared with CON (pre  $412 \pm 67$ ; post  $413 \pm 79$  m). Plantar flexion MVC force tended to increase with SET in both the revascularised (~11%) and non-revascularised legs (~15%), although this was only significant compared with CON in the non-revascularised leg. Plantar flexion endurance increased with SET in both the revascularised (pre  $541 \pm 318$ ; post  $1108 \pm 909$  s) and non-revascularised legs (pre  $623 \pm 319$ ; post  $1143 \pm 556$  s) compared with CON. The calf fatigue profile included an initial rapid exponential decay phase followed by slower linear phase, and there tended to be a shift in fatigue kinetics whereby there was a delay in the onset of the later phase following SET. There were no changes in resting or exercise blood flow in either group. **Discussion** This study demonstrates that supervised exercise improves walking capacity and calf muscle function in patients with PAD who have recently undergone revascularisation. These changes occurred in the absence of any change in blood flow, which supports notion that exercise tolerance is limited by both haemodynamic and non-haemodynamic factors in PAD.

### THE IMPACT OF LOCALISED EXERCISE TRAINING ON RADIAL ARTERY FLOW-MEDIATED DILATION AND LOW-FLOW CONSTRICTION RESPONSES FOLLOWING TRANSRADIAL CATHETERISATION

Dawson, E.A., Marsman, D.E., Alkarmi, A., Cable, N.T., Wright, D.J., Thijssen, D.H.J., Green, D.J.

Liverpool John Moores University

Transradial catheterisation leads to radial artery endothelial dysfunction. However, exercise training may ameliorate this response. Whilst the effect of exercise training on vascular dilator function has been studied, no previous study has examined the role of local handgrip exercise training on vasoconstrictor function of the radial artery following catheterisation. The aim of this study was to determine the effect of 6-week local handgrip exercise training post-transradial catheterisation on low-flow mediated constriction (L-FMC), flow mediated

dilation (FMD) and the difference between both responses (L-FMC+FMD). Eighteen patients were randomly assigned to either exercise handgrip training (N=9) or control group (N=9). Radial artery L-FMC and FMD of the catheterised radial artery were assessed using ultrasound one week prior to catheterisation and following six weeks of exercise training or similar control period. Data were compared using a 2 factor general linear model (GLM). L-FMC was unchanged in the exercise group ( $-2.14 \pm 1.42$  to  $-3.58 \pm 1.04\%$ ), but deteriorated in the control group ( $-3.26 \pm 1.19$  to  $-1.34 \pm 1.27\%$ ; interaction-effect,  $P=0.05$ ). Similarly, FMD was maintained in the exercise group ( $6.84 \pm 0.79$  to  $6.85 \pm 1.16\%$ ), but was impaired in the control group ( $8.27 \pm 1.52$  to  $4.66 \pm 0.70\%$ ; interaction-effect  $P=0.06$ ). Consequently, a reduction in L-FMC+FMD was found in the control ( $11.52 \pm 2.42$  to  $6.00 \pm 1.63\%$ ) which was prevented in the exercise group ( $8.99 \pm 1.57$  to  $10.43 \pm 1.97$ , interaction-effect  $P<0.01$ ). Our results demonstrate that exercise training prevents the prolonged decrease in FMD after catheterisation. Moreover, this is the first study to demonstrate the beneficial effects of exercise training on the L-FMC, given that training protects the decline in L-FMC and L-FMC+FMD after catheterisation.

### CHANGE IN SHEAR RATE IN THE COMMON FEMORAL ARTERY UPON CESSATION OF ISOMETRIC LEG EXERCISE PERFORMED AT INCREASING INTENSITIES

Swaine, I., Smith, J., Wiles, J.

*Canterbury Christ Church University*

**Introduction** Despite numerous reports of shear rates during dynamic exercise (Thijssen et al, 2008; Gonzales et al, 2009; Johnson et al, 2012), little is known about the shear rates during and after isometric exercise (IE). Therefore, the purpose of this study was to determine the shear rate responses in the common femoral artery during, and immediately after each stage of an incremental IE test. **Methods** 13 male participants ( $22.54 \pm 2.54$  years;  $180.02 \pm 4.20$  cm;  $77.83 \pm 10.16$  kg) completed a discontinuous incremental, bilateral leg-extension IE test. Each stage was 2 minutes, separated by 5 minutes rest. IE intensity was started at 10% EMGpeak (0.25 seconds prior to maximum voluntary contraction peak torque), and increased by 5% EMGpeak until participants reached volitional fatigue. Peak shear rate (s<sup>-1</sup>) was obtained in the common femoral artery during, and upon cessation of each IE stage, using Doppler Ultrasound. **Results** ANOVA revealed peak shear rates measured after IE were higher than those measured during IE ( $P<0.05$ ) for all IE intensities except for the lowest (30-40%). Mean peak shear rate (PSR) after IE was  $70.15 \pm 17.39$  s<sup>-1</sup>, whereas it was  $59.18 \pm 5.85$  s<sup>-1</sup> during exercise. PSR during and after exercise increased linearly with relative exercise intensity ( $r = 0.941$ ;  $p<0.005$  during;  $r = 0.993$ ;  $p<0.001$  after exercise). There was also a strong correlation between change in shear rate, upon cessation of IE, and relative exercise intensity ( $r=0.961$ ;  $p<0.001$ ). **Discussion** Shear rates during and after exercise were greater than those observed in dynamic exercise (Thijssen et al, 2008; Gonzales et al, 2008; Johnson et al, 2012) and they were intensity-dependent. Because shear rates were higher after exercise, than they were during it, this might indicate that the stimulus for training-induced adaptations might not only arise during this type of exercise, but immediately after it too. However antegrade and retrograde flow patterns need to be analysed before this can be confirmed. **References** Gonzales, J.U., Thompson, B.C., Thistlethwaite, J.R., Scheuermann. (2008). ### GENDER AND ETHNIC INFLUENCES ON AUTONOMIC CONTROL OF THE HEART IN CHILDREN

Eyre, E.L.J.1, Duncan, M.J.1, Franklin, C.1, Birch, S.L.1, Cox, V.1

*1Coventry University*

**Introduction** Reduced heart rate variability is associated with increased risk of cardiovascular disease (Tsuji et al., 1996). A number of physiological factors are known to influence heart rate variability (HRV) including gender and obesity. People from South Asian backgrounds have an increased risk of cardiovascular disease/metabolic diseases (Williams et al., 2011) which begin in childhood (Whincup et al., 2002) but no studies have examined or compared HRV in South Asian children. The aim of this study was to examine the effect of ethnicity and gender on heart rate variability in prepubertal children. **Methods** Following ethics approval and informed consent, weight status (BMI and waist circumference) was assessed in 150 healthy children (boys= 75, girls= 75, South Asian=40, White = 110, mean age  $\pm$  SD =  $8.01 \pm 0.05$  years) from primary schools in central England. R-R interval was measured during 5 minutes supine rest using Sunnto T6 heart rate monitors. Time domain (mean R-R, SDNN, NN50, pNN50 and RMSSD) and frequency domain measures (HF power and LF power) of HRV were calculated using Kubios HRV software (Biomedical Signal Analysis Group, University of Kuopio, Finland). A 2 (gender) by 2 (ethnicity) factor analysis controlling for both age and BMI was used to assess differences ( $P<0.05$ ). **Results** Preliminary results suggest no main or interaction effects of gender and ethnicity for mean RR, SDNN, RMSSD, pNN50, LF Power ( $P>0.05$ ). Girls had significantly higher NN50 scores (girls =  $94 \pm 65$  vs. boys =  $72 \pm 51$ ms,  $P = 0.002$ ). A significant ethnicity and gender interaction was observed for NN50. Girls had significantly lower VLF power scores (girls =  $23.95$  vs. boys=  $35.4\%$ ,  $p = 0.002$ ). Main effects of gender ( $P= 0.001$ ) and interaction effects of gender and ethnicity ( $P = 0.042$ ) were also observed for HF power whereby White girls had significantly higher HF power than South Asian girls and South Asian boys. **Discussion** Decreased vagal modulation of the heart has been associated with increased risk of cardiovascular disease (Thayer & Lower, 2007). Our results indicate that high frequency measures (nn50 and HF power) of HRV, which give an indication of vagal modulation of the heart, are higher in girls compared with boys ( $P<0.05$ ), and in White girls compared with South Asian boys and girls ( $P<0.05$ ) indicating increased vagal modulation of the heart in these groups and thus possibly a cardioprotective mechanism. Future studies need to explore mechanisms to improve HRV in children, especially those in groups where reduced HRV may prevail. **References** Thayer JF & Lane RD (2007). *Biological Psychology*, 74(2), 224- 242 Tsuji H et al., (1996). *Circulation*, 94, 2850-2853 Williams ED et al., (2011). *Heart*, 97(8), 607-9 Whincup P et al., (2002). *BMJ*, 242, 1-6

**EFFECTS OF LOW-INTENSITY SHIVERING ON ENERGY METABOLISM DURING EXERCISE IN THE COLD**

Gagnon, D.D., Kyröläinen, H., Herzig, K.H., Gagnon, S.S., Rintamäki, H.

*University of Jyväskylä*

**Introduction** Metabolically, shivering and exercise are not analogous processes (Tipton et al. 1989) as shivering relies more heavily on carbohydrates (CHO) as fuel (Haman et al 2005). Inconsistent findings in energy metabolism during submaximal exercise in the cold may partly be explained by the appearance of shivering which preferentially recruits type II muscle fibers. Therefore, the purpose of this study was to examine the influence of low-intensity shivering (LIS) on energy metabolism during exercise in the cold. **Methods** Nine male subjects, dressed in shorts and t-shirt, exercised on 4 separate days. Subjects entered a climatic chamber set at 0°C, then exercised for 60-min on a treadmill or, sat during a cooling period, prior to exercise, until LIS was induced (40% of shivering peak [ $\sim 15\%$   $\dot{V}O_{2\max}$ ]). Exercise was performed at 50% and 70% of maximal oxygen uptake in both LIS and non-shivering control (CON) conditions. Core temperature ( $T_{\text{core}}$ ), weighted mean skin temperature ( $T_{\text{skin}}$ ), heart rate (HR), and respiratory quotient (RQ) values were averaged over the last 10-min of every 15-min period during exercise. Blood samples were collected before entering the chamber (baseline) and at 30- and 60-min to measure serum non-esterified fatty acids (NEFA), glycerol (GLY) and glucose (GLU). Data was analyzed using a three-way ANOVA (factors: shivering, exercise intensity and time) for repeated measures with significance at  $p < 0.05$ . **Results** Both  $T_{\text{core}}$  and  $T_{\text{skin}}$  indicated lower values in LIS compared to CON within both exercise intensities from 15- to 45-min ( $p < 0.05$ ). HR was lower in LIS ( $129 \pm 10$  bpm) compared to CON ( $137 \pm 10$  bpm) in the first 15-min of exercise only ( $p < 0.05$ ). NEFA and GLU were not affected by shivering ( $p \geq 0.91$ ). Meanwhile, GLY concentration was greater in LIS ( $0.39 \pm 0.13$  mmol/L) vs. CON ( $0.31 \pm 0.11$  mmol/L) at 70%  $\dot{V}O_2$  ( $p < 0.05$ ). Finally, shivering did not modulate the RQ response across time or intensities (LIS  $0.87 \pm 0.04$  vs. CON  $0.86 \pm 0.04$ ,  $p = 0.84$ ). **Conclusion** LIS combined with submaximal exercise influenced  $T_{\text{core}}$ ,  $T_{\text{skin}}$ , HR and GLY, mostly in the early stage of exercise. Nonetheless, energy sources remained unaffected. The increase in CHO reliance from shivering was likely concealed by its limited contribution to total muscle activity and its partial inhibition from exercise. Future work should address higher intensities of shivering and lower levels of activity to examine possible interactions between both processes. **References** Haman et al. **EFFECTS OF HYDROTHERAPY ON ADAPTATION FOLLOWING A SIMULATED CYCLING GRAND TOUR**

Halson, S.L.1, West, N.P.2,3, Bartram, J.2, Stephens, J.2, Hopkins, W.G.4, Martin, D.T.2

1: AIS Performance Recovery (Canberra, Australia). 2: AIS Physiology (Canberra, Australia). 3: Griffith University (Gold Coast, Australia). 4: AUT University (Auckland, New Zealand).

**Introduction** Although cold water immersion is beneficial for recovery between bouts of high-intensity exercise, it may impair long term performance by attenuating the stimuli responsible for adaptation to training. Here we report a comparison of effects of cold-water immersion and passive rest on performance over a 39-day training block. **Methods** Thirty-four male endurance-trained competitive cyclists were randomized to cold water immersion or control (no recovery) groups for a simulated cycling grand tour consisting of 7 d of baseline training, 21 d of intense training, and an 11-d taper. Criteria for completion of training and testing were satisfied by 10 cyclists in the cold-water immersion group (age,  $20.2 \pm 1.7$  y; mass,  $70.9 \pm 6.5$  kg; maximal aerobic power,  $5.13 \pm 0.21$  W/kg) and 11 in the control group ( $19.8 \pm 1.7$  y;  $68.9 \pm 8.0$  kg;  $5.01 \pm 0.41$  W/kg). Cyclists completed two sets of performance tests each week: a combination cycling test consisting of 6-s sprints (MMP1s), a series of varying intervals, and a 10-min time trial on one day, and two 4-min bouts separated by 30 min of recovery (2xMMP4m) the next day. Cold-water immersion was performed 4 times per week for 15 min at 15°C following training and testing sessions. Uncertainty in mean differences between groups in the changes in mean performance power between tests following baseline and taper periods was estimated as 90% confidence limits and evaluated probabilistically in relation to a smallest important effect on mean power of 1%. **Results** Cyclists in the cold water group had an unclear change in overall 4-min power relative to control (2.7%,  $\pm 5.7\%$ ); however when subtracting the power in the first effort from the second effort, the cold water group showed a clear likely beneficial effect compared with control (3.0%,  $\pm 3.8\%$ ). The change in MMP1s in the cold water group also demonstrated a clear likely beneficial effect compared to control (4.4%,  $\pm 4.2\%$ ). Observed differences between groups for the 10-min time trial were trivial but the effect was unclear (-0.4%,  $\pm 4.3\%$ ). **Discussion** The primary objective of this study was to evaluate whether cold water immersion during a 3-wk phase of rigorous cycling training (simulating aspects of a Grand Tour) would impair cycling performance. In summary, data from this study do not support recent speculation that cold-water immersion is detrimental to adaptations to 3 weeks of increased training load in competitive cyclists.

**EFFECTS OF LOWER BODY COLD WATER IMMERSION ON PERFORMANCE OF SUBMAXIMAL ISOMETRIC CONTRACTIONS**

Willems, M.E.T., Clarkson, S.L.

*University of Chichester*

**Introduction** Muscle temperature influences the performance of successive isometric contractions of m. quadriceps femoris (QF) (Edwards et al., 1972). Muscle fatigue during sustained isometric contractions results in increased force fluctuations, i.e. a decline in steadiness. Such fatigue is associated with compensatory neuromuscular responses but less is known on the effect of cold water immersion on submaximal isometric performance. We examined the effect of cold water immersion of the lower body on the performance of submaximal isometric contractions of m. quadriceps femoris. **Methods** Men ( $n=11$ ,  $26 \pm 4$  yr,  $179 \pm 9$  cm,  $79 \pm 14$  kg, thigh skin fold:  $15 \pm 1$  mm) were tested in a temperature-controlled laboratory (control (C), 19°C) and following cold water immersion (CWI, 12°C) of the lower body for 30 minutes and ice-pack cooling of the leg during muscle testing. Skin temperature during muscle testing in CWI conditions was  $12 \pm 1^\circ\text{C}$  (Edale Instruments, UK). Subjects produced maximal voluntary isometric force (MVIF) of QF (knee angle  $90^\circ$ ), a 20%MVIF until exhaustion and 2 seconds after completion of the 20%MVIF a measurement of MVIF to quantify fatigue. Steadiness during 20%MVIF was quantified

by the coefficient of variation (SD/mean·100%). Surface EMG (Bagnoli-8, Delsys, USA) of m.vastus medialis (VM), m.rectus femoris (RF) and m.vastus lateralis (VL) was analysed for root mean square (RMS) and median frequency (MF). Data were analysed with 2-way ANOVA and paired t-tests with significance set at  $P < 0.05$ . Results There were no differences between conditions for MVIF (C:  $616 \pm 112$  N, CWI:  $615 \pm 102$  N), steadiness at similar time periods during 20%MVIF (e.g. 90-100% of time to fatigue (Tf), C:  $9.2 \pm 3.5\%$ ; CWI:  $7.4 \pm 2.3\%$ ) and fatigue index (C:  $30 \pm 16\%$ , CWI:  $29 \pm 11\%$ ). CWI resulted in 34% higher Tf (C:  $319 \pm 121$ s, CWI:  $426 \pm 166$  s) ( $P < 0.01$ ). During 20%MVIF, changes in RMS were lower for VL after CWI (0-10% to 90-100%Tf, C:  $25 \pm 5$  to  $48 \pm 14\%$ RMS; CWI:  $21 \pm 4$  to  $34 \pm 8\%$ RMS) with substantially lower MF values for all muscles after CWI and decreased MF values for VL only for control (0-10% to 90-100%Tf, C:  $96 \pm 15$  to  $87 \pm 18$  Hz; CWI:  $76 \pm 9$  to  $74 \pm 14$  Hz) (all  $P < 0.01$ ). Discussion Cold water immersion increased the time to fatigue for a sustained 20% isometric force of m.quadriceps femoris. Neuromuscular responses to cold water immersion were different for submaximal isometric contractions of the m.quadriceps femoris with lower levels of activation and no decrements in median frequency for the m.vastus lateralis but without an overall effect on steadiness for the m. quadriceps femoris. Peripheral mechanisms contributing to isometric fatigue of submaximal sustained contractions following cold water immersion seem to be muscle-dependent. ### EFFECTS OF RECOVERY INTERVENTIONS ON POSTEXERCISE PARASYMPATHETIC REACTIVATION IN ELITE SYNCHRONIZED SWIMMERS

Schaal, K., Le Meur, Y., Bieuzen, F., Petit, O., Toussaint, J.F., Hausswirth, C.

*Institut National du Sport, de l'Expertise et de la Performance*

The practice of synchronized swimming at the elite level has become increasingly demanding physically, combining high-intensity exercise with large hourly training volumes. In this context, improving postexercise recovery between sessions is a priority in order to manage fatigue and optimize performance ability across successive performances. The present study investigated the effect of whole body cryostimulation (WBC), contrast-water therapy (CWT), active (ACT) and passive (PAS) recovery protocols on parasympathetic reactivation and metabolic parameters of recovery between two full length competition ballets (B1 and B2). Methods: 11 elite synchronized swimmers performed all 4 trials in randomized order, one week apart. Peak oxygen consumption ( $\dot{V}O_{2peak}$  400) and blood lactate concentrations ([La]-b 400) were determined during a 400m swim time trial. Heart rate variability (HRV) was measured at rest (PreB1), 5min after B1 (PostB1), just before B2 (PreB2), and 5min after B2 (PostB2). Mean heart rate (HRmean), time-varying vagal-related indices (rMSSD and SD1), and power spectral density indices (HF, LF, LF/HF) were retained.  $\dot{V}O_{2peak}$  was measured at the end of B1 and B2, and [La]-b were obtained at PostB1, PreB2, and PostB2. Results: At the end of B1 and B2,  $\dot{V}O_{2peak}$  values were similar to  $\dot{V}O_{2peak}$  400, and [La]-b was higher than [La]-b 400. B1 and B2 caused significant decreases in rMSSD, SD1, HF and LF and increase in HRmean. At PreB2, all HRV indices had returned to PreB1 values with CWT, PAS, and ACT, while WBC yielded a 2 to 4-fold increase in vagal-related HRV indices compared to PreB1 (rMSSD,  $p = 0.01$ ; SD1,  $p = 0.01$ ; HF,  $p = 0.04$ ). [La]-b was significantly decreased during recovery with WBC and ACT compared to PAS ( $-9.2 \pm 2.2$ ,  $-8.8 \pm 1.7$ , and  $-8.0 \pm 1.4$  mmol.L<sup>-1</sup>, respectively). Further, WBC and ACT enabled a significant increase in  $\dot{V}O_{2peak}$  during B2, compared to B1 ( $+5.4\%$ ,  $p = 0.003$ , and  $+3.4\%$ ,  $p = 0.008$ ), while CWT led to no change, and PAS to a significant decrease ( $-3.6\%$ ,  $p = 0.003$ ). Conclusion: Even though each ballet required maximal aerobic energy production with large anaerobic contributions, elite swimmers displayed full parasympathetic reactivation 70 minutes postexercise, attesting to their highly trained status (Seiler et al. 2007). While cold water immersion techniques have been shown to accelerate postexercise parasympathetic reactivation after maximal exercise bouts (Buccheit et al. 2009, Stanley et al. 2011) WBC is the first method to show a large augmentation of vagal-related HRV indices beyond resting levels. WBC also results in similar effects as ACT on metabolic parameters of recovery and subsequent exercise capacity, and therefore appears as an effective recovery method in this context. ### DAILY VARIATION AND EFFECTS OF FLUID INTAKE MODIFICATION ON SALIVA OSMOLALITY

Klein, A.1, Barnouin, R.2, Stewart, A.3, Metzger, D.2, Pross, N.2, Girard, N.2, Guelinckx, I.1, Demazieres, A.2, Perrier, E.1

*(1) Danone Research, Palaiseau, France; (2) FORENAP, Rouffach, France; (3) Cantimer Inc., Menlo Park, USA*

Purpose: There is no consensus on a marker of hydration that is minimally-invasive and quick to administer. Because it is easily sampled, saliva osmolality (Sosm) may be a good candidate to assess hydration in real life conditions, particularly in athletes where rapid, convenient results are important. Tracking daily hydration status is important for athletes, and is critical for those performing under stressful environmental conditions. However, saliva physiology is still unclear, even at rest. The purpose of this study was to evaluate daily variation in Sosm, as well as the use of Sosm as a marker of hydration status in adults with habitually low or high fluid intakes. Because convenient measurement is critical for widespread use, a secondary aim was to evaluate accuracy of a portable osmometer (PO) compared to a freezing point osmometer (FPO). Methods: 52 participants ( $24.8 \pm 3.1$  yrs;  $22.3 \pm 1.6$  kg/m<sup>2</sup>) were classified as Low ( $n = 29$ ) or High ( $n = 22$ ) drinkers based on habitual fluid intake assessed by a fluid journal. Both groups completed a 6-day inpatient crossover design trial with both low (1.0 L/day) and high (2.5 L/day) fluid intakes. During baseline (Days 1-2), participants followed the fluid regimen similar to their habitual intake. On Days 3-5, fluid intakes between groups were reversed. Sosm was analyzed concomitantly by FPO and PO at 13 predetermined time points each day. Results: A between-groups comparison of Sosm revealed no significant differences at baseline, but significantly higher values during Days 3-5 in the group consuming 1L/d compared to those consuming 2.5L/d ( $72.0$ , 95%CI [70.1 ; 73.8] vs.  $65.7$ , 95%CI [63.9 ; 67.5] mOsm/kg, respectively;  $p < 0.001$ ). Significant daily variation in Sosm was also observed: overall time-by-time comparisons revealed that Sosm values were significantly higher at 07h compared to all other time-points with the exception of 12h. Globally, values were highest after waking and lowest following meals. A Bland-Altman plot revealed good agreement for Sosm values less than 120mOsm/kg (96% of values) with an intraclass coefficient of 0.6. Conclusions: Results obtained in this study suggest that 1) Daily variation in Sosm is present but likely more attributable to meals than to circadian rhythm; 2) Sosm does not quantitatively differentiate habitually Low and High drinkers due to high inter-individual variation; 3) But, a change in fluid intake results in Sosm changes, particularly for a fluid intake increase; 4) A portable osmometer displays similar analytical performance to the reference methodology (FPO). This study was funded by Danone Research

**PHYSIOLOGICAL RESPONSES TO WORKING IN HOT ENVIRONMENT IN THE MORNING AND THE AFTERNOON**

Racinais, S., Fernandez, J., Farooq, A., Eikebu, A., Vimeshkumar, J., Gaoua, N.

*Aspetar, Qatar Orthopaedic and Sports Medicine Hospital; Qatar Aluminium Limited*

Background: Core temperature generally follows a circadian rhythm peaking in the late afternoon. We recently described that this circadian variation persists in shift-workers in hot environment, but with a higher average core temperature. This suggests that physiological (e.g., heart rate) and behavioural (e.g., activity) responses could be different during a morning and an afternoon work-shift in hot environment. Objectives: To characterize the physiological (e.g., temperature, heart rate) and behavioural (e.g., activity) responses to working in a hot environment and the impact on health parameters (e.g., heat fatigue symptoms, dehydration, sodium loss) during morning and afternoon work-shift. Methods: Twenty-two aluminium smelter workers volunteered to be screened during their usual morning (07:00-15:00h) and afternoon (15:00-23:00h) shift-work for: core temperature (ingestible pill), internal helmet temperature (adhesive patch), heart rate (chest strap), activity (tri-axial accelerometer), fluid consumption, body weight loss, hydration (urine specific gravity), sweat sodium concentration and questionnaire on heat fatigue symptoms. Results: The average temperature recorded from the helmet was  $34.3 \pm 5.5^\circ\text{C}$  in the morning and  $33.8 \pm 4.1^\circ\text{C}$  in the afternoon, with maximum values reaching  $\sim 50^\circ\text{C}$  during the two shifts. Given the constant work requirement, participants performed a similar amount of activity ( $836 \pm 332$  vs.  $880 \pm 338$  steps/h,  $n=10$ ) with a similar average ( $101 \pm 13$  vs.  $97 \pm 11$  bpm,  $n=12$ ) and maximal ( $149 \pm 17$  vs.  $155 \pm 16$  bpm) heart rate in the morning and afternoon, respectively. Participants rated the work-shifts of similar difficulty ( $5.0 \pm 1.2$  vs.  $5.3 \pm 1.3$  over 10,  $n=16$ ) and reported equivalent symptoms scores ( $5.7 \pm 7.3$  vs.  $5.7 \pm 8.5$  over 78) in the morning and afternoon. The average core temperature was similar during the two shifts ( $37.5 \pm 0.2$  vs.  $37.4 \pm 0.2^\circ\text{C}$ ,  $n=14$ ), but displayed a different pattern of evolution during the morning (significant increase,  $p=0.03$ ) and afternoon (no variation,  $p=0.55$ ) shifts. Participants displayed similar levels of urine specific gravity ( $1.018 \pm 0.006$  vs.  $1.018 \pm 0.007$ ,  $n=19$ ) and water consumption ( $2943 \pm 1388$  vs.  $2467 \pm 1046$  mL,  $n=20$ ) during the morning and afternoon shift. However, the sweat loss ( $3.8 \pm 2.2$  vs.  $2.7 \pm 1.5$  L) and sweat sodium concentration ( $55 \pm 44$  vs.  $41 \pm 20$  mmol/L,  $n=12$ ) tended to be higher in the morning than the afternoon ( $p < 0.10$ ), leading to a greater sodium loss in the morning ( $164 \pm 118$  vs.  $109 \pm 87$  mmol,  $p < 0.05$ ). Conclusions: Working in a hot environment induced similar adaptations regardless of shift time. However, the time-of-day did lead to differences in sodium loss and temperature kinetic, without affecting work tolerance.

### IS-PM13 Evidence Based Physiotherapy (Cardiac Rehabilitation) (\*)

#### DOES EXERCISE IMPROVE ARTERIAL FUNCTION?

Fernhall, B.

*University of Illinois at Chicago*

Arterial structure and function are related to cardiovascular outcome and mortality. Measures such as intima-media thickness (IMT), arterial stiffness, and endothelial function can be considered indices of subclinical atherosclerosis and a substantial amount of epidemiological evidence support their use in various populations. Traditional endurance exercise training improves measures of arterial stiffness and endothelial function in both general population and patients with atherosclerotic heart disease, particularly in those patients with poor arterial function at baseline. The mechanisms for these changes are thought to be a function of improved nitric oxide (NO) metabolism, potentially as a result of decreased inflammation and reduced oxidative stress. New information on high intensity interval training suggests that this form of exercise training may be more effective than traditional endurance training, not only in the general population but also in cardiac patients. The effect of endurance training on IMT is less clear, and few studies have shown IMT regression following training. However, it is possible that endurance training may reduce progression of IMT in patients with atherosclerotic heart disease. Resistance exercise training is now generally recommended as an integral part of cardiac rehabilitation. However, the effects of resistance exercise training on arterial function are mixed. In young, healthy individuals, acute resistance exercise typically increase arterial stiffness, and in some studies, resistance exercise training of various durations has also increased arterial stiffness. Most studies though, show no change in arterial stiffness following chronic resistance exercise training, including studies in cardiac patients. Similarly, in young healthy individuals, high intensity resistance exercise training may decrease endothelial function, whereas moderate intensity exercise training increases endothelial function. In patients with atherosclerotic heart disease, resistance exercise training appears to improve endothelial function, while having little effect on IMT. Thus, for patients with atherosclerotic heart disease, the type of exercise usually conducted in cardiac rehabilitation programs, appear to produce mostly beneficial effects on arterial function.

#### EXERCISE INTERVENTION IN ISCHEMIC HEART DISEASE PATIENTS: HOW CAN WE MAXIMIZE THE CLINICAL BENEFITS?

Hansen, D.

*Hasselt University*

In patients with ischemic heart disease, the implementation of rehabilitation programs have been shown to significantly reduce mortality, and improve cardiovascular disease risk factors, exercise capacity, and quality of life. Within these rehabilitation programs, exercise training is a cornerstone. During the last few decades, great progress has been made regarding the proper selection of training modalities to optimize the improvement in exercise capacity in these patients (which correlates with lowering of mortality risk). Moreover, within populations of obese subjects and type 2 diabetes patients, the understanding of how to select training modalities to maximize adipose tissue mass loss and increase glycemic control has increased considerably. These data can be used to optimize exercise interventions in ischemic heart disease patients with obesity and/or type 2 diabetes. It will be summarized what training modalities should be selected to maximize the clinical benefits (exercise capacity, adipose tissue mass, glycemic control) of exercise intervention in ischemic heart disease patients. However, the implementation of exercise intervention in ischemic heart disease patients is associated with some typical difficulties. The proper determination of exercise training intensity remains complex, many of the clinical benefits are lost on the long term, to mention a few examples. These difficulties will be highlighted to increase the awareness of the current limitations of exercise intervention in ischemic heart disease patients.

#### EXERCISE OPTIONS IN PATIENTS WITH HEART FAILURE

Halle, M.

*Technical University Munich*

Although an overall decline in the incidence of cardiovascular disease has been observed during the last decade, the prevalence of heart failure (HF) is steadily increasing in the civilized world. This can certainly in part be attributed to the demographic change, but also an increasing unhealthy life-style behaviour including low physical activity. Currently it is estimated that in Europe at least 10 million people suffer from systolic heart failure (Heart Failure with Reduced Ejection Fraction, HFrEF), and that about the same number has heart failure symptoms with normal ejection fraction but myocardial dysfunction (Heart Failure with Normal Ejection Fraction, HFNEF). Besides an optimal pharmacological therapy, exercise training has evolved as a core treatment strategy to improve morbidity and mortality in these patients. In HFNEF this has particularly been confirmed by a large randomized trial enrolling >2,000 patients monitoring clinical endpoints for up to four years (HF ACTION Trial). Data showed that training may significantly improve quality of life and hospitalisation in the patients. However, compliance to the exercise program and mode of intervention is still under debate. In HFNEF exercise over 3 months reduced myocardial stiffening and symptoms in a pilot study, a finding which is currently investigated in a large randomized trial (Ex-DHF Trial). In addition, recent studies have suggested that exercise training at relatively high intensity seems to equally or even more effective than most current programs, in which the level of exertion is either moderate or not clearly defined. In a small cohort interval training improves physical performance, quality of life and outcomes associated with survival, such as aerobic capacity, left ventricular dimensions, ejection fraction, and prognostic factors such as brain natriuretic peptide levels. In summary, exercise is a key component of current heart failure treatment. Ongoing research will focus on the mode of exercise to improve clinical outcomes.

**08:00 - 09:30****Oral presentations****OP-SH05 Experimental Psychology****PASSIVE HYPERTHERMIA INDUCES AN OVERLOAD LIMITING COMPLEX COGNITIVE TASKS.**

Gaoua, N., Herrera, C.P., Racinais, S., El-Massioui, F.

*ASPETAR, Qatar Orthopaedic and Sports Medicine Hospital*

Purpose: To investigate the changes in brain electrical activity (EEG) during cognitive tasks in a hot environment. We expected EEG recordings to determine the effect of both task complexity and passive hyperthermia. Methods: Ten male subjects were tested in a counter-balanced order on two separate occasions in normothermia [CON, core temperature of 37.0°C ( $\pm 0.2$ ), neutral environment (WBGT = 21.1  $\pm 0.4$ °C)] and hyperthermia [HOT, core temperature of 39.0°C ( $\pm 0.2$ ), hot environment (WBGT = 40.2  $\pm 0.6$ °C)]. Subjects performed a One Touch Stockings of Cambridge planning task with simple (OTS-4) and complex (OTS-6) levels of complexity. EEG was recorded over the frontal lobe and theta power (4-8 Hz) was analysed. Results and Discussion: EEG recordings showed that theta activity was significantly increased in HOT compared to CON (2.18  $\pm 0.18$  vs. 1.97  $\pm 0.09$ ,  $p = 0.04$ ). This difference was already present before task engagement, with higher values presenting in HOT than CON. The difference persisted during OTS-4 in parallel with the increase in theta activity from rest to OTS-4. There was no difference in performance between CON and HOT during OTS-4. However, the difference in theta power between CON and HOT disappeared during OTS-6. OTS-6 performance significantly decreased in HOT ( $p = 0.003$ ). Conclusion: Hot environments represent a load on working memory capacity even prior to task engagement. The absence of difference in theta power observed between conditions during OTS-6 suggests that a critical threshold had been reached, possibly explaining the decrements in cognitive performance in HOT. The results demonstrate that the additional cognitive resources required for complex cognitive tasks are unavailable, given the allostatic load imposed by passive hyperthermia, which leads to decreased performance.

**NEUROSTIMULATION FOR IMPROVEMENT OF POST-SLEEP MENTAL STATE IN ATHLETES**

Abeln, V.1, Anderten, M.2, Kleinert, J.2, Vogt, T.1, Schneider, S.1, Strüder, H.K.1

*German Sport University Cologne*

Introduction Sleep has consequences on physical and psychological performance as well as well being (Mah et al., 2011). Although one is aware of the fact that sleep is an important variable for athletes' performance, literature in sport science about how to improve athletes' sleep is rare. Because time for sleep is often limited due to the tight schedule of top athletes, the aim of this study was to improve the sleep quality by using a neurostimulator during sleep and to investigate its effect on post-sleep mental state (effect of neurostimulator on neurophysiological level has been proved before, unpublished results). Methods 15 soccer players of the U17 and U19 teams of a German Bundesliga club slept under the influence of a neurostimulator for 8 weeks. Using binaural, monaural and isochronous tones, the neurostimulator stimulates the brain with deep-sleep frequencies (2-6 Hz). The scale for perceived physical state (PEPS) and a short form of the 'Eigenzustandsskala' (EZ-scale) were used in order to measure changes in post-sleep physiological and psychological mental state evoked by the neurostimulator in comparison to the pre-intervention state. The self-assessment questionnaires for sleep and awakening quality (SSA) and the EBF-Sport have been applied for monitoring of changes in sleep behavior and quality and in the sport related stress-relaxation state during the study duration. Nonparametric variables have been analyzed using the Wilcoxon test, parametric variables by using ANOVA. Results In comparison to the pre-intervention state, athletes sleep quality increased ( $p < .05$ ), whereas ratings of feeling sleepy decreased in the course of the intervention period. In the intervention period, subjects stated to sleep deeper ( $p < .05$ ), to have a more regenerating sleep ( $p < .01$ ) and quoted to feel less unwell ( $p < .01$ ) and in a better physical state compared to pre-intervention state. Sleeping behavior or stress-relaxation state did not change. Discussion The post-sleep mental state of young elite soccer players could be improved by the application of a neurostimulator stimulating the brain with deep-sleep frequencies. Accordingly, neurostimulation does not only change neurophysiological parameters but also mental state and might therefore be an efficient tool for athletes. Correlating positive effects on cognitive and physical performance are assumed, and will be investigated in further studies. References Mah, C. D., Mah, K. E., Kezirian, E. J., & Dement, W. C. (2011). The effects of sleep extension on the athletic performance of collegiate basketball players. *Sleep*, 34(7), 943-950.

**EFFECTS OF COMMERCIALLY AVAILABLE NEUROSCIENTIFIC METHODS ON PSYCHO-PHYSIOLOGICAL REGULATION AND COGNITIVE PERFORMANCE**

Finkenzeller, T., Amesberger, G.

*University of Salzburg*

Introduction The application of neuroscientific methods to improve sport performance in elite sports is getting more and more in vogue. However, many of the commercially available methods have not been evaluated empirically so far. Thus, two methods, the audio-visual perception enhancement method (AVWF@method) and the OGIRO@ modulation, have been selected for an empirical testing. Among other things, the AVWF@method claims to enhance autonomic balance and cognitive performance by listening to sound modulated music (Conrady, 2012). Similar effects are reported for the OGIRO@ modulation that influences brain activity by the use of transcranial magnet stimulation. Two studies should clarify if the two selected neuroscientific methods have a positive effect on autonomic balance and cognitive performance. Methods The sample of study 1 consisted of 57 male and female students (16 $\pm$ 8.6 years) of a college of physical education. Two experimental groups (group 1: AVWF@method,  $n = 25$ ; group 2: non-modulated music,  $n = 20$ ) participated in ten music intervention sessions over two weeks. A third group received no music intervention ( $n = 12$ ). In the pre-, post- and retention tests, an electrocardiogram for the determination of heart rate variability (HRV) parameters was recorded in a three minute resting condition (sitting, eyes closed). Cognitive performance was assessed via d2 attention endurance test (Brickenkamp, 2002), a stress tolerance and reaction time test (DT-S1; Schuhfried@; Neuwirth & Benesch, 2007), and a selective attention test (Krenn, 2008). In the second study, a randomized, double blind design was applied. A sample of 30 male sports students (24.7 $\pm$ 3.6 years) was divided into an intervention (OGIRO@ modulation) and a control group (dummy device). Over a period of 14 days, all of the subjects completed ten training sessions.

In a pre- and posttest, the same tests as in the first study were carried out. Results For all target variables, RM-ANOVAs were calculated with the factors group and time (study 1: 3x3; study 2: 2x2). No significant interactions were found in either HRV parameters or cognitive performance that would indicate intervention-related effects. Discussion Neither of the two studies could demonstrate a positive effect of neuroscientific methods on psycho-physiological regulation and cognitive performance in sports students. It seems doubtful that the two methods achieve the specified effects in high performance sports. The integration of empirical evidence into recommendations for practical use is discussed. ### ON THE PROBLEM OF THE TEMPORAL BODY

Hogenova, A.

*Charles University*

Keywords: pexis, internal perception of time, body schema, successivity, simultaneity, temporality Most people describe the body as a map, organ next to organ. We talk about their functions, structure, etc. But more important is the body that can generate many functions at once, at any one time. A dancing body is a very good example. Each body part is doing something different, legs and hands working independently of each other and yet the whole body of the dancer is like an effortless torrent. The body is able to create various movements at the same time and yet it is merely a focus of kinetic energy. Most bodily functions are explained successively, i.e. they are consecutive, but we are not interested in successiveness or simultaneity. We need to consider that during all of these movements man is able to think about what will be in the future, because he wants to prepare for that future. Here we show how causality, which focuses on changes in succession, is not able to describe or clearly explain everything in man. Aristotle defines time as the number of movement. It is perhaps the best known definition of time, which brings with it succession as the only possible interpretation of the movement of time. Everything happens consecutively, as cause and effect, creation and causal succession, by which science describes our common world. This is how the body is explained in physiology, anatomy, chemistry and physics. But the body's processes are diverse and happen suddenly. Thinking and motor skills emerge from the body as unique and elementary figures, they are not made up of several parts and they are not 'addition' because they are not a system: a system requires successivity as a condition for its onticity. Besides Aristotle's concept of time there is Martin Heidegger's so-called temporality. This is a totally different concept of time in which the past and future are concealed in the present. This is a totally different concept of time in which the past and future are concealed in the present. For the body, the physical flow of the present is only partially true.. Our temporal body is temporal in Heidegger's sense. It is not the temporality of Aristotle, where time is the number of movement and thus a line of past, present and future. It is not that simple. Of course, science is built on Aristotelian time as its basis, and therefore understands the body in this way. Temporality means that in present contains been-ness and the projective future. And Heidegger's temporality is the temporality we are most interested in. The basis of learning movement is the understanding of been-ness, which unconsciously lies "dormant" inside us and is the basis for teaching. Temporality of our bodies is important for learning any type of movement and for understanding human life in terms of presence (Dasein). This view of the body is not made use of and that is a shame. Therefore, we have devoted this paper to the topic. Literature: Heidegger, M. *Das Ereignis*. Frankfurt am Main: Vittorio Klostermann 2009.

### EFFECT OF SELF-DETERMINED MOTIVATION ON MORAL DISENGAGEMENT IN SPORT: THE MEDIATING ROLE OF RESISTIVE SELF-REGULATORY EFFICACY

Corrion, K., Canestrelli, C., d'Arripe-Longueville, F.

*Nice Sophia Antipolis University*

Introduction Several studies have shown that resistive self-regulatory efficacy was negatively related to moral disengagement in adolescents (e.g., d'Arripe-Longueville et al., 2010; Caprara et al., 2002). However the antecedents of self-regulatory efficacy variables are not well known. The motivational factors of moral disengagement in sport have been examined within achievement goal theory (e.g., Boardley & Kavussanu, 2010), and more recently within self-determination theory (Hodge & Lonsdale, 2011). In line with this study, the purpose of the present research was to examine the relationships between self-determined motivation and moral disengagement moral in sport, and to test the mediating role of resistive self-regulatory efficacy. It was expected that self-determined motivation would sustain resistive self-regulatory efficacy which in turn would affect moral disengagement. Methods Two hundred and ninety eight students voluntarily participated in the study. Participants were invited to complete three questionnaires: (a) the self-determination motivation scale for physical exercise (Vallerand, 1997); (b) the resistive self-regulatory efficacy in sport scale (Corrion et al., 2009); and (c) the moral disengagement in sport short scale (Corrion et al., 2010). Results The results indicated that resistive self-regulatory efficacy partially mediated the relationships between extrinsic/ intrinsic motivation and moral disengagement. The model showed (a) negative relationships between extrinsic motivation and resistive self-regulatory efficacy, resistive self-regulatory efficacy and moral disengagement; and (b) positive relationships between intrinsic motivation and resistive self-regulatory efficacy. Discussion These results confirm that self-determination would be a protective factor for moral disengagement (Hodge & Lonsdale, 2011) and highlight the mediating role of resistive self-regulatory efficacy in this relationship. Our findings also suggest that autonomy support might be encouraged to develop resistive self-regulatory efficacy in adolescents. Future studies could examine the role of self determined motivation on other self-regulatory efficacy variables (Bandura et al., 2001). **08:00 - 09:30****Oral presentations****OP-PM25 Sport Science****THE RELATIONSHIP BETWEEN AEROBIC CAPACITY AND SENSITIVITY TO PRESSURE AND ISCHAEMIC NOXIOUS STIMULI**

Jones, M., Booth, J., Taylor, J., Barry, B.

*University of New South Wales*

THE RELATIONSHIP BETWEEN AEROBIC CAPACITY AND SENSITIVITY TO NOXIOUS PRESSURE AND ISCHAEMIC STIMULI Jones, M.1, Booth, J.1, Taylor, J.2 & Barry, B.1,2 1: UNSW School of Medical Sciences (Sydney, Australia) 2: Neuroscience Research Australia (Sydney, Australia)

Introduction Anecdotally endurance athletes are stoical, but there is limited evidence that tolerance of discomfort contributes to enhanced endurance. There is some evidence that aerobic exercise training reduces pain sensitivity (Anshel and Russell, 1994), however it is unclear whether enhanced tolerance of discomfort contributes to this adaptation. Studies on athletes and pain sensitivity have yielded equivocal findings (Scott and Gijssbers, 1981). Methods Ten males (24.2 yrs; BMI 23.7; VO<sub>2</sub>peak 44.5 ml/kg/min) and 6 females (25.3 yrs; BMI 21.7; VO<sub>2</sub>peak 42.3 ml/kg/min) participated in this study. Pressure pain threshold was measured at muscular sites on the upper and lower body using an algometer. Pain tolerance was assessed using a submaximal effort tourniquet test. Participants performed repetitive hand grip exercise (30 % maximum force; 4 s grip, 4 s rest) with upper arm occlusion for as long as tolerable or a maximum of 10 min. Pain tolerance was quantified by the number of seconds subjects were willing to continue exercise under the ischemic conditions as well as by subjective rating of pain on a visual analogue scale every 30 s. A maximal aerobic test was performed on a cycle ergometer to determine the subjects level of aerobic fitness. Results No correlation was observed between ischaemic pain tolerance and aerobic capacity for males (r-squared = 0.001, p = 0.92), females (r-squared = 0.05, p = 0.65) or for the normalised data set combining both sexes and accounting for subject age (r-squared <0.001, p = 0.99). For pressure pain, there was a significant inverse relation between normalized aerobic capacity of the male subjects and pressure pain thresholds of the upper (r-squared = 0.41, p < 0.05) and lower body (r-squared = 0.75, p < 0.05). Hence, male subjects with relatively higher aerobic capacity tended to have lower pressure pain thresholds. For female subjects, these associations were weaker and opposite (upper: 0.34, p = 0.22, lower: 0.09, p = 0.57). Discussion Ischaemic pain tolerance, arguably the more similar to pain experienced during an endurance task, did not correlate with aerobic capacity. The inverse relation between pressure pain threshold and aerobic capacity in males possibly arose from fitter males having lower subcutaneous adiposity (Finocchietti et al., 2011), though anthropometric data in the present study do not support this. A larger sample incorporating subjects from a broader range of aerobic capacities will extend and verify these findings. References Anshel, MH and Russell, KG. (1994). *J Sports Sci*, 12(6), 535-547. **A CRITICAL EXAMINATION OF "FAIRNESS" IN PARALYMPIC ELITE MULTI-CLASS COMPETITION**

Barnes, C.

*Australian Institute of Sport and University of Canberra*

Introduction In Paralympic field events, up to 30 classes contest what for able-bodied athletes is a single event (discus, javelin, shot etc.). If each class were to contest each event separately the competition would be overly long; also, the standard of competition may be lower than desirable. Consequently some classes are combined to reduce the number of separate events, and to ensure maintenance of appropriate standards. For intra-class comparison, it is necessary to define appropriate standards for each class. We show that for most classes valid comparisons are possible; but in some cases, they are not. We use this analysis to investigate the "fairness" of the current International Paralympic Committee standards, and show that some of the proposed multi-class combinations are inappropriate. Methods A table of event results (including all trials for preliminary, semi-final and final rounds) was constructed for Paralympic and World Championship events from 1998 to 2011. Mixed modelling regression was used to attempt to minimise the influence of known effects: gender, year; implement weight, class; and competition type, as well as second order interactions. Provided that selected performances are all sufficiently large, and that one particular condition is met, residuals are expected to follow the two-parameter extreme value (EV) distribution asymptotically. The critical condition is that the distribution of residuals so determined is stationary (invariant in time). Failure to meet this condition is indicated by failing to reproduce a straight line on a log-linear plot of ordered residuals versus magnitude. Given this condition, performances can be compared, even though they come from different classes (or even different events), via percentiles of their appropriate distributions, subject to the uncertainties in the slope and intercept of their respective linear ordered-residual plots. Results For most event/class combinations, the method proved to be valid, and useful when the total number of performances exceeded 150. However, for several classes (e.g. cerebral palsy classes below F37) it appears that the above analysis of performances does not lead to stationary distributions, and these classes cannot be justifiably combined. Discussion Reasons for the observed non-stationarity remain speculative at this stage; but it can be observed that significant improvements have been made recently by a small number of competitors in these classes. Relatively low numbers of reported results mean that such a competitor was able to significantly influence the distribution, resulting in non-stationarity. Similar results have been seen in able-bodied events where there is likely to have been a decline in the use of performance-enhancing substances (due to more stringent rules and enforcement). We conclude that the current International Paralympic Committee rules for combined class competition are unfair in a small number of cases; adoption of our methodology should lead to increasingly valid comparisons in all classes as more results accrue.

**BIO-ELECTRICAL CURRENT RESPONSE IS ASSOCIATED WITH PSYCHOMOTOR SPEED IN TOP LEVEL SOCCER PLAYERS**

Hautala, A.J.1, Roivainen, E.1, Kiviniemi, A.M.1, Tulppo, M.P.1

*Verve Research*

Introduction Psychomotor speed has been used to monitor athletes training load and it has been proposed that psychomotor slowness is an early marker of overtraining (Nederhof et al., 2007). However, non-invasive home-based tools to evaluate the training status and recovery of neuromuscular function are missing. Therefore, the purpose of the present study was to examine if a new method, based on

bio-electrical current response (BECR), measured at home is associated with psychomotor speed and endurance performance in top level soccer players. Methods Fourteen Finnish top level soccer players (team AC Oulu, age  $21 \pm 5$ , BMI  $24 \pm 1$  kg/m<sup>2</sup>) performed an endurance fitness test (20m Multistage Fitness Test: BEEP Test) in the field conditions. After the fitness test training load for the players was minimized for one week. During this week psychomotor speed tests (Vienna Test System, SCHUHFRIED GmbH, Austria) with visual warning signals were performed in the laboratory. The inspection and motor phases of reaction time to a visual signal were analyzed. BECR (FAM Sports, Finland) was recorded at same time at home on three separate mornings immediately after wake-up, three times at each measurement session, from left hand with low frequency stimulation. Altogether nine measurements of BECR were averaged for final analyses. Results The average running time in the BEEP test was  $16.6 \pm 1.4$  min (range 14.1-18.4). Inspection time to visual signal varied from 109 to 212 ms ( $144 \pm 27$ ), motor time from 79 to 223 ms ( $116 \pm 38$ ) and BECR from 3 to 17 mA ( $6 \pm 4$ ). BECR correlated positively with motor time ( $r = 0.73$ ,  $p = 0.003$ ) and showed a trend of association with inspection time ( $r = 0.49$ ,  $p = 0.076$ ), BEEP test ( $r = -0.46$ ,  $p = 0.102$ ) and age ( $r = 0.41$ ,  $p = 0.148$ ). There was no association between BECR and BMI ( $r = 0.07$ ,  $p = \text{ns}$ ). Discussion Bio-electrical current response measured at home is associated with psychomotor speed, particularly motor time to visual warning signal. If the response to electrical stimulus is delayed, motor time is slower. It appears that bio-electrical current response method is a promising tool to evaluate neuromuscular status of soccer players at home conditions during training and recovery. References Nederhof E, Lemmink K, Zwerver J, Mulder T (2007) The effect of high load training on psychomotor speed. *Int J Sports Med* 28: 595-601.

### TRACKING OF COMMUTING PHYSICAL ACTIVITY FROM YOUTH TO ADULTHOOD: THE YOUNG FINNS STUDY

Yang, X.1, Telama, R.2, Hirvensalo, M.2, Tammelin, T.1, Viikari, J.S.A.3, Raitakari, O.T.3

1: LIKES - RCHS (Jyväskylä, Finland), 2: UJ (Jyväskylä, Finland), 3: UT (Turku, Finland)

Introduction Research on the stability of commuting physical activity (CPA) from childhood to adulthood is scarce and there is a lack of prospective data that show such a relationship. The aim of the study was to evaluate the longitudinal changes and secular trends of CPA over 27 years from youth to early middle-age in the Cardiovascular Risk in Young Finns Study. Methods Participants were 2157 healthy adults (971 men and 1186 women), who participated in the follow-up measurements from youth (since 1980) to adulthood (aged 30 – 45 years in 2007) in the ongoing Cardiovascular Risk in Young Finns Study. The way and distance of commuting to school or work were asked by a questionnaire in 1980, 1983, 1986, 2001 and 2007 separately for summer and winter conditions. The commuting was categorized into four types: car, bus, walking and cycling. Commuting mode to school/work was also transformed to weekly metabolic equivalent values (MET hours/week) and then dichotomized into inactive ( $< 3$  MET hours/week) and active commuters ( $\geq 3$  MET hours/week). Results The prevalence of CPA declined sharply with increasing age, particularly in men. Active commuting was more prevalent in women than in men during young adulthood. There was a significant decreasing secular trend in CPA in youth between years 1980/1983 and 1986, particularly in boys and girls aged 18 and 21 ( $p < 0.05$ ). No secular change in CPA was observed in adulthood between years 2001 and 2007. Spearman's correlation coefficient for tracking of CPA was higher in young adulthood ( $r = 0.22-0.65$ ) than in youth ( $r = 0.20-0.45$ ). However, correlation from youth over a longer period into adulthood was a weak and non-significant. Persistently active commuters in youth had more than 1.6-fold likelihood of being active commuters in adulthood compared to their inactive counterparts. The adjusted odds ratios of being active commuter in adulthood were highest for active commuters in young adulthood in three age groups, varying between 7.5–15.0 in men and 3.4– 6.6 in women, respectively. Discussion Proportion of active commuters declines with age in both men and women. CPA in young adulthood tracks better into early middle-age adulthood than CPA in youth. Accumulating active commuting in youth and in young adulthood is related to being active commuter in early midlife for both genders. Maintaining active commuting to school or work is an essential component of overall physical activity and healthy lifestyle along the life course. Promotion of physically active commuting in youth and young adulthood seems to be important in order to enhance physically active lifestyle later in life.

### ATTITUDES TOWARDS DOPING IN PARTICIPANTS OF A POPULAR LONG-DISTANCE ROAD CYCLING EVENT ACCORDING TO THEIR DOPING BEHAVIOR: USERS VS NON-USERS.

Morente-Sánchez, J.1, Freire, C.1, Ramírez-Lechuga, J.2, Zabala, M.1,3

1 Faculty of Sport Sciences, University of Granada (Spain); 2 Faculty of Sport, University Pablo Olavide (Seville-Spain); 3 Spanish Cycling Federation, Madrid (Spain)

Introduction The purpose of this study was to know the attitudes towards doping of participants of a popular long-distance road cycling event taking into account if they had used doping substances or not in the past. Methods A sample of 2022 amateur cyclists ( $40.95 \pm 9.42$  years) who participated in a long-distance (205 km) Spanish road cyclist event called "Quebrantahuesos" (UCI Golden Bike), was divided into two groups: users of doping substances ( $G1=164$ ) and non-users ( $G2= 1858$ ). On the other hand, in order to contrast similar and balanced samples, data from users was also compared with an equivalent group of non-users ( $G3=157$ ). Descriptive design was carried out by means of a validated questionnaire (Petroczi & Aidman, 2009) of 17 questions using a Likert scale from 1 (Strongly Disagree) to 6 (Strongly Agree) for different statements that supported the use of doping in sport. Mean value  $\pm$  Standard Deviation was obtained for each item and Mann Whitney test for independent variables with Bonferroni post hoc was carried out. Results Mean score (1 to 6) and overall score (17 to 102) for different groups were, respectively:  $G1=2.88 \pm 0.94$ ,  $48.87 \pm 15.98$ ;  $G2=2.41 \pm 0.70$ ,  $40.98 \pm 11.95$ ;  $G3=2.30 \pm 0.66$ ,  $39.14 \pm 11.76$ , ( $G1$  vs  $G2$  &  $G3$ ,  $p < 0.001$ ). For users, the highest score was observed for the item "The media blows the doping issue out of proportion" ( $4.36 \pm 1.76$ ) and for non-users, "Athletes are pressured to take performance-enhancing drugs" ( $4.16 \pm 1.63$ ) -4=Slightly Agree; 5=Agree-. For almost all the items significant differences were observed between  $G1$  vs  $G2$  and  $G3$  ( $p < 0.05$ ), being higher in  $G1$  than in  $G2$  and  $G3$ . Between  $G1$  and  $G2$  only there were not significant differences for four items ("Athletes are pressured to take performance-enhancing drugs", "Athletes who take recreational drugs, use them because they help them in sport situations", "Athletes have no alternative career choices, but sport" and "Recreational drugs help to overcome boredom during training"). Between  $G1$  and  $G3$  there were not significant differences just for four items: "Recreational drugs give the motivation to train and compete at the highest level" "Athletes have no alternative career choices, but sport", "Athletes who take recreational drugs, use them because they help them in sport situations". Discussion Confessed doping users scored significantly higher on the scale compared with those who reported not to use of banned substances. Similar results were obtained by Uvacek et al. (2011) for users' overall score ( $46.8 \pm 13.32$ ) while that non-users' overall score was lower ( $34.43 \pm 8.74$ ). References 1. Uvacek, M Nepusz, T, Naughton, DP. Mazanov, J. ## TEN MINUTES OF DAILY SCHOOL-BASED SLACKLINE TRAINING ONLY IMPROVES TASK-SPECIFIC BALANCE PERFORMANCE IN 9-10 YEARS OLD CHILDREN

Donath, L., Roth, R., Ruegge, A., Groppa, M., Zahner, L., Faude, O.

*University of Basel*

Introduction School-based exercise interventions that improve balance, strength and endurance performance seem beneficial since adequate childhood exercise behavior more likely track into a healthier adult lifestyle. Slackline interventions were recently employed to promote postural control and strength performance in young adults (Granacher et al. 2010). Comparable studies in primary school children are lacking. Thus, the present study was performed to examine effects of daily school-based slackline-training bouts on static and dynamic balance and jump performance in children. Methods Two school classes of the 4th grade of the Swiss canton Basel (Intervention, n=21 vs. Control, n=13) (INT, age: 10.1 (SD 0.4) y, height: 1.39 (0.05) m, weight: 33.1 (4.5) kg, weekly sports club participation (SC): 2.4 (1.9) h; CON, age: 10.0 (0.4) y, height: 1.40 (0.06) m, weight: 34.7 (7.4) kg, SC: 1.8 (1.2) h) were included. The intervention was performed 5 times per week for 10 minutes each day within 6 weeks. INT comprised e.g. double and single limb standing, walking, turning and backwards walking. Both groups were encouraged to maintain their habitual physical activity. Before and after slackline training, balance and jump performances were assessed by (a) 30 seconds static and dynamic single limb stance on a force plate (path length displacement of the center of pressure (COP)), (b) backwards balancing on three different balance beams (3, 4.5 and 6 cm width), (c) upright standing as long as possible (single and double limb) on the slackline and (d) countermovement jumps (CMJ). Results Attendance was 27.4 (1.2) of 28 provided sessions (2 sessions were canceled). No significant group x time interactions for each leg (left and right) and conditions (static and dynamic) was observed for COP displacement ( $0.40 < p < 0.92$ ) as well as for backwards balancing on the three balance beams ( $0.08 < p < 0.77$ ) and CMJ height ( $p=0.28$ ). In contrast, high significant group x time interactions ( $0.006 < p < 0.02$ ) were found for slackline standing time with significant increases in INT (double limb: 5.1 (3.4) s to 17.2 (14.4) s; right leg: 8.2 (5.8) s to 38.3 (36.0) s; left leg: 10.6 (5.8) s to 49.0 (56.3) s and no significant changes in CON. Discussion Daily bouts of slackline training resulted in large slackline-specific improvements of postural control. A transfer to common static and dynamic single limb balance performance tasks, backwards balancing or jump performance was not observed. Thus, the benefit of slackline training with regard to general neuromuscular adaptations should not be overrated. References Granacher U, Iten N, Roth R, Gollhofer A. (2010). *Int J Sports Med*, 31, 717-723.

### OP-PM26 Sport Medicine: Experimental Interventions

#### LOCAL ADMINISTRATION OF INSULIN-LIKE GROWTH FACTOR-I STIMULATES TENDON COLLAGEN SYNTHESIS IN HUMANS

Hansen, M.1,2, Boesen, A.1, Holm, L.1, Flyvbjerg, A.2, Langberg, H.1, Kjaer, M.1

*(1) Institute of Sports Medicine, Dept. Orthopedic Surgery M81, Bispebjerg Hospital and Center for Healthy Aging, Faculty of Health Sciences, University of Copenhagen*

Introduction: Collagen is the predominant structural protein in tendons and ligaments, and can be controlled by hormonal changes. In animals, injections of insulin-like growth factor I (IGF-I) has been shown to increase collagen synthesis in tendons and ligaments and to improve structural tissue healing, but the effect of local injection of IGF-I on tendon collagen synthesis in human has not been studied. The purpose of this study was to study whether local injections of IGF-I have a stimulating effect on tendon collagen synthesis. Material and method: Twelve healthy non-smoking men participated: age  $62 \pm 1$  yrs (mean  $\pm$  SEM), BMI  $27 \pm 1$ . Two injections of either human recombinant (rh) IGF-I (0.1 ml Increlex®) or saline (control) into each patellar tendon were performed 24-hrs apart. Tendon collagen fractional synthesis rate (FSR) was measured by stable isotope technique in the hours after the second injection. Simultaneously, interstitial peritendinous IGF-I concentration and procollagen type I N-terminal propeptide (PINP) concentration, as a marker for type I collagen synthesis, were determined by microdialysis technique. Results: Tendon collagen FSR and PINP were significantly higher in the IGF-I leg compared to the control leg ( $P < 0.05$ ). Conclusion: local IGF-I administration can directly enhance tendon collagen synthesis both within and around the human tendon tissue.

#### FIVE REPEATED APNOEAS AFFECT THE HYPERCAPNIC VENTILATORY RESPONSE IN ELITE APNOEA DIVERS

Bourdass, D., Konstantopoulos, A., Tsakiris, T., Pavlakis, K., Triantafyllou, D., Geladas, N.

*University of Athens, Greece*

Introduction Apnoea divers appear to be CO<sub>2</sub> retainers (Florio et al., 1979) which is assumed to decrease CO<sub>2</sub> sensitivity (Lin et al., 1974) and may lead to altered hypercapnic ventilatory response (HCVR) as it is expressed by the slope of  $\alpha = VE/PETCO_2$ . The aim of this study was to test if HCVR is reduced by repeated breath hold maximal efforts (RBHE) and the possible contribution of this on duration of apnoea's easy going phase (EPH) in elite divers and no familiar with apnoea subjects. Methods Elite breath hold divers (EBH=11) & normal subjects (NBH=10) visited the laboratory in two different days. In the 1st day (BM) subjects performed a HCVR test using the Read rebreathing method (Read, 1967). In the 2nd day (PRE) subjects completed five RBHE with face immersion in cold water (12°C), separated by 2min intervals and 2 min upon manuvres' cessation they performed a HCVR test. Afterwards, only the NBH group trained every day on a five RBHE separated by 2min intervals. Two weeks later (POST), only the NBH repeated the 2nd day session. During apnoeas diaphragmatic activity was recorded continuously in order to determine the end of apnoea's EPH. Results The subjects' BHT range was 274.0-400.0, 57.1-166.5 and 90.1-260.9 sec for the EBH and NBH group in PRE and POST conditions, respectively. The slope  $\alpha$  in EBH showed significant difference between BM ( $1.8 \pm 0.2$ ) and PRE ( $1.4 \pm 0.2$ ) ( $p \leq 0.05$ ). In the NBH group, the slope of  $\alpha$  was  $2.4 \pm 0.3$ ,  $2.9 \pm 0.4$ ,  $2.8 \pm 0.5$  respectively to three conditions, BM, PRE and POST with no significant differences among them. Alpha ( $\alpha$ ) slope of EBH group in PRE compared with the PRE and POST conditions of the NBH group was significantly lower. EPH did not differ ( $p > 0.05$ ) between PRE and POST condition in NBH. EBH group had significantly higher averages of EPH for each repeated BH than NBH in PRE and POST conditions, and the  $\alpha$  slope

showed a strong correlation ( $r=0.61$ ,  $p\leq 0.05$ ) with the cumulative EPh of the five repeated apnoeas (CEPh) in PRE condition; nothing similar was observed in NBH. Discussion The EBH developed reduced HCVR two minutes after the end of the five repeated apnoeas, delaying the chemical stimuli of breathing and increasing the BHT (Chang & Lundgren, 1996) in contrast to NBH. Moreover, the correlation of a with CEPh only in EBH supports the hypothesis that any increase in BHT achieved after apnoea training in NBH cannot be explained by EPh duration changes or/and any HCVR changes. ### TRAINABILITY: A MATTER OF GENE VARIANTS?

Ring-Dimitriou, S.I, Kedenko, I.2, Humenberger, M.I, Feichtinger, R.3, Stangl, J.I, Andress, M.I, Steinbacher, P.4, Förster, H.5, Müller, E.I, Paulweber, B.2

1&4: University of Salzburg, 2&3: Paracelsus Medical University

Introduction Beside exercise prescription single-nucleotide polymorphism (SNP) in genes important for mitochondria function such as PPARGC1A and PPARD have been reported to affect the change in anaerobic threshold in a retrospective study (Stefan et al., 2007). Therefore we prospectively investigated a 10-wk training response of men with SNP in these genes. Methods Genotyping (TaqMan, ABI 7900HT) was performed in 838 sedentary males for SNP in PPARGC1A (rs8192678) and PPARD (rs2267668). After intervention (supervised 10 wks cycling, 3x 60 min, HR@70-90% VO2peak) n=28 remained for post tests (59±7 yrs, 27.6±4.1 kg/m<sup>2</sup> BMI, 36.3±6.9 ml/kg/min VO2peak). Subjects were assigned to wild type (WT=13), SNP1 (minor risk allele for PPARGC1A, WT for PPARD, n=6), and SNP2 (risk alleles for both genes, n=9). Trainability was determined as the relative change in work rate P@VT (point of optimal respiration), P@AT (anaerobic threshold), and P@RCP (respiratory compensation point) based on gas exchange analyses (ZAN680, nSpire Health, US) during incremental cycling (Ergoline, Schiller). Mean differences within and between groups were determined by ANOVA with  $p<0.05$ . The study was approved by the Salzburg Ethics Committee and funded by National Bank of Austria (J14156). Results Significant differences were found within WT in P@VT (99±21 vs. 122±19 W,  $p=.005$ ) and @RCP (155±25 vs. 185±29 W,  $p=.009$ ) only. P@RCP was significantly lowest in SNP1 compared to SNP2 and WT (% 3±9 vs. 12±5 vs. 20±15;  $F=4.6$ ,  $p=.02$ ). VO2@VT and @RCP were significantly lower in SNP1 and SNP2 compared to WT (% 2±10 vs. 4±13 vs. 18±15,  $F=3.6$ ,  $p=.04$ , and 0±8 vs. 6±5 vs. 17±16 vs.,  $F=4.8$ ,  $p=.02$ , respectively). Discussion In line with the findings of Stefan et al. (2007), we found a diminished exercise effect at sub maximal performance level of untrained males with SNPs. The short-term response at these levels of >15% in WT was sufficient compared to other reports (Skinner et al., 2001) and could probably serve as trainability markers regarding to Vollaard et al. (2009). Although the power of our study is limited due to sample size and sex selection, our data indicate that the trainability of aerobic performance could be affected by gene variants. ### EFFECTS OF ONE-WEEK INTRANASAL LHRH APPLICATION ON THE HYPOTHALAMIC-PITUITARY-GONADAL AXIS IN HEALTHY YOUNG MEN

Krusche, T., Thomas, A., Schrader, Y., Thevis, M., Platen, P.

Ruhr-Universität Bochum

Effects of one-week intranasal LHRH application on the hypothalamic-pituitary-gonadal axis (HPGA) in healthy young men Krusche T.1, Thomas A.2, Schrader Y.2, Thevis M.2, Platen P.1 1Department of Sports Medicine and Sports Nutrition, Faculty of Sport Science, Ruhr-University Bochum 2Center for Preventive Doping Research and Institute of Biochemistry, German Sport University Cologne Introduction The misuse of intranasal LHRH in elite sports has frequently been reported during the last years. The aim of this project was to analyse hormones of the HPGA in healthy young men in order to develop a detection method for the misuse of LHRH in routine doping controls. Methods 10 healthy moderately trained students (22.8±1.7 yrs, 179.6±6.0 cm, 77.6±7.0 kg) were investigated 2 days before (d-2) a 7 day-period of intranasal LHRH application (every 1.5 hrs from 7am-10pm [in total 4.4 mg/day]), as well as during the 1st (d1) and 7th (d7) day of intranasal LHRH, and 2 days after cessation of LHRH application (d+2). On these days, we analysed serum concentrations of LH, FSH, total testosterone (T) and free testosterone (fT) at 9am. At 11am external stimulability of HPGA was tested with an intravenous LHRH stimulation test. Serum concentrations of LH, FSH, T and fT were analysed before and 60 min after intravenous LHRH. Results Basal LH increased from d-2 to d1 during the intranasal LHRH application period ( $p<0.05$ ), tended to remain elevated on d7 ( $p=0.09$ ), and declined below the pre-application level on d+2 ( $p<0.01$ ) (5.1±2.5, 19.2±11.5, 8.3±2.4, 1.4±1.0 mU/ml, respectively). FSH remained unchanged over time (5.1±7.0, 8.6±11.9, 4.4±4.5, 2.7±3.0 mU/ml, respectively). T increased from d-2 to d1 ( $p<0.05$ ), tended to remain elevated on d7 ( $p=0.08$ ), and declined below the pre-application level on d+2 ( $p<0.01$ ) (5.5±2.1, 7.4±2.5, 9.2±3.8, 4.2±4.2 ng/ml, respectively). fT remained unchanged on d1 compared to d-2, increased significantly on d7 ( $p=0.01$ ), and declined far below the pre-application level on d+2 ( $p<0.01$ ) (10.6±3.2, 14.1±6.8, 16.3±5.8, 4.2±1.7 pg/ml, respectively). LH increase 60 min after intravenous LHRH declined from d-2 to d1 and d7 ( $p<0.01$ ) and normalized again on d+2 ( $p<0.01$ ) (19.0±9.6, 5.4±6.2, 3.6±2.1, 12.7±4.5 mU/ml, respectively). FSH, T, and fT after intravenous LHRH remained unchanged over time. Discussion The study showed that 7-day intranasal LHRH application dramatically affected pituitary LH release and consequently increased peripheral testosterone concentrations in healthy young men. Spontaneous pituitary LH secretion and consequently T and fT concentrations were reduced at least up to 2 days after cessation of intranasal LHRH application. Simultaneously, external stimulability of the pituitary gland was reduced during intranasal LHRH application and became normal again 2 days later. This pattern of hormones might be used to test for LHRH application during doping control settings. This project has been carried out with the support of WADA.

### THE INFLUENCE OF VITAMIN-D SUPPLEMENTATION ON THE EFFECT OF 12-WEEKS RESISTANCE TRAINING IN HEALTHY UNTRAINED YOUNG AND ELDERLY MEN

Agergaard, J., Tørstrup, J., Uth, J., Vestergaard, J., Boesen, A., Schjerling, P., Langberg, H.

Bispebjerg Hospital

Introduction: Recently studies have shown that increased serum vitamin D levels improve skeletal muscle function in vitamin D insufficient elderly. The purpose of this study was to investigate whether there is an additive effect of vitamin D supplementation on skeletal muscle strength, mass and morphology during resistance training in young and elderly men. Material and Methods: The study was conducted

from December to April in Copenhagen, Denmark, where sunlight is not having an effect on serum 25(OH)D levels. Healthy untrained young (N=20, age 22.8 ± 2.0) and elderly (N=20, age 67.3 ± 4.3) men were randomized to daily supplementary intake of either 48 µg of vitamin D + 800 mg calcium (Vitamin D) or 800 mg calcium alone (Placebo) for 16 weeks. During the last 12 weeks the subjects underwent progressive resistance training 3 times/week of m. quadriceps femoris (leg extensions and leg press). Pre and post 12 weeks training hypertrophy were measured by cross sectional area (CSA) from MRI-scans and isometric strength of m. quadriceps femoris. Moreover, from muscle biopsies taken pre and post 12 weeks training muscle fiber type morphology were analyzed. Results: Due to 16 weeks of vitamin D supplementation serum 25(OH)D levels increased in the young and elderly vitamin D groups, and were elevated compared to the young and elderly placebo group respectively. Twelve weeks of resistance training increased CSA and isometric muscle strength of m. quadriceps femoris in both the young and elderly men. However, there was no evidence for an additive effect of vitamin D supplementation on muscle strength or hypertrophy. Nevertheless, the muscle fiber types in the young vitamin D group showed an increase in type IIa fiber percentage and percentage area compared to the placebo group. Discussion: Twelve weeks of resistance training gave an increase in CSA and strength of m. quadriceps in young and elderly healthy untrained men. However, during resistance training vitamin D supplementation did not have an additive effect on improvements in skeletal muscle function or mass. Only the muscle fiber type morphology in the young vitamin D group showed an improved training response. Studies showing an effect of vitamin D have looked at frail vitamin D insufficient elderly without any training intervention, whereas this study was performed on vitamin D sufficient healthy individuals with progressive resistance exercise applied. Hence, in the present study any possible effect of vitamin D may be overridden by the effective training protocol. Clearly it may also be speculated that only insufficient vitamin D levels may have a negative impact on optimal skeletal muscle function and response.

#### PLATELET-RICH PLASMA TO TREAT UPPER PATELLAR TENDINOPATHIES

Kaux, J., Croisier, J.L., Simoni, P., Brabant, G., Lapraille, S., Lonnew, V., Noel, D., Rodriguez de la Cruz, C., Colette, J., Le Goff, C., Gothot, A., Crielaard, J.M.

*University of Liège*

Introduction: Tendinopathies, especially upper patellar tendinopathy also known as jumper's knee, often remain rebel to conservative treatments. Several experimental studies have shown the healing properties of platelet and their growth factors. These factors have the potentiality to improve healing of different tissues: bones, muscles, tendons... Researches have specifically demonstrated the platelets action as mediator and/or enhancer of tissue healing. On the other hand, such treatment has been totally removed of list of doping treatments. The aim of our study was to investigate the effect of 1 injection of PRP in patients suffering from chronic jumper's knee. Methods: Patients performed imaging (US and MRI) and functional assessments, and a clinical examination using an algometer, before treatment and 6 weeks after PRP treatment. They were also invited to answer to questionnaire relative to pain and functional status. PRP was obtained from autologous blood using an apheresis system (COM.TEC, Fresenius). The injection of 6mL of PRP was realised without local anaesthesia into the proximal insertion of the patellar tendon. A 48h rest-time was recommended after infiltration. Afterwards, a submaximal eccentric reeducation was initiated 1 week after infiltration 3 times a week during 5 weeks. In case of pain, anti-inflammatory drugs were prohibited and patient were encouraged to take class I or II painbrakers. Our protocol was approved by Ethic Committee of University and University Hospital of Liège. Results: Twenty patients with jumper's knee were included in our study. Pre-injection tests revealed pain of the upper part of the patellar tendon just below the patella, associated with loss of function. Imaging exams confirmed diagnosis. Six weeks post-injection, the clinical status was improved for the majority of the patients, with a significant decrease of algo-functional scores. The pain reported during functional assessments was decreased (in particular for the eccentric actions), yet no significant improvement of physical performances was observed. We found no significant differences between imaging exams before and 6 weeks after PRP injection. Conclusion: One in situ injection of PRP clinically improved patients with jumper's knee 6 weeks after treatment. Most patients reported a decrease of pain during day-life and through physical activities. However nor functional performances neither imaging were improved. A followup at 3 months is actually in process to evaluate more long term efficacy of PRP treatment.

#### EFFECT OF KINAESTHETIC TAPES ON PLANTARFLEXOR MUSCLE PERFORMANCE

Csapo, R., Herceg, M., Alegre, L., Crevenna, R., Pieber, K.

*Carinthia University of Applied Sciences*

Introduction Kinaesthetic tapes (KT) are frequently used in physiotherapy and sports medicine to improve circulation of blood and lymph flow, relieve pain through neurological suppression, or enhance proprioception by cutaneous stimulation of peripheral afferent nerves. In addition to these therapeutic objectives, it has been suggested that KT-application may enhance motoneuron activity, purportedly facilitating contraction and increasing muscle strength (Hammer, 2006). However, studies performed to validate the proposed performance-enhancing effects have yielded controversial results (Vithoulka et al., 2010; Fu et al., 2008). The purpose of this study was to examine the effects of application of KT on plantarflexor muscle performance in different motor tasks. We hypothesised that taping of the triceps surae muscle would improve isometric plantarflexor strength and muscular endurance with no significant effect on drop jump performance. Methods Using a repeated-measures design, all performance measures were obtained in 12 male (age: 24.9±4.0 yrs; height: 1.80±0.06 m; mass: 74.0±6.2 kg) and 12 female (age: 24.0±3.6 yrs; height: 1.67±0.04 m; mass: 61.1±5.9 kg) participants on two separate occasions: without tapes (NT) and after application of KT over the triceps surae muscle. Isometric plantarflexor strength was measured by Biodex dynamometry. During strength tests, integrated electromyographic activity (iEMG) was obtained from both heads of the gastrocnemius muscle. To determine muscular endurance, participants completed an isokinetic fatigue test (30 consecutive contractions at 180°/s). Drop jump performance (jump heights and ground contact times) was assessed in a series of jumps from different drop heights (20, 40 and 60 cm), analysing the vertical components of ground reaction forces. Results The KT-intervention was associated with a general increase in

gastrocnemius iEMG activity. However, significant increases in isometric strength were only found at fully dorsiflexed ankle positions (KT:  $155.2 \pm 42.0$  Nm vs NT:  $140.5 \pm 51.5$  Nm,  $p = 0.037$ ). Strength gains were negatively correlated to baseline strength ( $r = -0.58$ ,  $p = 0.003$ ). In the isokinetic fatigue and drop jump tests, no significant differences were observed between NT- and KT-conditions. Discussion The application of KT over the triceps surae muscle promotes an increase in isometric strength and gastrocnemius iEMG activity. Our data suggest that these effects are joint-angle dependent and more prominent in weaker individuals. By contrast, the KT-intervention does neither improve drop jump performance nor muscular endurance. References Fu, T., Wong, A., Pei, Y. et al. (2008). *J Sci Med Sport*, 11(2), 198-201. Hammer, W. ### THE EFFECT OF BLOOD-BORNE FACTORS ON HUMAN TENDON CELLS: COUNTERACTING TENDON HEALING?

Bayer, M.L., Schjerling, P., Heinemeier, K.M., Herchenhan, A., Krosgaard, M., Kjaer, M.

*Institute of Sports Medicine Copenhagen and Center for Healthy Aging*

**Introduction** The use of platelet-rich plasma (PRP) as treatment following tendon injuries has received substantial attention in the last few years, both due to frequent use and due to lack of scientific evidence for an effect on tendon regeneration (de Jonge et al., 2011; Paoloni et al., 2011). Both PRP and serum contain a high amount of several growth factors, especially transforming growth factor-beta1 (TGF-beta1), and we aimed to study the effect of serum supplementation and the isolated effect of TGF-beta1 on the expression of key tendon matrix genes by human tendon cells. **Methods** Cell cultures were established from mature human semitendinosus and gracilis tendon, and studied in both monolayer (2D) cultures and engineered 3D tendon-like tissue. Tendon cells were subjected to culture medium with or without serum supplementation ( $n=5$ ). The effect of TGF-beta1 was tested by adding the growth factor to the medium (25ng/ml,  $n=5$ ). Subsequently, mRNA expression was analyzed by quantitative real-time PCR. **Results** Serum supplementation caused a decrease in mRNA expression of collagen type III, XII, XIV and fibronectin (FN) ( $p<0.05$ ). Addition of TGF-beta1 to human tendon cells had a marked negative effect on the expression of collagen type XIV and decorin mRNA ( $p<0.01$ ), whereas it caused an upregulation of collagen V, FN and fibromodulin. Collagen I expression was not affected by either serum supplementation or TGF-beta1. **Discussion** The results suggest that a high concentration of blood-borne growth factors and of TGF-beta1 specifically, impairs the expression of several key tendon genes, among which the decreased expression of collagen type III, XII, XIV and decorin are prominent. As these molecules are important early regulators of collagen fibrillogenesis (Banos et al., 2008), the lack of any of these molecules leads to structurally and functionally inferior tissue (Ansoerge et al., 2009). These findings upon human tendon cells *in vitro* raise the possibility that PRP, which has a composition comparable to serum, could have a detrimental effect upon collagen fibrillogenesis associated with tendon healing. **References** Ansoerge HL, Meng X, Zhang G, Veit G, Sun M, Klement JF, Beason DP, Soslowky LJ, Koch M, Birk DE. ### MULTIMODAL PHYSIOTHERAPY IMPROVES OUTCOME BEYOND PLACEBO INJECTION BUT DOES NOT ALTER EFFECTS OF CORTICOSTEROID INJECTION FOR LATERAL EPICONDYLALGIA.

Coombes, B., Bisset, L., Brooks, P., Vicenzino, B.

*University of Queensland*

**Introduction** The short-term benefits of corticosteroid injection for treating lateral epicondylalgia (tennis elbow) must be weighed against evidence of poorer long-term success (Coombes, Bisset et al. 2009) and higher recurrence compared to wait and see or physiotherapy treatment using elbow manipulation and exercise (Bisset, Beller et al. 2006). Clinically, practitioners frequently emphasise the importance of an active rehabilitation program, with recent evidence suggesting that mechanical loading may counteract the potentially deleterious effect of corticosteroid treatment on fibroblasts (Chen, Marymont et al. 2007). We aimed to investigate if the lower long-term success and greater recurrence of corticosteroid injection (1) can be ameliorated by addition of a multimodal physiotherapy program of manipulation and exercise and (2) are not placebo in nature. **Methods** 165 patients with unilateral lateral epicondylalgia participated in an injection-blinded placebo controlled trial, randomly assigned to one of four groups: corticosteroid injection ( $n=43$ ), placebo injection ( $n=41$ ), corticosteroid injection plus physiotherapy ( $n=40$ ) or placebo injection plus physiotherapy ( $n=41$ ). Multimodal-physiotherapy involved eight sessions of elbow mobilisation, progressive resistance and sensorimotor exercise, supplemented with a home program. Evaluation of the addition of multimodal physiotherapy, as well as the placebo effect of injection on success and recurrence 12 months after treatment were analysed on an intention to treat basis ( $p<0.01$ ). Number needed to treat (NNT) and 99% CI were calculated as a clinically meaningful measure of effect size. **Results** Compared to placebo injection, injection supplemented with manipulation and exercise improved all outcomes in the short-term (Success: 4weeks NNT 3 (2 to 21); 8 weeks NNT 3 (2 to 17)). Addition of manipulation and exercise did not improve the long-term success of injection, nor improve the recurrence of injection, which was 42% higher with corticosteroid injection than placebo (NNT -2 (-4 to -4)). **Discussion** Addition of eight weeks of exercise and manipulation to corticosteroid injection does not ameliorate the medication-induced delayed recovery in patients with lateral epicondylalgia. Patients ought to be made aware that for every two patients that have a corticosteroid injection, one will experience a recurrence within 12 months, regardless of whether they receive physiotherapy. **References** Bisset, L., E. ### AN AUDIT OF ROUTINE PRELIMINARY MEDICAL EVALUATION IN ATHLETES ATTENDING FOR LABORATORY BASED MAXIMAL EXERCISE TESTING

Mahony, N., Bailey, D.

*Trinity College Dublin*

**Introduction** Athletes attend the exercise laboratory to gauge fitness, individualise training prescription and monitor training effectiveness. Pre-exercise medical scrutiny based on standard guidelines (ACSM, 2002) is routinely performed in our laboratory despite uncertainty in the literature with regard to effectiveness and benefits of the process and outcomes (Wingfield et al., 2004). The aim of this study was to review medical findings, exclusions, restrictions, and recommendations made in preliminary medical evaluation procedures, in order to assess the value of the process and fulfil Irish Medical Council (IMC, 2011) requirement for audit of clinical practice **Methods** Preliminary medical questionnaire and examination results of athletes who attended the exercise laboratory between June 2010 and June 2011 are

currently being reviewed. Questionnaire consisted of; training, family, past medical, medications, menstrual, and immunisation history sections and systems review checklist. Examination consisted of resting pulse and blood pressure (Omron, Japan), head, neck, cardio-respiratory examination, and problems highlighted in the questionnaire. Further ancillary tests; pulmonary function (Micro-medical, UK) and full blood count (Coulter Electronics, UK) were performed to out-rule; airway limitation; and sub-clinical anaemia, dehydration, and infection. Anonymous medical findings and ancillary test data were recorded on a spread sheet for qualitative analysis. Results To date 132/210 records, (19F/113M) have undergone preliminary scrutiny and 20/210 records detailed analysis of ancillary pulmonary function and haematological data. Sports represented were; cycling, triathlon, running, rowing, sailing, and Gaelic games. Athletes were excluded from testing due to minor illness (4), athletic fatigue (2) and history of exercise related syncope (1); a further 6 athletes were restricted to sub-maximal testing due to age (>45yr), elevated DBP (102mmHg), family history of SADS and a previously undiscovered heart murmur. Main recommendations included; urgent cardiology opinion (1), routine ECG/Echocardiogram (8), iron studies (3), dietary analysis and iron supplementation (3), GP follow-up for minor illnesses (6), further rehabilitation of minor injuries (2), and DXA scan (1). No abnormal findings were found in menstrual history, physical examination and no previously unknown respiratory limitations were detected. In analysis of full blood count data 7 athletes had borderline low WCC, one athlete had iron deficiency anaemia and several had low MCH values. Discussion This study has shown that an abbreviated 10 minute pre-participation medical procedure can detect significant medical conditions relevant to both performance and health of the athlete; and in one case revealed episodes of exercise related syncope in a young tri-athlete that led to diagnosis of a serious cardiac conduction defect. ### IS-SH06 Psychological and Sociological Perspectives on Prevention and Rehabilitation of Sport Injuries

#### METHODOLOGICAL CHALLENGES IN THE PREVENTION AND REHABILITATION OF SPORTS INJURY: A BEHAVIORAL PERSPECTIVE

Johnson, U.

*Halmstad University*

This presentation will discuss methodological challenges in the prevention and rehabilitation research of sports injury focusing on especially the psychological domain. During the last 30 years several scholastic studies have been published in the sport injury field using contemporary research designs and theoretical frameworks. Frequently used designs typically consist of cross-sectional studies based on one or two questionnaires and using samples of university (male) athletes. However, many important research variables need further recognition for the advancement of the field. For example, there is a need for strong and integrated research design, maybe stimulated by Bahr & Krosshaug (2005) "Model of injury causation", a need for prediction of overuse injuries, a need for controlled and experimental studies as well as studies of the stress response in relation to pre- and post-injuries. Moreover, the use of standardized measures and proper statistics as well as recognition of expectancy effects in intervention studies is challenging methodological concerns in order to advance the field (Johnson, 2007). One particularly challenging concern is to integrate latent growth curve modeling (LGCM) in both pre- and post-injury research. Using LGCM, in contrast to more traditional analyses when examining change and dynamic relationships across time, entails several advantages, such as increased power of tests of mean differences and the possibility to model change in latent factors and flexibility to study how the latent factors of level and change may predict other outcomes (Duncan et al., 2006). Further research examining prevention and rehabilitation of sports injury aiming at athlete is warranted. References: Bahr R., & Krosshaug, T. (2005). #### ATHLETES RETURN TO SPORT FOLLOWING INJURY REHABILITATION: A PSYCHOSOCIAL PERSPECTIVE

Podlog, L.

*University of Utah*

This presentation will highlight sociological and psychological research examining athlete experiences in returning to sport following injury rehabilitation. In particular, the traditional wisdom that physical and psychological readiness to return-to-sport following injury are synonymous will be challenged by examining the key psychosocial issues facing returning athletes (Arden et al., 2011). In elucidating these issues, it will be suggested that a range of competence, autonomy, and relatedness based factors may exert a profound influence on athletes' return-to-sport outcomes (Podlog et al., 2011). Among the most commonly reported competence issues are re-injury anxieties, diminished confidence in return to play abilities, fitness concerns, and worries that one may not be skilled enough to maintain a position/role on the team. Internal and external pressures to return to sport indicate that autonomy issues may also be apparent (Charlesworth & Young, 2004). Finally, relatedness issues (i.e., connection to others) in terms of isolation from coaches, teammates, and training partners may occur as recovering athletes become removed from their usual training and competition venues and spend more time in rehabilitation settings. A lost sense of social identity and questions about one's value as a person without competitive involvement may also lead to feelings of disengagement from one's sport. Moreover, a lack of social support from coaches, teammates and significant others may heighten perceptions of a lack of relatedness with significant sporting others (Bianco, 2001). Collectively, these findings suggest that rehabilitation specialists, coaches, and teammates should address competence, autonomy, and relatedness issues in an attempt to enhance athlete return-to-sport outcomes. Further research examining the efficacy of interventions targeting athlete issues during the return-to-sport transition is warranted. References Arden, C.L., Webster, K. E., Taylor, N. ### **SPORTS INJURY PREVENTION: A PSYCHOLOGICAL INTERVENTION PROGRAM FOCUSING FLOORBALL**

Tranaeus, U., Johnson, U.

*Karolinska Institute/Halmstad university*

Sports injury prevention: a psychological intervention program focusing floorball. Tranaeus, U., 1, 2, Johnson, U., 2. 1: Karolinska Institutet (Stockholm, Sweden), 2: Halmstad University (Halmstad, Sweden). Sports injuries are an obstacle in most athletes' strive to achieve their goals. It is of importance to develop rehabilitation programmes and safe return to sport; also preventive intervention programmes are required. The aetiology of sports injuries shows multi-facetted natures. The results of psychological studies shows evidence that psychosocial factors affect the injury-risk exist (e.g. Johnson, 2011). One theoretical framework to intervention programme is Williams and Andersen's stress-injury model (1998). The model provides psychosocial factors which are activated by the athletes' cognitive and somatic stress-response. Over the years, psychological preventive intervention programmes have been evaluated, aiming to reduce the number of injuries through stress- management (e.g. Johnson et al., 2005). In our recently conducted study, the overall aim was to reduce the stress-response through a psycho-educational intervention and consequently lower the number of injuries. Out of the 22 participating Swedish elite male and female floorball teams, 10 teams were randomized to a preventive intervention programme. This programme was implemented during the first half of the season and consisted of six hour-long sessions with one whole team at a time, based on goal-setting, stress management, concentration, relaxation, self-confidence and emotions. The program was constructed to meet the cognitive and somatic reactions of stress. All sustained injuries were recorded at the start of the study and registered as they occurred during the eight months season's. The intervention-group sustained less injuries compared to the control-group. Reports of past and present research will be given at the seminar. ##### **EFFECTS OF AGE AND TRAINING ON TENDON STIFFNESS AND FAST FORCE PRODUCTION**

Blazevich, A.

*Edith Cowan University*

Tendons are elastic elements that transfer muscular forces to bones. As intermediaries between muscles and bones, their mechanical characteristics significantly impact on movement performance. In addition to promoting energy savings during tasks such as locomotion, tendon mechanical properties, in particular tendon stiffness, influence the rate at which forces are transferred from muscles to bones (i.e. electromechanical delay and rate of force development). This is because energy transferred by a muscle must travel in a wave-like manner through the tendon to reach the bone, and the rate of wave propagation is influenced by tendon stiffness, amongst other parameters. Tendon stiffness must therefore influence fast force production during athletic tasks as well as during postural stabilisation and balance tasks. There is considerable evidence that tendon stiffness is highly changeable. Chronic changes in both loading and unloading (i.e. changes in physical activity patterns) influence tendon stiffness, and tendon stiffness has been shown to increase through the lifespan from childhood to adulthood and then decrease in later life. What is not clear is whether age-related changes in tendon stiffness reflect a true aging response or are a result of age-related changes in loading patterns (i.e. exercise). Recent research hints that both may be factors in the development of tendon stiffness from childhood to adulthood, as indicated by both changes in tendon cross-sectional area and Young's modulus and by moderate correlations between tendon stiffness and age, body mass and peak muscle force. Although modelling studies suggest that changes in tendon stiffness should have a dramatic impact on movement performance, empirical testing has rarely been done to ascertain whether changes in tendon stiffness of the magnitude that occur with aging or physical activity (or inactivity) are sufficient to have a noticeable functional impact. In particular it is not clear whether such changes have a meaningful effect on the rate of force transfer from muscle to bone. Recent evidence from studies in children suggests that the impact is noticeable, but small. Specifically, the data suggest that changes in tendon stiffness from early childhood through to adulthood have a notable impact on rate of force development and electromechanical delay. However, significant (>30%) increases in tendon stiffness resulting from strength training probably has only a minor effect. Whether these small effects influence complex movement performance is still unclear.

##### **TENDON ADAPTATIONS TO OVERLOADING AS MEASURED IN VIVO: WHERE DOES THE DISCREPANCY COME FROM?**

Seynnes, O.R.

*Norwegian School of Sport Sciences*

Tendons' essential role during locomotion and movement relates to the tradeoff between enabling accurate positioning of the limb and the storage and restitution of elastic energy. The study of this role and how it might be affected with increased loading largely relies on i) precise methods to estimate tendon mechanical properties and ii) a comprehensive understanding of the adaptation process. Currently these properties can be estimated non invasively, in vivo, by obtaining the force-elongation relationship with combined ultrasonography and dynamometry. Using this technique, training studies generally indicate an increase in tendon tensile stiffness (1). Yet, partly owing to

methodological aspects, large differences between studies can be found in the magnitude of changes, ranging 15% to over 60%. Furthermore, increases in modulus or cross-sectional area (CSA) underlying tendon stiffening have not been consistently observed, preventing a clear understanding of this type of adaptation. The increase in tendon stiffness in response to overloading is usually ascribed to an increase in collagen content and in cross-linking of collagen molecules. These metabolic responses would in turn cause an increase in tendon Young's modulus and CSA. Intriguingly, animal studies suggest that tendon modulus is relatively independent from function, species or body mass, whereas damage resistance to prolonged stress correlates well with habitual stress (2, 3). In view of these observations, some authors have proposed the safety factor (ratio of failure stress to habitual stress), rather than modulus, as the essential property driving tendon adaptation and 'self-repair' as a central feature of this process (2). Although the precise mechanisms underlying tendon adaptation remain elusive, it seems that, in conditions of long term adaptations, adjustments in tensile stiffness are mostly achieved by changes in tendon dimensions, contrasting with reports of increased tensile modulus in human tendons subjected to overloading. Here we will propose a review of the technical considerations influencing in vivo measurements of tendon structural and mechanical changes to overloading. In a second part, current concepts of tendon adaptations and a possible model will be discussed. 1. Heinemeier KM, Kjaer M. Journal of musculoskeletal & neuronal interactions 11: 115-23, 2011. 2. ## TENDON PLASTICITY IN NORMAL, EXERCISED AND PATHOLOGICAL TENDON

Legerlotz, K., Screen, H.R.C., Riley, G.P.

*University of East Anglia*

**Introduction** Biological materials such as tendons must adapt their mechanical properties and matrix composition in order to remain functional. While loading is known to be required for tendon tissue homeostasis, overloading has been implicated as a contributing factor in the initiation of tendinopathies. The aim of our study was to investigate how defined loading or overloading regimes influence mechanical properties and gene expression in normal tendon fascicles from different tendons, and to analyse gene expression in pathological tendon tissue, with a particular focus on the inflammatory cytokine Interleukin 6 (IL6). **Methods** Tendon fascicles were isolated from 3 tendons: bovine foot flexor and extensor, or human hamstrings tendons. Fascicles were secured in custom made loading chambers (1) and subjected to a variety of different loading conditions, from no load to heavy loading, with different durations of static and cyclic strain. Loading was followed by either mechanical testing or gene expression analysis by qRT-PCR. Also, gene expression in human tendon samples from normal, ruptured or painful tendinopathic Achilles tendon (AT) and normal or painful tendinopathic posterior tibialis tendon (PTT) were analysed by qRT-PCR. **Results** IL6 gene expression was induced with loading in both bovine and human tendon tissue. Although the mechanical properties of bovine flexor and extensor tendons were different, with the extensor tendon failing at higher strain levels, there was no difference in the gene expression response to cyclic loading. In human hamstrings fascicles, the IL6 loading response was induced early, peaking at 3h of static strain. Only very low levels of strain were needed to induce IL6 expression relative to levels in freshly dissected tissue. Unloading also induced IL6 expression and to a greater extent than loading. Compared to normal tendon IL6 expression was upregulated in ruptured and painful AT (180- and 6.3-fold), but not in painful PTT. **Discussion** We have shown that IL6 gene expression is upregulated in different tendons with loading, and that only low levels of strain are needed to induce this response. Since IL6 is known to stimulate the synthesis of collagen, the main component of tendon matrix, IL6 might play an important role in tendon adaptation to exercise. However, we found IL6 also to be upregulated with unloading and pathological conditions of the AT also, suggesting that IL6 could also be involved in either the development of tendinopathies or the healing response. It remains to be established whether the difference in gene expression between pathological AT and PTT is due to differences in loading, tendon structure or composition or reflects a difference in the type, progression or healing of tendinopathy. **References** (1) Legerlotz et al. ### OP-BN06 Biomechanics

#### THE INFLUENCE OF HIP ANGLE ON DORSIFLEXION RANGE OF MOTION, PASSIVE ANKLE MOMENT AND NEUROMUSCULAR REFLEX ACTIVITY OF THE TRICEPS SURAE

Kay, A.D., Warren, L.A., Hammond, L.E.

*The University of Northampton*

**Introduction** Adopting a slumped position in the spine stretches the neuromeningeal tract, which is a common method to identify signs of neural tension including a pain response and limited range of motion (ROM) at the hip and knee (Boland & Adams, 2000). However, this phenomenon has not been examined at the ankle; therefore, the aims of the present study were to examine whether hip position, likely to illicit neural tension, would influence ankle dorsiflexion ROM, passive moment and electromyographic muscle activity of the triceps surae. **Methods** Eighteen recreationally active participants (10 men and 8 women: mean  $\pm$  SD age = 28.6  $\pm$  6.3 yr, mass = 73.3  $\pm$  12.9 kg, height = 1.7  $\pm$  0.1 m) volunteered for the study after giving written, informed consent, with ethical approval from the University of Northampton. Passive dorsiflexion ROM trials were performed on an isokinetic dynamometer across three hip positions (supine = 10°; semi-reclined = 55°; upright = 85°). Dynamometry data measuring dorsiflexion ROM and passive ankle moment were recorded during the trials with electromyographic (EMG) activity of the triceps surae also recorded; simultaneous 3D motion analysis also measured ROM. Separate repeated measures ANOVA's with post-hoc analysis determined the location of any significant differences between conditions; significance accepted at  $p < 0.05$ . **Results** Significant differences were detected in dorsiflexion ROM ( $p < 0.01$ ), passive moment ( $p < 0.05$ ) and EMG (Sol, GM) ( $p < 0.01$ ) between hip flexion conditions. Post-hoc analyses revealed no difference between supine and semi-reclined hip positions in any measure, while the upright position had significantly lower dorsiflexion ROM, significantly lower passive moment but significantly higher EMG activity at peak ROM than both supine and semi-reclined conditions. Paired analyses between dynamometry and motion analysis ROM data revealed dynamometry significantly ( $p < 0.01$ ) overestimated ROM in each condition although this did not explain the differences across hip conditions. **Discussion** Despite the reduction in dorsiflexion ROM in the upright position there was a

significant increase in EMG activity. As ROM was reduced it is unlikely that this was a stretch-reflex response from type Ia muscle afferents but may be the result of type IV nociceptors. The reduction in dorsiflexion ROM clearly has implications for dynamometry testing protocols and subject positioning when examining ankle kinematics and mechanics. Similarly, the motion analysis data also revealed that dynamometry analysis overestimated ROM, with significantly greater overestimation in the two reclined positions due to increased heel displacement from the dynamometer footplate. ### THE RATE OF FASCICLE STRETCH DURING ECCENTRIC EXERCISE AFFECT THE LONGITUDINAL ADAPTATION OF THE VASTUS LATERALIS MUSCLE

Sharifnezhad, A., Marzilger, R., Arampatzis, A.  
*Humboldt Universität zu Berlin*

**Introduction:** The longitudinal plasticity of muscle is a well-known phenomenon in the literature (Williams & Goldspink 1978). Butterfield & Herzog (2006) reported that the best predictors for a longitudinal adaptation in rabbit tibialis anterior muscle were the maximal moment and the amount of fiber strain. In humans there is little information about the effect of controlled eccentric loading on the longitudinal adaptation of muscles. The purpose of this study was to investigate the effect of magnitude and velocity of the applied eccentric stimulus on the longitudinal adaptation of the vastus lateralis muscle. **Methods:** We applied four different eccentric exercise protocols on two experimental groups. The first group (n=10) exercised the knee extensors of one leg (protocol 1) at 65% of the maximum voluntary contraction (MVC) and the second leg (protocol 2) at 100% MVC on a dynamometer. The angular velocity of the eccentric contractions was 90°/s and the range of motion from 25° to 100° knee angle in both protocols. The second group (n=10) exercised one leg at 100% MVC, 90°/s angular velocity and a range of motion between 25° and 65° (protocol 3). The other leg exercised at 100% MVC, 240°/s angular velocity and range of motion between 25° and 100° (protocol 4). The control group included 11 participants. In the pre-post measurements we examined the fascicle length of the vastus lateralis from 20° to 90° knee angle and the moment-angle relationship of the knee extensors. **Results:** We found an increase ( $p < 0.05$ ) in fascicle length of vastus lateralis compared to the control group only in the leg trained with the protocol 4. The increase in fascicle length was similar (~14%) for the whole range of the knee angle. During the training in protocol 4 the rate of fascicle strain of the vastus lateralis were ~3.3 times higher compared to the other three protocols. Furthermore the high strain velocity of the fascicles has been located in the phase where the moment decreased. The moment-angle relationship of the knee extensors has been improved in all protocols with a superior improvement in protocol 2. **Discussion:** Exercise protocol 4 was the only one that showed clear longitudinal changes in fascicle length. The findings give evidence that (a) not every eccentric exercise causes an increase in fascicle length and (b) the velocity of fascicle stretch seems to be important for the longitudinal adaptation. A rapid decrease of moment during the eccentric exercise may affect the rate and probably the magnitude of fascicle strain, due to the catapult effect of the tendon. **References:** Butterfield & Herzog (2006). *Pflügers Arch Eur J Phys*, 451, 688-700. ### MUSCLE AND TENDON CROSS-SECTIONAL AREA AND VERTICAL STIFFNESS IN HOPPING

Eriksrud, O., Ekeberg, M., Federolf, P., Bojsen-Møller, J., Cabri, J., Raastad, T.  
*Norwegian School of Sport Sciences*

**Introduction** The vertical stiffness of the locomotor system during running or hopping is regulated by the tension in the muscle-tendon systems crossing the ankle, knee and hip joints. This tension is controlled by neuromuscular activation, however, it may also be influenced by the mechanical properties of the muscles or tendons. This study investigated if muscle and tendon cross-sectional area contribute to the bilateral or unilateral vertical stiffness in hopping. **Methods** Seventeen athletes from different disciplines (8 power lifters, 7 distance runners, 3 high jumpers) were tested in bilateral and unilateral hopping for 15 seconds on a floor-mounted force plate (AMTI). The average vertical stiffness of 10 consecutive hopping cycles was determined according to Morin et al. (2005). The cross-sectional area of anterior and posterior thigh and leg muscles and of the patellar and Achilles tendon were obtained from MRI images. **Results** Bilateral stiffness ( $20.7 \pm 4.5 \text{ kN}\cdot\text{m}^{-1}$ ) was significantly greater than unilateral vertical stiffness ( $12.9 \pm 4.0$  and  $12.1 \pm 2.6 \text{ kN}\cdot\text{m}^{-1}$ ,  $p < 0.05$ ). The dominant leg was 6.6% stiffer than the non-dominant leg, however, this difference was not significant ( $p > 0.05$ ). No significant correlations were found between bilateral and unilateral stiffness and cross-sectional area of the thigh and leg muscles or patellar and Achilles tendon. **Discussion** The vertical stiffness measure in hopping reflects the overall function of the musculoskeletal system of the lower extremity where ankle (Farley and Morgenroth, 1999) and knee joint stiffness (Hobara H et al., 2009) have been found to be important. Cross-sectional area of muscles and tendons crossing these joints reflect force generation capacity, however this was not found to be correlated to vertical stiffness in this study. **References** Morin JB et al. (2005). *J Appl Biomech*, 21, 167-180. Farley CT, Morgenroth DC (1999). *J Biomech*, 32, 267-273. Hobara H et al. (2009). *J Biomech*, 42, 1768-1771.

### POSTURAL LEANING DIRECTION CHALLENGES THE MANIFESTATION OF THE TONIC VIBRATION REFLEX RESPONSE

Amiridis, I., Kanakis, I., Arvanitaki, C., Patikas, D., Hatzitaki, V.  
*Aristotle University of Thessaloniki*

**Introduction** The application of Tendon Vibration (TV) during standing leads to a postural shift in the direction of the applied vibration (Kavounoudias et al., 1999). Nevertheless, the vibration induced muscle tension regulation cannot fully account for the observed postural changes suggesting that the processing of proprioceptive input depends on the degree of instability of a particular task (Radhakrishnan et al., 2011). In this study, we hypothesized that the effect of TV on body posture and ankle muscle activation is dependent on a) the direction of instability induced by leaning and b) the active state-loading of the muscle. **Methods** Twenty young adults stood over the midline of two adjacent force platforms (Bertec, USA) in a) bipedal stance distributing Body Weight (BW) equally (50%) between the two platforms, b) forward and backward leaning by transferring 80% of BW in the front and back platform respectively. To maintain the required leaning position for 60s, subjects received on-line visual feedback of BW distribution matched to a target line into a large screen projector (Barco NV, Belgium). In each position, tendon vibration (frequency 80Hz, amplitude 1.5-1.8 mm, Technoconcept, France) was carefully applied during the middle 20 s over the Achilles Tendon (AT), the Tibialis Anterior Tendon (TAT) or both tendons (BOTH). **Results** TV resulted in a significant postural shift (deviation from the target) towards the vibration side and an increase of the Standard Deviation (SD) of the resultant BW distribution during as well as in the post vibration period. A significant Vibration x Inclination interaction indicates that these effects were diminished during forward leaning but were greater during backward leaning. The AT vibration resulted in a significant increase of MGAS and SOL EMG activity that was greater during mid stance and backward leaning but lesser during forward leaning. Similarly, TAT

vibration increased TAis EMG only in the backward leaning position, while this reflex response was attenuated in the mid stance and forward leaning positions. Discussion The greater postural fluctuations during TV application are due to an increase in reflex activity at the ankle. The effect of TV is modulated by the direction of postural leaning being inhibited during forward and facilitated during backward leaning. On the other hand this does not seem to be dependent on the degree of active state-loading of the muscle. The present results favor the hypothesis of higher order processing of proprioceptive signals arising from the ankle muscles. References Kavounoudias A, Gilhodes JC, Roll R, Roll JP (1999). *Exp Brain Res*, 124, 80-88. Radhakrishnan SM, Hatzitaki V, Patikas D, Amiridis IG (2011). *Exp Brain Res*, 213, 423-433.

## LOWER LIMB INTERNAL KINETICS AND EMG IN INTERNATIONAL RACE WALKERS

Hanley, B., Bissas, A.

*Leeds Metropolitan University*

Introduction Race walking is an Olympic event with rules which state that no visible loss of contact should occur and that the knee must be straightened from initial contact until the vertical upright position. Little research has been carried out on lower limb muscle activity in race walking despite such information being potentially useful to coaches and athletes. The aim of this study was to analyse lower limb joint moments, powers and electromyography patterns in elite race walking. Methods Twenty international race walkers performed multiple trials at their season's best pace in a laboratory setting. The group consisted of ten men (stature: 1.79 m ( $\pm$  0.06); mass: 67.0 kg ( $\pm$  9.4)) and ten women (stature: 1.69 m ( $\pm$  0.05); mass: 53.9 kg ( $\pm$  5.6)). Ground reaction forces (Kistler, Winterthur) were recorded of the contact phases of both legs (1000 Hz). Recordings of these kinetic data were synchronised with both 2D high-speed videography (100 Hz) (RedLake, San Diego) and electromyography of seven lower limb muscles (1000 Hz) (DelSys, Boston). The video data were digitised (SIMI, Munich) and de Leva's (1996) body segment parameter model was applied. Joint moments and powers were calculated from the force and video data using a link segment rigid body model (Winter, 2005). Results The ankle plantarflexors were one of the main contributors to forward momentum. This was due to an eccentric contraction of the triceps surae during midstance which aided a large concentric contraction during late stance in developing forward propulsion. The other main contributors were the hip extensors (gluteus maximum and biceps femoris) during late swing and early stance. The knee joint was hyperextended for 66% ( $\pm$  14) of the stance phase which resulted in predominantly eccentric or isometric contractions in the muscles surrounding the knee during stance. The knee muscles also underwent eccentric contractions during both early and late swing phases, with a particularly large magnitude of negative power in the knee flexors prior to initial contact ( $6.3 \pm 1.0$  W/kg). Discussion During stance, the hip forcefully extended at initial contact and the ankle powerfully plantarflexed prior to toe-off to maintain and generate forward momentum. The race walking rule which requires the knee to be extended during the first half of stance meant the knee muscles underwent little energy absorption or generation during stance. Rather, the leg functioned as a rigid lever which increased the importance of the hip and ankle joints. Because of the restricted motion of the stance knee the importance of the swing leg was increased. Training regimens which develop the strength of the key muscle groups are recommended. ## Oral presentations

### OP-PM28 Training and Testing: Elite Athletes

#### SWIM START PERFORMANCES AT THE TURKISH NATIONAL CHAMPIONSHIPS

GUMUS, M., AKALIN, T.C.

*Zonguldak Karaelmas University*

Introduction The start in swimming, together with the other elements of the race, is very important for achieving better results in championships. Start times were shown to consist of between 0.8% and 26.1% of the overall race time depending on the event. Getting a good (lucky)-start, or psyching your opponents out of a quick-start, can make all the difference it takes to get a world record or Olympic medal. The purpose of our study was to evaluate of starting reaction time of Turkish swimmers participated to 2011 Turkish National Championships. Methods In this study, 1738 official competition times of 313 swimmers (157 female, 156 male) who participated in 2011 Turkish National Championships. Competition was performed in 50 m indoor swimming pool by permission of Turkish Swimming Federation and the data of starting reaction time -the duration between the starting signal and when the feet leave the block- measurements were obtained by SWISS TIMING (OMEGA) that is official partner of FINA. Data were evaluated by using SPSS for Windows 16.0 software and mean values were represented as "arithmetic mean $\pm$ standard deviation". ANOVA test, student t test, posthoc bonferroni test and pearson correlation analysis were used for the comparisons between the measurements. Results of analysis were evaluated with 95% confidence interval. Results Participation in the competition all the swimmers an average starting reaction time (SRT) was  $0.78 \pm 0.09$ s. SRT was  $0.80 \pm 0.09$ s for female,  $0.76 \pm 0.08$ s for male and there was a significant difference between groups ( $p=0.001$ ). SRT was  $0.80 \pm 0.09$ s for youth,  $0.77 \pm 0.09$ s for junior,  $0.76 \pm 0.07$ s for senior and there was a negative and significantly correlation between SRT and age groups ( $r=-0.217$ ,  $p=0.001$ ). There was a positive and significantly correlation between SRT and race distance (short distance:  $0.76 \pm 0.08$ , long distance:  $0.81 \pm 0.09$ ) ( $r=0.186$ ,  $p=0.001$ ). In championship, there was a significantly difference between semi-final categories by SRT ( $p=0.001$ ) and SRT was  $0.79 \pm 0.09$ s for elimination races,  $0.77 \pm 0.09$ s for semi-finals and  $0.79 \pm 0.09$ s for finals. There was a positive and significantly correlation between SRT and rankings, the first three best placed athletes  $0.76 \pm 0.09$  and the others  $0.78 \pm 0.09$ s. Discussion In the men's 50 m freestyle final in the Sydney Olympic Games, there was only 0.05s separating 1st and 3rd places and in the same event at the 2003 World Championships, 0.52s separated 1st and 8th place. In 50 and 100 m swimming races, performance has been strongly linked to start performance. These values are laid down on the Turkish population in the coming years, and the races are very important in order to allow comparison. References Lytle, A. & Benjanuvatra, N. (2004). **ALTERATIONS OF PHYSICAL PERFORMANCE IN ELITE MALE HANDBALL PLAYERS DURING A SEASON**

Póvoas, S.1,2, Ascensao, A.3,5, Magalhaes, J.3,5, Seabra, A.4,5, Oliveira, E.2, Soares, J.4,5, Rebelo, A.4,5

*Maia Institute of Higher Education; Faculty of Sport, University of Porto*

ALTERATIONS OF PHYSICAL PERFORMANCE IN ELITE MALE HANDBALL PLAYERS DURING A SEASON Póvoas, S.1,2, Ascensão, A.3,5, Magalhães, J.3,5, Seabra, A.4,5, Oliveira, E.2, Soares, J.4,5, Rebelo, A.4,5 1: Research Center in Sports, Health Sciences and Human Development, 2: Maia Institute of Higher Education (Maia, Portugal), 3: Research Centre in Physical Activity, Health and Leisure, 4: Centre of Research, Education, Innovation and Intervention in Sport, 5: Faculty of Sport, University of Porto (Porto, Portugal) Introduction Handball is an intermittent sport that implies specific endurance and high-intensity physical performance demands (Póvoas et al., 2012). To cope with these demands during an entire competitive season, handball players are submitted to training and competition sets, which may induce variations in physical performance levels. We therefore aimed to analyse the effects of training and competition during an entire season on elite male handball players' anthropometric and physical profile. Methods Sixty-three players from six teams of the Portuguese Handball Professional Male League were evaluated three time points throughout the season (pre-season (T0), pre-competitive period (T1) and competitive period (T2)). The players performed the Yo-Yo Intermittent Endurance Test-level 2 (YYIE2), the countermovement (CMJ) and squat jumps, a straight sprint test (5 and 20 m), a sprint test with changes of direction (COD), and the running-based anaerobic sprint test (RAST) (for ref.'s see Póvoas et al., 2012). Results Significant increases were observed in YYIE2 and jump performance from T0 to T1 time points, although CMJ height decreased in T2 ( $p \leq 0.05$ ). There were no significant changes in the anthropometric profile as well as in straight sprint performance throughout the season. Nevertheless, COD performance increased in T2 and also in T1 when compared to T0 ( $p \leq 0.05$ ). RAST-related fatigue index decreased in T2 when compared to T0 ( $p < 0.05$ ). Discussion Our results show that training and competition induced alterations in physical capacities evaluated during a season, which is in accordance with other studies (Gorostiaga et al., 2006; Hakkinen, 1988). Training sessions and competitive matches favourably modulated specific endurance, repeated sprint and power-related abilities throughout the season, with the exception of CMJ. The specific pattern of handball movements and actions require particular neuromuscular demands also targeting positive influences on COD throughout the season, an agility-related test closely related to the ability to perform acceleration-deceleration movements, which in turn are associated to eccentric muscle contractions.
