Welcome message

It is an honour for us to welcome you to the 14th QMOD/ICQSS conference. The aim of the Conference is to focus on the three key themes of **LearnAbility, InnovAbility and SustainAbility**, all of which are necessary in today's business environments, which are constantly evolving towards higher complexity. All three key concepts indicate the importance of meta competencies in terms of our capability to learn (learnability), capability to innovate (innovability) and capability to sustain (sustainability). It is our belief that these meta competencies will become increasingly important in the coming years. Among the many issues which challenge modern management theories and practices are: The hyper competition, the increasing importance of intangible assets, cultural and ethnic diversity, the focus on quality of life, gender, organisational ecology, environmental sustainability, corporate social responsibility and risk management.

The QMOD conference has become one of the largest scientific conferences within the research fields of Quality, Service, Organisational Development and related research areas. The yearly QMOD conference is also proven to be a major forum where academics as well as practitioners from all around the world have the opportunity to exchange their knowledge and experiences and thereby built a '**QMOD Community**'. Through this forum, we can discuss and share our research and experiences in order to be able to draw a more accurate picture of organisational and business realities, and thereby to improve our diagnosing capabilities of current problems and improvement opportunities.

We take this opportunity through this written welcome to express our recognition of the effort and work put in by all those people who have made it possible to organise **QMOD 2011**: we pay tribute to the Scientific Committee who have assured the quality of the accepted papers, to the members of the organising committee for their keen motivation and to all the people who have directly or indirectly influenced the smooth progress towards the conference.

Finally, we would like to express much gratitude to all of the authors for contributing their papers. We hope you will find the conference schedule we have prepared interesting and worthwhile, and we encourage you to enjoy the delights offered to us by San Sebastian, our host city.

Donostia – San Sebastián, August 2011

Key words: Internet banking, customer co-production, self-service, customer knowledge.

Category: Research paper

Introduction

The role of the customer is increasingly put forward as a key factor for achieving a sustainable compatible advantage, not least within the evolving perspective of the service dominant logic (Vargo & Lusch, 2004, Grönroos, 2008). As co-creators of value the customers are recognized as a resource in the realization of the value proposition (Vargo & Lusch, 2004). By integrating resources – such as time, effort and skills – customers in practice become key “part time employees” within the service delivery system (as Bowers et al (1990) noted some twenty years ago). When it comes to skills, these are of obvious importance in self-service settings, where the customer is supposed to actually co-produce the service by performing operative tasks in the service process (Meuter et al, 2000). However, customer skills also profoundly related to value co-creation in the service experience (Lusch & Vargo, 2006): in order to experience the value of a service, the customer must be able to comprehend and understand it by putting it in to a meaningful context. That is, customers’ skills and knowledge, i.e. competence, is required both on an operative level and an experiential level.

Following this intensified focus on customers, ambitions to stimulate customer co-production are increasingly informing service design, giving rise to services and customer-company relationships that both assumes and promotes this active customer participation and even direct work efforts in the service process. These ambitions are readily apparent in the industry of our empirical study, internet retail banking, where customers are actively encouraged to perform many work tasks themselves that were previously carried out by bank clerks. Financial services are characterized by development where the customer is increasingly offered opportunities of producing her own services. In fact, this “offering” is often more or less mandatory for the customer in order to get access to the service (Auh et al, 2007). Despite the interest in gaining access to customer resources, research on customers as “service workers” is surprisingly scarce (cf. Woodruff & Flint, 2006). The lack of research could be due to the often stated assumption that customers are active, skilled and willing to partake in the service process (cf. Prahalad & Ramaswamy, 2000). This notion often hides the fact that not all customers want to, or have the capacity to, co-produce.

Notwithstanding the advantages of having the customer performing all these tasks, there is also a substantial risk involved when delegating service work to the customer, in that the customer is not a professional service employee. Customers might lack the

necessary skills and simply be incompetent “service workers”. This naturally causes problems in the service production and the realization of service value. It is argued that if customers do not have the skills needed to make use of the resources provided by the supplier, value-in-use will be lower than otherwise and maybe even non-existent (Grönroos, 2008).

It is clear that customers’ skills are crucial for service value co-creation and the lack of skills might cause severe problems. It is therefore relevant to scrutinize not only the skills required of the customers, but also situations where skills are absent and the customers are incompetent. The purpose of this paper is to illuminate such situations and in particular to address how customers have difficulties to fulfill their role as “services workers”. Consequently, this paper focuses on customers who are not qualified to fulfill their role as “service workers” within the context of financial services.

Methodology

In the paper, we take departure in customers’ actual behavior during the service process to broaden our understanding of customer co-production and the customers’ role as a co-creator of value. We problematize this role by drawing attention to potential conflicts between the idea of the value co-producing customer and service encounters *in practice*. The idea of the value co-producing customer instills a particular customer role, namely that of an active participant – “a part time service worker” – in the value creating process. It is this “service working customer” that is the object of our study. Our empirical object of study is young bank customers’ attitudes and behavior towards internet based bank services and financial life in general. Bank services are fundamental to the modern life and of particular importance for young people entering adulthood. Having an organized financial situation is a key step in becoming an independent member of society. Empirically we draw on a multitude of data sources, including focus group interviews, individual interviews, financial diaries and observations of customer self-service use documented by video recordings, each described below.

Five focus groups interviews have been conducted with bank customers in the age between 17-18 years. In groups of two to six people a total of 21 respondents participated. The interviews focused on a number of themes such as the customers’ attitudes towards bank services and financial matters, previous experiences of financial services, habits and behavior in practice regarding finances, knowledge and interest of economy and expectation and strategies. We constantly asked the respondents to exemplify, explain and reflect upon their experiences in order to obtain rich and vivid accounts. Focus groups interviews have several advantages, for example that the participants are given opportunity to develop themes that are most important for them, which in turn disclose unexpected issues (Wilkinson, 2008). Group discussion is closer to everyday conversations as it has a more naturalistic feature and information and description of the subject are more elaborated since the participants stimulate, react to and build upon responses of the other group members (ibid). In particular we noticed, in our study, how the participants talked about the issue, giving us insight into young customers habitually language.

Further, our empirical data also include diaries from 19 students. In a total the material consists of entries on approximately 270 days. A diary is a personal record which gives

account over time of daily events, observations and thoughts which allowed us to access ongoing everyday behavior, reactions, motives, feelings and activities of the respondents (Bolger et al, 2003). Diary studies has a great advantage in that it make it possible to attain knowledge about aspects that would remain hidden to traditional qualitative designs, for instance understanding of the world in which the young customers live and their motives (Patterson, 2005). The respondents have the opportunity to describe aspects that are personally meaningful as well as subjective perceptions of relevance for them at that point of time. As a consequence, through the diaries we gained knowledge about the young customers' context and behavior. During a period of three weeks the respondents were asked to document everything in connection to their economy and relation to bank services. The diaries consist of thick descriptions of the respondents everyday thoughts, behavior and problems in relation to financial services and foremost their own finances. As could be expected, some respondents made very brief notes, while others were more extensive. Patterson (2005) argues that people tend to write more than asked for, giving rich empirical data, which is also the case in our study.

Our third data set consist of 32 one-to-one interviews, 11 with respondents in the age between 18-19 years and 21 with 21-23-year olds. These groups were chosen because of their different economic situation. The younger group is still in school and has a limited amount of money. The older group has entered the labor market and has a higher income - a salary or unemployment allowance. By using one-to-one interviews we were able to capture the respondent opinions and experiences of financial issues. The interviews included questions about economical situation and how they handle financial matters, and it also included an experimental situation where the respondents performed a selection of predefined tasks. In the interviews we thus were able to gain access to both customers' attitudes as well as actual behavior when using the bank's self-service.

The observation part of the interview study focused on self-service use and were arranged to capture behavior in relation to commonly used services. Some of the assigned tasks were of an easy kind, like finding the opening hours on the webpage, while others were more advanced and connected to the use of self-service, like buying a fund. This task was appropriate since we considered it to be just enough complicated for this customer segment, considering that all applicable information is available on the banks webpage. We also offered them 100 SEK (app €10) if they completed this task. While the respondents tried to execute the assignment the computer screen was videotaped and they were asked to think aloud. In this way we came close to the actual perceptions of the customer (Echeverri, 2005) and it allowed us to analyze how they actually performed. Hence, we have a rich data material consisting of both statements and authentic behavior.

The transcription of the interviews and observation study as well as the diaries, were analyzed using NVivo qualitative data analysis software program, enabling us to categorize the material. Techniques of a grounded theory approach were applied to identify categories, concepts, and variables of key importance for our research aim. We also constantly used memo-writing about how they perceived emerged problems and how they solved them. A number of these "grounded" codes, such as, "insecurity", "awareness", and "laziness", were then arranged into categories. In this process we constantly compared and revised codes and categories in order to create a coherent structure (Miles & Huberman, 1994). In our result we chose to separate our findings

into two main categories, each representing “ideal types” (Weber, 1978). The ideal types of “non-doers” and wrong-doers” thus describe generic characteristics of incompetent customers.

Selected literature review

Customers’ contribution in the service process are well known and has been described as a competitive advantage for companies (Prahalad & Ramaswamy, 2000), including in the financial industry (Auh et al, 2007). It is also argued that customers’ individual participation and contribution in the service process are positively related to experienced beneficial outcomes (Lengnick-Hall et al, 2000). In service innovation and development research it is argued that customers as future users possess distinct knowledge and can provide unique experiences that are of great value when new services are to be developed (von Hippel, 1988). Besides being in focus for service development, customers’ competence is also pivotal for realizing the service as customers participate in and bring resources to the value creating process itself.

The concept of customer competence refers to the knowledge and skills they possess, their willingness to learn and their ability to engage in an active dialogue (Prahalad & Ramaswamy, 2000). Customer competence hereby constitutes a crucial service resource. Within the Service dominant logic a separation is made between operant- and operand resources, where the former denote resources, such as mental skills and knowledge, that has the capacity to produce effects on other resources, for example raw materials. The latter refers to resources that are used or consumed during the service process. The resources that the customers contribute with as a co-producer are primarily of an operant nature (Vargo & Lusch, 2004) that can act on operand resources provided by the company as well as by the customer herself throughout the service process (Kalaignanam & Varadarajan, 2006). Customer must learn to use and if possible adapt the operand resources to her unique needs, usage situation and behaviors (cf. Vargo & Lusch, 2004). However, our understanding of the customers’ competence in the creation of service value is still limited, although there are a few exceptions.

Xie et al. (2008) and Dabholkar and Bagozzi (2002) argues that customers’ inclination to engage in service co-production is dependent on attitude towards success, attitude toward the process and self-efficacy. The later refers to the customers’ know-how and competence regarding the service at hand. Hence, the more knowledge a customer possesses and how she evaluates her ability to perform, the more she tends to engage in value co-production. Expert customers have therefore greater ability to make meaningful contributions to service delivery (Auh et al, 2007). Customers’ propensity to actively engage in co-production can also vary depending on a range of system factors, such as service design, unclear directions, time constraints, economical limitation but also insufficient skills (Xie et al, 2008). Besides customers’ ability and motivation, role- and task clarity is of importance for co-production (Lengnick-Hall, 1996). In the financial service industry, one example is that the client- advisor communication in counseling sessions where clarifications of the customer role strongly enhance the customers’ possibilities to co-produce. The customer thus learns to fulfill her co-producing role more efficiently and conveniently over time (Auh et al, 2007).

The customer’s participative role is particularly significant in situation of self-service solutions (Meuter et al, 2000) where the customer is not only co-producing, but in fact

producing the service herself (Grönroos, 2008). Self-service technologies refers to technological interfaces that enables customers to produce a service independent of direct service employee involvement, for example banking by telephone and services over the internet (Meuter et al, 2000). Here, the customer constitutes part of the core competence of the service system.

Taken together, customers' role and contribution in the co-production is of great importance, but it also raises demands on customers both on operative skills and attitudinal inclination to engage in value co-creation. We would like to critically scrutinize customers' ability to fulfill this role by focusing on customers who in fact do not always possess necessary competence.

Result

In our empirical material we have identified behaviors and attitudes that indicate that the customers are not always embracing opportunities of co-production. Instead they seem markedly uninterested and even actively avoiding the service work required of them. The reasons for this can partly be related to interface and service design issues known from the literature. However, we also see clear evidence of direct resistance against engaging in co-production as such. The unwillingness to work in the service process is related to an apparent lack of interest in, and knowledge about financial services in general. In addition, we also identify a group of customers who indeed engage in co-producing activities but do so in an "erroneous", e.g. non-value producing way.

Below we elaborate on two main categories of manifested "incompetence" among the bank customers in our study: "non-doers" and "wrong- doers". Within each category we highlight a number of significant characteristics that together seeks to describe the essence of these two "ideal type" customers.

Non-doers

The non-doers are characterized by an avoiding behavior vis-à-vis invitation to co-producing activities. There might be several reasons for their position in this respect. Although it is obvious that they have the technical ability to use the banks self-service, as young adults they are familiar with internet based services, they lack important knowledge to carry out even simple financial tasks. However, the customers are aware of these shortcomings and because of this a common denominator for the non-doers is concern - and even fear - of doing wrong when trying to carry out bank services by themselves. Since they consider financial services imperative, as money and economical issues are vital parts of daily life, they are quite cautious, and sometimes they simply refuse to complete the service at hand.

I am usually very careful when visiting this kind of web page and then I do things I know how to do, because it is probably quite easy to lose [money] if you do something wrong...

This cautiousness is expressed in the interviews and in the diaries at several points, and often it is related to the respondents not having sufficient experience and knowledge.

Consequently, familiarity is important for customer co-production, and the absence of previous experiences results in insecurity.

R: I'm not that familiar with this. I don't think I have the guts actually.

I: What do you think could happen?

R: No, I don't know. (Laughing) No...

I: Why do you feel insecure?

R: Because I have sort of no idea what it is actually, or sort of...

This insecurity could be attenuated by embracing information, but in many cases they seem to avoid this possibility. Searching for information requires at least a minimum of interest and engagement, something that our respondents lack. During the interviews the respondent were given the opportunity to buy funds using the banks self-service via internet, and we provided them with the money needed for this task. Although they did not risk their own money (in fact they only received the money if they accomplished the task), many of the respondents were hesitant and some of them even chose to refrain from this assignment. The following excerpt illustrates how the respondents' lack of interest prevented him from going through with the exchange.

I: What do you say, would you like to go through with buying?

R: No, it seems quite complicated so you can take this [money] back... It, no... It doesn't interest me, actually.

As mentioned, customers need to integrate time, effort and skills to be able to co-produce services. In our study, these three aspects are closely interrelated seeing that the respondents' ignorance is partly due to a general apathy towards financial services. They do not want to spend neither time nor effort accomplishing bank services. Some respondents tried to understand accessible information, but they found it to be tiresome and too complicated and they still would not accomplish the task. In the below excerpt the respondent did not want to make the effort to even try. It took some persuasion, but once he was convinced that he was not risking his own money he started glancing at the web page but soon came to the conclusion that he simply would not buy funds.

R: No, I can't be bothered (to).

I: You can't be bothered (to)?

R: No. What am I to do with that?

As we can see, even though they are given the opportunity and have the technical ability, their insufficient knowledge prohibits them to actively engage in co-production. Some of them are aware of this knowledge gap, while others act anxious towards self-services even though they actually have adequate know-how. One customer expresses "Ugh, I'm really not good at this!", when using the bank self-services, although we got the impression that she was very experienced and in fact had the ability to perform the task we gave her. This is only one of the examples we found of customers that actually have necessary understanding of the banks services and how to enact, but do not seem to confide in their own knowledge. Hence, this results in avoiding or not fully utilizing all available service possibilities.

The lack of confidence in their own abilities induces the customers to ask others for help in executing the service in their place, instead of actively trying to find and

comprehend available information. Hence, they turn to someone who possesses the necessary skills. The two excerpts below illustrate how the customers rather address bank employees and thus avoid not only the work effort but also having to make a decision they do not feel qualified for. By turning to a bank employee, the customer can feel assured that any mistakes due to the customers own incompetence is reduced.

I don't, it feels like, I don't know, like I'm afraid that I might do something wrong or that there will be some hassle. So it feels better to pass it on and maybe consult someone about deals and what's best...

I didn't have the energy to check which debit card were the most suitable for me, for example. The last time I... Well, yeah... This one time I sent an e-mail [to the bank] asking 'what is suitable?' And then they replied immediately and I went with [their suggestion].

Hence, customers' reluctance towards self-service use causes them to seek help from a second part. In the above examples they conferred the bank staff, but we also found that they relied on personal network and thus consult friends and relatives when carrying out the service. One respondent always has her boyfriend to guide her:

Usually he just sits next to me and tells me what to do, and I do the clicking.

Since she is the one performing the task she obviously has the ability and skill to perform the task in practice, but when it comes to making a decision on her own she does not find her own knowledge trustworthy. Instead she chooses a "safe option" by buying a fund her boyfriend previously picked for her. Turning to her personal network for help is just another way of not having to make a decision that she does not feel qualified for.

To sum up, the fact that the customers are aware of their lack of knowledge, or does not confide in their knowledge, results in an anxiousness of doing wrong when executing the service. If they cannot turn to a professional or their personal network as discussed above, this leads to avoidance and they simply do not use the available service. This of course is problematic from a value creation point of view. However, at least the non-doers do not obscure the banks value proposition in itself.

Wrong-doers

In contrast to non-doers, our second category, the wrong-doers, have no problems acting in the service process, although they do so in a way that is not compliant with the envisioned service offering. In fact they might even act in a directly contra productive manner. Often they are unaware of their "wrong - doing" due to lack of knowledge. Hence, as they are not aware of their own ignorance they readily perform "co-production" activities and utilize the resources provided by the service supplier. Even if they, as in some cases, they are acknowledging their shortcomings they persist in their behavior anyway, and might provide quite elaborated explanations for their actions in self-service use. But without the required knowledge and insight, the result is seldom the full service value envisioned in the company offering. The customers do the wrong things, make the wrong choices and interpret both the service and their own role in the

value creating process in an erroneous manner, not only in regard to the banks version of the service concept but often also in regard to their own interests. The consequences of using financial services without having the necessary skills might at the best be confined to a mere absence of value creation, but there are also several cases where the effects are more severe, involving loss of money or even being put in debt.

When assigned the task of buying funds some respondents oscillated quite readily between, on the one hand, acknowledging their lack of knowledge and reluctance to actually do the tasks required (as discussed above) and, on the other hand, a far more active and certain approach. One respondent told us that he had conferred a bank employee about funds and been taught how to use the self-service in order to buy funds. At that time he found the administrative fees too high and therefore abstained. Despite this meeting with the bank employee, he is not showing signs during the interview of interpreting the information about the funds correctly and is actually acting against his previous insight of high fees. Eventually he selects a fund placed high in the listings and ignores the administration fee altogether. When asked about his selection, he explains the rationale behind his choice:

I: Why do you select a Japan fund?

R: I don't know. Looked good.

I: What made it look good?

R: I trust Japanese people so to speech. You know, they can't build cars, but they might be able to fix funds...

I: But you didn't click for further information, was it the information in the list that made you select Japan?

R: The list, yes, they were placed fairly high. Probably they have developed well, if I understand it right, Eh, and then I thought I'll buy...

When he is requested to approve his purchase he receives an error message and it turns out that he had confused the price of the fund share with the amount he was about to invest.

R: No, too small, change to a larger [amount]. No, all the same with Japan then! But don't they cost 45? 46?

What is interesting with this respondent is that he is indeed acting as a co-producing customer, and he does deem himself capable in his role. From our perspective though, he is acting against his own interest and ignores important knowledge that he actually possesses. This tendency to make un-informed financial decisions extends beyond the mere execution of operative service tasks to financial life in general. Although the respondents express that money and economical issues are crucial parts of life, many of them seem to lack fundamental understanding of economical issues and how to handle money.

I: Would you say you're a saver or a spender?

R: Spender.

I: Spender?

R: Definitely! I am. Since I haven't been able to save anything I am... I guess I have been able to [save] sometime, but then I reckon it's a lot more

fun to go out and spend it on something unnecessary (laughing). But that's not, it's not very clever, but... That's the way it is.

Although being well aware of herself being a “spender”, and at least implicitly expressing concerns about this, she shows no real ambition to modify her behavior. In fact, later in the interview she reveals that she had overdrawn her debit card and had it revoked for six months. Despite this clear warning signal, she is still spending (but now on a cash basis). From the bank's perspective, this lack of “proper” financial attitude is problematic as many bank services (and bank relationships) rests on the assumption that the customer has, or at least strives, for an ordered private economy. In the diaries as well as the interviews we have noted a tendency to overspend and “break the budget” and the respondents often complain about their shortage of money in the end of the month. The customer quoted below does attempt to keep track of his economic situation, but he fails in doing so in practice. He continues to do “wrong” although he knows that his behavior is not sustainable in the long run.

I: Do you make some kind of budget?

R: No, not a very complicated one but I know roughly how much money goes to bills and stuff, and how much I should save, generally. And so, so I almost have kind of a small ‘half-budget’... That I never stick to.

I: How come?

R: It is the impulsive shopping that breaks it.

The two excerpts above suggest that they are aware, or at least not entirely unaware, of that they should handle their economy differently, but we also have examples of people who actively do wrong without being aware of their “wrong-doing”. One respondent tells us that he uses his credit card for “essentials” (like gasoline for his car) when he runs out of money. He then “repays” to the credit card company, but always with a substantially less amount than his spending – although his income is high enough to cover this monthly expenditure. His credit card debt therefore continues to grow month by month. However, since he is ignorant towards economical issues in general, this poor financial situation does not seem to bother him. Another interesting phenomenon we have noticed among our young respondents is that they seem to save money when they are short of it and overspend when they have money. This rather counter-intuitive financial behavior could cause problems for the bank, as their services are usually designed to accommodate the opposite behavior. The ideal bank customers should save when they have money in order to cover economical downswings.

Discussion

It is previously known that customers face several impediments in financial self-services, for example complicated web pages, safety/privacy issues and technology failure. A common denominator of these obstacles is that they ascribe the problem to the design of the service and the service system. The customers' role and own ability to participate as “service workers” have often been neglected in service research. Our study suggests that customers' presumed service work and value co-creation are clearly obstructed by their ‘incompetence’, i.e. their lack of knowledge and/or capacity to act in the value creating process. This holds both for the operative activities related to direct service co-production and for the more profound role the customer has to play in the realization and appreciation of value.

The banking industry early adopted self-service systems and most services are nowadays offered in this way. In effect, this means that the customer has taken over many core activities necessary for the accomplishment of the service previously performed by service employees. Acting as financial service workers, not least in the context of self service, requires a substantial amount of professional knowledge. Lack of this competence makes the customer feel insecure and uncomfortable during the service process, and obscures the execution of the service. This is evident among the non-doers in our study: they frequently show signs of uncertainty and even fear when it comes to make even simple decisions and perform simple tasks in the service process. In fact, even in situations when they do possess the knowledge, we see examples of customers who refuse to perform their co-producing tasks.

Arguably, this is a reflection of the fact that customers' service work requires not only a significant effort from the customers, but also a responsibility for the service process and outcome. Consequently, the customer is held partly accountable for service failure in self-service use (Meuter et al, 2000). Obviously, the non-doers in our study are at least to a considerable extent aware of that the responsibility for the service process outcome is partly theirs. On frequent occasions we have witnessed how respondents try to escape this responsibility by transferring it back to the bank ("I want to go to the bank and talk to someone about this"). In some cases, they even resorted to their personal networks for advice and instructions. Although this might partly be due to knowledge deficits, it is also in effect a way to avoid the responsibility of making decisions.

Customer who will not perform their ascribed activities in the co-producing process due to lack of confidence even if they have the necessary 'technical' knowledge naturally poses a challenge for banks. However, too much confidence in the own financial ability could be equally detrimental for value co-creation as is shown by our wrong-doing customers. These customers readily perform tasks and make decisions with sometimes far reaching consequences without sufficient knowledge. It has recently been suggested in the literature – through the concept of value co-destruction – that value can actually be destroyed by customers (Echeverri & Skålén, 2011, Plé & Cáceres, 2010). The wrong-doers in our study clearly show signs of such destructive approach, even though they do not seem to be aware of this. There are several examples in our empirical material of customers engaging in destructive financial behavior who either firmly believe they are acting as responsible financial agents, or who simply ignore their acknowledged lack of competence and acts anyway. The latter group even includes persons who are explicitly aware of their "wrong-doings" (e.g. over-spending) but persist in their behavior anyway. The promotion of self-service banking strategies increases the opportunities for the wrong-doers as there is no representative from the bank present to correct their wrong-doings.

As the logic of active value co-production is central to the strategies of many banks and other financial institutions, the presence of "incompetent" customer poses a real managerial challenge for the financial industry. Naturally, all measures possible should be taken to make the customers co-producing activates as smooth as possible. The web-interface used by the bank in our study could for example be improved in several regards. However, our study indicates that simple measures like redesigning the bank's web pages or simplifying self service procedures are not sufficient to address the

problem. Instead innovative strategies for managing customer financial knowledge – *and lack thereof* – are called for.

Letting the customer do the work is inherently an attractive strategy for the bank as it often involve considerable cost reductions. However, one conclusion from our study is that self service, or even value co-creation in general, is not necessarily the best way for creating value with all customers. Prahalad & Ramaswamy (2004) contemplate if customers really should shoulder responsibility over possible risks when realizing the service. In some cases it might be better that the company performs the service work and makes the decisions for the customer. There thus lies a value in being relieved the role of being a value co-creator, and this value might even overweight the cost reductions gained by enrolling the customer as a “part-time service employee”. Many of the customers in our study express a preference for such an approach to value creating financial services.

This requires interaction/dialogue with the customer and not merely providing information about possible options available. Such a dialogue can reduce the customer’s responsibility and bring some of it back to the bank. Similar service concepts are common within private banking where they are offered to wealthier customer segments. Our study indicates that a corresponding service adapted to the cost level of retail banking might provide an important complement to the prevailing self-service strategies. Not least could such service concepts help prevent overzealous customer to engage in service activities that they are not qualified for and that could damage both themselves and the bank.

The identification of “non-doers” and “wrong-doers” in our study provides an important first step in developing a conceptual basis for a more nuanced view on value co-creation. To acknowledge “incompetent” and reluctant customers in the value creating process is not only a managerial endeavor, but in all essential a research challenge that needs further investigation.

Paper Type: Case Study

The lean six sigma approach

The lean Six Sigma method is a combination of both Lean Manufacturing and Six Sigma (Gitlow 2009, George 2005, George *et. al* 2004). The lean Six Sigma methodology is based on the Six Sigma DMAIC methodology, modified to include the Lean Manufacturing tools within each phase. Lean Six Sigma is introduced focusing on its importance within the service and non-manufacturing areas (Gitlow 2009, George 2005, George *et. al* 2004).

El-Haik and Al-Aomar (2006, p.23) suggested, “Lean Six Sigma provides a set of methods that companies can apply to any manufacturing, transactional, or services process to reduce variability, eliminate or reduce waste (non-value-added), and cut process lead time”. In other words, Lean addressed the waste aspect and Six Sigma addressed the variability aspect. When combined together, the rewards increased. To better highlight this fact Lean principles are addressed first and then the combination with Six Sigma is presented.

Lean is mainly based on improving the process cycle time by eliminating any waste or what is also called non-value added. George (2003, p. 28) suggested six principles that guide Lean.

Principle One

When flowcharts are drawn the activities will be divided into two parts value-added and non-value-added. Different colors are used for every category in order to show the waste within the process itself. George (2003) mentioned that organizations that did not embark on such improvement journey are likely to be faced with at least 50% of their activities falling into the non-value-added category. Eliminating these non-value-added activities would improve the lead times tremendously.

Principle Two

Lead time is a function of both work in progress and average completion rate as shown in the below formula.

Equation 1 Little's Law

Thus to decrease the lead-time we can increase the ‘average completion rate’ and/or decrease the ‘amount of work in process’. The first principle targets the average completion rate by decreasing the cycle time. Since a decrease in the cycle time would increase the average completion rate.

The second principle addresses decreasing the amount of work in process thus leading to an improvement of the lead-time.

Principle Three

Using the pull system is one of the key methods for decreasing the amount of work in a process. The pull system would provide the ability to businesses to know when to release or not items into the process so that the work in process stays in control. The ways of implementing the pull system depends on the nature of the process. Two such natures were identified:

- 1- Processes in which the customer is waiting in front of the clerk to be serviced.
- 2- Processes in which customers requiring the service are now in front of the clerk providing the service

In the first case where customers are physically present within the system the treatment becomes different, the only way of decreasing the lead-time is by increasing the average completion rate. This can be done through either increasing the capacity or making things faster (e.g., through automation, additional training...).

George (2003) mentioned that though from the theoretical point of view it is easy to evaluate the required average completion rate, however, from the practical point of view it is difficult. This is due to the fact that customers vary in their requirements from the system and their arrival to the system (e.g., for a teller at a bank branch, customers might arrive at any point in time to the branch and the time needed to tend to their wide range of potential transactions also varies a lot.). In this case a careful study should be conducted on the arrival rate and its variations, and the processing rate and its variations leading to better assess how many tellers are needed and/or a change in the way transactions are done.

In the second case, the planner or scheduler would know when to take or not take orders so that the work in process is kept to a minimum. Therefore, when the capacity is reached, an item is added to the process only when that item is completed and thus becomes outside the process.

The pull system ensures that processes are balanced and managed in a way that no over promising is done for customers. This guarantees a certain service level that is promised to customers. Items that are not admitted into the process are kept in a buffer until a place becomes available within the process, and only when admitted are customers then notified of the completion date and time. One main tool used in the pull case is the Kanban (translated from Japanese where Kan means ‘Card’ and Ban means ‘Signal’ (Ohno, 1988). Kanban or signal card is a “card attached to a storage and transport container” (El-Haik and Al-Aomar, 2006, p. 256). The card is used in a pull system for controlling the flow of materials and reducing the work in process. So whenever the quantities from a certain process have been consumed the Kanban card is used to place a similar order from the supplying arm and if it is being manufactured then this can be considered as an order to start the production.

Principle Four

$$\text{Process Cycle Efficiency} = \frac{\text{Value Added}}{\text{Total Lead Time}}$$

where

$$\text{Total Lead Time} = \text{Value Added Time} + \text{Business Value Added Time} + \text{Non-Value Added Time}$$

Equation 2 PCE

The PCE equation is related to the availability of waste within the process. The total lead-time is the amount of time needed to get the order through from beginning to end. The value-add time is the time needed to change the state of the work elements throughout the process. Time value maps are used to better display the stages work elements go through. Within the time value maps each activity is flagged as being:

- 1- Value-added work: this will be related to what the customer is willing to pay for
- 2- Waste also called business value added: are activities that the customer does not want but maybe needed for some other business internal reasons
- 3- Delays also called non value added: described previously as work in process

George (2003, p36) suggested different world class cycle efficiencies from different applications, the best being 50% PCE for service businesses processes.

Principle Five

The Pareto rule applies not just for sales but also in the case of Lean. It is suggested that when embarking on an improvement drive aimed at decreasing the lead time to focus on the activities that contribute the most to the waste. As Pareto rule suggests that 20% of activities contribute to 80% of the delays, and thus focusing on these 20% activities would improve the lead-time by up to 80%. George (2003, p. 38) calls these 20% of activities as “Time Traps”.

Principle Six

To better analyze processes the use of visual aids becomes very crucial. Within the Lean field Value Stream Map are the most common to use. The value stream map identifies the process work elements have to go through from beginning to end. Information like cycle time and people doing the work are included along with the average waiting times at the queues. The power of value stream maps becomes apparent when the activities are labelled and coloured using the earlier mentioned categories, thus the non-value added activities and the delays will be visually seen leading to better analysis and ultimately better improvement plan.

Comparison between lean, six sigma and lean six sigma

To better illustrate the power of LSS a comparison between Lean and Six Sigma is conducted while highlighting four major deficiencies that can be eliminated when both (i.e. Lean and Six Sigma) are combined together. El-Haik and Al-Aomar (2006, p.25)

compare both lean and six sigma on a set of characteristics that identify the similarities and differences between both approaches as follows:

	Six Sigma	Lean
Goal	To improve process capability and reduce variation	To reduce lead time and process waste
Focus	Process outcomes	Process flow and waste
Philosophy	Variability within specifications is cost	Time in system and overcapacity is cost
Tools	Statistical analyses	Factor physics
Application	Production and business processes	Production and business processes
Approach	DMAIC problem solving methodology	Value stream mapping and lean techniques
Major measure	Defects per Million Opportunities	Lead time
Major driver	Critical to Quality	Value-added
Project	Problem solving	Continuous improvement
Skills	Mainly analytical	Mainly process knowledge
Gains	Process accuracy	Process effectiveness and delivery speed

Table I Lean Vs Six Sigma as adapted from El-Haik and Al Aomar (2006, p. 25)

As the above table shows both Lean and Six Sigma have a lot to offer to improve the business. On the deficiencies side, the following four are identified whereby the first two relate to Lean and the following two to Six Sigma and it shows when combining Lean and Six Sigma together how those deficiencies are dissolved:

	Description of the Deficiency	Lean Six Sigma to the Rescue
Lean Deficiency 1	Lean does not have a structured approach	DMAIC is now used within LSS which resolved this deficiency
Lean Deficiency 2	Lean only attributes waste to non value added activities while ignoring financial waste (i.e. increased costs) stemming from process variations	Six Sigma process capability addressed in the measure and analyze phases mainly resolved this deficiency
Six Sigma Deficiency 1	Six Sigma focuses only on process outcomes while ignoring any further areas of improvement relating to non value added activities	Lean tools help in identifying the non value added activities which resolves this deficiency
Six Sigma Deficiency 2	Six Sigma focuses on process accuracy while not	Lean tools help in eliminating the non value

	addressing effectiveness and speed of delivery	added activities which resolves this deficiency
--	--	---

Table II Deficiencies addressed by LSS

The Lean Six Sigma approach as mentioned builds on both methodologies to create a stronger one that can tackle a wider range of problems.

When Six Sigma was first introduced all the efforts were focused on manufacturing processes, since the quality can be measured through defects rates. Six Sigma with its rigorous methodology provided a roadmap businesses can follow to improve processes. With years passing, businesses that improved their manufacturing processes to the perfection were still faced with variations. These variations were mainly originating from the transactional-based processes that were supporting manufacturing processes on both ends. As cited in George (2003, p.3), Bob Galvin the former CEO of Motorola stated, “the lack of initial Six Sigma emphasis in the non-manufacturing area was a mistake that cost Motorola at least \$5 billion over a four year period”. Anthony (2006) argues that implementation of six sigma in the service sector is still not as popular as it is in the manufacturing sector. In accordance, Kaushik and Khanduja (2009) found through their review of the literature that most Six Sigma work has so far been carried out in the manufacturing industries. They further argue that there is a scope for improvement in the service industries through the application of Six Sigma techniques.

Six Sigma is even a newer concept in the Arab countries (Salaheldin and Abdelwahab, 2009). One of the factors hindering the increased popularity of Six Sigma in the services sector in general and in the Arab world in particular could have been related to the fact that implementation of some of such projects were a total disaster leading to negative impacts (Gijo and Rao, 2005). Despite this, there is agreement in the literature that a fundamental objective of Six Sigma is to achieve customer satisfaction with continuous improvement in processes. According to Mahanti and Antony (2005), Six Sigma focuses on improving quality by helping organizations produce products and services better, faster and cheaper. Furthermore, Mathew *et al.* (2005) have also maintained that the main idea behind Six Sigma is doing things right and keeping them consistent. Despite all those benefits, the deployment of Six Sigma does not come easy or cheap, because in order to reap the benefits considerable investments (both financial and top management commitment) are needed. The following section addresses both an implementation framework for Lean Six Sigma and how change management can help in increasing the chances of a successful implementation.

Lean six sigma deployment

Since its inception in early 1980’s, Six Sigma has been adopted by a large number of large, medium and small sized companies (Snee and Hoerl, 2003). According to Harry and Schroeder (2000), many organizations that have implemented Six Sigma have achieved improvements in their market share, customer satisfaction, reliability and performance of their products and services with impressive financial savings. However, this is not always the case. In a few instances, the implementation of the six sigma methodology has not given the expected benefits. Snee and Hoerl (2003) argue that the success of the implementation varied from extremely successful to extremely not successful. They also argued that Six Sigma can work for all sectors irrespective of the company size even in the software sector where hard coding is the key to success (Mahanti and Antony 2009) and supply chain (Dasgupta 2003) demonstrated in their

respective papers. Irrespective of the applicability of Six Sigma the secret in reaping the benefits, lies in the deployment.

In this section, we will present the reasons behind a successful implementation of Six Sigma initiative and highlight the pitfalls that should be taken into account to help minimize the chances of implementation failure. This will help in providing the LLC Company with a clear roadmap for implementing the Lean Six Sigma.

Snee and Hoerl (2003) studied four cases of implementing Six Sigma, two of which were successful and two unsuccessful. The following table summarizes two tables taken from Snee and Hoerl (2003, p. 30 and p. 35) outlining the key attributes while deploying Six Sigma:

Successful Implementation	Unsuccessful Implementation
Senior Leadership (especially from the CEO) provided full commitment and support to this initiative	Senior management did not exercise any leadership at the corporate level
Six Sigma objectives were set earlier on and key performance indicators were put in place to evaluate achievements and ensure objectives are met	The choice of Master Black, Black and Green Belts was not based on talents
The best people were put on board to ensure effectiveness. Those chosen to take part were relieved from their day to day normal duties to focus on Six Sigma	The Master Black and Black Belts were part time and thus any Six Sigma project was an addition to their already busy schedule
An infrastructure to support projects identification, setting-up teams and following-up on results was put in place to ensure transparency and accountability	The project selection process was very poor, and they were not related to bottom line savings
Training programs and Six Sigma hierarchy were set-up earlier on	No clear objectives for Six Sigma were put in place
Focus of all projects should be directly related to bottom line financial results	There were no rewarding scheme to motivate the people
A good reward scheme for the success of Six Sigma initiative was put in place, creating a big boost among all employees	

Table III Key Factors for Successful and Unsuccessful Six Sigma Deployment

Snee and Hoerl (2003) recommended a process for the overall deployment of Six Sigma within any industry. This process was devised after reviewing the reasons behind the unsuccessful implementation of Six Sigma as shown in the table above. In their view, successful Six Sigma deployment needs the following main pillars:

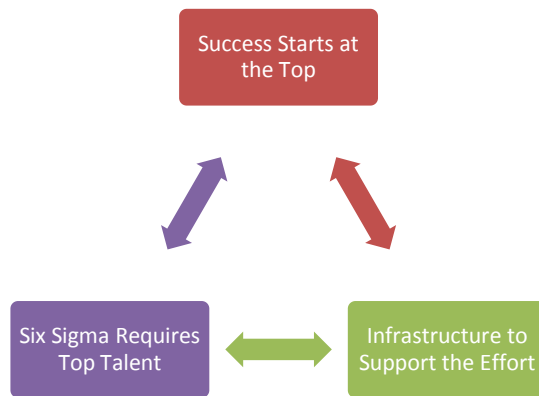

Figure 1 Six Sigma's Pillars of Success

To ensure the success of Six Sigma deployment Snee and Hoerl (2003, p. 53) suggested a framework illustrated below and described after:

Process

Major Transition Point

Keys to Success

Figure 2 Six Sigma Proposed Deployment Process

During the **launching phase** the following elements need to be completed:

- 1- Setting the overall vision and justification for deploying Six Sigma
- 2- Selecting an external Six Sigma provider if needed
- 3- Developing a long term deployment plan, including objectives
- 4- Developing a short-term implementation plan, based on the long term deployment plan. This task includes selection of initial resources and projects which as Kumar et. al. (2009) suggest that it is one of the most crucial criteria for a successful six sigma project though not well researched
- 5- Writing a clear communication plan to explain this direction to the entire organization

After starting the Six Sigma initiative **managing this effort** on either a large or smaller scale becomes very crucial. Also Snee and Hoerl (2003) proposed that the successful managing the effort process is composed of following requirements:

- 1- Place strong leaders in Six Sigma roles

- 2- Devise and run an effective project selection scheme
- 3- Provide a multitier project review system
- 4- Make sure that budgets are available
- 5- Make sure that a good communications plan is put in place
- 6- Devise the recruitment and progression plans within the organization
- 7- Create a rewarding scheme

Once the ball gets rolling and the efforts are being managed by **sustaining momentum growth** making sure that the same levels of savings are being achieved becomes an integral of the day to day activities. The main key requirements identified are as follows:

- 1- Define the organizational structure, especially a functioning Six Sigma Council. The Council will develop annual objectives and budgets, manage the Six Sigma systems and processes, and provide leadership for the overall effort
- 2- An in-house training centre will provide the required skills for new employees, as well as continuing education and training for experienced MBB's, Black Belt and Green Belt
- 3- Create and follow in accordance to the policies already in place both the refrigerated areas and the new one
- 4- Provide frequent reviews for Six Sigma

Once the effort has been managed for a period of time the ultimate achievement will be when Six Sigma becomes the '**Way we Work**'. Though this stage of the process needs a longer time to be attained, but once established continuous improvement becomes really the motor of the organization. Embedding Six Sigma within the organization.

Methodology

In the Mid 1990's General Electric and Allied Signal "popularised the Six Sigma approach" as Gitlow and Levine (2005, p.6) outlined followed by American Express, Boeing, Citibank as mentioned by Van Der Heuvel *et. Al.* (2006). The acronym used is DMAIC as described below:

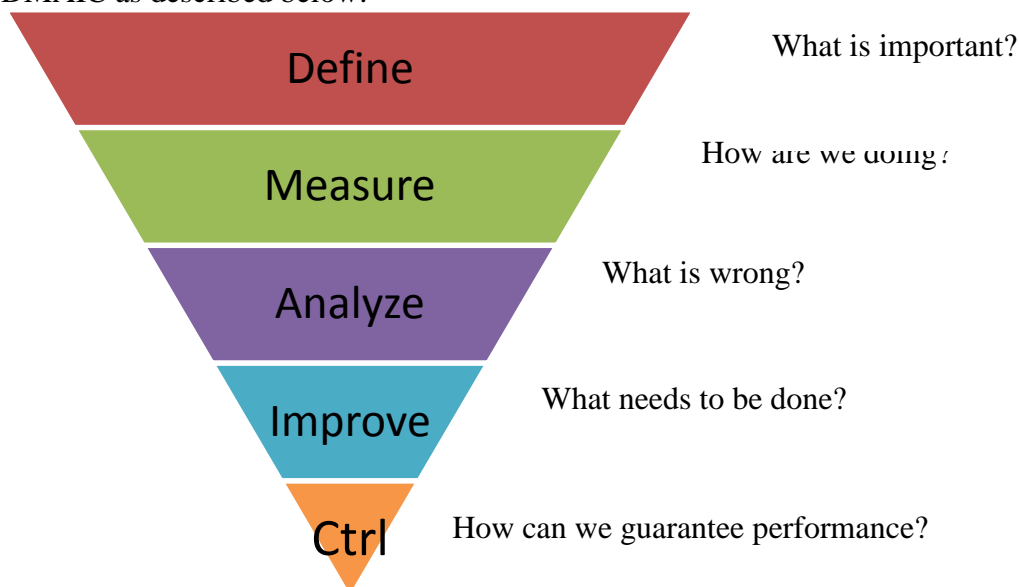

Figure 3 DMAIC Cycle Funnel

The lean six sigma project

The project described below follows the DMAIC methodology. Each stage is first described in terms of its objective and expected deliverables then how it was applied within the project.

Define Phase

According to Henderson and Evans (2000), this phase is used to define the problem and define what the customer requires. This initial phase allows the project team to hone in on the processes that are considered the most crucial to the organization and provide some kind of a project specific roadmap. There are two main deliverables:

- 1- Project charter: the charter is a living document that will outline elements that are specific to the project. This will include team members along with their roles and responsibilities, the area/scope of the improvement, the expected financial benefits, and the expected customer (internal or external) benefits. It ends with a projected timeline for completing each of the phases within the DMAIC.
- 2- SIPOCR: an acronym for Supplier, Input, Process, Output, Customer and Requirement providing a 50,000 feet view of the process under investigation for improvement. The Requirement within the SIPOCR will provide the team members with the voice of the customer.

The define phase is very crucial in allowing all parties involved in the project to better set their expectations. Pande and Holpp (2002, p.31) suggested that while building your team charters and the SIPOCR the following questions should be asked:

- 1- What are we working on?
- 2- Why are we working on this particular problem?
- 3- Who is the customer?
- 4- What are the customer's requirements?
- 5- How is the work currently being done?
- 6- What are the benefits of making the improvement?

To reach the expected outcome from the Define Phase, several interviews were conducted with the different stakeholders and the main theme that emerged was related to the delays in delivery and installation of the units at the customer site. After multiple reiterations, the following charter was produced:

<i>Project / Process Name</i>	<i>Delivery Note to Installation Process</i>
Project Description	Improve the process starting with Generation of the Delivery Note and ending with receiving the Customer Acceptance Form CAF to enable finance to issue the customer invoice
Project Owner	XXX
Project Type	Lean Six Sigma
Project Objective(s)	The objective is to reduce the time for issuing the invoice by 70%. This will reduce the cycle time from 42 working hours to

	just over 12 working hours		
Problem Statement	The time between Delivery Note and issuing the invoice is long resulting in customer complaints on delays in installation lead times and finance complaints on delays for issuing the invoice from time of order delivery and thus impacting cash flows		
Project Scope	The project focuses on the installation process for new machinery and it does not cover the installation of any additional features and peripherals to existing machines		
Project Goals	Reduce the lead time for customer deliveries from 42 working hours to just over 12 working hours		
Project Metrics	Customer delays and Internal Delays in working hours		
Defect Definition	1- Number of deliveries made after 12 working hours. 2- Number of invoices issued after 24 working hours		
Performance	Current	Target	Stretch
	42 hours	12 hours	10 hours
Project Timing	Estimated Start Date		Estimated End Date
	Oct/02/XXXX		Dec/29/XXXX
Customers	External: Customers who bought a new machine. Internal: Finance department		
Projected Return Benefits	AED = 2,700,000 for the first year		
Customer Benefits	Lead time decreased by 70%		
Project Concerns	Availability and access to data		
Team Members			
Role	Name	Title	Email
Project Sponsor	XXX	Sales Director	
Core Team	XXX	Business information System Consultant	
Core Team	XXX	Sales Administrator	
Extended Team	XXX	Services Director	
Extended Team	XXX	Account Manager	
Extended Team	XXX	Distribution Supervisor	
Extended Team	XXX	Logistics Manager	
Extended Team	XXX	National Service Support Exec	
Lean Six Sigma Advisors	XXX	LSS Master Black Belt	
Lean Six Sigma Advisors	XXX	Deployment manager - LSS Black Belt	
Project Reviews		Millstone	Date Completed
	Define	Oct/11/XXXX	
	Measure	Oct/25/XXXX	
	Analyze	Nov/1/XXXX	
	Improve	Nov/15/XXXX	
	Control	Dec/29/XXXX	

Table IV Project Charter

SIPOC

After completing the project charter, the high level map for the process included into the project was devised with the subject matter experts (SMEs). This map helps in providing a shell for the next phase. The SIPOC for the project described was as follows

Supplier	Input	Process	Output	Customer
Receptionist	Man Machine Interface(MMI) Form	Receive MMI Fax	MMI Form	Finance (Internal Customer)
Store Keeper	Delivery Note	Register MMI Form	Installed Machine	Client (External Customer)
Logistics Manager	Customer Acceptance Form	Enter the data on the system	Signed Customer Acceptance Form	
Assistant Store Keeper	Machine Delivery Schedule	Allocate, pick and place machines and accessories		
Customer Service Engineer	Machine	Prepare the Pre Installation Sheet		
Clearing Agent	Vehicles	Assemble Machine and Check its Operation		
Driver	Vehicles Maintenance Schedule	Stamp Check		
Sales Administrator	Machines Pre-Installation Checklist	Prepare Machine for Shipping		
Vehicles Maintenance Company	Training	Generate the shipping document		
Customer Machine Requirements	Engineer Schedule	Assign Driver		
		Dispatch Machine to customer site		
		Inform Engineer of Delivery		
		Engineer Installs Machine at customer site		
		Engineer Trainis Individuals at Customer Site		
		Sign the Customer Acceptance Form		
		Engineer Delivers a Copy of the Customer Acceptance Form to Sales and Finance		

Figure 4 Project SIPOC

Measure Phase

Once we identified what is important in the define phase we now need to evaluate how we are doing on the project metrics identified in Table IV. Thus, we need to measure our process capability compared with the customer requirements (Rasis et. al. 2003a-b). A data collection plan and the implementation of the plan are the two milestones from this phase.

The data collection plan as Eckes (2003, p.36) mentioned should address the following points:

- 1- What to measure: this is mainly driven from the voice of the customer (i.e. the requirements identified in the define phase).
- 2- The type of measure: team members should identify how many measurements are needed and the rule of thumb as Eckes (2003, p.38) mentioned is “two to three output measures, one or two input measures and at least one process measure”.
- 3- The type of data: the team members should decide if they are gathering discrete (e.g. pass/fail) or continuous data (e.g. weight, time...).
- 4- Operational definitions: this is the detailed data description allowing all team members to talk the same language with respect to values. This is essential because the last thing that is needed on a Six Sigma project is different data interpretations.
- 5- Targets/specifications: these targets and or requirements are taken from the voice of the customer. They are the boundaries or specifications limits against which our process should be assessed.
- 6- Data collection forms: in case the data is not already available, data collection forms will be designed.

After the plan is devised, the implementation starts and at this stage the calculation of the baseline sigma is conducted. Some tools like the Cause and Effect Matrix and the initial part of the Failure Mode Effect Analysis are also good tools to be used at this stage especially helping in the funnelling process of identifying the most critical inputs.

To bring this to the project level, the team mapped the process using a Spaghetti diagram and a flowchart. That was followed by a non-value added map that was

generated to help in pinpointing some of the non-value added routes that can only delay the process and make it none lean. The as is current process as shown in the below Spaghetti diagram shows that there are no straight through processing. The same departments are involved in the process at multiple stages. Redundancy is the common factor throughout the full process.

Figure 5 Spaghetti Diagram

The non-value added map detailed the process in stepwise and then every step was categorized as:

- a- Value Added
- b- Business Value Added, and
- c- Non-Value Added

The final analysis from the report showed that 71.17% of the process time is considered non-value added as shown in Table V below:

	Value Added	Business Value Added	Value Non-Value Added	Total
Time (Hrs)	11.3	0.73	29.7	41.73 Hrs
Percent Time	27.08	1.76	71.17	100%

Table V Value Added-Non Value Added Summarized report

This report helped in identifying the targeted time reduction for every process to 12 hours instead of 41.73, which is just over 70% reduction in the throughput time. The non-value added report triggered the usage of a filtering tool for prioritizing the process inputs that are contributing to the non-value added timings. The tool used is Cause and Effect matrix; this tool provides a venue for the subject matter experts to quantify the magnitude of the relationship between the inputs and the process output. The below snapshot provides the top inputs that affect the process outputs:

Rating of Importance to Customer >>		10	9	
Process Inputs		External Delays (Customer)	Internal Delays (Financa)	Total
1	Man Machine Interface Form	9	9	171
2	Delivery Note	9	9	171
3	Work control staff	9	9	171
4	Engineer	9	9	171
5	Delivery schedule	9	9	171
6	Sales Person	9	3	117
7	Machine and Accessories Inventory	9	3	117
8	Machine configuration	9	3	117
9	Requirement from Customer Site	3	9	111
10	SOP for checking delivery	3	9	111
11	Store Assistance	3	9	111
12	Machine Pre-Installation Form	1	9	91
13	Delivery note register book	0	9	81

Figure 6 C&E Matrix

The identification of the top inputs that are leading to the delays in the process were transferred to another tool called FMEA (failure mode effect analysis), which helped in identifying the main causes behind these defective inputs. Below is a snapshot of the

Key Process Input	Potential Failure Mode	Potential Failure Effects	SEV	Potential Causes	OCC	Current Controls	DET	RPN
What is the Key Process Input?	In what ways does the Key Input go wrong?	What is the impact on the Key Output Variables (Customer Requirements) or internal requirements?	How Severe is the effect to the customer?	What causes the Key Input to go wrong?	How often does cause or FM occur?	What are the existing controls and procedures (inspection and test) that prevent either the cause or the Failure Mode? Should include an SOP number.	How well can you detect cause or FM?	
Requirement from Customer Site	Inadequate/No Information on pre Installation Requirements	Aborted Delivery Installation	8	No Pre Site Durvey	7	Site Survey Requirement on MMI Form	10	560
Sales Person	Not meeting the Customer Requirements	Unsatisfied customer	6	Product Knowledge	8	Product Training and Testing	9	432
Man Machine Interface Form	Imcomplete/Wrong Information	Wrong Items/Incomplete Delivery	7	Accurate Information	6	None	10	420
Machine and Accessories Inventory	Unavailability of the stock when requested	Machine Model not available at time of request	8	Wrong sales forecast/Delays from supplier	7	Rigorous Sales Forecast Exercise	7	392
Delivery Note	Process not strictly followed	Wrong/Delay in delivery to customer site	8	Work Pressure/Miscommunication	5	Train and monitor compliance with the delivery process	4	160
Work control staff	Customer not getting required support	Inability fo meet the standard response time	8	High number of service and repeated calls	8	Ability to measure response time	2	128
Machine configuration	Unfulfilling Customer Requirement	Incomplete/wrong product delivery	8	Customer requiremet not understood	5	Machine pre-installation check list	3	120
Engineer	Inability fo meet the standard time	Delay in machine installation leading to customer dissatisfaction	9	Work load	6	Manpower Planning	2	108
Delivery schedule	Poor scheduling	Delay in delivery	8	Planning/Resources	6	Worl Load/Manpower planning	2	96

FMEA:

Figure 7 FMEA

The identification of the causes behind these defective inputs helped in devising a data measurement plan. The data gathered was transferred to Minitab and several graphs and reports were generated. The main one shown below (Figure 8) suggests that the process is not centered and not capable. The boxplot showed many orders that took an extremely long time to be delivered to customers. It also showed that more than 50% of

these orders took more than 12 hours (the median). This further resulted in 50% dissatisfaction from the delivery services.

Figure 8 Duration Data

Analyze Phase

There are multiple ways of analyzing the current situation. Irrespective of the method the aim of the analyze phase is to find the root causes (Snee and Hoerl 2003) that are contributing to the defects. As such, in this phase, data are analyzed in order to discover the causes of any problems (Kapur and Feng, 2005). Some authors, like Gitlow and Levine (2005) propose dividing the causes into two parts. These are *Common* causes and *Special* causes.

The common causes can be divided into 6 categories as outlined in the 6M's method (Snee and Hoer 2003, Rasis et. al. 2003a-b). **M**ethod: the way the activity is done, **M**achine: the actual machines or equipments used within the process, **M**aterials: the components used in the process, **M**easures: the actual capability of the measurement system used (i.e. we need to ask ourselves if the tools used for measuring good accurate enough), **M**other Nature: look for the effect of the environment on the process under investigation, **M**an: finally the human resources involved in the process. Some authors call this method differently 5Ms and 1 P (for people) or Cause and Effect as suggested by Pande and Holpp (2002, p.38).

After sifting through the data a fishbone diagram was created in order to better identify the root causes of the problem in the delays. The below diagram was completed with the SMEs and was a great help for both the green belt individual running the project and the SME who were able to see the big picture.

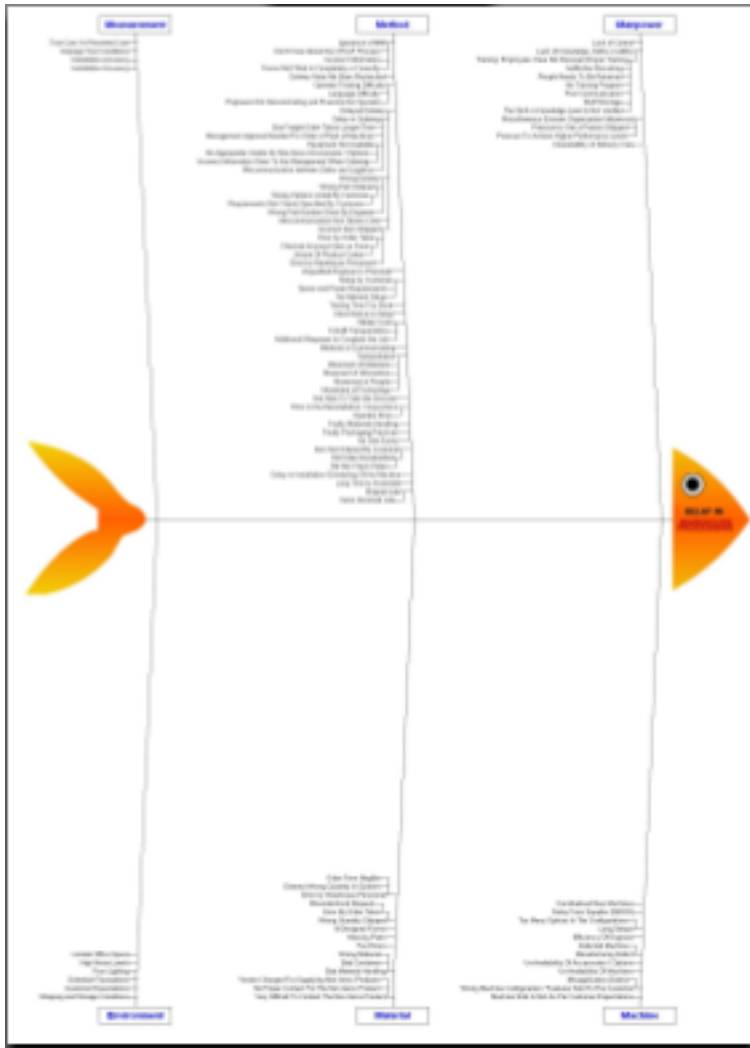

Figure 9 Fishbone Diagram

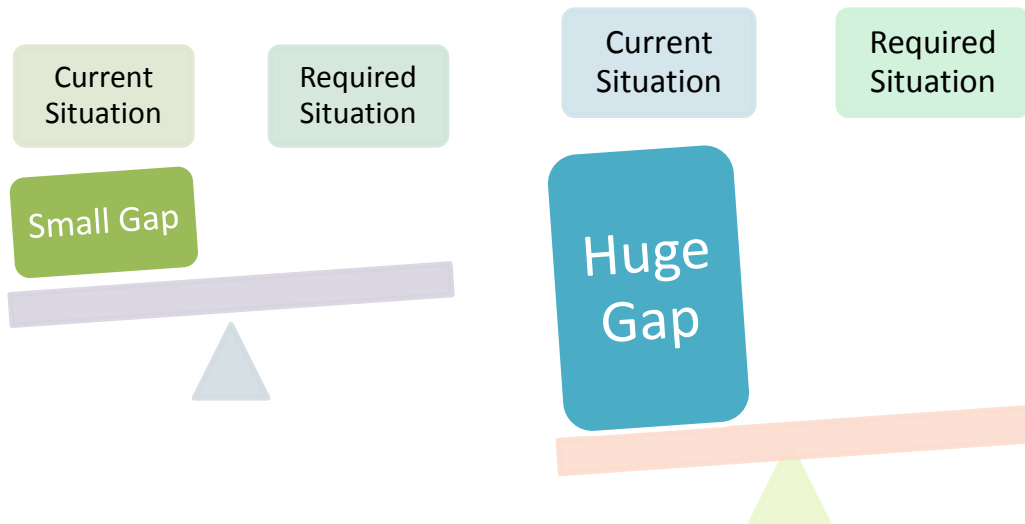

More in-depth analysis was conducted on the provided data; the main delays that are occurring can be categorized into two parts:

- 1- Time spent in office (average of 1.7 days)
- 2- Time spent at the warehouse (average of 15.2 days)

This narrowed down the search for solutions during the improve phase to those relating to the warehouse. Since a 50% reduction in that time will have a great effect onto the overall time required to deliver units to customers.

Improve Phase

Once the root causation is completed the improvement phase will provide a detailed solution (Mahanti and Antony, 2006). Depending on the gap between the current measure and the required measure, there are multiple methods that can be adopted during this phase.

In case of a small gap, some controls can be embedded within the system to address all the faulty inputs. In case of a huge gap, the common method used is business process re-engineering, where the team members will start from an empty sheet and build the process according to the set requirements in the define phase.

Due to the large gap between the as is situation and the to be a full re-engineering exercise was carried out. The process has been redrafted with the SMEs and a new spaghetti diagram and a value added report of the new process was generated

Figure 10 Reengineered Spaghetti Graph

Re-engineered process:

- 1- Sales consultant generated the orders
 - a. Before they generate the orders they should prepare themselves in accordance with the following requirements:
 - i. Check credit history and decide on whether it is valid or not.

- ii. Check product in stock before final agreement and filling of a customer purchase requisition form.
 - b. Sales people conduct their sales calls and will only transfer these calls into orders if they fit both the financial and availability of stock requirements.
- 2- Sales consultants will fill-in their orders on business workflow management system as such:
 - a. All the information will be provided through the use of drop downs to ensure readability, conformity and standardization:
 - i. Customer details
 - ii. Product details
 - iii. Customer requirements
 - b. Expected delivery date is generated in accordance with the new lead times and the vans schedules (a maximum of 12 working hours are allowed for delivery).
 - c. Transfer the order to five stakeholders at the same time
 - i. Sales manager
 - ii. Finance
 - iii. Warehouse for getting the products from the warehouse
 - iv. Engineers will prepare the product in accordance with the customer requirements
 - v. Delivery for scheduling the delivery
- 3- Sales consultants follow-up on the order delivery status.
- 4- PARALLEL Finance receives the approved order from the sales. They review the order and make sure that the financial requirements are met.
- 5- PARALLEL Warehouse get the product from the warehouse and place it in the work station area, once ready an automated message is sent to the engineering department informing of the status of the machine.
- 6- PARALLEL engineers fix the machine in accordance with the customer requirements that are available on the system. Small machines are delivered by the engineers directly and installed by them.
- 7- Delivery people pick-up the machine once a final confirmation from the engineers, financial and sales manager is generated.
- 8- Products delivered and the customer signs the form.

Control Phase

In order to maintain the gains that were made after implementing the solutions that emerged from the improvement phase, the next phase is the control phase. The aim of this phase is to ensure that defects do not re-occur (Mathew *et al.*, 2005). This phase pushes the Six Sigma team to draw a control plan (Rasis *et. al.* 2003a-b) which has the following components as mentioned by Mahanti and Antoy (2006):

- 1- Evaluation
- 2- Monitoring
- 3- Maintaining

This plan is divided into two parts as Eckes (2003, p. 61) mentioned:

- 1- Technical method of control: in here there would be some run charts reviewed on fixed intervals. The aim is to identify any deviations from the set objectives during the improve phase
- 2- Response plan: in case of any deviations an escalation mechanism is instigated. This plan will help to identify in a quick manner if the causes are common or special and assess their severity and potential occurrence

The review of Six Sigma presented the framework that needs to be followed along with some of the tools that are used in different stages.

Once the improved process has been designed and implemented a control plan was put in place in order to make sure that every individual involved in the process are working in accordance with the expected process outcomes. The control plan also allows higher management to identify any deviation from the expected output. The control plan presented the graphs and charts that are to be used in order to monitor the performance of the process.

Recommendations to top management

Different sources outline the requirements for a successful six sigma project, which can also be categorized in different ways. Mehrjerdi (2011) divided them into three types of critical success factors as such:

- 1- Executive Management
- 2- Communications
- 3- Projects

Zhang *et. al.* 2011 suggested that there are five core elements of Six Sigma stated below:

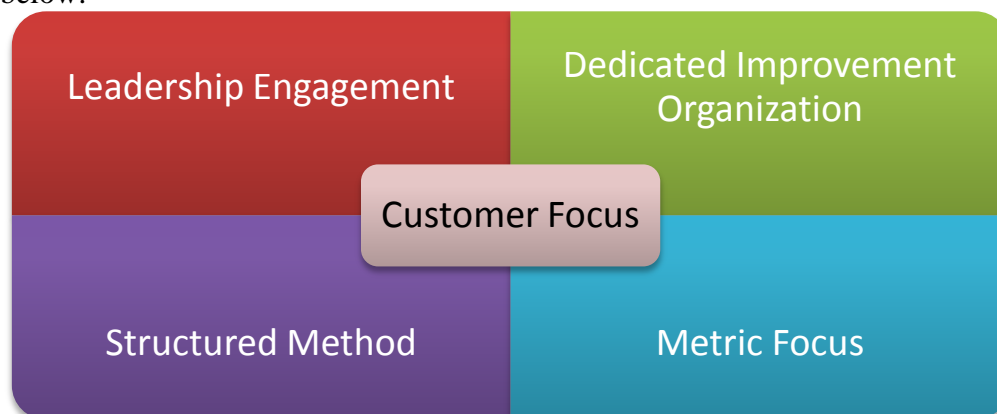

Figure 11 Five Core Elements of Six Sigma

Throughout the project described earlier two of the above core elements and two of the critical success factors described by Meherjerdi 2011 were not fully met and hence problems occurred and hampered the smooth progression to completion. Below a more detailed count of how low lack of leadership engagement and lack of overall Six Sigma drive strategy impacted the project.

Leadership Engagement

There was a problem in assigning a champion to oversee the project and be the link with higher management to get necessary approvals on time. This led to the emergence of a lot of friction between the team working on the project and the units' heads of the different departments that were involved throughout the project. Scheduling the necessary time with the subject matter experts was always problematic and multiple cancellations and rescheduling occurred.

In addition to that, all the time that needed to be allocated to the project was additional to the day-to-day activities the assigned team had to continue performance to the best on. The team worked extra hours and week ends in order to complete the project.

The lack of leadership support led to problems with the procurement department resulting in delays to order or acquire the necessary technological tools necessary to conduct the different analyses including the value added and spaghetti diagrams. Another result of the lack of leadership stumbling block was access to work areas where people can meet and discuss the different aspects of the project and in particular meeting the different stakeholders while running the mapping exercises.

Dedicated Improvement Organization

The lack of any project selection process made the process of finding a project itself problematic and thus the team had to set a large number of meetings before identifying a feasible project. By feasible it is meant that:

- 1- The project has the necessary elements for it to be considered a lean Six Sigma one
- 2- The people that will be involved in the project are willing to dedicate some of their time to the project
- 3- The expected returns are considerable

In addition to the long process of identifying a project, the lack of an overall improvement strategy that identifies the areas of improvement opportunities made convincing the finance department of the viability of the project problematic.

Based on the above pitfalls, it was recommended to the top management of the LLC that the following is needed before any full scale roll out to LSS:

- 1- Improvement strategy that builds on a customer (internal and external) satisfaction survey.
- 2- Mechanism of assigning champions with the right authority to shorten decision making timelines, and to have a scheme of relieving team members from some of their day to day tasks.
- 3- Design a project selection matrix that is in line with the improvement strategy.

Management faced with the high returns from running one project that exceeds some of the average returns as discussed by Miguel and Andrietta (2009). As a note, at the time of submitting the paper the company already conducted an improvement strategy stemming from their strategic planning exercise.

Based on the positive outcome from the above Lean Six Sigma deployment will be embarking on the deployment of LSS within local government and compares its results to those achieved by Furterer and Elshennawy (2005).

Conclusions

On the basis of the project results, the following conclusions have been drawn:

- 1- A successful business process improvement drive in general and six sigma in particular must be an integral part of the strategic plan of any organization that is planning to reach higher grounds of profitability and sustainability.
- 2- Leadership involvement in deploying the strategy is very crucial and to ensure its success adding it as part of their yearly objectives in the performance evaluation is needed.
- 3- Dedication of an in-house team makes sure the drive does not fade and benefits are sustainable in the long run.

An agenda for future research

Initiating Six Sigma projects in the services industry in the GCC can help organizations acquire rich dividends. More research on Six Sigma implications in service organizations in the GCC is required. This is necessary because it will allow us to design a specific deployment approach along with some additional tools and techniques needed for this region. The focus should be on how improvement in general and six sigma in particular become an integral part of the organizational strategic initiatives, and the use of more innovative tools that makes six sigma easier to grasp and adopt. One way of achieving the second part is through the use of Business Process Simulation (Abouzeid and Zeidan, 2011).

Introduction

It is commonly accepted that the rate of change is acceleration in all fields of society. Change Management is a common topic for private and public companies. Regional Development could be seen as part of this constant change. In Sweden all regions need to define long range goals and strategies. Seeing to the actual and future needs of all stakeholders is a formidable challenge. In most cases universities take part in development of their region. The regional university could be seen as the engine of Regional Development. One of the core values in Total Quality Management (TQM) is customer focus. This is often translated to the expression of having an outside-in perspective. However, universities traditionally could be seen to come from a tradition with more focus on their own knowledge – that is having an inside-out perspective. Universities in Sweden are required to include co-operation with the society both in education and research. This implies that there is a need for customer or stakeholder focus. In an organisational context TQM values and methodologies have been used successfully to improve performance. Often a process view is used where entire organisations can be viewed as processes. A region could be seen as a process that converts input to output in a repeated network of activities generating value to stakeholders. In Figure 1 a proposed generic process model based on common process theory and adapted from Isaksson & al (2008).

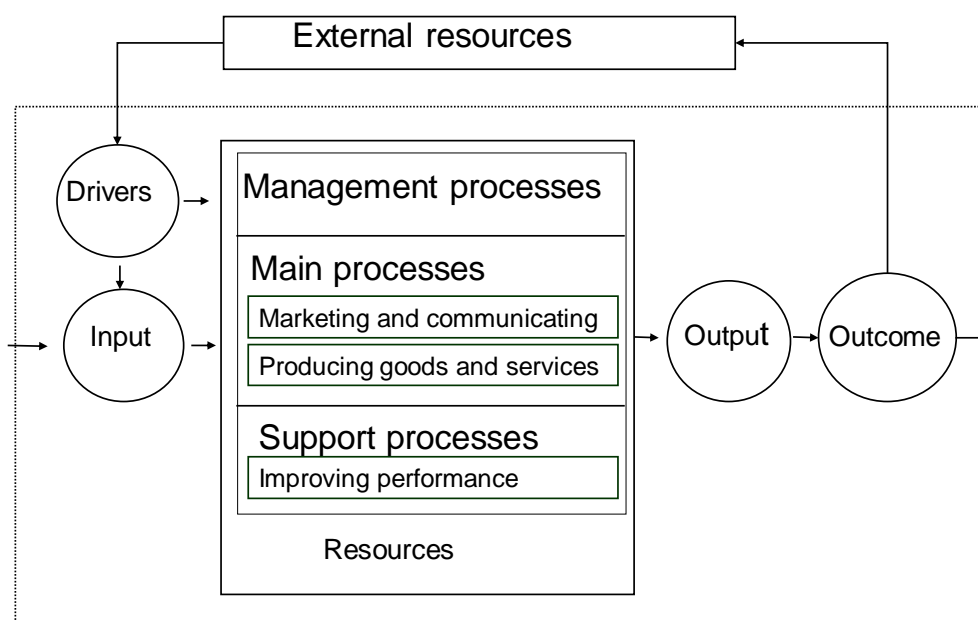

Figure 1. A process based system model proposing some generic main and support processes, adapted from Isaksson et al. (2008).

The general purpose of the study is to see how universities contribute and could contribute to regional development using quality management theory. The specific research questions in this study are:

For a region how can the present state, the visionary state and the chosen change strategies, be described with Quality Management values and methodologies with focus on the process view

How do the regional university mission, vision and goals align with defined regional objectives?

Methodology

An initial literature survey for how Quality Management has been used for regional development is carried out to create a structure for the data collection. We also look at general definitions of regional development.

The region of Gotland in Sweden has been chosen for a case study. Gotland is an island situated some 90 km from the Swedish mainland, which makes the regional and geographical limits very clear. Gotland is the smallest region in Sweden and Gotland University is the smallest university in Sweden and the only one on Gotland. This makes Gotland a well defined option for a case study.

The main documents describing visions and strategy for Gotland are studied. Responsibilities for regional development are clarified and people in charge are interviewed. Data is gathered from web sites and from interviews. The categorisation of information is based on a process perspective using process based system models adapted to the initial literature survey. The current change process is also portrayed. In order to see how the local university performance and plans align with the regional plans the Gotland University web-site is studied for relevant documents and persons involved are interviewed.

The regional performance is studied from a process perspective. This identification of processes is mainly done with the help of the official regional vision document. The current performance, the future performance and current improvement initiatives are described using officially existing information. The current state of progress is described and the potential for increased support from the university is identified. This is done by comparing the regional vision, goals and strategy with the university capacity within research and education. Additionally the university mission, vision, goals and strategies are studied to detect existing and possible synergies.

Theory background

The process view and process management are integral parts of Quality Management. The process view is used in many improvement approaches such as 6Sigma and Lean Management. The process view puts focus on value adding for customers and stakeholders. Based on the assumption that we can consider a region to be an

organisation we should also be able to describe it as a process. Dealing with the region as a system of processes might make it possible to use quality management values and methodologies to support more effective regional development. Common change management logic tells us to analyse the current state, visualise the future state and then decide on a strategy for change.

The process based system model in Figure 1 could be used to describe current and future state as well as the change process, see Figure 2.

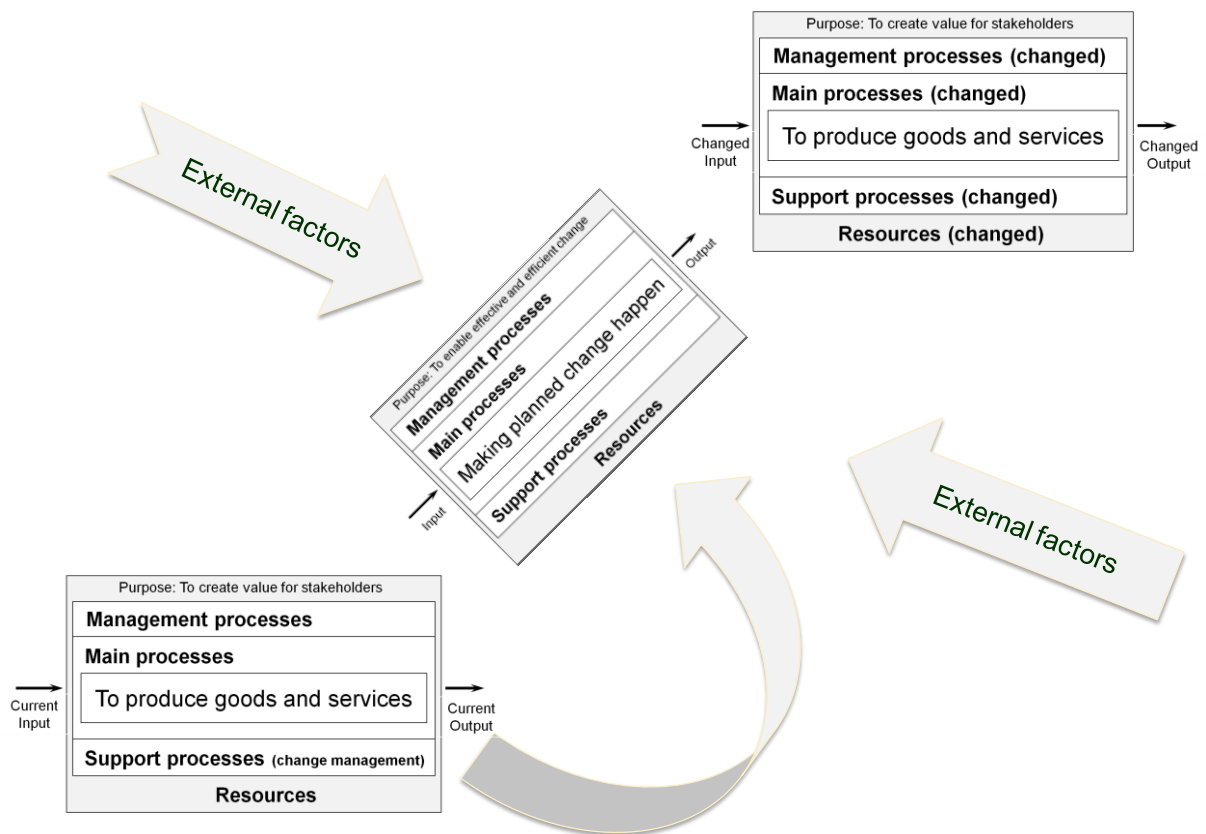

Figure 2. The current state and the future state as well as the change process using generic process models, adapted from Isaksson & al (2011).

Common change elements can be interpreted using the proposal of Bergman & Klefsjö (2010, 433) as mission, vision, goals and strategies. The mission or the purpose of the organisations sets the scene for the vision. The vision should give a good picture of the future state and it should be desirable and clear as well as easy to communicate, (Bergman & Klefsjö, 2010, 36). A good vision statement could be seen as an organisational resource. TQM could be seen as a management system that has an aim and that consists of Values, Methodologies and Tools (Bergman & Klefsjö, 2010, 419). The objective or aim of the system is to create increased customer satisfaction with less resource consumption (ibid). This objective should also be of help in the context of regional performance improvement as part of regional development. Proposed values in Bergman & Klefsjö (2010, 419) are Top Management Commitment, Focus on Customers, Improve Continuously, Focus on Processes, Let Everybody be Committed and Base Decisions on Fact. Methodologies supporting these values could vary but could include such as Process Management and Policy Deployment. The vision should be clear enough to be broken down in goals. Here the SMART goals system could be

used – Specific-Measurable-Accepted-Reasonable-Time set, (Bergman & Klefsjö, 2010, 439). The SMART goals can be challenged like with the Lean Management view of presenting challenging goals that might at least not in the beginning neither be accepted nor seem reasonable. However, as a starting point for an analysis with the purpose to see if TQM theory could be of help in describing and improving the change process the SMART goals are good enough. In order to categorise what to measure in the process we could use the logic of the Triple Bottom Line that divides performance in economic, environmental and social performance.

The customer is the one for whom the process is producing value. In the regional context there would be many customers and there are other stakeholders that need attention.

Additionally success factors and key processes should be identified, (Bergman & Klefsjö, 2010). Success factors should relate to the vision of a sustainable Gotland. Sustainable growth is described as economic development with concern for environment and social aspects (GRI, 2006). Economic performance could be measured as proposed in the GRI guidelines with sales value. Main environmental parameters are such as energy consumption and carbon emissions. Choosing a good social indicator for the region is not obvious. Here, we could use indicators for health, employment and wellbeing indices.

As a summary, existing information that describes the current and future state of the region and Gotland University are analysed based on what a vision should contain, which the guiding values and main methodologies are and how goals appear when using the SMART-approach including Key Performance Indicators for success factors and for key processes.

Results from the literature search

The literature analyses indicate that Total Quality Management (TQM) can be used with success within regional development. These principles and the ways of working with improvements are not limited to work places, but can also be used for improving life in local through collaboration (Brown *et al.*, 1994; Stratton, 1997). One way is through successful cooperation over organizational boundaries, with projects in, among others, the U.S., the U.K. and Sweden. One approach is the community health improvement model. The so-called ASQ/IHI model (American Society for Quality/Institute for Healthcare Improvement) provides a methodology and new approach to addressing important community issues in ten communities in the U.S., for instance, in Dallas (Texas), Denver (Colorado) and Waltham (Massachusetts); see Kinney (1998) and Knapp (1998).

Another example is provided by the community of Tacoma in Washington State, where the residents have worked with concepts from TQM and studied how compatible “The citizen-as-customer model” is to community-wide improvement work. In Tacoma most residents had little faith in institutions and elected officials. One aim of the project was therefore to rebuild public trust in the community as a viable unit for social and civic interaction. Another was to help the residents to find trust in their own capacities, as individuals, to make a difference. (Jaques, 1999).

Toqua village in the state of New York is another major example from the U.S. The programme, for a “total municipality of quality”, started in 1991 when a new mayor was elected. He became a central person in the daily management of the municipality. This programme had, besides a quality and customer focus, also strong efficiency in focus. The municipality established a Village Quality Council (VQC), with the mayor, the municipal department managers and two quality consultants. The Toqua village statement and quality policy were established and gradually accepted by the municipal executive board. (Hagedorn-Rasmussen, 2002)

In the U.S. there are several examples of organizations that have successfully applied concepts from TQM to other segments of society than just the commercial and public ones. The community of Pensacola in Florida has brought together people from different sectors to create a “Quality Community”. The state of Oregon is striving to create a high-performance society through benchmarking and human investments strategies. Communities in California, Wisconsin and Arizona are establishing mutually profitable partnerships among schools, city government and private business; see Osborne & Gaebler (1992) and Brown *et al.* (1994). These are examples of TQM-based collaborations over sector boundaries, where the community is seen as a system; see also Knapp (1998) and Scholtes (1997).

One example from the U.K. is the “Best Value Programme”, with the residents in focus. It is a governmental initiative in which the users of public services are invited to affect the shaping and the quality of the services. For further information, see www.audit-commission.gov.uk.

There are also examples in Sweden where municipalities work with quality in focus, after initiatives on either national or local levels. The Swedish communities of Gothenburg and Stockholm are two such examples where concepts from TQM have been transferred to community issues. The purpose is to inspire and stimulate quality development with the residents’ best in focus. See <http://www.goteborg.se> and <http://www.stockholm.se> for more information. The Swedish Institute for Quality (SIQ) supports quality work as well in Sweden, see <http://www.siq.se>.

Community work with improvements and the use of concepts from TQM are discussed in Crall (1998), Kinney (1998), Reavill (1999) and Corpuz & O’Hanlon (1999). The systematic approach, the system view and the preventive thinking in TQM can be used also for societal projects with a more limited scope. Examples are: to prevent negative economic and demographic trends; see Helling *et al.* (1998); to prevent domestic violence; see Corpuz & O’Hanlon (1999); and to reduce traffic injuries; see Knapp (1998).

Jacques (1999) cites Putnam (1995) when concluding that factors such as community wealth, educational levels, and political parties might explain why some community projects are successful, while others are not. However, the crucial factors in Tacoma turned out instead to be the skills of the community groups that brought people together for face-to-face conversations about local issues. Events and activities for training and awareness were important means of engaging the residents.

According to Jacques (1999), communication and work in processes are keys to overcoming political barriers in community improvement efforts. Quality professionals

involved in community work can contribute with their knowledge of improvement methodologies and system-approach thinking. Jacques refers to Scholtes (1997) when stating that poverty levels, unemployment rates and fiscal deficit are relevant measures for the outcome of the work. All this implies that new ways of thinking are needed to secure a successful outcome of community improvement projects.

The community of Åseda in southern Sweden provides another example of a local societal improvement project. It started in mid 1990's and is carried out with a system approach, with the aim of breaking a negative economic and demographic trend. The Åseda and Seskarö projects are two Swedish examples of the two different approaches, and both were motivated by the same type of negative trends in economy and demography. There was not enough public service, and it was difficult for the local industry to get competent personnel. In Seskarö it was important to develop the local industry and create employment (Fredriksson, 2004).

All these experiences, foreign and Swedish, give clues to a cooperation model based on TQM for organizations in regional development, which was developed (Fredriksson, 2004). In the start-up phase 1, the main issues are the leadership, the communication, the organization of the work, the education, the relations to others and the involvement. In this phase a core group is created, and it is preferable to have persons with experiences of work with Quality Management, because a systematic approach to improvement work is useful. It is essential that an inner core group is created in phase 1, consisting of representatives from the cooperational organizations, see Figure 3. According to Kinney (1998), community health improvement work benefits when a small group of key actors is established as a core team, then focuses on a specific aim, and acts to implement changes. This flexibility is crucial for success in implementing small cycles of change. The core team must achieve knowledge of customers, either through members or by other means. The membership in the core team should be updated regularly to maintain coherence between activities and membership.

In phase 2 (“establish”) the important factors of distinction and praise are added. The core group is extended with improvement groups and other advisory groups. In phase 3, where the continuous work is established, there might be a change of leaders, and the issue of a “public” mandate should be addressed. Two important factors permeate all three phases: leadership and communication. In the final phase 3 another enlargement is made in order to include other stakeholders in the community. Included here are the personal and professional networks of the core group and of the improvement groups, including the political sector. In each phase methodologies and tools from TQM can be used to systematize and structure the improvement work.

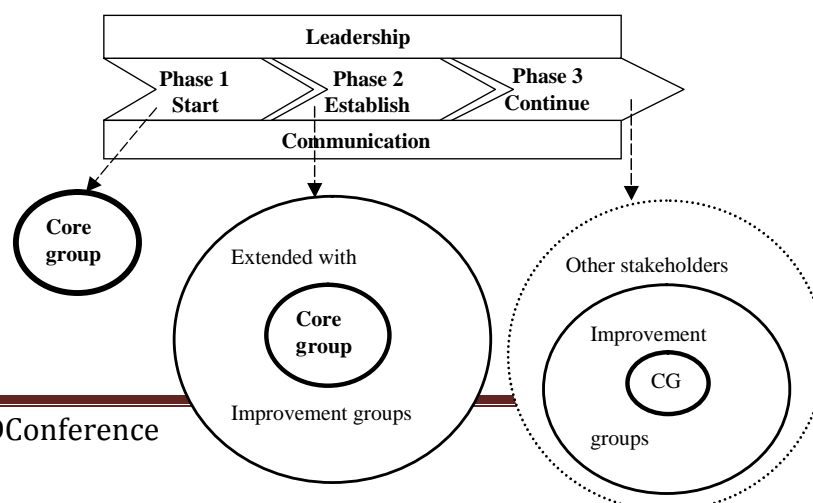

Figure 3. This figure is connected to the ASQ/IHI model (Kinney, 1998), and modified to illustrate how the improvement work in a local society such as within “Progressive Åseda” can be conducted in the three phases. An inner core group is created in phase 1 and extended with improvement groups in phase 2. In the last phase 3 another enlargement is made in order to include other stakeholders in the community (Fredriksson, 2004).

This core team should thoughtfully identify members to create an extended team and actively manage the connections with them. In this model the extended team should include the host organizations for team members, for instance, a public health department if the improvement work is a health issue. Kinney (1998) also suggests that the media and politicians be members of an extended team. The extended team can provide a foundation for sustaining the improvements achieved by the core team.

The model may be applicable to temporary organizations, such as networks, and to non-profit organizations. The model can be used from the municipal perspective, if politicians would like to take initiatives for improvements, or from the perspective of residents, if a “private” resident wants to do the same. A recommendation in the latter case is that the resident anchors the ideas in some organization, either a “private”, non-profit, one, or in “business”, such as a company or another organization. One conclusion from the case studies is that it might be difficult for a “private” person to get response for such ideas in a local community, if the ideas are not first anchored in smaller circles.

The region Gotland and the vision 2025

Gotland is an Island in the middle of the Baltic Sea. The land area is 3 140 square kilometres and the number of citizens is around 57 000. Agriculture/food, tourism, services and building material industry are the main businesses together with a number of small businesses. Around 26 000 people have employment. The city of Visby is the main city with around 23 000 citizens.

The municipal “Region Gotland” has the responsibility for the development of the region. This is documented and set in progress with the “Vision 2025” approved and communicated 2008. The foundation is a long-term sustainable development based on three interacting dimensions- economic, social and environmental. The Vision 2025 forms the basis for other plans and programs bearing on the development of the region. In order to satisfy overall objectives, a number of goals, brands and strategies have been defined.

Review of the Vision 2025, regional objectives and strategies

“Gotland is the Baltic region's most creative and magic place, characterized by closeness, sustainable growth and full of zest for life.” – Translated from the Swedish original.

”Vision Gotland 2025 is our regional development program”, (Vision 2025, 2008).

The Region Gotland has defined plans and programs according to a summary of objectives, strategies and activities for a specific area to achieve the vision / desired level.

The Vision 2025 document specifies the following overarching goals:

- At least 65 000 residents living on Gotland
- Gotland's prosperity is among the best in the country
- Gotland is the natural place for rendezvous in the Baltic Sea Region
- Gotland has a population with good health who experiences the highest wellbeing in the country
- Gotland is a world leading island-region of environmental and energy issues

The Specific programs and plans listed in the Vision 2025 are the overview, the growth program, the rural development program, the program for supplying apartments and houses, the health program, the cultural program, the plan for infrastructure, the energy plan and the environmental program.

The "Region Gotland" Balanced Score Card is used to follow up and inform citizens about the progress (Lindskog, 2011); (Region Gotland, Strategic plan and budget 2011–2013).

The Vision 2025 is assessed and evaluated against the elements in TQM according to Bergman & Klefsjö (2010).

- | | |
|----------------------------|--|
| • Values | Have not been identified and communicated |
| • Vision | Has been approved and communicated 2008 |
| • Missions | Partly described in Vision 2025 and described in special programs. |
| the | |
| • Goals | Partly described in Vision 2025 and actions plans |
| • Critical success factors | Partly described in actions plan |
| • Key Processes | Not identified |
| • SMART - Metrics | Suggested metrics in Balanced Score Cards for the goals |
| some of | |

The work that resembles work with values is the "learning map" that has been used in the implementation of the vision for the regional management and politicians, see Figure 4. We do not interpret that work as identifying and communicating values.

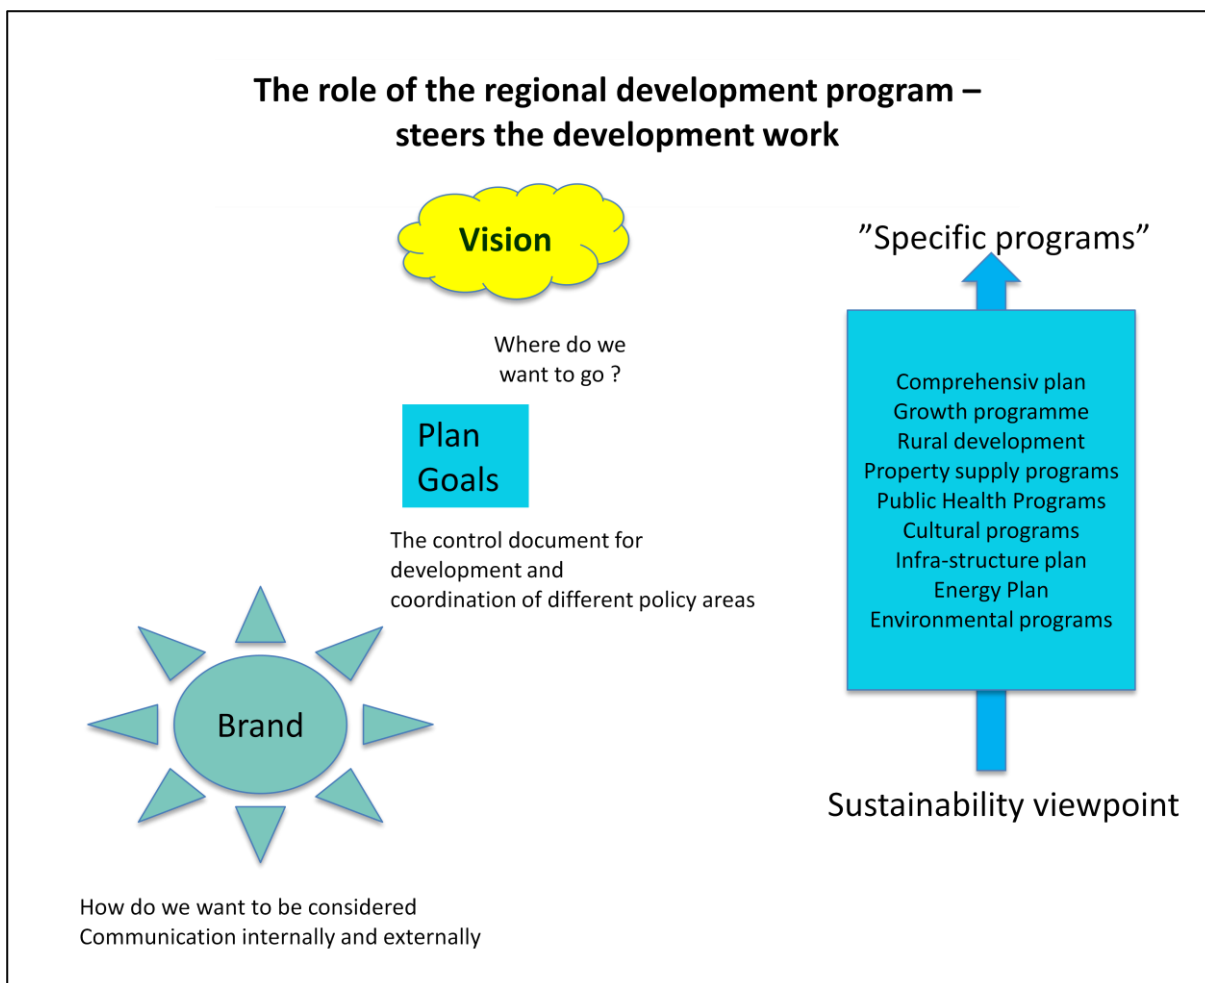

Figure 4. Overview of the Vision 2025 structure, (Vision 2025, 2008).

The expressed goals are not all corresponding to SMART requirements (Region Gotland, Balanced Score Card 2008-11-24), see Table I. The evaluation is carried out applying a positive interpretation, but even then we can see that 10 out of 24 goals are interpreted as not specified. Four out of 24 are not measurable and four out of 24 we do not interpret as reasonable. Most of the goals that are following SMART are goals connected to national goals and measurements. They are made specific by setting the level to average that of Sweden in general. From the goals in the Region’s Balanced Score Card we can also see that environment has few goals compared with the other overarching goals? This could be due to the fact that the overall responsibility for environment is divided between the region and the local government board.

Table I. Evaluation of the measurements in Region Gotland’s Balanced Score Card against the definition for SMART goals

Overarching goals	Specific	Meas-urable	Accep-ted	Reaso-nable	Time set
At least 65 000 residents living on Gotland	Yes	Yes	No	No	Yes
<ul style="list-style-type: none"> • More registered residents. • Reached targets for the number of homes 	No Yes	Yes Yes	Yes Yes	No Yes	Yes Yes

Gotland's prosperity is among the best in the country	Yes	Yes	Yes	No	Yes
• Share of employees (in private & public sector) in line with national average	Yes	Yes	Yes	Yes	Yes
• Business environment in line with national average	Yes	Yes	Yes	Yes	Yes
• New enterprises in line with national average	Yes	Yes	Yes	Yes	Yes
• Increased growth	No	Yes	Yes	Yes	Yes
• Increased share of the business in alternative form	No	No	No	No	Yes
• Increased tax capacity	No	Yes	Yes	Yes	Yes
• Education in line with national average	Yes	Yes	Yes	Yes	Yes
• Grade 9: Percentage approved in line with national average	Yes	Yes	Yes	Yes	Yes
• Improved education outcomes	Yes	No	Yes	Yes	Yes
• Percentage who go on to university in line with national average	Yes	Yes	Yes	No	Yes
• Proportion of foreign-born in employment in line with national average	Yes	Yes	Yes	No	Yes
Gotland is the natural place for rendezvous in the Baltic Sea Region	Yes	No	No	No	Yes
• Increased number of travelers	No	Yes	Yes	Yes	Yes
• More destinations	No	Yes	Yes	Yes	Yes
• Maintain frequency, capacity, time and price for communication to mainland	Yes	Yes	Yes	Yes	Yes
• Number of nights spent in hotels, etc.	No	Yes	Yes	Yes	Yes
• More meetings	No	No	No	No	Yes
Gotland has a population with good health who experiences the highest wellbeing in the country	Yes	Yes	Yes	Yes	Yes
• Citizen experience in line with the national average: Region / Municipality / influence	Yes	Yes	Yes	Yes	Yes
• The proportion of rural residents shall be maintained	Yes	Yes	Yes	Yes	Yes
• Equality indexed in line with national average	Yes	Yes	Yes	Yes	Yes
• Perception of security	No	No	Yes	Yes	Yes
• Public health figures	Yes	Yes	Yes	Yes	Yes

(including perceived health) in line with national average					
Gotland is a world leading island-region of environmental and energy issues	No	No	No	No	Yes
<ul style="list-style-type: none"> Green key figures in line with national average 	Yes	Yes	Yes	Yes	Yes

From the official web page of the region we have not found any systematical follow up of the goals. The vision was set in 2008 and three years have now passed which is more than 15 % of the time to reach the goals. Some of the activities should have produced results, for instance the increase in residents, see Figure 5.

Figure 5: The number of residents in the region of Gotland from 1945 to 2010.

At the official web page (www.gotland.se) we have not found any sign of process related activity or a general approach to collect and merge measurement from different areas and programs.

No key processes have been identified.

In Figure 6 some of the main value adding processes in the region have been identified and introduced to the model template in Figure 1. The vision could be seen as an interpretation of drivers. The strength of the drivers is depending on the feedback from stakeholders in the Swedish context where Gotland exists. Out of the 26000 people employed some 7500 work in public services, some 1500 in agriculture, forest and fishing and the rest are in private business or as self-employed. Due to the large number of people active in these processes they could be considered key processes. Tourism is a particularly important business with Gotland being one of the main Swedish tourist locations in summer. Gotland has 25% of its electricity generated by wind. This is more than ten times the Swedish average. In a sustainable future energy production is a key process. Gotland is the region with the highest per capita carbon foot print measuring about 33 t CO₂/person and year. This is five times the Swedish average. The reason for this is the limestone based industry and mainly the large cement plant situated on the

island. This is the reason for having identifying “providing mineral products” as a separate process.

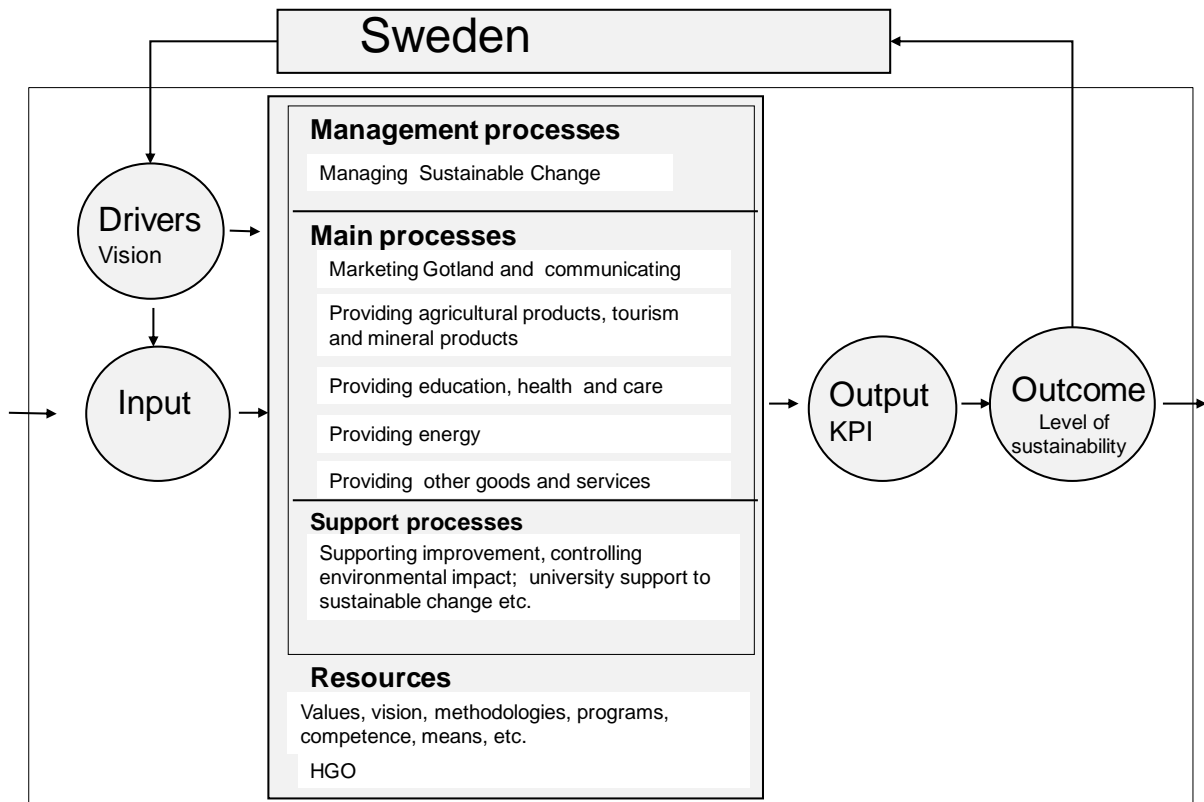

Figure 6. An interpretation of some of the main key processes in the region of Gotland based on Figure 1.

Current state of Gotland compared to vision

The current state is reviewed based on the main objectives of the Vision 2025 document.

- Population from 57000 to 65 000 residents in 17 years which means an increase of some 470 persons per year
- Gotland’s prosperity – Incomes per inhabitant lower than average for Sweden
- Gotland is the natural place for rendezvous in the Baltic Sea Region – No measurements or indication of status
- Gotland has a population with good health who experiences the highest wellbeing in the country – National figures show both good and bad results in different areas.
- Gotland is a world leading island-region of environmental and energy issues - Currently world level in Wind Power generation

Evaluation of change strategies

The vision has been active for three years and more than 15% of the time has passed. No systematic follow up of performance has been found in web page searches.

Population has increased two years in a row with some 30 persons per year which is less than 10% of the objective. It is unclear how the strategy looks to increase population. Employment is occasionally available but it is practically impossible to rent a permanent apartment and day care is struggling to cope even with current demand.

The first indicative results are that there is no “clear” connection from the vision to any type of SMART-goals that would be followed up. The main impression from how the current change process is working is that there are many opportunities for improvement.

Evaluation of the University mission, vision and goals

The University of Gotland is Sweden’s smallest University with around 7 000 students studying fulltime or part time. Converted to fulltime students the number is about 2500. The courses are given both at Campus Visby and as distance education. Seven out of ten students are using the distance option. The University of Gotland can also supply special customised courses that can be bought by organisations.

Vision of Gotland University

The latest vision for Gotland University was prepared and launched during 2010.

“The University of Gotland is a small university with a big idea. We are the leading university for modern education, Liberal Education. The quality of our training is strengthened by the link to our multi-disciplinary research environment and by our clear regional and international linkage.

The university is leading in flexible forms of teaching. Curiosity and a shift in perspective is the driving force for students and employees in accordance to the University's motto, "Passion and science".

Mission

The university law “Högskolelag” (1992:1434) defines the mission which can be expressed as:

Universities shall provide higher education and research that is based on scientific knowledge or art education and development which is based on proven experience.

The university’s task will also be to interact with the surrounding society and to inform of university activities and to ensure that research from the university will benefit society.

In the Research strategy 2010-2015 (2010-06-10 Dnr D11-2009/873) Gotland University has one goal for cooperation and interaction with the society.

Objective: High-quality research at the university should have noticeable effects outside the University

- The university will develop productive research collaborations with government agencies, associations and industry

- The university will contribute to knowledge transfer and long-term sustainable development regionally, nationally and internationally.

Goals

We did not find any connection between the goals and the vision. This could be due to the fact that the vision is rather new (February 2011). More worrisome is the indication we have found that almost none of the goals comply with the criteria for SMART. The goals in the investigated plans were mostly described as directions and improvements with no specified goals or measurements.

Identification of potential for HGo to participate in the work with Vision 2025

Education and research

The University of Gotland has several fields where education and research are carried out. A matrix is prepared comparing currently taught topics in Gotland University with five areas of importance for regional development, see Table II. The Triple Bottom Line logic has been used to identify Economy, Environment and Health and Care (Social) as being important and covering the main processes in Figure 6. Additionally management has been identified as a key area. The strength of the connection between the University topics and the identified core areas are rated from 1 to 5 with 1 as a weak connection and 5 as a strong connection. The rating has been done by the authors. The rating indicates the potential strength of the connection, not the actual situation. However, current activity has partly influenced the rating in practically indicating what is possible. For example training of Health and Care management in leadership by quality technology clearly demonstrates the possible strong connection.

Table II. Gotland University topics and an assessment of their connection to areas important for the regional development.

	Economy	Management	Health and Care	Education	Environment
Archaeology & Osteology			1		
Biology	1			2	5
Building Conservation	1		1	1	3
Cross-Cultural communication		2	2	1	1
Energy technology	4			3	5
English				1	
Etnology		1	1	1	
Business Administration	5	4	2	3	3
Geography	1			1	2
Geo science				1	4
History		1	1	1	
Law		3		1	2
Art history			1	1	

Quality technology	3	4	3	3	4
Teacher training		1		5	1
Mathematics	2		1	2	1
National economy	4	2	1		4
Software engineering			1	1	1
Renaissance studies					
Social geography	1		1	1	4
Game development	1		1	1	

The conclusion we can draw from the matrix is that Quality technology and Business Administration are the fields with the strongest connection to the core areas identified for regional development. The same relevance is assessed to exist with the goals and work with Vision 2025.

A summary of the result from the perspective of the overall goals for the Vision 2025:

- At least 65 000 residents living on Gotland
 - This is not really a pure vision, but the strategy that the region has chosen for achieving the vision. The unspoken assumption is that with more people there will be more tax money to pay for the public administration. This means that actually what is looked for is a higher earning potential. A direct link to the existing education and research fields could not be found.
- Gotland prosperity among the best in the country
 - Business Administration has basic higher education that fits in well with what the organization needs to fulfil the vision. Quality Technology and Management has evaluation models and development models for Organization Excellence (USK, MBNQA, EFQM)
- Gotland is the natural place for rendezvous in the Baltic Sea Region
 - This is not really a pure vision, but the strategy that the region has chosen for achieving the vision. A direct link to the existing education and research fields could not be found.
- Gotland has a population with good health who experiences the highest wellbeing in the country
 - Developments in health are clearly linked to the development of activities in service and the service sector. Lean in healthcare is the most obvious link for this. Quality Technology has higher education that fits in well with what the organization needs to fulfil the vision
- Gotland is a world leading island-region of environmental and energy issues
 - Environmental and climate issues are represented in several courses at HGO. Wind Power and Biology are among the topics that fit in well with what the organization needs to fulfil the vision. SWEDES and Quality Technology can provide good support in sustainable development, environmental management and monitoring and evaluation systems.

Research and knowledge transfer

The university has good facilities to perform research. The support from the combined university and regional library is good. The university should have a good possibility to encourage students to do their thesis work with issues relating to Vision 2025. We have not been able to find any examples of work that systematically builds on these connections, neither in Gotland University nor in the region. There probably are examples but the indication is that much remains to be done on the system level.

Conclusion

Using basic quality management practice and the process view enables to describe the region as a system based process. A review of the main elements of mission, vision, goals, strategies, critical success factors, key processes and metrics reveals that a good part of the basic elements cannot be found in planning documents. The objectives defined in Vision 2025 have not been translated in the SMART goals and there seems to be no systematically follow up. Provided interest the vision work structure could be considerable strengthened using quality management practice and using a cooperation model based on TQM. The conclusion is that for a region the present state, the visionary state and the chosen change strategies could be visualised more clearly using process models and quality management elements.

The Gotland University mission is defined by the state. The vision partly focuses on regional work, but it is difficult to find any clear objectives for this and there is no identifiable strategy.

Even with the current scope of curricula there would be good opportunities for increased collaboration between the university and the region that could support regional development.

Discussion

Both the vision 2025 and the University of Gotland has identifies the potential in co-operation between the region and the University. In a few groups and areas the work has been started and is in progress but we have still a lot unexplored identified common fields to work in.

Assessment of Enterprise Quality and Export Performance: An Empirical Study on the Pharmaceutical Industry in IRAN

Siamack Afazeli. Tamin Pharmaceutical Investment Company

Alireza Sattari Dabaghi. Exir Pharmaceutical Company, Tehran, Iran

Hossein Dadfar. Linköping University, Department of Management and Engineering, Linköping, Sweden

Jens Dahlgaard. Linköping University, Department of Management and Engineering, Linköping, Sweden

Key words: Export performance, domestic performance, EFQM, EXPERF, ILL Index, Iranian Pharmaceutical industry

Introduction

Pharmaceutical industry is one of the most profitable businesses in the world. History of the science of pharmacy refers to the early stages of civilization, when humans were injured or were getting sick. Humans were looking for a remedy for pain and wanted to find a magical solution to remain young and powerful and get rid of death or postpone it. These wishes were the human's motivation to create the science of pharmacy. New pharmaceutical science began at the late 19th century when the knowledge of pharmacology emerged and helped human beings to invent new drugs. In the 20th century manufacturing of pharmaceuticals was changed, and different companies started to produce drugs in an industrial scale. By the middle of the 20th century, export activities have become important in globalization of the companies and the markets. The competition was especially intensified in pharmaceutical industry. Products became various and this variety led to segregation among producers and markets. Therefore for pharmaceutical products of a country, regional market became unfeasible considering the fact that mass production can create low cost advantage for manufacturers. Hence export became rapidly important and subsequently giant multinational pharmaceutical trusts appeared (Hasskarl & McGuire, 2007).

In Iran, most of the pharmaceutical companies are concerned with responding to local needs. Iran has not yet joined WTO (World trade organization) so local production enjoys government support on custom tariffs and capability to produce what is under patent protection in industrial countries. This situation has enabled companies to enjoy the advantage of economy of scope. At the same time branding of pharmaceuticals is not in an advanced structure like what is found in western countries. Iranian pharmaceutical companies are going to pass from total generic nomenclature of drugs to banded generic form. It means that few years ago all of the companies were producing their products under the same generic name and there were no distinction between the products of one company with other competitors regarding name and price. Nowadays, most of the companies have one or several specific brand names for some of their products. Actually, the Pharmaceutical industry in Iran has had several up-and-downs in its activities during the last century (Hasskarl & McGuire, 2007).

The main purpose of this study is to explore the relationship between export involvement and domestic market performance with a focus on pharmaceutical firms. The study embarks on answering the following three research questions:

Q1: How can export involvement/performance of Iranian pharmaceutical companies be assessed?

Q2: How can domestic performance of Iranian pharmaceutical companies be assessed?

Q3: How can the relationship between export involvement/performance and domestic market performance be examined?

In the course of the study different models of assessing export performance as well as domestic performance were evaluated. The selected models were used to analyse the relationship between export performance of pharmaceutical companies and their domestic performance.

Pharmaceutical industry in Iran

According to Porter's model, there are different factors influencing export success. Some of them can be summarized as firm strategy, organizational structure, readiness for competition, government law, decision and role, demand trend conditions, and supporting and related industries. In addition to these factors there is another important factor which we call "Element of Chance".

At the same time, most of Iranian companies need to develop their standards which require a lot of investment to survive in the local market. Ministry of health (MOH) put more strict regulation to improve the quality of production and products every year. Companies which are not able to fulfill the required GMP (Good Manufacturing Practice) cannot get a new product license and will face the consequences which are considered by the government's bylaws. Therefore, every company is thinking about improving the quality and overall performance both domestically and globally (Farzandi & Mostafavi, 2010).

Generally, the major current obstacles of Iranian pharmaceutical companies can be listed as follow:

- 1- Controlled price of pharmaceuticals: Ministry of health is the only source of pricing and companies cannot put their own calculated price on their own products. It does not let the companies to include the cost of R&D and promotion in the final price of their products so they cannot compete with foreign competitors in the local market.
- 2- Unpredictable market: Because of irrational drug consumption, it is very hard to estimate and forecast the market of pharmaceuticals in Iran. It prevents companies from precisely forecasting the market and long term planning.
- 3- Rate of inflation: rapid rate of inflation reduces the profitability of pharmaceutical companies year by year due to the fact that pharmaceutical companies have no control on the pricing of their own products.
- 4- GMP improvement: GMP improvement is an ongoing and never ending process which needs a lot of investment. Recruitment of specialized employees which get higher salary than normal employees is mandatory to fulfill the GMP requirements.
- 5- Market challenges: Problems in the sale resulting from over-production of pharmaceuticals by too many active companies in the market have caused tough competition for survival. Generic and branded generic policy of MOH has worsened the situation (because of lack of differentiation among products of different manufacturers). (Farzandi & Mostafavi, 2010).

Export Analysis destination of Iranian medicines

According to reports published by Iranian ministry of commerce and Iranian ministry of health, Iranian pharmaceutical companies have started to export their products to other countries. Export destination of Iranian pharmaceuticals is mainly the neighboring countries (including Commonwealth of Independent States -CIS-countries) and African countries. There are some records about export to European and Far East countries although the quantity and value is not considerable.

Most of the exported drugs go to Iraq and Afghanistan due to several reasons:

- 1- These markets are not regulated markets, and there is no need for time and money consuming procedures of registration of the companies and drugs in these two markets.
- 2- Iranian companies have several problems in translation of the product dossier and packaging. Normally, the technical dossier of the product must be translated into the official language of the importer country. For these two countries there is no need for any change in the outer package of the product and what is made for local market can be exported to these two countries.
- 3- Because of tight cultural and religious bounds among the people of Iran and these two countries, distribution channels of drugs in these countries are accessible and reliable for Iranian companies and merchants. Furthermore, people of these two countries believe in the quality and efficiency of Iranian drugs. These facts have facilitated the export procedure of Iranian pharmaceuticals to these two countries.
- 4- Iranian drugs are cheap so these products are affordable for people of these countries.
- 5- Because of political and security instability and existence of operational risks international competitors do not have active presence in the market of these two countries. (Shanesaz, 2010)

Iranian pharmaceutical companies select two approaches for exporting their products:

- 1- **Direct export:** In this way the manufacturer company directly goes to the target country and makes a direct connection with the distribution channels of the selected market. There are several examples for this type of export. Presence of Darou Pakhsh Company in the market of Russia by establishing an office in Moscow or direct export of Exir Company to Iraq, Afghanistan and Ukraine are some of the vivid examples. This type of export is mainly selected by big Iranian companies which can afford to invest on the export activities.
- 2- **Indirect export:** Most of small Iranian pharmaceutical companies which cannot afford to invest on the export markets have selected this method. In this method, there is a trader company which buys the pharmaceuticals from the manufacturers and sells them in the destination market. From some aspects, this method is favorable with the organizational structure of the small companies because export is specialized and complicated procedures which small companies cannot handle by their own. However, long term risk of ignorance about the market situation can damage the manufacturer companies. Most of these trader companies are owned and managed by people who have no information about the pharmaceutical sciences and even international marketing but have close relationship with the distribution channels and active parties in the destination market. This is another threatening factor for the companies relying on indirect export, that without enough knowledge

about the market and product and especially registration procedure, rapid change of regulations can destroy the export market. Almost all of Iranian pharmaceutical companies have exported their products in different extents. (Shanesaz, 2010)

Methods to measure export performance

Basic concepts of EXPERF model as an export performance system

EXPERF is a three dimensional scale first developed and applied to American and Japanese companies. The three dimensions are financial export performance, strategic export performance and satisfaction export performance measure (Zou, Taylor, & Osland, 1998). It is important to develop or use a generalized scale for measuring export performance. EXPERF is a generalized scale, which enjoys the following qualities:

1. It is measurable at the export venture level (that is the product market level);
2. It incorporates the major perspectives of export performance used in previous studies;
3. It is consistent with the existing export performance measures used by studies in different countries.

In the final questionnaire tested by Japanese and American firms, the following items were tested measuring export performance (all of these factors were weighted equally in overall export performance of the companies);

- Financial export performance
 - Export profits,
 - Export sales,
 - Export sales growth,
- Strategic export performance
 - Contribution of the export venture to firm's competitiveness,
 - Strategic position,
 - Market share,
- Satisfaction with the export venture
 - Perceived success of the venture,
 - Satisfaction with the venture,
 - Degree to which the venture meets expectations (Zou, Taylor, & Osland, 1998)

Summary of literature on export performance

The determinants of export performance are shown in the following list.

Independent variables of export performance:

- Export marketing strategy
 - Marketing research utilization
 - Export Planning
 - Export organization
 - Product adaptation
 - Product strength
 - Price adaptation
 - Price competitiveness
 - Price determination

- Promotion intensity
- Channel adaptation
- Channel relationship
- Channel type
- Management attitude and perceptions
 - Management export commitment
 - International orientation
 - Export motivation
 - Managements perceived export advantages
 - Managements perceived export barriers
- Management characteristics
 - Managers international experience
 - Mangers education and experience
- Firm characteristics and competencies
 - Firm's size
 - Firm's international competence
 - Firm technology
 - Firm characteristics
 - Firm capabilities and competencies
- Industry characteristics
 - Industry technological intensity
 - Industry instability
- Export market characteristics
 - Export market competitiveness
 - Export market attractiveness
 - Export market barriers
- Domestic market characteristics

Dependent variables of export performance:

- Sales
- Profit
- Export growth
- Success in export venture
- Satisfaction in export venture
- Export goals achieved (Shaoming & Simona, 1998)

This article proposes a three-dimensional scale for evaluating export performance of the enterprises (in the article it is referred to as export performance). The three dimensions are:

1. Satisfaction with short term performance improvement of the enterprise;
2. Short term export intensity improvement of the enterprise, and
3. Expected short term performance improvement.

Although the scale shows convergent, nomological validity, the excess of subjectivity factors in the scale raises questions about its overall reliability (Fillip Lages & Raquel Lages, 2003).

The success factors in marketing management in developing countries are described as below (Das, 1994):

- Nature of product
- Number of years being in business
- Past experience in exporting

- His foreign experience
- Overall nature of industry In the course of the article, critical success factors of the export activities were verified which are classified in three levels as following:
- Export marketing policy
 - Market research
 - Planning and control intensity
 - Internalization of marketing functions
 - Marketing policy adaptation
 - Product strength
 - Price competitiveness
 - Communication intensity
 - Channels support
- Firm characteristics
 - General firm resources
 - Export experience
 - Top management support
 - Internal export organization status
 - Content of product technology and knowledge wise
- Market characteristics
 - Attractiveness of export market
 - Number of trade barriers
 - Distance to export market
 - Cultural distance to export market
 - Domestic market attractiveness (Madsen, 1988)

Methods to Measure Domestic Performance

Dahlgaard & Dahlgaard Park's ILL index

Dahlgaard & Dahlgaard Park's ILL index has been used as an enhancement to the EFQM model. Below is a brief insight into the nature and application of the Dahlgaard & Dahlgaard Park's ILL index.

Respondents are asked to assess the importance and agreement on different Key Performance Indicators (KPI) related to the 5 enabler criteria and 4 results criteria of the EFQM models. Each KPI is formulated as a statement which respondents assess on two dimensions – agreement and performance. The agreement and importance of each statement is determined on a 7-point Likert scale, and Dahlgaard & Dahlgaard Park's ILL index is calculated as average agreement divided by average importance for each enabler and results criteria of the model.

The most important statement areas are where there are the biggest gaps between importance and agreement. The gap concept implies that the optimal situation is characterized by equality between importance and agreement (Dahlgaard & Dahlgaard Park, 2010).

The underlying assumption is an over-simplification of the improvement cost issue. Some improvements are *easy to pick fruits* but other fruits are more difficult to pick. So the assumption should be questioned when prioritizing the potential improvement areas.

If importance is significantly higher than agreement in a certain area, the area should be prioritized. In case the agreement is higher than the importance, fewer resources should be dedicated to the improvement of that area. In other words, the improvement area should be less prioritized. But it should be remembered that reasons of giving less importance to some improvement areas should be discussed to avoid ignoring important points, and when calculating the ILL index, areas where agreement is higher than importance should not be included (Dahlgaard & Dahlgaard Park, 2010).

Dahlgaard & Dahlgaard Park's ILL index can be used as an overall index, which can be compared from time to time. When the ILL index moves toward 1 it is an indication that the organization is becoming healthier. It means that the importance and agreement on all questions are converging and the organization is improving. Therefore, it is indicative of enterprise performance. The questionnaire in Appendix B was designed to measure domestic performance of the enterprises

Summary of literature review on domestic enterprise performance

Marketing performance of the companies affects their domestic performance. Also frequency of reporting and size of marketing budget can act as a mediating factor in this relationship. Marketing capabilities not only affect the domestic performance of the enterprise but affect its export performance, as well. Senior management should pay more attention to enhancement of the marketing capabilities (O'Sullivan, AnderewV, & Hutchinson, 2008).

Benchmarking of enterprise performance for extended enterprises is the source of concern for many academicians. K.W. Lai (2010) suggests 16 performance measures in the 8 categories shown below:

- Management
- Supplier
- Customer
- Employee
- Operation
- Technology
- Environmental
- Financial

Applicability of different performance measurement models in extended enterprises is very important, not all performance measurement models are compatible with extended enterprises. The main conflict exists between intra and inter-organizational measures. The article was important in providing insight into ways to measure performance of enterprise (Lehtinen, 2009).

Models of measuring the performance of SMEs suffer from certain fallacies. These fallacies result from lack of formal performance management tools. They are reflected in inability of managers and owners to produce accurate financial and situation reports. The article proposes the use of "enriched DuPont model" specific for SMEs (Brulhart, Gherra, & Rousselot, 2010).

Performance management systems emphasize the use of non-financial measures along with financial measures to view performance of the organization. Contextual factors

such as business size, industry and market position act as mediating factor in performance measurement of the enterprises. Also personnel knowledge of the management tools affects the choice of measurement tools such as BSC.

Research Methodology and Results

Qualitative as well as quantitative approaches were used when measuring export performance of the pharmaceutical companies and relating it to the domestic performance of. In order to achieve a true representation of Iranian pharmaceutical industry, the companies went through a clustering process and the centroids of the clusters were used for verification of the relationship.

Pharmaceutical company clusters and Company ILL Assessments

The clustering method used in this project was K-Mean (Kanungo, Netanyahu, & Wu, 2002). After running the clustering algorithm (MATLAB software) six clusters emerged.

Ideas of an *expert panel* were utilized in the course of the research; the expert panel was composed of the following people;

- 2 CEO's of pharmaceutical companies having extensive experience of corporate level management
- 2 Export managers of companies having extensive experience of exporting Iranian pharmaceutical
- 1 senior official expert in regulatory affairs of Iranian ministry of health
- 1 senior EFQM model expert who had extensive experience of evaluating Iranian pharmaceutical companies

The expert panel advised us to concentrate on pharmaceutical companies that already had applied for EFQM evaluation and had finalized their declaration documents for self-assessment. Therefore, a questionnaire based on the EFQM model was designed (Appendix A). The questionnaires were filled out by the target groups suggested by the expert panel in each company. According to the guidance provided by the expert panel, the questionnaires were filled out collectively by the group members. Once the data were gathered, they were checked by the expert panel members for its "truthfulness". Questionnaires with "incorrect answers" were returned to the companies for correction together with comments of the expert panel, and the questionnaires were only accepted when a true and fair reflection of firm's domestic performance was achieved. The ILL index was calculated for all 90 companies, and the companies were clustered by using the ILL indices based upon the data collected through the questionnaires. The clustering created a clear map of the 90 pharmaceutical companies. Centroids of clusters were selected to see if the export performances of the centroids affect their domestic performances and vice versa.

Then a questionnaire based on the EXPERF model was designed (Appendix B). The questionnaire measuring export performance was sent to the chosen centroids. The questionnaires were filled out by the groups of people suggested by the expert panel, and according to the guidance provided by the expert panel; the questionnaires were filled out by group members collectively. Once the data were gathered, the data of the companies were checked for truthfulness by the expert panel members. The

questionnaires with “incorrect answers” were returned for correction to the companies with comments of the expert panel, until true and fair reflections of the firm’s domestic performance were achieved. The gathered data were cross-checked with export data published by Iranian ministry of commerce.

Clusters

Some brief information on clusters emerged from study.

Cluster 1

There are 17 companies in the cluster. Most of the companies in this cluster are private and some of them were subsidiaries of multinational companies before the Islamic revolution. They are risk averse. Most of them have problem with their GMP compliance. Some biopharmaceutical manufacturers are included in this cluster whose operation and sales is a bit far from picking up. The companies do not benefit from international alliances. The number of new products they offer to markets is limited. This cluster can be named *cluster of traditionalists*.

Cluster 2

There are 6 companies in this cluster. Most of the companies in this cluster are semi governmental. Some of the companies are cooperating on an international scale with foreign companies. Their portfolio of products is limited. This cluster can be named *limited portfolio*.

Cluster 3

There are 13 companies in this cluster. Most of the companies in the cluster have outsourced their production to other companies, and they seek to fill empty production capacity of other manufacturers. Most of them are at the beginning of their operation and are not properly established. Usually they are small in size. This cluster can be named *outsourcers*.

Cluster 4

There are 33 companies in this cluster. Similar to cluster three, companies placed in this cluster are outsourcing their production to other manufacturers. They are small in size. Some of the companies in this cluster are producing herbal products. This cluster can be named *small outsourcers*.

Cluster 5

There are 13 companies in this cluster. Most of the companies in this cluster are small to medium sized companies. They are either private or governmental. They do not have any international cooperation experience, and they mainly focus on local Iranian market. The cluster can be called *domestic focus*.

Cluster 6

There are 9 companies in this cluster. The companies are main dominators of the mentioned export markets and they are governmental owned. There is strong intention among them to cooperate with international reputable companies. All of them are enjoying rich augmented product portfolio. They can be called *governmental exporters*.

Results

EXPERF related variables were measured for the cluster centroids by using the questionnaire data. All EXPERF related variables were weighted equally in contributing to the companies' export performance. Then overall ILL index of all 90 companies were calculated, and the centroids of each cluster were chosen to figure out if there is a linear relationship between export performance and domestic performance (measured with ILL index). The below figures 1 and 2 provide an overview of Export performance and ILL indexes of centroids of the clusters.

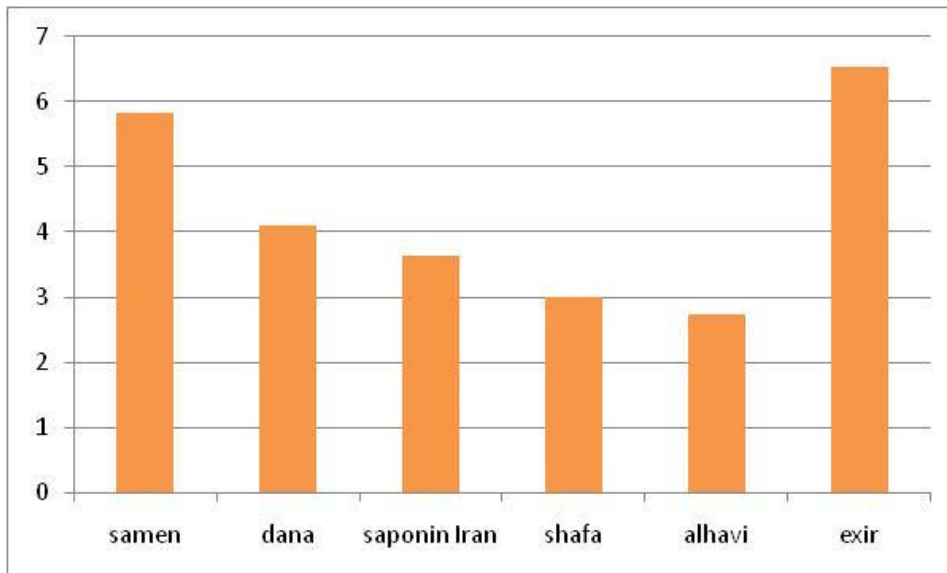

Figure 1: Export performance of the centroids

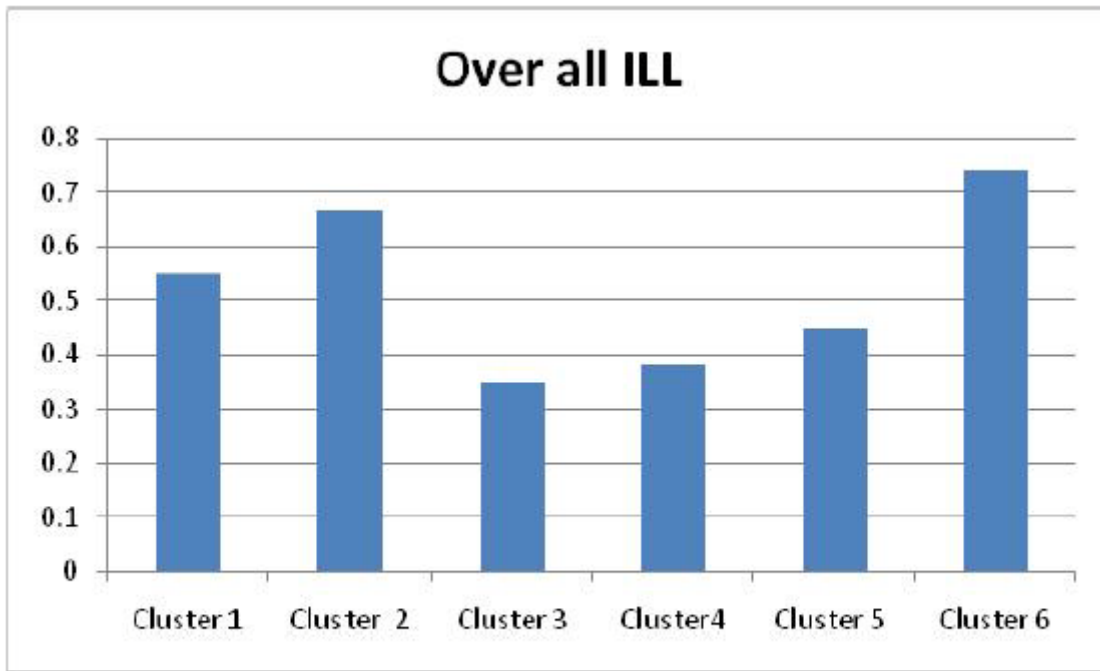

Figure 2 - Overall ILL indices of each cluster

The result of the statistical test are seen in the table 1 below (taken from SPSS software output).

Table 1: Correlations between Domestic and Export Performances

	E5	D7
Export Performance Pearson Correlation	1	.601*
Sig. (2-tailed)		.033
N	6	6
Domestic Performance Pearson Correlation	.601*	1
Sig. (2-tailed)	.033	
N	6	6

Based on the Pearson correlation coefficient ($r = 0.601$; Significance = 0.033) we conclude that for the six companies (the centroids) there is a significant positive linear relation between their domestic and export performance, which means that better domestic performance will result in better export performance and vice versa.

Discussion

The research questions outlined in the course of study were the following:

Q1: How can the export involvement/performance of the Iranian pharmaceutical companies be assessed?

Q2: How can domestic performance of Iranian pharmaceutical companies be assessed?
Q3: How can the relationship between export involvement/performance and domestic market performance be examined?

For measurement of the companies' export performance (Q1) the EXPERF model was used as the analytical framework. A questionnaire approach (Appendix A) was used to collect data from all 90 pharmaceutical companies.

For measurement of the companies' domestic performance (Q2), the EFQM model and Dahlgaard & Dahlgaard-Park's ILL indices were used. The results of the analyses together with the expert panel's view confirm that the EFQM model together with Dahlgaard & Dahlgaard-Park's ILL index constitute a proper framework for evaluation of domestic performance of the pharmaceutical companies.

After clustering the 90 Iranian pharmaceutical companies, Pearson's correlation coefficient was used to measure the strength of relationship (Q3) between export performance and domestic performance. The analysis showed that the two performance measures are positively and strongly related to each other. The export performance (involvement) of Iranian pharmaceutical companies positively affects their domestic performance and vice versa. The presentation will further try to elaborate on understanding the potential and most important cause-effect relations.

Appendix A

Dear participant;

The questionnaire below is designed to measure export performance of your company please kindly answer each question based the exact information. The information gathered by this questionnaire will be use for only scientific purposes, k= 1000\$ M=1000,000\$”

<i>Financial export performance</i>	1	2	3	4	5	6	7
F1 - How much is your export profit?	1-5%	5-10%	10-15%	15-20%	20-25%	25-30%	30-35%
F2 - How much is your export sales?	100k-500k	500k-1m	1m-5m	5m-10m	10m-20m	20m-25m	25m-Over
F3- How much is your annual export sales growth?	0 – 5%	5 – 10%	10-15%	15-20%	20-25%	25-30%	Over 30%
<i>Strategic export performance</i>							
S1 - How much export venture	Not						Very

contributes to competitiveness of the company?	at all									much
S2- How good is your strategic position in intended markets?	Very bad									Very good
S3 - How much is your markets share in intended target markets?	0-1%	1-2%	2-3%	3-4%	4-5%	5-6%				Over 6%

Satisfaction with the export venture

SE1 – How successful does your venture look?	Not at all									Very much
SE2 – How Satisfied are your customers with your venture?	Not at all									Very much
SE3 – To what degree your venture is meeting overall expectations?	Not at all									Very much

Appendix B

Dear participants;

The questionnaire below is designed to measure the Excellence Level of your company. Please kindly answer each statement based on the group's personal experiences. Please evaluate both Agreement and Importance of each statement on a 7-point scale. The information gathered through this questionnaire is only used for scientific purposes. No commercial goal is pursued in the course of the project."

Leadership - L		<i>Importance</i>							<i>Agreement</i>								
Statements (later translated into English)		Very unimportant	2	3	4	5	6	7	Very important	Completely disagree	2	3	4	5	6	7	Completely Agree
L1 - Organization has interaction with all customers		1	2	3	4	5	6	7		1	2	3	4	5	6	7	
L2 -Organization not only enforces culture of excellence but also it is culture of excellence's role model		1	2	3	4	5	6	7		1	2	3	4	5	6	7	
L3- Organization have individual involvement in assuring continuous improvement of management systems		1	2	3	4	5	6	7		1	2	3	4	5	6	7	
Policy and Strategy - PS		<i>Importance</i>							<i>Agreement</i>								
		Very unimportant	2	3	4	5	6	7	Very important	Completely disagree	2	3	4	5	6	7	Completely Agree

Introduction

In 1987, the International Organization for Standardization (ISO) published the first version of the ISO 9000 family of standards. Subsequently, in 1994, 2000 and 2008 updated the standard with new versions. The original 1987 version introduced some standards, applicable to the type of organization, while in the later revisions are intended to simplify and make it easier to apply, content focusing on continuous improvement and process management. ISO standards list the requirements to be followed by an organization to certify its quality management system (QMS), establishing a customer-oriented corporate culture and defining a management model aimed at meeting the needs and expectations of customers. We analyze what's the current situation in order to make a diagnostic. Initially, data from the world (International Standard Organization, 2010), reviewed the developments from 2004 to 2009, latest available year. According to the ISO survey conducted annually, the spread of global standard has increased (Table I), an increase in the total of certifications and the number of countries.

ISO 9000 \ year	2004	2005	2006	2007	2008	2009
world certificates	660.132	773.867	896.929	951.486	982.832	1.064.785
annual increase %	33%	17%	16%	6%	3%	8%
number of countries	154	161	170	175	176	178

Table I. ISO 9000 certified worldwide in 2004-2009. Source (International Standard Organization, 2010)

It can be seen as the growth rate of global certifications decreases from 2006 to 2008 and in 2009 was recovered. This rise was achieved despite the existence of these factors tend to reduce the total of ISO 9001: (i) the overall economic growth and (ii) the tendency of organizations to replace multi-site certificates a certificate covering all sites. This article analyzes the evolution of the ISO 9000 certification in recent years, trying to look for causes of the phenomenon of decertification. The phenomenon of decertification is not homogeneous geographical or sector level. In some countries a clear decertification is detected, while in other areas of growth is observed. Overall all indications are that the rate of growth in certifications will remain positive but lower rates than in the past.

The analysis focuses in Europe, the total number increases slightly, from a total of 455,332 in 2008 to 500,319 in 2009, which means an increase of 9.8%. The data analyzed again by countries and comparing the evolution of the last two years can be separated into two groups. One group, which is still in a growth phase with significant increases and a second group phase of decline (Table II).

Increase	Decreases
Russia (+230%)	Belgium (-19%)
Romania (+47%)	Greece (-25%),
Ukraine (+33%)	Slovenia & Spain (-13%)
Czech Republic (+39%)	The Netherlands (-10%)
Croatia (+21%)	Germany (-2,5%)
	France (-3.3%).

Table II. Countries with the highest increase and decrease in number of ISO9000 certificates between 2008 and 2009 in Europe. Source (International Standard Organization, 2010)

Globally, in 2008 there were 33,338 decertifications, while in 2009 a total of 110,791. It is another symptom, which represents an increase of 232% in relative terms, while the increase between 2007 and 2008 was 1.5%.

ISO 14000, is an internationally accepted standard that says how to establish an effective environmental Management System (EMS). According to the latest data published by the same ISO, the number of ISO 14000 certification worldwide at the end of 2009 was 188,815 (International Standard Organization, 2010). There is no doubt that the growth is spectacular, considering that just 10 years ago, the number of certifications worldwide was 7,887 (ISO, 1998).

ISO 14000 \ year	2004	2005	2006	2007	2008	2009
world certificates	90.554	111.163	128.211	154.572	188.815	223.149
annual increase %	39%	23%	15%	21%	22%	18%
number of countries	127	138	140	148	155	159

Table III. ISO 14000 certified worldwide in 2004-2009. (International Standard Organization, 2010)

The analysis focuses in Europe, the total number increases slightly, from a total of 78,118 in 2008 to 89,237 in 2009, which means an increase of 14.2%. The data analyzed again by countries and comparing the evolution of the last two years can be separated into two groups. One group, which is still in a growth phase with significant increases and a second group phase of decline (Table IV).

Increase	Decreases
Russia (+108%)	Slovenia (-12%)
Romania & Bulgaria (+76%)	Hungary (-9,5%),
Serbia (+69%)	Sweden(-6,3%)
Cyprus (+59%)	Poland (-2,9%)
Bosnia & Czech Republic (+40%)	
Croatia & France (+35%)	

Table IV. Countries with the highest increase and decrease in number of ISO14000 certificates between 2008 and 2009 in Europe. (International Standard Organization, 2010)

As a difference between table IV and II, there aren't as decreases in ISO 14000 as ISO 9000, it probably means that in this case still is in increase process. The doubt appear during the process we analyze the numbers of withdraws between 2008, 4,324 withdraws and in 2009, 22,607.

At the European level has been extended another management model, also entirely voluntary for organizations: EMAS (Eco-Management and Audit Scheme, or Community Regulation of Eco-Management and Audit-scheme). It is a more demanding than ISO 14000 in terms of content, but also voluntary. Indeed, EMAS is a voluntary regulation of the European Union recognizes organizations that have implemented an EMS and have acquired a commitment to continuous improvement, verified by independent audits. The EMAS recognized organizations-whether industrial companies, small and medium businesses, nonprofit organizations, government and international organizations, have a defined environmental policy, make use of environmental management systems and report periodically the operation of the system through an environmental statement verified by independent bodies. At European level, the number of certified organizations in 2010 was 4,460, located mostly in Germany, Italy and Spain.

The pressure created to preserve the environment has grown and has led to the SGMAS' proliferation and diffusion of these. Anyway, it begins to sense that in some sectors is slowing growth. Even in some countries there is a clear slowdown in the number of certifications (Casadesús, M. et al 2003),(Casadesús, M. et al 2005), (Marimon, F., et al 2006) It is good time to analyze what happens to these EMS based on ISO 14000. What are the causes for this reduction? Why are some companies that have made the effort to get certified in the past does not renew the certification? Which is the cost of continuing certification? Obviously, the reason why organizations decide not to renew the certification is because the costs associated with keeping outweigh the benefits they find.

Organizations are seeking through policies, procedures and tools make it possible to manage effectively and efficiently to achieve quality objectives. Among other areas that have a company to achieve this commitment to quality is the quality assurance which engages the whole organization. Therefore, the organization, planning and control of all activities and functions aimed at obtaining a quality according to predetermined requirements. To keep control of quality management according to quality assurance will be necessary to introduce a Quality Management System (QMS). Among the management systems for quality assurance system with more global acceptance is one that is based on ISO 9000. The ISO 9000 standards are a set of international standards are intended for the management and quality assurance companies.

Something similar has happened in the ISO 9000 evolution. It is a previously published standard ISO 14000 and has been successfully disseminated. According to ISO survey of certifications 2009, at the end of the year, there were 1,064,785 ISO 9000 certified worldwide. Meanwhile, ISO 14000 with 223,149 is five times more certifications. However, there are clear signs of decay in the rate of diffusion of this standard. In some countries, detects a clear setback: Companies are being descertified. In any case, other countries in which the number of certificates continues to grow and make notice that the world level increase growth. The literature has studied the recession that is taking place in this standard (Albuquerque, et al, 2007), (Casadesús, M. et al 2005), (Casadesús, M.

et al 2005c), (Franceschini, F., et al 2010), (International Standard Organization, 2010), (Stanislav K. et al 2010). Precisely this literature can show light to provide a possible similar behavior in spreading the ISO 14000 standard. There are no studies to determine reasons for decertification, (Marimon, F., et al 2009) claim that the main reasons for the decertification organizations for the standard ISO 9001 is the excessive paperwork generated and do not survive the process of re-certification. These are also possible reasons for the hypothetical recession in ISO 14000.

Figure 1, shows the comparative evolution of both standards worldwide. In the figure, both series have been scaled according to the maximum saturation level expected using the logistic curve as a yardstick to predict the future trend. The previous literature on the diffusion of these standards confirms that the logistic curve well describes this phenomenon. The figure shows that although ISO 14000 is more recent, in 2009 both reached the same level on their respective saturations. This makes ISO 14000 is at this time a growth rates higher.

Figure 1 - Evolution compared to both standards and its projected trend to 2014.

ISO 9000 and 14000 CERTIFICATION IN PULP AND PAPER INDUSTRY

Dominant nature paper's industry activity is one of the most impacts on the environment. It is well known to all agents involved and each one has its own role to regulate these impacts. On one hand, governments and state or local authorities and in some cases others are supranational regulations to mitigate the potential harmful effects on the environment. These regulations are mandatory in some cases and in others are only recommendatory. Companies themselves are also developing their own strategies in this field. In general, society and in particular direct customers are also sensitive to environmental performance of their suppliers. Indeed, from different scopes is influencing paper companies. From a more general level, the Kyoto agreement marks required emission limits to be met by countries and enterprises (Lansbergen, P. 2004). Also at the international level, ISO (International Standards Organization) released its first version of an environmental management system (EMS) in the early 80s. This rule has been updated over time and currently valid ISO 14001:2005 version. No doubt that

is one of the standards that have enjoyed growing popularity and success has spread throughout the world (Marimon, F., et al 2009).

The dissemination of the EMS, as well as dissemination of management systems for quality (QMS) has been analyzed in depth, both from the point of view of the explanatory diffusion's causes (Marimon, F., et al 2009) and from the dynamic point of view (Ruihua Joy J., 2003). Anyway, all these items are analyzed aggregate data by country, but there are still few studies focusing on the analysis of a sector industry. Data are available about the certification of ISO 14000 by sector since 1998, by the reports published annually by ISO. In fact, since that year, includes a section in which the certifications are structured in both ISO 14000 and ISO 9000 in 39 sectors. One of them is the paper: "Pulp, paper and paper products."

Figure 2, shows the development of paper industry certifications. Adjustment explains a large percentage of the variance ($R^2 = 0.925$) and the two coefficients are robust at the level of significance 0.05. The series shows an annual growth of 133 certificates, representing high growth rates. In fact, between 2001 and 2006 there was an average annual growth of 16.31%. The first two years and the last two are more irregular. In any case, there is a strong growth rate. There is no doubt that the standard has a strong acceptance in the sector.

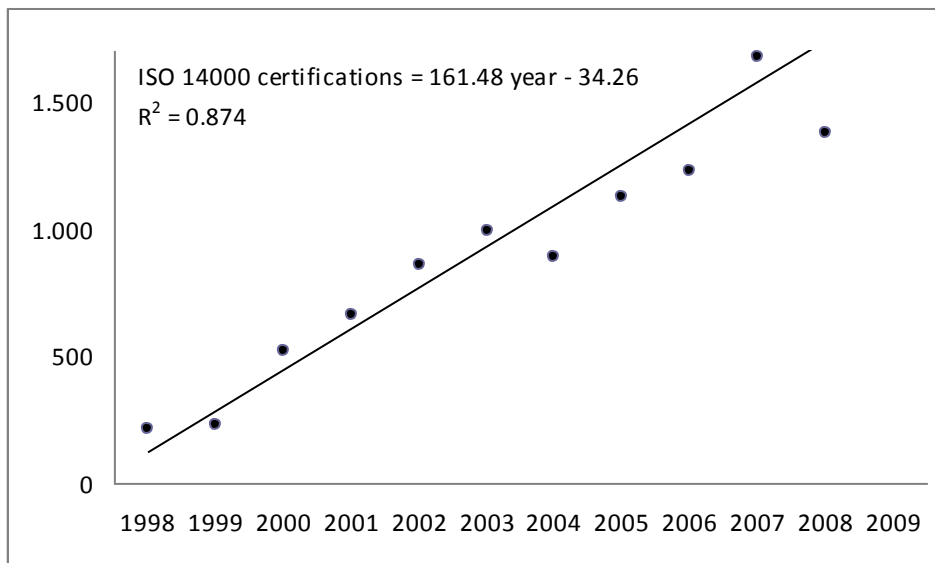

Figure 2- Linear regression ISO 14000 certification in the paper sector

Enclosed is a similar graph (Figure 3) shows the evolution of ISO 9000 certifications in the same period. It also notes that the first two years and the last two show a somewhat different pattern to the years from 2000 or 2006. During these middle years, the linear regression fits perfectly. The number of new annual certification of 235 (one hundred more than in the standard ISO 14000), however a relative level represents an average annual growth of 4.46% between 2001 and 2006.

Figure 3- Linear regression of ISO 9000 in the paper sector

Another interesting aspect to analyze is the sector evolution's ranking within the list of 39 sectors in the ISO annual report. Figure 4, shows this evolution for the two standards: ISO 14000 and ISO 9000 certifications ranking of pulp and paper sector.

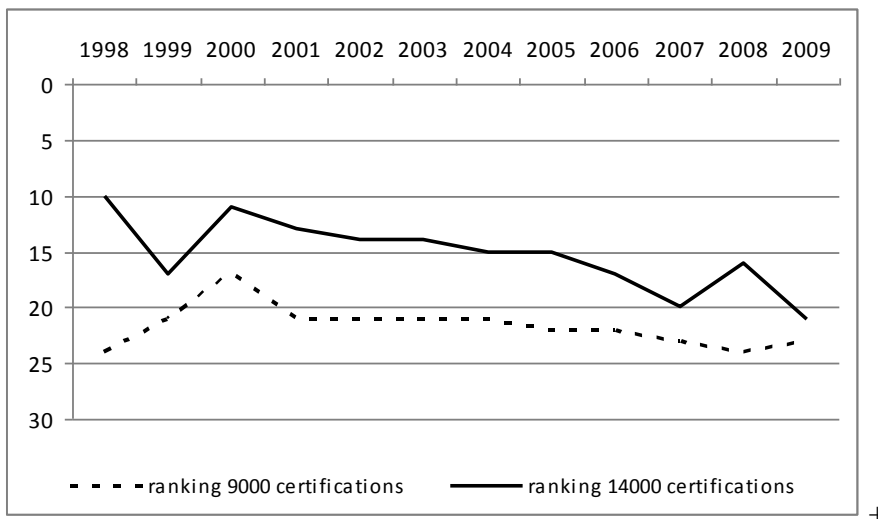

Figure 4 – Pulp & paper industry's ranking certifications by sector (in ISO 14000 and ISO 9000)

It is notice, that the sector has always been on the half top of ISO 14000 rankings (the contribution of this sector in the GDP (gross domestic product) of each country would provide a lower position in the ranking of ISO 14000). It is also noted that the position referred to the ISO 14000 certification has always been higher than ISO 9000. Indeed, the sensitivity for the environment sector has always been above their concern to maintain certifications in the field of quality management. Another phenomenon observed is a slight gradual decline in both rankings. This makes us wonder if there really is a widespread disinterest in the industry for this type (Philippe B., 2007) certification, especially the one in question in this work: the ISO 14000.

Figure 5 has a similar profile, show the percentage of the sector in total certifications. It is also noted that the share of the sector to analyze the ISO 14000 certification is always higher than the share of ISO 9000.

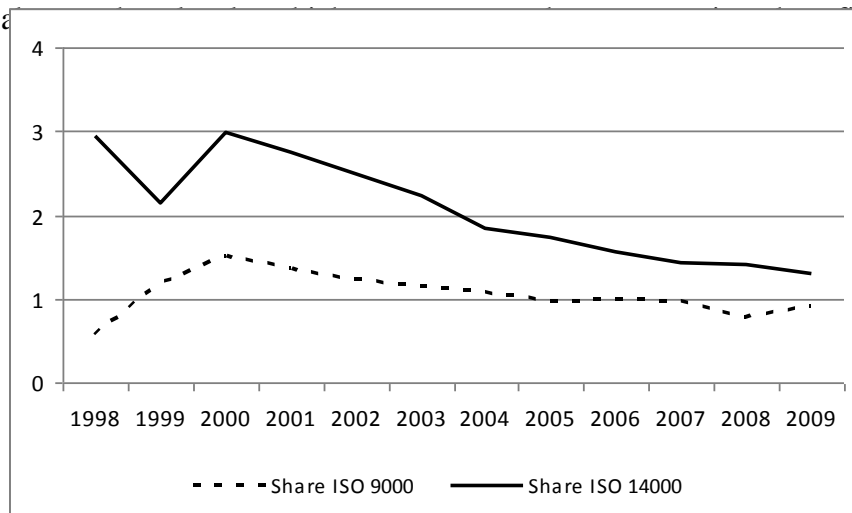

Figure 5 – Evolution of Pulp & paper industry certification's in percentage (ISO 14000 and ISO 9000)

Yet, another important aspect to be analyzed (Corbett, J.C. et al 2001) in parallel with the development of ISO 14000 certifications. As defined in the various ISO 14002,3,4,5,6 ... (Stanislav K. et al 2009), and the long journey that allows the standard itself.

FSC CERTIFICATION. In fact, new standards are emerging to ensure a good relationship between business and environmental organizations. One of the most important in this sector that is gaining strength over the past decade is the certifications from Forest Stewardship Council (FSC). FSC is an independent, non-Governmental, not-for-profit organization Established to promote the responsible management of the world's forests. Established in 1993 as a response to global Concerns over deforestation, FSC is widely regarded as one of the most important of the last decade Initiatives to promote responsible forest management worldwide. FSC is a certification system that provides internationally recognized standard-setting, trademark assurance and accreditation services to companies, organizations, and communities interested in responsible forestry.

The FSC label provides a credible link between responsible production and consumption of forest products, enabling consumers and businesses to make purchasing decisions that benefit people and the environment as well as providing ongoing business value. Over 16.000 certificates (March 2010), the number of companies along the forest product supply chain to FSC certification Committing Peaked at 50% in 2008 (FSC, 2010). The country that leads the ranking in this type of certification is the United States of America, 3,645 certifications, following the UK with 2,030 certifications, Germany 1,213 and China 1,142 certification. Then several countries under the 1000 certifications: Japan, Canada and Holland. In the Spanish sector, we have the breakdown by sector Table V, where, including the group of pulp and paper products along with printing, we've got 50% of this certificates are in pulp and paper industry.

PRODUCT	number	%
pulp and paper	49	26
comerce	1	1
printing	46	24
furniture, decoration, doors, windows	43	23
boards, panels	31	16
others	18	10
total	188	

Table V: FSC Spain certifications (2009). Source FSC Spain.

The paper sector is therefore a very important and is particularly interested in evidence to clients that they're an industry-friendly forestry. The analysis made in the previous section show that the paper industry is still active in the demand for new ISO 14000 and other standards which demonstrate an appropriate relationship with the environment. Superior sensitivity is perceived in this respect than the other sectors. Indeed, it appears that the industry's position in the ranking of ISO 14000 certifications has always been higher than the ranking of ISO 9000. Moreover it is observed that sector participation in the global certificates is decreasing in both types of certifications. It is noted therefore that a number of companies are certified and continues to grow the number of certifications, but at a slower pace than expected. This all leads to find the reasons for this imbalance occur in the evolution of certifications in both standards. Lot of printing customers of pulp a paper companies, consider that FSC certification is the highest available standard, if they are unable to use it in the short term they universally apply other standards to ensure that paper sourcing does not run contrary to environmental principles. The Program for the Endorsement of Forest Certification Schemes (PEFC) provides a framework for the mutual recognition of different national and regional certification schemes. It is their preference to use paper mills, printers and other suppliers who have gained or who have applied for EMS ISO 14001 accreditation. ISO 14001 is an internationally accepted standard that sets out effective Environmental Management Systems recognizing a commitment to effective management of waste, careful use of energy and ensuring recycling processes are in line with government standards.

Pulp and paper case

To investigate what will be the trend in 9000 and ISO 14000 certifications in the paper industry, an interview be conducted in depth to QMS and EMS responsible for in five companies of this sector.

The spread of SGC is a phenomenon that has been studied in depth (Marimon, F., et al 2009). Most studies work with aggregate data by country. There are still few studies focusing on the analysis of a sector of the industry. ISO provides data about the certification of ISO 9000 and ISO 14000 by sector since 1998 (International Standard Organization, 2010). In fact, since then, including a section in which the certificates are grouped in 39 industrial sectors for both ISO 14000 certification and ISO 9000. One of the sectors analyzed the role: "The pulp and paper products." To analyze the phenomenon of decertification we studied through interviews with companies in the role of nine companies, four large and five medium. Most companies interviewed were certified in late 90's and early 2000. According to interviews, the main impact of its implementation was the restructuring and management of the organization, thanks to the

incorporation of new procedures and tools, especially the improvement groups. On the other hand, was a major effort to obtain documentation of the certificate. The ISO 9000 compliance offers competitive advantages to companies that are not certified with respect to international markets.

The companies interviewed showed a clear desire to maintain the standard, but at this time do not appreciate that the rule gives the same intensity of competitive advantage offered in the early years. Maintaining certification because they do not behave a great exertion, they share a certain degree of integration with the ISO 14000 management standard. If in the future, the maintenance of the rule requiring a special effort, most likely abandon the certification.

Add some thoughts of different quality managers or managers of paper companies that allow us to set a trend for the future:

A-This company is certified under ISO 9001, while another in ISO 14001. The manager himself thought: "ISO 9000 certification was a fad in recent years and no benefit for my company. ISO 14000 on the other hand, provides improved image, improved competitiveness and facilitate better environmental management is also valued by the administration.

B- A company with close involvement of all staff. Is first certified under ISO 9000 and ISO 14000 later, prompting a major structural change and performance has ceased to be certified this year for the cessation of industrial activity.

C-In the company attaches great importance to ISO 14000. The quality manager commented "a few years ago, the ISO 9000 certification was requested by most countries and companies, while ISO 14000 does not, now the roles have been reversed."

D-The sector tends to be more environmentally friendly. According to the manager: "The reasons for the certification of quality were mainly commercial. The introduction helped to bring order, procedures, but it is too bureaucratic. The trend in our industry is to find the specialty through certification in environmental standards such as FSC, ... eco ...".

F-ISO 9000 certified company in 1998, something they helped a lot in his day. At present, does not provide a competitive advantage The key is differentiation, with greener products. The quality manager says: "... market demands force us to differentiate ourselves from competitors. This differentiation may come through the forest policy, respect the environment, etc ..."

These reflections show that companies see the ISO9000 as an advantage uncompetitive and unattractive. Interviewed companies place more importance on environmental standards such as ISO 14000 or the Eco-Management and Audit Scheme (EMAS). These allow certified companies in the chain of custody, understanding the process that permits monitoring and control of products throughout its supply chain transformation and Forest Stewardship Council (FSC).

FSC certification was born in early 90's to promote forest management and

environmentally responsible, socially beneficial and economically viable in the forests around the world, being supported by NGOs such as the World Wildlife Fund (WWF).

The recognition program certification Forest Certification System (PEFC) is a forest certification system was created in 1998 as an initiative of private forest. Another certificate on the rise and in order to differentiate the product or service, is the Carbon Neutral Certification, which certifies that the company manages the emissions of CO₂ to the atmosphere seeking compensation for carbon emissions. On the other hand, there are some laws on protection of forests promote forest certification systems, emphasizing the need to promote trade and responsible consumption.

Conclusions

We note that the rate of diffusion of ISO 9000 is in the process of slowing down. This is consistent with an increase in the number of decertifications. Some countries still in the process of industrialization can continue to enjoy a period of growth in certifications. Overall we are reaching saturation point described by various authors (Albuquerque, et al, 2007), (Casadesús, M. et al 2005a), (Casadesús, M. et al 2003), (Corbett, J.C. et al 2001), (Franceschini, F., et al 2010), (Marimon, F., et al 2009), (Marimon, F., et al 2006) (Stanislav K. et al 2010).

The main reason for maintaining the ISO 9000 certification by the companies interviewed is that there is great difficulty in maintaining it, except for your own cost and bureaucracy. Most companies concluded that it provides no added value and contributed about ten years ago, keep the certificate not to damage the image that would override it. Think of migrating towards an integration of standards and thus maintain the ISO 9000 with a small marginal effort.

Obviously, another reason that explains the decertification in 2009 is the cessation of activity of companies. Asking for reasons that will lead to decertification, the overwhelming response was: (i) no added value, (ii) bureaucratic effort required to update data and (iii) is not required by the market. The cost is not cause in these companies.

In the paper industry is estimated that in the future will demand more environmentally friendly certification (EMAS, FSC, PEFC, Carbon Neutral, etc ...) Moreover, the ISO 9000 certification will be integrated into an integrated management system standards.

Keywords: Mathematical model, ANN, Total Quality Management, Operational Flexibility, Hospital Performance.

Introduction and Literature Review

Quality has occupied a prominent place in the Japanese industries in the late twentieth century; which was affected by complex changes such as industrial change and marketing competition. These changes came as a result of political and economic variable and intensifying of economic competition in the local, regional and global developments. These changes were followed by the technological revolution in the fields of human knowledge, information systems technology and others. The significance of quality impacts such as the emergence of the phenomenon of the total quality management (TQM) in the early twentieth century was of great importance in achieving the goals of humanitarian organizations in the production and the service organizations.

This paper comprises of three parts aiming to provide four things: the first part is about TQM in health care services and its principles. The second part is about its operational flexibility. The third part is about the performance in hospitals, and the fourth is the artificial neural networks and results.

The literature of total quality management justifies the principles and methods that are the basis of the development of performance and productivity to its first pioneers such as (Deming), (Ishikawa), (Juran, (Crosby), and (Oakland). The method of total quality management is based on the ongoing performance philosophy and excellent production by that improve goods and services with higher abundance, at lower cost with the freedom from defects and imperfections "from the first time and every time," and customer satisfaction within and outside the organization. Total quality management (TQM) plays an important role in all health sectors. TQM is used to improve patients' satisfaction, reduce cost and reduce medical errors. In recent years, attention to TQM in the healthcare industry started to rise as a major concern to achieve the overall quality. TQM depends on continuous commitment in the organization to improve the operation of the organization. It also depends on the excellence of the highest level of management to the lowest level of employee; also raw materials supplier through the

supply chain to the end consumer. The requirements for the application of total quality management within the healthcare organizations depends on the organization manager to make some changes in the structure, process, system of work, and the employee for achieving the objectives of TQM. To impose all the principles of the program in all aspects of the health organization there must be a very strong commitment from the senior management (Smith and Offodile, 2008).

Artificial neural network

Basically, the artificial neural network (ANN) is numerical structures inspired by the learning process in the human brain. They are constructed and used as alternative mathematical tools to solve a diversity of problems in the fields of system identification, forecasting, pattern recognition, classification, financial systems and many others (Baker & Richards, 2002; Joaquim & Dente, 1997; Shaw et al., 1997). The interest in ANN as a mathematical modeling tool resulted in the consolidation of its theoretical background and the development of its underlying learning and optimization algorithms (Ang et al., 1998; Huang et al., 1993; 1997; Shaw et al., 1997). Modeling and simulation of chemical processes is one of those research areas of interest that made use of ANN modeling techniques but in education field the ANN is very rare in this field and represents the first time to be used. Neural network-based modeling can be used confidently as a substitute for such situations. This is due to the favorable features entailed in their use. Among these features are: simplicity, fault and noise tolerance, robustness and ability for modeling nonlinear systems. The ANNs can be categorized in terms of their topology such as the multi-layer feed forward networks (FFNN), feedback networks (FBNN), recurrent networks (RNN) and self-organized networks. In addition, they can be further categorized in terms of application, connection type and learning methods. FFNNs are the most commonly used type for function approximation. In this topology, the network is composed of one input layer, one output layer and a minimum of one hidden layer. The term feed forward describes the way in which the output of the FFNN is calculated from its input layer-by-layer throughout the network. In this case, the connections between network neurons do not form cycles. No matter how complex the network is, its building block utilizes a simple structure using the neurons. It performs a weighted sum of its inputs and calculates an output using certain predefined activation functions.

Sequential Quadratic Programming (SQP)

The SQP method allows us to mimic Newton's method for constrained optimization. At each iteration a method similar to Newton's method is used to generate a quadratic programming sub problem whose answer is used to determine a search direction for the solution as shown in Figure 2.

Neural Network Modeling of Education System

The data used for training the neural network model was generated from the non linear experimental work of the system as given in paragraph 2 for the newly developed improved mathematical model. Step tests data were generated in simulation for the model with change in input values for the leader ship, training, employee management, information and analysis, supplier management, process management, costumer focus, continuous improvement, internal flexibility and internal robustness as shown in Figures

1 to 4.

The input ranges for all inputs factors were formed (10-100). The selected ranges cover the whole spectrum of operating conditions including flooding conditions and outlet hospital performance. Data sets were divided into three subsets; training, validation and testing.

The neural network structure was selected based on testing different network configurations that vary in terms of structure and simulation parameters. The criterion for network structure selection is based on its simplicity, performance, and accuracy of model prediction. The finally selected network contains 1 hidden layer with 7 neurons. The activation function used in the hidden layer is the tanh function because it is more suitable for the highly non linear system, while the output layer contains linear neurons. The inputs and outputs to the network are as shown in Figure 2.

In Figure 3, shows comparison between actual and theoretical results.

So, we can specify the inputs as (leader ship(t,t-1,...,t-n+1)),training(t,t-1,...,t-n+1), employee management (t,t-1,...,t-n+1), information and analysis (t, t-1,...,t-n+1), supplier management (t, t-1,...,t-n+1), process management (t, t-1,...,t-n+1), customer focus(t, t-1,...,t-n+1) continuous improvement (t, t-1,...,t-n+1) internal flexibility(t, t-1,...,t-n+1), internal robustness (t, t-1,...,t-n+1)) and output hospital performance (t, t-1,...,t-m+1).The neural network predication shown in Figures 3 to 6 is for the training data set.

Simulation and Results

After collecting data from three hospitals in Jordan, which depends on hospitals leaders' perceptions by using convenient sample and a suitable questionnaire, using Likert scale from

Results are represented from Likert scale to percentage by using the following equation:

$$\text{Dimension percentage} = \frac{\text{Dimension Mean}}{7} \times 100\% \dots\dots\dots (A)$$

After that calculate the average (mean) for each item as can be seen in Table (1):

Table one display the result of our survey after we diverted from Likert scale to percentage through the previous formula, we did that to have all results suitable for mathematical model and artificial neural net work (ANN).

The neural network models obtained for training in the previous section were utilized in the model predictive schemes as described in Section 3.

Comparison of both modeled of network-predicted outputs with actual results are shown in the form of the error profiles in Figures 3 and 4. These Figures indicate low errors even under severe process excitations. Figures 3 and 4 are representing square error of training, comparison between actual and theoretical data, training performance and accuracy respectively for King Abdullah University hospital.

Conclusion

Advance mathematical model produced depends on the results of the first hospital King Abdullah University Hospital (KAUH). To reach high accuracy, more than 99% for the first time Artificial Neural Network technique is being used in the education field. This is because this technique was derived from human behavior that is similar to my system. And it also depends on the answer of human beings that allows the model to have a high accuracy of more than 99%.

The comparison results from the modified model and actual data for three samples which gave a very good indication about the accuracy of this model.

From the results above and after verifying the mathematical model, we can say that there is a need to make system identification definition. This is in order reach to the interaction between each inputs variables and output variable performance. Work is going to be done to improve these relations.

After that we can determine the weakness point which affect on hospital performance and improve it. This will lead to decrease the cost of performance improvement, and deliver medical services with high quality and safety.

Introduction

Last decade has changed radically the market conditions regarding travelling industry. Price competition, emerging tourist destinations, globalisation, a range of volatile political, economic, and technological factors; a greater environmental awareness, a growing concern about climate change and changes in consumer habits are main characteristics of this named *new market* (Macleod, 2004; Nicholls, 2004; Hall & Higham, 2005).

As a consequence of these developments, businesses in the tourism sector have recognised the need to adopt quality strategies (Casadesus et al. 2010). There has been a proliferation of standardised management systems in accordance with various national and international standards in recent years. These standards attempt to systematise various business functions, including: (i) quality management (e.g., ISO standards 9001:2008, ISO TS 16949:2009, ISO 10002:2004 among others); (ii) environmental management (e.g., ISO standards 14001:2004, EMAS III, ISO 50001 for energy management); (iii) workplace safety (e.g., OSHAS 18001:2007, PEOPLE), and (iv) ethical issues (eg., SA 8000, AA 1000, Global Reporting Initiative). All of these standards have a certain methodology, structure, implementation process, and testing procedure by a third party (Casadesus et al., 2010). In particular, two prominent families of standards issued by the International Standardization Organisation have become widely diffused in a variety of industries: (i) standards related to Quality Management Systems (QMSs) such as the ISO 9000 family of standards, and (ii) standards related to environmental management systems (EMSs), such as the ISO 14000 family of standards (Marimon et al., 2006).

According to the latest ISO Survey (ISO, 2010), up to the end of December 2009 there had been 1,064,785 ISO 9001 certificates issued to organisations in 178 countries, and 223,149 ISO 14001 registrations in 159 countries. Due to worldwide adoption, previous research has focused on these standards diffusion (eg., Franceschini et al., 2004; Marimon et al., 2006; Marimon et al., 2008; Casadesus et al., 2008; Marimon et al., 2010; Llach et al., 2011).

Moreover, little research attention has been paid to other QMS standards, apart from those published by ISO, that companies might have implemented. In view of these gap in the literature, the aim of the present study is to compare the diffusion of two QMSs within the Spanish tourism sector. The two QMSs for examination are ISO 9001 and 'Q', which is a specific certification standard developed for tourism in Spain.

The application of these two families of quality standards in the tourism industry in Spain is of interest for at least two reasons. First, Spain has emerged as one of the leading worldwide tourist destinations, with 52.6 million incoming tourists in 2010 (Frontur, 2011). The tourist sector in Spain has felt the impact of the above-mentioned changes in tourism in the past two decades, and there is a widespread acceptance in the Spanish tourist sector of the need to focus on improving the quality of their services. Secondly, in the tourist sector, Spain was the first country in the world to define specific quality standards for each sub-sector and a certification system by an independent third party (Casadesus et al, 2010).

This exploratory study analyses the diffusion of these quality standards in Spanish tourist enterprises, with the aim of gauging their real impact and forecasting their future important in the sector.

Literature Review

Diffusion of QMS standards

Most models of the diffusion of QMS standards have likened the process to the diffusion of technological and organisational innovations in society. According to Rogers (1995), the diffusion of an innovation is a "*process by which an innovation is communicated through certain channels over time among the members of a social system*".

Numerous studies have examined various aspects of such innovation diffusion. Mahajan et al. (1990 and 1995) investigated how an innovation spreads through an economy. Gurbaxani (1990) reported that new product innovations in many industries follow a so-called 'S-curve'. It means that a relatively slow rate of uptake at the beginning, followed by a rapid acceleration, and then a tapering in the rate of adoption as saturation is approached). Other studies have also supported this view, such as Teece (1980), Stoneman (1995) and Kumar et al. (2009).

Spanish tourist quality systems

Alonso-Almeida et al., (2009) and Casadesus et al., (2010) explained which is the situation in Spain with regard to tourist quality systems.

According to these authors due to the aforementioned situation and the need to provide tourism businesses with a tool for quality management adapted to their needs, the Spanish government launched the Spanish Touristic Quality System Project (STQS) in 1996 with the support of the State Tourist Administration.

Through this project, the Ministry of Tourism of the Spanish government has provided technical assistance in developing quality systems appropriate to the different tourist

sub-sectors (such as hotels, restaurants, travel agencies, and other fourteen systems more).

The STQS thus aimed to provide Spanish tourist enterprises with a methodological tool to enhance their competitive positions by improving the quality of their products and services. Institutional backing was provided in the form of the Spanish Tourist Quality Trademark (known as ‘Q’). The Instituto para la Calidad Turística Española ICTE (Spanish Touristic Quality Institute) is the main responsible to develop these systems.

The ICTE describes itself as ‘. . . a certification organization of quality systems created especially for tourist companies’; it also regards itself as ‘. . . a private, Spanish, independent, non-profit organization, recognized worldwide’.

Its basic functions are the following:

- Standardisation: the creation, development, updating, and reviewing of tourist quality standards in collaboration with all interested parties.
- Implementation: the provision of training courses, technical assistance, and publications to support tourist enterprises in their efforts to adapt traditional management systems to quality assurance systems.
- Certification: recognition of the implementation of quality systems by the awarding of the Spanish Tourist Quality Trademark.
- Promotion: promotion of the Spanish Tourist Quality Trademark (and the companies that hold it) through publicity campaigns, publications, representations in trade fairs, and press releases.

The Spanish ‘Q’ standard covers four main aspects: (i) facilities; (ii) the final service delivered to the client; (iii) organisational processes of client services; and (iv) functions and management tools for customer satisfaction. As such, the ‘Q’ standard is a self-regulated standardisation system that establishes quality standards compatible with the ISO 9000 and ISO 14000 series of standards (Alonso-Almeida et al., 2009; Casadesus et al., 2010).

Methodology

Data sources

Data on the diffusion of ISO 9001 was obtained from ISO annual reports (“ISO Survey”) and from annual reports provided by Fom Calidad (with regard to diffusion in Spain). Data on the ‘Q’ standard data were obtained from ICTE databases.

Data analysis

The model of the logistic curve has been applied in this research. According to this model, growth rate is at a maximum at the start, when there are very few individuals in the species that scarcely have to compete for limited resources, and it becomes zero once a certain size is reached. This is the size of saturation that the available resources permit. The model responds to the following expression:

$$N = \frac{N_0 K}{K - N_0 e^{-r_0 t} + N_0}$$

in which N represents the number of certificates, a function of time. N_0 represents the number of certificates at the starting point. K is the maximum level that may be reached: the saturation level. The initial growth rate is determined by r_0 . The independent variable time is represented by t .

This model has been successfully used by academics explaining the diffusion of the ISO 9001 and ISO 14001 standard. A number of authors as Franceschini et al. (2004), Marimon et al. (2006, 2009 and 2010), Casadesus et al. (2008), Llach et al. (2011) and Sampaio et al. (2011) have established that the logistic curve explains well the dissemination of these standards. It has been applied to other quality management standards; e.g. “Q” for the tourism sector in Spain (Casadesus et al. 2010). On the basis of the aforementioned work, Marimon et al. (2006, 2009 and 2010) perceive how the logistic model in question is also applicable to the diffusion of environmental management systems, particularly the ISO 14000 standard.

Analysis and Results

Comparison of diffusion of ISO 9001 and Spanish ‘Q’ standard

Figure 1 compares the evolution between ISO 9001 certifications in the ‘hotels and restaurants’ sector in Spain and the Spanish ‘Q’ standard using the logistic curve.

As it can be seen there has been considerable divergence in the graphs in the past years. Whereas the number of certifications under the ‘Q’ standard is growing, the number of certifications under ISO 9001 in this sector in Spain is decreasing.

These findings suggested that ISO 9001 standard has reached saturation in this sector in Spain in 2008, followed by a smaller number of certifications of this standard in 2009 (see Figure 1). In addition, it would seem that there is evidence of a phenomenon of ‘de-certification’ in 2009 as hotels and restaurants in Spain have not renewed their ISO 9001 certificate. However, the data for the latter phenomenon are not conclusive. It will be necessary to see what happens in the future to confirm this trend.

It suggested that the two standards are at different stages on the logistic curve. Whereas ISO 9001 (‘hotels and restaurants’ sector in Spain) is saturated, the ‘Q’ standard is still growing. Indeed, it would seem that the latter will not reach saturation until 2019. In seeking to explain why saturation has occurred so early in the case of ISO 9001 and why the Q’ standard continues to grow; qualitative data on the diffusion of the two standards in Spanish tourism were obtained from a selection of case studies.

Following two of these cases are presented.

Figure 1. Comparison between diffusion models of “hotels and restaurants” sector of ISO 9001 and Spanish Q standard

	Spanish Q standard		ISO 9001 (Hotels and restaurants in Spain)	
	Sum Sq	DF	Sum Sq	DF
Regression	2.68 E6	3	1,237,615	3

Source: Compiled from ISO (2010) and ICTE (2010)

Case 1 QMS in hotel chain

“H CHAIN” is a large hotel chain located in Spain. The first hotel in the chain was quality certified in 1999, and by 2006 all hotels had been certified.

In the decision to implement the 'Q' system of quality, internal factors had been especially influential, especially a desire to improve internal processes and the work of functional areas.

With regard to the main benefits that had been obtained from certification, the respondents nominated the improved services provided to guests and the enhanced image of the chain, not only by internal improvement but with foreigner customers due to the efforts of ICTE to advertise the "Q".

Given that hotel is 88 years old, this had made it necessary to adapt older installations and furniture to the specific requirements of quality certification. The hotel chain has created a quality department to centralize the quality documentation, internal audits and coordination with external audits.

Some comments of operations manager are:

*This quality system has strong both ownership and institutional support.
It is easy to implement because processes are familiar to us, we don't have to invent nothing only, we are focus on improvement.
This quality system is adapted to our business and these processes are well known for us.
Our employees have not presented any resistance given that their daily tasks do not really change too much.
ISO 9001 is very general for our business. We had had to create all without guide.*

These comments noted that Q standard is useful for hotels to improve all their departments and processes without resistance of the employees. This point is very relevant for companies because majority of internal projects fail in implementation due to it. These comments also suggested that the costs of implementation are lower given that it is faster and the benefits could flourish soon.

Case 2 QMS in restaurant chain

"R CHAIN" is a large restaurant chain located in Spain with more than 400 restaurants. All of them have been certified in 2010, The management team says that "*the company is compromised for the quality is included in all aspect: product, service, stakeholder and environment.*"

The Q standard regulates facilities, equipment, kitchen, cleanliness, customers' service and training and this situation assures "*the restaurants in working order*".

Conclusions

The present study has focused on the impact of two standards in the Spanish tourism sector. An analysis of these standardised management systems has enabled using a model verified in the literature (Marimon et al., 2006; Casadesus et al., 2008 and 2010). These findings allow making a reliable forecast of the future diffusion of these systems in the hospitality and restoration sector. Although the data are specific to Spain, the results do indicate future developments in other countries in which similar standards are being developed or in which the emerging ISO tourist standards are applied.

It is apparent that standardisation of quality management in tourism will increase in coming years (Casadesus et al., 2010). The worldwide diffusion of ISO 9001 in many service sectors (Marimon et al., 2006) and the findings of the present study with respect to the Spanish standards provide an indication of what is likely to happen in the service sector as a whole in most countries.

A definite tendency is growing, and the model does clearly demonstrate the importance of quality management standards in the tourist sector. As the number of issued certificates inevitably increases, more reliable forecasts will be facilitated as valid adjustments are made to the predictive model.

The findings also suggested that specific standards are very important for the industries; even they could help small companies to change and improve their business.

Finally, although the recent history of certification of tourist management systems has enabled general sectoral analyses and forecasts to be made, the relatively small number of standards in each sub-sector limits detailed analysis of each sub-sector individually. This represents an acknowledged limitation of early studies conducted in this field.

Acknowledgment.

This article was written as part of a research project entitled “Customers’ satisfaction improvement in Spanish organizations through standardization” (ECO2009-12754-CO2-01) financed by the Ministry of Science and Innovation within the aid program for R+D projects.

Category: Research paper

Introduction

Quality improvement initiatives have increased within the Swedish healthcare sector in recent decades. These efforts to improve quality can be seen as a response to demands for more cost-effectiveness and better medical results. However, studies have shown that less than 40% of these initiatives are successful (Olsson et al. 2007). The reason why specific improvement initiatives in healthcare fail or succeed is, therefore, a central question in studies of change. The need for more evidence about how to organize and manage new quality initiatives is therefore identified as an important task within studies of healthcare improvement (Walshe 2009, Olsson et al. 2007) Many improvement initiatives in Swedish healthcare uses the Breakthrough Series Collaborative methodology, developed by the Institute for Healthcare Improvement in Boston (IHI webpage). The methodology was introduced in Swedish healthcare by the Swedish Association of local Authorities and Regions (SALAR). This approach is based on a structure in which healthcare teams from various organizations create a joint learning experience. Despite the fact that the method has been practiced for a while and that it seem to be applied extensively in many healthcare systems, critical examinations of its use and application are very rare.

A frequently used measurement tool in healthcare settings is surveys (Streiner & Norman 2008). Surveys for assessment of innovation climate and innovation cultures have been developed. One of those is the Creative Climate Questionnaire (CCQ) aiming to measure the climate in an organization regarding creativity and innovations (Ekvall 1996). This survey was recently used in a study of implementation of new tools in primary health care centres (Carlfjord et al. 2010). Staff and management were shown to differ in their assessment of the organizational climate at the unit, with managers scoring higher. Olsson et al. (2003) developed a model (the Swedish OCM) connected

with a survey to predict outcomes of organizational change. Their model is directed towards predicting success or failure within a change project. A European project (MARQuIS) developed a web-based survey to measure quality improvement strategies in acute care hospitals in the European Union (Lombarts et al. 2009). The survey consisted of four sections, one at an overall hospital quality improvement level, the other three on quality management for medical conditions (acute myocardial infarctions, acute appendicitis and deliveries). Most broadly used strategies were related to external assessments, as ISO, and less implemented were activities related to patient involvement.

To the best of our knowledge, there are no surveys today in a Swedish context that can answer questions about how quality develops and improves over time within Swedish healthcare. Wanting to contribute to the understanding of development of quality improvements in Swedish healthcare by conducting longitudinal studies on innovation development, we needed a measurement mechanism. The Minnesota Innovation Survey (MIS) was found to be a comprehensive survey including different dimensions of innovations and at the same time was developed to measure over time (Van de Ven et al. 2000). It has a broad focus on change processes as well as antecedents and motivations/motors of change. Therefore the MIS survey, with its focus on several dimensions, could be used to investigate more aspects of change.

Minnesota Innovation Survey

The Minnesota Innovation Survey (MIS) was developed to measure how innovations emerge, develop, grow or terminate over time (Van de Ven et al. 2000). MIS is a comprehensive instrument consisting of 102 items including partial and open-ended questions, divided into two parts, the second concerning cooperation with others. In addition there are ten issues of demographic data. It has been used in different contexts, both in manufacturing and service firms, such as medical business, public schools, data processing technology and hospital organizations. The survey is built on a theory (process theory) of innovation management that encompasses five basic concepts: ideas, people, transactions, context, and outcomes. These concepts are seen as central factors concerning managers who direct innovation processes. The conceptual base framework consists of dimensions grouped into the four clusters: Internal dimensions, Situational/contingency factors, External innovation dimensions and Outcomes (Figure 1). Different psychometric tests showed evidences for convergent validity as well as discriminant validity (ibid.).

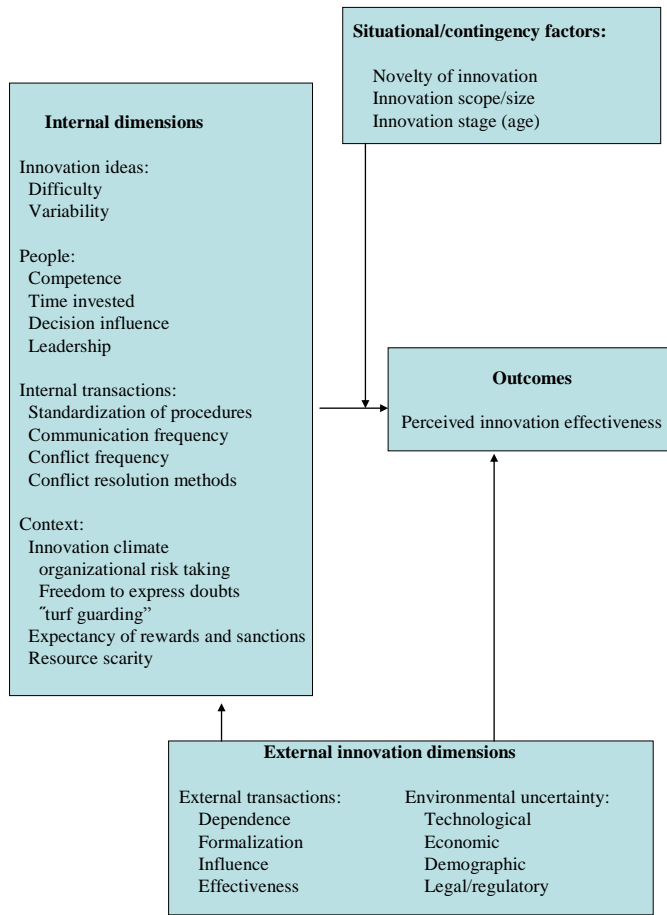

Figure 1, Dimensions in Measurement Model of Minnesota Innovation Survey
 Source: Van de Ven et al. (2000), p. 56

The Breakthrough Series Collaborative methodology

The Breakthrough Series Collaborative methodology was developed 1995 by the Institute for Healthcare Improvement (IHI) in Boston, United states (IHI webpage). The founders reasons were, amongst others, that there was a gap between knowledge and practice, and that we can learn more from collaborating than from working alone. The quality improvement methodology uses small-scale rapid tests of change, and there are eight key concepts that define the Breakthrough Series Collaborative. Those are; 1) Plan-Do-Study-Act cycles are used to test and implement changes; 2) Anyone can have and test ideas; 3) Consensus is not needed to test an idea; 4) Changes happen at all levels (not at or from the top); 5) All teams are required to address all of the Framework components simultaneously; 6) Ideas are stolen shamelessly; 7) Successes are spread quickly; 8) Measurement is for improvement, not research (from a presentation at a web conference 2004). The framework means to identify key components of an ideal system based on existing best practice and evidence, breaking the system down into manageable parts and allow focus on specific aspects within the system. There is also an emphasis on identifying key measures to monitor the progress. Other impotent part are sharing success and to steal shamelessly (ibid.).

The county council improvement program – the empirical context

The quality improvement program started in 2007 and was a political investment with the vision and aim to become a learning organization with welfare of patients in focus. The programme is implemented both from the top management level and at individual departments/clinics/primary health care centres. The program is described on the county council homepage (Kvalitetswebben).

There are several initiatives going on; one is the methodological guided improvement program inviting staff teams to work with an innovation idea in a program using the Breakthrough Series Collaborative methodology and supervisors/facilitators (IHI webpage). The county council has made some local adjustments, but generally they have followed the concept. As of autumn 2010 six of those programs have been started, involving about 130 teams and 610 staff members, the latest including staff and teams from some of the municipalities within the county council. To evaluate this improvement program initiative there was a need for a mechanism to show whether this is a good way of working with improvements in healthcare settings. Therefore, the aim of the present study was twofold; first to translate, revise and test the MIS survey, and then to use the survey to empirically evaluate the use of the Breakthrough Series Collaborative improvement methodology in a Swedish healthcare context over time, comparing the results from the first measurement at the beginning of the improvement program with the second measurement six month later.

Method and material

The Swedish version of MIS - adapting process

The original MIS was used with permission from its creators. Adaption and modification of the survey was done in several steps. Research team meetings were held between the different steps and during this process different ways to validate the survey were performed. The original survey in English was translated into Swedish by a

professional translator. Literally translated words and/or sentences were edited into more idiomatic Swedish and words were adapted to fit the Swedish healthcare and county council organization.

A focus group discussion was conducted with five former participants from earlier improvement programs. The focus group interview was tape recorded and notes were taken. Following the focus group's suggestions, some questions were paraphrased and others reworded. The answers and answer scales were revised and sometimes changed. Individual interviews were held with three support staff from the improvement program support. Their views and ideas were considered in a new revision, some questions were merged and some changed places. An alternative ("Do not know") was added to some questions. Background data questions were adapted, some were removed and some added.

An expert in quality management was then asked to review the revised survey. After his suggestions a revision was made, items were removed and merged, and the survey was shortened. A back translation was conducted by another translator and compared to the original. Some answering scales were further modified, some of which differed in the translation, for example "Very much" has been retranslated as "A lot". Although the overall agreement was good, changes between the original and final survey were, for example, "How big of an undertaking does this innovation represent?" versus "How much commitment do you feel toward the improvement idea?"

The change from using innovation as a construct towards improvement gives a more precise articulation of the content we aim to study. This also meant that the dimension Perceived Innovation Effectiveness was changed into Perceived Improvement Effectiveness. The introduction text was adopted to suit the study and fit the web layout. The survey was entered into the web-based survey program esMaker NX2. An answer was required to all items with fixed scales, otherwise it was not possible to proceed with the survey.

Participants and data collection

The present study contains data from two improvement programs, ongoing from September 2009 until November 2010. Employees within the county council (n=171) and the municipalities (n=39), a total of 210 participants, received the survey. In this paper data from the first measurement and a second measurement six month later are used. The participants received written and verbal information by the first author at the regular improvement program meetings. The survey was sent by e-mail and the informants consented by answering the web-based questionnaire. After one week and two weeks reminders was sent automatically to those who had not answered. The survey study was conducted according to general ethical standards and approved by the Regional Ethical Review board in Linköping, Sweden (Dnr 179-09).

Data analysis

Data was analyzed using Statistica version 8.0 (StatSoft, Tulsa, OK, USA). The results are presented in three answer alternatives, such as "Not at all/A little", "Some" and "Quite a bit/A lot". Descriptive statistics are presented as percentages, range, mean and standard deviation (SD). The repeated measurements are presented as total numbers as

well as percentages. Differences are analysed using Wilcoxon Match Pairs test and correlations between the two dimensions Perceived Improvement Effectiveness and Internal dimensions were made.

Drop out analysis

Drop outs were analysed by comparing the answers from those who only answered the first measurement (n=51) with those who answered both measurements (n=41) using Mann-Witney U test. No significant differences were found between the two groups. Background data were analysed and compared between the two groups, using t-test and chi2 test (Table 1).

Results

In this section the results from developing and testing the survey and the following empirical evaluation of the use of the Breakthrough Series Collaborative Improvement methodology are presented.

Revised version of MIS

The revised survey consisted of 72 items in the dimensions, Perceived Improvement Effectiveness (n=3), Internal dimensions (n=24), External Improvement dimensions (n=18) and Other Indices (n=27). The items consisted of both questions and statements, and were answered in a verbal five-point scale, the majority from “Very little” to “Very much” or “Not at all” to “A lot”. There were items with different scales such as, “Absolutely do not agree” to “Absolutely agree”. In the revised version the answer alternative “Do not know” was added. Likewise there were possibilities added to make comments. Completing the web-based survey took approximately twenty minutes. In the present study the results from the dimensions “Perceived Improvement Effectiveness” and “Internal dimension” are reported (Table 2).

Participants

Demographic data about the participants is presented in table 1. In the first measurement the response rate from county council employees was 45% (n=77) and from the municipal employees 38% (n=15). Seven of the twelve municipalities within the county council were represented. A total of 44% (n=92) participants answered the first survey measurement. The age of the participants ranged from 24-63 with the mean age of 46.3 (SD 10.0). The majority, 86% (n=79), of the participants were women and 14% (n=13) were men. The participant experiences in profession ranged from 0.5-41 years, with the mean of 19.2 (SD 12.0) years. The largest group participating were nurses (n=50), also showing the highest response rate 54%. In the second measurement the response rate from county council employees was 22% (n=42) and from the municipal employees 7% (n=14), a total of 29%. The differences between the participants answering only first measurement and those answering both first and second measurement are shown in table 1. The most striking difference is between the numbers of nurses; it has decreased to almost half as many in the second measurement. There was also a significant difference in working years. Those who answered only the first measurement had a mean working time experience of 21.8 years while the mean time was 15.9 years in the second measurement.

Table 1, Participant background characteristics and drop out analyse (differences between participants answering only first measurement and those answering both first and second measurement)

	Only first (n=51) n (%)	Both first and second (n=41) n (%)	p value

Survey results first measurement

The total of 27 items in the two dimensions “Perceived Improvement Effectiveness” and “Internal dimension” had a Cronbach’s alpha coefficient of 0.77. The overall item “How much commitment do you feel toward the improvement idea?” showed a large engagement in the improvement work: 90% answered “Much/Very much”, 9% “Moderate” and 1% of the participants answered “Very little/Little”. The time spent on working with the improvement idea during the last month ranged from 0 to 80 hours and on average the participants spent 12 (SD 10.6) hours on this work. Most of the time was spent on the participant's own education, mean 3.2 (SD 4.6) hours, followed by time for planning and administration, mean 2.9 (SD 3.3) hours. Least time was spent on acquiring economic funds and resources, mean 0.2 (SD 0.6) hours.

Having prior experience working with improvements was stated as “Quite a bit/A lot” 29% and “Some” 30%, while 41% were answered “None/A little. At the same time 50% of the respondents stated having “No education” in improvement work on beforehand, 35% answered “Participated in courses/training”, 10% “University/college-level education” and 5% “Other”. Those answering “Other” were mostly participating in earlier improvement programs.

The “Internal dimensions” consist of eight sub-dimensions with a total of 24 items (Table 2). The five items in *Recourse Scarcity* (item 35a-e) affects the work with the improvement idea differently. A majority of the respondents stated that they had to compete for time (item 35e) to work with the improvement idea (“Quit a bit/A lot” 52%, “Some” 26% and “Not at all/A little 22%), while competition for economic resources (item 35a) were stated “Quit a bit/A lot”12%, “Some” 17% and “Not at all/A

little” 71%. Least competition was about materiel, space and equipment (item 35b) 8% answered “Quit a bit/A lot”, 17% “Some” and 75% “Not at all/A little”. Regarding the item if the methods used supported the work (item 3) answered 44% “Much/Very much”, 46% “Moderate” and 10% “Very little/Little”. The item about receiving feedback from the support personnel (item 21) were answered by 51% “Quit a bit/A lot”, 34% “Some” and 15% “Not at all/A little”.

The dimension “Perceived Improvement Effectiveness” showed that the majority of the respondents were satisfied with their work and what they had accomplished, 76% answering “Quite a bit/A lot”, 17% “Some” and 7% “Not at all/A little” (item 22). That the improvement idea contributed to improving the work at the unit (item 24) were considered of 56% answering “Quite a bit/A lot”, 35% “Some” and 9% “Not at all/A little”. That the progress was above their expectations (item 23) were stated “Somewhat/Fare above” 42%, “As expected” 49% and “Far/Somewhat below” 9%.

The most common comments were about time; not getting enough time to work with the improvement idea and that it was hard to find time because of regular tasks. There were also comments about manager support, such as wanting help from the manager to plan time for the team to meet. Other comments were about methods of measurements and how to show results. Need for evaluations and assessments to show improvements and distribute achieved results to other colleagues not involved were commented on. Suggestions on improving the work were about getting more knowledge and using unit development days to work with improvements.

Survey results repeated measurements, first and second measurement

Results from the repeated measurements are shown in table 2. The significant differences between the “Decision Influence” items 6a ($p=0.0008$) and 6b ($p=0.0372$) due to the high amount of “No decision made” answers. Problems were stated to arise more often later during the work (item 7), and feedback decreased dramatically (item 21). The improvement program was finished when answering the second measurement. The item if the methodology supporting the work (item 3) is mostly answered “Moderate” in both measurements, 46% respectively. In the first measurement more respondents were answering “Much/Very much” (41%) than in the second measurement (34%). “Very little/Little” were stated by 12% respectively 19%. There were no significances between the measurements in this item, as well as most differences were not significant (Table 2).

The time spent on working with the improvement idea during the last month ranged from 0 to 50 hours and on average the participants spent 6.6 (SD 9.5) hours on this work. Comparing to all answers in the first measurement this is a decrease of about half time. Most time were spent on own education, mean 2.9 (SD 6.0) hours, followed by planning and administration, mean 2.4 (SD 2.8) hours. Least time was still spent on acquiring economic funds and resources, mean 0.1 (SD 0.4) hours.

Table 2, Items and results from the dimensions Perceived Improvement Effectiveness and Internal dimensions, n (%), participants (n=41) answering both measurements

Perceived Improvement Effectiveness	Not at all/A little		Some		Quit a bit/A lot		p value *
	First	Second	First	Second	First	Second	
22. Overall, how satisfied are you with the progress that has been made in the work to develop the improvement idea during the past month?	3 (7)	6 (15)	4 (10)	8 (19)	34 (83)	27 (66)	
24. How much does the improvement idea contribute to improving the work at your unit?	4 (10)	5 (12)	15 (36)	9 (22)	22 (54)	27 (66)	
23. To what extent is your progress with the improvement idea below or above your original expectations?	Far/Somewhat below		As expected		Somewhat/Far above		
	4 (10)	5 (12)	18 (44)	12 (29)	19 (46)	24 (59)	
Internal dimensions							
<i>Innovation Uncertainty</i>							
2. How easy is it for you to know ahead of time what steps are necessary to develop the improvement idea?	Very/Quite easy		Moderate		Quite/Very difficult		
	4 (10)	5 (12)	20 (49)	19 (46)	17 (41)	17 (41)	
7. How often in the past month did problems arise during development of the improvement idea?	Not at all/Once		Every other week		Every week/Every day		0.0344
	3 (7)	1 (2)	5 (12)	3 (7)	33 (80)	37 (90)	
<i>Resource Scarcity</i>							
35. How much must your improvement idea compete with other activities within your unit, when it comes to:	Not at all/Little		Some		Quite a bit/A lot		
a. Economic resources?	4 (10)	5 (12)	7 (17)	3 (7)	30 (73)	33 (80)	
b. Material, space, and equipment?	2 (5)	3 (7)	5 (12)	6 (15)	34 (83)	32 (78)	
c. Attention from the executive level?	7 (17)	9 (22)	8 (19)	7 (17)	26 (63)	25 (61)	
d. Personnel?	10 (24)	7 (17)	11 (27)	12 (29)	20 (49)	22 (54)

Decision Influence

6. How much influence have you had on each of the following decisions that might have been made during the past month?	None/Little		Some		Quite a bit/A lot		No decision made		p p value *
a. Preparing goals and measures for the improvement idea?	1 (2)	2 (5)	3 (7)	4 (10)	37 (90)	23 (56)	0	12 (29)	0.0008
b. Deciding which activities should be carried out within the improvement idea?	0	4 (10)	4 (10)	4 (10)	37 (90)	27 (66)	0	6 (15)	0.0372
c. Deciding on economic funds and resources for the improvement idea?	21 (51)	17 (41)	4 (10)	3 (7)	2 (5)	6 (15)	14 (34)	15 (36)	
d. Recruiting colleagues to work with the improvement idea?	13 (32)	11 (27)	3 (7)	1 (2)	13 (32)	13 (32)	12 (29)	16 (39)	

* only significant differences are shown (p <0.05), Wilcoxon Match Pair test

Correlations

Correlations were calculated between the item “*overall how satisfied are you with the progress that has been made in the work to develop the improvement idea during the past month?*” (item 22) in the dimension Perceived Improvement Effectiveness and all items in the Internal Dimensions. Only three significant item correlations were found, all in the first measurement. “*How much must your improvement idea compete with other activities within your unit, when it comes to: Time to work with the improvement idea?*” (item 35e) ($r=0.34$, $p=0.029$), “*The participants involved in the improvement idea are aware of their individual responsibilities*” (item 11) ($r=0.35$, $p=0.024$) and “*To avoid causing disorder I often feel I cannot say what I think about the work on the improvement idea*” (item 14) ($r=0.53$, $p=0.000$).

Discussion

The aim of this paper was twofold, first to translate, revise and test the MIS survey to be used in a Swedish healthcare context, second to evaluate and follow an improvement program using the Breakthrough Series Collaborative methodology using the survey over time. In our revision we have shortened the survey. Many of the earlier participants in the focus group and consulted experts agreed that the survey was too comprehensive. The different innovation dimensions in the original model (Figure 1) are still there, although some only have a few items left. Our choice to use improvement instead of innovation as a construct suits the work in Swedish healthcare better. The phrase innovation is seldom used; instead almost all organisations working with quality improvements are using that term (SALAR webpage). At the same time it gives a more precise articulation of the content we aim to study, an improvement program built on the Breakthrough Series Collaborative methodology.

First the survey was translated. There are considerations about translating such an instrument into another language, but if the cultures are similar, there can be an assumed agreement that concepts mean the same thing (Strainer & Norman 2008). To test the conceptual agreement we used a focus group interview (Kruger 2009) with participants from earlier improvement programs. Based on their statements wording was simplified. The focus group participants thought the language in the survey was difficult and not suitable in the healthcare context. After the quality management expert was consulted about item relevance, additional changes were made. We shortened the survey and sentences were rewritten in an attempt to clarify. Scales were kept close to the original, with only small adjustments, which has meant that there are different wordings in the answer scales, perhaps confusing the participants. A number of comments refer to this. The overall Cronbachs alpha was consider sufficient and the survey was sent out to participants following a Breakthrough Series Collaborative methodology program.

The sub-dimensions in “Internal dimension” are quite different, as items in “Standardization of Procedures”, “Expectations of Rewards and Sanctions” and “Learning Encouragement”. Therefore this study shows the results item for item and has not made any total scores.

The response rate was 44% in the first measurement and 29% in the second measurement. The comparison between the participants showed that nurses were the largest group not answering the second time (Table 1). There are different reasons for

not participating in a survey. Responses from participants indicated that there are a lot of surveys circulating in healthcare, which could be one reason why some of the respondents chose not to fill in the questionnaire. Perhaps healthcare professionals sometimes become survey-fatigued? The most common comments however were about lack of time. Perhaps another reason is that there is not time enough in healthcare both to work with improvements and answer a survey about the work. The respondents thought that they needed scheduled time so the whole team could meet and work together. The ordinary daily work always intruded. The time issue is supported by the fact that 52% (first measurement) stated that they had to compete for time to work with the improvement idea. But at the same time, most respondents were satisfied with what they had accomplished, and thought their work was useful to the unit and to the healthcare organization.

Through the application of the revised MIS survey, our empirical study in the county council reveals what it means to work in project teams within the context of Breakthrough Collaborative Series arrangements. The section below are highlighting and discussing the most significant findings.

There were not many significant correlations, but some interesting findings are that the overall satisfaction with the improvement work correlates positively to the awareness of the individual responsibilities and the feeling of openness, to express what you think about the work. Ekvall (1996) describes this in words of the organisations climate, implying a certain degree of openness, commitment, motivation and risk taking mentality. The more positive climate the more innovative organisation and more satisfied employees. He also claims that risk taking, dynamism and freedom play a roll to create an innovative organisation. In our study the items concerning decision influence were not showing this. But the awareness of the individual responsibility as well as the item about commitment (even if no correlations were found) can be factors having influence on the satisfaction.

The results showed variation on how Breakthrough Collaborative Series team members experience competition for resources. Respondents stated that they had to compete for time, which applies to the comments about lack of time. The least competition was mentioned with respect to economic resources. The fact that 62% (first measurement) stated that they did not have to compete for attention from management (executive level) is interesting. At the same time a recurring comment was about wanting more attention and support from management. Surprisingly there was a positive correlation between the overall satisfaction and the time competition with other activities (item 35e).

The items directly affecting the Breakthrough Collaborative Series methodology are quite interesting. The item if the methodology are supporting the work (item 3) values below the middle was reported, and quite a high amount have answered that they do not receive feedback from the improvement support staff (item 21). Discussing this with the support staff, they claimed that at the second measurement six month later the methodology program was ended. At the same time, there is a support organisation built up at local (administration) levels to be able to support improvement work going on at different levels in the organisation. One can assume that the respondents' answerers only concern the support during the program, and then this result will be understandably and corresponds to the explanation of the support staff. The answers that the

methodology does not support the work are more problematic. Are the instruments too complicated, not introduced properly or just not regarded as sufficient? There are a lot of healthcare organisations in Sweden using the Breakthrough Series Collaborative. There are only one evaluation made, that we are aware of (Øvretveit 2003). This report stated that the most important factor for those programmes to succeed in long-term are that the organisations after the program has ended can make use of the knowledge that the teams have accomplished. If this is the case, this study can not answer, more studies within this county council improvement program are to be accomplished.

This paper was the first evaluation of the revised survey. It is also the first analyze of data following an improvement program using the Breakthrough Series Collaborative. There is a need to do more testing to get the survey to apply better to the Swedish healthcare context. More data will be collected in this county council improvement program, and more analysis of the use of the Breakthrough Series Collaborative is forthcoming.

Conclusions

The survey methodology can be used to study and evaluate improvement initiatives in Swedish healthcare settings. Although the survey would benefit from some more development regarding the extent, language and uniformed standardized measurement scales.

Regarding the improvement program and Breakthrough Series Collaborative methodology the most striking results are that almost half of the respondents (46% in both measurements) stated that the methods only support the improvement work at a moderate level.

Keywords: Excellence, sustainability, management, business education

Paper Type: General Review

Introduction and Paper Objectives

“There was a rich man whose manager was accused of wasting his possessions. So the rich man called the manager in and asked him, “What is this I hear about you? Give an account of your management, because you cannot be manager any longer.” ... Whoever can be trusted with very little can also be trusted with much, and whoever is dishonest with very little will also be dishonest with much. So, if you have not been trustworthy in handling worldly wealth, who will give you true riches? And, if you have not been trustworthy with someone else’s property, who will give you property of your own? Nobody.

Jesus in the Gospel of Luke 16:10-12

The recent global multifaceted crisis is a direct consequence of the dominant paradigm of economic growth that followed the industrialization era, an argument highlighted by Marschall et al. (2010) in the recent Academy of Management Learning and Education special issue on sustainability in business education. This paradigm has been focusing on the self referent corporate unit that neglected its impact in the wider context and the right of future generations to meet their own needs by utilizing natural, social and human resources. The scientific over-fragmentation and relevant technocratic education, the centralized power structures and the unilateral economic growth mentality were responsible for the development of a consciousness trap that determined to a great extent the course of global and corporate action for many years. This means that managers’ perception was constrained into a discipline specific, organizational and cultural self referent mental framework that led them to specific behaviours and thus not allowing them to think differently, as Kuhn (1962) and Senge (1990) would agree.

Facts like a) the recent corporate scandals which shocked both the practical and the conceptual/theoretical constituents of management (eg Enron, Worldcom, Lehman Brothers), b) the financial crisis (credit crunch), c) the corporate greed, inertia and short-sightedness (according to America’s Union Movement in 2010, i) the gap between a CEO’s and an employee’s pay rose by 343 times in comparison to 42 times during the eighties, ii) the average US CEO pay for 2010 amounted to \$11.36 million and a pay cut of 30 % could assure the job of 33,000 employees that most of the times are thrown into unemployment, iii) there is \$ 1.93 trillion in corporate cash not invested, leaving 14 million people unemployed in the US, d) the percentage of hungry people that reached 13.1% of global population-1.35 billion of people live with almost \$1.25 per day (World Hunger report 2011) and e) the environmental disasters of Chernobyl, Fukushima and the massive oil spill in the Mexican Gulf and f) the human rights violations by major corporations could be described as human hubris for which the

global community and its corporations (to a variable extent) share responsibilities. It is truly a paradox, on the one hand spending billions of Euros to understand the fundamentals of universal creation (eg CERN experiment) or to advance our knowledge on the mystery of life and on the other still behaving with total disrespect to the preservation of life. What is the purpose of conquering Mars, of discovering the mysterious Higgs particle or even maximizing financial results, if humanity has lost its ability to understand its own nature and lives in a state of civilized barbarism, in which the teachings and values of the ancient world, enlightenment, renaissance seem to be fading away?

These are indications of multiple failures in various fields, namely not meeting the desirable or predefined objectives. However, it would be truly unwise, culturally inferior and scientifically incorrect to simply rely on a sheer and inexpensive criticism of these failures. Failure is indeed possible and sometimes beyond our control. However, mankind can choose to penalize it or understand it, learn and recover from it (Edmondson, 2011). Indeed, recovering is still possible. Gandhi used to urge people to “become the change they wish to see in the world”.

There is a clear need for a paradigm shift of the global growth model. Thomas Kuhn (1962) in his book “The structure of scientific revolutions” is describing the preconditions for that, when he talks about the anomalies that cannot be resolved by the prevailing paradigm. Scientists, practitioners and states are exchanging arguments and views on the realization of the sustainable management vision as specific factors like a) the increase of world population to 9 billion people until 2050, b) the diminishing natural resources, their cost increase and the easy attraction of financial resources for businesses which are socially and environmentally responsible, due to balanced long term performance prospects, c) the volatility of energy prices, d) the global preferences of human resources to be employed in socially responsible corporations, e) the corporate legislation which is becoming stricter and requires disclosure of all relevant information by companies and f) the consumers` demand and expectations for eco friendly products from companies that are accountable to them, g) the increase in waste and disposal cost, h) the opportunity for gaining competitive advantage, set the boundaries for future development (EFMD, 2010; WBCSD, 2010), which has no alternative than being sustainable.

According to the trends on sustainability published by CERES (2010), investors have a positive attitude to companies that implement sustainability strategies. In addition, structural changes inside companies are reported as well as an increase in the time devoted to the discussion of sustainability issues. Increased stakeholders awareness and engagement is also reported, while many companies proceed in the disclosure of sustainability data. There is also a high percentage of companies (from the Fortune 500, 2006 list) reporting that they have human rights practices (93%) and a respective high percentage (75%) of companies that provide information on human rights issues. While these facts are quite encouraging, a great number of global corporations have fallen into serious environmental and human rights violations (eg. ILRF,2008; UNEP Finance Initiative, 2010).

As Professor Stuart Hart from Cornell University states, sustainability should not be left solely to the state (Hart, 1997). Sustainability has entered the field of business education, where conferences and special issues by prestigious journals (Harvard Business Review, Academy of Management Learning and Education etc) focus on the

areas that need to be transformed so that future managers are educated to produce business solutions scientifically and ethically correct. This trend is strengthened by the criticism exercised on the effectiveness of business education and its contribution to excellence. Therefore, despite inherent ambiguities in defining sustainability, it is an issue of growing significance for business schools, which are expected not to confront this issue with negligence or approach it as a new fad or “a just business issue”. The sustainability imperative impacts all educational and managerial processes of business schools and in literature there are both information regarding the progress made so far and examples of how it can be approached (eg International Journal of Sustainability in Higher Education). However, even if sustainability is seen through the lenses of institutional strategy, teaching methods such as experiential learning, new and /or multidisciplinary courses and new research frontiers, success and the linkage to excellence can be achieved through a sincere amplified awareness and understanding of the world and its subsystems that results in “knowing thyself” (the ultimate aim of education that has been described by Thales of Miletus -one of the seven sages of Ancient Hellas). Only then, excellence becomes action not because of laws or some business model requirements but as a logical consequence of conscience. The sustainable management vision presupposes a fundamental paradigm shift in management, as a scientific corpus or a well respected profession. In addition, national initiatives, investments and legal frameworks along with the supporting market trends constitute important empowering pillars for the sustainable management vision for excellence.

Therefore, the aim of this paper is a) to analyze the meaning of sustainability and its relation to excellence, b) to present the global challenges for sustainable management of the future and finally c) to examine how sustainability should be approached by business schools.

Sustainability and the challenges for sustainable management

“A human being is a part of a whole, called by us “universe”, a part limited in time and space. He experiences himself, his thoughts and feelings as something separated from the rest... a kind of optical delusion of his consciousness. This delusion is a kind of prison for us, restricting us to our personal desires and to affection for a few persons nearest to us. Our task must be to free ourselves from this prison by widening our circle of compassion to embrace all living creatures and the whole of nature in its beauty.”

Albert Einstein , Quotes

During the last years, there is a continuing awareness of the need for simultaneous development of the economy, society and environment, a practice called “sustainable development”. Sustainable development is based on the concept of sustainability (from the Latin “sustinere” which means to persist, endure and last). In natural sciences, the term sustainability refers to the ability of biological systems to remain healthy and productive for a long time while in the social field it is associated with the multidimensional long term maintenance of prosperity/wellbeing. The environmental dimension focuses on the reduction of human impact and the improvement of ecosystems through environmental management and the management and use of natural resources. The economic dimension refers to those practices and actions that will be undertaken by present generations so that future generations can enjoy the same level of wealth and prosperity (Durlauf and Blume, 2008). The social dimension of sustainability is related to human rights, global poverty, peace, security, corporate power and citizen action (Blewitt, 2008). While the issue of sustainability is brought at

the global forefront rather recently, the preservation of harmony in human societies has been a major priority in the ancient times. Harmony (the core of the sustainability concept, expressing the interrelations of non contrasting laws) is an omnipresent value found both in the micro and the macro level. From the smallest material particle (atoms or quarks), to the cells and the human body, to the galaxy and the universe, harmony assures existence and the continuation of life.

Sustainable development (a concept that became popular in the 1980s) aimed to underline the significance of development that meets the needs of the present without jeopardizing the ability of future generations to meet their own needs (Brundtland,1987). Some years after, in 1992, the World Summit for Environment and Development convened in Rio de Janeiro and adopted Agenda 21 (a programme for motivating society towards sustainable development). Sustainable development is recognised as a main axis also in European policy level which has led to the adoption of the European Strategy for Sustainable development in Göteborg. In 2005, the United Nations world summit put the interdependence and mutual reinforcement of the three dimensions of sustainability at the core of economic development. Cultural diversity has also been suggested as the fourth dimension for sustainable development (UNESCO, 2001).

Sustainability is a rather broad, evolving and dynamic concept. Collins and Kearins (2010) describe it as *“a “glocal” system`s level concept that transcends entity or national boundaries to embrace notions of equity, equality and futurity in relation, but not limited to economic, social and environmental conditions that support life for all”*. Sustainability places the corporation at the heart of interrelated environmental, economic and social systems (Bradbury, 2003). At the individual level, a cultural transformation is necessary against the traditional short term orientation and rapid personal enrichment towards self awareness and the sincere willingness of managers to be truly constructive in society.

The teachings and practice of quality management have led to an extended view of the enterprise, emphasizing on the issue of balanced corporate performance. There is a continuing ambition and attempt made by many organizations to achieve excellence. Excellence, according to business related literature may be seen as a) a corporate value, b) a purpose, c) a mindset of doing business and d) balanced performance in predefined dimensions. In the managerial / organizational context, excellence can be described as a framework that offers systemic view, presupposes high engagement of people, enables self improvement and evolution and thus it contributes to constant change and conformance to new situations through quality monitoring at each stage and every process of the organization (Anninos,2007). Nevertheless, excellence cannot be restrained strictly into the frontiers of an organization, but it relates to a great extent with the organizational impact on society (i.e it is not possible for an enterprise to be excellent and neglect corporate responsibility issues and/or business ethics). So, there seems to be an interaction between the concepts of excellence and sustainability. There can be no excellence without sustainability and there can be no sustainability without excellence. The inclusion of social and environmental parameters in some organizational models for excellence (eg EFQM) should be combined with a sincere change in management motives that would ensure commitment and excellence itself, in the long term. These two interrelated concepts (excellence and sustainability) have contributed in shifting the national, corporate and sometimes individual mentality to include the world and the society.

As suggested earlier, it is impossible to deny that global scale problems deserve attention and they should not be left only to the states or supranational actors. Researchers like Kaplan, (2003), Bello, (2004), Schroyer and Golodik, (2006) and Banner (2007) among others suggest a necessary transformation of social operation in order to re determine the relationship of mankind with nature. Being in accordance with United Nations relevant resolutions (2005), organizations should develop and execute strategies for sustainable development.

Managers are sometimes confused by the blurred boundaries of corporate sustainability and corporate social responsibility proliferated definitions and thus they are not able to understand what their company is doing and to what direction (Montiel, 2008). Corporate sustainability is a wider term referring to both voluntary and compulsory environmental and social action through transformative leadership for re-shaping business mentality and processes, markets and developing sustainable innovations through an integrated business model that puts ethics (towards man, environment and society) at its core. To achieve that, different sustainability models have been suggested (such as the EFMD 7P model, the CERES roadmap etc). Regardless of the model used, the sustainability vision should be aiming at raising a company-wide awareness and spreading to all business functions, providing opportunities to human resources to be involved in sustainability experience, integrating sustainability to the corporate learning strategy and the company knowledge system (Haugh and Talwar, 2010).

The sustainability concept is being integrated in the corporate DNA through for example environmental friendly facilities and equipment, product design and production methods minimizing energy consumption and lowering emissions, ethics orientation, participation in social and humanitarian actions (Haugh and Talwar, 2010). Even though there are costs involved in such attempts (see for example Jaffe et. al, 1995), a number of researchers such as Porter and Van der Linde (1995); Ellen et al.,(2000); Orlitsky et al., (2003); Porter and Kramer,(2006); McWilliams and Siegel, (2001); Peterson, (2004); Aguilera et al.,(2007) and Brønn and Vidaver-Cohen, (2009) underline the benefits that a company can achieve through the sustainable management orientation.

Corporations will have to deal with challenges like a) the incorporation of externalities, the improvement in the use of resources and waste while lowering environmental aggravation and increasing their active initiative undertaking towards workforce and social well being, the design and production of innovative products that qualitatively transform the standard way of living, b) the structural and operational reengineering and the relevant corporate behaviors that should not only be confined to an on the surface rhetoric of sustainability. Corporations should proceed to a vigorous revision of organizational culture and operation, thus replacing the dogma of resource sufficiency (that promoted the sheer exploitation of nature), social negligence and self orientation along with its intellectual framework, c) the formulation of a sustainable management vision which requires a novel, broad in scope, perspective of corporations and management that would truly understand and utilize the natural, social, economic, technological and corporate system with respect to cultural and historical dynamics. This means that there may be different sustainability visions and certainly not a dominant one, as was the western till recently. In any case, corporations will have to satisfy both shareholders and stakeholders.

It is interesting to note at this point that CEO's business education impacts positively on the corporate environmental performance due to improved profit prospects (Slate and Dixon-Fowler, 2010). However, being responsible just for profits is different from being responsible due to transformed consciousness, values and altered world views and this is where the significance of a proper business education lies.

Sustainability in business education

"There's only one corner of the universe you can be certain of improving, and that's your own self. So you have to begin there, not outside, not on other people. That comes afterward, when you've worked on your own corner"
Aldous Huxley

It is without doubt to say that business education adds value a) to people (as individuals) and b) to organizations, as Longenecker and Ariss (2002) suggest, since it helps them achieve competitive advantage through i) exposing managers to new ideas and business practices which are needed in a changing environment, ii) motivating managers to improve performance and help them develop their skills, iii) providing opportunities for reflection, introspection and self appraisal, iv) increasing managers' confidence, reducing stress level and challenge them think in a different way and v) encouraging managers think about their career development and be the example for their subordinates, and finally c) to society by emphasizing on the development of mature and capable citizens to lead fulfilling lives and help sustain democratic and learned culture and on the provision of knowledge and skills to students to sustain a corporate economy.

A basic element for successful managerial activity is business education whose quality has a major impact on what managers perceive and understand regarding business activity, on their ability to analyze, evaluate and bring together management theory, experience and practice, on using management techniques and making decisions by taking into account hard and soft issues in order to produce wealth. The essence of business education, for more than a century, is perceived by managers and global academic leaders as being synonymous to the provision of a certain knowledge corpus that will enable individuals to acquire a global mindset and act to achieve high self and corporate performance levels.

Despite the fact that the business education model has incorporated all the major changes regarding structure and curriculum that were considered necessary during the 80s and 90s (such as emphasizing international dimension, training in soft skills and converging educational content with real business situation) (Pauca-Caceres, 2008), a significant number of researchers and renowned management gurus point out the need for restructuring and improving business education (e.g Mintzberg and Gossling, 2002; Pfeffer and Fong 2002; Ghoshal 2003, 2005; Bennis and O' Toole 2005; Holstein 2005; Tsurumi 2005; Ferrano et al. 2005).

While there is no empirical evidence to support the view that business schools should undertake fully responsibility for the current crisis (Neubaum et al. 2009), (as education is not the only enabler of human behavior), business schools must see this crisis as an opportunity to provide their students with an alternative perspective on management (by encouraging their students understand and think upon corporate responsibility and business ethics issues, equipping them with all necessary knowledge and skills to understand and critically approach management practice, managing problems of ethics

and involving them at the individual level in learning ethics through the analysis of actual cases (Anninos and Chytiris, 2012).

Sustainability (in management practice), innovation (in all business school processes) and integrated management approach (science, theory and ethics) are presented as key factors for excellence in the future. In the last 3-4 years the issue of sustainability is gaining momentum in the field of education (Holliday, 2010) due to the intensification of the aforementioned sustainability forces (Charan, 2009; Friedman, 2008). Business education is in a state of necessary transformation in order to meet the needs of a sustainable management vision of the future, something that as Marschall et al.,(2010) report, seems to be progressing at a slow pace. To avoid losing ground in competitiveness and become marginalized and outdated, business schools should quickly adjust the curricula and operation model to prepare graduates to respond to the new emerging sustainability paradigm. The development of the Principles for Responsible Education in 2007 by leading business schools and institutions is helping towards that direction. The leading MBA programs that have incorporated the social and environmental perspective into their curricula are ranked by the Beyond Grey Pinstripes survey (Kurland et al.,2010).

Sustainability should be integrated at the conceptual, theoretical and practical level of business education. In the case of the conceptual level, future managers must be able to understand the connection and interaction of basic principles and acquire a broad perspective of management through the study of philosophy, logic, ethics, metaphorical literature works and arts. This contributes to the development of meddlesome and inquisitive minds and personalities that critically approach and creatively doubt management models and theories. At the theoretical level, students participate and learn the scientific foundation of management and develop technocratic abilities through the study of the traditional business education curriculum from a multidisciplinary perspective. Finally, at the practical level, students engage in business-academia hybrid experiential learning activities and knowledge exchange systems and become aware of the interactions between the economic, social and environmental parameters and business decisions.

Between the two approaches of incorporating sustainability into the curriculum, namely the one suggesting that sustainability should be a distinct course (Gruenewald, 2004; Carrithers and Peterson, 2006) and the other suggesting that it should be diffused in all courses (Ghoshal, 2005; Stubbs and Cocklin, 2008; Audenrand, 2010), the second is most suitable as it allows for broadening and challenging students worldviews, better opportunities for knowing thyself and seeing the sustainability dimensions in every area of business activity.

There are certain literature findings that document an increasing trend in business schools regarding the incorporation of sustainability courses into their curricula, the use of experiential learning and immersion techniques and the integration of the sustainability logic in business thinking (Matten and Moon, 2004; Christensen et al.,2007; Wu et.al, 2010). However, Benn and Martin (2010) and Gray and Collison (2002) refer to a serious obstacle, namely the tendency of faculty to teach and research sustainability from their own discipline specific perspective. This is further complicated by the inherent obscurity of the meaning and content of sustainability in the business world. Thomas and Benn (2009) also refer to the issue of institutionalization of change

and the management of complexities both inside institutions and among universities and communities. To effectively overcome the above barriers, sustainability should be approached as a strategic issue for business schools, embedded initially in the institutional organizational model, something that was noted in a relevant issue of the Journal of Management Education (Rusinko and Sama, 2009). Deans and faculty should show commitment to the sustainable management vision and practice. Transformative leadership, cultural web, use of resources, emphasis on satisfying the stakeholders demand as well as institutional accountability constitute organizational parameters that display the sustainability orientation of a business school.

With regard to the educational functions, namely teaching, research and social contribution, business schools should become cells of extended physical and web based networks for facilitating knowledge, experience and best practice exchange in which private, social and state actors participate. This is also highlighted in the works of Bartunek, (2007) and Brydon et al.,(2003). Teaching and research should be multidisciplinary, interdisciplinary and multithematic since business education is primarily university/higher education. It is based on (at least at the university level) mental, methodological and scientific processes that should help students acquire a holistic perspective of the world. The more holistic approach is implemented in business education, the more possible it is for future managers to proceed towards knowing themselves which leads to the revision of personal goals, the acquisition of empathy, the undertaking of company-wide sustainability initiatives, the rejection of the ego/corporate centered mentality and the conscious and influential practice of ethics for the sake of ethics and not due to deceptive stimuli that wear out the foundations of a corporate economy. As Stubbs and Cocklin (2008) admit, the presentation of sustainability issues from a business education perspective is a challenge. The following table presents an example of how different fields could contribute to the setting of foundations for the sustainable management vision (Table I).

Table I: The contribution of different fields to sustainability

Fields	Examples of future managers` critical abilities for sustainability
Business core areas: Management - Human Resources Management/Organizational Behavior – Marketing – Production/Operations Management -Economics- Finance and Accounting and relevant quantitative courses	Ability to efficiently and effectively manage resources, train and develop HR, incorporate externalities, develop and execute a sustainable strategy and policy, understand and utilize challenges for competitiveness, evaluate multidimensional performance, deal with corporate governance issues, build innovative products and services, understand how theories and models of macro and micro economics affect human prosperity and corporate actions, understand limitations, ability to maximize shareholders (and stakeholders) wealth, ability to design and operate efficient and effective business processes and procedures for products and services, knowledge of production techniques, use of technological potential for sustainable competitive advantage
Environmental Sciences	Interdisciplinary approach of the environment and environmental problems through the study of fundamentals of natural and biological sciences, ability to understand how environmental problems impact the organization and vice versa
Information technology – Knowledge management	Abilities to use modern technology to create, share and diffuse knowledge and ideas related to sustainability challenges and relevant corporate actions
Sociology	Ability to understand human social activities, the interaction of micro and macro systems and social structures
Politics	Ability to perceive and understand how politics can affect management decisions and act to deal with sustainable management problems
Urban Studies	Ability to understand how economy, planning, architecture, ecology, transportation, social relations in urban areas affect organizational issues and decision making

Ethics and Philosophy	Analysis and study of morality, critical and systematic approach, rational argumentation and constant inquiry and dialogue relevant to existence, mind, knowledge, ideas and values, reason and language
Psychology	Ability to understand the human mind and behaviour, the mental processes that determine the what and how of human behaviour
Culture	Abilities to understand and utilize a diversified workforce, understand how cultural issues affect management decisions, how cultural factors co develop the way of living, thinking and behaving
Literature and arts	Abilities for self awareness, for reflecting and discovering changes of cultural values, for discovering new frontiers of scientific endeavours

Scientific collaboration in research as well as in teaching should also be encouraged and recognized. Creative thinking, experiential learning and critical abilities to investigate the potential impacts of management decisions in various fields should also be emphasized through co curricular activities and social contribution (eg opportunities for recycling, participating in waste and energy management joint business academia projects and undertaking of socially supportive actions).

Conclusions

The greatest challenge for the 21st century manager is walking on the path of self awareness. The awareness of this reality is enough to reshuffle the human mind, engage it to mental processes that contribute to the higher understanding of life through the perception of mankind in relation to the whole universal structure.

The intensity and the rapid enlargement of environmental and social consequences of the dominant global growth model push towards a revision of our scientific and mental way of thinking and living on a national, corporate and even personal level. As basic institutions of modern culture, corporations should reconfigure their business models and their underlying values and beliefs of their mission to respond the aforementioned sustainability challenges and maintain their competitiveness through excellence. Some positive steps have been reported, however working towards a sustainability vision requires greater attempts in scale. It is to be reminded that as excellence may take different expressions, there are many ways of progressing towards sustainability that can be generated through the combination of culture specific elements and management knowledge corpus.

A basic precondition for moving to a new kind of management practice is refining the mental software of managers, which is their education. Progress –even if it is slow- is indeed noted regarding the integration of the sustainability concept in business education and practice. Bearing in mind that education is only one parameter that defines human behaviour, multi and inter disciplinary and inter-thematic approach of management is needed to help future managers develop sounder hypotheses in their understanding of the world and their own selves, thus conquering knowledge which is attained through stronger foundations of approaching the mind, something that Plato considers as the ultimate goal of man. This will lead to the integration of sustainability at the conceptual, theoretical and practical level of business education, impacting on the values, purpose and methods used by corporations to serve mankind.

Keywords: Budgeting, Budget Ratcheting, Target Setting, Production function.

Introduction

Target setting is at the core of the planning processes in organizations. Targets define an expected level of performance and converge into planning documents such as the budget. Coordination, resource allocation, and performance evaluation are organizational activities intimately associated with planning and target setting. Managers use a diverse set of information sources to set targets and weight these different sources depending on a myriad of factors particular to the organizational unit (Fisher et al. 2002).

While traditional researchers investigating target setting have assumed fixed targets (Holthausen et al. 1995; Gaver et al. 1995), some theoretical as well as empirical studies (Alison et al. 1991; Leone and Rock 2002) suggest that past performance may be optimally used to set targets. The use of past performance, known as the ratchet principle (Weitzman, 1980) happens when targets for the current year are influenced by the difference between last year's performance and its target. In particular, a favorable variance last year is associated with an increase in the target for the current year, while an unfavorable variance is associated with a decrease in next year's target (Lee and Plummer 2007; Ettredge et al. 2008).¹

Past performance may provide relevant information to set targets if variances (actual versus expected performance) are associated with permanent (versus transitory) changes in performance. If so, unbiased expectations about future performance will incorporate the magnitude of these variances leading to ratcheting. In contrast, if variances capture transitory changes, then unbiased expectations will not incorporate these variances. The challenge is, therefore, to separate permanent from transitory components of performance improvements. To do so, it is necessary to understand the ultimate source of variance and to explore its expected change in the future.

¹ We use a broad definition of ratcheting without constraining it to be symmetrical (Weitzman, 1980) or asymmetrical responses (Leone and Rock 2002) to favorable and unfavorable variances. Our empirical findings indicate that the asymmetry of these response coefficients vary with the information environment of the manager setting targets. Symmetrical as well as asymmetrical responses are observed with varying information environments.

Permanent innovations (e.g. improvements in efficiency) can be sustained without posterior increases in effort, whereas transitory innovations require agents to continue increasing their effort in subsequent periods. Thus, investigating the relation between effort exerted and performance achieved, as the economic theory does in the production curve, will be of help in separating the two types of improvements. Although the production curve is a significant part of the economy applied to various circumstances and situations, it that has generally been ignored in the budgeting literature. Prior budget research assumes that the relation between effort (the input) and performance (the output) is linear and unbounded, in contrast to the assumption made in the production curve theory that this relation changes across the production curve. As effort levels increase and maximum capacity is approached, more effort is required to achieve the same improvement in performance, and consequently, the improvement potential will depend on the current position on the production curve or the current level of effort.

In this paper we incorporate the productive capacity as a source of information in the target setting process. We study how the level of effort implied in the current target affects the revision in subsequent periods. That is, how the level of current targets in relation to the productive capacity affects targets' revision. We investigate both a direct effect together with an indirect effect that comes from the change in the informational content of past performance (interaction effect with budget ratcheting). In so doing, we use the budgeted and actual performance of 376 branches of a travel agency between 2002 and 2006 (for a total of 1,105 branch-year observations). Though these branches vary in terms of the local market, their size, and individual talent, they are similar in that they sell comparable products with pretty homogeneous marketing and operating practices. Therefore, targets and performance of other branches may have information content relevant to decisions making. Specifically, the performance in relation to comparable branches (relative performance evaluation -RPE) can be used analyze current variances, and targets in relation to comparable branches (relative target setting -RTS) can be used to revise targets. Hence, actual performances (targets) can be a good proxy of the position on the production function at which the branch operates (is asked to operate).

Consistent with prior results, we first find evidence of the ratcheting phenomenon in revising sales yearly targets. We also find that relative target setting (RTS) is associated with next year's target. In particular, branches whose targets for the previous year were above the average of comparable branches have their targets for next year reduced and branches bellow the mean have them increased. Branch's location on the production curve affects targets as well as past performance does.

Second, we find that RTS and past performance (ratcheting) interact. The magnitude of ratcheting changes depending on the value of RTS: targets for those branches performing above the mean and having favorable variances are not ratcheted as much as targets of branches performing below the mean and having favorable variances. Conversely, targets for those branches performing above the mean and having unfavorable variances are reduced more than targets of branches performing below the mean and having unfavorable variances.

Moreover, while previous works have provided empirical evidence of ratcheting being asymmetric, i.e., there is an asymmetric response to favorable and unfavorable variances with the effect being more pronounced for favorable variances (Leone and

Rock 2002), we found that this results is only a particular case that applies for branches located on the left side of the production curve. For those branches around the middle of the curve the ratcheting coefficients are symmetric, and finally, for branches on the right side of the production curve the ratcheting coefficient for unfavorable variances is higher than that for the favorable variances.

The paper contributes to our knowledge of target setting within the context of the budgeting process and control in decentralized organizations. The evidence is consistent with past performance and economic information about productive capacity being relevant to form expectations about future performance. The results also indicate that these two sources of information interact. The paper reinforces the presence of ratcheting in organizations. Yet, it highlights that the significance of the ratcheting and its shape across favorable and unfavorable variances (symmetric versus asymmetric response) is not fixed but rather responds to the position on the production function of the target against to which the performance is measured. The paper identifies relative target setting as good proxy for the branch's location on the production curve and then as relevant variable to the budgeting process.

The research setting is limited to one company and the results cannot be generalized to other settings. Rather they are intended to provide evidence consistent with theoretical predictions associated with managers' use of information. Future research may extend the findings in the paper to other settings and investigate how alternative characteristics of the target setting process may affect the relevance of past performance and relative target setting on future targets.

The rest of the paper is organized as follows. Next section presents theoretical arguments leading to the prediction of ratcheting and production function influence and develops the hypotheses empirically tested. Section 3 describes the research setting and the research design. Section 4 presents and discusses the results. Section 5 concludes.

Theory and hypotheses

In a dynamic setting firms tend to revise targets over time. Managers are uncertain about the performance potential of employees for the information is by no means complete and precise. Yet the firm presumably learns over time and uses information on current target deviation to identify what is feasible in future periods and how to set subsequent targets. This tendency to base target adjustment in the subsequent period according to reported performance relative to budgeted performance in the current period, coined the "ratchet principle"² (Weitzman, 1980), has later been documented in empirical studies such as Leone and Rock (2002), Leone et. al. (2006) or Bouwens and Kross (2011).

Current target deviations are certainly relevant when setting future targets. However its information content about employee performance potential will surely depend on the type of innovation that caused the favorable (unfavorable) deviations. In this regard,

² Also designated with the term target ratcheting. Though Weitzman (1980) describes a symmetric response to positive or negative departures from budget, Leone and Rock (1992) interpret it in an asymmetric manner. That is, positive variances in performance from budget lead to greater absolute changes in the following period's budget than do changes associated with negative budget variances of the same magnitude.

Leone and Rock (2002) distinguish between permanent innovations and transitory innovations. Permanent innovations (e.g., improvements in efficiency) have a permanent effect on performance and can be sustained without posterior increases in effort. On the opposite extreme, transitory innovations refer to positive performance effects that can only be sustained by agents continuing to increase their effort in subsequent periods (Bowens and Kross). The two types of innovation have radically divergent implications in terms of future effort. Consequently, when revising targets, managers should account for the type of the innovation that caused the current target deviation. This is theoretically the spirit of the ratchet principle. In practice, there is likely to be a combination of transitory, permanent, and partially permanent innovations and it is improbable that firms will be able to discern the persistence of a given innovation. The consequence of this grouping is that each improvement in performance will most probably require an increase in effort: the raising of targets is always more demanding in terms of effort.

The question is how much the effort of the agent (a branch in our empirical analysis) should increase to reach the more exigent target. In the short run, where technology is fixed, the production function theory suggests that it is likely that output will increase with the level of input, but it does so at a decreasing rate (see, for instance, Varian). Using effort as input and performance as output, economic theory predicts a concave relationship between effort and performance: as effort levels increase and maximum capacity is approached, more effort is required to achieve the same improvement in performance. Alternatively, the performance improvement potential is conditioned to the current position on the production curve or to the current level of effort.

If the production function is a significant part of economic theory, why has it generally been ignored in the budgeting literature? In our own judgment, the reason lies in the fact that effort is an extremely difficult construct to quantify in each different setting. Testing our predictions necessarily requires the development of a quantitative variable able to capture the position of an agent on the production function with effort as input.

Conceptually, how hard a person works (effort) is different from job performance. Rather, it is necessary to search for a suitable point of reference. In other disciplines such as finance, it is common to look for a benchmark against which to compare the performance or the returns of a financial asset (for instance the Capital asset pricing model). Relative performance is a coined term that refers to the performance of a security compared to that of a relevant index.

In compensation theory, if the shocks to firm performance are correlated across firms in an industry (i.e., under common underlying uncertainty), then the optimal incentive scheme compensates a firm's manager on the performance of her firm relative to those of other firms (see Holmström (1982)). Relative performance evaluation (RPE) has often been identified as an effective way of eliminating noise in performance evaluation and enhancing its effectiveness (Holmstrom 1982; Holmstrom and Milgrom 1987). At the top management level, relative performance evaluation is associated with external criteria such as the level of performance of comparable companies ("peer group") (Aggarwal and Samwick 1999; Garvey and Milbourn 2003). Comparable companies relevant to RPE have been shown to be companies not only within the same industry but also similar in size, technology, and complexity (Albuquerque 2009). At a

responsibility center level, centers are more comparable the closer they are in size, operational structure and market environment.

H1: There is a decreasing relation between expected changes in performance and current relative performance with respect to peers.

Diminishing returns to effort (i.e., the performance-effort concavity shape) have important implications on target setting. First, the increase in targets that can be rationally requested from agents should be linked to their current position on the production curve, determined by the current level of effort. Second, when targets ratchet, “agents make a trade-off between the current rewards derived from favorable performance and the future losses derived from the assignment of higher targets. If an agent becomes convinced that manipulating future targets—for example, by reducing their current performance—will increase the total wealth they stand to gain from current and (expected) future performance, they will do so.” (Bowens et al. 2011, p 6).” The strength of this pervasive incentive effect, referred to in the literature as the “ratchet effect” (see, e.g., Murphy (2000), Bowens et al. 2011.), is expected to increase with the current level of effort. Those agents already near their maximum capacity will tend to hold back effort to avoid any over-fulfillment of targets (positive deviation from targets) that would result in even more difficult future targets. However, the moral hazard problem will not be as severe for easier current targets. Equal deviations from targets, and equal target revisions, will trigger different reactions in terms of effort on the part of the agents. Aware of this phenomenon, senior managers would react rationally by conditioning the strength of target ratcheting to the position on the production curve.

As far as we know, prior budgeting literature has overlooked these two implications: the dependence of the target revision process, and the incentive problems that come along, on the production curve. Both in the theoretical work of Weitzman (80) and in the empirical tests of Leone and Rock (2002), the change in targets is modeled as an independent increment, which represents how much the target would change if it were exactly met, plus a linear function of the deviation in performance from target -- strength of the ratchet principle (equation 3 in both authors).

The independent increment is the same for all observations (business units from the North American division of a large multinational corporation in the case of Leone). For example, if business-units A and B exactly met the profit target before interest and taxes in period t (there was no deviation), both would see their target increased by the same amount, even if the target in period t was \$1.911M for unit A and \$7.641M³ for business-unit B. The difference in the level of targets between units, A and B, would also imply differences in the relative degree of effort. This, leveraging on the diminishing returns to effort, we claim that the revision in targets for each observation in the sample (business-units or branches in our empirical analysis) should adjust for the level of effort implied in its current target. That is, when revising targets, senior managers should complement past performance information (i.e., ratcheting) with an additional source of information that captures the relation between effort and performance, as the performance levels increase. In other words, we predict a direct effect of effort on the revision target process. In the comparison of each agent’s performance to that of their peers, targeted performance is considered instead of actual,

³ Figures are from Leone and Rock’s Table 3, Q1 and Q3.

we will measure the relative degree of difficulty -- effort – implied in the given target. In this case, we will refer to relative performance with the term relative target setting (hereafter RTS). Then

H2: Relative Target setting is negatively associated with performance targets.

In relation to the modelization of the ratchet principle, the budgeting literature (Leone and Rock, 2002,...) has used a linear equation. The coefficient represents the change in targets associated to a change in the variance from the previous year's target. For example, in Exhibit 4 of Leone and Rock (2002) the estimated coefficient is 0.868⁴. The target for the next period will increase in this amount per dollar of positive variance. The fact that this coefficient is modeled as a constant implies the same target revision per unit of variance.

However, the improvement potential upon a certain positive deviation from current targets, and the strength of the moral hazard problem, depend considerably on the current level of effort. As effort level increases and agents move to the right on the production curve, any further improvement in performance is more costly in terms of effort. Similarly, agents confront higher moral hazard problems. For both reasons, the informational content of past performance varies with the position on the production curve, and, [consequently, the coefficient that captures and incorporates this source of information into the target revision process should also vary: equal positive deviations from targets (i.e. ratcheting of the same magnitude) will have to trigger different changes in targets. That is, senior managers will increase targets to a lower extent as agents move to the right on the production curve. We predict a negative sign for the interaction effect.

H3: Higher relative target setting (RTS) reduces the impact of target ratcheting on performance targets.

Research Design

Description of the research site

This study uses quantitative and qualitative field data from a large European travel company together with official government data for the industry. The company has operations in all of the stages of the industry's value chain including: travel agencies, tour operators, airlines, receiving agencies, and hotel chains. The travel agency has four business units: (1) vacation (individual), (2) business travel, (3) conventions and incentive trips and, (4) conference organizing. The research site for this study is the vacation division within the travel agency division that had a revenue of €444 million in 2006, about 60% of the travel agency's revenues.

The vacation division had between 244 (2003) and 361 (2006) branches located in a European country and structured around 13 geographic areas, each one managed by a regional director. These branches, treated as a separate responsibility centers, sell only vacation products; the other three business units use different distribution channels for their products with a heavy emphasis on a direct sales force. Each year branch managers

⁴ The modelization of the ratchet principle is asymmetric in Leone and Rock (2002). For a negative variance, the next year's target decreases in \$ 0.521 (0.868 -0.347).

have a revenue target for their branches linked to economic compensation. This target is set for what the company calls “guided sales.” These are sales of products from other divisions in the company (tour operator, airline, receiving agencies, and hotels) and specific suppliers considered as strategic for the company. The ratio of “guided sales” to total branch sales (which has been increasing throughout the years) is decided at the division level. Therefore, once a target “guided sales” is defined, overall sales are also set through this ratio. The target profit for the branch is also set through expense ratios (such as representation expenses over sales, discounts over sales, etc) in a similar way as total target sales are determined. Thus, once the target “guided sales” is decided, the rest of the branch’s income statement is created mechanically through mathematical calculations.

The “guided sales” budgeting process starts with a negotiation between the branch manager and the regional director. This negotiation takes into account last year’s performance, expected changes in the industry, changes specific to the particular geographic area of the branch, and any relevant unique issues that the branch may face. Once “guided sales” targets have been set for all branches, regional directors review the overall target with the general manager of the division to insure that branches’ targets reach the financial objectives set for the division. Regional directors then inform branch managers about their final “guided sales” and associated profit target.

The incentive system works at the branch level and the bonus for the branch is assigned to the employees of the branch according to their professional rank. Table I describes the incentive system. The bonus accounts for 10 to 20% of a branch employee’s salary. Half of the bonus is associated to “guided sales.” This part of the bonus is paid bimonthly and kicks in from the first euro sold (much like a commission). The other half of the bonus is determined at the end of the year and is based on profits. This part of the bonus has a floor at 70% of the targeted profit below which this half of the bonus is not paid. Between 70% and 130% of the targeted profit there is a linear relationship between target achievement and the bonus; if the branch reaches 70% of the profit target it receives 70% of this part of the bonus, at 100% the branch gets the full payment associated with this piece of the bonus, and at 130% it gets 130%. Beyond this threshold, the bonus does not increase. For example, a branch that precisely meets its “guided sales” and its profit targets, would get 100% of the bonus. A branch that sells 10% above its target “guided sales” would receive a sales-related bonus of 55% of the expected total bonus ($110\% * 50\%$); if this branch’s profit was 20% above the targeted profit it would receive an additional 60% ($50\% * 120\%$) of the expected total bonus. The total bonus would be 115% of the expected total bonus.

Table I
Incentive System for Branches

Estimation period: One year

Performance measures	Weight	Thresholds and caps
“Guided sales”	50%	None
Profit	50%	Less than 70% of the target: 0% of the bonus Between 70% and 100% of the target: linear; full bonus payout if it reaches 100%

		Between 100% and 130% of the target: linear up to 130% of full bonus payout Beyond 130% of the target: 130% of the full bonus payout
Non-financial performance measures Internal audit Database management Discounts Bad debt	Associated with prizes and/or penalties	Based on scales Based on scales Proportional Based on scales

In addition to this two-piece bonus, branches have rewards (and penalties) associated with the outcome of internal audits, quality of the customer database, level of discounts given, and bad debt expense. A subjective bonus may be added to this incentive scheme to account for exceptional events at a particular branch.

Data collection and variable description

The study is based on a total population of 376 branches of the vacation business unit during the period between 2002 and 2006. For a branch-year to be included in the analysis, we require performance information actual (A_{t-1}) and budgeted “guided sales” (B_{t-1}) for year $t-1$, budgeted “guided sales” (B_t) for year t , and other relevant variables for year t (all of them available if B_t is available). Thus, our first year of analysis is 2003 (using budgeted “guided sales” for 2003 and actual performance in 2002) and our last year is 2006 (using budgeted “guided sales” for 2006 and actual performance in 2005). The total number of branch-year observations is 1,105. Table II describes how the final sample is determined. For a certain year only offices that worked the previous year and were not closed during the current year (for which there is no budget for the year as the decision to close is made before the year starts) are eligible. For instance, to build the 2005 sample, we start with the 294 branches that worked in 2004 and thus their actual versus budgeted performance is available ($A_{t-1} - B_{t-1}$). We subtract the 11 branches that were closed during 2005 for a 2005 final sample of 283. In addition, 78 branches were opened during 2005 (for which we have B_t but not $A_{t-1} - B_{t-1}$) giving a starting number of branches for 2006 of 361.

Table II
Sample Construction

	Years				Total
	2003	2004	2005	2006	
Number of offices with information available from the previous year: $A_{t-1} - B_{t-1}$	244	238	294	361	
Number of offices closed for which there is no information on the current year: B_t	7	4	11	9	
# Observations for the year	237	234	283	352	1,106

Number of offices opened during the year for which there is no information from the previous year: $A_{t-1} - B_{t-1}$	1	60	78	38
Missing data				<u>1</u>
Final sample				<u>1,105</u>

Table III, Panel A provides descriptive statistics from 2002 to 2006 on budgeted and actual average branch “guided sales” and total sales and the relationship between these two variables. During this period, target “guided sales” grew from €647,596 to €929,385 and the percentage of target “guided sales” to total sales also grew from 67.6% in 2002 to 76.8% in 2006. The budget increase for “guided sales” varied from 15.5% (2003) to -0.54% (2006). Actual “guided sales” growth varied between 15.9% (2003) and 3.6% (2005). Finally, Panel A, Table 3 indicates that the percentage of branches that exceeded the “guided sales” budget varied between 25.2% (2005) and 50.7% (2004) (the average percentage of year-branches that exceeded this target was 42.3%).

Table III, Panel B provides additional descriptive statistics on the previous variables. The average “guided sales” are €766,615 compared with an average target of €840,329. The average percentage of actual “guided sales” over total sales is 75.7% while the average target is 73.9%. Finally mean branches’ “guided sales” were €28,932 below their targets.

Panel B: Descriptive Statistics of the Sample

Variable	Mean	Std. dev.	Q1	Median	Q3
A_t	766,615	406,855	494,597	689,608	956,919
B_t	840,329	406,005	580,131	754,141	1,024,311
A_t/AS_t	0.757	0.101	0.703	0.773	0.826
B_t/BS_t	0.739	0.086	0.690	0.748	0.801
$(A_t - B_t)$	-28,932	154,660	-120,145	-28,486	58,288
$(A_t - B_t) > 0$	104,934	116,572	33,539	75,935	135,577
$(A_t - B_t) < 0$	-122,951	-98,739	-51,141	-100,072	-173,937

A_t is actual "guided sales," B_t is budgeted "guided sales," AS_t is actual total sales, and BS_t is budgeted total sales.

Our variable of interest is the change in budgeted “guided sales” defined as $(B_{i,t} - B_{i,t-1})$. The ratcheting effect predicts a relationship between this change in budgeted “guided sales” and last year’s actual “guided sales” relative to their target defined as $(A_{i,t-1} - B_{i,t-1})$. We further define a dummy variable to capture the possibility of an asymmetric impact of the ratcheting effect depending on whether the variance is favorable or unfavorable. $U_{i,t-1}$ is equal to 1 for unfavorable variances ($A_{i,t-1} < B_{i,t-1}$) and zero otherwise (see Leone and Rock, 2002).

Supervisors can incorporate information from comparable branches to remove noise from the target and to make evaluation more effective. In our setting, branches meet the necessary requirements to be considered as comparable for they sell similar products with pretty homogeneous marketing and operation practices. In addition, once targets are set for all branches, these have negligible influence over accounting decisions (e.g. discretionary accruals), pricing policies or investment expenditures. To increase performance, branches have few options other than expending more effort (much in line with the argumentation elaborated by Bouwens and Kross (forthcoming JAE). Sales activity in this setting could be considered as an effort-intensive task, and according to our arguments, the actual performance of a branch relative to those of its peers will capture the relative level of effort, and therefore, will signal the location on the production curve. Relative performance per branch (RP) is measured comparing its actual “guided sales” per employee (to consider size effects) to the average actual “guided sales” per employee for the branches in its region. In particular we define it as:⁵

$$RP = A_{i,t-1} / employees_{i,t-1} - (\sum_{j=1}^n A_{j,t-1} / employees_{j,t-1}) / n$$

Where n is the number of branches in the region. A positive RP indicates a current relative level of effort higher the average level of effort for the branches in the same region. The larger is the value of RP, the further to the right on the production curve is a branch. RP is the measure used in testing hypothesis 1.

Hypotheses 2 and 3 examine the interplay of the factors that influence the target setting process. Targeted “guided sales” is the variable of interest, and therefore we develop a measure of the relative degree of difficulty of targets: relative target setting (RTS). RTS conveys the same idea as RP, and also has the same definition but substituting budgeting “guided sales” for actual “guided sales”. The definition then is:

$$RTS = B_{i,t-1} / employees_{i,t-1} - (\sum_{j=1}^n B_{j,t-1} / employees_{j,t-1}) / n$$

As in the above formula, a positive relative target setting indicates a challenging target in that it is higher than that of the branches in the same region. A negative RTS indicates the opposite.

In addition to the main variables in the model, we control for variables that may affect changes in targets over time. Branches that have additional resources to their disposal are likely to see their targets increase. Our research site has a service orientation and its main resource is the employees who perform the commercial transactions. The main

⁵ We use last year’s targeted performance to avoid transitory components that may affect actual performance. We also ran all our tests using the same variable definition but replacing budget with actual performance. The results reported are robust to using last year’s actual performance instead of targeted performance unless reported otherwise. The correlation between RTS using budget and actual performance is 61%. We also ran tests incorporating both variables together to explore whether relative difficulty (budgets) has a different effect from relative performance (actual).

resource is the number of people working at the branch. We measure the “additional branch resources” variable as the change in the number of employees in the branch from the previous to the current year. This definition considers the fact that most decisions about the size of a branch (in terms of number of employees) are made during the planning period. Because at certain periods during the year temporary personnel is hired, we define number of employees as total number of hours worked divided by the working hours of a full-time employee. To control for size we include number of employees.

We control for changes in the level of competition as an increase in the number of competitors will affect the expected level of sales. We capture the change in competition as the change in the number of travel agencies’ branches (our research site as well as its competitors) per thousand inhabitants. This data comes from the government statistical office. We compare the current to the previous year. We measure this variable at the regional level.

Because the uncertainty around the performance potential may vary among branches, we separate new and mature branches using a dummy that identifies those branches older than four years.

We also control for changing economic conditions across time using dummy variables for each year. Targets may vary year to year depending on expectations for the coming year and whether the economic situation will improve or deteriorate.

Finally, we include a dummy for each region to control for the potential effect associated with the supervisor. Because the target setting process is negotiated between the branches and the regional supervisor, this person’s approach to the target setting process may affect the final targets.

Table 4 presents descriptive statistics on these variables. The average increase in “guided sales” target is €71,101.84 with more than 25% of the branches having their target reduced from one year to the next. Relative target setting (RTS) has a value of -€37,337 in its first quartile (25%) and €38,877 in its third quartile (75%) indicating significant variation of effort across branches. Half of the branch-year observations do not see changes in their number of employees consistent with most branches working at a steady state regime. Finally, branch density shows a high dispersion across regions and increases during this period at about a 4.6% yearly rate.

Table IV
Descriptive Statistics for the Sample

Variable	Mean	Std. Dev.	Q1	Median	Q3
$(\mathbf{B}_t - \mathbf{B}_{t-1})$	71,101.84	166,795.5	-19,561	73,951	156,575
RTS_{t-1}	0.000	68,264.81	-37,337	475	38,877
Emp_{t-1}	2.614	1.010	2.000	2.5	3.000
ΔEmp_t	0.171	0.608	-0.080	0.060	0.450
$Comp_{t-1}$	340.97	140.65	245.89	325.92	392.58
$\Delta Comp_t$	12.811	14.172	4.030	12.770	24.090

\mathbf{B}_t is the “guided sales” target for the current year, \mathbf{B}_{t-1} is the “guided sales” target for the previous year

RTS_{t-1} is the relative target setting defined as $B_{i,t-1} / employees_{i,t-1} - (\sum_{j=1}^n B_{j,t-1} / employees_{j,t-1}) / n$, Emp_{t-1} is employees in the previous year, ΔEmp_t is defined as $(employees_t - employees_{t-1})$, $Comp_{t-1}$ is the density of travel agencies' branches (number of branches divided per thousand inhabitants) in a region in the previous year and $\Delta Comp_t$ is the change in the density of agencies from the previous to the current year.

Results

Test of hypothesis 1

Hypothesis 1 proposes the relative performance (RP) of a branch as a proxy for its position on the production curve. Relative performance actually captures changes in the relation between effort and performance as performance levels increase. Intuitively, as effort levels increase and maximum capacity is approached, more effort is required to achieve the same improvement in performance. For instance, suppose that the maximum sales capacity for an employee is 1. Increasing sales in one period from .90 to .92 requires significantly more effort than moving from .50 to .52.

To empirically test if a branch's changes in performance depend on its current relative performance, and if these changes exhibit diminishing returns to scale, we apply two approaches. In the first one, for each branch we calculate the change in actual "guided sales" per employee as $(A_{i,t} / employees_{i,t} - A_{i,t-1} / employees_{i,t-1})$ and we regress it against relative performance ($RP_{i,t-1}$). The estimated coefficient (table V, panel A) is negative (-0.33) and statistically significant ($p < 0.05$).

Table V

Test of Hypothesis 1. Decreasing returns to effort

Panel A: linear regression

Model (1)

$$(A_{i,t} / Emp_{i,t}) - (A_{i,t-1} / Emp_{i,t-1}) = RP_{i,t-1} +$$

$$+ \alpha_1 comp_{n,t} + \alpha_2 Emp_{i,t} + \alpha_3 Year_04_i + \alpha_4 Year_05_i + \alpha_5 Year_06_i + \sum \eta_j Z_j + \varepsilon_{i,t}$$

Variable	Coefficient	Predictions	Results
			Model (1)
Intercept	□	?	121,015.8 ** (2.27)
RP _{i,t-1}	□	-	-0.33 *** (-11.98)
Comp _{n,t}	□ ₁	-	-378.65 ** (-2.30)
Emp _{i,t}	□□	-	5,123.4 ** (2.14)
N			1,276
Adjusted R ²			20.29%

For the second approach, we use a probabilistic model. We run a binary logistic model in which the dependent variable equals 1 if performance improves from one year to the

next (i.e., $A_{i,t} / \text{employees}_{i,t} - A_{i,t-1} / \text{employees}_{i,t-1}$ is greater than 0), and otherwise equals 0. We test the significance of the coefficient (table V, Panel B) and conclude that RP has a significant effect on the probability of an increase in the targets (z-statistic=-9.41, $p < 0.01$ for a two tailed test).

To ease the interpretation, we estimate the predicted probability of an increase in the targets for two different values of $RP_{i,t-1}$, with control variables held at their mean: a value in the upper quartile (€112,994.2) and another value in the lower quartile (€753.81). The predicted probabilities are 0.3820 and 0.6513 respectively, and the confidence intervals for these probabilities are [0.3238, 0.4402] and [0.6230, 0.6797]. At these values, we are 95% confident that the probability of an increase in the targets for a current target in the upper quartile of effort is approximately 20% lower than the probability for a current target in the lower quartile⁶.

*, **, *** Statistically significant at 10%, 5% and 1% respectively. *t*-statistics are in parentheses.

$A_{i,t-1}$ = Actual performance for year *t*-1 for branch *i*.

Comp_{n,t-1} = #branches/Million of habitants from year *t*-1 to year *t* in geographic area *n*.

Emp_{i,t-1} = number of employees

Year_0x = 1 if observation year corresponds to year 200x. These three variables are included but not reported.

Zx = 1 if branch belongs to region x. These thirteen variables are included but not reported.

RP = Relative performance defined as

$$A_{i,t-1} / \text{employees}_{i,t-1} - \left(\sum_{j=1}^n A_{j,t-1} / \text{employees}_{j,t-1} \right) / n$$

⁶ As robustness check, we have estimated the predicted probabilities for other values in the quartiles, obtaining consistent results.

Empirical evidence for both approaches supports H1, and it is consistent with the interpretation that relative performance of a branch with respect to its peers captures the position of this branch on the production curve.

Basic Ratcheting effect and the direct effect of relative target setting (Hypothesis 2)

Having proven that RP is a good proxy for the position on the production curve, hypotheses 2 and 3 test whether or not, when revising targets, managers consider not only performance variances on previous year target but also the relative position of this target with respect to that of comparable branches (RTS).

As a starting point and to empirically examine the evidence of target ratcheting and to compare it with the work of Leone and Rock (2002), we estimate the following regression model (2):

$$(B_{i,t} - B_{i,t-1}) = \alpha + \beta(A_{i,t-1} - B_{i,t-1}) + \lambda U_{i,t-1} (A_{i,t-1} - B_{i,t-1}) + \varepsilon_{i,t}$$

Where B_t is the current year's budget, B_{t-1} is the budget for the previous year and A_{t-1} is the actual performance for the previous year. β is the ratcheting coefficient for favorable variances and λ is the differential coefficient for unfavorable variances (U_{t-1} is one for unfavorable variance and zero otherwise). We estimate the model controlling for region, year, employee growth, change in local competition, number of employees, and branch maturity. To handle heteroskedasticity, we use Huber-White robust standard errors clustered by store.⁷

We predict both coefficients to be significant and of opposite signs ($\beta > 0$ and $\lambda < 0$), consistent with evidence of asymmetric target ratcheting in prior work, being moreover more pronounced for favorable variances (Leone and Rock 2002; Lee and Plummer 2007; Ettredge et al. 2008). Asymmetric response coefficients are consistent with various arguments. First, empirical evidence indicates that managers are rewarded for events that they do not control but that benefit their performance measures (luck) and are spared from being penalized when these events move against their performance (Bertrand and Mullainathan 2001). Consistent with this argument, targets would not incorporate favorable variances to facilitate managers' meeting these targets but do so when unfavorable variances provide excuses to ease targets. Because targets are associated with future rewards, including unfavorable variances and excluding favorable ones facilitate meeting targets ($\lambda > 0$). Second, if contracts are written on earnings, accounting conservatism leads to earnings increases that are more permanent than earnings decreases. Accordingly, next year's budget will be more responsive to increases than to decreases. Thus, favorable variances will have a higher impact on next year's targets than unfavorable ones ($\lambda < 0$). However, if targets are written on revenues, accounting conservatism becomes less relevant and this reason for asymmetry may disappear. Third, ratcheting parameters may be asymmetric to provide incentives for managers to invest in actions leading to permanent rather than transitory performance

⁷ An alternative solution for heteroskedasticity is to scale all variables as Leone and Rock (2002) did. Excluding the control variables, a natural candidate for the deflator could be either last year's budget or last year's employees. As a robustness check, we also run the scale modifications obtaining results that are comparable to the results reported here when the model is estimated in absolute terms (euro variances). However, if control variables are included, such as competition, their interpretation, once scaled, turns out to be rather difficult. To the extent that a commonly proposed solution for heteroskedasticity in the literature has been to define variable in percentages (see Barth and Clich 2009), we opted for running the regression in percentages as well. Although not reported in the paper for the sake of brevity and clarity, empirical evidence supporting the hypotheses is also obtained.

improvements.⁸ Fourth, managers' incentives often have a call option shape bounded at zero if the minimum performance is not met. Favorable variances are rewarded through the bonus while unfavorable variances are bounded at zero bonus (rather than becoming negative). The magnitude of ratcheting influences the level of reward and punishment to changes in performance.⁹

Table VI reports the results. The R^2 is 64.81% suggesting that there is still a significant amount of variation that ratcheting does not explain.¹⁰ Ratcheting is indeed present, consistent with prior evidence.¹¹ Each euro increase in last year's performance over its target is associated with a 0.57 increase in this year's target compared to last year's. Different from previous studies though, the coefficient of asymmetry (λ) is not significant.

Table VI

Test of Ratcheting and RTS in absolute terms

Model (2)

$$(B_{i,t} - B_{i,t-1}) = \alpha_0 + \beta(A_{i,t-1} - B_{i,t-1}) + \lambda U_{i,t-1}(A_{i,t-1} - B_{i,t-1}) + \alpha_1 \Delta Emp_{i,t} + \alpha_2 \Delta Comp_{n,t} + \alpha_3 Emp_{i,t-1} + \alpha_4 Mature_i + \alpha_5 Year_04_i + \alpha_6 Year_05_i + \alpha_7 Year_06_i + \sum \eta_j Z_j + \alpha_8 U_{i,t-1} + \varepsilon_{i,t}$$

Model (3)

$$(B_{i,t} - B_{i,t-1}) = \alpha_0 + \beta(A_{i,t-1} - B_{i,t-1}) + \lambda U_{i,t-1}(A_{i,t-1} - B_{i,t-1}) + \gamma RTS_{i,t-1} + \alpha_1 \Delta Emp_{i,t} + \alpha_2 \Delta Comp_{n,t} + \alpha_3 Emp_{i,t-1} + \alpha_4 Mature_i + \alpha_5 Year_04_i + \alpha_6 Year_05_i + \alpha_7 Year_06_i + \sum \eta_j Z_j + \alpha_8 U_{i,t-1} + \varepsilon_{i,t}$$

⁸ Leone and Rock (2002) provide a numerical example on this argument.

⁹ An expansion of the example in Leone and Rock (2002) that illustrates the implications of this type of bonus structure is available from the authors upon request.

¹⁰ In contrast, Leone and Rock (2002) have an R^2 of about 75%. This difference implies that despite both research settings deal with internally set targets, our research site appears to rely to a much less extent on the previous year performance when setting targets.

¹¹ We also run the model controlling for change in sales in the previous year to include an additional control for growth. This model loses all the observations from the first year. The results were comparable.

*, **, *** Statistically significant at 10%, 5% and 1% respectively. *t*-statistics are in parentheses.

$B_{i,t}$ = Budget performance (performance target) for year *t* for branch *i*.

$B_{i,t-1}$ = Budget performance (performance target) for year *t-1* for branch *i*.

$A_{i,t-1}$ = Actual performance for year *t-1* for branch *i*.

$U_{i,t-1}$ = 1 if $A_{i,t-1} < B_{i,t-1}$, 0 otherwise.

$\Delta Emp_{i,t}$ = Change in number of employees from year *t-1* and year *t*.

$\Delta Comp_{n,t}$ = Change in #branches/Million of habitants from year *t-1* to year *t* in geographic area *n*.

$Emp_{i,t-1}$ = Prior year's number of employees

Mature = 1 if branch *i* at time *t-1* is 5 years old or older, 0 otherwise.

Year_0x = 1 if observation year corresponds to year 200x.

Zx = 1 if branch belongs to region x. These thirteen variables are included but not reported.

RTS = Relative target setting defined as

$$B_{i,t-1} / employees_{i,t-1} - \left(\sum_{j=1}^n B_{j,t-1} / employees_{j,t-1} \right) / n$$

Despite the fact that our results at this point seem to be inconsistent with the results of previous work¹², we will ultimately show how the introduction of the productive capacity into the model helps to reconcile the findings. Once the consequences of productive capacity are discussed, our results will be comparable to those of Leone and Rock (2002), notwithstanding the apparent contradiction.

As a first step in this discussion, we test the direct effect of RTS on the target setting process. Table VI presents the results of testing the predictions of hypothesis 2. Model (3) includes the relative target setting variable as well as the control variables. If the target for the previous year of a branch relative to comparable branches (branches in the same geographic area) affects the target revision process, then the coefficient on RTS is expected to be different from zero. Moreover, if relative performance information captures the branch position on the production curve, then the coefficient will be

¹² Even though empirical studies support asymmetry, theoretically, there are several arguments in favor of symmetry. The symmetric design would be consistent with managers valuing favorable and unfavorable performance similarly. It is also consistent with accounting conservatism not being relevant to the financial measure used for bonuses. Managers may want to set symmetric incentives for permanent performance increases and decreases because both have similar informational content.

negative. This argument is consistent with supervisors increasing the target for branches that had demanding targets the previous year (targets located to the right in the production curve) to a lower extent than those that had easier targets. The model tested is:

$$(B_{i,t} - B_{i,t-1}) = \alpha + \beta(A_{i,t-1} - B_{i,t-1}) + \lambda U_{i,t-1} (A_{i,t-1} - B_{i,t-1}) + \gamma RTS_{i,t-1} + \varepsilon_{i,t}$$

In consistency with the arguments exposed, the coefficient on RTS is negative and significant (-0.62). The coefficient of ratcheting does not change. It is still significant and symmetric, and it has a magnitude comparable to that of the relative target setting. The amount of variance explained increases from 64.8% (Table 5) to 69.2% if RTS is added to the model in Table 6¹³

Test of hypothesis 3: the interaction between budget ratcheting and productive capacity

Model (4) introduces interaction effects to capture the third hypothesis: whether ratcheting might interact with RTS inasmuch as it signals the position on the production curve. Thus, the impact of ratcheting might not be constant but decrease with RTS. The coefficient on this interaction term is expected to be negative as higher values for RTS are associated with more exigent targets that leave less room for further favorable variances. In addition to this, the higher level of effort necessary to meet the more demanding targets will trigger more severe pervasive incentive effects that will also tend to reduce favorable variances from targeted values.

The model (model 4) tested is:

$$B_{i,t} - B_{i,t-1} = \alpha + \beta(A_{i,t-1} - B_{i,t-1}) + \lambda U_{i,t-1} (A_{i,t-1} - B_{i,t-1}) + \gamma RTS_{i,t-1} + \phi_1 RTS_{i,t-1} * (A_{i,t-1} - B_{i,t-1}) + \phi_2 RTS_{i,t-1} * U_{i,t-1} (A_{i,t-1} - B_{i,t-1}) + \varepsilon_{i,t}$$

The coefficient for the interaction term between RTS and favorable variances is \square_1 . Table VII reports the results. In comparison with Table VI, the coefficients on ratcheting remain positive, significant and symmetric. Likewise, the coefficient of the direct effect of RTS remains negative and significant (-0.48). This result indicates that when the previous year's actual was equal to its budgeted level ($A_{t-1}-B_{t-1}=0$), RTS modifies the increase in targets estimated in the intercept (€71,739.2). Targets will increase to a lower extent for branches that were above the region's average, i.e. for positive values of RTS. On the contrary, for branches below the average, RTS amplifies the increase in targets captured by the intercept.

Table VII

Test of interaction between ratcheting and RTS

Model (4)

$$(B_{i,t} - B_{i,t-1}) = \alpha_0 + \beta(A_{i,t-1} - B_{i,t-1}) + \lambda U_{i,t-1} (A_{i,t-1} - B_{i,t-1}) + \gamma RTS_{i,t-1} + \phi_1 RTS_{i,t-1} * (A_{i,t-1} - B_{i,t-1}) + \phi_2 RTS_{i,t-1} * U_{i,t-1} (A_{i,t-1} - B_{i,t-1}) + \alpha_1 \Delta Emp_{i,t} + \alpha_2 \Delta Comp_{n,t} + \alpha_3 Emp_{i,t-1} + \alpha_4 Mature_i + \alpha_5 Year_04_i + \alpha_6 Year_05_i + \alpha_7 Year_06_i + \sum \eta_j Z_j + \alpha_8 U_{i,t-1} + \varepsilon_{i,t}$$

¹³ Defining RTS using actual performance in the previous year instead of targeted performance leads to identical conclusions. The coefficient for RTS is negative and significant (-0.31) as well as the coefficients on the ratcheting effect.

*, **, *** Statistically significant at 10%, 5% and 1% respectively. *t*-statistics are in parentheses.

$B_{i,t}$ = Budget performance (performance target) for year *t* for branch *i*.

$B_{i,t-1}$ = Budget performance (performance target) for year *t-1* for branch *i*.

$A_{i,t-1}$ = Actual performance for year *t-1* for branch *i*.

$U_{i,t-1}$ = 1 if $A_{i,t-1} < B_{i,t-1}$, 0 otherwise.

$\Delta Emp_{i,t}$ = Change in number of employees from year *t-1* and year *t*.

$\Delta Comp_{n,t}$ = Change in #branches/Million of habitants from year *t-1* to year *t* in geographic area *n*.

$Emp_{i,t-1}$ = Prior year's number of employees

Mature = 1 if branch *i* at time *t-1* is 5 years old or older, 0 otherwise.

Year_0x = 1 if observation year corresponds to year 200x. These three variables are included but not reported

Zx = 1 if branch belongs to region x. These thirteen variables are included but not reported.

RTS = Relative target setting defined as

$$B_{i,t-1} / employees_{i,t-1} - \left(\sum_{j=1}^n B_{j,t-1} / employees_{j,t-1} \right) / n$$

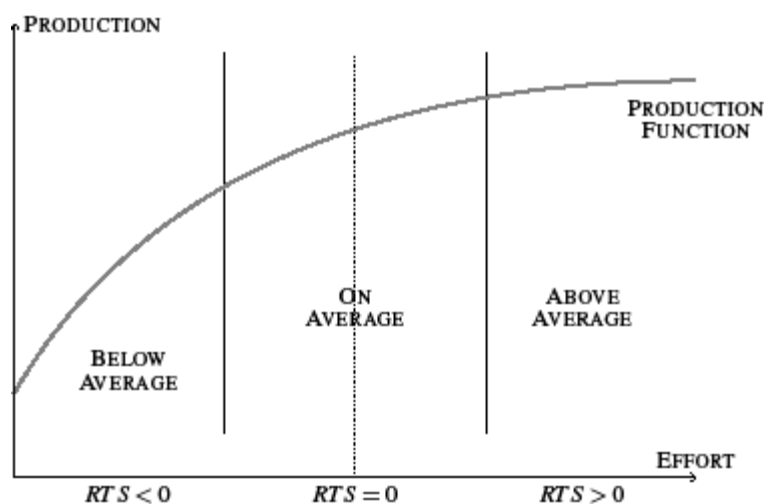

The coefficients of the interaction term for favorable variances, \square_1 , is significant, and in the expected direction. The negative sign indicates that the increase in targets following

a favorable variance is attenuated for those branches having a positive RTS the previous period. Thus, considering the definition of RTS, the negative sign of the coefficient implies a lower ratcheting for those branches which had a challenging target higher than that of the average of branches in the same region. On the other hand, those branches with negative RTS will see their targets increased to a higher extent in this model as a way to incorporate the fact that on the left side of the production curve there is considerably more room for performance improvement.

As an additional test to support the argument that the level of ratcheting depends on the position on the production curve, we grouped the observations into three equal groups according to the magnitude of RTS (see Figure 1) and estimated models 1 and 2 for each zone of the figure. The first group (named below average) included the 33 percent of the bottom branch-year observations for the RTS variable, the medium group (on average) included those with a magnitude of RTS in the range of 33 percent to 66 percent of the sample distribution, and the large RTS group (above average) included the upper 33 percent.¹⁴

Figure1.

Ratcheting effect and regions of the production curve

The region “Below Average” includes the 33 percent of the bottom branch-year observations.

The region “On Average” includes sample data with a magnitude of RTS in the range of 33 percent to 66 percent of the sample distribution.

The region “Above Average” includes the upper 33 percent of the observations.

The main results, shown in Table VIII, can be summarized as follows. First, ratcheting diminishes as we move from the average group to the above average group.

¹⁴ To divide the sample in three equal groups, the exact percentage used was 33.33%.

Branches on the top 33% will see their target increased in €0.47 (or €0.49 in model 2) per dollar of favorable variance, in contrast to an increase of €0.64 for the branches located in the middle zone (i.e., on average). Consistent with our arguments, the increase in the target that follows a favorable variance is smaller the closer the branches get to maximum capacity.

The second important result obtained from the analysis of the three zones is that RTS is not significant in the average target difficulty zone. When targets are exactly fulfilled and variances are null, the budget changes are of the same magnitude for all branches. This is not the case when the values of RTS are in the bottom and in the upper percentiles. For branches here, the position on the production curve is taken into account in the target revision process.

The third result to discuss is related to the asymmetry of ratcheting. To this respect, the three zones clearly exhibit a different behavior. For those branches with a target difficulty value around the average, i.e., small values of RTS located in the average zone of the production curve, the coefficient of asymmetry ($\alpha=0.07$) is not significant. Senior managers do not distinguish between favorable and unfavorable variances when revising targets. Branches are located in an intermediate zone in terms of the effort required to increase performance; there is room for performance improvement as well as for performance worsening. This fact leads to a lack of asymmetry in ratcheting. Very much on the contrary, the asymmetry of ratcheting is significant on the two extremes of the production curve. Not only are the coefficients of asymmetry significant, but also and more importantly, they have opposite signs: negative (-0.30, model 1) in the below average and positive (0.34, model 1) in the above average zone. The negative sign implies that positive variances in performance lead to greater absolute changes in the following period's budget than do changes triggered by negative variances of the same magnitude. The result in this zone is in line with the findings of previous empirical studies such Leone and Rock (2002) and B&k (2010). The positive sign rather means that the decrease in targets undertaken upon an unfavorable variance is greater than the increase that follows a positive variance of the same magnitude. Senior managers perceive an unfavorable variance performance as a sign that branches are about to reach maximum capacity. Targets seem to be too exigent and might trigger the undesired effect of demotivating employees (Fisher, Peffer and Sprinkle 2003, JMAR).

Summarizing, the level and asymmetry of ratcheting is ultimately linked to the production curve. Budget ratcheting and productive capacity interact: the magnitude of the target change, and the degree of asymmetry, resulting from a favorable or unfavorable performance variance will vary with the position of a branch in the production curve. This theory, supported by our empirical analysis, enables us to reconcile and provide an explanation for the difference in the asymmetry of ratcheting between our results and those obtained in previous studies. While for the complete sample we estimate a symmetric ratcheting, Leone and Rock (2002) and B& K (2010) reported an asymmetric coefficient of a greater magnitude for favorable variances. This negative asymmetry is consistent with our results for the below average zone. Ultimately, the asymmetric coefficients would reveal the senior managers' beliefs about the specific position of the majority of branches on the production curve. If managers had the idea that the branches of the firm were generally operating in the bottom part of the production curve, the change in targets would follow this pattern. In light of our results, if managers thought that branches were mainly operating in the middle zone of the production curve (with small values of RTS), we then would observe a symmetric ratcheting coefficient. Similarly, if senior managers would perceive that branches are close to reach maximum capacity, the ratcheting would exhibit a positive asymmetry. In the end, the level and asymmetry of ratcheting will depend on the managers' beliefs about the position on the production curve, and consequently the improvement potential of branches.

Conclusions

This study uses field data from branches of a large European travel company to investigate the extent to which productive capacity in an effort-intensive setting influences the level of subsequent targets. Our results show that the effect of the productive capacity (RTS) on the target revision process is twofold. In addition to the direct effect, we find evidence of an interaction effect between productive capacity and budget ratcheting. The level and asymmetry of ratcheting depend on the managers' beliefs about the position of a branch on the production function.

The results reported are relevant in several aspects. First, they highlight the significance of the productive capacity, RTS, as a source of information in addition to past performance associated to budget ratcheting. The results indicate that RTS is relevant in magnitude as it is budget ratcheting, and therefore future research may want to better understand the role of peer groups in setting targets.

Second, the results indicate that past performance, used as a source of information, is not independent of the performance of comparable responsibility centers. The reason is that this performance signals the relative degree of target difficulty or the relative position on the production curve. Traditionally, empirical tests of budget ratcheting have used linear models and have found evidence consistent with asymmetric ratcheting. The constant targets response coefficients of linear models imply an unbounded relation between effort and performance. Senior managers believe that increases in performance are always attainable and require the exertion of the same increment in effort. Consequent with this reasoning, the process of revising targets would be undertaken irrespective of the degree of difficulty of the current targets. Yet, we find evidence that the coefficients in the lineal equation vary with RTS. For branches located in the upper (bottom) zone of the production function, favorable target variances result in performance target increases that are smaller (larger) than decreases associated with unfavorable variances of the same magnitude. The shape of budget ratcheting reported for the lower zone of the production curve, i.e., negative asymmetry, is consistent with the results of previous studies. The equations estimated in these previous studies could be considered as a particular case of our general model; that in which senior managers believe the majority of observations are located in the bottom part of the production curve and have relatively easily achievable targets. The fact that the asymmetry has a positive sign in certain settings and a negative sign in others indicates that target setting is not a structured process (such as formula based incentive systems), managers form their beliefs and weigh the various sources of information differently depending on the overall information set. Thus, target setting is a subjective process but consistent with an information value framework.

The results offer a more complex picture of the target setting process that reflects the interplay of different sources of information available to managers. This process is interesting because it is highly subjective and managers can readily adapt their decisions (reflected in targets) to the information set at their disposal. The research setting is one division within a company. As such, it allowed a research design that controlled for a significant amount of variables that are common across the division that increases the power of the tests. However, the results and especially the magnitudes of the various effects are particular to this setting and cannot be generalized. The results provide empirical evidence consistent with an information processing framework and therefore

support the importance of understanding the information set available to managers in target setting processes.

The results open new questions for future research. First, the asymmetry of the ratcheting effect appears to vary with the information setting. Previous explanations of this asymmetry were unrelated to information available to the manager setting targets. Second, target setting is a complex process, the paper identifies RTS as an additional dimension but other variables may also be relevant beyond past performance and peer group performance. Third, deviations from targets and relative performance may not only be relevant for setting new targets but may be relevant for resource allocation decisions. Again, resource allocation decisions may not only depend on these two variables but a broader set of variables.

Introduction

The technological prediction analysis provides useful indications to guide the investments of market operators belonging to different sectors, with the aim of assuring their competitiveness. The two Garthner's Hype Cycle curves, respectively from 2008 and 2010, show the maturity level of technologies and their development in the market: the x-axis represents the time and the y-axis the visibility. The comparative analysis shows that in only two years, the Augmented Reality changed its position on the curve from a starting phase of the technology to the peak of expectations. This demonstrates that the market operators can consider it as an interesting element of attractiveness.

Figure 1 - Hype Cycle di Garthner, 2008, 2010

Starting from the considerations made on Garthner's curves, the actual level of diffusion of the Augmented Reality in the Italian Cultural Heritage sector will be verified, analysing strengths and weaknesses, opportunities and threats to its implementation.

But what does Augmented Reality mean? With the technology of Augmented Reality, additional information is added on the real scene and this allows the interaction, in a completely innovative way, with the real situation to which the technology is applied. In literature the Augmented Reality (AR) is constantly considered as an evolution of Virtual Reality (VR). In fact, VR represents a three-dimensional interactive environment generated by an IT technology connected with a computer. The diffusion of VR in the scientific and economic fields contributed to the success of its use as first technology able to provide, in the specific context of application, the interaction in real time between user and artificial environment. The environment, in this case, is completely fictitious and distinguished from the environment surrounding the user. The latter can interact with the artificial environment through equipments such as haptic interfaces. Differently from the VR, which operates through a replacement real world-user not taking into account the surrounding environment, the AR enriches the real environment with information through virtual objects performing complex tasks. The result for the user is the coexisting vision of objects of different nature, both virtual and real, in same scene space, increasing the perception and interaction with the addition of visual information, which would not be possible to detect naturally. In 1990, at Boeing

laboratories, the researchers Tom Caudell and David Minzell, both working on a prototype that would substitute the control instruments of an aircraft, created the prelude technology to the current HMD, wearable by the pilots and able to quickly visualize the route, take off and landing information. The technology created was defined Augmented Reality, as information of different nature was added to the real perspective (Aloisio, De Paolis, 2007). Since then, the international technological scenario was characterized by the development and production of more and more sophisticated systems and mainly by the implementation of the same technology in different contexts. The tight link between the two technologies is easily deducible from the description of the taxonomy, according to which the real world and virtual environment are two extreme conditions, on the inside of which the AR is closer to the real environment, as the data collected refer to the real system and symmetrically the augmented virtuality is closer to the virtual technology highlighting the smaller quantity of real data (Milgram, Kishino, 1994).

Figure 2 - Simplified representation of a "virtuality continuum".

Source: After Milgram *et al.* (1994)

The Augmented Reality consists of the overlapping of different levels of information (virtual, multimedia, data delocalization, etc.) to the real experience that a user can carry out while employing a service. The technologies that enable to “augment” the value of the reality are added through devices using different technologies and mainly through mobile devices, in particular last generation mobile phones (*iPhone* or *Android*), or fixed base supports such as personal computers equipped with dedicated accessories as a webcam, vision devices, VR glasses, headset or handling devices and technical use of technology, adding multimedia information to what is naturally perceived in the real scene. The overlapping of these virtual elements with real elements creates a situation of “mixed reality” generating a new service category.

The innovation of AR is not strictly technological, in fact, by adding virtual contents, interactive graphic systems are created, allowing to overstep the limits of reality in real time. With the support of appropriate rendering or motion-tracking devices, maker recognition through virtual vision and the building up of modified environments containing sensors and electronic actuators, the AR enables to mix a live video with three-dimensional objects and animations in real time and with perfect synchronization. The AR technology category includes all the applications aiming at increasing the visual perception of a physical space. An essential principle for the correct use is the parallel coexistence of the two environments, real and virtual, put side-by-side by the freedom of movement of the user in the scene and by the possibility of interacting with it having the impression that the two environments are indistinguishable. The main developments of this technology are based on the use of videos digitally processed, placed side-by-side with graphic components digitally created.

Application of AR to the Cultural Heritage Sector

The use and application of AR technologies implies many advantages in several sectors such as architecture, building, didactic and vocation, entertainment, manufacturing and design, marketing, medicine and psychology. Nevertheless, perspectives of great interest for the development of the AR are those offered by the Cultural Heritage sector. Starting from the 1990s this sector, particularly complex considering the strong professional difference of the actors working in it and the strongly multi-disciplinary character, is affected by a process of transformation and updating providing for the adaptation of the modality of the offer, with the aim of answering to the new social behaviours of visitors, through the introduction of additional services to museums and State owned archaeological sites (Ronchey's Laws, 1993; Cultural Heritage Italian Codex, 2004). It is interesting to highlight that the process of utilization of a cultural good is characterized not only by objective factors, but also by aesthetic, symbolic, psychological and emotional factors, and is therefore marked by a strong subjective and functional worthiness. In fact a double relation takes place between visitor and work of art/performance, but also between service offered and context of reference. The necessity to involve new users and promote the development of the sector pushed towards the exploitation of the good and of the cultural experience through the introduction of additional services, enriching the traditional offer, and new modality of utilization of the visit, with the use of technological applications (First Report of Nomisma on the Ronchey's Laws application, 2000). In particular, the recent developments of technological convergence amplified the impact of innovation on cultural organizations, creating new opportunities to exploit the cultural heritage through the optimization of internal processes, the development of integrated networks and the definition of modalities of service utilization in multi channel. Also the behaviour of those utilizing the cultural goods evolved as consequence of the new social trends based on the increase of income, instruction level and free time, on the enlargement of the offer of services and alternatives connected to the cultural experience (Grandinetti et al., 2004). The most traditional and common instruments used to inform the visitors during the tours are since always paper guides, maps and information panels along the cultural paths (Vlahakis *et al.*, 2004). Nonetheless, the ability of these traditional instruments to positively influence the visitor perception and his learning capacity are not particularly high. In fact, these instruments, although still extensively used, may transform the visit in always more complex experiences in terms of utilization and involvement. In the light of the socio cultural evolution, the users of this type of services are directed to the continuous research of new modalities to satisfy their senses and this along the years translated into a progressive introduction of more and more sophisticated, and at the same time creative and interactive instruments. The introduction of the first technologies in the cultural heritage sector dates back to the 1980s with the application of the primordial tape audio guides (Vlahakis *et al.*, 2003). These models, although very limited in their functioning, had a positive impact on the visitors' ability to live an experience and easily learn during the visits. Along the years, these first instruments were refined with the purpose and making more pleasant the enjoyment of cultural paths and were progressively replaced with sophisticated hardware devices equipped with an internal memory. In this context the first mechanisms of active participation of the user of the service were introduced, and these automatism were considerably developed with the passage to VR technologies. For instance the diffusion of pen-tablets, or rather e-book like devices, through which it is

possible to reproduce presentations also in VR, simply by orienting the tablet towards specific information points located on purpose along the path. This evolution allows the visitors to live realistic historic scenes, dipping into an interactive static context. Nonetheless, following an analysis of the sector, it is possible to state that the Augmented Reality, still in its experimental phase, shows broad potentiality of development in the Cultural heritage sector. In particular, the main advantages offered by the AR derive from the possibility of exploiting this technology through the use of smartphones, whose request on the market is constantly increasing. According to an OFCOM research (OFCOM, 2010), the British Authority for Telecommunications, in Italy reveals the highest diffusion of smart phones in the world, represented by the 26% of the population above 13 years and 66% of the regular Internet users. It is interesting to highlight that according to the same research, the Italian users are among the first in the world regarding the utilization of the most advanced and sophisticated applications for smartphones, and this is a factor that should be taken into account when defining the potentiality of AR application to this specific context.

Results

With the purpose of evaluating the degree of diffusion of AR in the field of Cultural Heritage, an explorative analysis was carried out, aiming at pointing out the main modalities of application of this technology in the sector, the main realizations in operational environments and possible best practice. What comes out is both a broad potential of the supply and a highly fragmented and heterogeneous picture, characterized by lack of integrated databases. The study highlights that the diffusion of this technology is still in an experimental stage, although the many projects in development and the less isolated cases of application demonstrate that this technology is quickly rising in the sector. The application of AR in the Cultural Heritage sector provides the possibility to superimpose to a monument or to an archaeological site observed in the reality a broad range of additional information (through texts, pictures, links, videos, etc) with the simple sharing of application developed on purpose for smartphones. One of the great advantages offered by those applications is that these can be used “*in mobility*”, showing to the user in movement the updates in real time on what is being visited. This aspect represents the contact point between current AR and the first prototypes based on this technology developed by Caudell and Minzell. What makes them different is the fact that complex and elaborated systems of tracking and overlapping are replaced by light interactive applications that connect the mobile to the web to download information. In the Cultural heritage sector, in the functioning mechanism of AR applications, the user, through the digital photo camera on the device, frames the point of interest as for instance a monument, a picture or a statue. In this way, the GPS system of the device and the integrated compass locate the user with regard to the point of interest (POI), and exploiting the connection (web or Wi-Fi), the application displays on the screen of the device several georeferenced information useful to describe and to talk about the POI. Thus, the data obtained can be classified and visualized by the user according to his needs and can be combined with other information signalling other possible elements of interest (for example restaurants, museums, hotels, etc.). This information can originate from public archives or from archives created on purpose, as for instance by the manager of the POI, but can derive also from *crowdsources* (e.g. *Wikipedia*, *Flickr*, etc.). The above described elements have the strength to contribute to the improvement of the capacity to build an experience going beyond any expectations of the visitor, making him an active user, directly

involved in the personalization of the learning level on the basis of the specific need and personal tastes. This type of technology, allowing the visitors to manipulate and interact in real time with the POI and with the other connected elements, enables to have a certain influence on their overall level of satisfaction. In other words, through the AR it is possible to strengthen the complexity of the experience and emotion of a visit, challenging the visitors to interact with an exhibition or monument (Rothfarb, 2011), in the effort to increase exponentially their level of involvement. Thus it is possible to offer to the clients an additional service with a high competitive value, thanks to the distinctive peculiar competences, highly technological, that characterize it. It is interesting to underline that many international museums approached this technology, attracted by the high potential of development and implementation, but most of all by the possibility to increase the qualitative and experiential level of the services provided.

From a desk analysis it is possible to find some best practices for the AR application i.e. *Powerhouse Museum of Sydney*, *Street App of London Museum*, *Getty Museum of Los Angeles*, *Andy Warhol Museum of Pittsburgh*, the reconstruction of the appearance of Cluny Abbey in France before the destruction due to time. The purpose is that of collecting of works of art and historical pictures in digital format in order to make them usable also outside the museums, or tracking them (applying a tag) in the places they depict. Hence, visiting these cities, the users can utilize a combined visualization *ex ante* and *ex post* of a POI accompanied by suggestive stories on the social and urban changes that took place along the years. Also the *Stedelijk Museum of Amsterdam* developed a project called *ARtours*, made of several programs of different nature based on AR, and aiming at testing all the different forms of interaction between art and users that can be realized through this technology. The mission of the project is that of managing the art in an innovative way, with the purpose of increasing the target of reference of visitors of the museum, trying to involve and make loyal new groups of people (Schavemaker *et al.*, 2011). In 2010, the AR model was also implemented by a dedicated team of DOR (*Departement of Records*) of Philadelphia, with the purpose of making available a huge amount of historical pictures of the city, contained in several historical archives, in order to superimpose them to the observed reality through the use of smartphones (Boyer, Marcus, 2011).

The Italian picture consists of several projects trying to exploit this technology in the field of Cultural Heritage. Two projects already active were developed by the city of Savona and Ferrara. In both cases, the Local Bodies used the application *Layer*, already available on smartphones, building up specific levels (layers) with reference to the two cities. The users, through the free download of *Layer*, can visualize in modality AR information geolocated with reference to point of interest (POI) in the territories of Savona and Ferrara directly on their mobile phones. Once the application is launched the user can chose the level referring to the city of interest, and moving the photo camera of the smartphone, he can visualize on the screen all the POI nearby. The user of the service can therefore get in relation with these data on the basis of his information need: for instance he can visualize the path to reach a POI from the exact point where he is, read the description, listen to the audio guide, visit the official web site and contact the office via telephone or email. Furthermore this application enables the user to visualize the screen in three modalities of scene: *reality*, with the addition of augmented information; *list*, with the list of all the available activities from the closer to the further; and *map*, with the visualization of the same activities overlapped directly on the bi-

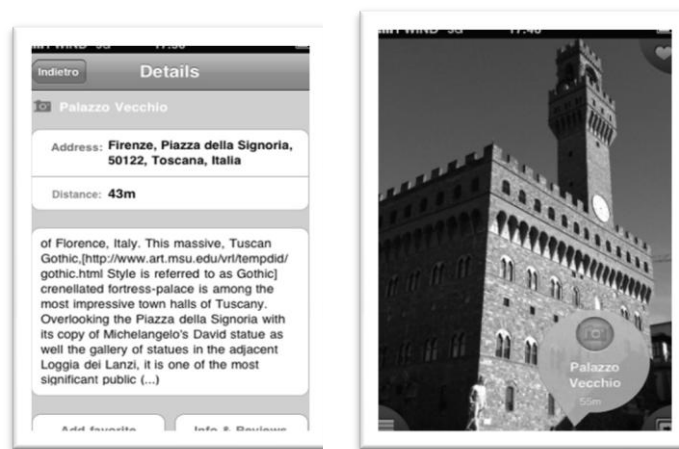

dimensional map of the city territory. In each of these cases, clicking on every POI, a range of additional information is obtained.

Figure 2 - Examples of Layer views on smartphone in Ferrara and Savona.

In a similar way Tuscany Region, created its own free application called *Tuscany Plus*, with the aim of providing to the visitors of Tuscany territory an interactive touristic guide enabling to produce an exponential service from a cultural and technological point of view. In this case a double modality of visualization is offered: *live* and *map*.

Figure 4 - Examples of Tuscany Plus views on smartphone.

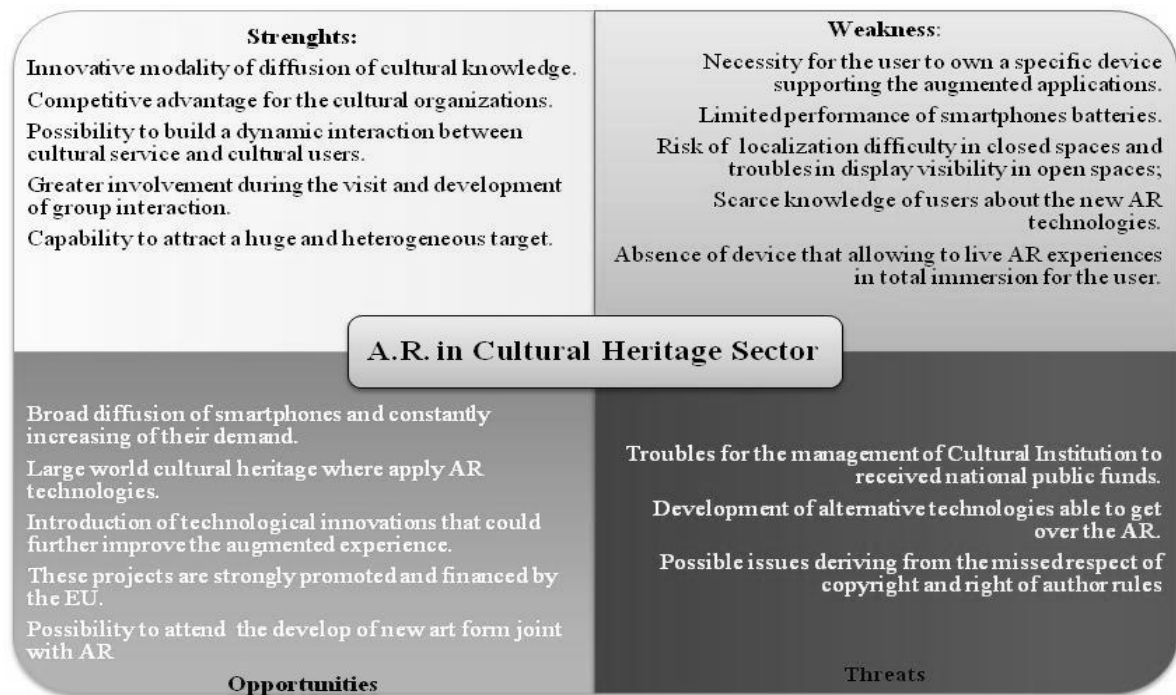

In order to implement these projects according to predefined modalities, during the planning phase, each element of interest in the above mentioned territories was positioned directly on the map, using as parameters latitude and longitude with the aim of guaranteeing the precise localization. Furthermore, for each POI a precise description was created, with the double audio guide Italian and English. The three innovative projects were supported by a dedicated communication activity, especially on the website of the city of Savona, on the touristic website of the city of Ferrara realized by the Province and on the touristic website of Tuscany Region, with the aim of explaining in a simple and direct way the innovative and technological potential of AR to impact on the cultural and touristic experience.

Also the MiBAC has recently manifested its interest for the exploitation of these new technologies, with the aim of capturing new targets and increase the level of cultural

services provided. In the specific case, it introduced on the market the guided application for smart phones called i-MiBAC Voyager, through which, by the means of GPS, compass and accelerometer, it is possible to visualize on the screen of the telephone 3D historical reconstructions (at the moment only for the Fori Romani in Rome) with a georeferenced correspondence 1:1. The i-MiBAC Voyager is indeed able to recognize autonomously the framed monuments providing an audio guide on the POI observed (MiBAC, 2011). Tuscany region carried out one of the most relevant studies on the adoption of AR in the Cultural heritage sector. The study was part of the project Technologies and Cultural Heritage, promoted by the EU and through an analysis carried out at a National level, revealed that the augmented reality, currently experimented by the 20% of the sample and present among the technologies with the higher penetration potential on the market, is perceived by the cultural organizations only with fairly good possibilities of penetration and growth (Report Te.Be., 2009). Following the explorative analysis, an investigation was carried out on the impacts and potentialities linked to the use of AR technologies with regard to users of cultural services and the possible evolution. In the effort to provide a rational answer to this question, through the study of literature, a SWOT analysis was conducted, aiming to detect the point of strength and weakness, opportunity and threats deriving from the use of AR in the Cultural Heritage sector when the service is used through smartphones. The results of the analysis are summarized in the following table:

Figure 5. SWOT Analysis on the application of AR used with smartphone.

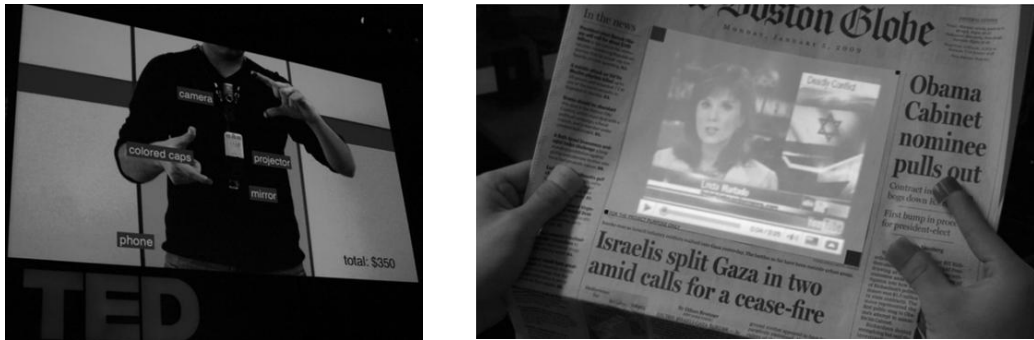

It is possible to detect through the SWOT Analysis that there are several points of strengths and opportunities connected to the exploitation of this technology. There isn't any doubt, in fact, that it represents the innovative modality of diffusion of cultural knowledge, otherwise difficult to transmit to a huge and heterogeneous public. Furthermore, these concepts are shared leaving to the addressees of the message the possibility to interact directly and in presence with the information in an interactive and procreative way. It is necessary to point out that the mechanisms of inclusion and

participation can generate further dynamics of group involvement. In *Stedelijk Museum*, for instance, during the test phase of AR technology, sharing behaviours of the experience were observed, both for the necessity to be confronted with the other users to understand the employment of the application and for the curiosity of the users without the latest generation mobile phones attracted by the originality of the service (Schavemaker, 2011). What was described can only be translated in a competitive advantage for the cultural organizations, until the point of transforming the attractive quality of these services in a distinctive capacity of his own offer. Beside strength elements some opportunities exist, occasions offered by the market and more in general by the perspectives of future development in the environment context. A broad diffusion of smartphones, constantly increasing, can foster a penetrating extension of the studied phenomenon. Let's consider the broadness of the world cultural heritage to which the AR could be applied and the quick introduction of technological innovations that could further improve the augmented experience. In addition, these types of projects are strongly promoted by the EU that is investing into projects aiming at the use and development of AR technologies in the Cultural Heritage sector. The project *Lifepius* in Pompeii, for instance, has the purpose of building up a technological prototype enabling the visitor of the excavations to interact in real time with the ancient environment partially reconstructed. Through a helmet and dedicated devices the user of the service receives information on the elements he is observing, but most importantly he has the possibility to live daily scene from the roman period (Vlahakis *et al.*, 2004). With reference to most critical aspects in the SWOT analysis, it is clear that the main critical point derives from the necessity for the user to own a specific device supporting the augmented applications. This element is a possible barrier for the use of the service and consequently the cultural structures deciding to invest in these technologies could find themselves in the position of excluding part of their public. In reality, it is appropriate to consider this element as an additional service to the traditional visit. To this respect, the demand of smartphones is constantly increasing, mainly in Italy. In addition, some weaknesses are detected in tight connection with the technical characteristics of smartphones. Currently, these devices are limited due to poor performance of batteries while using the AR applications and to the integral visibility of the display in open spaces. In closed spaces, the devices might present network issues, hindering the proper functioning of localizing mechanisms and therefore, more generally, the augmented experience. Another critical point can be that of the scarce knowledge of users about the new AR technologies. In order not to waste all the technology efforts, it is important to transmit in an effective way the initiative with communication campaigns reaching a broad and heterogeneous public. Finally, among the opportunities there is also the possibility to apply technology still at prototype stage and therefore not available (and therefore currently classified in the SWOT analysis as weakness points), allowing to live AR experiences in total immersion for the user, or without the intercession of the display of device. It is quite likely that this limit will be overcome easily thanks to the future development in the R&D field. Some of these prototypes in this direction have been already developed and an example above all is that of "*Sixth Sense*", an innovative technology realized at MIT laboratories and presented at the *TED India Conference* in 2009 by the inventors *Pattie Meas e Pranav Mistry*. This first prototype must be put on the neck and is made by a projector, a video camera, a small *computer/smartphone*, a mirror and several coloured sensors that are placed on the tips of the fingers. Through this device the user can record the reality surrounding him and project on it all the information that he is able to gather through a research on Internet. Thus the user acts directly on the context surrounding him,

augmenting it through simple manual gestures with a series of news he considers useful and interesting.

Figure 6 - Sixth Sense presentation at Ted (www.pranavmistry.com)

At last, the threats detected are those related to the investments necessary to develop these technological applications and the connected investments return for the organizations adopting them, as well as the development of further alternative technologies able to get over the AR and possible issues deriving from the missed respect of copyright and right of author rules.

Conclusions

The analysis highlighted the potentiality of the offer and also a quite fragmented and heterogeneous picture, characterized by the lack of integrated databases. The spread of this technology in the Cultural Heritage sector is still in the experimental phase, although strongly rising in this sector. In particular, a high interest of the Cultural Institutions is detected with reference to the use of the potentialities connected to the AR applications with the aim of establishing a new relation with their visitors. Through these technologies, in fact, the cultural and historical contents are more broadly accessible, underlying in a particular way, the differences with the past, present and possible future scenarios. In this sense, the union between culture and technological innovation is an important instrument to provide services with a high emotional impact, able to attract interested subjects not only towards cultural contents, but also to the application of new technologies, accomplishing a function of diffusion and sharing of knowledge, and also the role of a highly instructive instrument. However, the proposed study is preliminary and the gathered data are only qualitative and hence, it is necessary to enriched the work with a structured survey that will involve both the visitors and the Cultural Heritage Institutions in order to know respectively the users' perceptions about the application of new and preferred technologies to the cultural site or museum and the return of investment for the organizational point of view.

Category: Research paper

Introduction

To be able to meet future demands all organizations have to reconceive: the co-workers and the leaders in the organizations have to allow everyone to constantly and simultaneously both lead and follow (Hock, 2006). To make this possible the work environment has to become more creative in order to support the co-workers in their work to meet future customer demands, (Bäckström et. al, 2011). ‘By emphasizing entrepreneurship, traditional organizations could probably better transform into tomorrow’s more creativity-based organizations’ (ibid p. 194). The leaders in societal entrepreneurship are visionary and engage and mobilize others, and this initiative of the social entrepreneurs can be referred to as the management of the future, (Moe, 2009). Eskildsen, Dahlgard, and Nørgaard (1999) conclude that there is a need for a change-oriented environment for the co-workers if an organisation wants to achieve business excellence. The creative way of learning could probably be more suitable when organisations work on developing their business towards more experience-oriented and transformational-oriented products or services, an approach which Pine and Gilmour (1999) consider is a necessity to be competitive in the future. How leaders act and behave influences the attitudes and behaviour of the rest of the co-workers, (Schein, 2004). By using Appreciative Leadership the creative potential among the co-workers can be mobilized and turned into positive power (Whitney and Trosten-Bloom, 2010).

According to Yukl (2006), there is an agreement between most behavioural scientists and practitioners that leadership is a real phenomenon which is important for the effectiveness of organizations. If leadership behaviours according to Quality Management are complemented by entrepreneurship and creativity and can generate more competitive organizations in the future, (Bäckström et. al 2011). An unstructured way of learning by asking questions can support the creativity in organizations, (ibid). Another more structured way of asking questions to support creativity and transformation within organizations is the act of formulating and asking appreciative questions, Ludema et al, (2000). This Appreciative Leadership behaviour has emerged from the Appreciative Inquiry approach that ‘suggests that human systems grow and construct their future realities in the direction of what they most persistently, actively and collectively ask questions about’, (ibid.). Appreciative Leadership sets learning and innovation in motion (Whitney and Trosten-Bloom, 2010). Appreciative questions lead to powerful performance and are tools for learning and performance management (ibid).

This form of inquiry is focused on studies where the emphasis has been on studying, learning and changing to the better by using examining ‘a root-cause of success analysis’, rather than looking at the root causes of failure which up until recently has been the most commonly used approach within Quality Management. When focusing on problems instead of possibilities, organizations are prevented from using their full potential which leads to decreased organizational capacity (Whitney Trosten-Bloom, 2010). Leadership that served well in the past seems not to be efficient enough to address the challenges of the twenty-first century (ibid). Appreciative Leadership, which is about harnessing that positive power, addresses those challenges as a leadership approach, (ibid). To meet the challenge the leaders must be aware of and respond to trends defining the social milieus of organizations and communities (ibid).

The purpose is to examine how leaders can manage the philosophy and tool Appreciative Leadership and to examine what effect it can have.

Methodology

The research started with a literature review focussing on the area of Appreciative Leadership. A successful preschool that had been recognized for working with Strange-based Leadership and Appreciative Leadership was then studied with focus on how the leader manages Appreciative Leadership. A chapter in the book ‘Den offentliga sektorns entreprenörer – en porträttbok’ (In English: The public sector entrepreneurs - A portrait book), Sundin (2004), was studied. The chapter describes the case of the manager in question. Workshops, interviews, observations and conversations were then held with her, both face-to-face and by telephone, in order to understand how she manages her leadership. Her co-workers participated in the workshops.

The co-workers at the preschool were asked to fill in a questionnaire on the measurement approach which measures health-related Quality Management (Lagrosen et.a. 2011; Bäckström 2009; Lagrosen and Bäckström 2005; Bäckström and Lagrosen, 2007). The measurement approach questionnaire was written earlier and had been tested and evaluated several times (ibid). The approach measures the extent to which the values ‘Leadership Commitment’ and ‘Participation of Everybody’ permeate the organization (Lagrosen et al. 2011; Bäckström 2009). The measurement approach questionnaire was handed out, filled in and collected in one sitting in summer 2009. Each dimension in the measurement approach was constructed by means of three different statements that represent the specific dimensions, (ibid). The respondents were asked to mark on a seven-point scale to what extent they agreed with the statements. This kind of graphical scale is known as an interval scale (Lekvall and Wahlbin, 1993). The scale ranged from “Disagree completely” to “Agree completely”. Another reason for using the measurement approach questionnaire was that it had been used earlier at 8 schools where 139 co-workers had filled it in. This made it possible to compare if the leadership used in the preschool had had any effect. 40 co-workers filled it in, which gives a response rate of 80% as there are 50 employers.

Appreciative Leadership

Appreciative Inquiry is an approach to organizational change which borrows practices from the context of organizational development as it is an invitation to a positive revolution in change, Withney et. al., (2010). The focus is on what is best for the

organization - in the past, present and the future within the Appreciative Inquiry activities, practices and processes (ibid). Bushe, (2007) emphasises the importance of generativity within Appreciative Inquiry, which he believes is both an input and an outcome. Cooperrider and Srivastva, (1987) also maintain that generativity is the core of Appreciative Inquiry. Many other approaches are deficit-based and focus on problems and how to overcome them, Withney et. al., (2010). Appreciative Inquiry is, in contrast to a deficit-based approach, a positive approach for change, (ibid). In Appreciative Inquiry the focus is on generativity instead of problem-solving, (Bushe, 2007). The problems should not be ignored but by focusing on strengths, this approach is more effective, particularly when a transformation of a situation, relationship, organization or a community is wanted, (Withney et. al., 2010). 'Appreciative Inquiry enables leaders to create natural human organizations – knowledge-rich, strength-based, adaptable learning organizations', Withney and Trosten-Bloom (2010) p. 19 .

Appreciative Leaders are, according to Withney and Trosten-Bloom (2010):

1. Willing to engage with other members of their organization or community to create a better way of doing business or living.
2. Willing to learn and to change.
3. True believers in the power of the positive.
4. Leaders that care about people, often describing the work of their organization or business in terms of helping people learn, grow and develop.

The five core Strategies of Appreciative Leadership are: Inquiry, Illumination, Inclusion, Inspiration and Integrity. Appreciative Leadership is a greater leadership and about positive power (ibid.).

Appreciative Leadership is a philosophy, a way of behaving and a set of strategies that give rise to practices applicable across industries, sectors, and arenas of collaborative action. Appreciative leaders are affirmative by choice; they use positive approaches to create sustainable values, they also more often see the potential in human beings and occasions when other leaders do not, (Withney and Trosten-Bloom, 2010). When appreciative leaders see such a potential they take action and talk with others about it and engage with others, (ibid). In a study of schools Bushe, (2007) found that the best predictor of success in an Appreciative Inquiry project was the quality of school leadership.

Health related Quality Management

Bäckström (2009) found that organizations that have achieved healthy co-workers with low sickness absence through their conscious and well-structured work were also working according to Quality Management. Workplace practice include managers giving guidance and taking their time to coach the co-workers so that they dare to prioritize and take decisions by themselves; carrying out regular personal development talks with the co-workers, really listening and trying to find drivers for action, as well as giving everyone the opportunity to be aware of the customer and what their own contribution is: who they are creating value for (ibid). Furthermore, Wreder (2008) found, when studying successful organizations, that leadership in the form of 'management commitment' was a supporting value and a prerequisite for Quality Management practices such as employee involvement, delegation and coaching when working with co-worker health. In addition, this is in line with Lagrosen et. al., (2007) and Wreder et al., (2008) who maintain that Quality Management can improve the

health status of the co-workers by bringing in more humane and effective practices and at the same time improving the working conditions. To organize healthier and safer workplaces and achieve excellence in product and service quality the same kind of overarching management system is needed Warrack and Sinha (1999). The Quality Management values 'Leadership Commitment' and 'Participation of Everybody' have been shown to correlate with the co-workers' perception of their health, (Lagrosen et. al., 2010). The underlying dimension of the values 'Leadership Commitment' and 'Participation of Everybody' regarding the relation to co-worker health was examined by Lagrosen and Bäckström (2005) and Lagrosen et al. (2010). In that study, it was pointed out that integrity, presence and communication, empathy and continuity are underlying dimensions of 'Leadership Commitment'. 'Development', 'Being Informed' and 'Influence' were found to be the underlying dimensions of the value 'Participation of Everybody'. These dimensions were also found to be established methodologies, values and practices in successful organizations that have achieved good workplace health and efficiency, (Bäckström, 2009). With these underlying dimensions a measurement approach was developed, in order to help managers examine to what extent the values 'Leadership Commitment' and 'Participation of Everybody' permeate their organization (Lagrosen et al. 2011).

The case organization

The preschool under study is situated in the town of Norrköping in Sweden. It is actually two preschools (A and B) which are located 1,3 km from each other. At each preschool there are four departments which are each led by one division leader. There are 172 children between 1-5 years old in the two preschools. There are 50 co-workers employed, of whom 44 have permanent positions including eight division leaders and one manager for both preschools. The current manager started as manager at Preschool A in September 1999 and then also at Preschool B in January 2001. When she started at Preschool B 50 % of the co-workers were on long-term sick leave. One year after the manager had started all co-workers were back at work except one who had retired.

According to Sundin (2004) the manager convinced the local authority to allow a new way of working with quality. From a analysis based on joy at work and quality she made a workplace analysis. The result was a work- and development plan for the preschool and a description of the improvement work called Life, Joy and Growing Power. This became a source of inspiration to other preschools' quality work, (ibid.). 2003 the manager wrote a essay called; 'The dream of the good' which was a project to accomplish improvement and development within the preschool. This essay and the project was about creating better conditions for children and co-workers who work with children, (ibid.)

Leadership within the case organization

The leader describes herself as a positive, driving person, Sundin (2004). The leader believes that she can rapidly transform theory into visible action in her preschools. She looks for possibilities and applies them in her own way. She believes that she finds it easy to engage and arouse enthusiasm among her co-workers and make them work for the creation of a good workplace with good work structures. She also says that she never gives up, (ibid). In their improvement work and in everything they read, they ask

each other questions. How is it? How do we want it to be? How can we create that? Who does what and when will it be done and when do we follow up? (Sundin, 2004).

The co-workers describe their leader as a person who is always one step ahead, (Sundin, 2004). They describe her as a glad, positive and a driving person who is good at convincing people and at marketing her preschools. She has a great circle of contacts and does not hesitate to seek for funding outside the community. She has a matter-of-fact manner and is knowledgeable. The co-workers also say that their leader is an inspiration who works for progress and knowledge development keeping the children's best as her first priority. They think she is a person that acts and never gives up. She gives her co-workers big challenges and creates job satisfaction, (ibid).

The manager manages a sustainable leadership and constantly aspires to have participation from everybody. She gives her co-workers appreciation in different forms and she believes in the act of seeing people's 'strengths'. Every Friday the eight division leaders and the manager have executive meetings which have an agenda and for which all are prepared. They use learning conversations and give each other seriously committed feedback when they talk. After that, they ask each other more penetrating questions. They continuously conduct workplace meetings, meetings with parents and study tours together for the two preschools. The managers have written several applications to different foundations for money for development and education for the co-workers. On one occasion they received 6 million SEK for education. They have conducted several courses in instant yoga, Life conversation, health promoting activities and the "dream of the good" method. Study trips to other countries have also been carried out. The managers ask their co-workers to "dream of the good" and to write it down when they work with organizational development. Then they work together to realize and implement their dreams. She maintains that courage and wisdom are important ingredients in her leadership as well as never giving up.

The results from the measuring approach

The results from the measuring approach are presented in Table 1 together with the mean score from the eight schools in the other project mentioned above as a comparison. The mean score for the two preschools are all over 6 on a seven-point agreement scale which can be considered as high. It can also be observed that Preschool A has higher scores for all dimensions than Preschool B.

	Empathy	Presence/Communication	Integrity	Continuity	Development	Influence	Being informed	Health
Preschool A	6.58	6.61	6.78	6.66	6.68	6.71	6.68	6.69
Preschool B	6.25	6.31	6.43	6.65	6.33	5.82	5.86	5.86
Total	6.44	6.48	6.63	6.65	6.53	6.33	6.33	6.34
Mean score	5.11	4.93	5.01	4.83	4.59	4.74	4.53	5.53

at 8 schools								
--------------	--	--	--	--	--	--	--	--

Table 1. The mean score from the measuring of the dimension.

The comparison with the eight schools confirms that the results from the measuring approach are high. It can also be noted that the co-workers in the preschools perceive that the health-related Quality Management values ‘Leadership Commitment’ and ‘Participation of Everybody’ permeate their organisation. They also think they have good health.

Conclusions

The leadership, the methodologies and behaviour the manager in the preschool is using are not unique or new. Similar leadership methodologies and behaviours have been found in other successful organizations examined (Bäckström, 2009, Harnesk et al., 2005). According to Oakland (2001), it is important that managers believe that co-workers want to achieve, accomplish and influence activity, and that they do not need to be coerced to perform well. The leadership can also be described as an Appreciative Leadership since, for example, the four points of a Appreciative Leader, as described by Whitney and Trosten-Bloom (2010), can be found in the way the manager conducts her leadership. The leadership style which can be described as an Appreciative Leadership and that the manager at the preschool uses, can be confirmed as leading to good effects on the working environment as all the measured dimensions have a high score. The effect of her sustained leadership can be seen in the higher score at Preschool A which she has managed for more than one year longer than Preschool B.

The creative and visionary leadership that the manager in the case organisation is using has similarities with the initiatives of the social entrepreneurs that Moe (2009) referred to as the management of the future. These managers have used the creative potential among the co-workers which they have mobilized and turned into power in the manner that Whitney and Trosten-Bloom, (2010) have described as Appreciative Leadership. This style of management could probably be used within social entrepreneurship with positive effect.

It would be interesting to carry out further research by interviewing the co-workers and asking them how they perceive the leadership and then comparing that with the description from the leader. Interviews with the eight division leaders would also be very interesting. To examine how and if they had been influenced by the manager and then to examine how they are performing their own leadership. It would also be interesting to examine other leaders who are practicing Appreciative Leadership and to find out how they practice their leadership and what it has resulted in.

Keywords: lean; change management; organizational development; transformation; SMEs; medium sized companies

Type of paper: Case Study

Introduction

A majority of all research in the area of change revolve around larger companies, and there is a lack of studies demonstrating applied examples in smaller companies. From most perspectives, this is peculiar since the national economies rely on small and medium enterprises (European Commission, 2008). With an ever increasing competition for manufacturing companies due to globalisation, it has however become a priority for national policymakers to support their industries by change programmes. Industry Forum in United Kingdom, which has its origin in the automotive industry, is one such national programme. This programme has served as a role model for the Swedish programme Produktionslyftet which has the objective to enhance the performance of medium sized (in these case 30-250 employees) manufacturing enterprises (MMEs).

Produktionslyftet (PL) is a stimulating case to study, not in least because the programme has been involved with changes in over 100 companies. The original Produktionslyftet (PL1) was initiated in 2007 and worked with 60 companies before its end in 2010. PL2 was started in 2010, and involves 40 companies (as of May 2011) which are planned to be expanded to 100 companies before the programme end in late 2012. The objective of PL is to stimulate enterprises to evolve as learning organizations with inspiration from the Toyota Production System concept, under the term Lean Production. The programme consists of 3 interacting activities: an education in Lean Production for at least 2 employees, workshops on the companies for education and training, and finally two consultants from the programme stays at the company and aid in their transformation. All in all, this takes 18 months.

From the start, PL was expected to build upon “off-the-shelf” workshops and consultancy services, with a non-significant budget for development. The perception from Industry Forum was that it was all about introducing a battery of “standard solutions” to individual companies. However, it soon became apparent for the actors within the programme that the approach had to be improved, and it continued to evolve ever since.

From the start in 2007, the approach to managing change in this programme has changed in a few ways and there has been a collective maturity process for the consultants involved in this programme. Together, these changes have moved the programme approach from a focus on tools to a focus on understanding each company

and contextualising the approach. The purpose of this case study paper is to describe how Produktionslyftet operates, and to reflect on how the methodology has evolved in Produktionslyftet.

According to Palmer, Dunford and Akin (2009), there are two main approaches to managing change: Management as Control and Management as Shaping. The first of these treats the organisation as a machine; with managers directing, people being assigned roles and resources being allocated for efficient performance. The second approach treats the organisation more as an organism; with managers shaping, people being encouraged to be involved in decisions and organisational capabilities are enhanced for effective functioning. The first approach has theoretical proponents such as Kotter and Pettigrew while the second has proponents such as Lewin and Weick (Palmer, et al., 2009).

Beer and Nohria (2000a, 2000b) describe an adjacent view on change with the help of what they entitle Theory E and Theory O (see Table VI). Theory E comes close to Management as Control, while Theory O is closer to Management as Shaping (Palmer, et al., 2009). Beer and Nohria (2000a), while warning against an arbitrary mixing of these archetypical ways, argue that the most effective approach to organisational change is to carefully integrate Theories E and O. Burns and Stalker (1961) provide yet another way of describing change and empowerment: the “mechanistic” approach, which is close to Theory E and Management as Control, and the “organic” approach, which is close to Theory O and Management as Shaping. Quinn and Spreitzer (1997), while using this theory to analyse employee empowerment, also come to the conclusion that a combination of approaches is the best way to go.

Table VI: Theory E, Theory O, and Combined (Beer & Nohria, 2000b)

Dimensions of Change	Theory E	Theory O	Theories E and O Combined
Goals	maximize shareholder value	develop organizational capabilities	explicitly embrace the paradox between economic value and organizational capability
Leadership	manage change from the top down	encourage participation from the bottom up	set direction from the top and engage the people below
Focus	emphasize structure and systems	build up corporate culture: employees' behavior and attitudes	focus simultaneously on the hard (structures and systems) and the soft (corporate culture)
Process	plan and establish programs	experiment and evolve	plan for spontaneity
Reward System	motivate through financial incentives	motivate through commitment—use pay as fair exchange	use incentives to reinforce change but not to drive it
Use of Consultants	consultants analyze problems and shape solutions	consultants support management in shaping their own solutions	consultants are expert resources who empower employees

Method

This case study paper is co-authored by two. One of these is employed at the consultancy company which is one of the driving forces behind Produktionslyftet. This co-author has been heavily involved, as a consultant and workshop facilitator, in the

operation of PL since late 2009. The other co-author is a university researcher that is external to the project, the only contact with PL being through interviews and discussions with people from the programme, as well as accessing material provided by the other co-author. The participation of the internal co-author ensures high access to the empirical material including own experiences and first-hand reflections, while the external co-author contribute with an external perspective and a theoretical view.

The description of the case is based on interviews with PL staff, inside experiences and PL material. The interviews were conducted solely by the external co-author, recorded, transcribed and put together. Afterwards, the internal co-author filled gaps, as well as contributed with additional perspectives. The access to PL materials, from different periods of the programme, makes the view on the evolution of the programme more robust.

Produktionslyftet

The description that follows in this section depicts the norm for how the change work is done and may seem quite static. It is in the interviews emphasised that the approach are to some extent dynamical.

Produktionslyftet, together with partners (universities, company networks etc.), arrange so called “insight seminars” where the programme is described in overview. Some of the participants on these events usually become interested in more fully exploring the opportunities of PL and apply to be part of it. These seminars are today becoming less and less important due to word of mouth, since there are plenty of applicants even without active “marketing”.

The programme direction review the formal conditions regarding, among others, size and business sector and also visits the company in order to evaluate the chances for successful interventions. Assuming a company is accepted, the company is allocated a pair of consultants, or “coaches” as it is called within the programme. To each company the consultants’ time budget is roughly 350 hours, where most of this time is spent on the actual company site.

One of the first steps is a pure educational one. Each accepted company needs to send at minimum two people, one aspiring so called lean coordinator and one supporting, to a university openly organised course in Lean Production.

The first arrangement at the actual company, phase 1, consists of five different workshops, each being one full day accompanied with “homework” that needs to be completed before the next session. This phase constitutes the first 3-6 months. The workshops are attended by a so called Lean Steering Group, which is similar to a “project board”. The group consists of the executive team expanded by key stakeholders, for example the labour union. Some companies choose to include even more people, which results in a diversity of sizes of such steering groups. If the group become too large it usually transforms into a reference committee and an operative work group emerges. The workshops are relatively standardised with regards to approach and format, but what is discussed in them is related to the topical company.

1. General introduction to lean, together with “lean games” for understanding. A lean game is an activity that with simple means shows how practices such as flow, pull and good communication really can enhance a production line, for example by letting the attendees simulate manufacturing by more and more efficient assembling of Lego pieces. Homework: Create a pulse board that is visualising for the group and for all employees what PL is, who are participating, and what activities there are.
2. Change workshop. Participants are discussing leadership, motivation, and respect for the individual, which usually are new ways of thinking. Homework: Start thinking on an appropriate pilot area for work.
3. Value stream mapping of one flow: looking at a flow and identifying what part that are value added and what are not. A flow can for example be from order receiving to start of production, or from start of production to end of production, or from end of production to delivery. Most usually this is made in the manufacturing area, and this is the first encounter with the operations. This is used in order to further develop ideas for pilot area to work in. Homework: Consider important KPIs. Where does the company want to go, and what does it want with PL? How KPIs could/should be used to enhance the work.
4. In some companies, the steering group can initially not articulate a sense of direction other than that it should make money. This workshop covers areas such as “How does the company ‘think’?” and “Where does it want to go?”. The starting points of these discussions are often any existing business and quality policies. These are scrutinised and vague formulations such as “we aim to enhance our productivity” are discussed in terms as how to reach these goals and what principles the company should work according to. This workshop is focusing on why the company should be good in certain areas, for example high quality and connecting it to company goals. Sometimes it is hard to manage this workshop in one day, why it if so needs to be complemented with an additional day. Homework: Make a summary of workshop 4 and condense this into, for example, a pamphlet about stating the core principles of the company.
5. Summary of the four earlier workshops. The ideas and discussions so far are put together, and the pamphlet is being refined. It is also detailed what area that will be first piloted.

The main idea of phase 1 is to create a common sense on basic values, for the company as well as the participation in the programme. The “end product” of this phase is an “action plan”, and the steering group has by this time also decided on a pilot area for starting the change work.

With an action plan developed after phase 1, the idea is that the steering group “mounts the barricades” and announce the plans and intentions to the whole organization. One common way to support this process is to have a lean game with all or most employees.

By the end of phase 1, a lean coordinator has also been appointed. This person will work with supporting the drive in the following day to day activities: following up on

results and becoming more and more confident in running the new lean initiative. From this time, the whole steering group will not be as active, but more of a reference group; promoting the initiative throughout the organisation and supporting the various change activities. During phase 2, the steering group is gathered for continuous evaluation approximately every month.

The next step, phase 2, starts with work in the pilot area that was identified. For example, if the paint shop has been identified as a bottle neck in the performed value stream map, this may have been appointed as a pilot area. The change process starts by gathering all the people from this paint shop and again establishing a common sense on what goals the company has with this particular process step. This group constitutes a pilot group that performs changes within its boundaries, while being supported by the lean coordinator and the consultants. Thus, several education workshops are run with this group. These workshops, and education areas that are needed, are identified both in phase one with the steering group as well as together with the group. Examples on such workshops are further value stream mapping, standardised ways of working, reduction of machine downtime, and “5S”. These workshops are supported by a common standardised PL pool of “tool knowledge”; educational and support material for using the various methods and tools. It should be pointed out the knowledge/educational pool is standardised, but the selection of what workshops that are appropriate is not. For example, if the pilot group together with the consultants and coordinator decides that the root causes are that people often need to search for tools, “5S” might well be an appropriate place to start. In the beginning, the consultants often have large roles in supporting the process of identifying such problems and helping the group understand the problems.

After a few weeks with the first pilot area, when the changes in this is well underway, new pilot areas are started with following similar educational and change processes. With each new area that is started the lean coordinator assumes more and more responsibilities. Also, with each new pilot group, it is desirable to have individuals from the steering group included effecting the steering group to be operationally active. It varies a lot how many pilot areas that are started during phase two, but four to six of them can be considered normal. A common outcome is that more permanent improvement groups are formed in these pilot groups.

At the end of phase 2 (which is 18 months after the start of phase 1) the PL representatives leave the company with the ambition of having initiated internal drive within the company. The interviewed consultants are quite humble with what that can have happened during these 18 months: “during these 18 months the companies have merely started to have more insight in lean thinking, and the lean work has just only begun”. Every now and then, the consultants are hired as continued consultants to check back on the company, for example every quarter. However, such initiatives are outside the PL programme, and on the initiative of the companies.

The dominating idea of the programme is to distribute knowledge throughout the organisation and to have people from the companies take on leading roles in the lean change work within each company. According to one consultant, lean is all about working smarter, not harder. This may sound natural, but this consultant state that one main problem in many companies are that individual issues steal the attention of too many people; there are no systems in place to ensure proper and proportional responses

to arising issues, which in the end drains a lot of resources. The perceived most important effects by the 19 first companies are shown in Figure 11. Effects such as smaller batches and better delivery precision are mentioned, but the most important effects are perceived those that relate to ways of thinking, communication and culture.

Figure 11: Effects perceived as most important by representatives of the 19 first companies in PL1. Adapted and translated from Swedish language Produktionslyftet material

The evolution of the programme

Throughout the life of Produktionslyftet, there have been regular meetings among the consultants, with the intent of discussing and bringing the programme forward. These help the programme to evolve both continuously, and even more so in-between PL1 and PL2. There are three issues that are brought up as the major differences between them: forming coherent views within the companies, a more context sensitive approach, and personal development of the coaches.

At the start of PL1, it was assumed that the individuals in the companies shared a common sense of direction for the company, and a common view on what was going on inside the company. This was later shown to often not be the case; many of the people in the steering group had previously never actually had any discussion together, and especially not on these matters. As a consequence of this revelation, the programme does today focus much more on phase 1. In PL1, the most important thing in each company was to start “doing things”. Today, the most important thing is rather seen as creating a common understanding within the steering group, with the purpose of having these people as a strong team to work with lean production. These changes does not necessarily result in longer calendar times for phase 1, but show in a stronger emphasis during the sessions as well as the substantial “homework” to be done in-between the sessions.

Throughout the life of PL, it has always existed a toolbox with support for the usage of tools and methods, for example 5S, VSM and SMED. In PL2 this toolbox has been expanded with better support and also support for more methods. More importantly, there is stronger emphasis on deciding together with the company on what tools and methods being appropriate to start using, while in PL1 there was a bit more of pushing.

This seems to be both due to a central move in this direction, but also due to a change in the mind-set of the individual consultants. This personal development of the consultants is accentuated as a major advantage in the programme. With experiences from earlier companies, it is easier to provide companies with a clearer picture on what they will go through. It is generally also easier for the consultants to identify strengths and weaknesses, identifying good candidates for being Lean Coordinator and so on. These individual learnings are also spread throughout the programme by both the regular consultant meeting, and by the presence of assistant consultants (which normally are active in multiple companies at the same time). Today, the programme is perceived to having a clearer and sharper overall structure.

Some of these changes can also be illuminated by reviewing PL material describing the overall structure of the programme. For the start of PL1 (Figure 12), the steering group had a “lean-intro” and was subsequently thought of as self-driven. The next step was to implement the building blocks that were the standard tools, which always started with “5S”. Change management appears somewhere in the end in-between “Ergonomics” and “Measurements”. Furthermore, the action plan was something that was done “on the side”. Today (Figure 13), “learning” is central. It is more of together growing a new behaviour and fertile culture, starting with the steering group. There are still tools and methods, but they are more depicted as a toolbox to choose from and to gather support from.

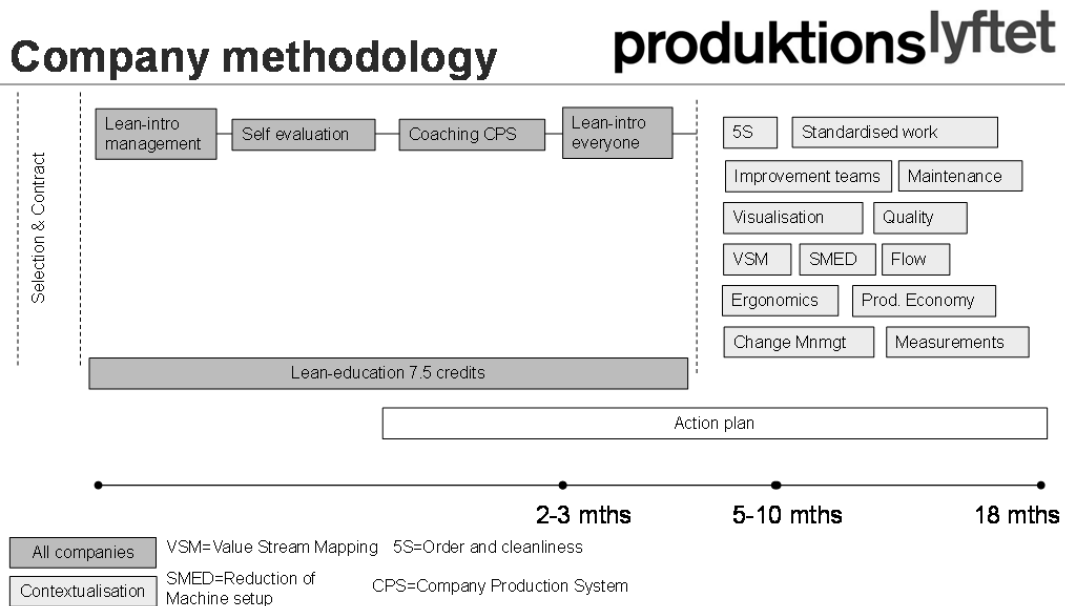

Figure 12: The approach in the early stages of PL1. Translated from Swedish language Produktionslyftet material.

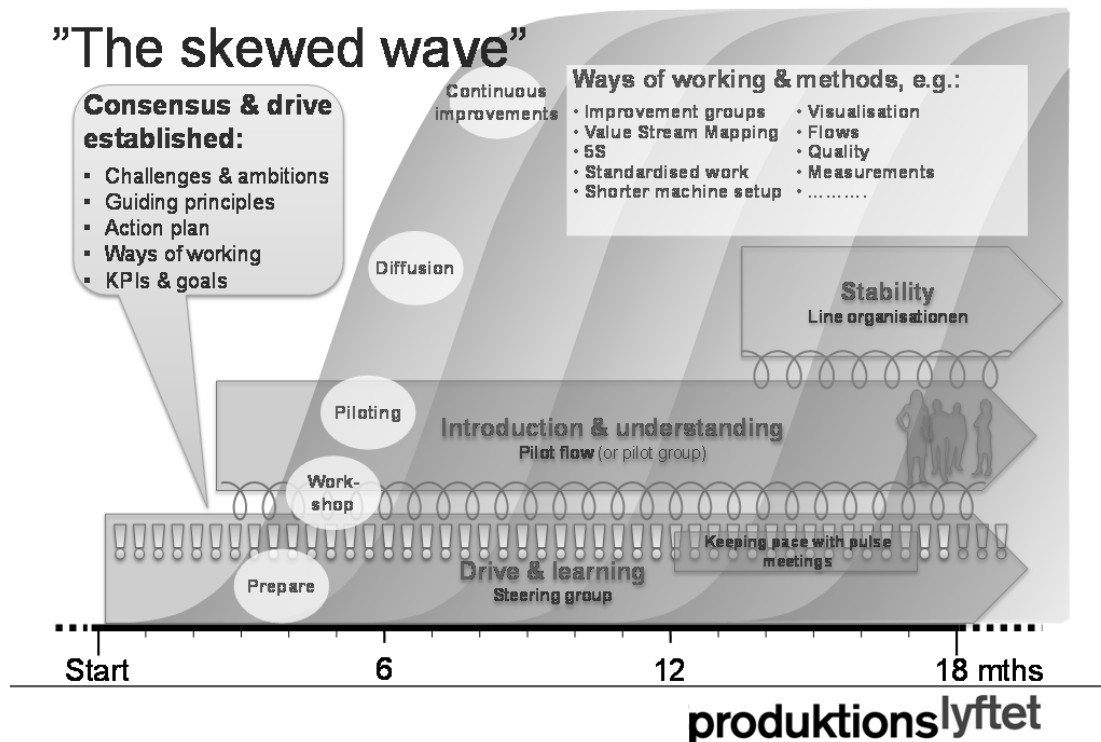

Figure 13: The approach by the middle of PL2. Translated from Swedish language Produktionslyftet material.

There were also four other issues that were brought up as noteworthy in the interviews:

- PL1 was fundamentally organised and managed from Swerea IVF AB and Chalmers University of Technology, both situated in the Gothenburg area. For PL2, Sweden was divided into 8 regions, each of them being managed by a university, in order to better continue working with more medium-sized industries all over the country. This also means that the two central organisations provide less main consultants, while still making sure to be represented by assistant consultants maintaining an overview of the activities in the companies, as well as bringing in experiences from other companies.
- Already in PL1 there was a demand on an active top management. However, this was not always the case in reality, why in PL2 there is a stronger focus on the necessity on management commitment, with higher demands on their presence and commitment. It is made sure that the MD does not simply sign on for the project and then delegate the participation.
- There is now a stronger focus on measuring, by developing and using appropriate KPIs etc.
- There are now many competitors to PL; entities that are offering similar types of company development support. During PL1, PL was more alone on the market.

Discussion

Table VII shows how PL1 and PL2 relates to Theory E and Theory O (Beer & Nohria, 2000a). During this time, the programme has moved towards a combination of Theory E and Theory O. By the start of PL1, the programme had an approach to change that roughly resembled a mechanistic approach with focus on tools to implement, while today it has moved towards an organic approach deciding on changes together with participation from all parts of the companies (Burns & Stalker, 1961; Quinn & Spreitzer, 1997). It should be noted though, that the most valuable effects in companies was already for the first companies in PL1 perceived as not being about tools or efficiency, but rather about culture and new ways of thinking.

Table VII: PL1 and PL2 in relation to Theories by Beer and Nohria (2000b)

Dimensions of change	PL1	PL2
Goals	E	EO
Leadership	E(O)	EO
Focus	E	EO
Process	E	EO
Reward System	-	-
Use of Consultants	E(O)	EO

The move towards a combination of mechanistic and organic approaches is endorsed by both Beer and Nohria (2000a) and Quinn and Spreitzer (1997). However, these changes have primarily evolved from the collected and individual experiences of the involved coaches. Meetings and deliberate efforts have changed the programme overall, while individual experiences has changed the approach of the individual coaches. The people involved in the programme has decided that no matter how useful tools such as 5S are, it has to be considered what the company really needs, and that it has to come from the people inside the companies, not from the outside.

Category: Research paper

Introduction and background

Work-life balance has a major impact not only on business productivity but also on the economy as a whole, (Hughes 2007) and Wolf (2008) maintain that implications for the workplace are enormous as mental disease goes hand in hand with significant productivity losses. According to Janssen et al., (2003), the occurrence and causes of sickness absence are affected by several factors, many of which are work-related and organizational. Examples of the former are work content and work conditions. The latter include, for instance, company size, the existence of health promotion programmes, and absence policies (ibid). When implementing corporate health promotion, the responsibility should mainly rest with the management (Plath et al., 2008). Thus health promotion activities are important in order to improve co-worker health and in the long term the efficiency in the organization. Advancing knowledge in the area of leadership for health promotion could make valuable contributions to increasing the health of the population, Andersson et al., (2005). Vinberg (2006) claims that increased workplace health and performance are connected to a good working environment and work organization.

The salutogenic approach to health, identifying factors that promote good health, (Antonovsky, 1987) instead of identifying and limiting those leading to ill-health has been common in health research. Viewing co-worker health as a resource for corporate quality, success and competitiveness is in line with this approach, (Wreder et al., 2008). Leadership theory research in general has shown that leadership behaviour can be used to predict co-worker health outcomes (Skogstad, 1997). Management strategy based on humanistic core values, supported by Quality Management, has been pointed out as important for co-worker health, (Wreder, 2008). Correlations between co-workers' perceptions of their health and values within Quality Management have also been found (Lagrosen, 2004; Lagrosen et al., 2007). A well-developed, structured approach for health-related quality management can be used as a management tool in order to assess and improve employees' well-being, satisfaction and motivation (Lagrosen et al., 2011). Taken all in all, research, knowledge and support to the management within the health promotion area are important.

The purpose of this paper is to describe health promotion activities conducted within a project and to measure the conditions for sustainable health within the case organizations. The purpose is also to test earlier previously developed measurement approach, which measures health-related Quality Management (Lagrosen and Bäckström, 2005 and Lagrosen et al., 2010).

Health promotion and measuring health-related Quality Management

Correlations between Quality Management on a company-wide scale and improved co-worker satisfaction and health as well as improved external customer satisfaction and financial results have been found in research, see for instance, (Park Dahlgaard and Dahlgaard, 2003; Dahlgaard and Park Dahlgaard, 2003a, 2003b). Wreder (2008) maintains that one way of working with co-worker health is to strategically and systematically work on creating a culture based on core human values, by choosing methodologies and tools which support the values present within Total Quality Management (TQM). Studying successful organizations, she found that leadership in the form of 'management commitment' was a supporting value and a prerequisite for Quality Management practices such as employee involvement, delegation and coaching when working with co-worker health. In addition, Bäckström et al (2009) found that organizations that have achieved healthy co-workers with low sickness absence through their conscious and well-structured work were also working according to Quality Management. Workplace practice includes managers giving guidance and taking their time to coach the employees so that they dare to prioritize and take decisions by themselves; carrying out regular personal development talks with the employees; really listening and trying to find drivers for action; as well as giving everyone the opportunity to be aware of the customer and what their own contribution is: who they are creating value for (ibid). This is in line with Lagrosen et al., (2007) and Wreder et al., (2008) who maintain that Quality Management can improve the health status of the co-workers by bringing in more humane and effective practices and at the same time can improve the working conditions. To organize healthier and safer workplaces and achieve excellence in product and service quality the same kind of overarching management system is needed Warrack and Sinha (1999). There is also research which describe how Quality Management can be practiced to support sustainable health among co-workers and also what is of most importance within Quality Management to influence co-workers' sustainable health (Bäckström, 2009, Lagrosen et al, 2010). The results show that the value 'Leadership Commitment' and the value 'Participation of Everybody' are important to support sustainable health among co-workers when Quality Management is practiced (Bäckström, 2009, Lagrosen et al., 2011) The underlying dimension of the values 'Leadership Commitment' and 'Participation of Everybody' regarding the relation to co-worker health was examined by Lagrosen and Bäckström (2005) and Lagrosen et al., (2010). In that study, it was pointed out that integrity, presence and communication, empathy and continuity are underlying dimensions of 'Leadership Commitment'. Development, being informed and influence were found to be the underlying dimensions of the value 'Participation of Everybody'. These dimensions were also found as established methodologies, values and practices in successful organizations that have achieved good workplace health (Bäckström, 2009).

A measurement approach was developed, with the found underlying dimensions as a base, in order to help managers examine to what extent the values 'Leadership Commitment' and 'Participation of Everybody' permeate the organization (Lagrosen et al., 2011). The measurement approach can be used to point out to what extent the organization is practicing the health-promoting values of Quality Management and in what areas improvement is needed to increase co-worker health, (Bäckström, 2009, Lagrosen et al., 2011). The measurement approach can also be used longitudinally to assess before and after carrying through an organizational change, (Lagrosen et al., 2011).

Description of the health-promoting project

The health promotion project was initiated in 2009 and school leaders and teachers in elementary schools in the county of Jämtland in Sweden were chosen as a target group. This county has a high unhealthy rate in terms of not being able to work due to sick-leave, compared to other counties in Sweden. Elementary schools as organizations were chosen since teachers, as an occupational group, are vulnerable because of increasing demands from society. Investigations from the Swedish Work Environment Authority show in self-report questionnaires where teachers were asked to evaluate their working conditions that more than 60 % of teachers were not planning to work or probably would not manage to work until pension. In today's society health is critical in the competitive labor market. During elementary school, the teacher is a role model for young children and has a major influence on the process of learning. It is important to create a working environment in which teachers feel physically, mentally, and socially healthy. To be able to investigate their needs a pre-project was conducted with funding from The European Social Fund (ESF). A survey containing 59 questions concerning health-promoting aspects was sent out. The results showed that there were both direct and indirect needs for capacity building. Direct needs were, for example, more knowledge about factors that promote health and indirect needs included aspects concerning the individual's health such as stress management in the working environment. Hence, the outcome of the pre-project showed that there were needs for improvement of qualifications and competence within the health-promoting area. Since there were obvious needs the project management decided to apply for funding from ESF to be able to carry out a health-promoting project.

Eight schools in the municipality of Östersund, and Krokoms were invited to participate in the project, which resulted in a target group of about 185 school leaders and teachers at seven municipal schools and one private school. The project, based on the findings from the pre-project, started in February 2010 with funding from the sport association of Jämtland-Härjedalen (Jämtland-Härjedalens Idrottsförbund), ESF and the county council of Jämtland, and in cooperation with Mid Sweden University who funded the project. The vision was to energize health promotion and sustainable development of society. The aim of the project was to create good conditions for the target group through capacity building and to give the teachers knowledge and tools to implement a health-promoting approach, both educationally but also in everyday life. Equality and availability are aspects that were fundamental conditions in planning and implementing the health-promoting activities. In the long run this health-promoting intervention will hopefully lead to a more health-promoting work environment and a decrease in the sickness rate. The activities conducted in the project are described below.

Methodology

The health-promoting project described above was studied with focus on the healthpromoting activities that were carried out. The project management informed the researcher about the project; its purpose, the participating schools and the planned activities within health-promoting areas in the initial stage of the project. In December 2010, information concerning changes to the original plan, what sort of health-promoting activities were planned and how they were to be conducted, were provided by the project management. A revised plan for all activities planned for the remaining project time was also provided.

Information on the Quality Management health-related measurement approach was distributed to the co-workers at the eight different schools at the beginning of the project. The target group had been informed about the project and the purpose of the measurement. Totally 141 questionnaires were collected but two were omitted from analysis, as they were not filled in properly. A total of 139 questionnaires were analyzed out of 185 possible co-workers, which gives a response rate of 75%. The questionnaire was developed based on the dimensions of the values 'Leadership Commitment' and 'Participation of Everybody' developed by Lagrosen et al., (2005, 2011). Each dimension in the questionnaire was constructed by means of three different statements that represent the specific dimensions, (ibid). The respondents were asked to mark on a seven-point agreement scale to what extent they agreed with the statements. This kind of graphical scale is usually considered to be of the interval type (Lekvall and Wahlbin, 1993). The extremities of the scale were "Disagree completely" and "Agree completely". To test the internal consistency and reliability of the statements within each construct, Cronbach's alfa analysis was carried out using the SPSS reliability analysis procedure (Malhotra and Birks, 2000). Correlations were then calculated using the Pearson Correlation Coefficient and its corresponding test-statistics. The Cronbach's alpha coefficient was computed for each dimension in order to test the internal consistency reliability. A value of 0.6 or less is generally considered unsatisfactory (Hair et al., 1998; Malhotra and Birks, 2000) and the coefficient tends to increase with the number of items or statements.

When the results from the measurement approach were analyzed, each school leader was informed about the result at their specific school and the mean value of all the schools in the project. A description of the meaning of each dimension that had been measured was handed out to the leaders. They were also informed of possible methodologies, behaviors and values that could help them to be able to increase sustainable health among the co-workers (Bäckström, 2009).

Health promotion activities accomplished within the project

Depending on the needs of the different schools, those involved in the education and the further training were different for different activities. Some of the activities were aimed at the leaders; the headmasters and the headmistresses and some of the activities were aimed at all; both co-workers and leaders within the school. In the first phase, the focus was on preparing the school leaders for what their co-workers would go through during the project. By doing so the project management could be more confident that the main target group would get the right information and resources to follow through. To ensure

participation the school leaders were involved in planning the practical aspects of the activities. This enabled customized solutions for every school and their co-workers. The activities for school leaders started in May 2010 and for co-workers in August 2010.

Activities aimed at the leaders

The activities for the school leaders were divided up into six different meetings during the 12 months of the project. Four of these were carried out during 2010 in May, June, September and October and the remaining two in 2011 in January and March. The first activity for the school leaders was a one-day lecture about salutogenic leadership and workplace health promotion. The salutogenic approach focuses on the factors that promote health instead of the factors that are detrimental to health. The kickoff for the directorate (group of school leaders) was carried out in June: two days with the purpose of letting the leaders get to know each other and to start the process of capacity building in the health-promoting area. This included lectures on communication and other tools for implementing the health-promoting perspective in the elementary schooling system. In September the leaders got together to summarize the development so far and to discuss the needs of every specific school and their co-workers. In October the school leaders met for a half-day about diet, and physical activity and exercise. In January the group met again to talk about progress made and how and in which way the project had affected the schools and their co-workers. The last activity for the directorate was in the end of March to discuss and plan the future. The reason why the school leaders had separate activities, besides being one step ahead of the main target group, was that when the project ended they as a group could help and support each other to keep up the health-promoting work.

Activities enriched to the co-workers

The first step in launching the project was to inform all co-workers of the eight schools and outline the project and their participation. This took place in May 2010 and at the same meeting the co-workers were asked to fill in a questionnaire on the measurement approach. During the project there were two meetings where all the 185 participants in the project would be gathered all at the same time. The first time was during the kickoff which took place in August; two days of introduction of the health-promoting perspective, and approach. The second time will be on June 13th 2011 when the “starting point” for the future takes place. During two days in September all coworkers were invited to participate at a half-day lecture in diet and physical activity and exercise. In October a series of workshops in communication started and, depending on the needs of each school, the communication activities were followed up and took place in the working environment of each school. There was also a day of different workshops and lectures to learn more about the salutogenic approach and integration of health promotion. During the whole project time the participants were offered personal trainers, students at the sport science program at Mid Sweden University, who they met once a week during a period of five to six months.

The activities in the project were planned to go from general, involving all co-workers, to become more school-specific and individualized. In October the co-workers got a menu of different health-promoting activities to choose from. These activities were: salutogenic leadership as a practical pedagogic, coaching I, coaching II, yoga, mental

training, physical activity and exercise, diet, balance in everyday life, movement and mental practice in the classroom, and motorical development as a foundation for learning (MUGI). Each teacher had an amount of hours to spend on one of the activities described above. The activities were optional and no one was forced to participate against their will. The aim of these activities was that each individual, regardless of position, could do something that he or she felt was meaningful as a person, not only a teacher.

The project ends with a “starting point” for the future that will take place in June 2011. This day will summarize the whole process and the co-workers’ experiences of being a part of a health-promoting project. At this stage the project management will hand over to the directorate whom together with their co-workers will continue the health-promoting process at each school. During this meeting the participants will fill in the questionnaire on the measurement approach as a way to evaluate if the health-promoting activities have had an effect on the co-workers’ perception of their health and if the permeation of the health- related values within Quality Management have increased.

Measuring of the starting conditions within the schools

The results of the measuring in the beginning of the project are illustrated in Figure 1, which illustrates the mean value of the dimensions and health status at all schools. The mean value for all schools for all dimensions varies from 4.53 to 5.54. The dimension that varies most between the schools is ‘Continuity’ which varies from 2.81 to 6.30. The health index is the dimension that varies least between the schools which varies from 5.18 to 6.03 which is rather high on a seven degree scale. These results from the measuring approach show that the conditions for sustainable health vary quite a lot between the schools.

	Empathy	Presence/ Communi- cation	Integrity	Continuity	Develop- ment	Influence	Being informed	Health
School A	5.67	5.93	5.73	6.30	5.80	5.70	4.37	6.03
School B	4.89	4.89	4.82	4.96	4.62	4.81	4.65	5.39
School C	5.83	5.33	5.54	4.88	5.23	5.17	4.35	5.60
School D	5.85	5.74	5.52	4.89	5.00	5.48	5.63	6.26
School E	3.38	3.57	3.33	2.81	3.05	3.24	4.29	5.29
School F	5.26	4.64	5.36	4.43	4.74	4.71	4.45	5.71
School G	5.41	5.51	5.39	4.76	4.71	4.57	4.25	5.18
School H	4.74	4.26	4.56	4.86	3.83	4.30	4.44	5.44
Total	5.09	4.93	5.00	4.82	4.59	4.74	4.53	5.54

Table 1. The results from the measurement in all the schools.

As the leader was informed about their own mean value they could compare their own results with the mean value of all schools. The results gave the leader information about the co-workers’ perception of their health, and the co-workers’ perception of to what extent the values ‘Leadership Commitment’ and Participation of Everybody’ permeate the schools. It also gave them information as to which areas they as leaders had possibilities to improve.

1. The test of the measurement approach

DIMENSION	MEAN SCORE	ST.DEVIATION	CRONBACH'S ALPHA
Empathy	5.0983	1.11962	0.837
Presence/Communication	4.9257	1.05489	0.637
Integrity	5.0024	1.06284	0.783
Continuity	4.8177	1.34249	0.671
Development	4.5947	1.29583	0.752
Influence	4.7386	1.16079	0.552
Being Informed	4.5276	0.95797	0.535
Health -index	5.5372	1.03832	0.789

Table 2. The results of the internal consistency reliability analysis of the measurement approach.

The Cronbach's alpha coefficient was computed for each dimension in order to test the internal consistency reliability. A value of 0.6 or less is generally considered unsatisfactory (Malhotra and Birks, 2000), and the coefficient tends to increase with the number of items or statements, (Hair et al., 1998). Six of the dimensions score higher than 0.6. The dimensions 'Influence' and 'Being Informed' score less than 0.6 which can be considered rather low. There is also some variation in the data where 'Continuity' has the highest standard deviation indicating a substantial variation in perception of that dimension among the co-workers. In earlier tests that dimension also had the highest variation. The dimension 'Continuity' also has a high variation.

We also calculated the Pearson correlation between the results on the statements regarding the dimensions and the statements regarding the health index. The results are presented in Table 3.

DIMENSION	PEARSON CORRELATION	SIG.
Empathy	0.206*	0.015
Presence/Communication	0.217 *	0.010
Integrity	0.180 *	0.033
Continuity	0.134	0.115
Development	0.082	0.336
Influence	0.328**	0.000
Being informed	0.238**	0.005

Significance level: * $p < 0.05$; Significance level: ** $p < 0.01$

Table 3. Correlation between the dimensions and the health index

As can be seen in the table, the two dimensions 'influence' and 'being informed' were highly significantly correlated with the health index with a p-value for the first mentioned dimension of only < 0.000 . A significant correlation can also be seen between 'integrity', 'presence/communication', 'empathy' and the health index. Thus, we can conclude that most of the dimensions are related to good health among the employees.

Discussion and Further research

The description of the health promotion activities accomplished within the project can help managers and project leaders to plan and carry out their projects and activities in their striving for sustainable health among the co-workers and for efficient organizations. Before the project is finished the co-workers will be asked to fill in the measurement approach questionnaire once again. Then a comparison between the results in the beginning of the project and the results in the end of the project can be done. That comparison can confirm if the health promotion activities have influenced health among the co-workers. The comparison can also confirm if the underlying dimension to the values 'Leadership commitment' and 'Participation of Everybody' permeates the schools to a higher extent after having conducted all those health promotion activities. It would also be interesting to follow up the schools later maybe after a year and test if the values have permeated to a greater or lesser extent. Another interesting further object of research is to interview the leaders and the co-workers to investigate their experience of the health-promoting activities in the project. In those interviews it could be interesting to investigate if the co-workers think the leaders have changed their leadership after the health-promoting activities and if the leaders think they have changed their own leadership and also if the co-workers think they have changed their way of teaching the children.

Since two of the dimensions had lower Cronbach's alpha than 0.6, a factor analysis would be valuable in order to investigate which the underlying factors are in this material. New dimensions could be found which perhaps can give new insight into correlations with employees' perceptions of their health. In our previous research (Lagrosen et al., 2011,) the dimensions 'Development' and 'Influence' had Cronbach's alpha higher than 0.6. However, that research study was carried out in a manufacturing company (Lagrosen et al., 2011). A manufacturing environment is quite different from an elementary school environment. This could be a reason for the different results.

Paper type: Case study

Introduction

The global competition obliges organizations to search for new sources competitive advantage. At present the organizations, which do not differentiate products and services as well as competes only by prices, have little possibilities to survive. Patterson et al. (2008) state that when creating the desired experience for a customer the organizations, in fact, offer exceptional service. However, modern organizations, though well knowing habits of customer purchase, not sufficiently go deep into customer experience that determines his / her satisfaction and loyalty. A customer who does not have any experience does not exist. Every customer acquires positive or negative experience. So every organization should organise service rendering so that customer's experiences would form positive experience at every point of his / her interaction with the organization as well as would ensure long-term collaboration with the service provider. Thus the positive experience of service customers is not dissociated from the financial results of the organization, which are achieved when having a larger number of satisfied and loyal customers.

Lithuanian transport and logistics sector distinguishes in a large number of market and acute competition. Transteda Ltd is the company of private capital registered in Lithuania. The main activity of the company is international and domestic transport services by road. The company provides wide range of the services: transportation of cars; transportation of cargos' covers the carriage of full, partial, frozen, hazardous goods in the entire Europe; transportation of part loads is the service used by the customers, who want to deliver the shipment that does not make the full cargo; transportation of cargos in containers is used to carry the goods by sea from such countries as China and the USA; additional insurance of cargos is the additional guarantee to the customer when an expensive cargo is transported. The transportation directions are very different, starting with Western Europe and Scandinavia, and ending with Turkey and the CIS countries. Some part of the vehicles is working for regular customers on regular routes, while the other part serves the irregular needs of the customers. Transteda Ltd creates added value for each customer safely and effectively, with enthusiasm, accuracy and reliability. In its services company emphasizes exceptional attention to the customers, quality and safety of the provided services, as well as the coordination of information. The managers of the company coordinate company's activity effectively and thus can suggest the most optimal transport solution for the customers.

Transteda Ltd fast develops; it pursues not only to enlarge the number of its customers, volumes of transported cargos but also to improve relations with its customers; thus the enterprise faces the objective how to ensure satisfaction of service customers and to strengthen their loyalty for the enterprise. One of the ways to solve this objective – is to manage the formation of positive experience of customers.

The aim – is to envisage the possibilities to advance the management of service customers’ experience at Transteda Ltd.

Customer experience: a brief literature review

Defining customer experience

One of the main features of today’s service customers – increased expectations and requirements for services organizations. This is true for business-to-customer and business-to-business customers. The management of positive experience at every touchpoint of interaction with the organization can help to win intelligent customers’ satisfaction and loyalty. Temkin (2009) notes that an average \$10 billion company can generate \$284 million of additional revenues from customer experience improvements. Johnston and Kong (2011) study has suggested that there were three areas of perceived benefit; the customer, the staff and the organisation. Thus satisfying customer experience is needed. Customer experience leads to customer satisfaction, which in turn acts as an antecedent of brand loyalty, customer retention, market growth and the overall profitability of the organization (Garg et al., 2010). Unfortunately, most companies do not fully understand this link.

The notion of the customer experience has emerged from a synthesis of six concepts: paradigm shifts in ideas of the customer, relationship marketing, customer lifecycles, service framework theories, customer spending psychology and services sciences, management, and engineering (Ojiako, Maguire, 2009). Customer experience has been defined in various ways. Some definitions are presented in Table I.

Table I. Definition of customer experience

Researchers	Definition
Gentile, Spiller and Noci, 2007, p. 397	„The customer experience originates from a set of interactions between a customer and a product, a company, or part of its organization, which provoke a reaction. This experience is strictly personal and implies the customer’s involvement at different levels (rational, emotional, sensorial, physical, and spiritual)”
Meyer and Schwager (2007), p.118	„Customer experience is the internal and subjective response customers have to any direct or indirect contact with a company. Direct contact generally occurs in the course of purchase, use, and service and is usually initiated by the customer. Indirect contact most often involves unplanned encounters with representatives of a company’s products, service or brands and takes the form of word-of-mouth recommendations or criticisms, advertising, news reports, reviews and so forth.”
Howard (2009), p.1	„Total Customer Experience (TCE) can be defined as the overall impression a customer develops about a company, based on perceptions and experiences at every point of interaction with that company”.

Verhoef et al. (2009), p.32	„Customer experience construct is holistic in nature and involves the customer’s cognitive, affective, emotional, social and physical responses to the retailer... the customer experience encompasses the total experience, including the search, purchase, consumption, and after-sale phases of the experience, and may involve multiple retail channels“. “This experience is created not only by those elements which the retailer can control (e.g., service interface, retail atmosphere, assortment, price), but also by elements that are outside of the retailer’s control (e.g., influence of others, purpose of shopping)”.
Shaw, Dibeehi and Walden (2010), p. 3	„A customer experience is an interaction between an organization and a customer as perceived through a customer’s conscious and subconscious mind. It is a blend of a an organization’s rational performance, the senses stimulated and emotional evoked, and intuitively measured against customer expectations across all moments of contacts“
Walter, Edvardsson and Öström (2010), p. 238	“Customer experience is defined as the customer’s direct and indirect experience of the service process, the organisation, the facilities and how the customer interacts with the service firm’s representatives and other customers. These in turn create the customer’s cognitive, emotional and behavioural responses and leave the customer with memories about the experience.”
Johnston and Kong (2011), p. 8	“The customer’s experience is their personal interpretation of the service process and their interaction and involvement with it during their journey or flow through a series of touchpoints, and how those things make the customers feel.”

According to customer experience definitions in the literature, all customers have experience (good, bad or indifferent) during an interaction with the organization and it is inherently subjective and personal.

As Schmitt (1999) states, experiences provide sensory, emotional, cognitive, behavioural, and relational values that replace functional values. Schmitt notes that, while customers may frequently engage in rational choice, they are just frequently driven by emotions because consumption experiences are often directed toward the pursuit of fantasies, feelings, and fun. Palmer (2010) argues that a combination of three factors - stimulies, context and situational variables - help shape a consumer’s attitude to an event. People perceive a stimulus differently according to its sensory characteristics and information content. In perceiving stimuli with a given set of characteristics, individuals will also be influenced by the context of the stimulus. Situational variables in which the information is received, including social, cultural and/or personal characteristics - perceptions are greatly influenced by individual characteristics, including prior experience with a particular product or service offering.

The brands are important for customer experience formation as well. As Howard (2009) notes, the brand and new channels of interaction, based on new technologies, influence the customer experience. From brands the customers are looking for something real and authentic and not just ad slogans and messages. They want something that engages their senses and touches their hearts, something that excites or intrigues them (Schmitt, 2009).

Brakus et al. (2009) distinguish the product, shopping, service and administration experiences. Experience of the product formed when customer search for, examine and evaluate products. It can be direct, when the customer has physical contact, and indirect, when the product is in a virtual space or advertised. Shopping and service experience is under the influence of customers' interaction with the organization employees, physical environment, work policies and practices. The customer experience takes hedonic, emotional, fantasy and alike tones, in other words, it is multidimensional. Also Kim et al. (2011) study provides evidence that the customer experience construct is multidimensional and therefore hierarchical in nature. Kim et al. (2011) developed the index that identifies and measures the underlying dimensions of the customer experience. Their research resulted in a seven-factor model comprised of the following dimensions: environment, benefits, convenience, accessibility, utility, incentive, and trust.

According to Frow and Payne (2007), experiential consumption emphasises emotions and contextual, symbolic and nonutilitarian aspects of consumption where value resides not in the object of consumption but in the experience of consumption.

Table II illustrates the factors what form the user experience in different phases of use.

Table II. The factors of customers experience in different phases of use (Adopted from Arnould et al., 2004; Venkat, 2009)

CUSTOMER EXPERIENCE			
<i>Pre-purchase consumption</i>	<i>At purchase / consumption</i>		<i>Post-purchase</i>
	<i>Buying experience</i>	<i>Usage experience</i>	
<ul style="list-style-type: none"> • search (specific, using traditional means, the Internet, friends' recommendations) • future purchase planning; • finance proportion planning; • expectations 	<ul style="list-style-type: none"> • option; • payment; • service encounter; • atmosphere 	<ul style="list-style-type: none"> • feeling and experience (testing, contact, feeling, attitude); • glut; • excitement; • changes 	<ul style="list-style-type: none"> • memories of past experiences; • stories; • comparison of old experiences with new ones; • sharing experiences with friends; • the desire to re-use the same service

Each phase of the use is imposing new points of contact with the organization in determining the customer experience (Mascarenhas et al., 2006). Venkat (2009) argues that every customer, during service delivery from the contact with the organization, takes appropriate decisions on their future behavior. Thus it is important to identify all touchpoints where interests of customers and the organization are concurrent. As each individual aspect of the service forms the customer experience, the organization activities, which are likely to influence the customer experience, must be constantly monitored and each customer's response requires attention. All these things influence customer experience and ultimately the level of customer satisfaction or dissatisfaction.

Customer experience dimensions and clues

Customer experience is dynamic and by organization is not created exactly the same way for every customer. Anything perceived or sensed - or conspicuous in its absence - is an

experience clue (Berry and Carbone, 2007). An organization cannot manage customers' emotions, but it can manage the clues embedded in customers' experiences.

Schmitt (2003) indicates five types of experiences: sensory experiences (*sense*), affective experiences (*feel*), cognitive experiences (*think*), physical experiences, behaviors, and lifestyles (*act*) and social-experiences that result from relating to a reference group or culture (*relate*). Gentile, Spiller and Noci (2007) assume six components of the customer experience. They are similar to Schmitt (2003), but Gentile, Spiller and Noci *act* type of experience define into *lifestyle* and *pragmatic*.

Gentile, Spiller and Noci (2007) make a distinction between two kinds of customer value: *utilitarian value* (or functional value) and *hedonic value* (or experiential value). Angelis et al. (2010) state that in addition to the components required in services provision, such as appropriate physical environment, implemented processes and sufficient staff, managers must also incorporate behavioural components. These can be grouped into emotions and participation activities (Fynes and Lally, 2006).

Pine and Gilmore (1998) think about experiences across two dimensions (the customer participation and the connection, or environmental relationship) and classify customer experience into four parts: entertainment, educational, escapist, and esthetic. Entertainment experience is those in which customers participate more passively than actively; customers connection with the event is more likely one of absorption than of immersion. Educational experiences involve more active participation, but customers are still outside the event. Escapist experiences involve greater customer immersion. During esthetic experience customers are immersed in an activity or environment, but they themselves have little or no effect on it.

As Berry and Carbone (2007) state, experience dimensions are emotions, attitudes, and behaviours. Emotions represent how customers feel about themselves, attitudes - how customers feel about the company, behaviors - how customers act. According to Berry and Carbone, an organization's first step toward managing the total customer experience is recognizing what the authors call clues: the signals or messages given off by everything involved in the buying process. Berry and Carbone declare three main categories that form the experience clues: functional, mechanic, and humanic. Functional clues concern the technical quality of the offering. It means that anything that influences the customer's perception of technical quality is a functional clue. Mechanic clues make influence on sensoral processes. The building design, equipment, furnishings, displays, colors, textures, sounds, smells, lighting etc visualize the service and communicating with customers. Human clues come from the behavior and appearance of service providers, for example the choice of words, the tone of voice, the level of enthusiasm, the body language, appropriate dress and neatness. Human interactions in the service experience provides the primary opportunity to extend respect and esteem to customers and, in so doing, exceed their expectations and cultivate emotional connectivity.

Summarised the dimensions and clues of customer experience are presented in Table III.

Table III. The the dimensions / clues of customer experience

Researchers	Customer experience dimenstions / clues
Pine and Gilmore (1998)	Entertainment, educational, escapist and esthetic
Schmitt (2003)	Sensory (sense), affective (feel), cognitive (think), physical, behaviors and lifestyles (act) and social (relate) experiences
Gentile, Spiller and Noci (2007)	Sensorial, emotional, cognitive, pragmatic, lifestyle, relational components
Fynes and Lally (2006)	Emotions and participation activities
Berry and Carbone (2007)	Emotions, attitudes and behaviours
Berry and Carbone (2007)	Functional, mechanic and humanic clues

Pine and Gilmore (1999) argue that, in an experience economy, companies must make memories and create the stage for generating greater economic value, rather than simply making goods and delivering services. Thus we can state that organizations must manage customer experience clues, if they want to offer their costumers memorable activities.

Research methods

The experience of the Transteda Ltd customers was analysed by applying quantitative and qualitative methods: survey-in-written and semi-standardized interview.

The respondents of the survey-in-written are the representatives of the fixed drivers, who per month transport not less than 10 tons of the cargo. Having designed the diagram of service rendering, nine interaction touchpoints were identified, in which customer experience is forming: 1) search for information, 2) clarification of needs, 3) search for a cargo, 4) cargo offering, 5) cargo order, 6) preparation for transportation, 7) cargo loading, 8) cargo delivery and 9) document registration. Referring to them, the questionnaire was formulated. Its aim is to survey customer experience before using the service, when using the service and after using the service as well as to identify the most important components of the experience of the representatives of the enterprises participating in the survey – behaviour, viewpoint and emotions – at every touchpoint of customer interaction with the Transteda Ltd company. The data of the survey were processed by the programme SPSS 18 *Statistics*.

The semi-structured interview was performed with five informants:

- the first informant – the director who has managed the enterprise for two years, before this he worked as purchase manager at this enterprise. Interview duration – 75 min.;
- the second informant – the purchase director who has worked for three years in this enterprise; he is responsible for the offering of the possessed cargos to customers. Interview duration – 60 min.;
- the third informant – the sale director who has worked for three years in this enterprise, before he worked as sale manager and directly communicated with ther enterprise’s customers. Interview duration – 55 min.;
- the fourth informant – the purchase manager, his work experience is two and a half years. Interview duration – 75 min.;
- the fifth informant – the purchase manager, his work experience is two years. Interview duration – 60 min.

The purchase managers directly communicate with the customers of the Transteda Ltd company; form the value added for the enterprise's customers and at the same time they convey the customers' opinion about the enterprise for the directors.

As the agreement of the informants to record the interview was obtained, later the transcription of the records was performed.

The analysis of the results

The results of the survey-in-written

Transteda Ltd collaborates with 52 fixed drivers. 35 questionnaires were sent, 31 was returned (the feedback of the questionnaires is 88.6 percent). The characteristics of the respondents are presented in Table IV.

More than one fifth of the respondents represent the enterprises, which diversify their activity, i.e. transport new and used cars, sell them, and execute transportations in Europe. Only five respondents represent specialised enterprises of drivers. The enterprises represented by the respondents are very different according to the duration of functioning in the market. Most respondents are from the enterprises, which have been working for three – seven years. The number of the employees and trucks defines the enterprise's size. According to the number of the employees, the representatives of the small enterprises, which had up to 10 employees and up to 5 trucks, took part in the survey mostly. More than one fifth of the respondents are from the enterprises, which have collaborated with Transteda Ltd from one to four years.

Table IV. The characteristics of the respondents who participated in the survey

Criteria	Groups	Respondents	
		number	part (percent) in the total number
Character of enterprise's activity	Transportation of new and used cars	26	83.9
	Work in regular routes in Europe according to long-term contracts	13	41.9

	1-4	27	87.1

Below we will discuss what influences customer experience in interacting with the Transteda Ltd company.

Search for information. Two thirds of the enterprises represented by the respondents accumulate the information about cargo transportation enterprises in their database. Despite this every time in searching for optimal price, the proportion of the quality and transportation deadlines, the information is searched for by other channels, i.e. the phone calls to the enterprise (45.2 percent of the answers) or e-mail is used (64.5 percent of the answers). This was pointed out by the representatives of the companies, most frequently of small ones, that did not have any database. The Internet website as information source, according to the respondents, is important only when starting collaboration when the main information about an enterprise is necessary. More than half of the respondents (n=16 or 53 percent) confirm that the answers to the e-mails come very fast from Transteda Ltd, i.e. in the same day or the next day; the rest part of the respondents (n=15 or 47 percent) indicates that the answers come in several days. Most respondents (n=27 or 87 percent) point out that the priority is given to a phone call when choosing whether to write an e-mail or to phone because in this way issues are solved more efficiently. Usually the enterprises represented by the respondents wish to fast find a cargo – more than half of the respondents (n=16 or 51.6 percent) indicate that they dedicate up to several hours for the search of a cargo, more than one third (n=10 or 32.3 percent) – several hours. In such situation communication by phone is more convenient. However, the respondents point out that direct contact with the representatives of Transteda Ltd by phone not only enables to get and / or to specify the information, however it can cause unpleasant feelings – the enterprise’s employees sometimes are inaccurate, hasten, ask for the information, which they should know, according to the respondents.

Clarification of the need. The level of service quality and customer satisfaction depends on how a service provider is able to find out about the needs. 61.3 percent (n=19) of the respondents state that the employees of Transteda Ltd efficiently react to the needs of the customers; however, the rest part of the respondents (almost one third) would wish faster reaction of the managers. One respondent stated that he did not feel managers’ interest in the needs of the enterprise he represented.

Search for a cargo. When choosing an offering, the respondents give the greatest importance for road taxes and faster payment of the provided services (by 71 percent responses), transportation complexity (58 percent) and route length (54.8 percent responses). The actions of the enterprises represented by the respondents when the need for the cargo transportation emerges are inadequate. In such case a bit more than one fifth of the respondents (n=7 or 22.5 percent) directly contact only with the Transteda Ltd company; however, most respondents (n=18 or 58.1 percent) – present their queries to several service providers. When answering the question how Transteda Ltd distinguished among enterprises functioning in the same business, the respondents pointed out the diversity of the provided services (n=14 or 45.2 percent) and its attention to the customers (n=13 or 41.9 percent). The respondents representing smaller enterprises state that large enterprises pay less attention to the desires or claims of small enterprises. It could also be said about Transteda Ltd ($p \leq 0.01$, and $r = -0.516$). As it is mentioned above, in the *business-to-business* market experience elements are the same as of *business-to-customer* market customers. Thus it is hard to properly communicate

with the employees, who perform the search for cargos. 64.5 percent of the respondents state that the owner of the director of the enterprise carries out the search for cargos, 35.5 percent – one or several managers.

Cargo offering. Though most respondents (n=24 or 77.4 percent) think that Transteda Ltd reacts to the needs, 7 respondents answered this question negatively. 5 of them (71.4 percent) immediately address competitors' enterprises, 2 respondents indicate that they do not communicate with the surveyed enterprise till it shows the initiative. When they get several analogous offers, the respondents' enterprises not necessarily choose the enterprise, with which they collaborate for a long time and with managers of which friendly relations are created ($p \leq 0.01$, and $r = -0.702$). Customer flexibility plays much more important role in agreeing for prices and the guarantee that the services will be paid immediately ($p \leq 0.01$, $r = -0.752$). Priority cargo offers are provided for the enterprises, which have long-term agreements with Transteda Ltd. The respondents admit that the long-term agreements with Transteda Ltd have both advantages and disadvantages. Some advantages are mentioned: the long-term agreements ensure better conditions (8 answers) and help spare time (10 answers). Among disadvantages it was mentioned that it needed a lot of investments (12 answers), the enterprises do not have the drivers able and willing to work in the European market for a long time (8 answers), they fear to lose flexibility in the market (6 answers). The speed of the solution about a cargo by the enterprise represented by the respondents is influenced by the precise information about the cargo conveyed by managers (22 answers), provision with the cargo in the further route (12 answers). The enterprises choose competitors' offers in case little information about the cargo is given by the managers at Transteda Ltd ($p \leq 0.01$, and $r = -0.744$). Thus the more precise offers would be given to the customers by Transteda Ltd, the greater probability to increase amounts of transported cargos.

Cargo order. When choosing the Transteda Ltd cargos from several alternatives, the ensurance of the payment for the services (16 answers), good work relations with the manager (15 answers) and the attractive price (9 answers) are important for the enterprises represented by the respondents. The customer experience is negatively influenced by negative critical events. In the surveyed services one of such events is the cancellation of the cargo order. 11 out of 31 respondents state that their enterprises have not faced this. Though seldom but in 18 out of 31 enterprises represented by the respondents this happens. 10 of them point out that instead of the cancelled cargo the Transteda Ltd offers another one; however, 7 respondents stated that Transteda Ltd tried to avoid its responsibility. In the stage of cargo order the rationality is inseperable from emotions. The enterprises of most respondents who participated in the survey have collaborated with Transteda Ltd for a long time. In business relations with this enterprise the respondents positively value their emotional state (they feel trust in the enterprise and are sure for fair collaboration, consider themselves as exceptional customers) (15 times), as well as negatively (they feel as ordinary customers, exploited through service prices, fear for harms) – also 15 times.

Preparation for transportation. The results of the Transteda Ltd activity depend on how successfully the drivers cope with their tasks. Thus the company also contribute to cargo transportation: exceptional insurance conditions are offered (mentioned for 17 times), fuel cards are given (mentioned for 5 times), and cheaper ways of cargo transportation are chosen (mentioned for 4 times). Nevertheless the respondents pointed out for 13 times that the driver takes the responsibility for cargo transportation. In order

to prepare for transportation more fluently, Transteda Ltd has formulated the transportation recommendations for drivers. Most respondents (n=25) state that the drivers of their enterprises know well these recommendations and follow them.

Cargo loading. The results of cargo transportations are influenced by how the discrepancies of the cargo and documents are being fixed. Here the most important role goes to drivers. The respondents point out that the fixing of the discrepancies are impeded by drivers' poor knowledge of foreign languages (mentioned by 16 times), their irresponsibility (the discrepancies are not announced) (mentioned by 12 times). The respondents assumed that after the trainings held by Transteda Ltd the drivers acquired enough knowledge and that, having started the collaboration with the enterprise administrating discrepancies, they diminished significantly (mentioned by 6 times).

During the cargo loading the drivers face different problems. The most frequently mentioned reason is when the cargo is not available (n=17). Other reasons are the discrepancy in the number of transported vehicles and incorrect addresses (by n=13), Lithuanian drivers' discrimination (n=12), dishonest behaviour of the employees in the place of the cargo loading (n=5) and indifference of the Transteda Ltd employees (n=2).

Cargo delivery. Time management is the important factor of customer experience. According to the opinion of 45.2 percent (=14) of the respondents, suitable planning of the use of transport vehicles increases the trust in Transteda Ltd. More than one third (n=10) of the respondents point out that the discrepancies of the time planning become the reason for conflicts with Transteda Ltd.

Document registration. The enterprises represented by the respondents present the documents on a transported cargo during the period from one week to one month and longer; however most frequently it lasts for two weeks. Almost two thirds (n=23) of the respondents representing the enterprises point out that, when presenting the documents, Transteda Ltd does not create any exceptional conditions in comparison to other enterprises. 25.8 percent (n=8) of the respondents state that Transteda Ltd forces the drivers to present the documents too fast. Several respondents (n=3) pointed out that the enterprise requires too many documents proving the cargo transportation and that the rush in presenting documents when one needs to take the services of express transportation agencies is too costly (n=2). Though the respondents evaluate the requirements for the deadlines of document presentation at Transteda Ltd more unfavourably than favourably, most respondents (64.5 percent or n=20) admit that faster document presentation to Transteda Ltd helps to ensure faster service payment for the drivers.

Transportation analysis and report. The long-term collaboration with Transteda Ltd increases the probability to get better cargos and attractive price (correspondingly 58 percent (n=18) and 48.4 percent or n=15). Some respondents (n=6) think that the long-term collaboration does not provide any exceptionalism. Most respondents (58 percent or n=18) when answering the question whether the enterprises represented by the respondents presented any claims about the services for Transteda Ltd pointed out that they expressed their discontent to the manager by phone. The claims by e-mail or having met face-to-face were mentioned by 22.6 percent (n=7) and 25.8 percent (n=8) of the respondents. Almost one third (n=9) of the respondents who participated in the

survey did not claimed for the services of Transteda Ltd. Transteda Ltd does not react to the claims: 48.4 percent (n=15) of the respondents were sure of it. However, 41.9 percent (n=13) of the respondents were of opposite opinion.

Most respondents think that the amounts of cargo transportations through Transteda Ltd could increase due to more attractive prices and payment improvement (correspondingly, 80.6 percent or n=25 and 58.1 percent or n=18). More than one third of the respondents (35.5 percent or n=11), when continuing the collaboration with Transteda Ltd, would wish bigger offer of cargos. Despite the expressed remarks, even 87 percent (n=27) of the respondents who took part in the survey would recommend Transteda Ltd for their acquaintances.

Table V presents the factors and means making the greatest influence upon Transteda Ltd customer experience as well as the prevailing experience at different stages of using the service.

Table V. The experience of the surveyed Transteda Ltd customers and the factors influencing it

Consumption stages	Experience components	Factors and means forming experience	Clues	Prevailing experience
Pre-purchase / consumption	Behaviour	Communication by e-mail	Mechanic	Positive
		Reaction to queries about the cargo	Technical	More positive
At purchase / consumption	Viewpoint	Diversity of services	Technical	Positive
		Size of an enterprise	Technical	More negative
		Time during which a cargo is offered	Technical	More positive
		Relations with managers	Human	Positive
		Trust	Technical	Positive
	Behaviour	Detailed offer	Technical	More negative
	Emotions	Attention to customer	Human	More positive
Sense of customer exceptionalism		Human	More negative	
Post-purchase	Viewpoint	Collaboration succession	Technical	More positive
		Collaboration conditions	Technical	More negative
		Payment for services	Technical	More negative

The results of the semi-structured interview

First of all, the respondents were asked to express their opinion about the Transteda Ltd customers. “<...> a customer – is a helping hand when seeking for long- and short-term aims of the company <...>” (the first informant); “<...> customers give the possibility to earn more, <...> to realise oneself as employee <...>” (the fourth informant); “<...> a customer – is a direct carrier of the profit for Transteda Ltd <...>” (the third informant). Thus the interview participants perfectly understand the importance of Transteda Ltd customers for the company. The customers are related not only to the financial profit for the company, the material wellbeing of the employees but also to their self-expression. The answers to the question how they are divided at Transteda Ltd reveal the prevailing viewpoint of the informants. “<...> customers are not classified at all, unless in the thoughts of the managers <...>” (the first informant); “<...> I divide customers into potential and working <...>” (the fifth informant); “<...> customers are

particularly classified according to regions and countries; work character (tents, auto-vehicles); the country of cargo transportation destination <...>“ (the second informant). Customer distribution is important in respect of experience management – different groups of customers possess unequal needs, expectations, use unequal services, different frequency and alike; thus for them Transeda Ltd should formulate different suggestions and choose suitable communication means. The informants’ answers show that the stable system of customer classification does not exist in the company.

Expectations are one of the important factors forming customer experience. “<...> *I think that competitive prices and stable payments are the most important for drivers <...>*“ (the first informant); “<...> *a driver as any other customer hopes that the company will meet his needs; perhaps, more precise information, good service <...>*“ (the second informant); “<...> *three things: good, i.e. less than competitors, prices, regular payment and precise information about cargos <...>*“ (the third informant); “<...> *the cargos adequate to needs, fast payment <...>*” (the fourth informant); “<...> *alongside cargos, payments it is important for the drivers whether they will be pleasantly served, how easy it will be to collaborate <...>*” (the fifth informant). The analysis of the informants’ answers allows drawing the conclusion that the drivers from Transteda Ltd hope not only for sufficient amount of cargos, reasonable prices, timely payment for the services, precise information, but also for pleasant serving and constructive collaboration.

The informants differently answered the question what customer experience was. “<...> *this is the emotional state of a customer, which he / she experiences after the purchase of a service. This involves the positive or negative assessment and experienced financial profit of the company providing services <...>*” (the first informant); “<...> *company’s responsibility, adequacy of the need, managerial communication, personal relations with managers, service quality, the competitive ability of prices and payments in time for the provided services <...>*” (the second informant); “<...> *the company’s manager forms customer experience by communicating with customers, what can influence positive and negative customer experience <...>*” (the third informant); “<...> *customer experience depends on the number of transported cargos, it is influenced not only the experience acquired during service rendering by Transteda Ltd but also by previous experience when using competitors’ services <...>*” (the fourth informant). When defining customer experience, the informants point out not only cognitive but also emotional state, which is determined by different factors. The informants think that the greatest part of customer experience is formed by service quality, price, loading conditions, as well as harm and payment deadlines. The informants consider employees to be the important factor for customer experience formation “<...> *work interaction with customers depends on the level of employees’ responsibility <...>*” (the fifth informant) and professionalism of the customers “<...> *experience consists of work professionalism of the customer <...>*” (the fourth informant).

The informants gave different answers to the question what problems the customers faced due to the actions of the Transteda Ltd company: “<...> *that we work respectably, there no big problems, perhaps some small <...>*” (the first informant); “<...> *sometimes a driver gets not the cargo he was waiting for or the cargo is cancelled on the whole <...>*” (the second informant); “<...> *sometimes customers get*

unpleasantly surprised that the price of the service does not correspond <...>” (the third informant); “*<...> I feel uneasy when drivers reproach for the deadlines determined by our company, everyone wants to get money for the provided service as soon as possible. Everyone needs circulating asset <...>*” (the fourth informant); “*<...> sometimes we change the time of cargo loading or we cancel the cargo <...>*” (the fifth informant). It is possible to state that the informants admit the mistakes made by Transteda Ltd, due to which the drivers face problems; thus timely solution of the problem could help neutralise negative experience. However, Transteda Ltd unwillingly takes the responsibility for problem solution: “*<...> we do not speak about the compensation till the customer does not claim for it because in the company the viewpoint that it is possible to compensate the costs for the customer in the case if the company sees the would-be or gets the direct profit <...>*” (the first informant); “*<...> sometimes, when we cancel the cargo transportation, we offer the drivers financial compensation. We more often do this for the customers who collaborate with our company for a long time <...>*” (the second informant); “*<...> if we cancel one cargo transportation, we compensate it by another <...>*” (the third informant); “*<...> theoretically we should compensate unfulfilled promises and pay certain sum of money, but practically it happens very seldom. The Transteda Ltd company does not possess any special finance reserve. The truth is that not so often cancel cargos, we need to possess some finances, from which we could compensate the drivers. We do not accustom the drivers to this <...>*” (the fourth informant).

Information communication technologies are applied for the management of customer experience. The question whether Transteda Ltd uses the programmes helping to ensure long-term information about the customers was also given. It became clear that till 2011 the MS Excel programme was used for accumulating the data on the customers, however “*<...> it was faced with the problem when some part of the data on the customers occasionally disappeared from the lists when the information on the customers was shared by enterprise’ employees <...>*” (the second informant). In addition, the data about customers are “*<...> renewed seldom enough <...>*” (the fifth informant) or “*<...> only the most important information is renewed if some new information about the customer is provided and it is important for the company <...>*” (the third informant). The amount of the data, which the enterprises will possess about the customer “*<...> depends on every employee’s accuracy and responsibility level <...>*” (the fourth informant). In the beginning of 2011 the CRM systems has been launched; it gives the possibility to accumulate the data about customers in one programme, to do statistical calculations, it is the most important “*<...> to see the evolution of the collaboration with the customer in analysing previous records <...>*” (the first informant).

The informants differently explain why customers should continue the collaboration with Transteda Ltd: “*<...> Transteda Ltd is a responsibly and honestly working enterprise <...>*” (the first informant); “*<...> our enterprise has long-term goals, does not flounce about, does not look for easier way, we work for our customers. They get profit from the collaboration with our enterprise <...>*” (the second informant); “*<...> an infrequent enterprise is strong in transportation offers. It is very important for the customers <...>*” (the third informant); “*<...> we have a lot of advantages in comparison with other market players. I would say that the personnel of Transteda Ltd are very competitive. I am pleased that the customers say that for them it is not useful but also pleasant to communicate with our personnel <...>*” (the fourth informant).

The long-term collaborator with the customers for the Transteda Ltd “<...> ensures stability <...>” (the first informant), “<...> ensures the possibility to obtain recommendations, to attract new customers <...>” (the second informant) and “<...> to enlarge organization’s profit <...>” (the third informant). In order to retain the customers, the Transteda Ltd “<...> suggests competitive prices <...>” (the first informant), “<...> shorten payments, provides fuel cards <...>” (the third informant), “<...> offers exceptional insurance proposals and administration <...>” (the second informant).

When summarising the results of semi-structured interview, it is possible to draw the conclusion that the organization understands the importance of customers’ experience as well as the mechanism of its formation, envisages the shortcomings of its activity that negatively influences customers’ experience; however, in most cases it values itself better than the customers who participated in the survey.

Conclusions

More than half of the representatives of the regular customers participated in the survey of customer experience in Transteda Ltd company. This suggests that research findings on the company actions and means that form the experience may be relevant to other customers. As the company declares long-term and mutually beneficial relationships with their customers, their satisfaction and loyalty to the company, it should audit the customers’ experience and on the basis of the results, prepare the strategy of customer experience management.

The experience of surveyed customers cooperating with Transteda Ltd. is highly diverse. The companies’ actions and means at different stages of service delivery process vary in diversity and complexity. Thus the experience expresses in customer behavior, attitudes, and emotions. The greatest influence on the formation of experience is made by the technical clues that influence more customers’ rationality than emotions. However, the customers’ acquired experience is understood differently by interviewed Transteda Ltd employees compared with surveyed customers.

In the pre-purchase/consumption stage, the customer has two points of contact with the firm - in search for information and presenting his/her needs. Transteda Ltd company communication (information on the Internet, e-mails, calls to firms, customers’ needs identification, price negotiation and account guarantee) allows the formation of positive customer experience. The behaviour dimension that influences the mechanical and technical clues dominates. *In the purchase/consumption stage*, the customer experience forms during the seven touchpoints with the company: cargo searches, bidding, ordering, and preparation for transportation, cargo loading, delivery and documents registration. In this stage, which is the longest one of service delivery, customers acquire more positive than negative experience. Technical and humanic clues influence the customers’ behavior, attitudes, and emotions. *In the post-purchase stage*, the customer contact with the company in the transportation analysis and presentation of the report. In this stage, negative experience (precisely negative attitude), which is resulted by the proposed cooperation and payment terms of Transteda Ltd company, dominates. The representatives of the company understand the importance of customer experience, its formation mechanism; see the business weaknesses that have negative impact on the

customer experience, but nevertheless self-assessment in many cases is better than the answers by surveyed customers.

In order to seek for customer satisfaction and loyalty, long-term cooperation with customers the Transteda Ltd company should follow the basic principles. These principles could be the beginning of the customer experience management: to know better its customers, go into customer reactions in all stages of service process, to use better software for collecting and analyzing customers' information.

As an experienced player in the transportation market, Transteda Ltd company should initiate the creation of loyalty programs, which up to now are not in this business in Lithuania and propose more innovation in services.

Introduction

Besides the time-consuming and cost-intensive impact of an inspection plan's implementation on the production, large periods of time are attached to inspection planning within production scheduling. It is necessary to parallelise the planning discipline within the Simultaneous Engineering approach with other departments and entrepreneurial processes in order to reduce the time-to-market continuously. This confronts the inspection planning with competitive challenges as decisions have to be made fast and precisely taking into account interdependencies in order not to retard the development process. Since at the time of planning not all relevant data is disposable planning activities often have to be carried out with uncertain input information. Other criteria that increase the requirements of inspection planning are the augmented complexity of products and processes, which base on shortened innovation cycles and an increased number of product development processes as well as the dynamics of the economic sphere of activity. For example, differentiated inspection plans have to be developed for several varieties and integrated into the respective process structure. However, in the last years inspection planning was only insignificantly modified or further developed in order to react on the amplified requirements.

Situation analysis

Inspection planning

Inspection planning is defined as planning of the quality inspection (DIN, 2004) and was formerly exclusively focused on the product (VDI/VDE/DGQ, 1985). It consisted of the planning itself, data collection and analysis (Pfeifer, 2002). Nowadays the equipment and the production process become more and more part of inspection planning. The term inspection planning also subsumes planning the inspection of services (Pfeifer, 2001; Pfeifer, 2002). It can be classified into product-dependent as well as product-independent inspection. While the latter includes the development of inspection methods and the inspection-data processing, the former contains the creation of an inspection plan.

Through planning inspections of the different production steps inspection planning pursues the goal to control and regulate the quality within a company (Pfeifer et al., 2007). It should transfer quality requirements of products or processes into the structural conditions of the company and, therefore, plan the quality inspection of the entire

production process, beginning with incoming goods and ending with the delivery of the product (VDI/VDE/DGQ, 1985).

The main tasks of inspection planning are, in addition to the selection of inspection characteristics and the evaluation of the necessity for inspection, to guarantee the determination of type, point in time, extent, location and personnel of the inspection as well as to choose the inspection equipment and to create the instruction (VDI/VDE/DGQ, 1985). Quality can be inspected by two different types of inspection: whereas the attribute inspection provides a “simple, discrete response”, the variable inspection obtains the “quantitative value of the quality characteristics” (Liangsiri, 2007). Besides, it has to be defined at which point in time inspection should take place: either at the beginning, during or at the end of the production process. To avoid that defective intermediate products are further processed the inspection should take place as early as possible. However, some product characteristics can only be inspected at the end of the process chain due to constructive or practical reasons (Eversheim, 2002). The inspection extent which ranges from “no test to random and intermittent tests and all the way to a 100% test” (Liangsiri, 2007) influences inspection and defect costs significantly. Whereas the 100% test is mainly applied for safety relevant parts (Liangsiri, 2007), generally the sample size for inspection has to be considered according to published standards or intra-company directives in order to assure quality and at the same time minimise costs (Pfeifer, 2001; Pfeifer, 2002; Liangsiri, 2007). The decision on the inspection location is influenced by the inspection characteristics and equipment as well as the work piece size and the production flow (Melchior & Lübbe, 1999; Pfeifer, 2002). In addition, the decision on the inspection location is highly connected to the choice of inspection personnel (Bernards, 2005). Three different types of inspection personnel are considered: external as well as internal highly skilled inspectors and workmen who inspect their work themselves. One advantage of self-inspecting at the production place is the high commitment of the manufacturing personnel which can prevent defects and therewith costs (Pfeifer, 2002; Schmitt & Pfeifer, 2010). For selecting the right equipment many criteria must be taken into account, such as the inspection type, the measuring range and inaccuracy, the accessibility, the capability, directives and the availability as well as environmental influences and, of course, costs (Bloch et al., 2000; Pfeifer et al., 2007; DIN, 2006). Further explanations on interactions between inspection planning’s attributed tasks can be found in chapter 4.

One approach to challenge inspection planning within the product creation process is Simultaneous Engineering and, thus, the parallelisation of processes within a company (Stoffels, 2001; Westkämper, 2004). Figure 1 illustrates both the sequential and parallel steps within the production cycle with increasing product maturity. In case of the sequential product creation process each step on the way to a product’s market maturity is brought to a close before the next step is started. The results of this procedure are long development periods (Eversheim et al., 1995) as well as high defect costs (Eversheim, 1997). While the long period to product maturity can be explained by the sequential order of the processes, the high defect costs are a result of the timeframe between the ‘early’ defect origin on the one hand and the ‘late’ defect detection and adjustment within the product creation process on the other hand (Pfeifer, 2001).

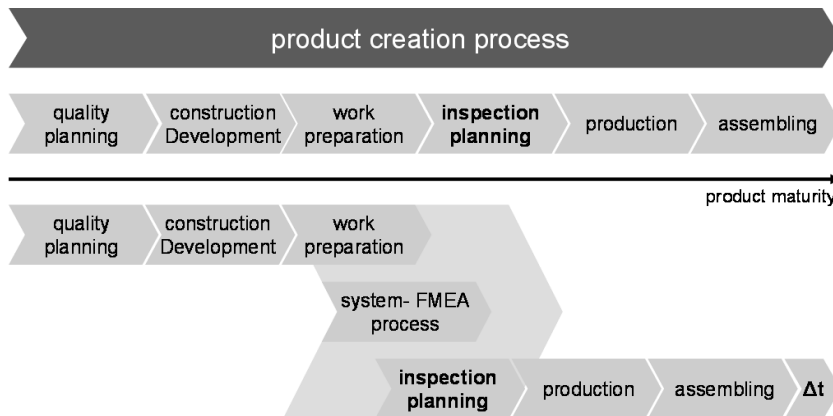

Figure 14: Simultaneous Engineering approach.

The bottom part of figure 1 shows the parallelised steps of inspection planning as well as the resulting shortened time to market (Pfeifer, 2001; Schloske, 1999). For this the application of QM-methods like the system-FMEA process plays an essential role. Since for creating the inspection plan information from the work plan is needed, the tasks of work and inspection planning can only be executed in an overlapping, non-parallel way (Schloske, 1999; Pfeifer, 2001; Brauchle, 1996). Parallelisation serves to increase the requirements for the inspection planning process. Decisions must be made quickly considering the interdependencies in order not to slow down the development process. In addition inspection planning must take place with uncertain input information since not all relevant information is available at this stage.

Decision Theory

Decision theory is based on a logical and empirical analysis of people's rational decision behaviour. It focuses on the deduction of descriptive respectively prescriptive statements concerning the result of a decision (Bamberg & Coenenberg, 2006). Descriptive statements specify how decisions were made in the past. They are based on the research of the structure of factors that had an influence on the decision. In contrast prescriptive statements specify the rational limiting factors of a decision without containing any information about the actual result of the decision itself (Laux, 2007). A possible solution for a decision problem is given by the action alternatives which describe how the decision maker can react to a decision problem (Nitzsch, 2002). Those alternatives must be mutually exclusive and practicable (Laux, 2007; Sieben, 1994; Eisenführ & Weber, 2003). If at least two action alternatives differ in their results and, thus, a selection of those alternatives has to be made, we call this a decision problem (Laux, 2007). The decision situation that can lead to a solution by implementing decision models follows the decision problem (Kahle, 2001). An optimal solution is defined as attaining a fundamental goal (Nitzsch, 2002) - only one action alternative can be realised (Engels, 1962). In the literature different decision models by different authors (Nitzsch, 2002; Engels, 1962; Eisenführ & Weber, 2003; Laux, 2007; Sieben, 1994; Meyer, 1999; Kahle, 2001) can be found which have a similar basic structure.

The Aachen Quality Management Model as a framework for Process Planning

The Aachen Quality Management Model provides a holistic visualisation of the corporate quality management in order to cover all economical requirements taking into account “the articulated and implicated customer demands, the defined management strategy and the actual companies’ ability” (Schmitt et al., 2008). Quality is understood as the overlap between customer requirements, corporate orientation and corporate skills (Schmitt et al., 2008), figure 2. Hence, quality refers to capability factors within a company as well as human resources or technical equipment. This clarifies why quality management has to be embedded in any section of a company (Schmitt et al., 2010).

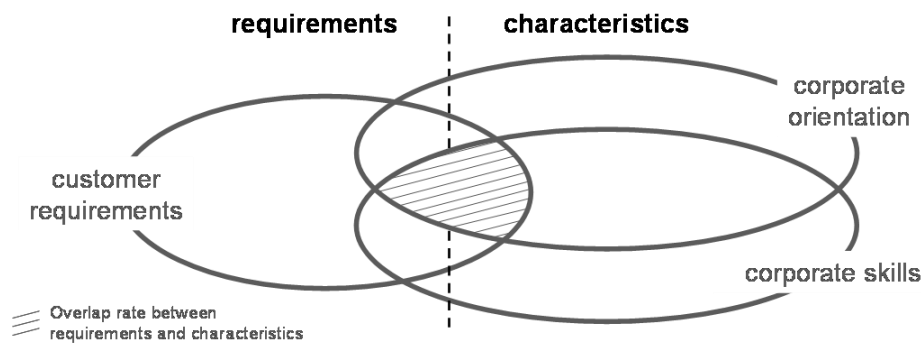

Figure 15: New definition of quality (Schmitt et al., 2008)

By enabling companies to visualise, harmonise and align their project and process landscape the production systems’ efficiency and effectiveness is significantly increased. Unlike other quality models like EFQM or the ISO 9000 family, the Aachen Quality Management Model provides this holistic view. The constitutional elements of the Aachen Quality Management Model are Market, Management, Quality Stream and Resources & Services (Schmitt & Pfeifer, 2010).

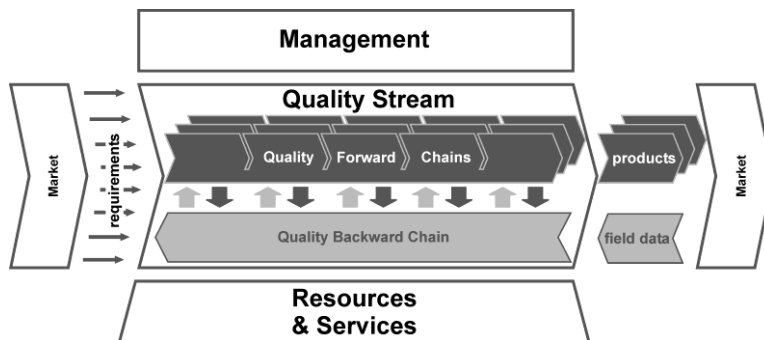

Figure 16: The Aachen Quality Management Model

Figure 3 illustrates that the Market is both initiator and recipient of the company’s performance. As initiator it demands a specific product and, consequently, defines the requirements. At the same time the Market represents the consumers which receive the products and supply the company with field data.

The Quality Stream, as the core element of the model, refers to the quality-creating processes within a company. It consists of two structural elements: the Quality Forward Chains and the Quality Backward Chain. While the Forward Chains include the proactive and preventive measures per product group, e.g. the inspection planning, the

Quality Backward Chain organises the reactive and corrective actions for all product groups. The links to the Backward Chain via control and improvement loops point out the holistic and bidirectional structure within the Quality Stream (Schmitt et al., 2008).

The alignment of the Quality Stream is specified by the Management. Hereto the demand and accomplishment of the company's vision and the related values and convictions are particularly important. The Management represents the pursuit of strategies and goals, forms organisational structures and establishes a management system to support the process organisation (Schmitt et al., 2008).

The element Resources & Services describes the company's skills, which empower the Quality Stream, among those employees and equipment as well as the existing infrastructure, technology and methodological knowledge.

The Aachen Quality Management Model is both an illustration of quality-orientated processes and a tool to design them. Thereby, it is crucial to define the objective of modelling the business processes. The model helps companies to adjust their quality-creating operations and to illustrate them transparently. Each component of the constitutional elements serves as a reference point for a company-specific arrangement of quality-orientated tasks.

The illustration allows the allocation of specific tasks, departments and processes of a company as well as both the linkage between them and the highlighting of cause and effect coherences. Thus, on the one hand the Aachen Quality Management Model creates transparency concerning the origin of performance. On the other hand it allows the identification of capabilities.

An Approach to develop inspection planning within the Aachen Quality Management Model

This paper develops inspection planning within the company's environment. Modern processes are often non-transparent and products are often very complex which is why it is not trivial to define the optimal point of inspection and to detect all possible defects and their consequences. In the last years the methodological development of inspection planning has basically stagnated. This leads to the challenge of incorporating it into internal processes and, thus, to develop new methods and to detect new interfaces of inspection planning for a holistic model. Hence, the integration into an overall entrepreneurial structure is of essential interest. The Aachen Quality Management Model acts as the framework for this implementation. It enables inspection planning's holistic definition and helps to identify interfaces, interdependencies and relevant information flows with adjacent divisions and operating areas.

The interactions inspection planning displays within the Quality Stream are of special interest and will be focused in this paper. This integrated approach serves as a basis for subsequently defining a decision model to inspection planning.

Figure 17: Positioning of inspection planning within the Quality Stream.

Integrating inspection planning into the Aachen Quality Management Model:

Inspection planning as a quality-creating process is positioned within the Quality Forward Chains, figure 4. As an activity belonging to the production preparation phase it is located at an early stage of the Quality Forward Chains. It proactively plans the realisation of inspections in production processes and facilitates the preventive assurance of quality demands in products. Especially due to its proactive character and its consequences on subsequent steps of the product creation process, decisions made within this planning discipline have great effect on the production process. Thus, it is essential to analyse the steps of decision-making in inspection planning and scrutinise it regarding the entrepreneurial background.

The first challenge is to identify the interfaces and interdependencies existing between inspection planning's own attributed tasks. Focussing on the planning discipline itself, we gather a deep inside view into interior information flows, figure 5. By analysing the interfaces, it is possible to specify groups of activities which have to be determined jointly for logical reasons. Several inspection planning tasks require identical input information, partially from other criteria/ tasks addressed within inspection planning. Additionally a number of tasks provides data and information bilaterally.

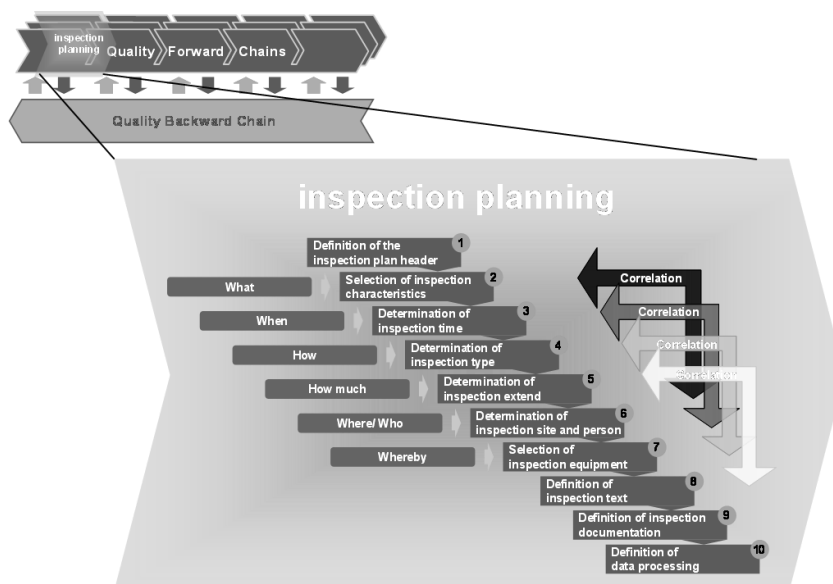

Figure 18: Correlations within inspection planning's attributed tasks.

Especially the four functions inspection location, personnel, equipment and point in time are interlocked closely. Therefore, it is not useful to separate the determination of

these tasks (Bernards, 2005). Several correlations are obvious, e.g. the need to measure an item with a coordinate measuring machine determines the inspection location, i.e. an isolated room beside the production line, and the inspection personnel. But for example also the inspection type has an influence on other tasks, e.g. the inspection equipment's choice. Some of these interactions are already mentioned in the state of the art.

Besides all these internal correlations also economic aspects determine the inspection planning tasks' definition. The relevant interactions have to be considered when specifying a decision model for inspection planning.

Furthermore, a specification and analysis of the interactions inspection planning exhibits with adjacent areas of the Quality Stream is of interest. The focus lies on areas located in the Quality Forwards Chains as well as the reactive processes of the Quality Backward Chain. Inspection planning is dependent on several information on and from previous, parallel and subsequent processes. Additionally some of these processes depend on this planning discipline reversely.

According to VDI/VDE/DGQ guideline 2619 (VDI/VDE/DGQ, 1985) knowledge concerning the function and application of a work piece, the production steps, production and technical documents as well as the available inspection equipment is of relevance when defining the inspection plan.

Interfaces with proactive processes are mainly derived from the research within the field of Simultaneous Engineering which can be transferred to the Quality Stream:

Quality planning specifies product features based on customer evaluation. These features are highly critical to product quality as a failure within one of them influences customer satisfaction negatively. Thus, inspecting these features' quality is exceedingly important. Quality planning supplies inspection planning with the relevant information concerning the items which are critical to customer satisfaction (Eversheim, 2002) but also relevant concerning laws, guidelines or safety regulations. Consequently, quality planning uses inspection planning as facilitator of its quality goals to work preparation. Furthermore, it provides inspection planning with the necessarily to use classical quality management methods like Failure Mode and Effects Analysis (FMEA) or Quality Function Deployment (QFD).

Planning a product's quality goes hand in hand with an *economic evaluation*. The application of certain quality assurance methods within production has to be compared with the cost of a defect potential (Raffo, 2000). In order to determine the inspection cost inspection planning has to provide the costing department with cost centre related information on inspection location, personnel and equipment. Inspection planning uses information on the cost of a defect potential to assess the inspection need. As a consequence it is possible to align quality planning's information on necessary inspection items with this additional data to plan the assurance of quality demands reliably. Furthermore, the costing department supplies inspection planning with facts on value-added steps. According to the appreciation in value it is one of inspection planning's goals to minimise possible scrap costs through an earliest possible inspection. Costs play a central role concerning decisions of inspection planning. Hence, a decision model has to consider costs obligatorily.

Inspection planning receives information on the work piece concerning overall functionality, required safety issues as well as product life time from *construction*. This includes knowledge on safety-critical work piece items and the concomitant tolerances in particular. Special effort for coordination is needed as construction requires information on the available inspection equipment and its performance. This is essential to plan the possible manufacturing and inspection effort.

In coordination with *production planning* and *work preparation* inspection planning establishes the prerequisites for the economic and requirements satisfying manufacturing and inspection of products (Pfeifer et al., 2007). The process sequence has a huge impact on planning the inspections as several of them have to be carried out before additional value is added to the product in order to recognise failures in an early stage of product creation. Furthermore, the cycle time has to be taken into consideration as the different process steps have to match.

The inspection plan which is built on the information gathered and restrictions defined through the steps described before determines when, how and how many inspections have to take place in the production process. Contrary, production itself supplies inspection planning with data on lot sizes, schedules, capacity plans and material flow as this information influences the inspection plan generation. It is obvious that a closed control loop has to be integrated in order to enable dynamic inspections adjusted to the environmental conditions.

This approach is seized and the following deliberations concentrate on the integration of additional closed control loops to inspection planning.

Current research activities of the Laboratory for Machine Tools and Production Management study inspection planning's integration with the reactive processes located in the Quality Backward Chain, figure 6. Until now the data contained in reactive processes is not reprocessed completely in order to use it in inspection planning. The information included in this data is regarded as an essential input factor for the definition of inspection planning and the adjustment with the proactive process data. Reactive process data provide information on the performance of downstream to inspection planning located processes. Consequently, a detailed specification of the interfaces of the Quality Backward Chain with this planning discipline and the analysis of the transferred data is of special interest.

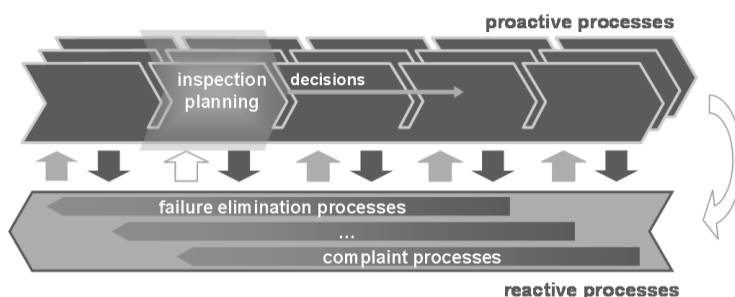

Figure 19: Interfaces of the Quality Backward Chain with inspection planning.

Inspection planning receives data within the long-run analysis of inspection data. These data e.g. enable to dynamise the inspection extent by adjusting it accordingly to the results of previous inspections completed in the production process (Eversheim, 2002).

The effect of inspection data on inspection planning is implemented into several ERP systems used in companies. Nevertheless, it is not worked out scientifically in detail and interdependencies between inspection data and data of other reactive processes have not been an issue of research at all.

Former research activities do not focus on usability studies of information which reactive processes, such as failure elimination or complaint processes, contain for inspection planning.

Consequently, an implementation of these data into the planning discipline is not developed yet. Field data, e.g. giving information as to the performance of certain product respectively inspection features and the customer satisfaction, hold high potential for defining inspection planning in terms of a holistic approach. In correlation with the inspection data it is possible to discuss new methods for the inspection plan's design when focussing features which were approved as OK but fail on the market. The same accounts for product failures occurring in the production process.

Relevant reactive processes have to be subject to a detailed analysis in order to figure out which data are essential for inspection planning. For a holistic investigation inspection planning's requirements for these reactive processes have to be analysed. Hence, the development and definition of interfaces can be carried out on a reliable basis that considers the planning discipline's own requirements as well as the entrepreneurial orientation.

The reactive data contain an amount of information that can be efficiently used in inspection planning. In correlation with proactive data a holistic decision model can be formed. Special focus lies on interactions with the economic evaluation. Decisions concerning an inspection plan's adjustment have to be made based on a reliable economic evaluation. As a consequence, reactive information can not be evaluated isolated. Rather a holistic examination is of interest in order to meet the macro- and mirco-economic situation.

Conclusion

The determination of all relevant interfaces and interactions inspection planning reveals and the holistic design within the Aachen Quality Management Model constitute the development of a decision model for inspection planning. The planning discipline's own attributed tasks describe several interdependencies with each other. These interdependencies are by some means easy to consider in a decision model as they are not characterised by a huge complexity. Interfaces inspection planning exhibits with other entrepreneurial processes are in their entirety not obvious. Additionally the consequences on inspection planning following distinct decision in different processes are manifold, partly antipodal and not always predictable. The same applies for decisions made in inspection planning itself. Thus, it is highly important to get a holistic image of all of inspection planning's interfaces, the information flows and their interdependencies. Especially the data contained in reactive processes, which provide information on the results of processes that are located downstream to inspection planning, has to be considered when aiming a decision model that reflects the overall economic and entrepreneurial situation.

Category: Research Paper

Purpose: How to identify and evaluate characteristics that are difficult to quantify

In the marketing research literature many approaches exist that make it possible for producers of goods and services to understand how customers distinguish between their products and the products of competitors. So, e.g., in the perceptual mapping approach (see, e.g. Carroll, Green 1997, Bijmolt, Wedel 1999, Borg, Groenen 2005 for recent reviews) (dis)similarity ratings of customers with respect to pairs of offers are collected (using scales like 0=“completely similar” to 100=“completely dissimilar” for rating a pair of offers). Then, an MDS procedure is used to transform the matrix of observed dissimilarities into a representation of the products by points in a low-dimensional space (e.g. 2- or 3-dimensional) in that way that the ranking of the Euclidean distances correlates to the ranking of the observed dissimilarities. That means a representation is derived where points for similar products are positioned nearby whereas the points for dissimilar offers are positioned far away from each other. Figure 1 shows a sample application of the perceptual mapping approach using MDS: Five products have been rated by customers on a dissimilarity scale and a 2-dimensional representation has been derived. If the derivation was successful, one can say that the perceived dissimilarity of the products can be reproduced using two dimensions. As the representation can be rotated, mirrored or stretched without losing its meaning, normally it is rotated in that way that the dimensions of the low-dimensional space can be interpreted (e.g. “high quality”, “modern”).

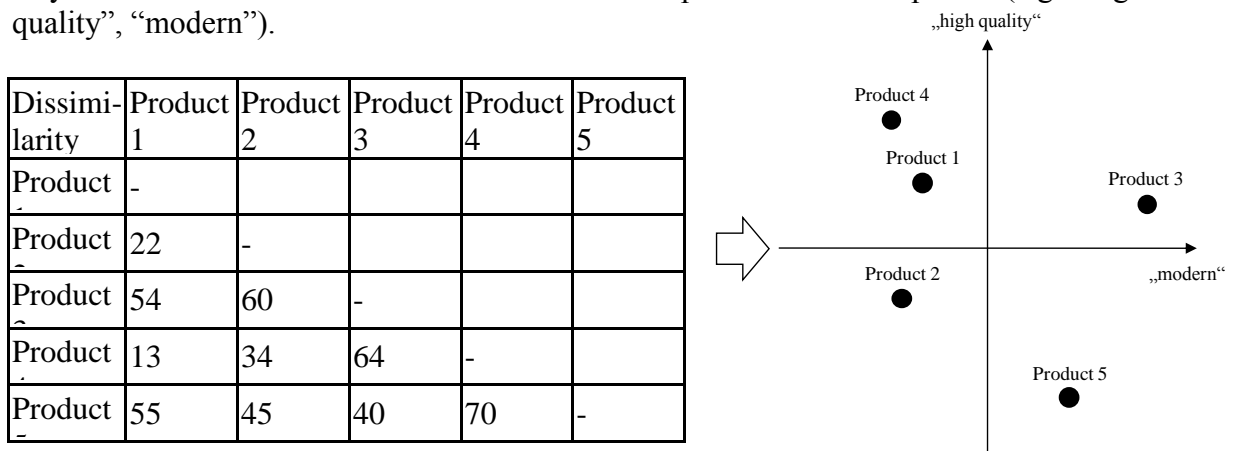

Figure 1: Identification of characteristics using multidimensional scaling: Observed dissimilarities between products on rating scales (0=“completely similar” to

100=“completely dissimilar”) are transformed into a two-dimensional representation, the representation then is rotated in order to identify characteristics (“high quality”, “modern”)

The derived perceptual map can then be used to discuss the positioning of the different products, e.g. to look for uniqueness and improvements, or to develop advertisement goals to improve the positioning of the own products. Many alternative procedures exist for this purpose, e.g. procedures that integrate preference ratings of customers or customer segments via ideal points or procedures that derive optimal positionings for new products (see, e.g. Baier, Gaul 1999). However, whereas these approaches are quite good in deciding how many characteristics/dimensions are needed to describe the customers’ perception of the products, the naming or the categorization of these characteristics/dimensions still is an open question: For describing two orthogonal dimensions of the two-dimensional space in Figure 2, of course, many (correlated) namings are possible (e.g. “high quality”, “expensive”, “reliable” and so on). Whether they really reflect the customers’ view on the market is unclear. Therefore, in the following, a psychometric method is proposed.

New approach: Applying the repertory grid technique for this purpose

In the mid 1950s George A. Kelly (1955) developed the repertory grid technique within his psychological theory of personal constructs. This theory assumes that human beings form construct systems in order to evaluate themselves, their environment and their relationship to one another. Constructs are assumed to be dichotomous distinctions that are determined in relation to real objects (e.g. persons, situations, issues or possible solutions). After its construction using real objects these dichotomous distinctions become abstractions. They help to classify new objects or to evaluate them (Catina, Schmitt 1993: 14f.).

To use the individual construct systems in psychotherapy Kelly developed the so-called role construct repertory grid (Kelly 1955). The survey instrument was later also in the non-clinical field applied and became known as the repertory grid technique (Scheer, Catina 1993: 9, Stewart 1997). The repertory grid technique is usually applied in a vague environment with concrete objects, where a construct system is searched for that individuals use to distinguish between known and possible new objects.

The basic shape of the repertory grid technique basically consists of a series of dichotomous discrimination tasks in which a person divides three relevant elements of a given set of objects into two nonempty groups by a self-selected distinctive way (triad comparison). The person then is asked for the underlying criteria for grouping the objects into two groups, which is then understood as the (personal) construct. The aggregation of these criteria about all triad comparisons is identified as the (person-specific) construct system. Applying this interviewing technique to a sample of persons and aggregating the results across the persons is assumed to develop target group-specific construct systems.

The main application field of the repertory grid technique is psychology, however it has also been used in the field of marketing or quality management (see, e.g. Sampson 1972, Marsden, Littler 2000, Baier, Kohler 2008, Heine 2009). Figure 2 shows a sample application to the market already analyzed in Figure 1: A sample of customers is

individually presented all possible triads of the five products, i.e. the 10 triads (Product 1, Product 2, Product 3), (Product 1, Product 2, Product 4), (Product 1, Product 2, Product 5) and so on. For each triad the customer is asked to group them into two non-empty groups, e.g. (Product 1, Product 2) vs. (Product 3), and to describe what separates the products of the two groups.

Triads	Please group the three products!	What separates the groups?
1) Product 1, Product 2, Product 3	Product 1, Product 2 ⇔ Product 3	“modern”, “fresh”
2) Product 1, Product 2, Product 4	Product 1, Product 4 ⇔ Product 2	“expensive”, “high quality”
3) Product 1, Product 2, Product 5	Product 1, Product 2 ⇔ Product 5	“high quality”
4) Product 1, Product 3, Product 4	Product 1, Product 4 ⇔ Product 3	“modern”, “new”, “colored”
5) Product 1, Product 3, Product 5	Product 3, Product 5 ⇔ Product 1	“modern”
6) Product 1, Product 4, Product 5	Product 1, Product 4 ⇔ Product 5	“fresh”
7) Product 2, Product 3, Product 4	Product 2, Product 4 ⇔ Product 3	“established”
8) Product 2, Product 3, Product 5	Product 3, Product 5 ⇔ Product 2	“established”

...

Figure 2: Application of the repertory grid technique to five products: All triads of products are presented to a customer, for each triad she/he is asked to group them into two nonempty groups and to name separating characteristics

As a result, we receive identified characteristics that customers use to distinguish between products in our market, e.g. “modern”, “fresh”, “established”, “expensive”, “high quality”, which now, in a last step can be used for rating the five products according to these characteristics and deriving perceptual maps by via dimensional reduction techniques like, e.g., principle components analysis.

Application of the new approach to the field of cell-phones

The new approach is applied to the selection of dimensions in the field of cell phones for students (see, e.g., Abu Assab, Baier 2010 for an application of QFD and conjoint analysis for a similar purpose in the cell phone market). A sample of 20 customers was interviewed using the repertory grid technique for perceptual mapping as described in the previous section. The customers were 19 to 28 years old, 23 on average, 30 % female and 70 % male students which represents quite good the student population at a technical university. All of them already have a cell phone, most of them planned to buy a new cell phone within the next six months. The concrete products which were used for the interview were the following: LG Optimus 7, Sony Ericsson Xperia X10, LG Optimus One, Nokia E75, HTC Desire, Samsung Wave II, Blackberry Bold, HTC

Touch Pro, Nokia C7, Apple iPhone 4. The customers were shown all cell phones using real products and real product brochures. Then, they were asked to choose five out of available cell phones. The selection of the five should be done under a “relevant set” assumption, that means simulating their next cell phone purchase. Afterwards – as described above in a repertory grid application – they were presented all possible triads of the five cell phones. In each case they had to group them into two non-empty groups and to describe what separates the products of the two groups. Finally, they were asked to rate all cell phones according to their chosen characteristics on a 7-point rating scale. The interview lasted for each customer roughly 60 minutes.

Afterwards, the characteristics and ratings were aggregated across the customers. Table I shows the mean values for all cell phones and the most named characteristics. From Table I one can see, that a huge range of characteristics was developed to distinguish between the cell phones, ranging from “angular vs. round” to “limited vs. good readability”.

	angular vs. round	complicated vs. simple	handline	unhandily vs. handily	complicated vs. simple	writing	heavy vs. light	dark/light	vs.	crimsy/feindlich	vs.	traditional vs. premium	business vs. private	sensitive to shock vs.	traditional vs. sunstn	irrect vs. direct	seratei-sensuive	vs.	traditional vs. modern	form	cold vs. warm material	unprecise vs. clear	deralat vs. intuitive	remmhe vs. masculine	dati/rebmy	vs.	bad	two-hand	vs.	one-hand	hand operation	playful vs. useful	un/orunary	vs.	bad vs. good	brand	limited	vs.	good	readability					
LG	1.	5.	2.	2.	3.	1.	3.	4.	2.	3.	4.	6.	3.	3.	3.	6.	6.	6.	1.	3.	3.	3.	3.	5.	1.	6.

Samsung	1.	3.	2.	2.	3.	2.	2.	3.	2.	3.	3.	6.	3.	3.	1.	3.	5.	5.	1.	3.	2.	4.	2.	4.	2.	4.	5.																		
Blackberry	5.	5.	6.	6.	4.	1.	3.	3.	1.	6.	5.	3.	7.	4.	5.	4.	2.	3.	6.	5.	5.	5.	5.	3.	4.	2.																			
HTC	1.	4.	4.	6.	1.	1.	2.	1.	2.	5.	3.	3.	6.	2.	4.	3.	2.	6.	3.	1.	4.	5.	1.	2.	2.																				
Nokia C7	6.	4.	6.	3.	5.	5.	6.	5.	5.	4.	4.	6.	5.	2.	4.	5.	6.	1.	6.	5.	5.	4.	6.	4.	5.																				
Apple	3.	4.	5.	3.	3.	1.	5.	7.	2.	3.	7.	6.	4.	6.	2.	7.	6.	3.	3.	6.	3.	3.	7.	5.	6.																				

Table I: Application of the repertory grid technique to a cell phone market: For 10 cell phones 25 most often named characteristics are listed and mean ratings for the cell phones (scale: “1” = first level of the characteristic, “7” = second level is appropriate, e.g. “Sony Ericsson” is rated “angular”, “LG Optimus One” and “Nokia C7” are rated “round”)

Finally, the data matrix from Table I can be analyzed using principal components analysis and varimax rotation. It shows that the 25 found characteristics are highly redundant (at least in a statistical sense): five principal components (PC1, ..., PC5)

already explain 94.5 % of the variance in the data. Table II shows the loadings of each characteristic on each principal component, highest loadings for each characteristic across components is marked:

- PC1: “angular, unhandily, heavy, dark/unfriendly, clumsy, business look, masculine design, tall/roomily, two-hand-operation” vs. “round, handily, light, colored/friendly, sporty/slender, private look, feminine design, compact/harmonious, one-hand-operation” (39.5 % of the variance),
- PC2: “complicated handling, complicated writing, sensitive to shock, direct menus, intuitive control, playful, good readability” vs. “simple handling, simple writing, robust, indirect menus, default control, useful, limited readability” (27.7 %),
- PC3: “traditional materials, traditional image, unprecise display, bad workmanship, dull/ordinary” vs. “premium materials, stylish image, clear display, good workmanship, brilliant/elegant” (13.6 %),
- PC4: “scratch-sensitive, cold” vs. “scratch-unsensitive, warm material” (7.9 %),
- PC5: “bad brand experience” vs. “good brand experience” (5.7 %).

	angular vs. round	complicated vs. simple handling	unhandily vs. handily	complicated vs. simple writing	heavy vs. light	dark/unfriendly vs. colored/friendly	clumsy vs. sporty/slender	business vs. private	sensitive to shock vs. intuitive control	traditional vs. modern	imprecise vs. clear	bad workmanship vs. good workmanship	dull/ordinary vs. brilliant/elegant	scratch-sensitive vs. scratch-unsensitive	cold vs. warm material	bad brand experience vs. good brand experience									
PC1	0.9	0.0	0.7	-	0.8	0.8	0.8	0.3	0.7	0.2	-	0.0	0.1	0.1	0.3	0.4	0.1	-	0.8	0.4	0.7	-	0.4	0.0	0.0
PC2	0.2	0.8	0.5	0.9	-	-	-	-	0.9	0.1	-	0.2	-	0.0	-	-	0.1	0.4	-	0.4	0.6	-	0.0	-	-
PC3	0.2	0.5	0.2	-	0.3	-	0.5	0.7	-	-	0.9	0.3	0.0	0.7	0.0	0.8	0.3	-	0.2	0.6	-	-	0.7	0.1	0.4
PC4	0.0	-	0.1	0.1	0.1	-	0.0	-	0.0	0.1	0.0	0.9	0.2	0.9	-	-	-	-	0.2	0.2	0.1	-	0.1	-	-
PC5	0.0	-	0.1	0.1	0.1	-	0.0	0.2	-	-	0.2	-	0.0	-	-	-	-	-	0.1	0.3	-	0.5	-	0.9	0.0

Table II: Component loadings for the first five principal components after varimax rotation (PC1, ..., PC5); highest loadings for each characteristic across components is marked

Scores with respect to these principal components can be calculated in the usual way and are given in Table III. So, e.g., with respect to PC1 we can see that cell phone “HTC Touch Pro” fits best to “angular, unhandily, heavy, dark/unfriendly ...”, “Nokia C7” fits best to “round, handily, light, colored/friendly, sporty/slender ...”. Figure 3 gives the corresponding map.

	PC1	PC2	PC3	PC4	PC5
LG Optimus 7	-0.98	-0.24	0.85	-0.80	-1.72
Sony Ericsson Xperia X10	-1.07	-1.15	-0.94	0.99	0.80
LG Optimus One	1.40	-0.59	-0.75	0.52	-1.21

Nokia E75	0.45	1.50	-0.72	-1.76	0.20
HTC Desire	0.86	-0.52	0.64	0.47	-0.81
Samsung Wave II	-0.62	-0.90	-0.91	-1.14	0.73
Blackberry Bold 9780	0.01	1.58	0.64	1.30	0.67
HTC Touch Pro	-1.10	1.07	-0.83	0.83	-0.59
Nokia C7	1.49	-0.31	0.02	-0.02	1.09
Apple iPhone 4	-0.43	-0.43	2.00	-0.38	0.84

Table III: Positionings of the 10 cell phones with respect to the five principal components after varimax rotation (PC1, ..., PC5, low values indicate fitting to first levels of the component, high values fitting to second levels)

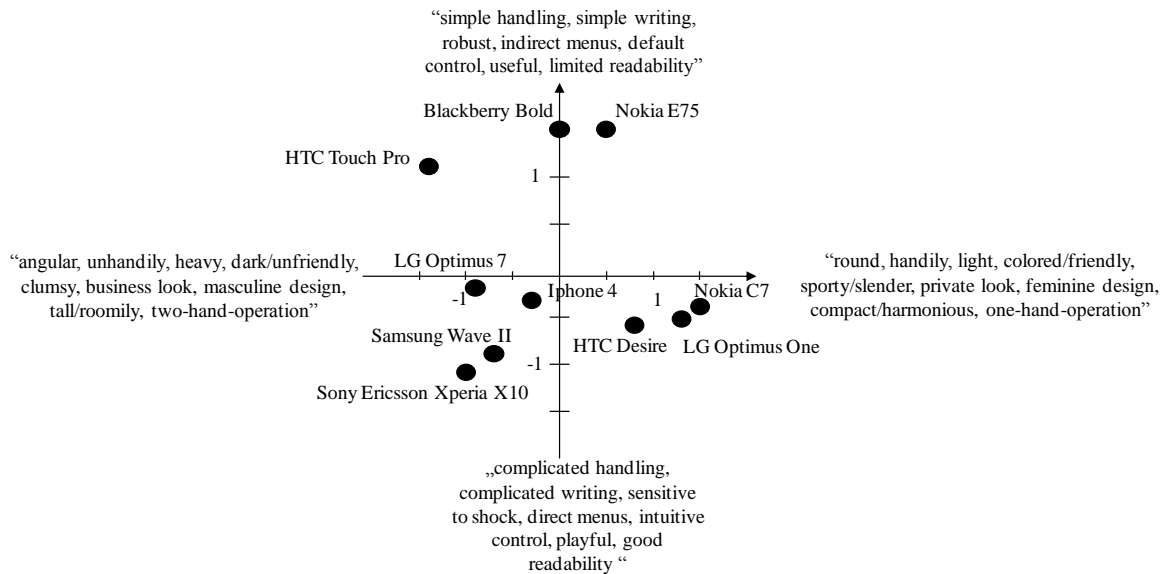

Figure 3: Positionings of the 10 cell phones with respect to the PC1 and PC2 (perceptual map)

Conclusion and outlook

From the first results of an application of the repertory grid technique for perceptual mapping we can see how the approach can be used to identify and evaluate characteristics that are difficult to quantify. A second, larger scale application in cooperation with a large German manufacturer of motorbikes is underway. This large-scale application will show whether the approach is viable in a real-world setting.

Key words: Higher education, improvement work, student participation, case study

Introduction

Systematic improvement work for increasing quality and competitiveness has long been of interest (Imai, 1986; Rapp and Eklund, 2002; Motwani, 2003; Weisbord, 2004; Spear, 2005). Also universities have been subject to studies on possible improvements. These include reports about improvement work on e.g. how to improve teaching and educational programs (Felder and Brent, 1999; Östlund et al, 2007), improve university performance (Numprasertchai and Poovarawan, 2008) or challenges to create sustainable development principles in university activities (Lukman and Glavic, 2007). There are several stakeholders for a university who have different needs and expectations of university operations, such as lecturing and research staff, administrative and service staff, students, graduates, employers, professional associations, other lecturing and/or research organizations, and society (Álvarez Suárez et al, 2009). However, from a consumer perspective, the students may be regarded as a primary customer of higher education service which is delivered by the universities (Hill, 1995). This service consists of, among other things, the teaching offered. Good teaching may be defined as "instruction that leads to effective learning, which in turn means thorough and lasting acquisition of the knowledge, skills, and values" (Felder and Brent, 1999). From an engineering perspective, this teaching should aim at preparing the engineering students to meet future challenges, why focus in their education should be professional practice, in which technical knowledge and skills of practice should be integrated (Sheppard et al, 2008).

With respect to preparing the students for future professional work, managing changes and improvement work is likely to be part of engineering tasks, no matter if employment will be in the private or public sector. Here, it is important that the students learn to look at change management from different perspectives. One way to prepare the students for this is to combine teaching about theories and supporting the students in applying this knowledge to a real case. This paper describes how students in a university course in operations management and control can combine theoretical studies and practical implementation by applying theories in quality management on their own school of engineering. A further aim of the paper is to highlight how a university course in operations management and control based on quality literature may be used to identify suggestions for improvements of university operations from a student perspective.

Change management and participation

Both private and public organizations nowadays face demands for frequent changes and improvements. These demands emanate from conditions in an organization's external

and internal environments. These contextual issues include external conditions such as governmental regulations, development of technology, and competition from other actors. The internal conditions include degree of work specialization due to existing technology, degree of organizational slack, and experiences with earlier changes (Armenakis and Bedeian, 1999). There are different means to manage changes and improvement work. Some organizational choices to manage improvement work must be made by management according to the following dimensions (Lillrank et al, 2001):

- Social dimension: whether improvement work should be carried out by individuals or groups
- Magnitude of issues: involvement by single or multiple functions, single hierarchy level or multiple hierarchy levels
- Organizational configuration: organized in parallel with or integrated in ordinary work
- Assurance of continuity: permanent organization or continuously evolving vision (or both)
- Goal setting and implementation of changes: centralized or decentralized

Involving “everybody” in improvement and development activities has been advocated from a quality and ergonomics perspective to improve motivation, increased learning and better quality solutions (Eklund, 2000). Advantages with participative change processes are for example that suggestions made by those performing tasks may be especially constructive since they have thorough knowledge about the situation which will be changed (Hackman and Oldham, 1980) and therefore they can contribute to higher quality of decision making (Wagner et al, 1997). One way of classifying participation is to define it according to the following operative dimensions (Haines and Wilson, 1998), see also Table 1:

- to what extent the participative initiative is applied
- whether participation is used for implementation, design or general work organization;
- whether it is used in everyday work or for specific change projects
- whether everyone is involved, sub-groups or representatives for groups
- whether it is formal participation in meetings, teams or committees or informal participation integrated in everyday work
- whether it is compulsory according to a management strategy or voluntarily
- to what extent the employees make or influence the decisions
- the extent of coupling; whether the employees influence their situation directly or remotely through questionnaires, statistics, etc.

Table 1. Operative dimensions of participation (Haines and Wilson, 1998)

Extent/level	Organization ----- Work system ----- Workplace----- Product
Purpose	Work organization ----- Design ----- Implementation
Continuity	Continuous ----- Discrete
Involvement	Direct (full/partial) ----- Representative
Formality	Formal ----- Informal
Requirement	Voluntary ----- Compulsory
Decision-making	Workers decide ----- Consensus----- Consultation
Coupling	Direct ----- Remote

There are thus a number of issues to take into consideration when managing changes and improvement work; first a number of organizational choices to make at an overall level, then a reflection of reasons behind the use of a possible participative approach, and if chosen, making a standpoint regarding the operative dimensions of participation.

Methods

The students' suggestions for improvement of the university operations were reported within the course "Operations management and control". There were 31 (24 male and 7 female) students attending the course at a School of Engineering. The students were third year Bachelor students majoring in Logistics.

The course consisted of eleven different topics related to theory on quality management and control (see further description in section 4.1), and the students were to apply these theories in a reflection on the school of engineering within their own university. The students elaborated each topic in group work (with groups of normally four students) and their results were reported verbally with the aid of large flipcharts and discussed with the other student groups. Data was collected through observation of these reporting sessions and analysis of the written documentation. Written documentation from students who could not participate at any reporting session was also analyzed.

Results

Description of the course "Operations Management and Control"

The course constituted 50% of full-time studies during one semester for third year Bachelor students in logistics at a school of engineering. In parallel with the course, the students also worked on their thesis projects in collaboration with different companies. It was the first time that the course was given.

The course consisted of four parts; the integrated company, change management, project management, and communication capabilities. The two first parts, the integrated company and change management, were based on literature about the Toyota way

(Liker and Meier, 2006) and change management from a quality perspective (Elg et al, 2007). These two course parts are focused in this paper and in subsequent parts named “the course”.

The students were organized into groups who elaborated eleven different topics related to quality management and control and applying these on their own university as a case study.

The course consisted of eleven topics related to quality management, see Table 2. Each topic was highlighted during one day according to the following procedure:

- In advance, the students were assigned to write a reflection (minimum 400 words) about specified literature related to the topic of the day.
- During each course day, the topic of the day was introduced in a morning lecture given by the teacher and group tasks were assigned to the student groups. The tasks consisted of a number of reflective questions regarding theory and/or application of the theory. The theory was to be applied either to the students’ own university (the school of engineering), its operations or the students’ study situation. This served as the case study used throughout the course.
- The student groups (normally four students) worked on the topic during approximately three hours (including lunch break).
- In a subsequent afternoon session the students reported and discussed the results of their group work.
- For those students who were not able to participate any course day or had not submitted a written reflection on the literature before the lecture, a reflection of at least 800 words was required for that specific topic.

Table 2. Course topics and examples of applied questions

Course topic	Examples of questions related to the university operations or the student situation
Customer orientation	<ul style="list-style-type: none"> • Which are the customers of the school of engineering and what are the customer needs? • How may customer needs be identified and how may knowledge about these needs be used to improve operations?
Improvement work	<ul style="list-style-type: none"> • Identify different improvement areas within the school of engineering. • How would you organize improvement work related to these areas?
ISO9000	<ul style="list-style-type: none"> • What are the main processes of the school of engineering? • How does the school of engineering work with quality assurance of its processes? • What documents exist that are related to quality issues?
Accidents	<ul style="list-style-type: none"> • What risks for accidents and illness are there within the school of engineering? • How is it possible to work with continuous improvements to mitigate these risks?
Production levelling	<ul style="list-style-type: none"> • Which are the value flows within the school of engineering from a student, teacher or other personnel's perspectives? • Identify non value activities in the identified flows. • How is it possible to work with value flows, standardized processes and production (work) leveling to improve the students' study process (including different groups within the school of engineering)?
Use of suitable technology	<ul style="list-style-type: none"> • Analyze the technology used within the school of engineering in relation to the overall process, possible wastes, possibility for flexibility, etc. • How is technology adapted to human work and what improvement possibilities can be identified?
Development of leaders and team associates	<ul style="list-style-type: none"> • What are motivating factors for you as students? • Is it possible to achieve team work among students and if so, how can that be achieved? • In what way may the leadership at the school of engineering influence the students' study results?
Measurement and evaluation	<ul style="list-style-type: none"> • What are the visions for the school of engineering and how are these related to the students' situation? • What may be measured in the university operations and how may measurements be used to control the students' results?
A culture that solves problems	<ul style="list-style-type: none"> • What characterized the culture at the school of engineering (among students and in other groups)? • How are problems handled within the school of engineering?
Problem solving	<ul style="list-style-type: none"> • Identify any problem related to your study situation and apply "5 why" to the problem. • Identify a problem on which 5S could be applied in practice. Reflect on any advantages/drawbacks for both methods.
Improvement tools	<ul style="list-style-type: none"> • Apply any improvement tool/s to analyze "Why do not students start studying for the exam a long time in advance"?

Results of the reporting sessions and individual written reflection

In the reporting sessions and the individual written reflection the students highlighted a number of areas which could be improved at the school of engineering. These suggestions were related to course evaluations, university integration with society, procedures for examination, student accommodation, integration between Swedish and foreign students, standardization of organization of courses, the teachers' use of IT-tools to administrate and organize courses, student information, etc., see Table 3.

Table 3. Areas for improvements suggested by the students

Improvement area	Examples of specific suggestions for improvements
Development of courses and teachers	<ul style="list-style-type: none">• Development of courses should be in collaboration between several teachers• Improved information and feedback to students about fundamental ideas behind different courses• Standardize course organization by for example developing a template for course start-ups, how to order course literature, etc. and include all teachers• Organize the education with the students only taking one course at the time and not several courses in parallel• More use of IT-support in a consistent way between all teachers. Clear instructions to teachers.• More didactic education to teachers
Student information and follow-up	<ul style="list-style-type: none">• Introduce individual discussions on progress, including future plans. Positive results include deepened contact between student and teachers and easy sharing of views.• Ensure that students receive feedback of measures taken based on the course evaluations
University integration with society	<ul style="list-style-type: none">• Adapt educational programs to the needs of industry• Perform research related to actual industry needs• Increase contacts with host companies throughout the education program
Course examination	<ul style="list-style-type: none">• Need to develop procedure for evaluation of course examinations• Develop electronic examination which will be more efficient for the student, less paper work and easier to mark for the teacher• Have minor but larger number of examinations
Conditions for students	<ul style="list-style-type: none">• Ensure that students who are accepted to any educational program also have accommodation and that there are sufficient number of teachers, study halls, restaurants, etc.• Make it possible for students to connect personal computers to the university network and print at the university printers
Integration between students	<ul style="list-style-type: none">• Increase integration between students from different nationalities through integrated accommodation and other arenas to meet

Evaluation of the course and input to improvement of university operations

The students thought that the course in Operation Management and Control united earlier courses in their educational program even if there was some overlap with earlier courses related to organizational management and lean production. Although necessary with some overlap to keep together the course, more coordination with earlier courses was recommended. The students approved of the course division into topics, which facilitated their own planning and applying theory related to the topics in specific group work. They also found the preparatory written assignments with personal reflection on the literature as suitable for their learning. The use of their own school of engineering as case study on which to apply the theories gave further insights beyond the student perspective. However, the students perceived that the use of one case study objects resulted in repeating some issues several times. The students believed the course would gain by applying the theories on some manufacturing company as well.

From a teacher perspective, the organization of the course into specific topics, one for each course day, worked out very well. Sometimes there was an initial challenge to avoid overlap between different topics, which appeared to be very closely related e.g. between “a culture that solves problems”, “problem solving”, and “improvement tools”. However, this was coped with by relating the specific topic to other theory outside the course literature, for example by relating the topic of “a culture that solves problems” to theories about organizational culture. By this, a deeper discussion could be achieved during the lectures and student group work. The students’ preparation of the literature by written assignment before the lectures was successful, as they had better understanding of the topic and therefore could participate more actively. The use of the school of engineering as case study was interesting. They directly had to apply the theoretical models in practice, which gave new insights. Furthermore, the students were encouraged to take on the perspective of other university stakeholders, which widened their perspective on their own study situation. However, the scope of the students’ group work depended to a large extent on their own personal motivation to go in depth with the different topics, search for official university documents, make short interviews of university personnel etc. Therefore the outcome of the group work varied between the groups.

The results of the students’ group work within the course included a number of suggestions for improvements of the school of engineering and the students’ work situation. These suggestions for improvements will be used at the school of engineering as a direct input to an ongoing investigation of how to strategically improve the education at the school of engineering. The suggestions will be very useful in a later stage when more specific suggestions for improvements will be identified and discussed.

Discussion

The identified number improvement suggestions were related to course evaluations, university integration with society, procedures for examination, student accommodation, integration between Swedish and foreign students, standardization of organization of courses, the teachers’ use of IT-tools to administrate and organize courses, student information, etc. Some of these were developments or increased use of already existing channels for communication or technology, while others were less

known improvement areas. The use of student suggestions as input to the ongoing investigation of how to strategically improve the educational programs constitutes one type of participation in improvement work. There are established sources, such as course evaluations, for the students to influence their study situation. These are integrated in their daily work (Lillrank et al, 2001), however remotely coupled (Haines and Wilson, 1998). The input from this course is another form of participation in improvement work. It is discrete for a change project, which will emanate from the ongoing investigation, and there are many possibilities to develop the dimensions (Haines and Wilson, *ibid*), in which the students may actively contribute to developing the future school of engineering.

Throughout the course the students actively worked with theory and applied it in practice to their own organization. Although having a natural focus on a student perspective, they were also encouraged to analyze the university operations from other perspectives, such as different groups of employees, future employers and society. The idea of integrating theory and practice fits well with desired aims for an engineering education (Sheppard et al, 2008). However, the students sometimes found it difficult to regard themselves as part of an organization, their studies as work, and that they were service consumers (Hill, 1995). Furthermore, being used to apply other courses on mainly manufacturing industry, it was sometimes challenging for the students to apply the theories to a service producing organization.

Being the first time the course was given, it resulted in a great deal of learning. The results of the students' group work were good. However, these could have reached a higher level for some of the groups. As described earlier, the results of the group work depended on the students' own work motivation, and it was sometimes difficult for them to find useful material for their group work during the few hours of group work. Possible improvements for future development of the course therefore include giving the students more time for group work within the different topics and possible integrate some topics into real mini-projects at the school of engineering. If chosen voluntarily by the student groups, it will strengthen their work motivation (Schein, 1996). Furthermore, it will give deeper knowledge and experience in how to carry out improvement work in practice. Other potential improvements include the development of the teacher role into more of a mentor role guiding the students regarding methodological issues and reflection about different perspectives in their projects.

Conclusion

The study showed that it is possible to use output from students' group work in a course in operations management and control as input from a student perspective to improvement work at a university. By this the students get the experience of analyzing their own organization, which will probably be a future task, they can directly contribute to the development of university operations, and they learn how to apply theoretical models in practice. By being forced to take an outside view of their own class, it also enhances the students' understanding of an operating work system with different interested parties. Furthermore, the study showed that challenges in offering such a course include how to guide the students to separate different topics in operations management and provide help in identifying and applying theoretical models in practice.

Keywords: Knowledge Intensive Business Services, KIBS, Relationship Marketing, Transaction Cost Theory, Trust, Customer Loyalty

Introduction

The structural change in the "service economy" has been facilitated by the development and establishment of new forms of work organization e.g. transition from stable permanent jobs to contingent or alternative positions (Neumark 2004), decentralization of decision making (Miles 1993) and outsourcing (OECD 2000; Schettkat & Yocarini 2006) among others. In this context, one of the most important outcomes is the emergence of Knowledge Intensive Business Services (KIBS). This is one of the sub-sectors of services with a high contribution to the productivity of countries.

Considering the importance of KIBS and the considerable increase of competency in this sector (Zhang & Zhu 2009), it becomes necessary to analyze the relations between these types of companies and their clients. Citing Bagdoniene et al. (2007, p.13): "*The relationships between providers and clients are the most important feature of services. When efficiently managed, they become an essential asset of organizations*". In this context, this study will take loyalty as a reference of measurement for the performance of the relationships between the KIBS and their clients.

This work comprises of a contribution to the call of Spath & Ganz (2008) to develop new models and methods for the efficient design of services through the definition of the factors of influence in client loyalty. In summary, the present work looks for the answer to the following questions:

“What are the factors of KIBS that affect the direct relationship with the client?”

“How do these factors interrelate to benefit and increase the loyalty of the clients of the KIBS?”

Literature Review and Hypothesis

Trust and Loyalty

The relationship between trust and customer loyalty has been frequently studied in the literature of business relationships (e.g. Doney & Cannon 1997; Ganesan 1994) as well as the services sector (e.g. Palmatier et al. 2006; Bendapudi & Berry 1997). From the point of view of the Theory of Transaction Costs, the relationship between loyalty and trust is based on the reduction of opportunistic behaviour between clients and service providers (Lee & Cunningham 2001; Doney & Cannon 1997). On the other side, from a

relationship marketing point of view, Berry (1983, p.1) believes that "*trust is the basis for loyalty.*" For business consulting services, which belong to KIBS, trust is one of the most effective means to improve the quality of customer relationships (Mitchell 1994). This relationship quality increment will be reflected in the formation of loyalty between the parties. Other authors affirm the importance of building trust to establish long-term relationships between KIBS and their clients (Miles 1993). Based on the statements given above, the following hypothesis is defined:

H₁: Trust of the clients with their KIBS-suppliers is positively related to customer loyalty.

Transaction Specific Assets (TSA) and Trust

According to Lohtia et al. (1994, p.261), "*A TSA is an asset, either tangible or intangible, that has little value outside of a particular relationship*". TSA is one of the main factors in making decisions in choosing forms of governance for the processes of production of goods and services. Vandaele et al. (2007) give us a TSA proposal closest to the special characteristics of services. These authors argue for the dimension of asset specificity in the case of services: "more emphasis should be placed on human and procedural asset specificity instead of physical aspects because of the intangible nature of services" (p. 254). Therefore, TSA in services is mainly represented by the company's investment in the training, knowledge acquisition and changes in service delivery processes for a specific customer.

Considering risk as a factor of analysis, if one party invests in a TSA, the danger of the emergence of opportunistic behavior places this party in a vulnerable position. However, this could be considered as an act of commitment to the relationship (Ganesan 1994). Bendapudi & Berry (1997) use the same reasoning to explain the relationship between TSA and trust in the case of services.

Taking this point of view, KIBS require TSA, especially with regard to knowledge. These investments are needed to adjust their services offered to clients' specific requirements. In relation to this, Handfield & Bechtel (2002) present a model, which assumes that investment in "*human specific assets*" for a particular client allows the generation of cooperative relations and trust between customers and suppliers. These positive effects of TSA are attributed to the relational orientation of the Relationship, in which these investments are seen as generating stronger links between the parties and that can enhance competitiveness (R. Mudambi & S. M. Mudambi 1995). This leads to the following hypothesis:

H_{1a}: TSA of a KIBS is positively related to the trust of the KIBS client's.

Contractual safeguards and Trust

The contractual Safeguards are considered as necessary tools for the protection of the parties against the possible emergence of opportunistic behavior in a relationship. Likewise, trust is viewed as a mechanism of protection against the risks of opportunism in inter-firm relationships (Judge & Dooley 2006). However, both factors need not necessarily be viewed as mutually exclusive, but may have supplemental characteristics (Das & Teng 1998). An empirical study by Bennett & Robson (2004) has shown that

both trust and contractual regulations may occur in parallel and their combination contributes to higher customer satisfaction levels. Other studies (e.g. Handfield & Bechtel 2002) confirm this statement wherein formal contracts could become elements that enhance the confidence that the customer deposits with the provider.

In the case of services, Berry (1995) confirms the influence of service guarantees in generating trust. In this context, trust and contractual safeguards function like mechanisms for increasing the control of service providers by clients. With these mechanisms the customer can ensure the results provided by the KIBS. The problems of control of the results, in the case of KIBS, generate the need to develop complex control mechanisms which allow a firm to decrease the uncertainty on the part of customers. The presence of trust based on social and personal relationships are often not enough to reduce this uncertainty. Therefore, the contractual safeguards can be a means for generating additional confidence to establish relations between KIBS and their clients. Based on this, this study proposes the following hypothesis:

H_{1b}: Defined contractual safeguards by the KIBS are positively related to the trust of the KIBS client.

Expertise and Trust

Another important factor that influences the buyer's trust of a service is the expertise of the service provider. Empirical evidence of this relationship in the commercial sector can be found in several studies (e.g. Palmatier et al. 2006; Doney & Cannon 1997). For example, through a meta-analysis study of literature of the factors that influence the effectiveness of RM, Palmatier et al. (2006) confirm a significant relationship between the expertise of the vendor and customer confidence. Similarly, there are also empirical studies based on surveys of retailers companies, which confirm that expertise is one of the antecedents of trust (Doney & Cannon 1997).

In the case of services, Bendapudi & Berry (1997) propose a model in which the expertise of the service provider directly influences client trust. The inclusion of expertise as an influential factor for the study of the relationship between KIBS and their clients is very important because the knowledge that houses this expertise is the main selling point of these businesses. Therefore:

H_{1c}: KIBS Employees' expertise is positively related to the trust of the KIBS client.

Information and Trust

Stump & Heide (1996) argue that the ability to monitor the activities of industrial suppliers is based on the availability of information held by the client to detect non-compliance of the agreements. The difficulty in performing these monitoring activities, in the case of services, raises the problem of performance ambiguity (Ouchi 1980). One of the causes of this problem is information asymmetries between clients and service providers (Bowen & Jones 1986). The reduction of these information asymmetries may reduce the problem of performance ambiguity and build customer trust with the service providers.

Gallouj (1997) affirms that trust can help reduce informational asymmetries between service providers and their customers. For instance, in the case of electronic banking

services, if customers have more information about these kind of services, it will increase the client's trust in electronic banking (Ba 2001). In the case of KIBS, providing the customer with details of your skills and experience is important. This is because making this type of information available to the client allows him to recognize the skills and capabilities of KIBS for the development of a project (Zhang & Zhu 2009). On this basis, we propose the following hypothesis:

H_{1d}: Information provided by the company to its customers is positively related to the trust of the KIBS client.

Level of Implementation of RM strategies and Loyalty

One of the basic assumptions of RM is that the interactions between buyers and suppliers are one of the main elements of marketing, because the nature and quality of management of these relationships will define the buying behavior of customers. (Grönroos 2000)

This theory is well suited to the case of KIBS where the customer does not just passively take part in the production process but is actively involved in service delivery. Roberts et al. (2003) illustrate a case study of medical and banking services where managing relationships with customers has a role, even more important than the quality of the service. This leads us to conclude that we must consider the strategies of building a proper relationship with clients as a major factor in maintaining customer loyalty. Therefore, selecting the right customers to achieve long-term relationship may be the best strategy for the development of a service company (Karantinou & Hogg 2001). Too et al. (2001) provide empirical support for a positive relationship between relationship marketing orientation of the organization and customer loyalty in the case of commercial companies. As a final conclusion we propose the following hypothesis:

H₂: Level of Implementation of RM strategies in KIBS is positively related to the customer loyalty of the KIBS' clients.

The assumptions listed above are summarized in the following model (see Figure 1)

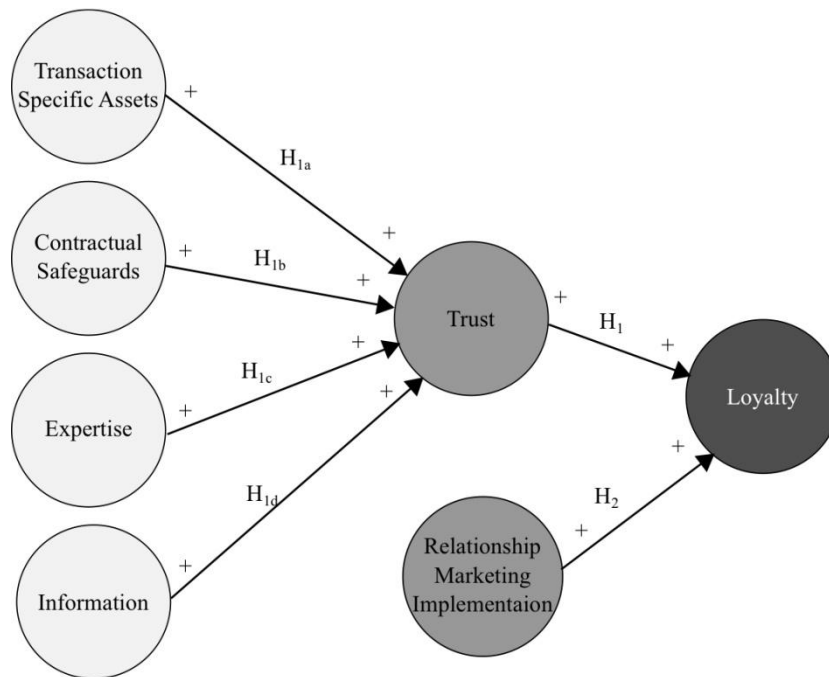

Figure 1. Proposed Model

Methodology

The field study was conducted in Lima, Peru. With average GDP growth rates of 6% between 2002 and 2006 and close to 9% and 10% in 2007 and 2008, Peru is one of the Latin American countries with more stable constant growth. This growth has been especially favored by the increase in mineral prices and, to a lesser extent, by the increase in exports of agricultural products. In this context of constant development, the number of business support services to the extractive industries and producing drivers increased.

In this context, between December 2007 and February 2008, 50 consulting service firms in the information technology and sanitary engineering sectors were surveyed in Lima (Peru). The data were collected either via face-to-face or web-based interviews. The research model is evaluated by a Partial Least Squares (PLS) regression analysis.

Results and Discussion

The model presented in Figure 1 was analyzed using the method of Partial Least Squares (PLS). The model used formative indicators to define constructs of TSA, Contractual Safeguards, Expertise and Information. Statistics relating to quality of these constructs is presented in Table I. In case of all of the constructs, multicollinearity of the indicators are below the prescribed limit ($VIF < 10$). Furthermore, the correlations among the indicators of formative constructs were below 0.9 and Communality was greater than 0. About the validity and quality of the reflective constructs (see Table II), all meet the condition of having an $AVE > 0.5$, $Composite Reliability > 0.7$ and $Communality > 0$.

Table I. Quality Criteria of the Formative Constructs

	VIF	Indicators Correlations	Communality
TSA	all<10	all< 0,9	0,40
Contractual safeguards	all<10	all< 0,9	0,25
Expertise	all<10	all< 0,9	0,36
Information	all<10	all< 0,9	0,30

Table II. Quality Criteria of the Reflective Constructs

	AVE	Composite Reliability	Communality
Customer Loyalty	0,88	0,93	0,88
RMS	0,59	0,80	0,59
Trust	0,74	0,85	0,74

The results for the acceptance of the hypothesis of the proposed model are presented in Table III. The hypotheses were accepted when they had a path coefficient > 0.1 with a significance level of $p < 0.10$. Following these parameters, we could accept the hypothesis about the positive effect of TSA in Trust. This result confirms the importance of the implementation of TSA in KIBS. Due to the complexity and variability of the requirements of consumers of such services, such investments are essential in order to provide clients with customized solution. The assumptions that define the Contractual Safeguards, Expertise and Information as forming factors of trust in KIBS could not be accepted due to the lack of significance of these relationships. R^2 values of 0.30, in the case of trust, show that the variance in trust could have been described in a moderate way by the expertise, information, contractual safeguards and TSA factors.

We can also accept the hypothesis of positive relationships between customer loyalty and trust, as well as customer loyalty and level of implementation of RM Strategies. However, R^2 values of 0.10 determined that the variability in customer loyalty can not be attributed to the influence of trust and level of implementation of RM strategies.

Table III. Summary PLS Results and Hypothesis Test

	β	T	Hypothesis Test
TSA->Trust	0,41**	3,9134	H _{1a} : accepted
Contractual safeguards -> Trust	0,17	1,4258	H _{1b} : declined
Expertise->Trust	0,14	1,3801	H _{1c} : declined
Information-> Trust	0,18	1,5426	H _{1d} : declined
Trust->Loyalty	0,19*	1,6931	H ₁ : accepted
RMS->Loyalty	0,21*	1,7493	H ₂ : accepted

** $< .05$, * $< .10$

Conclusions

The results of this study confirm the importance of the inclusion of transactional factors in the analysis of the relationships between KIBS and their clients. The inclusion of transactional factors, not only relational, it is necessary to explain the elements that contribute to the formation of trust. The predictors of trust based on factors like: contractual safeguards, expertise and information could not be verified. This could be explained because all of these factors were expected by the clients of KIBS as typical

characteristics of these kind of services. For this reason, these factors could not act as trust builders in the interviewed KIBS. However, the inclusion of Contractual Safeguards, Expertise and Information in future studies should not be discounted due to the varied literature that supports these relationships.

On data collected for the verification of the model, surveys of Peruvian KIBS were made in the initial period of the country's economic growth. The KIBS sectors surveyed had to face increases in demand and in the required quality of services they provided. This could have caused these firms to invest in training or staffing to cover the new requirements of its customers. Only in this way were the companies able to win the trust of customers and begin to establish long-term relationships with them. Another important external factor to consider is the relatively limited number of local KIBS that existed at that time in Peru. This factor may have had an influence on the variability of the customer loyalty and can not be attributed to the influence of trust and the Level of Implementation of RM strategies.

Among the main limitations are that the study did not consider surveys of customers or the analysis of dyads for analysis of relations between KIBS and their consumers. The inclusion of dyadic studies can provide a picture issues that may go unnoticed if you only take the perceptions of one part of the relationship (Samiee & Walters 2003).

Introduction

The proliferation of management systems (MSs) standard certifications has experienced a continuous growth since their publication (see ISO, 2010). The most widespread international standards are those published by the International Organization for Standardization (ISO), ISO 9001 for quality management systems (QMSs) and ISO 14001 for environmental management systems (EMSs). The last available data provided by ISO, “*the ISO survey*”, show that the number of ISO 9001 certifications worldwide is higher than one million, 1,064,785 certifications in December 2009 (see ISO, 2010), representing an 8% growth from 2008. The number of ISO 14001 worldwide certifications has also dramatically increased, 223,149 certifications in December 2009, 22% more than the previous year (see ISO, 2010). Other management systems have also been widely implemented by the organizations, such as the occupational health and safety MSs (e.g., OHSAS 18001), corporate social responsibility (e.g., SA 8000, AA 1000, ISO 26000), food safety MSs (e.g., ISO 22000 with a 69% of growth from 2008) or customer satisfaction (e.g., ISO 10000 series).

In this context of great creation and proliferation of international standards, research about the diffusion of standards has appeared. The investigation about this phenomenon refers to the factors affecting this diffusion, such as direct foreign investment (Prakash and Potoski, 2007), the influence of having other standards implemented (Corbett and Kirsch, 2001 and 2004, Vastag, 2003), positive institutional environment (Delmas, 2002), geographical and cultural affinity (Albuquerque *et al.*, 2007), and supply chain (Corbett, 2006 and 2008). Other research deals with the diffusion models, where forecast about the future spreading of these standards is analyzed. Evidence shows the saturation level that will achieve these systems in the near future, mainly in European countries (see e.g., Franceschini *et al.*, 2004 and 2008, Marimon *et al.*, 2006, 2009 and 2010, Albuquerque *et al.*, 2007, Casadesus *et al.*, 2008). The majority of these studies about diffusion consider all sectors, but new research is analyzing the phenomenon by sectors (see Llach *et al.*, 2010).

In this situation, an organization may have multiple management systems implemented and has the option to manage them either separately or integrated. The result of the latter possibility is an Integrated Management System (IMS), that can be defined as a “*set of interconnected processes that share a pool of human, information, material, infrastructure, and financial resources in order to achieve a composite of goals related to the satisfaction of a variety of stakeholders*” (Karapetrovic and Willborn, 1998a). Several studies on integration conclude that an integrated management system means

becoming more efficient and taking profit of synergies among the management systems (see e.g., Karapetrovic and Willborn, 1998a, Zeng *et al.*, 2007, Karapetrovic and Casadesus, 2009, Asif *et al.*, 2010, Lopez-Fresno, 2010).

Taking the above into account, the main aim of this study is to analyze the integration process in organizations that have implemented and are certified to multiple management systems, through the analysis of each integration stages.

The structure of the paper is as follow. In the next section, the literature review is presented and in the third section, the methodology is described. Next, the results are detailed and discussed and finally, the conclusions are proposed.

Literature review

The process of integrating multiple management systems can be divided in four main issues or phases (see also Bernardo *et al.*, 2011), namely: a) integration strategy, b) integration methodology, c) integration level, and d) systems' auditing integration.

The “integration strategy” refers to the implementation order, because the first MS that is chosen to be implemented can provide the base for the integrated management system. The most common strategies, based on Karapetrovic and Wilborn (1998a), are to establish:

- (1) First the QMS and second the EMS
- (2) First the EMS and second the QMS
- (3) QMS and EMS simultaneously

According to the existing empirical research, the majority of organizations are establishing first the QMS and second the EMS, mainly because of its chronological publication (see, e.g., Douglas and Glen, 2000, Labodová, 2004, Karapetrovic *et al.*, 2006, Zeng *et al.*, 2007, Griffith and Bhutto, 2008, Salomone, 2008, Bernardo *et al.*, 2011). In Karapetrovic and Casadesus (2009), they present four different cases where companies applied different strategies and the IMS is based on: 1) QMS and EMS, 2) QMS, EMS and OHSMS; 3) QMS, EMS, OHSMS and corporate social responsibility MS; and 4) EMS and QMS.

The second issue refers to the “methodology” used in the integration process. This integration methodology may be based either on a guideline published by a standardization body (e.g., SAI Global, 1999, Dansk Standard, 2005, AENOR, 2005, BSI, 2006 and ISO, 2008), or on methods and frameworks proposed in the existing literature (e.g., Karapetrovic and Willborn, 1998a, Karapetrovic, 2003 and 2005, Labodová, 2004, Zeng *et al.*, 2007, Asif *et al.*, 2010, Lopez-Fresno, 2010). For example, in Asif *et al.* (2009), they present a methodology to achieve excellence composed by four stages: 1) core processes specifics of an organization, 2) excellence in operations, 3) integration within strategy and operations, and 4) business excellence.

The third issue refers to the “degree of integration” of the integrated management system (IMS). There are different levels of integration defined in the literature (such as Karapetrovic, 2002a and 2003, Kirkby, 2002). For example, in Bernardo *et al.* (2009) the authors analyzed a sample of 435 Spanish organizations where the 86% has

integrated their management systems. They classified the levels into four: (1) no integration, (2) initial partial integration, (3) advanced partial integration, and (4) full integration. In each of these groups, the processes are integrated at a higher level than the objectives and documentation resources.

The last issue refers to the “integration of systems’ audits”, both internal and external, that may result in benefits such as the optimized use of resources (e.g., Karapetrovic and Willborn, 1998b, Douglas and Glen, 2000, Karapetrovic, 2002b, Zeng *et al.*, 2007, Salomone, 2008), and reduction of time because of multidisciplinary auditors who have the capacity of auditing different management systems (Douglas and Glen, 2000, Kraus and Grosskopf, 2008). In Bernardo *et al.*, (2010), the results show three different groups according to the level of audit integration, where the internal audits are more integrated than the external audits and the most integrated aspect is that of human resources (auditors or auditor team).

Although the literature analyzing the integration process of ISO management systems is increasing, the existing empirical studies are not yet adequate to describe in-depth the integration process. It is for this reason that the main aim of this study is to analyze the integration process in organizations that have implemented and are certified to multiple management systems, through the analysis of each one of the above key integration issues.

The methodology applied is explained in the next section.

Methodology

The case-study approach is used in this study in order to effectively describe and analyze all basic issues related to the subject under study. More specifically, five extended case studies were conducted in selected Greek organizations that were implementing at least two ISO management systems and particularly ISO 9001:2008 and ISO 14001:2004. The research is descriptive in nature in order to provide a better insight and understanding of the integration process and to identify general propositions regarding the observed practices (Eisenhardt, 1989, Yin, 2009). This methodology was extensively used from several authors that have studied the same subject in order to analyze the complex process of adoption and internalization of management systems and its impact on the organizations (Labodová, 2004, Karapetrovic and Casadesus, 2009, Lopez-Fresno, 2010, Simon and Bernardo, 2010).

Internal validity was assured by the search for common patterns intended to explain the understanding of the phenomena under study, while the reliability is guaranteed with the use of structured interviews with the same order and number of questions and an assessment protocol cases against each factor. In-depth knowledge about each organization, as well as qualitative information from all interviewees was obtained.

The sample consists of five selected industrial organizations that were judged as normal, ordinary, and representative, and the only requirement for the organizations to participate was to be certified, at least, against the ISO 9001:2008 and ISO 14001:2004. The data gathering was carried out through extensive and in-depth interviews in all five organizations asking the organizations’ quality manager, using a semi-structured questionnaire with open-ended questions. The main purpose was to collect data and

produce basic information, enabling qualitative observations concerning organizations' management systems integration. Each site was written up as an integrated case study, with the focus on drawing out the commonalities of meaning and understanding each site. The data analysis provides some ground for generalizations, even though subjective judgments were also made from the analysis of the cases.

Interviews and visits were made in pairs and the members of the research team had a proper training in the subject under study. None of the interviews was recorded; notes were taken by two researchers then cross-contrasted, such as recommended in the literature (Maxwell, 1996). In the process of comparison between cases and inference aiming to achieve the objective, clearly exploratory, the grounded theory method was used, which integrates appropriately with the general methodology of case studies (Binder and Edwards, 2010). This is a content analysis method with a strong potential in complex social phenomena as the present one. According to a systematic process, qualitative evidences are categorized and grouped to try to interpret them more easily (Glaser and Strauss, 1967). To this end, all interviews were coded a posteriori. Atlas.ti (version 5.0) was applied to facilitate the structuring of information and the encoding process.

The questionnaire used was divided into three main parts: management systems, integration of MSs and future. In the first part, questions were about the implementation of each management system, the implementation reasons, advantages and disadvantages, etc. In the second part, interviewees were asked about the integration process, the level of integration, the difficulties faced during the process, the benefits, etc. The future certifications were the main questions in the last part. For this study, the first two parts regarding implemented and integrated management systems are used.

Results and Discussion

The results presented are based on the comparison among cases in order to ease the interpretation and readability. The within-cases are not presented because of space limitation.

The data analysis of the organizations under study follows the integration process' issues, as these were presented in the literature review section, and it is divided in the four main areas: a) the integration strategy, b) the integration methodology, c) the integration level, and d) integration of systems' auditing. This approach gives us the opportunity to have a better view of possible convergence, similarities, differences and overall deviations in our findings (Table II summarized the comparison).

In order to assure privacy and confidentiality, the names of the organizations will not be revealed. Instead, companies will be identified as C1, C2, C3, C4 and C5. A brief description of the characteristics of each company is presented in Table I.

Table I. Sample organizations' characteristics

Companies	Profile		
	Ownership	Size	Sector
C1	Family	Medium	Chemical
C2	Multinational	Large	Food and beverages

C3	Multinational	Large	Aluminum products for various applications
C4	Family	Medium	Flexible packaging converting
C5	No family	Large	Food

Integration strategy

All the organizations of the sample have at least, two standards implemented, as it was one of the conditions to participate in the study. Specifically, four out of five organizations have implemented more than two ISO management systems, while only one of them (company C1) had only the two required systems in place (ISO 9001 and ISO 14001).

Regarding the implementation order, three companies are following the most implemented order that is, implementing first the QMS, second the EMS and then other management systems. From these three, C2 and C3 have the OHSMS in the third place, while C4 has implemented the food safety management system (ISO 22000). This result is logical as these companies might follow the chronological publication of both standards (similar results are found in Bernardo *et al.*, 2011). It is noticeable that company C4 has implemented the second and third standards simultaneously, taking profit of the synergies between these two systems (see e.g., Karapetrovic and Willborn, 1998a, Karapetrovic, 2003, Zeng *et al.*, 2007, Karapetrovic and Casadesus, 2009, Asif *et al.*, 2010).

For the two companies following a different order, both have implemented first the EMS and secondly the QMS. The reason for this order, as commented by the interviewee in company C1, was the sector where it operates. Company C5 has implemented the third standard, food safety, simultaneously with the ISO 9001 standard. In this case, as this organization is not integrating its MSs, the synergies are probably not profitable as for organization C4.

It is specially the ISO 22000 the only standard that companies have implemented simultaneously both with ISO 14001 and ISO 9001. This situation can lead us thinking that this food safety system is compatible with both standards, and has no problems to be integrated with the rest of the systems implemented. Another important note is that Greece is in the top three in number of certifications according to ISO data, with 987 certifications (see ISO, 2010).

Table II. Comparison of the organizations' integration process

Org.	Ownership	Strategy	Methodology	Level	Audits	
C1	Family business	EMS+QMS	Common elements	Fully integrated	Internal and external	more than
C2	No family business	QMS+EMS+OHSMS+FMS	Common elements	Fully integrated	Same level internal and external	internal
C3	No family business	QMS+EMS+OHSMS+ sectoral	Common elements	Partially integrated	Not integrated	
C4	Family	QMS+EMS-	Common	Fully	Same level internal	internal

	business	FMS + sectoral	elements	integrate d	and external
C5	No family business	EMS+QMS- FMS	No integration	No integrate d	Not integrated

Integration methodology

Four organizations have integrated their management systems at a certain level. All of them have followed the same methodology, doing an analysis of the common elements of the MSs. Companies highlighted the difficulty of applying the process and the easiness of using this methodology. The organizations have compared the standard requirements and have adapted their own requirements to standards' requirements. There is only one difference, in company C4, they applied the analysis based on their internal procedures, not on the standards. In interviewee's words, we "*have adjusted the systems to our internal processes and try to make the standard fit for purpose*". This methodology has been seen as common in other studies, such as in Karapetrovic *et al.* (2006) and Bernardo *et al.* (2010b). In the latter, the authors found that for a Spanish sample of 362 organizations that have integrated the systems, the integration level is higher in those that are applying a combination of management models, being the most used tool the process approach (Bernardo *et al.*, 2010b).

Another common characteristic at this stage is the use of software. In companies C1 and C2, they highlighted the importance of using software to integrate the systems, that ease the integration and allows them to have the systems fully integrated.

Level of integrated system

Three companies of the sample have their management systems fully integrated, C1, C2 and C4. Company C3, has a partial integration of its MSs and finally, C5 has not integrated.

For the fully integrated companies, as company C2 interviewee said, "*the system is one*", and the reason in company C4 is that "*it makes it easier to manage them*" (similar results can be found in, e.g., Douglas and Glen, 2000, Karapetrovic *et al.*, 2006, Zeng *et al.*, 2007, Salomone, 2008, Bernardo *et al.*, 2009, Karapetrovic and Casadesús, 2009). They have all the objectives, resources and procedures fully integrated. However, in company C1, there are two people managing the system because they were two before integration and they cooperate to manage the IMS, as each has the specific knowledge for each implemented system and wanted to maintain it. A similar situation was found also in Bernardo *et al.* (2009), who found that the person or people managing the system is not significant in the integration, in other words, no matter who is managing the system if it is properly managed.

In company C3, the responsible of the MSs wants to integrate all the systems into one, but there are not enough resources to manage it. The integrated procedures are: training, evaluation of suppliers, specific measurements such as internal control, preventive and corrective actions and document control. They integrate partially because "*the function-specific part of each system makes the difficult to integrate*". Another added problem is

that the top management does not understand and share the necessity of institutionalizing the integration process.

Finally, in company C5, they declared not integrating their management systems, but they manage some aspects of management systems and human resources management in an integrated way.

Following the classification obtained in Bernardo *et al.* (2009), who found four groups of companies depending on the MSs level of integration: no integration, initial partial integration, partial integration and full integration, companies of this study can be classified accordingly. Companies C1, C2 and C4 would be in the last group, as they have fully integrated their MSs. Company C3 could be classified in the partial integration group and finally, company C5 is not in the first group, and might be grouped, timidly, in the initial partial integration cluster.

The main characteristics highlighted by the interviewees have been the availability of resources to apply the integration and the top management commitment. If these two elements are present in the organization, the integration process has ended with a fully integrated system.

Integration of systems' audits

The integration level of audits has been measured considering the integration of audit team, time, process, plan and report and results. Before explaining the cases, a brief explanation about these concepts will be given. In the interview, participants were asked to say if, e.g., the auditors team was the same for all norms (fully integrated), the same for some norms (partially integrated) or was different (no integration). The levels are based on Karapetrovic (2003) proposed levels: partial integration and full integration. In the case of time, if the audits were realized simultaneously for all norms, they were fully integrated; if they were simultaneously done for some norms, the level is partial; and finally, if the audits are carried out in different moments, it was not integrated. For the rest of the concepts, the same logic is applied (the same levels are considered in Bernardo *et al.*, 2010a and 2011, Simon and Bernardo, 2010).

This is the integration stage where more work can be done. Only company C2 has the internal and external audits fully integrated in terms of team, time, process, plan and report, and results.

Comparing the organizations with full integration of MSs, C1 and C2 have all the internal audit elements fully integrated. C4 have full integration in auditors' team and audit time, and has a unique audit plan and different final reports. This organization is not integrating the audit time or the results, as the internal audit only detects nonconformities. C3, that is integrating its systems partially, the internal audits are not integrated, only the audit plan is unique, but the final reports are different for each norm.

For the external audits, C1, C2 and C4 are not similar as they are in the internal audits. The common elements are the audit time and results. The audits are done simultaneously and in all three companies the external audits suggest opportunities to improve each norm and the integrated system. C2 have full integration in all the audit

elements, but C1 and C4 present different levels of integration. In C1, the auditors' team is different for each norm, the systems are audited as interrelated and the audit plan and final report are the same for all norms. In C4, the auditors are the same only for some norms, the systems are audited as separated and there is a unique audit plan but a final report for each norm.

Finally, C3 audit results suggest opportunities to improve each norm and the integrated system, but the other audit elements are not integrated, and C5 has the external audit team, process and results partially integrated, but the time and audit plan and final report are not integrated.

These companies can also be classified into the three groups find in Bernardo *et al.* (2010a), where companies were grouped according to the internal and external audits level of integration. Company C2 can be group in the third cluster, as it has the highest levels of integration in both internal and external audits. The other companies integrating the audits, cannot be classified exactly, as the level of integration does not fit with the study results, but, approximately, C1, C2 and C3 could be grouped in the first cluster, as internal audits are more integrated than the external (Bernardo *et al.*, 2010a). Company C5 cannot be classified because in the study, all the Spanish organizations were integrating the audits at a certain level, and this is not the case for this company.

Conclusions

The main objective of this study is to analyze the integration process in organizations with multiple management systems implemented, through the analysis of the different integration stages. This aim has been achieve as this paper presents how Greek organizations are realizing the integration process, in those that have integrated their management systems. After the analysis, five conclusions can be extracted.

First of all, the integration of management systems is a process applied in the majority of Greek companies. The main reason posed by the interviewees is the ease of management, allowing them to be more efficient and taking profit of synergies among the management systems (as found in, e.g., Karapetrovic and Willborn, 1998a, Zeng *et al.*, 2007, Karapetrovic and Casadesus, 2009, Asif *et al.*, 2010, Lopez-Fresno, 2010). Only one company is not integrating its systems.

The second conclusion is twofold. First, the majority of the organizations have more than two MSs, meaning the importance of these systems to make them competitive in the market, more important in the present economic situation (e.g., Karapetrovic and Willborn, 1998, Douglas and Glen, 2000, Karapetrovic, 2002a, Karapetrovic *et al.*, 2006, Zeng *et al.*, 2007, Griffith and Bhutto, 2008, Salomone, 2008, Karapetrovic and Casadesus, 2009). Second, also the majority of organizations are following the most common implementation order, namely, implementing first the quality management system and then the environmental. In this particular case, three out of five organizations are following it and the other two have implemented first the EMS and then the QMS (see e.g., Karapetrovic and Casadesus, 2009). This last strategy is justified for the sector of activity.

Thirdly, it can be stated that the most common methodology used to integrate the MSs in Greek companies is applying the analysis of the common elements, as it has been

applied for all the participant organizations (similar results in Karapetrovic *et al.*, 2006). The main reason highlighted has been the facility in its application.

Systems' audits are the weakest point in the majority of organizations in terms of integration. Only one company has the internal and external audits fully integrated, and the others have some aspects. In general, internal audits are more integrated than the external (as in Bernardo *et al.*, 2010a), and the most integrated aspects are audit time, plan and results. In this aspect, Greek companies can be helped by the next publication of the ISO 19011 as it will expand the MSs considered not only to quality an environment, also to all the MSs that a company can have implemented (ISO, 2011).

Finally, no conclusions can be made about if the size and ownership are conditionings of the integration process. In the present study, the only situation that can be said is that two out of three companies that have fully integrated their MSs are medium-size and family business.

Managerial implications are for those companies that have not integrated their management systems, because integration can make them becoming more efficient (see Karapetrovic, 2003, Zeng *et al.*, 2007 and 2011), an important point in the present situation. Governments and certification bodies should take an initiative to help these organizations promoting the integration as a way of reducing costs and having a better understanding of both the management systems and the entire organization.

The main limitation in this paper is the sample size; however the authors strongly believe that the subject under study –MSs integration– typically follows certain patterns in terms of adaptation and implementation (Wilkinson and Dale, 2001). According to Beckmerhagen *et al.* (2003), “*the integration of management system standards will continue to be a part of future research in the area of IMS, not only because minor differences among the standards still exist, but also because new standards that will stretch the boundaries of what we currently consider as “management systems” will appear*”. The future research will be focused on analyzing the differences between the integration process depending on the sector of activity and the ownership.

Acknowledgments

This article was written as part of a research project entitled “Customers' satisfaction improvement in Spanish organizations through standardization” (ECO2009-12754-CO2-01) financed by the Ministry of Science and Innovation within the aid program for R+D projects. The project has possible with a mobility grant financed by the Faculty of Economy and Business of the University of Barcelona.

Recovering from the Crisis: Is an Excellence Approach a Reference Point for LearnAbility, InnovAbility and SustainAbility?

Dr Louise Boulter, Middlesex University Business School, London,
l.boulter@mdx.ac.uk

Professor Jens Dahlgaard, Linköping University, Sweden jens.jorn.dahlgaard@liu.se

Keywords: Excellence, LearnAbility, InnovAbility, SustainAbility, EFQM Excellence Model

Introduction

LearnAbility, SustainAbility and InnovAbility as concepts for companies should be pervasive, and all embracing especially during the economic downturn where companies have to do more with less resource. However, these concepts appear not to have necessarily been very well thought through or applied by companies. Furthermore, historically, companies have been poor at learning from failures in relation to new product development, an essential building block for ‘innovability.’ (Antoni et al, 2005). Whilst it is still early-days post ‘boom’ times, perhaps this lack of clarity and application can be attributed to the possible ambiguity surrounding the ‘real’ meaning, and potential of LearnAbility, SustainAbility and InnovAbility, as well as having no clear framework either for their application nor for fostering a culture to build Learnability, Sustainability and Innovability.

Dahlgaard-Park and Dahlgaard (2010) lend much clarity to the concepts of LearnAbility, SustainAbility and InnovAbility. They define the three concepts in the following way:

LearnAbility is ability/ capability to study and to learn while *InnovAbility* is about ability/ capability to innovate. Both are Meta competences because it’s not about to learn and innovate for a certain, single project. They are a way of life and a way of being for people and organizations. *SustainAbility* is ability/ capability to sustain which will be assured through continuous innovations which are based on continuous study and learning. Hence, the three words or concepts are interdependent and together they form a powerful system for recovery and progress. For recovery from the recent economic crisis we need to be able to build such powerful systems; as individuals, organisations, nations, communities as the European Community.

Further, Bendell et al (2010) put forward axioms for LearnAbility, InnovAbility and SustainAbility as follows:

- Thinking short-term is insufficient; we need also to think long-term
- We must not ignore shareholders; a balanced stakeholder approach is superior to a narrow shareholder-focused one
- We need to be responsible as an organisation
- Everything in our organisation is joined up and interrelated, and our organisation is joined up with everything (the System Thinking paradigm)
- You may never achieve perfection, but you can always get better and approach perfection
- You have to keep working at improving everything – People, Partnerships, Processes and Products (the “4P”).

- A result facilitates more of the same action: so success builds on success, failure on failure (the virtuous and the vicious circles).
- Sometimes when obstacles, that act as barriers to us, improving are all in the mind; we need to have the right attitudes, we have to want to do it
- We all have to live and drive the desired culture
- There is no Failure other than in Giving Up

These axioms are described by the authors as being ‘speculative’ and being ‘based on the authors’ combined experience in the field over many years. In spite of this speculative interpretation, however, it is clear that the axioms that are put forward by the authors embrace some of the fundamental principles upon which the European Foundation for Quality Management Excellence model is founded. The European Foundation for Quality Management (EFQM) Excellence Model (Figure 1.0) is a tool and method that helps organisations achieve business success by measuring where they are on the path to excellence; helping them understand the gaps; identifying potential solutions for bridging the gap; and providing an approach for implementing the gap-bridging solutions.

The EFQM Excellence Model was introduced in 1992 as the framework for assessing applications for The European Quality Award. Today, the EFQM Excellence Model is widely used throughout Europe and has become the basis for national and regional awards in Europe and other parts of the world. The EFQM Excellence Model is recognised as an effective business performance management system. (Van der Wiele, 1996a, 1996b; Bemowski & Stratton, 1995; Coulabidou & Dale, 1995; Godd et-all, 1996; Teo & Dale, 1997; Van de Wiele et. al., 1999; and Vos and Blackmon, 1996).

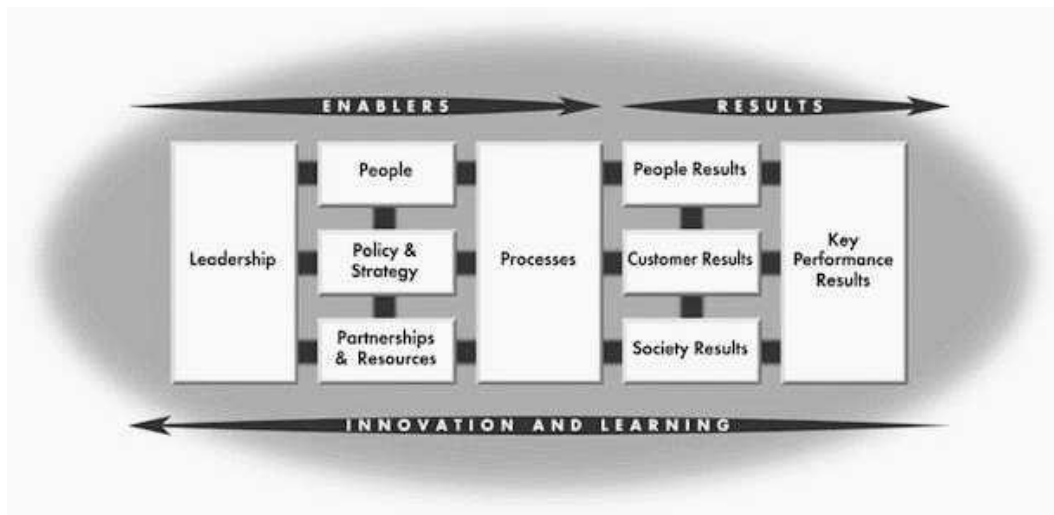

Figure 1.0 The EFQM Excellence Model (copyright EFQM)

The next section of this paper considers a study of companies that have successfully implemented the principles of Excellence in terms of TQM planning, implementation, learning and improving. These companies that have been recognised as achieving excellent levels of performance in view of having received an Excellence award.

A Study of the Successful – Key Performance Measures

Whilst in the US a comprehensive study has been conducted by Singhal and Hendriks (1997, 2001) that clearly demonstrates a positive link between the adoption of principles of Excellence such as embedded in the Malcolm Baldrige National Quality Award and improved organisational results, there has been little systematic study of the impact of the principles of the EFQM Excellence Model on business performance in Europe. Many of the previous research studies in Europe on the link between the effective implementation of organisational excellence strategies and improved financial performance have used survey methodology or case studies to collect data. Whilst these studies have provided valuable information on how the EFQM Excellence Model is perceived, and implemented, these studies have a number of shortcomings with the most serious one being the inability to independently assess the effectiveness of the implementation of the EFQM Excellence Model and its impact on financial performance.

Two sets of performance measures have been used for the study; these are share value and accounting based measures, with share price performance being a primary measure of performance. Share price performance is important to various stakeholders including senior management, employees, suppliers, mutual fund managers, institutional and individual investors. The return on shares that an investor would have earned by investing in companies that have effectively implemented the principles of the EFQM Excellence Model have been calculated. The share returns include capital gains, regular dividends and special dividends.

Time Period for Analysing Performance

Any attempt to identify the correlation between the effective implementation of the principles of the EFQM Excellence Model and improved financial performance needs to examine performance over a reasonably long period of time. This is because the principles of the EFQM Excellence Model require a suitably long horizon to be fully absorbed and integrated in the normal operating mode of how things are done at a company.

Existing literature does not provide much theoretical guidance regarding the appropriate time of analysis (Hendriks and Singhal, 2001). However by determining the date when the company won its first award we can at least establish a date for when the company had an effective programme in place. In this study where data has been available, the change in the performance of companies has been analysed over an 11 year time period anchored around the year when a company received its first award. To measure the net benefits from the effective implementation of the principles of the EFQM Excellence Model share value and accounting based performance measures have been computed before and after a company has received a first award. The first period of time, “the implementation period” starts 5 years before and ends one year before a company received a first award. The second period of time, “the post implementation period” starts one year before and ends 5 years after a company received a first award.

Industry and economic conditions, whether prevailing in a specific country at a particular point in time or a specific industry impact upon the performance of all

companies, and this will be true whether or not a company has effectively implemented the principles of the EFQM Excellence Model. To compare the performance of companies that have effectively implemented the principles of the EFQM Excellence Model and to adjust for country and industry economic conditions, comparison companies have been selected.

For each award winning company a comparison company was selected based on key criteria. This is that the comparison company;

- i. Has the same country of incorporation of the parent company
- ii. Has the same accounting data available over at least the same time period
- iii. Has at least the same first digit industry code as classified by Datastream
- iv. Is closest in size as measured by total assets at the fiscal year end before the winning of a first award, with the constraint that the ratio of value of assets is always less than a factor of 3

Key results that are reported in the next section of this paper are based on 120 award winners and 120 comparison companies. The key overall results report the average difference in percentage change in performance between each of the award winning companies and its comparison company.

Overview of Findings

The study found that compared to the comparison companies award winning companies experience significant higher increases in share value within a short period of time after having received a first award.

Results for the post implementation period indicate that generally the award winning companies outperform the comparison companies up to 3 years after first winning an award and sometimes this is statistically significant. Whilst the comparison companies generally outperform the award winning companies in the implementation period, this is not statistically significant.

Figure 2.0 Mean percentage change in the performance of the award winning companies compared to the comparison companies for Share Value

An analysis of the share price performance for the award winning companies reveals some interesting results. In the year that the award winning companies receive a first award, they experience on average a 3% higher return in share value compared to the comparison companies. Additionally, the award winning companies experience higher increases in share value up to three years after having received a first award compared to the comparison companies. By two years after having received a first award the award winning companies have experienced a higher return in share value by an average of 24%, and by three years after having received a first award the award winning companies have experienced a higher return by an average of 36%. The last two average differences of 24% and 36% are statistically significant.

Overall, the study found that compared to the comparison companies award winning companies experience higher increases in share value, sales, capital expenditure over assets and capital expenditure over sales, higher growth in assets and further reduction in costs over sales within a short period of time after having received a first award. (Figure 3.0)

Figure 3.0 Award Winners: One Year Improvements in Financial Performance

Three years after receiving an award, the award winning companies outperform the comparison companies by an average of 36% for share value, 17% for sales, 5% for

sales over assets, 4% for capital expenditure over sales, 20% in assets and a better reduction in costs by 1.4%. (See Figure 4.0).

Figure 4.0 Award Winners: Three Years Improvements in Financial Performance

For the final year that performance was tracked, the award winners experienced even greater increases. Compared to the comparison companies, the award winning companies experienced higher growth in sales by an average of 77%, higher increases in operating income by an average of 18%, higher increases in capital expenditure over assets by an average of 28% and capital expenditure over sales by an average of 30%, higher growth in assets by an average of 44% and further decrease in costs over sales by 4.5%. (See Figure 5.0)

Figure 5.0 Award Winners: Five Years Improvements in Financial Performance

Concluding Comments

The Award Winner’s superior performance appears to be linked to the characteristics of these companies that made them Award Winners. Since all the award winners’ frameworks used were based directly, or indirectly, on the EFQM Excellence Model criteria, a natural conclusion is that these companies were taking seriously the axioms of *LearnAbility*, *InnovAbility* and *SustainAbility*. Apparently, the comparison companies were not, and they fared much worse. Interestingly, the study also gave evidence that the superior performance was not primarily due to the efficiency and cost performance of the Award Winners, but rather to their superior speed of growth (for example in relation to sales, See Figure 2.2) that appears to be directly linked to their implicit emphasis through the EFQM framework on the *LearnAbility*, *InnovAbility* and *SustainAbility* axioms. To conclude, the overall evidence indicates that when the principles of the EFQM Excellence Model have been implemented effectively, performance improves in both short and long periods of time. This should prove to be

reassuring for those companies that have made an investment and long-term commitment to the principles of the EFQM Excellence Model, and it provides evidence to support the continued commitment to the principles of the EFQM Excellence Model for those companies that might be thinking of replacing their Excellence strategy with something else. Furthermore, it provides positive evidence to those companies that are contemplating implementing the principles of the EFQM Excellence Model of the benefits that their company can reap from its effective implementation. Finally, the results provide evidence that the EFQM Excellence Model is a valid framework and reference point for LearnAbility, InnovAbility and SustainAbility.

Paper type: Research paper

Introduction

The increase of competitive pressure while ongoing globalization and labor division is well known and still an actual phenomena. Short production cycles, individualized product demands as well as continuously changing customers' requirements characterize the competitive environment. Enterprises are subjected to a high innovation pressure caused by a powerful dynamic including permanently changing demands and conditions. According to Bullinger (2008) the global competition has to be seen as an innovation competition. In between this global competition enterprises are forced to align their innovation strategy strategically to assure their competitive position.

Innovation strategy and the existing innovation potential assure an enterprise's competitive position. 'The innovation ability of an enterprise is nowadays not just safeguarding the future, but as well often a condition to get a successful position at the market and to reach a superior market position' (Spielkamp, Rammert 2006). Nevertheless, the estimation and evaluation of the innovation potential is difficult. It is a dynamic development process. Even to manage an innovation process at all, means to plan something non-predictable. Plans cannot be drawn on routines, because innovations are projects having an open end.

According to Stern and Jaberg (2010) innovation is the process of transferring an invention to market use. This hypothesis is going along with Schumpeter's assumptions. And it underlines that the invention of a product is not yet sufficient. Therefore, innovation success has to be put on the same level as economic success. Innovation itself can refer to a product, a process, an organization, a market or to social and cultural aspects.

Retrospectively success factors for already successfully driven innovation strategies can be derived and analyzed. It is important to deal with the success factors off innovation and competition strategies to ascertain the current position of an enterprise prospectively. By deriving specific success factors the innovation strategy can be re-designed and re-aligned towards future competition requirements.

This paper offers as a first step a short overview of the current state of the art concerning success factors and innovation strategies as well as a critical evaluation. Further on, a derivation of the most important success factors, their classification and the development of guidance for innovation strategy alignment is presented. As a third

step the success factors and the guidance are implemented into the NetInnoCheck model (Bredtmann 2009). The paper ends up with a summary of the most important results and an outlook.

Success Factors for Innovation Strategy

Success factors are factors and values or ratings which have a significant impact on the achievement of the overall goal of an enterprise. According to Rehkugler (1989) success factors are, in general, the main influencing variables of success of an enterprise (or a smaller module), these factors are long-term effective and they cause the competitive advantage. Success factors are therefore seen as success variables whose use influences the achieved profits sustainably. As Steinle, C.; Schmidt, C.; Lawa, D. (1995) phrase it they are ‘characteristics [...] having a significant impact on the success of an enterprise’. The success factors research was developed in view of the question what drives enterprises being successful and what characterizes them (see Rehkugler, H. 1989, page 626). The starting point of success factors research was the qualitative analysis ‘In Search of Excellence’ by Tom Peters and Peters Waterman (McKinsey consultants) in 1982, where they analyzed 62 American enterprises concerning their business success. This analysis was based on the concept of the 7 S-factors according to McKinsey, which had already been described in 1980 in an article called ‘Structure is not Organization’. Peters and Waterman developed -based on this concept- 8 attributes which describe an excellent organization.

The 7 Ss and their connections are illustrated in figure 1.

Figure1. : Concept of 7S according to McKinsey/ (Peters/ Waterman 1982)

The perspective, that an enterprise includes more than just its structure, was taken for the very first time with the 7S-model. This concept creates a new approach by taking hard aspects as well as soft aspects into consideration. The S-factors strategy, structure, and system are so called hard aspects.

Quoting Irwin/Zwick/Sutton 1999 p. 316-317 (related to Peters / Waterman 1982) the 7 S are defined the following way

‘Strategy – The strategy of an enterprise embraces all measures which generate a competitive advantage.

Structure – The structure of an enterprise is the condition for any possible specialization and co-operation. The structure is defined by strategy, size of enterprise, and product and service performances of the enterprise.

Systems – The systems of an enterprise include all formal and informal processes of strategy in between the given structures.

The soft aspects of the 7 S- model are the style, staff, skills und shared values.

Style – The style of enterprise is related to the enterprise culture. This concerns values and standards as well as management culture and leadership.

Staff – Staff are the employees of the enterprise. But this S also includes the structuring of the human resource development and the participation of the employees.

Skills – Skills are the summation of the abilities and competencies of the enterprise as well as any measure towards expansion and further development.

Shared Values –Shared values are related to the fundamental and essential ideas on which the enterprise is based and to all connected visions. Additionally shared values define the alignment of the enterprise.’

Based on the analysis of 62 enterprises by the 7 S- model Peters and Waterman (1982) developed 8 attributes which characterize excellent organizations:

(1) **A bias for action** - getting on with it and overcoming the inertia that often occurs with size.

(2) **Close to the customer** - understanding the needs of ‘lead’ users and providing the desired levels of service, quality and reliability.

(3) **Autonomy and entrepreneurship** - devolution, providing space and support for creative ideas that lead to innovative product and service launches.

(4) **Productivity through people** - people is seen as the primary source of productivity gains.

(5) **Hands on, value driven** - the organization's values result in a distinct and binding culture which gives direction to action by all members.

(6) **Stick to the knitting** - concentration on and development of the organization's areas of distinctive competence.

(7) **Simple form, lean staff** - simple organization structures, with efficient management supported by small staff teams.

(8) **Simultaneous loose-tight properties** - an effective balance between central direction and individual authority.

The scientific discussion evaluated the results of Peters and Waterman as being too subjective due to the fact that they are based on expert interviews on the one hand. And on the other hand these interviews just offered a snapshot of the enterprises. Nevertheless, the 7 S-model and the 8 attributes are one of the first approaches to identify success factors of enterprises.

The analysis of success factors has always been criticized. Dellmann (1991) criticized that enterprises were analyzed which had been successful in the past. The extracted success factors were projected into future by universally valid success rules. The current dynamic of exterior influences was not taken into consideration. Just a consideration of these influences can generate success potentials according to Dellmann. It is necessary to recognize such signs at an early stage to remain at market successfully (Dellmann, 1991, p. 433; Burgstahler 2001).

Parallel to the further development of the success factors research the point of view changes from the all embracing success factors to so-called critical success factors. This reduction to the critical success factors should point out the factors having a significant influence on the business success. A further division towards success factors which influence business success long-term (Daschmann 1994, p. 13, Rehkugler 1989, p. 627). This leads to an overwhelming number of papers dealing with the identification of success factors.

This paper deals with the current state of the art of the success factors research concerning success factors for innovation strategies. A literature research concerning success factors of innovation strategies -based on the last three years to assure actuality- just leads to two relevant sources which offer a specific context of success factors of innovation strategies.

The first source is the project KompNet2011 'Strategical Alignment and Innovation Activity of SMEs in the area of Jena (Germany)' (Sauer and Stoetzer 2010) and second source is 'Manual Successful Innovation Management; Success Factors – Basic Patterns – Case Studies' (Stern and Jaberg 2010).

The project KompNet2011 investigated on the success factors of regional innovation networks. 225 enterprises having at least 5 employees were interviewed to gather the relevance of different innovation kinds, innovation barriers, and innovation supporter. Data gathering was carried out through personal standardized expert interviews. As a central element and, therefore, as a success factor 'strategy definition' was identified within KompNet2011. The strategy definition affects the base for long-term goals. Secondly the importance of the customer who is central for an innovation was exposed followed by the current competitors, who enhance the innovation pressure. It turned out that barriers are not driven by financial aspects but by negative attitudes of employees and of the management. This means that the employees as well as the entire management are success factors for innovation strategies.

Stern and Jaberg (2010) offer guidelines for enterprises to fix innovation successfully at the market. The tasks of an innovation management according Stern/Jaberg are offered by table 1.

Table1: Tasks of Innovation Management according to Stern/Jaberg 2010

Tasks of Innovation Management
1. Determination and persistence of innovation goals and innovation strategies.
2. Proper recognition of costumers' requirements in time and adequate response in kind of market conform products and performances.

3. Decision concerning realization of innovation.
4. Targeted designing and steering of innovation processes to ascertain a faster and better transfer of business ideas than competitors do to assure market success.
5. Generating an innovation supportive enterprise structure and enterprise culture.

The main problems occurring are the uniqueness of innovation processes, the great number of influencing factors, and the uncertain results. Innovation processes are complex and hardly controllable. It is difficult to generalize these processes and to apply them on different enterprises. The solution for this problem offered by Stern and Jaberg is the creation of a basic pattern out of similarities which has to be aligned with the characteristics of the specific enterprise. Stern and Jaberg developed out of 53 success factors 11 basic patterns. The basic patterns are transferred to checklists applicable on each enterprise.

Table 2: patterns and success factors according Stern/ Jaberg 2010

Basic Pattern	Success Factor
<i>Driving/Motivation</i>	Innovation driving at high enterprise level Existing aim system Aim system is well known to all employees (aim system ‘arrived’) Vision based strategy is persisted (aim system is basis of actions) Innovation is an enterprise aim and an assignment
<i>Leadership</i>	Leadership concerning target agreement (MbO – Management by Objectives), innovation aim in target agreement Reward of innovation activity Supervisors as coaches Employees as intra-preneurs Flexible, react able, responsible small units (fractals) Flat hierarchy, short distances
<i>Enterprise Culture</i>	Open communication Clime Free passing of knowledge (no retaining of knowledge due to power considerations) Participation and information of employees concerning all important decision at an early time
<i>Area of Priorities based on customers, competition and enterprise</i>	Knowledge management: Does external information reach the enterprise and does it reach all internal participants? Customer orientation of all employees Competition orientation of all employees Basic pattern success factor All employees are aware of aims and resources of the enterprise

<i>Closeness to customers</i>	<p>Acceptance of customer's wish concerning innovation process</p> <p>Application of different methodologies of closeness to customers</p> <p>Active co-operation with customers</p>
<i>Innovation team</i>	<p>Participation of employees of all units of the enterprise (interdisciplinary brainstorming team)</p> <p>Adequate priority of innovation activity for all employees (harmonization of events of the day)</p> <p>Exhaustion of all resources for brainstorming</p> <p>Application of brainstorming methodologies (creative methodologies)</p> <p>Co-ordination of brainstorming process by innovation manager</p>
<i>Value Innovation</i>	<p>Development team aim at focus of customer's wish</p> <p>Focusing on most important factors for ordering</p> <p>Team pursues unit selling points/ is willing to leave conventional paths</p> <p>Competition orientation of team: Monitoring and beating the competition</p> <p>Courage towards persistent development/ early recognition of future customer's wish</p>
<i>Chance and Risk Analysis</i>	<p>Clear criteria to evaluate ideas</p> <p>Priorisation of ideas by criteria and development of measures</p> <p>Interdisciplinary preparation of decision</p> <p>Application of strategy portfolios or comparable tools</p> <p>Financial scenarios</p>
<i>Process organization</i>	<p>Flexible project organization, participation of employees of all enterprise units</p> <p>Responsibility for the team (delivering responsibility top down, empowerment)</p> <p>Adequate equipment of resources</p> <p>Adequate priority of innovation activity for all employees (harmonization of events of the day)</p> <p>Adequate existing of motivation, experience and qualification in between the team</p> <p>Application of project management methodologies like goal setting, Gantt chart methods, scenario methodologies</p> <p>Application of development methodologies (e. g. QFD, FMEA, Target Costing, Simulation, Rapid Prototyping)</p> <p>Learning enterprise: fruitful retrospective view</p>
<i>Core competence management</i>	<p>Awareness of core competencies</p> <p>Focusing on core competencies</p> <p>Conscious development (knowledge management)/ task</p>

	of core competencies (cc-strategy) Openness for alliances/buying-in Development of synergies (platform concept, use of same parts)
<i>Internal Marketing</i>	Participation of employees of all areas of activity starting early (interdisciplinary) Participation/information of all employees starting early Participation/information of additional enterprise fields/companies starting early Application of different methodologies of internal marketing (e. g. postings, innovation adoption)

Beside these basic patterns the innovation process has to be considered due to its phases. The following four phases are estimated:

1. Brainstorming
2. Evaluation of ideas
3. Internal Implementation
4. External Transfer

Additionally the project points out the existence of two different basic patterns. The first basic patterns appear in all four phases of the innovation process, they are called permanent basic patterns. They are related to interpersonal dealings, the soft skills. The second kind of basic patterns includes all of those which just appear during one or two phases of the innovation process. They are called variable basic patterns.

Soft skills contain driving/motivation, leadership, enterprise culture, and area of priorities based on customers, competition and enterprise. These four basic patterns can only be changed by long-term run due to their long-term growth and because they reflect the thought and activity patterns of the concerned people.

The basic patterns lead to seven tools being needed by an enterprise to carry on innovation successfully.

1. Innovation manager and innovation team
2. Establishing of customers' requirements by closeness to customers
3. Value innovation
4. Management of core competencies
5. Chance and risk analysis
6. Internal Marketing
7. Process organization
- 8.

The basic patterns influence each other and they develop their total impact by interacting. The interaction of the basic patterns and the chosen classifications are similar to the 7S-model and the 8 derived attributes. A parallel to the 7S-model -which started the success factor research- can be shown. The results of the approaches are implemented to the methodology of the NetInnoCheck by Bredtmann to extend the InnoCube.

Comparison of Approaches and Implementation in NetInnoCheck

The main focus of this chapter is gathering clusters by analyzing success factors and innovation strategies. The demonstrated approaches by Peters/Waterman (7S-model) and Stern/Jaberg (11 basic patterns) are compared and lead to scheme describing the actual success factors and innovation strategies. These results are implemented in the NetInnoCheck to evaluate the innovation potential of an enterprise.

Table 3: Comparison of 7S-model and 11 basic patterns:

7 S – Peters and Waterman 1982	11 basic patterns – Stern and Jaberg 2010
Strategy	Driving/Motivation
Structure	Leadership
Systems	Enterprise Culture
Style	Area of Priorities based on customers, competition and enterprise
Staff	Closeness to customer
Skills	Innovation team
Shared Values	Value Innovation
	Chance and Risk Analysis
	Process organization
	Core competence management
	Internal Marketing

Areas being relevant concerning the estimation of the innovation potential of an enterprise are directly compared in table3. The combination of these areas assures an all-embracing estimation of the innovation potential. The following fields come out which conceive the areas of the success factors concerning innovation potential estimation by combining the two approaches.

Table 4: Combination results

7 S – Peters and Waterman 1982	11 basic patterns – Stern and Jaberg 2010	combination
strategy	Driving/motivation (aim system)/ incentive aim	strategy aim
structure	leadership / direction leadership	structure and leadership
systems	enterprise culture	systems and process organisation
style	<u>area of priority</u> between customer, competition and enterprise	enterprise culture
staff	<u>closeness to customers</u>	(innovation) staff
skills	innovation team	skills and core competencies
shared values	value Innovation	shared innovation values
	opportunities and risk analyse	customer and customer involvement
	process organisation	opportunities and risks analyse - focus competition
	core competencies management	
	internal marketing	

The comparison and combination of the two approaches lead to 9 fields in which success factors can be identified.

- strategy aim
- structure and leadership
- systems and process organisation
- enterprise culture
- (innovation) staff
- skills and core competencies
- shared innovation values
- customer and customer involvement
- opportunities and risks – focus competition

By combining the different fields the new developed areas having an alignment towards innovation and innovation management offer the possibility to extend the InnoCube concerning the estimation of the innovation potential of an enterprise.

The methodology of the NetInnoCheck is summarized shortly in the following chapter, for detailed information see (Bredtmann 2009, Hoeborn/Bredtmann 2009; Bredtmann 2010a; Bredtmann 2010b, Bredtmann/Hoeborn 2010).

NetInnoCheck

The approach and methodology of the NetInnoCheck (Bredtmann 2009/2010) evaluates the ability and competence of innovation and at the same time the ability and competence of joining a network. Both competencies are determined each by three dimensions such as ability, volition, and permission. In between the NetInnoCube these three dimensions describe the shaping related to innovation (InnoCheck) and related to networks (NetCheck).

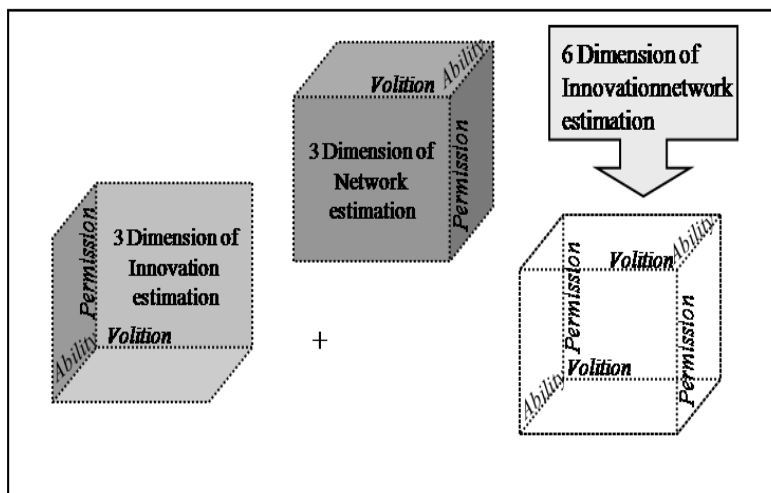

Figure 2: The six dimensions of the NetInnoCheck /Bredtmann 2009/

The process of evaluation of the total NetInnoCube is divided into the two steps InnoCheck and NetCheck. Both steps have to be passed to carry out a total evaluation and grading. This grading is concerned to the status quo concerning the abilities of generating innovation and joining a cross-company network. Each enterprise is estimated, assessed through the parameters being included in the three dimensions particularly. After passing successfully the application of the NetInnoCube the enterprise specific position is worked out.

To implement the derived results of success factors areas of innovation strategies the InnoCube is considered more closely. In between the InnoCube a division into the three levels ability, permission and volition is carried according to the Netcube. Further on this 3 levels are divided into three categories /Bredtmann 2010a/:

- staff related;
- related to project group or department
- related to company

This leads to a specific subdivision as mentioned below quoted from /Bredtmann 2010a/:

‘Ability – Innovation Potential:

Staff related:

- experience
- age
- education and training
- length of service with a company
- individual knowledge and experience of methodologies
- individual skilled knowledge and experience
- additional – not job related- abilities (hobbies, volunteers)
- social competencies

Related to project group or department:

- work and environment conditions
- involvement and participation of employees
- space and time for creativity
- life-long-learning, further education

Related to company:

- culture of company
- company policies
- style of leadership
- organisational environment conditions
- involvement and participation of employees concerning strategic decisions

Dimension of volition concerning innovation potential evaluates the position of the enterprise concerning will and motivation towards innovation. Therefore, it leads to the following subdivisions:

Volition – Innovation Potential

Staff related:

- individual motivation

Related to project group or department:

- support
- incentive systems
- motivation

Related to company:

- motivation
- policy guidelines
- company culture
- external economic situation
- funding programmes and access to

The dimension permission concerning innovation potential evaluates and mirrors the position of the enterprise; it describes the shaping of the enterprise of being financially and formally able to generate innovation. This leads to a subdivision as mentioned below:

Permission – Innovation Potential

Staff related:

- financial resources
- objective resources – technology, machines, plants
- allowance, empowerment

Related to project group or department:

- financial resources
- number of employees
- objective resources - technology, machines, plants
- allowance, empowerment

Related to company:

- financial resources
- number of employees
- objective resources - technology, machines, plants
- allowance, empowerment

A comparison between the quoted aspects of InnoCube /Bredtmann 2010a/ and the results of the comparison and combination of 7S-model as well as of the approach of Stern/Jasberg shows that the aspects of InnoCube go along with the 9 derived areas of success factors concerning innovation strategy but areas as strategy aim, enterprise culture and customer involvement have to be extended.

The aspect strategy aim is an addition of the level permission related to all three categories staff related, related to project group or department and related to company. This complement is very important for the InnoCube because it is precondition for the existence of innovation potential.

The aspect enterprise culture complements the level of volition. Just if innovation culture was aimed at and lived at all levels of an enterprise the basis of innovation potential is given.

The aspect of customer involvement complements two levels of InnoCube, the levels ability und volition. Again this aspect customer involvement considers all three sub-fields.

Structure and leadership can be found in the InnoCube level ability related to company.

The part systems and process organisations is by volition related to project group or department.

The part staff or innovation staff and although the part skills and core competencies are at all levels of the InnoCube – ability, volition and permission considered.

The aspect shared innovation values can be found at the level permission related to all 3 categories staff, related to project group or department and related to company with the aspect of allowance, empowerment.

The part opportunities and risks – with the focus competition are an immanent aspects and part of the NetInnoCheck approach.

Conclusion and Outlook

The success factors are critically discussed due to their past based derivation and the derived activity. The forecast of success is a critical point.

To carry out an estimation of the innovation potential and to extend the NetInnoCheck the success factors are an excellent complement. By combining and adding of general enterprise success factors of innovation strategy aspects to analyze and evaluate the innovation potential could be derived.

Due to the extension of the InnoCube by aspects of strategy aim, enterprise culture and customer /customer involvement a detailed ascertainment of the innovation potential by InnoCube can be assured. At the same time this offers the possibility to specify an extension of the NetCube concerning success factors.

Concerning a further development of the NetInnoCheck it has to be taken into consideration that the detection of a success factor just leads to success itself if the competition has not anticipated it yet /Nicolai/Kieser2002/. Nevertheless, the NetCheck can further developed by taking success factors network and co-operation strategies into consideration. This is even more important because ‘future ... belongs more and more powerful networks of enterprises which optimize their innovation processes mutually’ /Duschek 2002, p. 2/. A parallel consideration of network and innovation potential is therefore requested, particularly because they can influence each other. This further development of the NetInnoCheck and its application will be the next research aim.

Operationalization of market orientation concept in higher education institutions

Professor BUGANDWA Mungu Akonkwa Deogratias. Managing Director of Higher Institute of Applied Computer Sciences and Management (ISIG/Goma, North-Kivu, D.R.C). Associate professor in the Faculty of Economics and Management Sciences. (Catholic University of Bukavu, D.R.C). Main Research Field: Development and Implementation of Marketing in Higher education, Quality, Governance and Management in Higher education institutions, Triangulation Qualitative /Quantitative methods in management sciences. Postal Address . Rue Lambert Fortune, 101. 1300 Wavre.Belgium.. E-mail: dbugandwa@yahoo.com

Keywords: Market Orientation, Higher Education, Stakeholder Orientation, Competitive Orientation, Collaborative orientation, Inter-functional Coordination, Responsiveness, Scale Measure..

Introduction

The market orientation philosophy began to be conceptualized in the 1980s, through the seminal papers of Narver and Slater (1990), and Kohli and Jaworski (1990). The strategy is still a present-day topic in marketing research, and has been extended to different sectors: charities (Balabanis et al., 1997; Cervera, et al., 2001; Ignacio et al., 2002), healthcare: (Bhuan and Abdul-Ghader, 1997; Wood et al., 2000; Tsai, 2003), arts and culture: (Sorjonen, 2002; Gainer and Padanyi, 2002).

In higher education, which is the focus of the present paper, two trends can be pinpointed: The first merely suggests that Market Orientation is necessary if institutions are to face successfully their changing environment. Braun and Merrien (1999) hold for example that: “...market orientation is one of the ways the governance of higher education is to evolve” (cf. figure1). De Jonghe and Vloeberghs (2001) suggest also that «A market orientation is supposed to take place in universities, but this does not always happen in the optimal way.” According to Davies (2001), the introduction of quality systems that recognize Customer Orientation and Market Orientation is an important step towards sustaining entrepreneurial endeavour in higher education. Haug (2001) adds that competition between national institutions and trans-national suppliers of education and formation, coupled with a greater freedom of choice among institutions, may affect institutional strategy. He contends that *institutions which recognise new demands and adapt their supply will be more likely to develop and overcome challenges.*

The second trend is that of scholars who transpose, in empirical studies on higher education, the Kohli and Jaworski's or Narver and Slater's models of Market Orientation. (Caruana, et al., 1998a, 1998b; Wasmer and Bruner, 1999; Flavian and Lozano, 2006; Webster, Hammond and Harmon, 2006).

From then on, it is clear that Market Orientation is either implicitly or explicitly seen as a potential managerial solution to the changes undergone by higher education institutions.

In a recent study published in the International Journal of Quality and Service Sciences, Bugandwa Mungu-Akonkwa (2009) highlights the way market orientation rhetoric or research is emerging as a new management paradigm in higher education, and provides a relevant critic in the way market orientation is being introduced into the sector. The point in his work is not to dismiss the relevance of the above strategy for higher

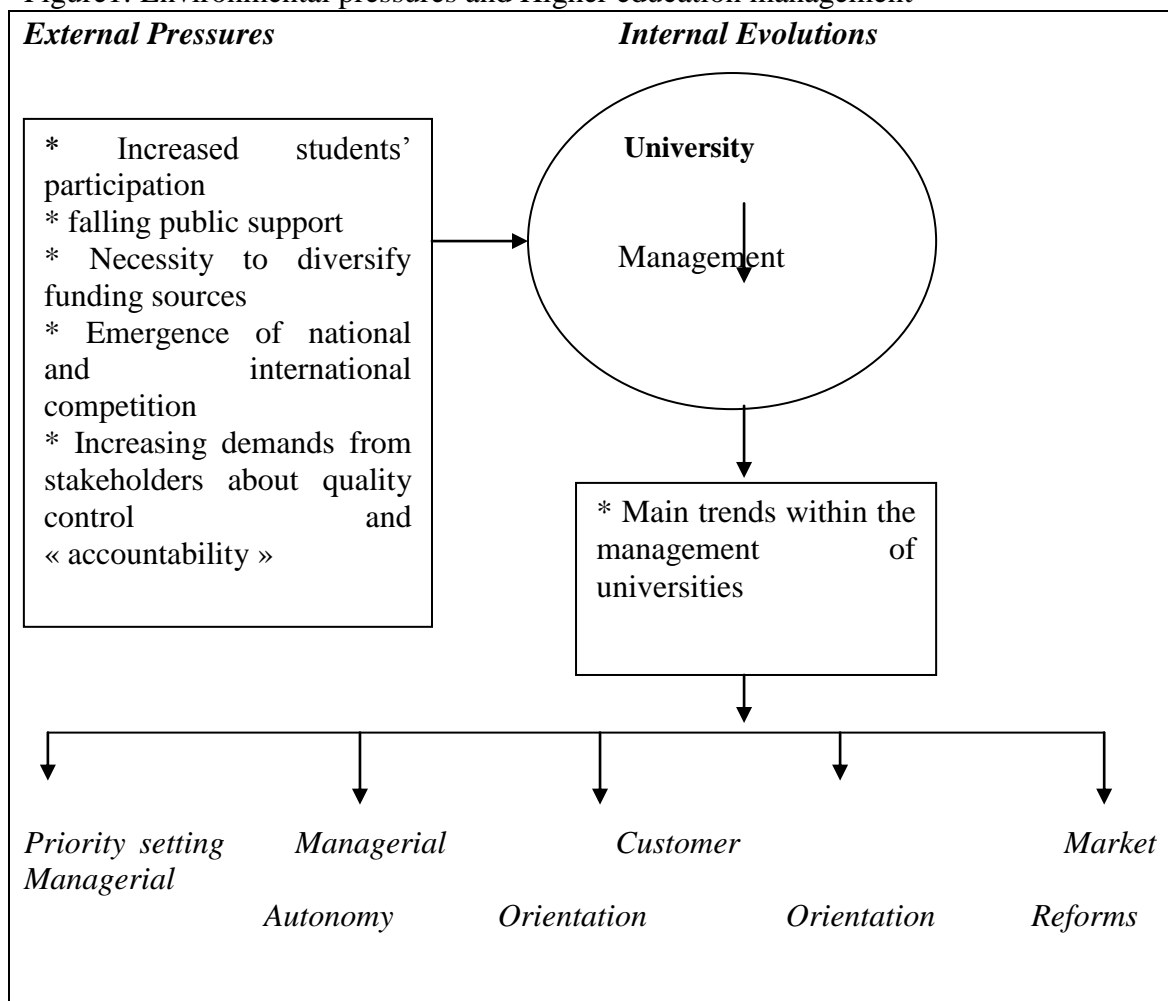

education. Rather, while criticizing its theoretical transpositions in such a particular sector, he contends that market orientation is to be implemented in higher education to face the changing environment.

This paper goes further in purporting to identify the key dimensions for an operational definition of the market orientation concept in higher education. After discussing the literature on market orientation and its extension to a non-profit organization, a scale is proposed, containing items which attempts to capture the complexity of marketing in higher education. The novelty of this outcome is its reliance on a stakeholder perspective and the fact that it adds the Collaboration dimension which has been missing in current conceptualizations of market orientation in higher education.

The context of higher education

The changing context of higher education and its confrontation with market forces are exerting intense pressures on the management of these institutions. Bugandwa-Mungu-Akonkwa (2009) has used the New Public Management framework to understand the link between higher education context and Market Orientation. This theory allowed him to delineate the changes undergone by institutions, and the ways the latter could adapt to these changes. From a broad managerial literature on higher education, figure1 below sums up the institutional adaptations to directions that institutions are likely to follow:

Figure1: Environmental pressures and Higher education management

Source: Bugandwa Mungu Akonkwa (2008).

Market orientation concept in managerial literature

The Market Orientation concept is at the heart of modern marketing and strategy (Narver and Slater, 1990; Lambin, 2000), through the attention paid to it by academic textbooks and scholarly papers.

Two broad perspectives entangle the conceptualization of Market orientation: cultural and behavioural perspectives. The first stresses organizational values and beliefs. It is rooted in the cognitive sphere and influenced by personal factors which determine the organizational characteristics: goals, strategies, systems and structures. According to Deshpandé and Webster (1989), the marketing concept defines an organizational culture constituted by a set of shared beliefs and values putting the customer at the heart of the organization, its strategies and operations. Researchers and practitioners contend that this perspective implies that the effective implementation of marketing strategies relies on a set of dynamic and flexible values, founded in the organizational culture (Bonoma, 1984; Webster, 1991; Gonzalez-Benito and Gonzalez-Benito, 2005). The basis of cultural perspective is the researches that demonstrate a positive relation between organizational culture and efficiency in marketing actions (Dunn, et al., 1985) A number of researches on the development of Market orientation have stressed that this orientation is the necessary outcome of explicit and/or implicit cultural values (Webster, 1990; Mavondo and Farrell, 2003).

The behavioural perspective focuses on activities that are supposed to be conducted in a market oriented organization, and the behaviour that the strategy assumes from all organizational members. It is the assessment of these activities which will allow to conclude whether an organization is market orientated or not, and even to measure the extent of this orientation. This perspective prevails in empirical researches on market orientation and thus, can be seen as a new paradigm in the marketing literature (Kohli, Jaworski, and Kumar 1993; Ruekert, 1993; Greenley and Foxall, 1998; Asmat-Nizam, et al., 2006; etc).

The coexistence of these two perspectives while defining Market orientation can be frustrating and source of problems both for researchers and practitioners. Actually, practitioners need concrete information to effectively implement this strategy. Hence, it is necessary to integrate the two perspectives, because they are so enmeshed that it would be difficult to dissociate them. On the one hand, values that are shared by organizational members are the basis for the different conceivable strategies and can influence their implementation (Detrie, 1999). On the other hand, the implementation of specific market oriented activities can illustrate their gain and thus determine the emergence of marketing culture in the organization (Kotler and Fox (1985, Gainer and Padanyi (2005; Carr and Lopez, 2007). Matsuno, Mentzer and Rentz (2005) have confronted the two perspectives and found that market oriented behaviour is the source of organizational performance. Their finding is consistent with Wasmer and Bruner II (1999) and Gainer and Padanyi (2005) for whom market oriented behaviour explained organizational performance, and which, as a consequence, explains the emergence of a market oriented culture in the organization.

This paper focuses on the behavioural perspective to develop operational items for the Market orientation concept in higher education. The next paragraphs present the main conceptualizations of Market Orientation, whatever the perspective considered, and will

show the predominance of behaviour and its link with cultural perspective. Two main approaches are considered, which are the cornerstones of other conceptualizations and the pillars of empirical research.

First, Kohli and Jaworski (1990), Jaworski and Kohli (1993) have defined Market Orientation through three behavioural dimensions:

“Market Orientation refers to the organization-wide generation of market intelligence pertaining to current and future needs of customers, dissemination of intelligence within the organization, and responsiveness to it”.

Market intelligence generation refers to the collection and assessment of customers' *current and future needs/expectations, and the understanding of exogenous factors such as competition, political regulation, technology, economic and political constraints, etc.* that influence the development and refinement of those needs. Market oriented organizations endeavour to get a clear knowledge of customers' needs from a number of perspectives. Market intelligence generation implies systemic methods of organizing, storing, and retrieving current information, an intelligence network for gathering new data through qualitative and quantitative methods, and a process for analyzing this information for decision making purposes. However, this activity is not often conducted in a systematic and integrated approach in universities. It is possible for universities to carry out surveys and obtain feedback from informal observation and discussion. As such, intelligence/information generation in the model is a broader concept than simply customers' stated needs and preferences.

Intelligence Dissemination refers to the process and extent of market information exchange within different units of a given organization. This dissemination of intelligence occurs both formally and informally and involves sharing information with everyone in the organization. Responsiveness is the action taken in response to intelligence that is generated and disseminated. Action on the basis of market intelligence captures the speed and coordination with which marketing programs are implemented to respond to customers' needs. Jaworski and Kohli have defined responsiveness component as comprising two sets of activities: (1) response design (using market intelligence to develop plans) and (2) response implementation (executing such plans). This means that responsiveness involves developing, designing, implementing and altering products and services in response to customers' current and future needs.

In order to measure the extent of market orientation in an organization, the authors used the “Markor” which is a Likert's scale with 5 points: 6 items for « Market Intelligence Generation», 5 items for “Market Intelligence Dissemination” and 9 items for “Responsiveness”.

Narver and Slater (1990), Slater and Narver (1994; 2000) provide the second conceptualization of Market Orientation. According to them, *“Market orientation is a business culture that most effectively and efficiently creates superior value for customers. It is the organization culture that most effectively and efficiently creates the necessary behaviours for the creation of superior value for buyers and, thus, continuous superior performance for the business”.*

Three behavioural components (Customer orientation, Competitor orientation, and Inter-functional coordination) and two decision criteria (long-term focus and

profitability) are suggested to operationalize their definition. Hereunder, we focus on the first three dimensions.

(1) Customer orientation is the sufficient understanding of one's target buyers in order to continuously create superior value for them. It implies the organizational endeavour to always work to improve customer's satisfaction.

(2) Competitor's orientation means that a seller understands the short-term strengths and weaknesses and effect of a long-term capability and strategy of both the key current and potential competitors (Porter, 1985).

(3) Inter-functional coordination is based on information about stakeholders' expectations and on competitors. It entails business's coordinated efforts, involving not only the marketing department, but all departments and organizations' resources to create superior value for stakeholders. Hence, creating value for stakeholders is more than just a marketing function; it is a job for the whole organization. Every organizational function is concerned with the sharing of information in order to improve customer's satisfaction; and every organizational member is supposed to adopt the behaviour that is positively linked to higher value for stakeholders. The key indicator of this component is the total commitment of all members to a marketing philosophy and the integration of marketing activities to provide value to stakeholders. Typical behaviour would include: departments and teams working together to meet student's needs; departments and teams sharing market information; teams and departments integrating strategies; all sections working together to offer value to students; and teams willing to share resources, etc.

Theoretical integration of the two definitions

Although the two definitions actually differ, they can be shown to converge towards the main dimensions of Market Orientation strategy. In attempting to sum these up, **Wood and Bhuian** analyze the concept from different perspectives and present a model including four key elements that are common to them: customer emphasis, intelligence generation, intelligence dissemination/inter-functional coordination and intelligence responsiveness/taking action. In his ongoing research which attempts to adapt the market orientation concept to Higher Education, Bugandwa Mungu-Akonkwa (2008; 2009) has suggested the following integrating definition:

Market orientation is a culture and a set of behaviour or activities oriented towards current and latent customers' needs, the analysis and understanding of both competitors and the macro-environment in order to adapt the organization's supply to the requirements of customers and external environment, and hence, to improve the organizational performance in terms of market-shares, customers' loyalty and retention, return on investment...

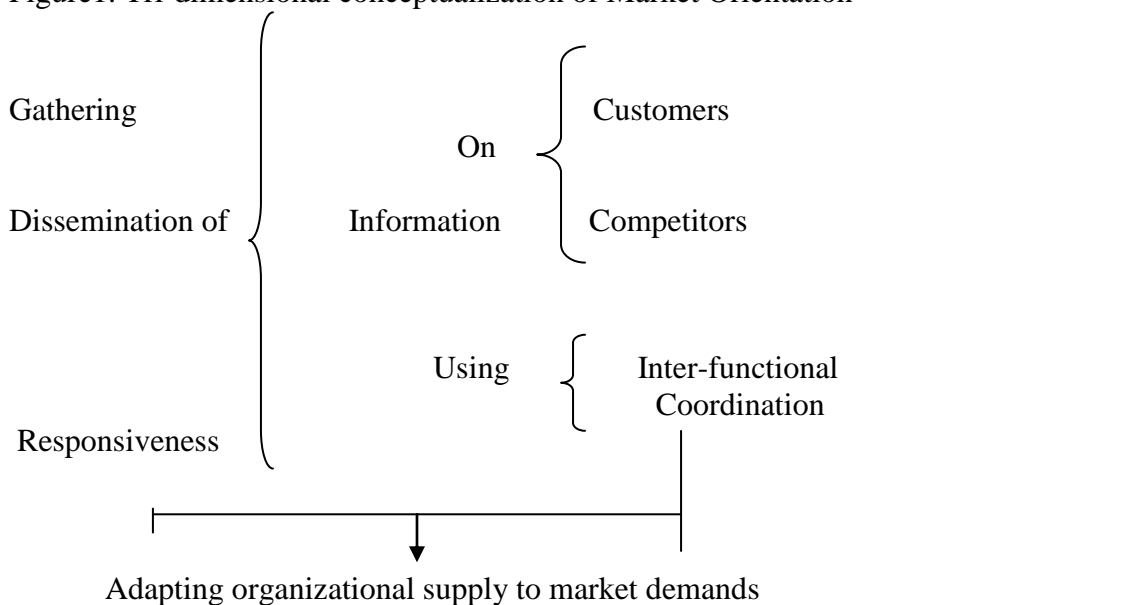

According to the author, whose argumentation partly relies on Cadogan and Diamantopoulos (1995), in spite of the differences between Narver and Slater and Kohli and Jaworski's approaches (for example the absence of inter-functional coordination in Kohli and Jaworski's conceptualization), the general philosophy of Market Orientation implies *"the understanding of markets' developments, sharing gathered information*

with all personnel, and adapting the organizational supply to these changing market (Jaworski, Kohli et Sahay, 2000).

Actually, Bugandwa Mungu-Akonkwa (2009) realizes that all existing market orientation approaches stress the role of information at the heart of marketing activity. For instance, dimensions such as “Market Intelligence Generation” and “Market Intelligence Dissemination” focus information about customers, competitors as well as social, economic and political environment (what Lambin, 2000 call « the Macro-environment »). Hence, these activities from Kohli and Jaworski meet Narver and Slater’s « Customer Orientation » and « Competitor orientation », while focusing on activities about *acquiring information about customers, competitors, and macro-environment* as well as the *dissemination of this information towards different organizational departments*. Further, the dissemination of both formal and informal information implies participation of all organizational members to be effective. According to Cadogan and Diamantopoulos (1995), this activity, to which they add intrapersonal relations (organizational members’ cohesion), allows not only an easy circulation of information towards different functions, but also an effective organizational response to the gathered information (this is “responsiveness dimension in Kohli and Jaworski’s conceptualization). Differently stated, the more effective the inter and intra functional mechanisms, the more effective the organizational response.

Based on this analysis, Bugandwa Mungu-Akonkwa (2009) has suggested the following figure to sum up different conceptualizations of Market Orientation:

Figure1. Tri-dimensional conceptualization of Market Orientation

Source: Bugandwa Mungu-Akonkwa (2009).

This figure highlights the place information occupies in both Kohli and Jaworski and Narver and Slater’s conceptualizations. Indeed, all the activities involved in acquiring information about customers and competitors in target market and disseminating it throughout businesses are included in the Customer orientation and Competitor orientation dimensions. Inter-functional coordination is an invaluable tool for the efficient responsiveness to information gathered and disseminated. It entails a fluid

circulation of intelligence within departments and between organizational members. So the following variables can be retained from the conceptualization of Market Orientation:

Customer orientation;

Competitor orientation;

Inter-functional Coordination.

Responsiveness: Assuming that all the organizational members, through different functions, have access to the organizational information, they have in return to respond to stakeholders' demands by adapting the organizational offer to these demands and requirements. .

The dimensions above-mentioned have been extensively used in empirical research. Following recommendations from Jaworski and Kohli (1993), Kohli, Jaworski and Kumar (1993) and Narver and Slater (1990), Market Orientation models have been extended to non-profit organizations, including higher education institutions.

Empirical research on Market orientation in higher education

Several researches have been conducted on the market orientation strategy in higher education. We have shown that most of them are from Anglo-Saxon countries, as illustrated by the works quoted below: Caruana et al. (1998) and Keneley and Hellier (2002) for Australia; Liu and Wilson (1998); Liao, Foreman and Sargeant (2000); Sargeant, Foreman and Liao (2002) for the UK; Wasmer and Bruner (1999), Webster, Hammond and Harmon (2006), and Hammond, Webster and Harmon (2006) for the United-States. Few works have been encountered in the Continental Europe; the work from Flavian and Lozano (2006) in Spain, and more recently from Bugandwa-Mungu-Akonkwa (2008, 2009).

Developing a Market orientation scale for higher education institutions

As discussed in Bugandwa Mungu-Akonkwa (2009), there are enough reasons for the market orientation strategy to be effectively applied to higher education. Kotler and Fox (1985), in their masterpiece on "Strategic Marketing for Higher Education institutions", demonstrate that Higher education institutions resort to marketing when their "markets" or more globally their environment undergoes changes such as massification and change in the quantitative and qualitative nature of the demand for higher education, need to diversify funds, rise of stakeholder control in terms of quality control and accountability, professionalization, crumbling public funding, increasing competition, technological changes, increasing requirements from students and other stakeholders, etc. The same trends have been stressed by other researchers who sought to uncover different contexts: Slaughter and Leslie (1999) in their seminar work on Academic Capitalism (Australia, Canada, the UK, the USA), Thys-Clement (2001) for Belgium and Europe, Kaiser et al. (1999) and Salerno (2004) for the Netherlands, Theisens (2003) and William (2004) for the UK, Kaiser (2003) and Chevallier (2004) for the French Republic. To face these changes, institutions have adopted different responses: some of them have increased recruitments budgets as is the case in Australian institutions (Coaldrake, 2002); others prefer to implement a sustainable strategic marketing (analyze their macro-environment, their markets, their strengths and

weaknesses; develop a clear sense of mission, etc.) Thus, higher education institutions are increasingly feeling the need to ensure that they are flexible and dynamic in their structures and strategies and are implicitly adopting market orientation concept. The following section deals with operationalization of this concept and tries to analyze items that should be considered in this process.

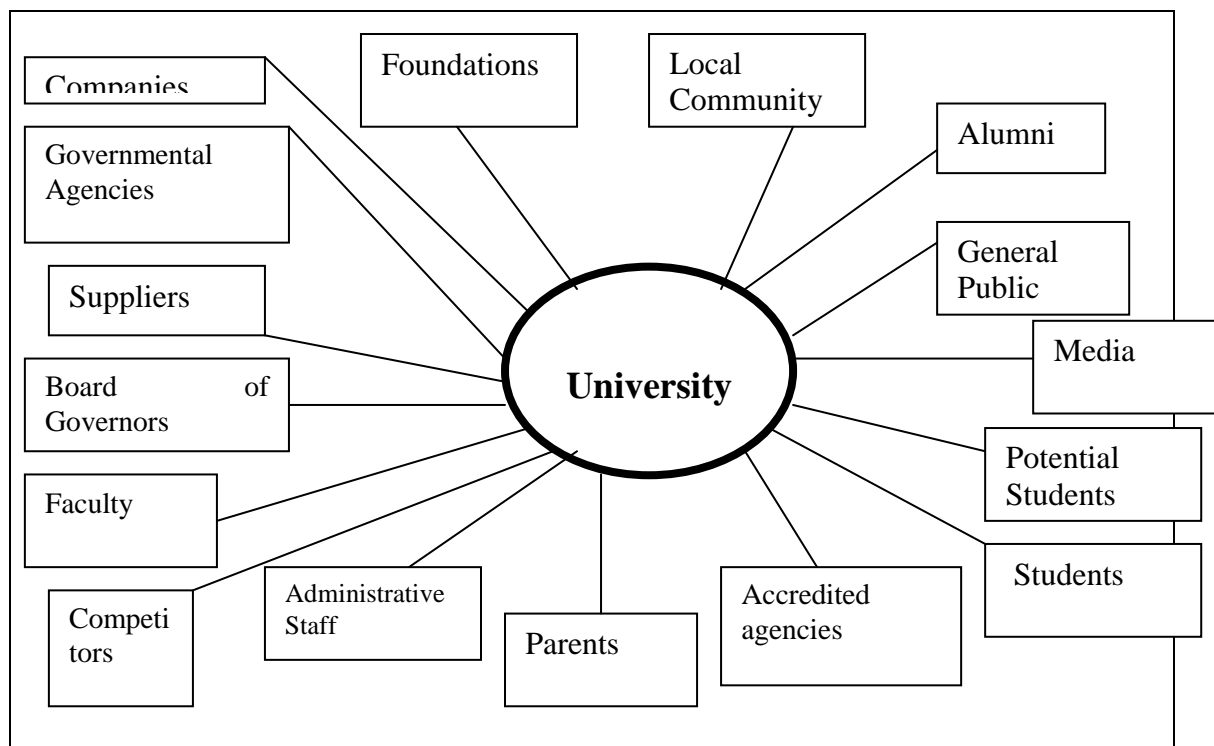

Stakeholder Orientation vs. Customer Orientation

Although the “Customer Orientation” dimension has been used by several researchers in their analysis of Market Orientation strategy in higher education (Siu and Wilson, 1998; Caruana, Ramaseshan and Ewing 1998a; 1998b; Wasmer and Bruner 1999; Smith, 2003); it still raises controversies in the marketing literature (Driscoll and Wicks, 1995; Franz, 1998; Lowe, 2004). The debate can be synthesized as being both ideological – is the “customer” concept semantically the right one to design students? – and operational (who are customers in Higher Education, and how to satisfy their multiple and conflicting needs?). This problem led a number of authors to reject the dimension “Customer Orientation” in the conceptualization of Market orientation, preferring that of “Stakeholder Orientation” (Sargeant, Foreman and Liao, 2002; Gainer and Padanyi, 2002; 2005; Greenley and Foxall, 1998). This paper supports these authors’ point of view and hereunder, justifies such a position through three points: (1) increasing role of stakeholders in higher education, (2) necessity to identify these stakeholders, (3) presentation of theories that can help operationalize this concept as a dimension of Market orientation.

About the first aspect, the issue of stakeholders in higher education has become so acute that authorities in Academia⁽ⁱ⁾ as well as researchers⁽ⁱⁱ⁾ are consecrating to it a growing importance. This trend is probably rooted in the fact that institutions are required to demonstrate effectiveness and efficiency through service provision, to compete with private providers in the endeavour to diversify their sources of funding (Gürüz, 2003); a trend which is likely to continue. This requires institutions to be open to their external environment and create structures aiming at managing complex relationships with their stakeholders.

The issue of “whose these stakeholders are” can seem trivial. Yet, several studies have looked into it without finding a consensus (Kotler and Fox, 1985; Conway, Mackay and Yorke, 1994; Newby, 1999; Raanan, 2003). Some of them have wrongly treated the student as the unique customer of higher education (Caruana et al. 1998; Keneley and Hellier, 2002). In a more recent paper, a list of stakeholders from Kotler and Fox’s (1985) perspective has been considered as more complete (Bugandwa Mungu-Akonkwa, 2009). It is used here as the unifying thread (see figure below):

Figure: Multiple stakeholders in higher education

Source: Kotler and Fox (1985).

This diagram defines the area of possible exchanges between higher education institutions and their public or stakeholders. Among these, it is important to mention the specific and complex role played by students, and which is at the heart of a heated controversy. We chose to address this debate following the angle of the Malcolm Baldrige National Quality Award Education pilot Criteria. Indeed, while dealing with “customers” of higher education, the MBNQA distinguishes, on the one hand, students, and on the other the “other stakeholders”. And replacing the concepts “customer focus” and “satisfaction” respectively by “student focus” and “students and stakeholder satisfaction”, the MBNQA recognizes not only the diversity of stakeholders but also the peculiarity of students among these. The scale of measure we suggest will reflect this by including items that capture the aspects of students’ learning as well as support services. The two aspects, according to the existing literature in education, constitute the two dimensions of students’ satisfaction (Dweck and Elliot, 1983; Bowden and Marton, 1998; Halbesleben et al., 2003; Sirvanci, 2004; Lammers et al., 2005; Eagle and Brennan, 2007). The other items will attempt to reflect the links between higher education institutions and firms (through research contracts, life-long learning, receiving students for internships, and organization of profession formation by institutions). Also will be considered the relation between decision makers and higher education institutions.

The third issue is then “how to take account of this stakeholder orientation for the operationalization of Market Orientation in Higher education”. This question entails a search for a relevant theory which is likely to underlie the inclusion of stakeholder orientation. Two sets of research are seen here as able to provide such a framework: The first categorizes stakeholders in different types and suggests possible strategies for their management (Savage et al., 1991; Donaldson and Preston, 1995). The second is more normative in suggesting items which should be considered to operationalize the stakeholder orientation (Greeley and Foxall, 1998). Bugandwa Mungu-Akonkwa (2008)

has analyzed these researches in every detail and his analysis has highlighted the possible items that can operate the stakeholder orientation. The key behaviour of a stakeholder-centred approach include not exhaustively: researching needs; commitment to students and other stakeholders; providing services of value; focusing on student and stakeholder satisfaction; measuring and reporting satisfaction, encouraging stakeholders' comments and complaints.

Competitor orientation

In a Nonprofit organization, competitors are groups, organizations or any other alternatives which attempt to attract the attention and loyalty of funders and beneficiaries (Kotler and Andreasen, 1996). In higher education, Meek and Wood (1997), Mok (2000), Thys-Clément (2001), and Bugandwa Mungu-Akonkwa (2008; 2009) have explained how competition is emerging and becoming fierce, both at national and international levels. Competitor orientation can be defined as any activity aiming at understanding the strengths and weaknesses of the main organization's competitors (current and/or potential), and the way the organization reacts to these competitors' strategies and actions (Narver and Slater, 2000; Liao, Foreman and Sargeant, 2000). Although Nonprofit and public organizations such as universities generally balk at seeing similar organizations as competitors (Kotler and Andreasen, 1996), they are aware that competition is a major step of marketing implementation process (Kotler and Fox, 1985; Wood, Bhuian and Kiecker, 2000).

Collaboration as a new dimension of the market orientation concept in higher education

Vazquez, Ignacio and Santo (2002) show that the attitude of Nonprofit organizations vis-à-vis competition and the nature of the latter varies according to whether the organizations act in the user's perspective or the backer's perspective. In the users' perspective, the institutions providing the same public utility are to be considered, not as mutual threats, but as partners and thereby, source of collaboration. So institutions will engage in efforts to increase capacities to maintain a more effective provision of social benefits for all parts. Thereby, it is clear that beyond competition, collaboration is a dimension to be included in any conceptualization of market orientation for higher education institutions. Trim (2003), quoting Guzkowka and Kent (1999), defines collaboration as "a shared unity of purpose". Liao, Foreman and Sargeant (2000) define "collaborative orientation" as the extent to which an organization focuses its efforts on the exploitation of the whole potential of collaboration with other organizations, for both resources acquisition and mutual provision of non commercial goods and services. This paper has taken advantage of the above contributions to include the "Collaborative dimension" in the operation of market orientation in higher education.

Inter-functional Coordination

It covers all activities – information transmission, processing and control – aiming to insure that different functions constitute a coherent set to contribute to the organizational endeavour to improve its products/services. The very first publications about coordination go back to Lawrence and Lorsch (1967), Khandwalla (1972), Mintzberg (1979), and Ford, Armandi and Heaton (1988) who supported that when environment uncertainty and complexity grow, coordination or integration of different

organizational parts become very important. Inter-functional coordination implies the degree to which information on stakeholders and macro-environment is shared in the whole organization. It also refers to the sense of common values and beliefs and their relation with reaching organizational objectives. This supposes that the process of creating value for stakeholders is not the matter of only one function, but the whole organization (Porter, 1985; Kohli and Jaworski, 1990). Inter-functional coordination implies a clear understanding and fluid circulation of information about customers' expectations and organizational beliefs, and their communication through formal and informal means (meetings, brainstorming, etc.) to all organizational members (Shapiro, 1988; Cadogan and Diamantopoulos, 1995). It mainly purports to improve the way the organization is supposed to respond to its market.

Responsiveness

Universities are increasingly required to be responsive to multiple societal demands (OCDE, 2002). The responsiveness dimension as defined by Kohli and Jaworski (1990), Jaworski and Kohli (1993) and Kohli, Jaworski and Kumar (1993) consists in organizations' actions to respond to their markets. It implies development, adaptation and implementation of organizations' services, programs, systems and structures to meet their stakeholders' requirements. According to Kohli and Jaworski (1990), an adequate response to the market includes: selection of target markets, supply of products/services for current markets, conception of new products/services for potential markets; production, distribution and promotion of products/services in a way conducive to a positive feedback from customers. Applying this to higher education, Mora (2001), quoting Neave and Van Vught (1996), states that a higher level of market orientation is an excellent way to increase the institutional response to social demands. It is very necessary to clarify that more than any other organizations, higher education institutions should not limit their actions to responding to external pressures. In spite of staying under such pressure, they are called to act proactively on their environment. This is especially important for higher education institutions since students and other stakeholders can misunderstand their needs or institutions' actions. The scientific approach called "Driving the markets" (Jaworski, Kohli and Sahay, 2000) or the marketing of supply creation can help them find valuable solutions to non articulated needs. These approaches refine the theory of market orientation to show that this strategy goes beyond reacting to environmental changes – which could be dangerous for organizational survival and missions. Instead it includes making effort to modify stakeholders' behaviours: (explaining to students the requirements of quality in higher education, helping them to inward their role in learning process, discussing with policy-makers and enterprises, on different issues concerning higher education, etc.).

The major outcome of this literature review is a set of 71 items which we suggest to operationalize the market orientation concept in higher education (see Annexe table1).

Concluding remarks and future research perspectives

This research is part of a more general ongoing endeavour to develop relevant scale for the measure of market orientation in higher education. The underlying assumption that although higher education sector is evolving towards market mechanisms, it keeps specific features that make it different from other organizations of commercial sector. For that reason, we have deemed it important that a different and more adapted scale be

envisaged when it comes to measure the extent of market orientation in these institutions. This paper contributes to that objective in discussing the main dimensions of market orientation in higher education. It reviews the context in which higher education institutions evolve in order to justify why the concept has emerged as a relevant strategy for the management of higher education. Confronting the different existing conceptualizations, we highlighted the main dimensions of the concept as evidenced in the literature on commercial sector, and as applied in several empirical researches. The present paper skims through the empirical research on market orientation in higher education and presents them through a synthetic table. The main finding in this table is that some empirical studies have plugged in the model of market orientation developed in commercial settings, and have relied on a simplifying assumption that the model developed by either Kohli and Jaworski or Narver and Slater can be transposed to higher education institutions. Although it is my contention that market orientation can be a relevant strategy for the management of higher education institutions, I uphold that such transpositions are irrelevant and meaningless since higher education is quite different from commercial enterprises. Thereby, its peculiarities may resist any attempt to transpose it; models that have been developed in and for commercial sector. To fill this gap, we have discussed the use of market orientation concept and suggested that two concepts be added in the prevailing model: these are “stakeholder orientation” and “collaborative orientation”. We support that a more relevant model of market orientation for higher education should consider these two dimensions to take account of the peculiarities of higher education. Henceforth, we suggest a model of market orientation that includes 5 dimensions: Stakeholder orientation, Competitor orientation, Collaborative orientation, Inter-functional coordination, and Responsiveness. After splitting the stakeholder dimension into 3 sub-dimensions (Students, Enterprises, and Policymakers), the whole model comprises 71 items which, in further research, should be refined through a factor analytical procedure. The operationalization we suggest for the “responsiveness” dimension as shown through the items, is particularly interesting as it considers the necessary proactive role higher education institutions are supposed to play. Indeed, they should not passively confine themselves in undergoing their external environment’s pressures.

The main contribution of this paper is that it has generated from a multidisciplinary literature, a more relevant tool to measure the market orientation concept without neglecting higher education’s complexity. However, and that is the main limit, the suggested tool (scale) is still a crude one and needs be refined to become an accepted and usable measure. This refinement is an important track for further research. Conducting such a research will be a major contribution to the endeavours to the development and extension of marketing research to other fields.

Students’ orientation

Number	Items	
1	The institution gathers information on current and future needs of current and potential students.	
2	Conducts activities aiming at attracting and retaining students	
3	Complaints and remarks formulated by students are analyzed in order to find solutions.	
4	Students’ satisfaction towards university facilities is assessed on a regular basis.	

5	Perceived service quality is regularly assessed	
6	Teaching methods stress dynamic students' learning.	
7	Programmes are set with the aim to stimulate active learning	
8	The institution uses information technology to improve teaching and students' learning.	
9	Individual information is gathered from students and their needs to improve their success.	
10	The institution uses all available techniques and experiences to stimulate students' commitment.	
11	The institution creates a social, participative and welcoming environment for students.	
12	Teacher – Students' interactions are encouraged and stimulated	

Stakeholder Orientation « Enterprises » (7 items)

Numbers	Items	/7
1.	The institution believes formal and informal research is important to understand enterprises stakes.	
2.	The institution believes that managers' judgement is important to understand enterprises' stakes	
3.	The institution discusses the importance of different constituencies engaged in different debates within the institution.	
4.	Enterprises are stated to be important in the institution's mission statement.	
5.	Strategies are planned to face the interest of enterprises.	
6.	Endeavour is done to reduce institutional dependence towards enterprises.	
7.	Enterprises are encouraged to participate in the decision-making process of the institution.	

Orientation towards Policy-makers (7 items)

Numbers	Items	/7
1.	Formal and informal research is seen as important to understand policy-makers.	
2.	The importance of responsible people for the judgement in order to understand the policy of decision-making people's interests as concerned parties.	
3.	Internal discussions see policy-makers as important actors in the institution.	
4.	Policy-makers are stated as being important in the institution's mission statement.	
5.	Strategies are planned to face policy-makers' stakes.	
6.	Endeavour is done to reduce dependence to policy-makers.	
7.	The institutions' stakeholders are encouraged to participate in decision making.	

Competitor Orientation (10 items)

Numbers	Items	/7
1	The institution knows its main competitors	
2	Competitive strategies of other institutions are an issue for the institution.	
3	The institution searches information from competitors' programmes and services.	
4	Strategies are developed to gain a competitive advantage towards competitors.	
5	The institutions survey its stakeholders' perception towards its programmes and services.	
6	The institution knows how its stakeholders perceive competitors' programmes and services.	
7	The institution anticipates competitors' actions in order to gain a competitive advantage.	
8	An effective and rapid information system is set to gather data about the evolution of competition.	
9	The institution knows its strengths vis-à-vis its main competitors.	
10	The institution takes opportunities which are likely to improve its competitive position.	

Orientation collaboration (10 items)

Numbers	Items	/7
1	The institution believes it participates with other institutions to the achievement of same objectives.	
2	The institution develops partnerships and collaboration with other institutions.	
3	The institution collaborates with other institutions to interpret higher education policy.	
4	The institution searches the means to influence higher education policy	
5	The institution informs its stakeholders about its plans and priorities.	
6	The institution participates in alliances with other institutions in order to improve quality of teaching and research.	
7	The institution collaborates with enterprises to determine their needs and expectations vis-à-vis different faculties/departments/units	
8	The institution shares resources to provide some teaching and research	
9	The institution collaborates with other institutions, enterprises and governments for economic, cultural and social development.	

Coordination inter/intra-functional (17 items)

Numbers	Items	/7
1	The institution work in synergy with different faculties and departments to meet the needs of stakeholders.	
2	Discussions are organized on missions, values, and beliefs shared by	

	employees.	
3	Information collected on stakeholders is disseminated towards all departments.	
4	Institutional resources are shared to all departments to realize the missions.	
5	Team spirit is a value shared by the whole members. The institution reinforces as shared value	
6	A feedback is sent to departments about their contribution to the achievement of institutional mission.	
7	The institution organizes meetings to discuss major changes in external environment.	
8	Institutional members work together to improve students' learning	
9	Institutional members are committed together to improve the way services are perceived by all stakeholders	
10	Formal and informal exchanges are encouraged between the different departments.	
11	Marketing strategies are built in concert with all departments.	
12	The objective of satisfying students is accepted by all members of the institution.	
13	The objective of satisfying stakeholders is shared by all institutional members.	
14	The institutional members' knowledge and experiences are shared with departments to sustain organizational learning and innovation.	
15	A memory group records ideas raised in meetings, to be used in the strategies.	

Responsiveness (12 items)

N°	Items	/7
1	Programs and services are developed on the basis of information gathered	
2	Quality of programmes and services is defined in terms of stakeholder satisfaction.	
3	The institution reacts to the evaluation done by students about its functioning.	
4	The institution reacts to the evaluation done by other stakeholders about its functioning.	
5	Students' complaints are treated effectively and rapidly.	
6	The information collected is used to identify new segments of funders and their expectations.	
7	Information gathered is used to identify new segments of students, new needs and expectations.	
8	Students' feedbacks are used to improve the learning process	
9	Students' feedbacks are used to improve their satisfaction.	
10	Strategies are developed to modify the rules of the socioeconomic and political environments.

Keywords: services' quality, multiple linear regression, marketing strategies.

Introduction

This paper is part of a broad research stream about the drivers of service quality and its perception by customers. The study focuses on the services supplied in a shopping mall environment.

Shopping malls' structure has substantially changed over the years, leading to widen the offer to a broad variety of services (Crawford, 2000). Those changes are pulled by a latent demand for services expressed by different segments of customers (Bloch et al., 1994) who want to expand their experience of the malls beyond just shopping (Crawford, 2000).

Customer satisfaction towards the shopping experience in the malls is therefore linked both to the quality of products and the quality of services provided (Anselmesson, 2006; El-Adly, 2007). The latter is often decisive for a number of issues the management is interested in. On one hand, there is evidence that the perceived quality of the services provided is able to influence the willingness of customers to spend money in the mall (Laroche et al., 2005). On the other hand, customer satisfaction for services is highly related to loyalty (Fullerton and Taylor, 2002).

In a competitive environment the offer of services can play a very important role for competition, as it may act as an element of differentiation between shopping malls (Allard et al., 2009).

This paper fits this research field, focusing on the factors affecting the customer perception of service quality in shopping malls. Some of these factors are directly related to the features of the services and to the characteristics of the customer who is evaluating them. Some other are related to the comparative assessment based on previous experiences in other malls.

The aim of the paper is to analyse the importance of these different drivers for the construction of an overall customers' judgement about the mall quality.

To this purpose, the paper is organized as follows: in the first part some general issues about consumer perception of service quality are discussed; then the empirical research is presented through the description of the methodology used and the results; in the

following part, results are discussed and interpreted in order to draw some conclusions at the end of the paper.

Consumer perception of service quality

Researchers interest towards service quality dates back in the 1980s, when Parasuraman and his colleagues started reviewing the literature on the topic with the aim of developing a multi-item scale resulting in a quantitative assessment of service quality (Parasuraman et al., 1985), whose first version appeared in 1988 (Parasuraman et al., 1988). This effort raised a vibrant debate about the value and limitations of the scale, and its applicability to different sort of services.

Service quality is clearly more difficult to evaluate than product quality (Parasuraman et al., 1985). This is due to the intrinsic characteristics of the services, namely intangibility, heterogeneity, and inseparability (Parasuraman et al., 1985). Services are intangible because they are performances rather than objects, so their quality cannot be measured, tested or verified before delivery. They also are heterogeneous because the performance varies from producer to producer, from customer to customer and from day to day. It is due, on one hand, to the role of the personnel whose behaviour can change in different situations and, on the other hand, to the customer participation which is able to highly affect the service delivery. Moreover, the moments of production and consumption of services are inseparable, so that no quality control is possible before delivery, as it is the case for products.

Due to these specific features of the services it is likely that consumer evaluation process differs between goods and services (Zeithaml, 1981). This led to a big research effort to understand the drivers of consumers' perception of service quality. Parasuraman et al. (1988) found five fundamental dimensions for service quality perception: tangibles, reliability, responsiveness, assurance, empathy. In their model, customers' quality judgement comes out from a comparison between the perceptions and the expectations on these dimensions. Critical remarks and improvement to this model have first been made by Cronin and Taylor (1994) and later by Brady and Cronin (2001). In the latter a new model of service quality perception is proposed, basing on a hierarchical approach in which interaction, physical dimensions and outcome quality are the drivers of the customer perception. Such dimensions are then further specified through a set of sub-issues related to ambient conditions, social factors, personnel behaviour and expertise, which are evaluated in their level of reliability, responsiveness and empathy (Brady and Cronin, 2001).

The role of comparative evaluation in the formation of the overall quality judgement is demonstrated for goods (Olsen, 2002) while this element is not directly taken into account in the case of services. Indeed, the inclusion of customers' expectations in the multi-item scale for quality evaluation (Parasuraman et al., 1988) refers only indirectly to previous experience with similar services. This study represents an attempt to explicitly include the influence of comparative assessment on customers overall quality appraisal of a mall.

Methodology

The empirical analysis is part of a broader survey planned by the management of the shopping centre located in the town of Viterbo (central Italy) in partnership with the University of Tuscia. The mall includes 42 shops, a hypermarket and some fast-foods and bars. It is typically structured in order to benefit of cumulative attraction (Nelson, 1958) from different types of stores: one large-surface food store, specialized retail shops and public services.

The general objective of the survey was to study the profile and motivations of the mall's customers. To this purpose, a questionnaire has been administered to the customers in the shopping mall's premises. Six interviewers have been involved in the survey. They stood at three different entrances of the mall – one for pedestrians, one from the underground parking lot, one side entrance - asking customers to take part in the survey. As it was very difficult to identify the size of the customer population of the shopping centre, a non-probabilistic sampling was adopted, namely an accidental sampling as it is widely accepted in marketing research. The survey was carried out within one week in November 2010 trying to avoid distortions due to a longer lasting data collection. Different days and hours have been scheduled for interviews in order to get the best representation of different types of mall customers.

A total of 500 consumers has been interviewed in the survey.

The questionnaire is made up of three sections. The first is focused on customers' motivations to visit the shopping centre. In the second section customer satisfaction for the services offered within the mall is investigated. The final section is devoted to collect socio-demographic and behavioural information about respondents.

Out of the 34 questions included in the questionnaire, 17 are considered in this paper. This is because in the construction of the database for our research we only take into account the questions whose answers are more relevant for the analysis of the drivers of customer satisfaction towards the shopping centre in the overall.

The selected questions, listed in table I, refer to different issues related to customer satisfaction for the services offered at the mall.

Table I – Selected questions from the questionnaire used in the survey

Question code	Question type *	Question text	List of answers
Q2	MC	How often do you visit the shopping centre “Tuscia”?	Every day; Two/three times a week; Once a week; Once/twice a month.
Q3	MC	In which days of the week do you usually visit the shopping centre “Tuscia”?	Monday; Tuesday; Wednesday; Thursday; Friday Saturday; Sunday; no preference.
Q7	MC	In which time slot do you usually visit the shopping centre “Tuscia”?	Morning; Lunchtime; Afternoon; Evening.
Q10	MC	How often do you visit other malls of the town?	Every day; 2/3 times a week; once a week; once/twice a month.
Q11	MC	Which other shopping centres outside the town of Viterbo do you usually visit ?	Soratte (65 km); Valdichiana (125 km); Porta di Roma (75 km); Roma est (95 km); Other.
Q14	MC	What are the two more important motivations for you to go in other malls?	More choice; Leisure; Convenience; Other.
Q15	LS	How important are the following reasons for you to visit the shopping centre “Tuscia”?	Purchases in the hypermarket; Purchases in the shops; Meeting place; Leisure; Eating in the restaurants.
Q17	LS	How would you rate the courtesy of the staff in the shops of the mall “Tuscia”?	-
Q19	LS	How would you rate the quality of the following services of the mall “Tuscia”?	Parking lots; Surveillance; Events.
Q20	LS	How would you rate the cleanliness of the following areas of the mall “Tuscia”?	Shops; Parking lots; Toilette; Lobby and corridors.
Q21	LS	How would you rate the assortment in the offer of products and services at the mall “Tuscia”?	-
Q24	LS	How would you rate the value for money of products and services at the mall “Tuscia”?	-
Q27	LS	How would you rate the services offered at the mall “Tuscia” with respect to other malls?	-
Q28	LS	How would you judge your satisfaction for the shopping centre “Tuscia”?	-
Q29	MC	Gender	Male; Female
Q30	MC	Age	Younger than 18; 18-25; 26-33; 34-41; 42-49; 50-57; 58-64; 64-70; Older than 70.

Q32	MC	Area of origin	Town of Viterbo; Province of Viterbo; Outside the province.
-----	----	----------------	---

* MC: multiple choice question; LS: Likert scale from 0 (not important/very bad) to 6 (very important/very good)

Four questions (Q2, Q3, Q7, Q15) address some consumers' characteristics that might have an influence on their satisfaction. We refer to this category of variables as Intrinsic Quality related to consumer behaviour (IQcons).

Five questions (Q17, Q19, Q20, Q21, Q24) directly refer to customer satisfaction for individual services offered in the mall. Therefore, we set these variables together in a group named Intrinsic Quality of Services (IQserv).

The third category of variables is made up of four questions (Q10, Q11, Q14, Q27) related to consumers' perception of the shopping centre involved in the survey in comparison with other malls they usually visit. We refer to this group of variables as comparative Assessment (CA).

Three more questions (Q29, Q30, Q32) refer to demographic characteristics of the respondents, such as gender, age and area of origin. They are coded in a further category named Demographics (DEMO).

Finally, question number 28 (Q28) detects consumers' overall quality judgement about the shopping centre "Tuscia", so it is not coded in any group but it represents a summary of all the issues raised by the above categories.

The selected questions have been used as the base to investigate the drivers of customers' overall judgement, with a specific focus on the different role that variables related to intrinsic quality and comparative assessment can play. A linear multiple regression analysis (Montgomery et al., 2006) is used as a statistical tool to accomplish this objective. Indeed, through the regression we are able to analyse the contribution of the 16 explanatory independent variables (X_i) to the values of the customers' overall judgement dependent variable (Y).

Before running the regression model some variables have been processed in order to turn them to a quantitative scale (where possible) or to summarize very correlated items in a single variable. Specifically, questions number Q11, Q14, Q27 and Q29 have been turned to dummy variables; questions Q2, Q3 and Q10 have been changed to a numeric scale; some multi-items questions (Q11, Q20, Q25) have been reduced to a single variables when a high correlation was detected among the original items. The final set of variables used for the statistical analysis is listed in Table II; it includes one dependent variable and 21 independent variables.

The ANCOVA model (Rutherford, 2001) is used for the regression analysis in a XLSTAT software. This model allows for the inclusion of categorical data among the explanatory variables. The outputs include indicators of the quality of the analysis, such as r-squared and a Fischer test to assess the significance of the model, together with parameters and significance of the selected explanatory variables.

Table II – Variables included in the selected for the regression model analysis

Variable code	Question code	Scale	Description
Y	Q28	0 - 6	Overall customer satisfaction.
IQcons_1	Q2	0 - 20	Frequency (days per month) with which customers visit the shopping centre.
IQcons_2	Q3	1 - 5	Customers preference for specific days within the week: 1 (just one day) to 5 (5 of more days preferred).
IQcons_3	Q7	A; B; C; D	Time slots in which customers usually visit the mall. A: morning; B: lunchtime; C: afternoon; D: evening.
IQcons_4	Q15A	0 - 6	Customer's evaluation of the motivation "purchases in the hypermarket".
IQcons_5	Q15B-E	0 - 6	Average of customer's evaluation of the motivations: "purchases in the shops"; "meeting place"; "leisure"; "eating in the restaurants".
IQserv_1	Q17	0 - 6	Customer's evaluation of the courtesy of the staff in the shops.
IQserv_2	Q19A	0 - 6	Customer's evaluation of the parking lots offered at the shopping centre.
IQserv_3	Q19B	0 - 6	Customer's evaluation of the surveillance offered at the shopping centre.
IQserv_4	Q19C	0 - 6	Customer's evaluation of the events organized at the shopping centre.
IQserv_5	Q20A-D	0 - 6	Customer's evaluation of the cleanliness in the shopping centre premises.
IQserv_6	Q21	0 - 6	Customer's evaluation of the value for money of products and services.
IQserv_7	Q24	0 - 6	Customer's evaluation of the assortment in the offer of products and services at the shopping centre.
CA_1	Q10	0 - 20	Frequency (days per month) with which customers visit other malls of the town.
CA_2	Q11A-E	0 - 1	Customer's attendance of other shopping centres outside the town. 0: no; 1: yes.
CA_3	Q14A	0 - 1	Motivation "more choice" for visiting other shopping centres outside the town 0: not mentioned; 1: mentioned.
CA_4	Q14B	0 - 1	Motivation "leisure" for visiting other shopping centres outside the town 0: not mentioned; 1: mentioned.
CA_5	Q14C	0 - 1	Motivation "convenience" for visiting other shopping centres outside the town 0: not mentioned; 1: mentioned.
CA_6	Q27	0 - 6	Customer's evaluation of the services offered in the shopping centre "Tuscia" in comparison with other malls.
DEMO_1	Q29	0 - 1	Gender. 0: male; 1: female.
DEMO_2	Q30	A; B; C	Age. A: younger than 25; B: 26 to 50 years old; C: older than 51.
DEMO_3	Q32	C; D; E	Area of origin.

Results

Out of 500 questionnaires completed during the survey, 489 have been considered for the regression analysis with the ANCOVA model. This is because 2 respondents were not able to express an overall judgement, thus having missing values in the dependent variable (Q28), while 9 of them had missing values in one or more of the explanatory variables. Data referring to these customers have therefore been excluded from the analysis.

Table III displays the quality of the regression model explaining the overall customers' judgement with the 21 selected variables. The model seems to fit the data well enough as evidenced by the R^2 values, which are both around 0,4. The quality of the model is also tested through a F test, which shows a very high significance.

Table III – Quality of the model

Goodness of fit	Value
Observations	489
Sum of the weights	489
Degrees of freedom	463
R^2	0,426
Adjusted R^2	0,395
Mean Standard Error	0,604
Analysis of variance	Value
F	13,757
Pr > F	< 0,0001

In table IV the parameters of the model are reported. The contribution to customers' overall judgement about the shopping centre is calculated for each variable and it is tested with a t test.

The intercept and five of the selected explanatory variables are significant at a 99% level of confidence. The significant variables are:

- IQserv_1, referring to customers' evaluation of the courtesy of the staff in the shops;
- IQserv_9, IQserv_10 and IQserv_11, reporting customers' rating of cleanliness, assortment and value for money;
- CA_3, which is related to the comparison between the surveyed shopping mall and other competitors in the same area for what regards the choice of products and services.

The four issues related to the intrinsic quality of services all show a regression coefficient greater than zero, meaning that their contribution in determining the overall quality judgement is positive. The fifth significant variable (CA_3) shows a negative contribution to the evaluation of the shopping centre by customers.

The variable DEMO2, referring to the age classes of respondents, shows negative coefficients, only one being significant at a 90% level of confidence. This led to further investigate on this issue, using an analysis of variance with the aim to check the

existence of a relationship between the age of the respondents and their overall assessment of the quality of the services in the shopping centre. The model used for such analysis is an ANOVA (Rutherford, 2001), where the mean overall judgement is compared among the age classes of customers. The goodness of fit of the model, reported in table V, shows that the analysis is significant at a 99% level of confidence.

Table IV – Parameters of the model

Variable code	Question code	Parameter	Standard deviation	t	Pr > t	Lower limit (95%)	Upper limit (95%)

Table V – Outputs of ANOVA

Source	Degrees of freedom	Sum of squares	Average of the squares	F	Pr > F
Model	2	10,757	5,379	5,489	0,0044
Error	486	476,265	0,980		
Adjusted total	488	487,022			

Figure 1 shows the mean overall judgement about the shopping centre by customers belonging to different age classes. Young respondents show a lower evaluation, under 4,5 on average (on a scale from 0 to 6), while older respondents' judgement goes up to nearly 4,9.

Figure 1 – Mean overall judgement of different age classes

A Tuckey test run on these results detects a significant difference between the judgement of the “older than 51” class with respect to the other two age categories. It means that older customers rate higher than the other ones the overall quality of the shopping centre “Tuscia”.

Table 6 – Outputs of Tuckey test

Categories compared	Difference	Standardized difference	Critical values	Pr > Diff	Significance (95%)
older than 51 <u>vs.</u> younger than 25	0,421	3,272	2,344	0,003	Yes
older than 51 <u>vs.</u> 26 to 50 years old	0,337	2,662	2,344	0,021	Yes
26 to 50 years old <u>vs.</u> younger than 25	0,084	0,848	2,344	0,673	No
Category	Estimated means	Groups			
older than 51	4,860	A			
26 to 50 years old	4,524	B			
younger than 25	4,440	B			

Discussion

As pointed out in the results, 5 out of 21 explanatory variables are significant. They can be considered as major drivers of customers' overall judgement about the shopping centre.

The value of the intercept in the regression analysis shows that, before considering any driver influencing the customers' rating of the mall, the judgement levels to 1,34. Indeed, the judgement increases or decreases as more information is considered, depending on which variables are added to the analysis. The interpretation of the regression coefficients helps to understand what kind of influence each variable plays in shaping the overall judgement value. In particular, this effect can be highlighted for the significant variables (Figure 2).

Four of them, referring to the intrinsic cues of the quality of services, have a positive influence on customers' overall satisfaction. The most notable is the value for money of products and services offered in the shopping mall (IQserv_7): each extra-point in the evaluation of this issue is able to increase by 0,210 the final score. To enhance the value for money of products and services offered is then a chance for the shopping mall management to increase customers overall satisfaction up to 1,26 points in a 0 to 6 scale. Nearly the same effect can be noticed for the assortment of products and services (IQserv_6), which seems very important to achieve a positive perception of the mall among the customers. Less strong but still remarkable, the perception of cleanliness (IQserv_5) and the courtesy of the staff (IQserv_1) are able to improve the overall judgement by, respectively, 0,79 and 0,60 points if the maximum evaluation for these variables is achieved. On the contrary, the overall score of the mall services might be negatively affected by customers' perception of a wider variety of products and services in other shopping centres located in the same area. Customers' negative appraisal due to a lack of variety in the surveyed shopping centre compared with other malls could lower the overall judgement by 0,33 points.

Figure 2 – Contribution of the significant variables to the overall judgement (for an extra-point of each variable)

On the whole, it is probably useful to highlight that the perceived quality of the services offered in the shopping centre is the main driver for the construction of an overall

judgement in the mind of consumers. One issue that clearly emerges in this analysis is the importance of assortment in the offer of products and services to improve the evaluation of the mall by the customers. It is especially true when customers base their evaluation also on experiences they had in other malls of the area: when it is the case there is a high risk that the judgement on the mall is negatively affected by the comparison with other shopping centres. This is less likely when customers' appreciation for other shopping centres revolves around other issues like spending leisure time and achieving more convenience.

None of the issues related to habitudes in visiting the mall (frequency, days of the week, time slots within the day, motivations) nor the demographic profile seem to affect customers' overall judgement about the shopping centre: the significance of these explanatory variables is very low and the coefficients' values are negligible. Therefore, it might seem that the customers' profile is not relevant in the explanation of their appraisal of the mall. Nevertheless it is worth to further investigate on the variable describing the age of the customers, because it shows a slight significance in one coefficient. As reported in the results, we run an analysis of variance with the aim to check the similarity in the overall judgement of respondents belonging to different age categories. The results show a significant difference between the judgements, namely older customers have the tendency to rate higher the shopping centre. Such greater satisfaction might be due to the lack of experience in other malls. As table VII clearly highlights, 90% of the young customers and 80% of the respondents belonging to the 26-50 years old category usually visit other shopping centres in the surroundings of Viterbo. This is not the case for the older customers, as only 56% of them usually go out of town to travel to other shopping centres. Therefore, it seems likely that the younger customers' judgement is negatively affected by the comparison with other structures.

Table VII – Experience in other malls by age

Category	Usually visits other malls in the area
Younger than 25	90%
26 to 50 years old	82%
Older than 51	56%

Conclusions

In this paper the internal and external drivers of customer judgement about services quality is investigated, basing on the data gathered in a survey at a shopping mall in central Italy. The large database provided allows to set up a methodology to investigate the drivers of the customer overall judgement about the services offered in the mall. This type of analysis is of great interest when considering the lively debate on the dimensions of service quality.

The model chosen for this analysis fits the data well enough and the results seem robust thanks to the large size of the sample. We were able to explain the overall opinion of the customers through a set of variables related to the behavioural and demographic characteristics of the consumers, the intrinsic quality of the services offered in the mall and the comparative appraisal with other malls.

Findings suggest that the characteristics of the consumers are not very relevant in the construction of the overall quality judgement, even though significantly different opinions have been expressed by consumers belonging to different age categories. Customer perception of the single services is the dimension which is able to explain most of the overall opinion. The role of the assortment in the product and services is very significant, both in absolute terms and in comparison with other shopping malls.

Some limitations of the analysis should be noted, mainly the representativeness of the sample and the choice of the explanatory variables in the model: both are affected by the objective and the organization of the survey, originally suited for a different purpose. Another limitation is the large number of explanatory variables selected for the regression model, which affect the significance of the analysis and the contribution of the single variables to the explanation of the overall judgement.

Nevertheless the findings of the research might be useful for managers in order to improve the consumers' perception of the shopping mall image. To this purpose increasing the variety of products and the quality of some specific dimensions of the services provided results as a key issues to gain a favourable comparison with other shopping centres.

Key words: winning organisations, benchmarking, measuring performance, organisational excellence

Category: Research Paper

Introduction and background

The original research (Hubbard et al., 2007) that produced the Winning Framework has been well received but increasingly decision makers have been challenged with questions about how to emulate the practices of winning organisations and in so doing, improve their own managerial practices. This paper summarises recent initiatives to address these questions through a benchmarking process driven by the organisation itself – one that can be best described as self assessment in which the organisation undertakes a rigorous and objective review of its internal characteristics, strengths and weaknesses rather than relying on an external consultant’s analysis. This creates a deep understanding of issues and ownership of the survey outcomes.

The quest for excellence usually commences with choosing an appropriate framework that defines “excellence” and then benchmarking the organisation against that framework. This measures and diagnoses the current performance of the organisation and when done rigorously, should lead to a number of logical opportunities for change and improvement. There are numerous frameworks available. Arguably some of the most popular and best documented versions are embodied in the Business Excellence Award frameworks in different countries (e.g. Malcolm Baldrige Awards in the USA, EFQM Excellence Model in Europe and Business Excellence Awards in Australia). All of these are legitimate choices but the one chosen for this work is the Winning Framework that has been previously described by the author (Cocks, 2009). This framework has been widely acknowledged by executives in Australian organisations because of its focus on the role of leadership, the pragmatic message and recent publication date. For these reasons it was selected for this study as an appropriate business excellence framework. The elements in the Winning Framework were used to construct survey questions that could be used by organisations to benchmark their performance. Relevant insights into the original research that generated the Winning Framework are summarised in Section 2.

The winning framework for benchmarking performance

The diagnostic tools and survey instruments discussed in this paper are based on the extensive research by the author into the characteristics of long term high performing organisations in Australia (Hubbard et al., 2007). This research commenced with a survey of 1000 senior executives who were asked to nominate successful organizations against a set of criteria that included taking a balanced scorecard perspective, internal efficiency and long term growth, financial and market performance, innovation and productivity measures. Following detailed analysis, the final number of organisations was narrowed to eleven and their performance was studied in depth over a 25-year period from 1982 to 2007. Where possible, data were used to compare their

performance with other organisations in similar industries to confirm their winning status. Over this period these winning organisations outperformed the stock market index by almost three times, although financial performance was only one of the criteria and several organisations were not publicly listed for at least half the period.

Annual reports for the 25 year period and other published material were researched and summarised according to key events and drivers of success. The study included interviews with several executives from each organisation, selected for their extensive knowledge and experience about their organisation's strategies and evolution, to gather additional unique insights into the specific causes of success. The causes were analysed for each organisation by the research team to determine common themes that were subsequently classified into nine key elements for success.

The research dispels several current myths about the characteristics of winning organisations. Being a winning organisation in Australia has little to do with charismatic leaders, seeking great breakthrough ideas, setting stretch goals, rolling out precise mission and vision statements or creating the perfect organisational structure. More significantly, nine key elements for long-term success have been identified from the eleven organisations:

1. *Effective Execution.* Winning organisations do what they say. They announce what they plan to do, they plan and budget for it and they meet the plans and budgets. To do this, they have clear processes that are accepted within the organisation. They have good control systems, use quality management principles, people take personal responsibility for their work and they rigorously measure performance. They learn from mistakes and do not cross subsidise under performing business units. Winning starts with effective execution which forms the pivotal element in the framework.
2. *Perfect Alignment.* Practising a culture of continuous improvement, winning organisations use measurement and systems as the critical foundations for alignment. They seek to align culture, leadership, people and perceptions to strategy. Alignment is to external needs as well as internal forces.
3. *Adapt Rapidly.* Times change so that even if perfect alignment is achieved, it will have to be changed, and changed rapidly. Flexibility is a key but change comes with control. Innovation is sought in process as well as in products and services.
4. *Clear and Fuzzy Strategy.* Winning organisations have a clear strategy, though it can be expressed in many ways and does not necessarily exist through a vision or mission statement. But there is fuzziness at the edges of the strategy. Winning organisations are always seeking to take advantage of incremental opportunities, even if they lie just outside their current clear strategy.
5. *Leadership, Not Leaders.* Leadership is about teams of leaders. Leaders set up an emotional 'cause' for the organisation, a reason for existence. Leaders exhibit 'captain-coach' styles and are players on the field, showing captaincy skills and sharing the work. They are available, egalitarian, supporting their people from close by, not setting difficult challenges from afar. The vast majority of leaders come from within winning organisations and have been with the organisation for nearly twice the industry average.

6. *Looking Out, Looking In.* Winning organisations are externally focused. They are aware not just of customers, but also of their environment, community, international industry and international trends.
7. *Right People.* Winning organisations hire people who believe in their ‘cause’, whose values and attitudes fit, not the ‘best’ people who demand the highest pay. People who do not fit are actively managed out of the organisation quickly by a measurement system that balances performance with adherence to values.
8. *Manage the Downside.* Despite rapid growth, innovation and looking outwards, winning organisations are conservative. They plan carefully beforehand, considering the downside, not just the upside, of major decisions. They measure risk and seek to share risks with other organisations, customers and their people.
9. *Balance Everything.* Rather than trying to choose between alternatives, winning organisations choose both. For instance, while they are conservative, they are also entrepreneurial. While focusing on the long term, they also focus on the short term. While focusing on financials, they also focus on delivering value to customers, employees and the community.

The Winning Wheel Framework (Figure 1) shows how these nine elements fit together and are interconnected – all elements are important and change in one element precipitates change to others.

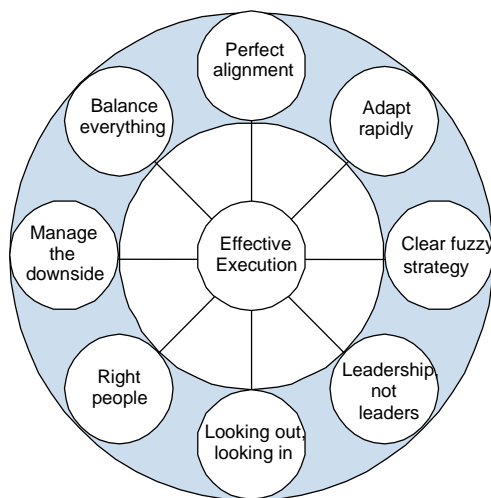

Figure 1 The Winning Framework for Organisational Excellence

It shows the critical role of effective execution that is depicted as both an element of the framework and as representing the outcome of the total framework. Organisations that effectively execute their strategic plans are defined as winners. These nine timeless elements of success are highly relevant to listed companies in the private sector in a wide range of industry sectors together with service, not-for-profit and public sector organisations of all sizes.

Research design and the benchmarking process

Benchmarking Objectives

The concept of benchmarking originally described by Camp (1989) has now taken on a myriad of definitions. Arguably there are three generic forms:

1. Internal - comparing between groups or units within the same organisation
2. External - comparing key metrics against competitors in the same industry
3. Best Practice - comparing against the best that can be found world-wide, irrespective of industry type.

The concepts in this paper are intended to address internal benchmarking but future work should see potential to embrace all three popular forms of benchmarking.

The journey commences by first understanding exactly what the organisation is trying to achieve (the strategic plan) and what its current position and performance levels are. It should also include an analysis of the external environment using models described in strategy texts such as Forster and Browne (1996) and Hubbard et al. (1996). The next step involves defining the capabilities of the organisation and what it has (or plans to have) to give a sustainable competitive advantage. To this end, business models such as that proposed by Tracey and Wiersma (1993) are highly relevant – questions such as whether the advantage is to be derived from process effectiveness, customer intimacy or product innovation? Then the organisation needs to know its current performance level in key parameters such as financial, market/customer, internal efficiency performance and long term growth and development initiatives. At this point the executive team is in good shape to assess its overall strategic position and articulate what needs to be improved. The journey of improvement can then commence by assessing how the organisation performs against the nine elements in the Winning Framework. The survey instruments described in this research are applied at this stage as part of the benchmarking process. This logic and methodology is presented in Figure 2.

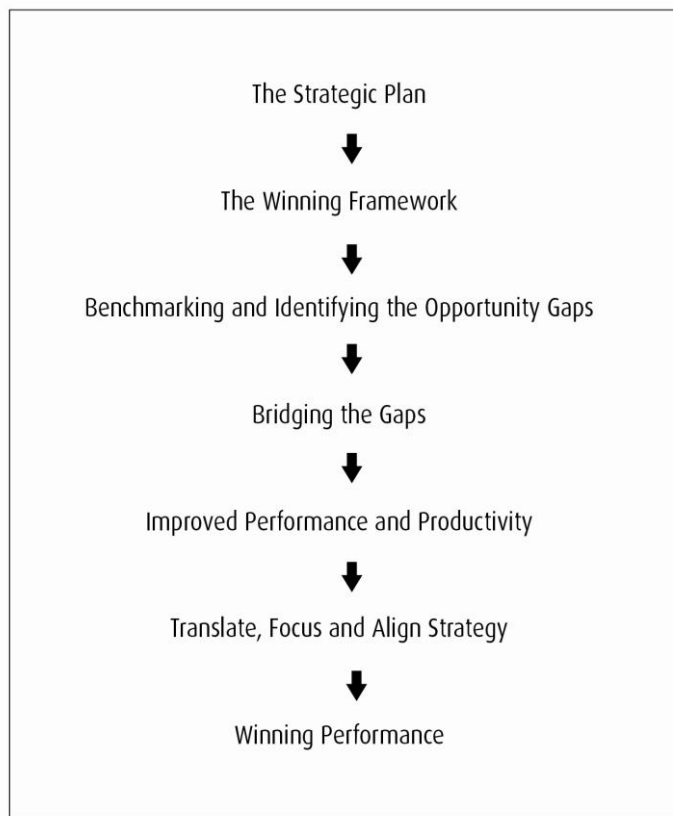

Figure 2 The Pathway to a Winning Performance

The Diagnostic Survey

The web- based diagnostic survey consists of 90 core questions built around the 9 elements in the Winning Framework. The survey uses a bi-variant approach in which respondents rank each question on a scale 1 to 7 according to their views on both “Performance” and “Importance” to their organisation. This structure allows for simultaneous rankings and gives more granularity to the final analysis. The survey also allows for qualitative feedback from respondents in addition to the structured diagnostic questions. The on-line diagnostic approach is explained further by Taylored Assessments UK Ltd. (TAUK 2011).

Outputs from the survey can be compared to the practices that have been identified from the research into winning organisations in Australia - those that lead to sustainable and above average performances. This allows organisations to rapidly and effectively benchmark their own performance and drive improvement in a targeted way. Statistical data analysis is carried out on the quantitative responses and presented automatically in reports that are highly visual and simple to understand by using priority matrices, heat maps, color coding and radar diagrams. Most importantly, individual responses and comments are treated confidentially.

Designing the Approach

A significant number of participants is needed to complete the diagnostic survey and they are encouraged to take an organisational view rather than a functional or personal view and consider the ‘normal’ response to each question, not the odd or unusual

response. The questions are targeted at those people who should know most about how their organisation is currently performing and where they might need to focus for future success. Typically the diagnostics are completed by the CEO, direct reports to the CEO and the next level of management and (optionally) members of the Board of Directors. Collectively these executives are in the best position to provide objective input for the organisational - wide performance analysis.

The survey should also engage people from throughout the organisation to provide more accurate information about where to focus attention for future success. Therefore it should ideally be run with multiple levels of management and operational personnel in numerous departments and business units and in different locations where appropriate. Where an organizational-wide survey is not realistic, benefits can still be derived by applying the benchmarking process to discrete divisions of the organisation. Indeed, experience to date is that a useful approach is to select a pilot project where the initial gains and demonstrated success should capture the attention of management so the process gains momentum and is progressively rolled out across the entire organisation.

Analysing the Data

The data can be sorted in a wide range of alternatives such as by organisational level, location, areas of most concern, elements in the Winning Framework and variations within responses to each question in the survey. The starting point is to plot the results on the Winning Wheel and include the benchmarks from the winning organisations in the original research. Further detailed analysis then follows – for example a powerful indicator is the “opportunity gap” which is defined as the difference between the “Performance” and “Importance” percentages. These gaps are then presented in matrix form, ranked and prioritised. The objective is to identify the largest gaps which in the spirit of continuous improvement should be treated as the most significant opportunities rather than viewed as major problem areas.

Initial Trials

The diagnostic is designed for use across all industry sectors and can be regarded as a generic model for all types of organisations. Initial benchmarking applications have included health authorities, government bodies and not-for-profit organisations, an educational institution and manufacturing enterprises. Potential sponsors and end users include Boards, CEO’s, CFO’s, HR practitioners, senior change agents, quality and improvement managers and consultants.

To date the process has only been designed to facilitate internal benchmarking by participating organisations. As the number of organisations increases over time, more accurate and extensive benchmarking data will be revealed such as by industry sector, organisational size and geographic location. More sophisticated forms of benchmarking will be then possible.

Findings and discussion

The Overall Picture

Figure 3 shows typical results from an organisational survey plotted against the Winning Wheel and presented as a radar map. This gives an immediate view of how the

organisation is performing relative to all nine elements and locates major imbalances around the Wheel. It identifies “whole of organisation” strengths, weaknesses and gaps. The overall averages for each element are included. Considerably more value is derived with deeper analysis and Figure 3 also compares the results for both the executive team and front line operators and these are plotted against the benchmarks for the winning organisations. Many conclusions can be drawn – not only is this organisation under-performing against all the benchmarks, there are significant differences between the executive and front line levels. The overall averages indicate that “People” and “Alignment” are the worst performing elements (51-54%) with “Outlook”, “Execution” and “Managing the Downside” showing the best results (61-62%).

Figure 3 The Winning Wheel as an Organisational Radar Map

Segmenting and Reporting the Data

There are many alternative ways of reporting the survey results. One interesting approach has been to plot the range (variation) of results for individual questions or element in the Winning Framework (Figure 4).

Clearly, the variations between the highest and lowest score ranges are quite large and different for each element – in this example from 40 respondents “Alignment” is reasonably consistent but there are major differences in the way respondents judge “Execution”. This spread of data can be used to encourage discussion and debate around the reasons why some people in the same organisation or business unit respond to the same question in quite different ways. Consensus and unique insights into the root causes of problems are often the result. This positive outcome is less likely to be achieved if averages alone are considered.

Figure 4 Performance Ranges and Averages

Another approach is to sort the data according to organisational level (Figure 5) which brings more granularity to the action planning stage than using the overall data in Figure 3.

Level	Strategy	Alignment	Outlook	Adaptability	People	Leadership	Risks	Balance	Execution	Average
1.1	71	77	79	78	79	80	75	75	84	78
1.2	81	75	75	65	65	78	70	76	75	73
2	68	57	62	60	54	50	63	63	62	60
3	48	46	65	46	40	45	56	67	52	53
4	27	39	65	24	16	20	46	27	33	33

1 Executive Team
 2 General Managers
 3 Supervisors / Team Leaders
 4 Front Line Operators

Figure 5 Typical Survey Results Sorted by Organisational Level

It has been found that most executive levels consistently rate higher than their direct reports and the gaps between their results and those from the supervisor and front line operators is major – in this example the average difference range up to a huge 45%. The implications of this gap are numerous but may imply management hubris or over confidence, lack of feedback, poor communication, low alignment or little or no understanding of the organisational strategy within the organisation. These are all the responsibility of the executive team and such gaps need to be addressed to become a winning organisation.

Some additional alternatives available in the Winning Wheel benchmarking process to present the data include:

1. Performance Gaps – this involves calculating the difference between the “Performance” and “Importance” data. Further work is currently being undertaken to interpret the significance of these gaps and how they can be used to develop action plans.
2. Geography, gender, maturity, tenure with the organisation all help to fine tune future initiatives.

Trends and First Impressions

Although the survey is in its infancy some initial trends are emerging:

1. All survey results fall below the benchmarks from the organisations that were researched to generate the Winning Framework.
2. The executive team ranks their organisation consistently higher than front line operators especially in the “Leadership” element. This implies poor communication and alignment throughout the organisation, concerns about leadership style and lack of support for the needs of operational personnel.
3. The “softer” issues around right people and leadership appear to be the most difficult ones to address in Australian organisations. By comparison the “harder” issues such as alignment are more manageable and of less concern.
4. The gap between those that formulate strategy and those that execute strategy implement strategy is substantial and suggests that major barriers to the execution of strategic plans are ongoing and difficult to resolve (Cocks, 2010).

At the more macro level, the survey and benchmarking process provides a robust platform to create and implement structured and targeted action plans to drive improvement at the deepest level of the organisation. Rather than adopting a broad analytical approach to improvement and change by resorting to management fads and acronyms, the Winning Wheel survey has been commended by its users to date for bringing clarity and focus to organisational improvement by identifying the critical areas that need immediate attention. The reporting process identifies the opportunity gaps within the organisation to locate areas that require specific attention to improve management, systems, processes and operating performance.

The initial trials indicate that methodology is both rapid and effective. It avoids the more tedious alternatives of interviewing, gathering, sorting and analysing data that characterise more traditional consulting processes. Some organisations have already

discovered that it also offers a pathway to continuously improve by using the Winning Framework as the standard on an ongoing basis. Annual surveys can be used to monitor and quantify improvements thereby maintaining momentum and motivation to teams and individuals. This might eventually culminate in the approach being used to systematically measure team and individual performance and using it as a basis for performance management systems and staff appraisals.

Conclusions

The principles and success factors identified in the Winning Framework, coupled with the benchmarking and diagnostic processes that are described in this paper, have been shown to provide leadership teams and individual leaders with a practical methodology to boost their organisation's productivity and business performance.

The diagnostic surveys have successfully identified "whole of organisation" characteristics and provide objective data rather than subjective opinions. The options for detailed analysis to determine the opportunity gaps and to segment the data help to define the critical opportunities to improve. Resources and management attention can then be targeted on these opportunities rather than simply adopting a broadly based approach to improvement and change management.

Over time, it is anticipated that a benchmarking data base will be developed which should allow organisations to measure their performance against competitors or to extrapolate into best practice benchmarking where comparisons can be made irrespective of industry sector, location or business model.

Key words: Governance competence, shareholders, independent directors, SME governance, board reform

Manuscript Type: Conceptual/Analytical.

Background of the Development of Demand for Independent Directors

The traditional view of the board of directors is of a group of individuals (traditionally middle-aged men) with significant experience in the market within which that company operates and with significant experience of the workings of that company. Consequently, the membership of such boards was also traditionally and overwhelmingly constituted by insiders, who might include family members (if a family company) friends, professional advisors (lawyers or accountants) or substantial shareholders or their nominees. Even as late as the 1980s when the idea was more likely to be debated in political and business circles, the very notion that outsiders should be included was to some conservative thinkers an anathema. After all, what could such individuals possibly contribute to a company they didn't understand?

Consequently, such a presence was resisted in some other jurisdictions dominated by the Anglo-American model of a unitary board (having the roles of both supervision and management), as in Australia and New Zealand as well as the United States and the UK. Critics of the idea cited a range of reasons for their position. Inter alia, those include the fact that for many such directors their interests are artificial (lacking strong links between the company's wellbeing and their own); a characteristic that reduces their motivation to maximise performance; they may lack experience and understanding of the business environment; they may well have a seat on a range of boards, reducing loyalty and adversely affecting their focus on the company and its wellbeing.

Despite such objections, however, and as stated earlier, the independent director is a must for the boards of public companies in a range of jurisdictions, increasingly mandated or encouraged by legal and quasi-legal rules. In order to provide an overview, three exemplar legal/regulatory frameworks will be considered, these being in turn the UK, United States and Europe.

In 1991 in the UK, the Financial Reporting Council, London Stock Exchange and the accountancy profession moved to address low levels of confidence in financial reporting, control and standards and investor disillusionment after some enormous and

unexpected company failures. These included that of the Bank of Credit and Commerce International (BCCI) that failed owing billions after an international investigation into lending practices and lack of regulation of its activities, the Maxwell group of companies where investigations revealed millions of dollars worth of fraud and misappropriation of pension funds and Polly Peck Ltd where for years financial records had been falsified. Consequently they set up a committee headed by Adrian Cadbury to report on how to improve corporate governance practices. This committee's report (Report of the Committee on the Financial Aspects of Corporate Governance (the Cadbury Report, 1992) included a range of recommendations, one being the inclusion of independent directors principally to fulfil a control function in relation to decisions being made by the executive directors (Cadbury, 1992, p.21).

However, by 2002 some major financial scandals, including those of Enron, WorldCom and Tyco, put the issues of corporate misfeasance back into the sights of regulatory bodies in the UK. As the root cause for many of these was identified as poor corporate governance practices the Government initiated another report (the Higgs Report, 19xx) that, while supporting the maintenance of the "comply or explain" (Pass, 2008, p. 291) approach instigated by the Cadbury Report, also advocated that Boards should be responsible for ensuring a proportion (at least 50%) of members are independent. It is important to note that this code refers to non-executive directors but clearly includes independent ones. A similar approach has been adopted by the Australian Stock Exchange. While the New Zealand code (New Zealand Exchange, 2010) requires that at least 25% of directors should be independent (rule 3.3.1) it leaves it to the company to identify those who fall into that category.

In America, the trajectory and outcome of initiatives to improve corporate governance through the participation of independent directors has been somewhat different. Despite a lack of any requirement or strong recommendation, their presence was already well established by the turn of the century. Bhagat and Black (1998) estimated that in 1991 more than two-thirds of the 957 largest United States companies had a majority of independent directors on the Board while also making reference to the fact that Spencer Stuart in their survey of 100 of the largest companies in 1996 reported that no fewer than 50% had a maximum of two insiders on the board. Gordon (2007, p. 1476) cites studies that put the proportion much higher than that – in a study conducted by Korn/Ferry in 2003 65% of respondent companies reported fewer than three insider directors. One year later that had increased to 91%.

However, the financial and confidence shock sparked by the Enron and similar collapses were to spark a fundamental shift in the mechanisms used in the United States to assure good corporate governance. One of the first steps taken by the Federal Congress post Enron was the passage of the Sarbanes-Oxley Act 2002. One of its main provisions (s301(2)) is the requirement that audit committees be composed entirely of independent directors, and it also by analogy mandates the membership of such directors on the board. Consequently, and shortly after the passage of this legislation, both the New York Stock Exchange and Nasdaq moved to require boards of listed companies to have a majority of independent directors (Wallison, 2006, p. 1; Ritchie, 2007).

Insofar as continental Europe is concerned, the historical background is again different. This is largely due to the use of a two-tier board structure as found in the Netherlands,

Germany, Austria, Finland and Denmark (Jungmann, 2006). With a management board (made up of those with industry and company experience and often working in the firm) and a supervisory (of those representing stakeholder interests) there was far more room and logic for the inclusion of independent directors).

These various initiatives, be they recommendations, code, rules and law, all reflect acceptance of, and enthusiasm for, independent directors on the boards of companies. However, the jury is still out on the question of whether this move has improved corporate governance practices in affected companies. This question, and the debate that surrounds it, is documented in the following section.

Contribution of Independent Directors

By way of introduction to this section we refer to the role of the board of directors more generally: The OECD states “The corporate governance framework should ensure the strategic guidance of the company, the effective monitoring of management by the board, and the board’s accountability to the company and the shareholders” (2004, p.24). Clearly then, the three main roles of the Board are to determine strategy, monitor management and to account to shareholders for the use of company assets and resources (Carver and Oliver, 2002). In achieving those roles, the Board is responsible for ensuring legal requirements are met (including those specifying the form of financial and other reporting to shareholders and, if listed, the requirements of the particular exchange or other body involved in determining rules). The growing support in the courts, specialists and some business groups led to the mandating of independent directors as an integral part of the governance structure in the Sabarnes-Oxley Act (Wallison, 2006, p.1).

By reference to those roles, and in an attempt to clarify the situation as to whether and what independent directors contribute to the company, the following section documents the arguments that have been made for independent directors by reference to two principle roles and qualities often attributed to them – improving shareholder value (an aspect not only of accountability but also of strategy) and monitoring of management (also inclusive of strategic guidance).

However, board independence is not such a favourable factor when we examine the empirical evidence which shows that the presence of independent directors on the board can harm the innovation and creativity of the organisation (Baysinger and Hoskisson, 1990). In the non-profit sector, where directors are volunteers and without compensation, the recruitment of independent directors is thought to come with certain disadvantages. Independent directors may not only lack specific knowledge to support innovation, but they are also hard to retain (Brody, 1996). The most significant issue is how to recruit and retain outsiders (Pati, 2007). As mentioned above, the motivation of directors is a good gauge of their effectiveness on a board (Taylor, Chait and Holland, 1991). This applies to independent directors and in general it is advisable to recruit directors who have a connection to the organisation. These directors are more likely to be available for recruitment, and will be more motivated (Taylor, Chait and Holland, 1991). Unfortunately many independent directors do not have such connections and those directors who are insiders are more easily recruited, easier to retain and have stronger motivation (De Andres-Alonso, Azofa-Palenzuela and Romero-Merino, 2009).

The ‘Ideal’ Independent Company Director in New Zealand

As discussed previously, independent directors on board are still more rare than the norm and are only mandated for publicly listed firms. With 98%+ firms in New Zealand being unlisted, such regulatory mandates do not extend to the vast majority of business, and a reasonable inquisition is that if independent directors deliver value, firms where their inclusions is optional and not required, might decide on the inclusion of outsiders on the board.

As independent directors interact more with the other board members than with shareholders, directors might be in a better position to determine whether independent directors add value to boards in New Zealand. One facet of our longitudinal research into New Zealand company board composition therefore asks which criteria shareholders, senior managers and existing directors would prefer in newly appointed independent directors.

This research was designed to capture a broad cross-section of responses throughout New Zealand and for a period of several years. In order to reach New Zealand business of all sizes and industry classifications, the survey instrument was distributed to the client lists of several supporting organizations. Further supporting the argument that the discussion of ‘Governance’ is highly relevant in New Zealand, more than a dozen national organizations participated in the survey distribution, creating one of the largest data sets on governance in the country.

Using distributors from different industries and in many locations throughout New Zealand was intended to reduce bias in the sample group.

Distributing organizations were:

BNZ, ANZ, National Bank, Simpson Grierson, Business New Zealand, Employer and Manufacturers Association (Northern), Otago Southland Employers, PriceWaterhouseCoopers, 3 Media Group, Cameron Partners Investment Bankers, Swann Recruiting, The New Zealand Shareholders Association, Venture Taranaki, NZ Institute of Management, Unitec, Waikato Chamber of Commerce, Business Mentors of New Zealand, Employers and Manufacturers Association Central, Canterbury Employers Chamber of Commerce, New Zealand Venture Capital Association, Ministry of Womens Affairs, Te Puni Kokori, Chartered Secretaries of New Zealand, Human Rights Commission, Crown Company Monitoring Advisory Unit, Waikato Management School.

There is no doubt among directors, shareholders and senior managers that independent directors contribute positively to the board, although there is a difference between shareholders and directors, to what degree these independent directors contribute. Shareholders report a contribution by independent directors to a slightly lesser extent than directors do, likely because they do not have first-hand experience of the contribution of individual directors during board meetings. This raises an issue of transparency when directors report back to shareholders, to make sure shareholders understand the substance of board deliberations, the benefits of vigorous debates and the strong unified leadership when the board instructs senior management. When shareholders do not understand how directors contribute to the creation and

maintenance of an effective and resilient governance system in the firm, they likely will be less appreciative and understanding of the decisions directors make.

The overall appreciation for the contribution of independent directors should be good news for those shareholders, owner/operators or senior managers of SMEs in New Zealand, who have not yet found a compelling reason to add independent directors into the governance structure of their firms.

Diversity as Part of the New Independent Director Search

Diversity is an often-discussed issue in relation to governance, most often in the context of age and gender, presumably with concern that women and younger people are underrepresented in governance roles. Without doubt, an 8% participation of women in governance roles in publicly listed firms is appalling in New Zealand that prides itself of having been the first in the world to grant women the right to vote, and where only a few years back all key roles government were held by women (Prime Minister Helen Clark [prior Prime Minister Jenny Shipley], Speaker of the House Margaret Wilson, Governor General Sylvia Cartright, Chief Justice Sian Elias).

With a keen interest to identify whether shareholders, directors and senior managers had preferences as to gender, age and other factors, this research offered them to select which attributes of an incoming director would be most valuable to contribute to diversity in the boardroom.

With a range of factors available to select from, a clear picture of preference emerged, and not necessarily a pleasing one for those who had hoped that there is an outcry for age and gender diversity among New Zealand boards. We can dispose of the matter of age and gender quite easily: Neither of these two factors (gender more convincingly than age) was ranked as being a contribution to diversity among boards. There is an indication that the average age of 52 among New Zealand directors might be high for some, but no strong preference was expressed for any specific age band. During the interview sessions with younger (<40) shareholders, senior managers and owner/operators it became quickly evident that these individuals not infrequently preferred director candidates who were at least 15 years older than themselves, to balance a board of much younger people. There generally was no expression for directors to be younger than the ones we currently see in boardrooms in New Zealand. On one hand, this deals a blow to those who believe company directors in New Zealand are an ageing group of predominantly males, but more importantly, this research confirms that there is no preference for any specific age group, thus allowing access to the board roles to people irrespective of age or gender. Decision-makers in the area of governance do appear to recruit directors with specific emphasis on gender or age.

What then do Shareholders, Executives and Directors look for in new Independent Directors?

Immediately apparent is what is not considered a desirable attribute for new independent directors: (a) Holding multiple directorships, (b) being an employee of the firm, and (c) holding a directorship-training certificate.

Multiple Directorships

Being a director can be a part-time or full-time profession for individuals, who then seek multiple directorship mandates and thus practice governance simultaneously for several firms. On the positive side, holding multiple directorships might indicate that the person has developed better-than-average skills in the area of governance and is appreciated for the contribution to boards by several other firms. This might lessen the risk for a firm to recruit an under-qualified director. A 'professional director' might also gain current knowledge about governance issues in some firms that might be applied to the governance at other firms, thus possibly contributing to an effective transfer of knowledge. And, lastly, a professional director might have directorship mandates in firms in similar/related fields and thus might be able to contribute specific knowledge of value, subject to conflict situations.

All of this foregoing does not seem to constitute valid arguments for shareholders, senior managers and directors in their search for new independent directors. Only 2.5% believe it is important that new independent director holds multiple directorship, while 67% believe it is not important.

Following from the individual discussions with directors and owner/operators it seems clear that professional directors are not perceived to have current practical management/leadership experience and thus are suspected not to be able to contribute in those areas. There also appears to be some sense of mistrust as to the commitment a director has to each board if he/she sits on many boards at the same time.

A Director as an Employee of the Firm

Much to the relief of those pushing for more independent directors on boards, 74.1% of shareholders, senior managers and directors do not wish a new director to be an employee of the firm (which would make that director non-independent). Whether there is the awareness that the status of being an independent director precludes employment at the firm, or whether there are other motivations at work, clearly employees are not seen as adding value to the board.

In the discussion with directors and owner/operators they clearly expressed an appreciation of the 'independent' status of directors and that employees would not meet this requirement. This allows the cautious conclusion that there is a value attribution to being independent which appears to contradict the historic notion that outsiders could not contribute as directors due to lack of specific firm knowledge.

The Value of Having a Director Training Certificate

Slightly more than half of the respondents (52.3%) believed holding a Qualified Director certificate was important (offered in New Zealand by Directions – Understanding Governance Ltd, a private provider with a roster of corporate leaders as presenters), while only 48.4% thought the same for a certificate from the Institute of Directors. For neither institution this a sign of endorsement by the market, and it appears that no superior value is placed on the completion of a directorship-training course.

This situation should sound alarms among educators, regulators and corporate leaders. If the current training regimes are not appreciated as being important, then either there is a lack of knowledge of the director skills gaps (not knowing what one doesn't know...), or there is a lack of appreciation for the learnings a participant can take away from these training events. In either case, a campaign to raise awareness might be required to drive more directors to upgrade/update skills through some vehicle of formal governance education. There is a need in New Zealand for more directorship training events that deliver value, and this research shows that it is not only novice directors who would likely benefit from training, but that there is a serious skills gap among sitting and presumably more experienced directors.

When turning to the attributes most desired in a new independent director, shareholders, senior managers and directors are strongly unified. They are keen on independent directors who have (a) a good reputation, (b) can form and defend their own opinions, (c) have a track record of success in business, and (d) have company-specific market knowledge and experience. To a clearly lesser degree, directors are desirable when they (d) have global business experience and (e) can communicate effectively with shareholders.

The Reputation of Directors

Nearly 70% of respondents consider the reputation of directors to be very important, and more than 27% consider it somewhat important, making this the single most important attribute for independent directors. It is not clear what exactly 'reputation' means, but the in-depth discussions with directors identified several areas included in this definition: (a) Absence of public failures such as bankruptcies, criminal/civil prosecutions and other scandals; (b) 'being known' in the industry specific to each firm, and (c) being held in high regards by the current directors.

Although 'having a good reputation' appears to be easily defined, it is important that future research better identify the characteristics associated with 'good' and 'bad' reputation. For instance, would a director who regularly does not go along with a majority of other directors suffer a reputational damage for being troublesome? Events such as being a director of an insolvent firm or being convicted of criminal acts would justifiably affect the reputation of a director, but what about the director of a firm that voluntarily liquidates because it has come to the end of its useful corporate life? 'Reputation' as a term invites the application of a value system that will be subjective rather than objective, and thus care must be taken to not adversely affect the eligibility of directors who can effectively contribute but might be tainted by irrelevant activities.

A Director with A Strong Opinion

67.7% of respondents find it 'Very Important' (and a further 28.2% find it 'Somewhat Important') that a director can form opinions and then defend them vigorously during a debate among directors. This outcome seems to indicate the true value independent directors have, and suggests a belief by the respondents that such a vigorous debate does not currently exist on boards.

In general, this sentiment by respondents seems to indicate a fear of directors banding together for the wrong reasons and thus manifests a level of distrust against directors

that is disturbing. If it needs a director with the stamina to maintain a vigorous defense for his/her argument to succeed, does that mean that less strong directors will not be heard? Is there a fear that directors' valid opinions might not be debated if the fervor and fighting spirit are missing? It appears from the discussion with shareholders and senior managers that a lack of understanding exists over the operation of board meetings. There seems to be a prevailing belief that directors decide based on established alliances in the boardroom, and that newcomers would have no chance to present alternative viewpoints unless they are able to fight for them. This seems to be a naïve interpretation of board routines and likely more wrong than correct. A remedy for this widespread misconception might be to invite shareholders and senior managers to attend board meetings, at least those sessions that discuss matters not commercially sensitive or otherwise not suitable for immediate public consumption, so that they get a first-hand impression of the dynamics of a board meeting. Re-iterating points made above, in this context it seems appropriate to refresh the suggestion that board minutes appropriately reflect any debate and intense discussion of issues, so that there can be no doubt that directors have a forum in which to debate matters fully and effectively.

The Practical Knowledge of Directors

95.4% of respondents desire directors with industry-specific knowledge presumably so that they can overcome the lack of insider knowledge at the firm with transferable relevant skills and knowledge from the outside. This would intuitively be the fastest approach to get independent directors up to speed in understanding the business, but does this provide for the largest possible pool of director candidates to choose from?

If many of the skills required by directors are transferable skills, such as understanding the legal obligations of directors, being able to interpret financial statements and performing audit function, creating long-range visionary strategic plans, communicating strategies to the CEO and management, and communicating with shareholders and other stakeholders, why does a new director have to understand the minute details of how the operation works? Would this not be a skill that can be learned quickly, and be complemented by insiders such as senior managers, who can provide specific operational details?

It is noticeable that there is little interest in adding directors to the board who hold professional qualifications such as "solicitor" or "accountant" but do not work in an executive role in business. While solicitors and accountants have historically been asked to come onto the boards of SMEs, likely as arbitrators of the various owner factions and to provide 'free' professional advice, shareholders, senior managers and directors now are far less likely to be asked to serve. The majority of respondents believed that professional degree holders had too narrow a scope of expertise to be able to contribute to general management issues. Although accountants and solicitors might very well have amassed a lot of knowledge while dealing with clients in a wide range of industries and situations, it appears that this 'knowledge by proxy' is deemed insufficient for the current challenges of independent directors. This means conversely that it is no advantage for an aspiring independent director to hold such qualifications.

This research identifies the necessity to better inform shareholders, senior managers and directors about the purpose and benefits of independent directors. If the approach by firms is to seek directors with knowledge as close as possible to that of the current

inside directors, then this will likely reduce the pool of available candidate to those being the mirror image of the existing directors and thus be less-than-useful as truly independent contributors of governance resource.

The Global Experience of Directors

85.4% of respondents consider it somewhat or very important for a new independent director to have global business experience. With New Zealand being dependent on foreign direct investment and exports, to create a trade balance surplus, the connection to a business world beyond New Zealand is important for competitiveness, growth and sustainability. In the in-depth interviews, many business operators and shareholders of SMEs expressed concern over their lack of knowledge to take their business onto the global scene. There are concerns over the cost and risk of an expansion, uncertainty over the appropriate methods of market entry overseas, fears to not understand the cultural needs of those markets and the beliefs that expansion beyond New Zealand is “too hard”. However, when offered the option to have a director on the board that understands how to operate beyond New Zealand, considerable interest was voiced in such a person and the associated business knowledge.

Conclusions

We conclude that shareholders, senior managers and directors consider an independent director as an advisor of a special kind with contributions in multiple areas and based on solid work experience, preferable also in the global arena. While there is no significant expression of preference for age and gender, competence ranks highly in the minds of the key stakeholders, more so that professional qualifications.

This opens the door to many current executives who wish to step up into a board/governance role but as reported previously (Mueller et al, 2006), there is considerable concern over the available recruitment vehicles available to satisfy this growing demand for independent directors.

Quality management in hotels in the Basque Country

Anna Colomer, Industrial Engineer

Prof. C. Jaca

Prof. E. Viles

Prof. M. J. Alvarez. mjalvarez@tecnun.es

Industrial Management Department, Tecnun, University of Navarra.
Paseo Manuel de Lardizábal, 13 San Sebastián, 20018 (Spain)

Key words: Quality Management System, Quality Standards, Quality in tourism sector.

Introduction

The tourism sector is considered very important for the Spanish economy. In 2010 Spain received 52.6 million visitors, which generated nearly 10% of the GDP. However, starting in the early 90s, the companies in this sector became aware of the fact that there were new destinations with exotic appeal and competitive prices. Tourists demanded more value for their money and better service.

In response to this situation, the Spanish tourism sector decided not to compete on price (which involves the risk of substitutability) but to have companies in the sector stand out by implementing strategies addressing quality. Quality can be the key to improving performance and service in a competitive environment (Ingram and Daskalakin, 1999; Costa, 2004). In fact, Spain is the first country in the world to define specific quality standards for each subsector and create a certification system handled by an independent third party.

Companies in the tourism sector in Spain reacted to the threat of new exotic and more competitive destinations by focusing on improving the quality of service and management. In fact, Spain has been a pioneer in the implementation of voluntary quality certification systems for hotels. The Quality Club of Rural Homes in the region of Valencia (*Club de Calidad de las Casas Rurales de la Comunidad Valenciana*), created in 1999, and the Plan of Excellence in Hotels in Puerto de la Cruz (*Plan de Excelencia Hotelera de Puerto de la Cruz*), developed in 1993, are two illustrative cases.

The quality approach spread to Spanish tourist companies more generally in 1996 when the Spanish Tourist Quality System (*Sistema de Calidad Turística Española, SCTE*) project was started. This project was run by the State Tourist Administration, and it provided technical support for the development of quality systems suitable to the different subsectors: hotels, travel agencies, restaurants, etc. The SCTE aimed to provide Spanish hotels (and other tourist companies) with a methodological tool that helped them to manage their businesses with a focus on quality, and it made it possible for them to be more competitive and to offer high quality services and products. The institutional backing was provided in the form of Spanish Tourist Quality Trademark known as **Q for Quality**.

In the first years of the project, the SCTE developed specific quality systems for the tourist subsectors, all of them with certification for business and implementation of continuous quality improvement in organizations. In the year 2000, the tourism sector,

with the support of the State Department of Trade and Tourism, created the Spanish Institute for Tourist Quality (*Instituto para la Calidad Turística Española*, ICTE). The ICTE is a private, independent non-profit organization created specifically for the tourist sector with the mission of standardizing and implementing tourist quality standards, certification of quality systems (specifically Q, the Spanish Tourism Quality Trademark), and promotion of quality systems in this sector.

The Q standards take into account the requirements of ISO 9001:2000 and ISO 14000:2004, but they are not identical; rather, they have a certain complementarity (Casadesus, 2010).

Framework and objectives of the study

The first aim of this study was to find out the approach that hotels take regarding quality management: what managers understand by quality management, and what motivations drive them towards quality. Many organizations are motivated to adopt quality systems by external factors such as pressure from clients, pressure from competitors, and the desire to enhance the image of the company. Other companies are motivated by internal factors such as improving efficiency, reducing costs associated with poor quality, and product improvement (Casadesus and Heras, 2005; Shannon et al. 2001).

The second aim was to discover what quality standards companies use and the scope that these standards cover in hotels in the Basque Country. Several methodologies for quality management have been developed, including the ISO 9000 series, Six Sigma programs, the EFQM business excellence model and within Spain, the trademark Q for tourist companies. Some authors note that providing quality tourism experiences remains problematic. The characteristics of tourism as a service—intangibility, heterogeneity, perishability and simultaneity—as well as the diverse nature of the tourism experience represent significant challenges to the successful implementation of quality management procedures (Sharpley, 2003). In particular, in Spain there was a poor penetration rate of the ISO 9000 family in the tourism sector in spite of the fact that Spain is the fifth country in the world in terms of the number of companies with ISO 9000 certifications (Casadesus, 2010). However, Spain was the first country in the world to define specific quality standards for companies in the tourism sector and a certification system run by an independent third party.

One of the aspects that we wanted to study was employee commitment to quality service. Some authors point out (Witt and Mühlemann, 1994; Sharpley et al, 2003) that the factor that links all models of quality management is the people involved in the delivery of service. The success of quality initiatives depends on the willingness and ability of staff to respond to the demands for increased quality in the delivery of services. As a consequence, positive employee attitudes are vital to customer satisfaction. In other words, helpful behaviour from the service provider is one of the fundamental aspects of management quality in tourism.

Methodology

Our empirical study was carried out in the Basque Country. This Spanish region has a long tradition of tourism due to the geographical and cultural characteristics that make it a destination of the quality tourist.

A survey of hotels located in the Basque Country was conducted from September to November 2010. The hotels were selected from the “Guía Empresarial del País Vasco, 2010.” We selected 223 hotels, and after explaining the aim of the study over the telephone and asking them to participate in the survey, we sent them an e-mail with a link to a web page where they could respond to the questionnaire. Over the course of a month, we sent them an e-mail every week in which we reminded them about the survey. The response rate was 16%.

The questions about the concept of quality and motivations are in the following table:

What do you understand by quality? (Do not mark more than 3)
Possible answers: <ul style="list-style-type: none"> ▪ It is a philosophy that tries to satisfy the customer needs. ▪ It is to fulfil/implement the ISO standard. ▪ It is to manage quality as a competitive advantage. ▪ It is a method to get everybody in the company involved with the company's objectives. ▪ It is a method to improve the company's processes. ▪ It is a method to prevent mistakes. ▪ It is a method for achieving the continuous improvement.
What are your main reasons for applying quality management? Do not mark more than 3)
Possible answers: <ul style="list-style-type: none"> ▪ To improve our relationship with the environment. ▪ To fulfil compulsory norms. ▪ To increase profit. ▪ To get more customers. ▪ It was a requirement of the group the company belonged to. ▪ To manage quality as a competitive advantage. ▪ To bring about a cultural change within the company. ▪ It is “in fashion” or it enhances the company's image. ▪ Out of conviction.

Table I

In order to discover what quality systems are used and the scope of quality management, we asked hotels which certifications or quality systems they use and the processes that they use, as seen in table 2.

Do you have quality certifications, homologations, etc?
Possible answers: <ul style="list-style-type: none"> ▪ No ▪ Q touristic ▪ ISO 9001 ▪ Awards ▪ Others
Which processes have you documented in your hotel?
Possible answers: <ul style="list-style-type: none"> ▪ Reception ▪ Check in ▪ Check out ▪ Cleaning ▪ Bar ▪ Maintenance

<ul style="list-style-type: none">▪ Accommodation▪ Purchasing▪ Others
Are the documented processes evaluated?
Possible answers: <ul style="list-style-type: none">▪ No▪ Yes How? - Internal audit<ul style="list-style-type: none">- Person in charge- System- Other
Are there critical points in the documented processes?
Possible answers: <ul style="list-style-type: none">▪ No▪ Yes For instance: _____
Does your organization have a system of continuous improvement?
Possible answers: <ul style="list-style-type: none">▪ No▪ Yes

Table II

With respect to employees and other stakeholders in the companies, such as suppliers and managers, the questions were:

Does a teamwork structure exist in your organization?
Possible answers: <ul style="list-style-type: none">▪ Yes, it exists and it is well developed.▪ Yes, it exists but it requires further development.▪ It practically does not exist.▪ It doesn't exist but we are thinking of developing one.▪ It doesn't exist and we are not thinking of developing one.
In terms of the quality management that you carry out, do you think that employee commitment has:
Possible answers: <ol style="list-style-type: none">1. decreased drastically?2. decreased?3. stayed the same?4. increased?5. increased drastically?
In terms of the quality management that you carry out, do you think that manager satisfaction has:
Possible answers: <ol style="list-style-type: none">1. decreased drastically?2. decreased?3. stayed the same?4. increased?5. increased drastically?
In terms of the quality management that you carry out, do you think that supplier satisfaction has:
Possible answers: <ol style="list-style-type: none">1. decreased drastically?2. decreased?3. stayed the same?4. increased?5. increased drastically?

Table III

Results and discussion.

Motivations and approach to quality

Most of the hotel managers (83%) identify quality with a philosophy that tries to satisfy customer needs. 63% of them identify quality with a method for implementing continuous improvement. And 43% of them think that quality is mainly a method to get everybody in the company involved in the company's objectives.

As for the motivations that drive hotels towards quality management, most of the hotels (80%) pointed out that managing quality was a competitive advantage. 40% of them said that they applied quality management out of conviction. The third (37%) the fourth (20%) most cited motivations were to get more customers and to increase profit.

Figure 1: What hotels understand by quality (percents)
 Motivation is primarily related to results. The purpose of having a competitive advantage is to get more customers or profit. Those managers who applied quality management out of conviction are usually seeking greater efficiency, which leads to an increase in profit as a consequence.

Certifications

43% of the hotels have the Q certification (the Spanish tourist quality certification), 29% have other certifications and 28% of them do not have any certification. Among those that do not have any certification, most of them said that they have a tailored system. They have a quality management system although they don't have any certification.

11% of the hotels have ISO 9000 certification, and all of those have the Q certification as well. As we mentioned above, the Q and ISO 9000 certifications are complementary standards. The same thing is the case with ISO 14000.

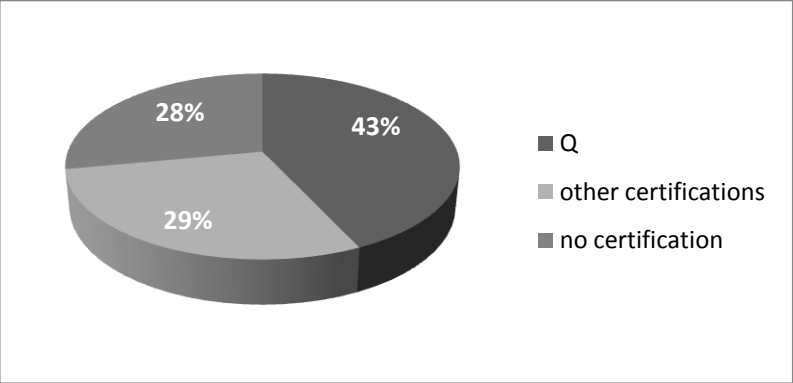

Figure 2: Certifications

74% of the hotels have a continuous improvement system, which means that some of the hotels that are not certified have this kind of system. But it is clear that the hotels that don't have a continuous improvement system are not certified. 96% of those hotels have a formalized suggestion box system, 73% have a method for solving problems and 50% use the 5S methodology.

Most of the hotels surveyed documented their processes with written procedures. 63% of them have documented procedures for the following processes: reception, check-in, check-out, accommodation, cleaning, and maintenance. 34% have one or more of their processes documented, and only 3% have none of their processes documented.

Processes are evaluated periodically. 51% of hotels evaluate their processes through an internal audit, and in 29% of the cases the person in charge carries out the evaluation of processes. 11% evaluate their processes using other methods and, finally 9% of them do not evaluate their processes at all.

Almost half of the hotels declared that they have critical point in their processes. When they were asked to give more details, the recurring idea was that the most critical point is where there is direct connection with customers. How customers feel they have been treated greatly influences their level of satisfaction. This fact is closely linked to the next section.

Employee involvement

60% of the hotels believe that they have a teamwork structure and that it is well developed; 29% report that they have a teamwork structure in place but that it needs further development; 6% think that it practically doesn't exist, 3% said that they don't have a structure but they are thinking about developing one and, finally, 3% respond that they don't have any structure and that they are not thinking about developing one. Most of the cases where there is a teamwork structure that needs further development are hotels that do not have any kind of quality certification.

With regard to employee commitment as a consequence of implementing a quality management system: 48% believe that it has increased, plus another 7% that think that it has greatly increased, and 38% answer that the level of commitment has stayed the same. Only 7% report that employee commitment has decreased.

Manager satisfaction is also affected: 48% of respondents think that levels have increased, and another 3% that think that levels have greatly increased; 45% believe that the manager satisfaction has stayed the same, and only 3% consider that it has decreased.

As for suppliers, none of the hotels believe that supplier satisfaction has decreased. 34% report that it has increased, plus another 7% that think that it has greatly increased. 59% think that the supplier satisfaction levels have stayed the same.

Figure 3: Results regarding the implementation of quality management.

Results

With respect to the results regarding the implementation of quality management in these organizations, the overall impression is that it has been very positive for the company. Regarding customers, 37% of the hotels report that the number of customers has increased, while 55% think that the number has stayed the same and only 6% think that the number of customers has decreased.

When asked about profit, 41% say that profit has increased, another 41% report the same level of profit, and only 17% report a decrease in profit.

The results for customer satisfaction are the most relevant: 66% of respondents think that customer satisfaction has increased, 31% report that it has stayed the same, and only 3% believe that it has decreased.

Overall, 79% of the hotels believe that the quality system has been implemented successfully, as opposed to the 21% who they do not consider it to be successful.

Conclusions

As a general conclusion, we see that the philosophy of quality is extensive in hotels in the Basque Country. Almost 80% (79%) of the hotels surveyed reported that the quality system has been successfully implemented.

The concept of quality that they have is related to customer satisfaction and continuous improvement, whereas the motivation to adopt a quality system is connected to results, which was the most frequently cited motivation for managing quality as a competitive advantage.

The hotels in the Basque Country have a culture of quality management: most of them have a quality system, of which 72% have quality certification. The most popular is Q touristic, the Spanish Trademark for the tourism sector.

The use of a quality management system led to an increase in employee involvement in 55% of the cases. This fact is very important because it is closely related to customer satisfaction. Additionally, 60% of the hotels surveyed have a well developed teamwork structure in place. Increases in manager satisfaction and supplier satisfaction are reported in 51% and 41% of the cases, respectively.

The results of the survey clearly show that hotels consider that having a quality management system in place has led to increases in customers, profit and customer satisfaction. These results are even more significant when we consider that the survey was conducted during a period of economic crisis.

As for research limitations, the first is that the hotels that completed the survey could be those that are committed to quality management. That fact could introduce a bias which makes the situation seem better than it really is. The second limitation is the small size of the sample.

Key words: requirements from methods to method user, individual characteristics, method-selecting in the development process

Category: Conceptual Paper, Research Paper

Introduction and necessity of method selection

In today's global competitive environment, it is essential that companies not only direct their activities towards customer needs but also cope with cost pressure and demands for higher flexibility and individual products and services. By considering the demand of individual products, which comprise more integrated functions in the product, the product, its development process and its production become more and more complex.

For the production of high quality products numerous aspects have to be considered. So, on the one hand requirements of several stakeholders have to be considered and on the other hand, during the whole time period of planning, developing and production, numerous problems have to be solved and the productions has to be proved. Only at coverage of requirements a product can be developed which is accepted by the customers. With regard to the development process these requirements have to be conductively converted to products, that means components and assemblies, which are produced in the following.

For those different processes and sub-processes, which do consequently base on each other, several varied methods can be applied. For instance, within the planning of a new product, different methods for capturing of requirements can be used. In this case, the Conjoint Analysis as well as structured interviews can be named as example.

During the development numerous aspects have to be worked out and numerous problems can be healed. In doing so, practicable solutions for the requirements must be found, which are transferred in the product afterwards. For such a search for solutions, methods of brainstorming or also methods concentrating on conflict solutions like the Theory of Inventive Problem Solving (TRIZ) are capable.

At the following planning and realisation of the products, again various methods can be used which result in a reduction of rejects and costs. For example, the surveillance of

production can be held via SPC. The following figure once again shows those examples with potential applicable methods for each appearing application.

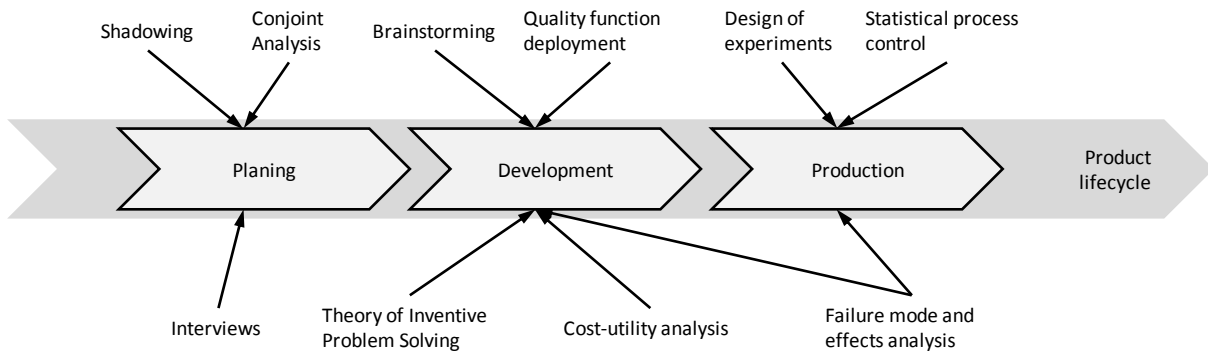

Figure 20: Examples of applicable Methods for planning, development and production process

Figure 1 already shows that for several processes and phases of the product life cycle methods of different sectors can be used. Resulting from this, for each application it has to be determined which method fits best in this situation. For this, numerous criteria can be considered. The chosen method having the aim of requirement collecting, for example, depends on the number of questioned participants. By choosing such a method also the result is inevitably influenced, so that when choosing a non-suitable method either useable results cannot be worked out or additional expenditure is involved in those. Consequently, the choosing of method is a key position when thinking of a reduction of productions time and its involved costs.

In this paper a way of proceeding is presented, which supports the user of methods when choosing methods with reference to several criteria. In doing so, the general approach and the adaption of this procedure to the development process is presented as a possible process. For this, firstly, the main factors involved of the development process are presented, which are considered by several criteria at the actual chose of methods. Finally, the proceeding for comparing the methods is introduced. This process consequently presents the compendium which can or has to be adapted to each considered process, to the problems that have to be dealt and to the involved application of method. Only by identifying the based main factors involved and the criteria deduced from that, a purposeful choose of method can happen.

The developing process and its main factors involved

The VDI-Guideline 2221 (Verein Deutscher Ingenieure 1993) describes the development process by an iterative model considering four main phases and seven steps. There are several additional models which describe the development process (i.e. development process following Pahl and Beitz (Pahl et al. 2006), development process following Ehrlenspiel (Ehrlenspiel 2003) or the Munich process model (Ponn 2007)), but most of them are very similar to the VDI-Guideline 2221. To each of this phases different methods can be assigned, from which many are useable alternatively. Figure 21 shows the Phases and Stages of the VDI-Guideline 2221.

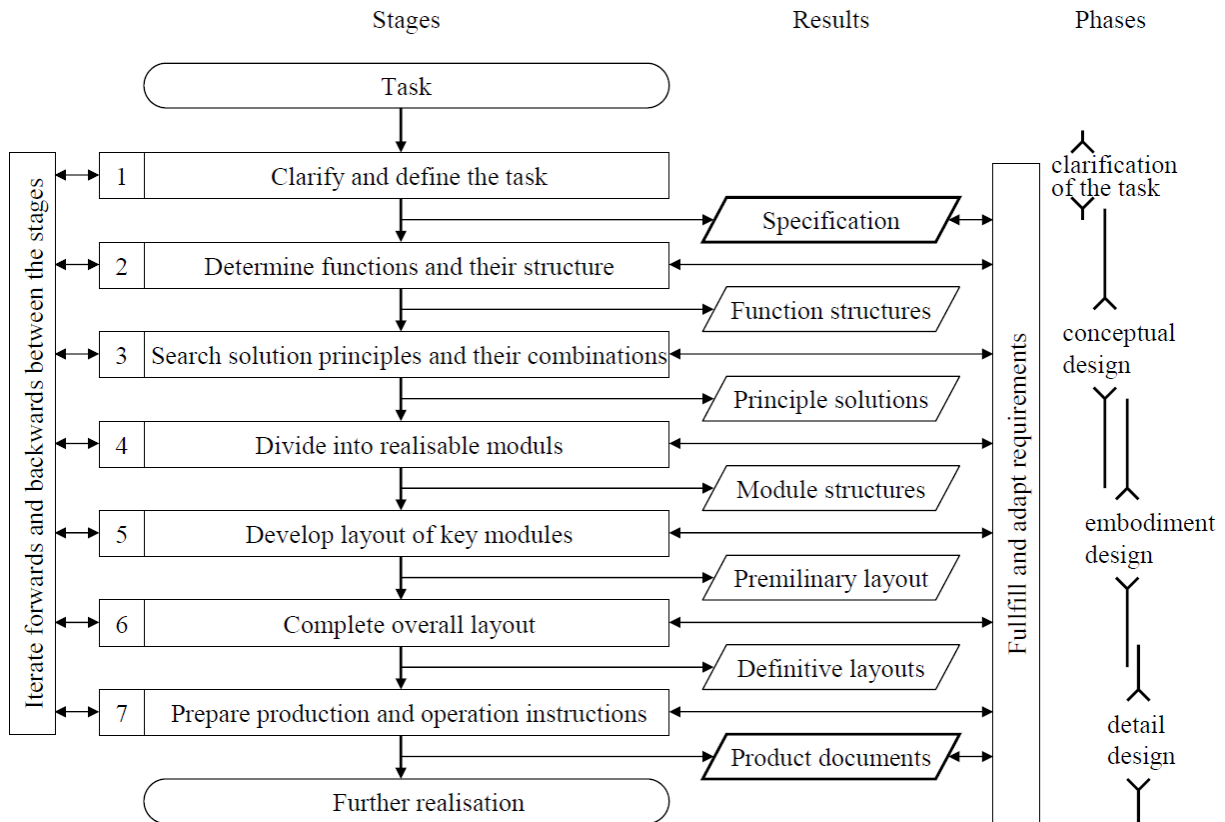

Figure 21: Development process following VDI-Guideline 2221 (Verein Deutscher Ingenieure 1993)

In a first step the scope of task has to be clarified, in which a list of requirements arises. Afterwards, solution neutral functions for the requirements are defined, for which principle solutions are declared in step 3. From this, modular structures are deduced on which base a rough concept is developed. Finally, the definitive layout and the production documentation are worked out.

Following (Günther 1998), there are four main reciprocal influence factors on the development process:

- Framework conditions (planned time for development)
- Product (for example, a car)
- Problem (new solution principles needed, old ones cannot be taken)
- Problem solver (great team of developers, all with different knowledge bases)

As an example, a new car has to be developed. Then the car is the product which influences the development process by, for example, its complexity. There are several problems occurring during the development process, for example, a new solution principle for the motor has to be chosen. Because of the global competitiveness the development process has to be shortened. Thus, time is a framework condition that influences the development process strongly. Therefore several developers are needed, of which everybody has another degree of experience, everyone knows different methods.

For an optimal method-selection the characteristics of the problem as well as information about the developer and the framework conditions have to be considered. There are some models supporting the developer choosing a method, but most of them choose a method considering only characteristics of the occurring development problem as well as information about certain framework conditions. By the lack of considering characteristics of the method-user, i.e. his experience, knowledge and creativity, the results of the used methods are not optimal. Thus there are unnecessary iterations in the development process associated with a waste of time and money. For solving this problem and improving the result of the method selection, a new model has been developed which is described in this paper. By using this model the best fitting methods for creating solutions, combining partial solutions and for evaluating can be chosen and one of them selected. For this, information about the framework conditions and characteristics of the development problem and of the developer will be considered. Furthermore it presents the basic implementation of the developed model for selecting methods in a tool.

Existing models for structuring and selecting a method

If developers want to solve a problem, they can choose from a large number of methods, of which he probably knows only some. There are some existing models for structuring and selecting a method. These models establish a two step approach for selecting a method. The objective of the first step consists of exclusion of completely unsuitable methods. Therefore, commonalities of the methods are identified, thus, clusters of methods can be defined. In some approaches cluster are only defined by the objectives of methods, another approaches analyse methods in detail for clustering them. In the second step, an evaluation of the methods concerning different criteria is done. For example, it is analysed whether a use of a method is better or lesser suited during a phase of the development process. So far, a lot of different rough models for structuring methods have been developed, of which some are presented below.

The VDI-Guideline 2221 implies a rough guide for selecting a method in the previously described two step approach. In the first step of the VDI-Guideline 2221 methods are analysed and structured concerning their object which is shown in Figure 22.

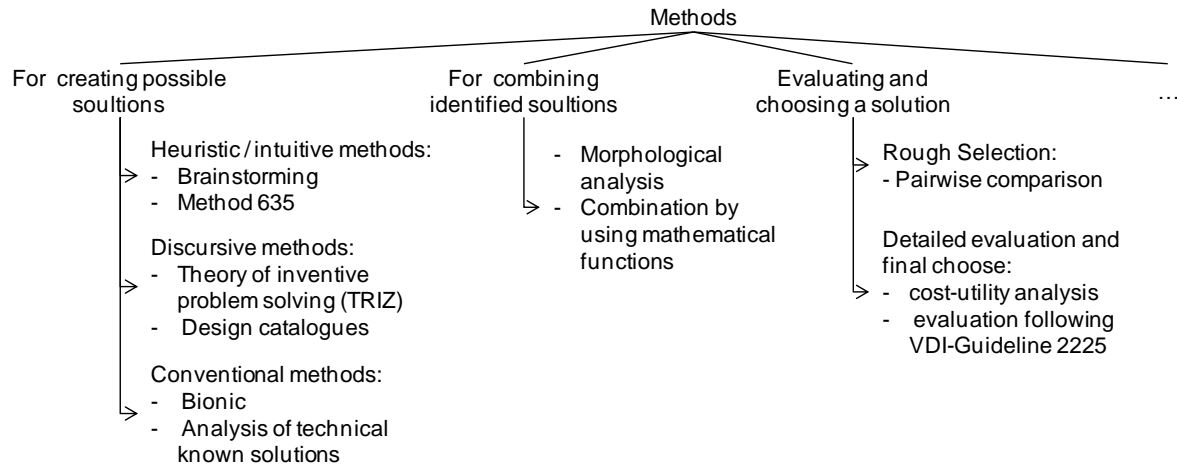

Figure 22: Rough structure of development methods following VDI 2221

For example, it will be differentiated between methods for creating possible solution ideas and methods for evaluating these solutions and choosing one of them. Because there are numerous methods for creating possible solution ideas, there is another differentiation by the Guideline which distinguishes between heuristic methods, also known as intuitive methods, discursive methods and conventional methods. Heuristic methods mainly base on creativity and on a sudden idea for solving the problem. Examples for this approach are the classical Brainstorming and Method 635. Discursive methods are characterized by a deliberate step by step process, which can be communicated and followed easily. Therefore, the problem is analyzed and divided into several smaller parts. Examples for this approach are TRIZ and the use of design catalogues. Conventional methods try to identify new solutions by analysing and adapting existing solutions. Hereby, existing technical as well as natural examples are studied. Examples therefore are Bionics and analyse of known technical solutions (Verein Deutscher Ingenieure 1993, Pahl 2006).

The second group consists of methods which are used to combine identified partial solutions to one overall concept. One example for this group is the systematic combination of the partial solutions like it is done at the morphological analysis. Another example is the combination using mathematical functions (Verein Deutscher Ingenieure 1993, Pahl 2006).

In the last group there are methods, which are used either for a rough selection of solutions or for a detailed evaluation followed by the selection of the methods. It is the objective of the rough selection to exclude unsuitable solutions and therefore to reduce the number of solutions which have to be evaluated. Hereby, the pairwise comparison is one possible method. The remaining solutions have to be evaluated, thus a final solution can be selected. This may be done by the cost-utility analysis or by the evaluation method following VDI-Guideline 2225 (Verein Deutscher Ingenieure 1993, Pahl 2006).

In the second step, the methods are analysed in respect of their suitability during each of the seven phases. These methods are differentiated in suitable, limited suitable and not suitable ones. (Verein Deutscher Ingenieure 1993).

Strasser as well as Ponn analysed existing models including the previously described one and came to the conclusion, that the selection process of a method is not optimally

supported. Based on the previously described approach better suited models have been created (Strasser 2004, Ponn 2007): Firstly, Strasser analysed the methods more detailed and created a profile of each method, which includes its most important characteristics (i.e. Ability of a method raising the degree of innovation, Ability of a method expanding or diverging the solution space), thus suited clusters of methods can be defined. Furthermore, he developed a detailed checklist for analysing the development problem, which helps to preselect a cluster of possible methods. Thus a method is selected based on the comparison of problem and the profiles of the methods (Strasser 2004).

Based on the previously described two step approach Ponn developed a modularised process of selection of a method. Therefore he identified several process components as well as their input and output based on the Munich procedure model. Subsequently, the methods are described by profiles developed by him. Additionally, these methods are assigned to the different phases of the development process as well as to the process components. In this model a method is selected based on the characteristics of the problem which are used for determining the process components and detailed method characteristics (Ponn 2007).

Although the developer affects the development process and hence also the developed product, none of the previously described models consider the developer characteristics. Thus, another model for selecting the methods, which additionally considers the developer and its personal characteristics, has to be developed. Thereby, the structure of the VDI-Guideline 2221 will be used in the new developed model. Hereby, the most unsuitable methods can be excluded at an early stage and will not be compared in detail.

Created Model for selecting development methods

Developing is a process in which several problems considering a great number of requirements have to be solved (Pahl et al. 2007). Before a problem can be solved, based on the identification and definition of the problem suitable methods can be selected.

The developed model bases on the following three theses:

- By considering the degree of novelty development problems can be distinguished into original designs, adaptive designs and variant designs. Original designs are designs, where new problems are solved by using new solution principles or new combinations of known solutions principles. The solution principle remains unchanged at adaptive designs, only the embodiment is adapted to new requirements. Variant designs describe a development process in which only the sizes and arrangements of parts and assemblies are varied (Pahl et al. 2007).
- The developer often has to change used methods. Main criterias for selecting a method are the situation of the development process and its individual characteristics.
- Because of the lack of information about weightings of different individual characteristics at the beginning, the weighting factors of all used characteristics of individual and of the situation were set equally.

Although adaptive and variant designs are the most common ones, there are specific parts in each design which have to be developed newly (VDI 2222), for example, the interfaces of a variant design has to be changed or an alternative solution principle has to be selected.

Considering the interactions on the development process, already shown, as well as the theses, described previously, individual characteristics, criteria of framework conditions and the situation of development are considered in the developed model and illustrated in Figure 23.

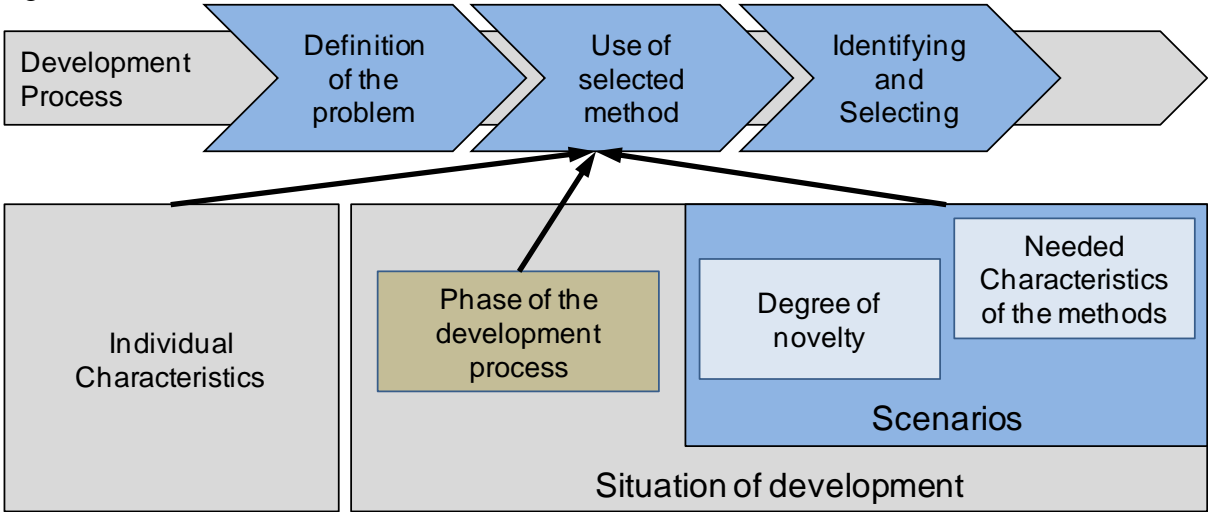

Figure 23: Considered Influence on the process of selection

The situation of development is an objective description of the occurring problem, for which a method is needed. It includes among other things the moment of the development process allocated following VDI-Guideline 2221 to one phase of the development process as well as the type of design considering their degree of novelty. Thus, based on the situation of the development situation needed characteristics of the methods can be identified, i.e. methods which are needed for creating possible solution ideas. Additionally, these ones should be useable with low effort and without a team.

In this new approach the needed characteristics of the methods and the type of design are combined as scenarios. These scenarios describe typical situations of the development process, which can occur more than once at various points of time. Furthermore, the individual characteristics of the developer as method user have to be taken into account. Hereby, for example, his ability to work in a team and his creativity are respected in the selection process of the new developed approach.

The new developed model of this paper bases on the general two step approach like the ones previously described. Thereby, in the first step methods are pre-structured for excluding the unsuitable ones and thus limiting the number of methods, which has to be analyzed and compared in detail. After that in the second step the actually evaluating is done by considering characteristics of the problem as well as of the developer.

The identified scenarios are presented at chapter 0; chapter 0 presents examples of individual characteristics and given models of ergonomics for structuring them. The process of analysing the methods in detail followed by the selection process is described in chapter 0.

Scenarios and needed characteristics of methods

Considering the individual characteristics as a criterion for selecting a method is important, but without considering the situation the results are not optimal. Therefore, a developer would have to analyse the development situation and derive needed method characteristics from it. Strasser developed a model for analysing the situation by using an extensive checklist. Although, this is a very powerful tool, its use is combined with high effort, thus it is not possible using it practically each time a method is selected during the development process. For reducing this effort and developing models which can be used every time a method is selected, scenarios are defined which describe typical, often recurring situations of the development process.

By analysing the properties of these scenarios and their framework conditions, several criteria can be identified for the detection of suitable methods. Afterwards, the needed degree of fulfilment concerning each criterion can be defined. By analysing the methods with regard to each of the criteria one dimension for selecting a method is available. Table VIII shows three examples of such scenarios of which the first one is described subsequently.

One possible scenario describes the case of an occurring emergency, for example, the recall of a product at which a change of the solution principle is needed. Thereby a functional solution principle for the problem has to be found very fast. This means for switching the solution principle methods are needed which can be used, for example, with low effort for preparation and execution. Additionally, the chance of getting a suitable alternatively usable solution principle should be high.

Scenarios	Needed characteristics of the methods and their needed degree of fulfilment		
	Effort for execution	Effort for preparation	Chance of getting suitable results
Emergency	low	average	high
Driver of Innovations	average	average	low
Rationalisation	high	high	average

Table VIII: Link of method characteristics and defined scenarios

Individual characteristics and given structure of ergonomics

There are some research projects in which several individual characteristics that are needed for successful developing have been identified. Two of them are presented subsequently.

For example, Dylla investigated the individual development process of ten participants by a given development problem. The development process of 6 participants has been analysed in detail. Hereby, Dylla identified among other things the methodological skills, the knowledge of the developer and the competence of drawing of the participants (Dylla 1990).

Jänsch analysed the occurring problems of the introduction of new methods and identified appearing weak points. Based on this, she developed a new model for developing and introducing methods. Therefore, Jänsch summarized the results of given research projects that identified several important factors as the abilities and knowledge of developers (Jänsch 2007).

These identified abilities and knowledge can be structured based on findings of ergonomics, illustrated in Figure 24. The working performance depends on his work capacity as well as on his readiness to work. Thereby, the work capacity describes the theoretical possible performance someone can provide, thus it is a measure for the theoretical maximum performance. The readiness to work describes the readiness to bring this performance (BAuA 2007, Günther & Tempelmeier 2004).

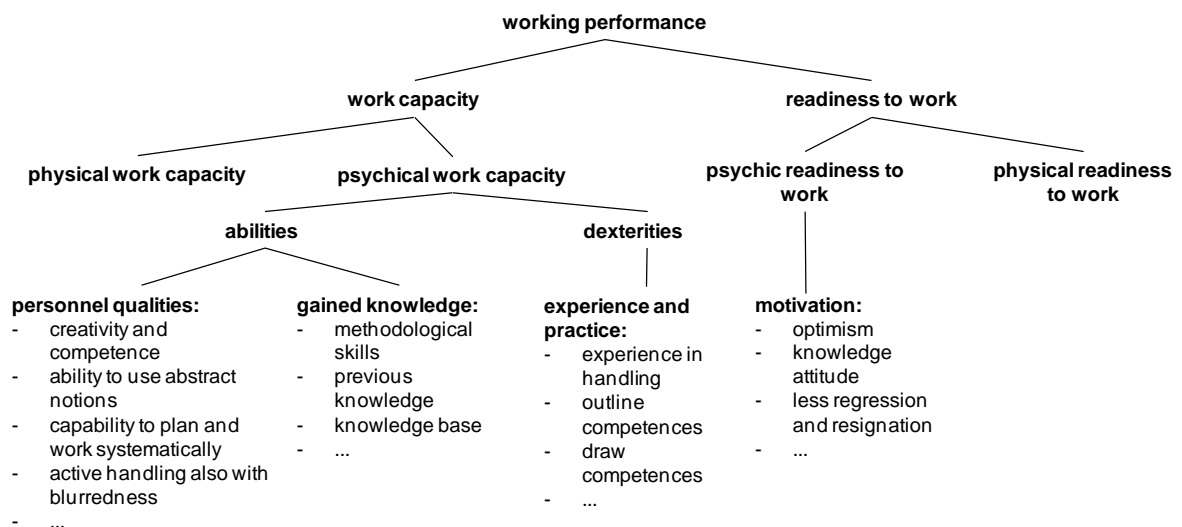

Figure 24: Structure of personal characteristics following (BAuA 2007, Günther & Tempelmeier 2004)

The work capacity can be distinguished between physical and psychical components. Examples for the physical work capacity are mobility or endurance. The psychical component implies the individual characteristics and basic skills as well as the knowledge he gained. Because of the mainly intellectual character of the development process as well as of used methods, only the psychological capacity for work is considered (BAuA 2007, Günther & Tempelmeier, 2004).

This can be further subdivided into the abilities and the dexterities. On the one hand the abilities contain personal qualities like creativity or ability to use abstract notations and on the other hand the gained knowledge, i.e. methodological skills. The dexterities describe the degree of practise and experience. Experience in handling and the competence of drawing

are examples for dexterities needed by developers (BAuA 2007, Günther & Tempelmeier, 2004).

The readiness to work can be distinguished into a physical and a psychical component, too. Thereby, the term physical readiness to work is understood to describe, for example, the daily rhythm as well as sign of fatigue. Because of the individuality of these criteria and the need of collecting this information every day, it is not possible to gather this information practically. In consequence, the physical readiness to work is not considered in the developed model.

The psychological readiness to work is a direct measure for the motivation of the user which is directly affected by his mental and physical wellness. Although the motivation affects the working performance, because of its great dependence on the situation and the problem, it is not an individual characteristic which has to be solved. For example, a developer can be highly motivated to solve a single problem, but no other one. Additionally, his motivation can be influenced by tangibles stimuli, i.e. his wage, and intangibles stimuli like a promotion or he is praised by his superior member (BAuA 2007, Günther & Tempelmeier, 2004). Because of the problem of measuring the motivation and each influence, it is not possible to consider the motivation practically in the developed model.

Most of the individual characteristics consisting of the abilities and the dexterities can be measured by known methods and techniques of psychology. The ability to work in a team, creativity, sense of responsibility, power of judgment and flexibility are already recorded and evaluated during assessment centres using standardized questionnaire and tests (GGP 2007, Florysak 2006).

Detailed analysis of methods realizing the selection process

For analysing the methods the pairwise comparison of the methods concerning each criterion is used. Thereby, the pairwise comparison has the advantage, that it can be used to derive a ranking of methods for each criterion without having knowledge about the maximum or minimum of a criterion. Additionally, another advantage of the pairwise comparison is its ability to work without quantitative information. Some characteristics of the individuals and of the situation can be measured using quantitative scales but most of them can be measured only using qualitative scales, hence, their evaluation implies several uncertainty [Ponn 2007].

In the following Table IX the pairwise comparison is presented. Thereby, for each criterion an individual pairwise comparison has to be compiled. Because of its importance for further selection process, this work has to be done by experts concerning the analysed methods.

This form of pairwise comparison only allows a statement if a method is estimated to be higher or lower than another method concerning a single criterion. Thereby, a 2 in the matrix defines, that the method on the row is better than the method on the column, a 0 implies the method of the row is lower than the method of the column. If a 1 is selected, the methods are evaluated equally.

Pairwise Comparison of Methods concerning an individual or a method characteristic		Methods				Sum of line	Normalized sum of line
		A	B	C	D		
Methods	A	x	0	0	2	2	0,33
	B	2	x	1	2	5	0,83
	C	2	1	x	1	4	0,67
	D	0	0	1	x	1	0,17

Table IX: Pairwise comparison of the methods

Subsequently, the sum of each line is calculated and normalised by the possible maximum sum of a line, hence, a ranking of the methods can be specified. Although, it seems to be possible to achieve an exact ranking, the results of the pairwise comparison contain some errors, because of occurring errors during measuring as well as errors of the pairwise comparison itself. Thus, clusters of methods based on their ranking concerning each single criterion are defined. At first, three clusters are defined by dividing the scale of the normalised sum of line into three. Subsequently, these limits were rounded, hence, the “high”-cluster includes all methods those normalized sum line is greater than 0.7. The “low”-cluster includes methods those values are lesser than 0.3.

For example, if the pairwise comparison of Table IX would present the comparison concerning the needed creativity, method B belongs to the group of methods that needs a high amount of creativity (highlighted in red). Methods A and C belong to the same group of methods needing an average amount, although method C needs less than A (highlighted in yellow). Method D needs only a minimum of it (highlighted in green). The result of the pairwise comparison and the ranking is summarized in Figure 25.

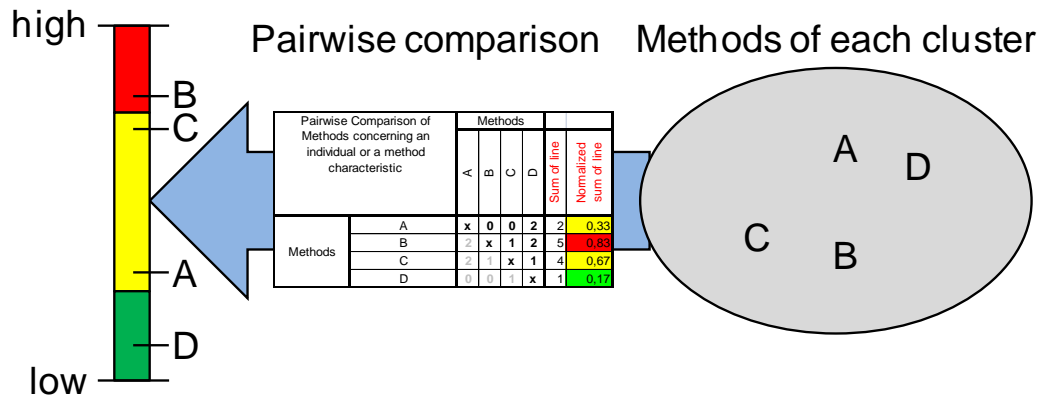

Figure 25: Clustering of methods concerning their results of the pairwise comparison

By using these exact limits for clustering, methods with a normalized sum line in proximity to one of these limits could be easily grouped to the wrong cluster. Using the example of Table IX, if method A would be evaluated being equal to method C, instead of being a member of the “average”-cluster A would be a member of the “low”-cluster (normalized sum line would be 0.17), thus, a change of only one pair of elements of the

pairwise comparison could switch a method from one cluster to another one. For solving this problem transient areas (limit ± 0.05) are defined. A method with a value insight the defined transition area is assigned to the main cluster considering its exact normalized sum line as well as to the other cluster with reservation is highlighted in squared brackets. Using the example of Table IX the methods A and C each are assigned to two clusters, presented in Table X.

		Methods
Criterion	high	B, [C]
	average	A, C
	low	[A], D

Table X: Clusters of methods

Concerning some characteristics of the individuals or situations, it is not meaningful to define three clusters, because of its binary type of decision. For example, a method can be used meaningfully during one or more phases of the development process. It only has to be decided if the method meaningfully is useable during each phase or not. This decision has to be made for each phase of the development process.

Selection process by using the defined clusters

Finally, the process of selection itself will be presented. Therefore, on the one hand the clusters of the methods as well as the identified characteristics of the methods and individuals are used. Experts have to identify these suitable characteristics as well as they have to evaluate the pairwise comparisons. Additionally, on the other hand information about the developer, his grade of each individual characteristic as well as his description of the development situation have to be collected and ranked using the same tripartite scale.

During the process of evaluating and selecting a method, the results of this survey of the developer as well as the results of the clusters are compared. Figure 26 presents this process that is subsequently described in detail.

For example, the developer states that the current development process is in the phase of the conceptual design. Furthermore, he states his own degree of an individual characteristic (i.e. his own creativity) to be low and another individual characteristic (i.e. his ability to work in a team) to be high. These results of the survey are highlighted in black at Figure 26.

After finishing the survey about the individual characteristics and the development situation, at first, it will be checked, whether a method can be used in the stated phase, e.g. the phase of “conceptual design”. Next, the results of the methods are compared with the statements of the developer concerning each individual characteristic. For example, a method A (highlighted in green) only needs a low degree of individual characteristic A and a high degree of individual characteristic B. Instead of this, method B demand a high degree, the individual characteristic A and an average degree of individual characteristic B.

Thus, the degree of conformity can be calculated for both methods. The calculated degree of conformity of Method A is 100%, the one of method B only 33%. Therefore, method A is a better choice for being used by the developer in the development situation. By calculating this degree of conformity, best suited methods can be selected and furthermore, it can be estimated, how well suited they are.

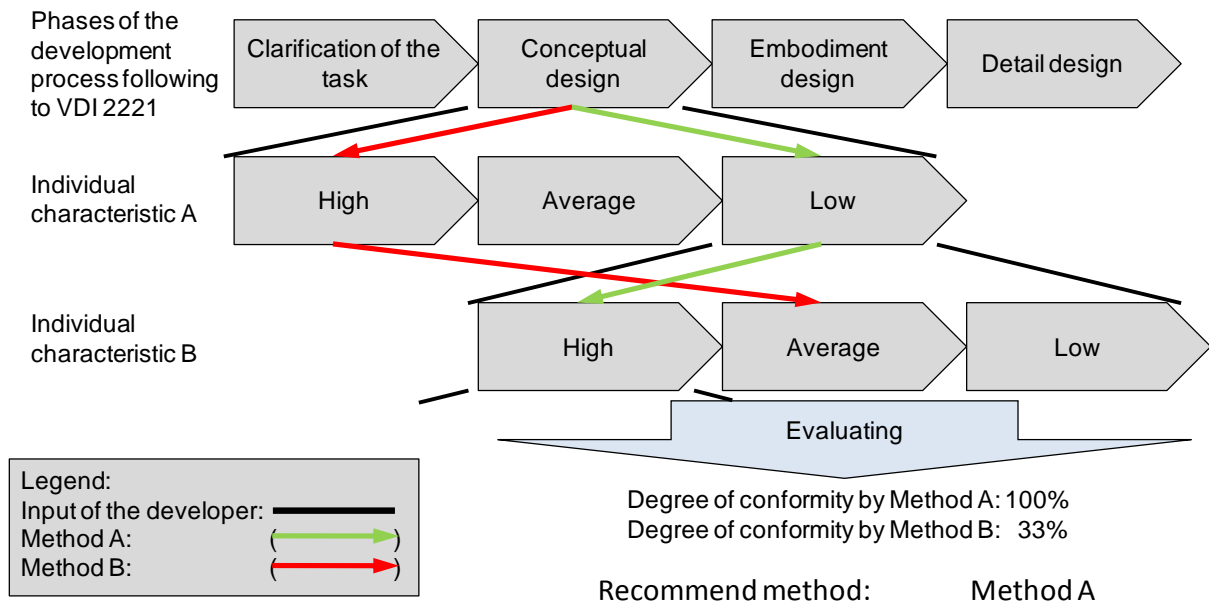

Figure 26: Process of Selection in the developed model

First evaluation of the model with a selection of methods

There are 21 criteria which are used for the first evaluation of the new developed approach to select suitable methods. Thereby, eight of them represent necessary characteristics of methods, e.g. suitability of the method to use it without a team or effort needed executing the method. Additionally, there are 13 individual characteristics (e.g. creativity, spatial sense, ability to work in a team).

As a result there are some criteria, which present the same aspect of different perspectives, first from the point of view of the method and its properties, secondly of the personal characteristics needed for the use. As an example, criteria “Team size” and “Ability to work in a team” can be mentioned. Necessity of a team for the successful use of methods is classified by the aspect of the team size. On the other side the ability to work in a team is a degree for the developer’s ability to work with other persons in one group. The criteria “Systematization level” and “Capability to plan and work systematically” are another example. On the basis of the development process situation, it may be necessary to choose methods with a high level of systematization. Otherwise, individual capability to plan and work systematically reflects the aspect of personality characteristics. In this connection a high tendency to plan and work systematically means that degree of systematization of the method should be lower. The developer can otherwise be pressurized to resign his own systematic in favor of the method systematic. Somebody who works and plans chaotically needs a support by systematical approach.

In contrast to the procedure of an assessment centres the characteristics are for this first evaluation collected by a self-assessment of the user in this approach. This means, the user will be asked how he estimates his own creativity, for example. Hereby, the developer estimates each individual characteristic by the same tripartite scale that is used for ranking and clustering the methods, thus a direct comparison as shown in chapter 0 is possible.

The developed Excel-Tool for evaluating this model is useful to implement the pair-wise comparison, which can automatically derive the ranking of methods and helps to detect properties of each characteristic. In contrast to the procedure of an assessment centres the characteristics are collected for this first evaluation by a self-assessment of the user in this approach. This means, the user will be asked, how he estimates his own creativity, for example. Hereby, the developer estimates each individual characteristic by the same tripartite scale that is used for ranking and clustering the methods, thus a direct comparison as shown in chapter 0 is possible.

On the one hand, the following Tables Table XI, Table XII as well as Figure 27 present the results of pair-wise comparisons of the methods for creating possible solution ideas and also the ranking of the methods which is derived from the comparisons. Additionally an excerpt of the developed Excel-Tool for the detection of personal characteristics and development situation is presented.

Table XI illustrates the pair-wise comparison matrix for the individual characteristic “Creativity”. Methods for creating possible solution ideas are compared with each other concerning their creativity, which is needed for the successful use of methods. As a result, the heuristic / intuitive methods might need more creativity than discursive or conventional ones.

Analysed criteria: Creativity				Methods															
				creating possible solution ideas															
				heuristic / intuitive						discursive				conventional					
				Brainstorming	Gallery method	635 Method	Delphi method	Six thinking hats	Disney creativity strategy	systematical analysis of physical correlations	classification schemes	Design catalogues	Theory of Inventive Problem Solving (TRIZ)	Literature research	Bionic	Analysis of known technical systems	Pilot schemes	Sum of line	Normalized som of line

Please evaluate your own spatial imagination (Please mark only one field with a "x").		x	
Are you personally characterized by creativity? (Please mark only one field with a "x")	x		
Are you experienced in using methods? (Please mark only one field with a "x")	x		
			Number of accordances between your statements and the analysis of methods (max. 20 possible)
Auswertung Here are the best suited methods presented	Synectic, Triz, Bionic		13
Here are additional restriction of the methods presented. Some of these restrictions are very special, others are very general.	- For using bionic as a method, natural system which can be used for it, must exist and have to be known		

Figure 27: Extract of the Questionnaire for selecting a method for creating possible solutions

Summary

Following the development process, among others, developers have to solve a lot of problems. Many of these problems cannot be solved immediately; hence, one or more methods have to be used for solving them. For many types of problems, there are several

useable methods, thus, the developer has to select one of them. Therefore, the developer has to be supported by a guide, for example. Many models, which have been developed, support the developer by selecting a method by the consideration of the development problem. For this a more or less detailed guide and a questionnaire were developed. By neglecting individual characteristics for the process of selecting a method, the optimal method cannot be chosen, thus, the influence of the problem solver to the problem will not be considered. Hereby, the result either of the method selection are not optimal or there is a waste of time reaching them. Therefore, this paper improves these models by proposing the use of individual characteristics as another dimension for selecting a method. Hereby, a better support for selecting a method is being ensured.

A first verification of the developed model had been performed. Therefore, the selection process has been tested by using 22 methods for creating possible solution ideas, combining identified solutions and for evaluating and choosing a solution. For the consideration of individual characteristics, 13 of them were identified and are considered. Additionally, eight method characteristics are identified and used for characterizing the problem. The identified characteristics of the problem and the developer are surveyed by a questionnaire as a part of a developed tool.

Even though in this paper only the way of proceeding was presented and adapted to the development process. This proceeding can also be used in other sectors after it has been adapted. For that the main factors involved as well as the appropriate criteria have to be worked out. Afterwards, this proceeding can be used for all divisions of a company leading methods with various aims. In this way, a further reduction of costs for extra work or rather iterations and its costs involved can be achieved.

Introduction

The periodic health examination (PHE) plays an important role in the preventive health care service. The research provided by Lin et al. (2011) indicates the significant effectiveness and value of periodic health examinations which can promote early treatment of the major and manageable diseases such as hypertension, diabetes and hyperlipidemia. Lin et al. (2010) showed that the health examination data of the middle-aged Taiwanese employees can be efficiently applied to predict the metabolic syndrome development. Chang et al. (2010) indicated that the PHE is an important health promotion strategy. Earlier diagnosis and treatment of manageable diseases are the main purposes of PHE and the stepping stone to achieving good disease control. It can be seen from literature that, by means of the PHE, the preventive health service can provide main functions, such as risk assessment by disease screening and prediction, laboratory testing, and health counseling. Therefore, the periodic health examination can act as a link between the patient and the health care system.

According to the research of O'Connor et al. (1988) and Rashid and Jusoff (2009), the service quality in health care can be categorized into three aspects: service elusiveness, employee diversity, and interrelatedness. In health sector, it is not easy for consumers to understand the essence of health service products in their mind. It is because of intangibility nature of the service or service elusiveness. The provider can help consumers to understand the quality of a specific service by manipulating the tangible aspects. For the phase of employee diversity, discretion is widespread in health care because of the highly customized and judgmental nature of the service. For the phase of interrelatedness, educating patients about the use of particular service helps them understand the service, making them alert in the consumption, and improving their perceptions of a service. According to the evidence report of investigating the value of the periodic health evaluation

which is conducted by the Johns Hopkins University (2006), the periodic health evaluation could have an effect on more proximal outcomes, thus potentially leading to improvements in patients' quality of life. The report also indicated that the patient-physician relationship is important in affecting patient satisfaction, adherence to clinical recommendations, and receipt of appropriate clinical counseling and care. Based on the above concepts and evidences, the service quality of PHE can be improved if PHE provides good services such as accurate predication in identifying diseases or conditions at an early stage and thus helps postpone the development of subsequent adverse outcomes.

As Bureau of National Health Insurance (NHI) of Taiwan initiated a free preventive care service program (usually called health examination) in 1996 for adults with age over 40, the adult PHE started receiving attention by the public of Taiwan in recent years. However, Chang et al. (2010) presented that the utilization rate of PHE by the elderly in Taiwan was less than 50%. They concluded that further promotion of preventive health services in Taiwan is necessary. As shown in the literature (Borders et al. 2003), service quality can affect people's willingness in receiving health examination. Borders et al. (2003) demonstrated that the strategies of improving the quality in medical care service would lead to the increases in the chances of women receiving a clinical breast examination.

One of the purposes of this research is to provide a model for predicting diseases with high accuracy so that the PHE provider can improve the service quality of the patient-physician relationship by offering better health counseling and risk assessment. Once the quality in the preventive health service is improved, it would be possible to increase the utilization rate of the PHE.

Colon cancer is one of the most common malignancies which is accounting for over a million new cases and about 500,000 deaths per year worldwide. It is the third leading cause of cancer mortality in both genders in Taiwan. Accumulating evidence has indicated that the early detection and removal of colorectal adenomas greatly reduces the mortality and incidence of colorectal cancer. Reliable detection and resection of colorectal neoplasia before they become malignant is the underlying principle for colorectal cancer screening. By way of modern techniques such as chromoendoscopy, magnifying endoscopy and narrow band imaging, improvement of diagnostic accuracy of colonoscopy examination can be achieved. However, the utilization rate of colon cancer screening through the colonoscopy examination in Taiwan is less than 20% (Tseng, Lee and Wu 2009). This is due to the colonoscopy examination is an invasive procedure which will affect people's willingness in receiving this examination. Most of the colon cancer literature has focused on the study of the screening, diagnosis and treatment of this cancer. Not much research can be found in the prediction of the incidence of the colon cancer. Therefore, another purpose of this research is to provide a good predicted outcome for the incidence of the colon cancer which would be helpful in promoting people to receive the colonoscopy examination as they have received the preventive health examination.

Data mining is the collection of methods which offers methodological and technical solutions to find hidden patterns, trends and relationships in data. Over the last several years, data mining tools have been widely applied in dealing with the analysis of medical data and the development of prediction models to assist in disease diagnosis and in the

choice of treatment. Bellazzi and Zupan (2008) presented a review paper to discuss the scope and role of the research area of predictive data mining and to propose a framework and guideline for constructing, assessing and exploiting data mining models in clinical medicine. Chou et al. (2004) presented a hybrid breast cancer diagnostic model by integrating artificial neural networks and multivariate adaptive regression splines. Some other examples of the breast cancer prediction are provided by Ryu, Chandrasekaran and Jacob (2007) and Jonsdottir et al. (2008). Kurt et al. (2008) applied logistic regression, classification and regression tree, and neural networks methods in prediction coronary artery disease and presented the comparison of the performances of each prediction method. Chang, Wang and Jiang (2011) proposed a two-stage analysis procedure with six data mining techniques to simultaneously predict hypertension and hyperlipidemia by the common risk factors.

Hence, in this paper, based on the data of the preventive health examination and data mining methodology, we present a systematic approach for (1) finding the risk factors which are highly associated to the presence of the colon cancer; and then (2) predicting the risk of contracting the colon cancer using the obtained risk factors.

Methodology

In this paper, we proposed a systematic approach which applies the data mining methodology to predict the risk of contracting the colon cancer. This systematic approach has two-stages data analysis procedure: (1) finding the risk factors; (2) developing the predictive outcome model.

Data sources

A retrospective cohort analysis was performed with 342 adult subjects (with age from 25 to 81) who had received both preventive health examination and the colonoscopy examination at a medical center of central Taiwan in 2008. The components of the physical health examination (with 60 examined items, including assessment of blood pressure, height, weight, pulse, and examination of breasts, cardiovascular system, pulmonary system, abdominal region, neurological system, gynecological or urological systems, and etc.) are the independent variables (i.e., the predictor variables). The result of the colonoscopy examination is the dependent variable, which is classified as abnormal (with the suspected malignant neoplastic lesions) and normal (without any neoplastic lesions).

The First Stage: Finding the risk factors

According to the literature of data mining in medical applications (Jonsdottir et al. 2008), when the choice of attributes (or the input features) is too large, a great effort is usually devoted to reducing the number of attributes. Since the physical examination for each subject consists of 60 attributes (which are the independent variables), it would be appropriate to apply data mining and/or statistical methodologies to reduce the number of the attributes to find the important attributes as the risk factors for predicting the incidence of the colon cancer. In the first stage, we use the logistic regression analysis and the discriminant analysis methods to obtain the risk factors.

The Logistic Regression Analysis method

Logistic regression analysis (LRA) extends the statistical methods of multiple regression analysis to the situations where the outcome variable is categorical. When constructing the logistic regression function, the maximum-likelihood ratio was used to determine the statistical significance of the variables (Hosmer and Lemeshow 2000). The model for logistic regression analysis assumes that the outcome variable, Y , is categorical, but LRA does not model this outcome variable directly. Rather, LRA is based on probabilities associated with the values of Y where $Y=1$ represents the subject constructing the colon cancer and $Y=0$ otherwise. The conditional probability of having the colon cancer is given by $P(Y=1|\mathbf{X}) = \pi(\mathbf{X})$ where $\mathbf{X} = (x_1, x_2, \dots, x_p)$ represents the vector of p independent variables (which stand for the risk factors in this study) selected by the logistic regression approach. The LRA model for p risk factors can be expressed as

$$\ln\left(\frac{\pi(\mathbf{X})}{1-\pi(\mathbf{X})}\right) = \beta_0 + \beta_1 x_1 + \dots + \beta_p x_p$$

where $\beta_0, \beta_1, \dots, \beta_p$, are the regression coefficients.

The forward stepwise method is used to increase the significance (with p value < 0.05) of the risk factors and to calculate the correct classification rate. Then, a logistic regression model with the best correct predictive rate can be obtained, and the indicators obtained in this model are the risk factors of the colon cancer. In this research, SPSS statistical software is used to perform the LRA. Among the 60 examined items, 18 items are significant to the outcome (dependent) variable Y and are denoted as the risk factors. Table I lists the selected risk factors with the p -value shown in the parentheses.

Table I. The Risk Factors selected from the Logistic Regression Analysis Method

1. Age (0.0438)	2. Weight (0.0047)	3. Diastolic blood pressure (DBP) (0.0019)	4. Fat rate (0.0321)
5. Platelet count (0.0068)	6. Neutrophil (0.0068)	7. lymphocyte (0.0071)	8. monocyte (0.0074)
9. Eosinophil(Eos) (0.0061)	10. Erythrocyte sedimentation rate (ESR) (0.0453)		
11. beta-oxybutyric acid test urine specific (0.0351)	12. gravity (0.0253)	13. Urine occult blood (0.0140)	
14. Homocysteine (0.0310)	15. Fasting plasma glucose (0.0251)	16) Alkaline Phosphatase (Alk-p) (0.0020)	
17. Blood Urea Nitrogen (BUN) (0.0170)	18. hemorrhoids (0.0001)		

The Discriminant Analysis method

In this study, the discriminant analysis (DA) is also applied to find the risk factors. The model is built based on a set of observations where the classes (or categories) of the outcome are known. Noted that the outcome in this study is the dependent variable Y defined in the LRA method. The initial set of observations is referred as the training set.

Based on the training set, the DA method builds a set of linear functions (called the discriminant functions) for the predictors shown as following

$$Y = \beta_0 + \beta_1 X_1 + \dots + \beta_p X_p$$

These discriminant functions can then be used to predict the classes of outcome for a new observation with an unknown class. In this study, there are two classes of outcome (normal and abnormal) from the colonoscopy examination. Each new observation is evaluated by these discriminant functions and is assigned to the class with the highest value of the discriminant function. Finally, the decisive function is obtained with the X_i having significant weight β_i , where $i = 1, 2, \dots, k$ and $k < p$, as the risk factors for the colon cancer. The established model is implemented by SPSS statistical software. There are 37 examined items are significant to the outcome variable Y . Table II lists the selected risk factors with the p -value shown in the parentheses. Obviously, the number of the risk factors selected by using the DA method is much more than by using the LRA method.

Table II. The Risk Factors selected from the Discriminant Analysis Method

1. Age ($<10^{-5}$)	2. Height (<0.0001)	3. Weight ($<10^{-5}$)	4. Waistline ($<10^{-6}$)
5. systolic blood pressure (SBP) ($<10^{-6}$)	6. Diastolic blood pressure (DBP) ($<10^{-6}$)	7. Fat rate (0.0208)	
8. Body mass index (BMI) (0.0035)	9. erythrocytes ($<10^{-6}$)	10. Hemoglobin ($<10^{-6}$)	
11. Hematocrit ($<10^{-6}$)	12. Mean cell volume (MCV) (0.0416)	13. Mean cell hemoglobin (MCH) (0.02460)	
14. Mean cell hemoglobin concentration (MCHC) (0.0449)	15. Platelet count (0.0110)		
16. Erythrocyte sedimentation rate (ESR) (0.0022)	17. Urine occult blood (0.0345)		
18. Urobilinogen (UBG) (0.0216)	19. Alpha fetoprotein (AFP) (0.0064)		
20. Carcinoembryonic antigen (CEA) (0.0014)	21. Homocysteine (0.0001)		
22. Fasting plasma glucose (0.0047)	23. Albumin (0.0421)	24. Albumin Globulin (A/G) Ratio (0.0031)	
25. Direct bilirubin (BC) (0.0077)	26. Total bilirubin (0.0269)		
27. Glutamic Oxaloacetic Transaminase (GOT) (0.0049)	28. Glutamic Pyruvic Transaminase (GPT) (0.0106)		
29. r-Glutamyl Transpeptidase (r-GT) (0.0066)	30. Alkaline Phosphatase (Alk-p) (<0.0001)		
31. High-density lipoprotein cholesterol (HDL-C) (0.0001)			
32. Low-density lipoprotein cholesterol (LDL-C) (0.0144)			
33. Total cholesterol /HDL cholesterol (TC/HDL) ratio (<0.0001)	34. Triglyceride (TG) (0.0001)		
35. Uric acid (<0.00001)	36. Ferritin (<0.0001)	37. hemorrhoids ($<10^{-6}$)	

The Second Stage: Developing the predictive outcome model

In the second stage, the methods of artificial neural networks (ANNs) is applied to develop a predictive outcome model for the colon cancer based on the risk factors selected by the LRA and the DA method, respectively, in the first stage.

The Artificial Neural Networks method

Artificial neural networks are analytic techniques which mimic the processes of learning in the cognitive system and the neurological functions of the brain. The ANNs can predict new observations (on specific variables) from other observations (on the same or other variables) after executing a learning process from existing data. An ANN architecture called multi-layer perceptron (MLP) with back-propagation (a supervised learning algorithm) is known to be a powerful approximating function for prediction and classification problems. It is perhaps the most commonly used and well-studied ANN architecture (Haykin 1999).

The error correction learning works of ANN is described as follow. From the response at neuron j at iteration t , $r_j(t)$, and the desired response $y_j(t)$ for a given input pattern, the instantaneous error $e_j(t)$ is defined by $e_j(t) = y_j(t) - r_j(t)$. Using the gradient descent search algorithm, the weight connecting the output of neuron k to the input neuron j at iteration $t+1$, $w_{jk}(t+1)$, can be adjusted by the following equation

$$w_{jk}(t+1) = w_{jk}(t) + \eta \delta_j(t) x_k(t),$$

where η is the learning rate parameter which will affect the searching speed of the gradient descent search algorithm; $x_k(t)$ is the value of neuron k at iteration t ; $\delta_j(t)$ is the local error which can be directly computed from $e_j(t)$ at the output neuron or can be computed as a weighted sum of errors at the internal neurons.

In this paper, the feed-forward MLP based prediction model was implemented with three layers (one input layer, one hidden layer and one output layer). Integrating the two stages, we constructed two predictive outcome models, the LRA-ANN model and the DA-ANN model. For the LRA-ANN model, the learning rate is set by trial and error and is set as 0.9 for both models. For validation of the models, k -fold cross-validation method is applied. After testing different k -fold, it is revealed that the 10-fold with 9 training sets and 1 testing set is better than the others and is used in this study.

The Artificial Neural Networks method

The confusion matrix shown in Table III and three evaluation indices which include sensitivity, specificity and accuracy are used to appraise the performance the two proposed predictive outcome models. The higher values of the sensitivity, specificity and accuracy imply that the model has better performance in predicting the outcome. The definitions of these evaluation indices are presented as below.

Table III. The Confusion Matrix for the Colon Cancer

Outcome predicted	Real Outcome	
	Having colon cancer	Not having colon cancer
Having colon cancer	TP	FP
Not having colon cancer	FN	TN

- Sensitivity (SEN) – the probability of correctly predicting a subject having the colon cancer.

$$SEN = TP/(TP + FN)$$

- Specificity (SPE) – the probability of correctly predicting a subject not having the colon cancer.

$$SPE = TN/(FP + TN)$$

- Accuracy (ACC) – the accuracy rate of classifying each subject into the correct category.

$$ACC = (TP + TN)/((TP + FP + TN + FN))$$

Results and Discussion

In order to compare the performance of the two predictive outcome models, we constructed 10 experiments by using the 10-fold cross-validation method where the combination of the training sets and the testing set are different in each experiment. The comparison of the sensitivity (SEN), specificity (SPE) and accuracy (ACC) for the two predictive outcome models with 10 set of data groups are presented in Table IV.

Table IV. The Performance of the proposed LRA-ANN and DA-ANN models

Experiment	SEN		SPE		ACC	
	LRA-ANN	DA-ANN	LRA-ANN	DA-ANN	LRA-ANN	DA-ANN
1	66.67%	77.78%	96.00%	100.00%	88.24%	94.12%
2	50.00%	50.00%	84.62%	92.31%	76.47%	82.35%
3	85.71%	71.43%	88.89%	100.00%	88.24%	94.12%
4	33.33%	66.67%	96.43%	92.86%	85.29%	88.24%
5	45.45%	81.82%	86.96%	91.30%	73.53%	88.24%
6	60.00%	70.00%	95.83%	91.67%	85.29%	85.29%
7	53.85%	53.85%	95.45%	95.45%	80%	80%
8	61.54%	76.92%	100.00%	100.00%	85.71%	91.43%
9	45.45%	63.64%	95.65%	100.00%	79.41%	88.24%
10	50.00%	50.00%	96.67%	93.33%	91.18%	88.24%
Average	55.20%	66.21%	93.65%	95.69%	83.33%	88.02%

It can be seen From Table IV that the DA-ANN model has better performance in all three evaluation indices. The probability of correctly predict a subject not having the colon cancer (SPE) is much higher than the probability of correctly predict a subject having the colon cancer (SEN) in both models. This may be caused by the differences of the selected risk factors in the first stage. However, the overall accuracy of prediction is over 80% in each model. This implies that both models have good predicting effect in the colon cancer.

Conclusion

In this study, based on the data of the preventive health examination and data mining methodology, we present a two-stage approach for finding the risk factors which are highly associated to the presence of the colon cancer and for predicting the risk of contracting the

colon cancer with high accuracy. Therefore, the PHE provider can utilize the predicting models to improve the service quality of the patient-physician relationship by offering better health counseling and risk assessment. Moreover, this research provided a good predicted outcome for the incidence of the colon cancer which would be helpful in promoting people to receive the colonoscopy examination once they have received the preventive health examination.

Key Words: Job satisfaction, Service quality; Ethical climate; Elderly; Care attendant

Introduction

Ageing now was an important universal issue the rate of elderly people increased continuously, and the population ageing phenomenon not only had impacts on economic, medical treatment, family, and all walks of society, but also was an influential factor for the future society. Twenty years ago, there were 1.3 million elders, which was 6.53% of the population; nowadays it was nearly one times than in the past, till February of 2011, there were about 2.4 million elders, which held 10.75% of the population (MIO, 2011). The more the elders were, the more people with chronic diseases and impaired functions were. So far, there were about 1,459 elderly care institutions (MIO, 2011). The institutions of elderly care had taken the place of family, and shown interchangeability. As a result, the quality of elder institutions should be comprehensive, and it is not only an index and evaluations. Service quality was an important performance indicator of service industry (Parasuraman, Zeithaml & Berry, 1985). It could also be considered as the level to content customers' need and expectation, and represented customers' opinions to the level of general superior service. It was a kind of cognitive quality, and it depended on if an enterprise could fulfill its customers' requirement (Juran, 1974). An enterprise had to solve inner customers' requirement before conveyed good service quality to outer customers (Hallowell, Schlesinger & Zornitsky, 1996). Hence, Job Satisfaction of workers was a major factor for affecting service quality at the same time (Hartline & Ferrell, 1996 ; Snipesa et al., 2005). That was because when there were satisfied workers, there were pleased costumers.

The human resources in long-term care institutions were care main attendants, their job satisfaction and service quality were imperceptibly the principal links of management in elder care institutions. According to this research, service quality had positive influence on both customer satisfaction and profit-making ability of an enterprise (Parasuraman, Berry & Zeithaml, 1988). Among studies on the correlation between job satisfaction and service quality, most of them investigated the relationship between management and satisfaction of the staff or the service quality (He. P , Murrmann & Perdue, 2010 ; Travis,

2006 ; Hallowell, Schlesinger & Zornitsky, 1996); However, a few of them examined directly the correlation between job satisfaction of the employee and the service quality. Therefore, it was one motive for this research to probe into it.

Although there were a lot of researches on service quality, most of them were about service quality of enterprises (Elmadag, Ellinger & Franke, 2008 ; Prince & Simon, 2009 ; Ahmad et al., 2010 ; Siddiqui & Sharma, 2010 ; Akbar et al., 2010). It seemed that there were a few researches done on the service quality of elderly care institutions. However, more and more employees engaged in the elderly care industry, and it was a major industry promoted by the government. The care attendants in elderly care institutions were chief research subjects. Hence this research took attendants as the research subjects, and stretched to the topic that whether different subjects would affect the correlation between job satisfaction and service quality. This was the second motive for doing this study.

The job nature of “elderly care” was a kind of “service”. The purpose was to offer supportive actions for elders with declining physical and mental states. These actions could improve elders’ physical condition and ameliorate their living quality. With the lift of customers’ rights and interests, elders and their families anticipated higher service quality. Yet care attendants might have a prejudice against, or a negative attitude towards, elders (Reyna, Goodwin & Ferrari, 2007), because they spent lengthy time taking care of bedridden, chronic or alienated elders, and even did not have enough knowledge or ability (Schaefer & Moos, 1993). Therefore, their prejudice formed negative attitude and behavior (Reyna, Goodwin & Ferrari, 2007). Elders’ physical functions might degenerate, mind might attenuate, and they might often express themselves unclearly, so how to ensure they would receive high service quality? According to related literatures (Victor & Cullen, 1988; Charles & Schwepker, 2001), it found ethical climate was worth discussing, too. Ethical climate referred to the ethical atmosphere in organizations; the staff could feel the direction of ethics, require permitted behaviors keenly, and know the forbidden behavior. Most former studies about ethical climate all put emphasis on the staff in enterprises and schools (Parboteeah & Kapp, 2008 ; Stone & Henry, 2003 ; Keiser & Schulte, 2009 ; Lau & Wong, 2009), but a few of them aimed at the ethical climate of elderly care institutions, so this research studied the influence on service quality in the interaction between job satisfaction and ethical climate. This was the third motive.

The two purposes of this research, one we understand the influence of job satisfaction on service quality. Another we know if the correlation between job satisfaction and ethical climate would have moderate effect on service quality. The research result was for suggesting the future promotion of service quality for organizational management.

Literature Review and Hypotheses

Job Satisfaction

The first scholar who proposed job satisfaction was Hoppock, and it referred to the subjective response of employees to working situations. Job satisfaction was from the

consciousness of employees that whether their own ability could satisfy customers' need (Heskett et al., 1994). Job satisfaction was an attitude towards work, and it was a positive or pleasant emotional state of workers from assessing their own job or working experience. Generally speaking, it would make employees work hard, and then increased achievements for organizations (Petty, McGee & Cavender, 1984). With higher job satisfaction, the employment turnover rate would greatly decline, or the increase in turnover rate would reduce productivity and lower customers' satisfaction.

While organizations rewarded employees with fair salary and fulfilled their inner expectation, it would strengthen their job satisfaction and willingness to engage in organizations. Cron and Slocum (1986) proposed that salaries, promotion, colleagues, job nature, and supervisors were all the factors which affected job satisfaction. According to Minnesota Satisfaction Questionnaire (MSQ) studied by Weiss et al. (1967), job satisfaction had both intrinsic and extrinsic satisfaction. The former closely related with job itself such as accomplishment, self esteem, salary, promotion and so on; the latter related indirectly with job itself- practical policies of a company, treatment to employees, job stability and so on. The general job satisfaction referred to an overall satisfaction of individuals.

Service Quality

Gronroos (1984) had an idea that service quality was the cognitive level of everyone's experience and feelings while participated in the process. Because "service" comprised features of intangibility, inseparability, variability and perishability (Fisk et al., 1993), it was different to concrete products. Thus, service quality was often uneasy to assess objectively with quantified measurement. Parasuraman, Berry and Zeithaml (1988) thought customers would judge the service quality according to the gap between early service expectation and latter service cognition. When effective service exceeded customers' expectation, it was a good service. After proposed SERVQUAL, a famous service quality scale.

Good or bad management mostly depended on the interaction between frontline employees and customers (Hartline, Maxham & McKee, 2000); Furthermore, it would influence feelings of customers about service quality. Service quality of attendants would directly affect customers' satisfaction (Crosby, Evans & Cowles, 1990). Because customers always used attendants' behavior to judge service quality received, attendants' behavior during service process was extraordinarily important (Parasuraman, Zeithaml & Berry, 1985). Likewise, service behavior of care attendants was the first condition when conveying service quality. Care attendants were in the boundary-spanning position between the operation of organization and direct contact with customers. As a result, how to give employees mental or substantial assistance to enhance their emotional attachment and bring sense of obligation to help organizations achieve goals was considered more and more important during these years (Eisenberger, Fasolo & Davis, 1990).

The Influence of Job Satisfaction on Service Quality

Fishbein and Ajzen (1975) proposed Theory of Reasoned Action (TRA) whose purpose was to understand and predict personal behavior. It advocated that attitude towards behavior and subjective norms would have influence on behavior intention. According to this theory, whether a person conducted certain behavior depended mainly on individual attitude towards behavior and subjective norms; especially, the attitude towards behavior (Khazanachi, 1995).

Hom, Prussia & Griffeth (1992) believed that job satisfaction was a kind of emotional state, and its nature a type of attitude. When employees had higher job satisfaction, they would be more enthusiastic workers. For instance, while employees were satisfied with their job, the manner to repay grew suddenly. It also facilitated them to dedicate themselves, repay the organization (Organ, 1990; Williams & Anderson, 1991), and promote the service quality. Korman's research (1977) indicated that job satisfaction of employees would inspire working willingness, motive, and sway work efficiency and effects. To sum up, job satisfaction and service quality had positive correlation. Propose following hypotheses:

H1 : Job satisfaction had positive correlation with service quality

H2a: Intrinsic job satisfaction had positive correlation with service quality

H2b: Extrinsic job satisfaction had positive correlation with service quality

Ethical Climates

From Victor and Cullen's (1988) points of view, ethical climate referred to organizational practice with ethical connotation and a procedural universal consciousness. Schwepker (2001) also indicated ethical climate was an individual general consciousness about related codes, policies, and supervisors' action in organizations. Malloy and Agarwal (2002) deemed that forming ethical climate was to form the members' structure of psychological consciousness which fit in with the organization, and it made the staff understand what the common values and goals were in the organization. Consequently organizational ethical climate would also affect many policy decisions; besides, supervisors played an important role in its continually existence and formation (Schein, 1985).

Reflections and applications of ethical climate on elderly care was to proceed an action, among the elders, caretakers, and care institutions, which fit human nature, establish good relationship, and accomplish both sides' criteria. This research based on Schwepker's view (2001) and gave ethical climate a definition-when offering elderly service, the related ethical behavior codes and policies set up and carried out by the supervisor; or a consciousness about ethical subject formed with norms among colleagues. Therefore, stretch the viewpoints of Schein (1985) and Schwepker (2001) supervisors of care institutions and norms among care attendants both played crucial roles in continuous existence and formation of ethical climate.

The moderating Effect of Ethical Climate

Based on Social Cognitive Theory presented by Bandura (1989), cognition and other individual factors, behavior, and external environment would affect each other. In this theory, individual dimension included personality, cognition; external environment

included social norms, codes, and peer encouragement; behavior dimension included individual concrete behavior. Wood and Bandura explained human behavior from the point of triadic reciprocal causation, and said behavior was formed by both individual factors and external environment. High consciousness of ethical climate would make care attendants follow supervisors' requirement about work ethic by mastery modeling. Such an effective modeling would raise the intention of ethical behavior. Moreover, due to the high positive ethical climate, care attendants would perceive supervisors' insistence and regulations, and peer encouragement or norms. These regulations or behavior would also have instructive feedback to care attendants, make them bring self-regulatory and self-reflective (Wood & Bandura, 1989), and then promote the service quality. In other words, forming positive ethical climate should promote the service quality of organizations. Consequently, this study reasoned a following hypothesis:

H3: Employees will enhance service quality moderating effect between high job satisfaction and positive ethical climate.

Research Methods

The methods of this research were designed to explain the relation among research hypotheses- aimed at care attendants of eight elderly care institutions in Taiwan about the job satisfaction, service quality and ethical climate.

Sample and process

This research adopted care attendants of eight elder care institutions in Taiwan as sample- three public and five private ones. The questionnaires were mailed, instructions were given above the questions, and subjects were told to fill out the questionnaires anonymously. After the questionnaires were filled out, they were mailed back. The total questionnaires were 310, and the valid ones were 285- those with incomplete and consistent answers were subtracted. The valid return rate of this survey was 92%.

Measures

The validity and reliability of this research's measuring means of important elements, job satisfaction, service quality and ethical climate, were all examined. The descriptions are as follows:

Job Satisfaction

Owing to different industry, this study adopted measure of job satisfaction based on short form Minnesota Satisfaction Questionnaire, by Weiss et al., (1967). More, it used a self scale which focused on interviews with seven outstanding senior care attendants recommended by managers. According to the expert's advice the form was consisted of 5-point Liker scale statements, and it had 10 items. The intrinsic satisfaction comprised 6 items-receiving respects in work place, being able to offer service, playing ability fully, having opportunities to develop, always having things to do, and managing ability of supervisors; the alpha was 0.81. On the other hand, extrinsic satisfaction comprised 4

items- policies of institutions, treatment from supervisors, working situation and environment and praise received; the alpha was 0.86. Responses range of this form was from 1(very dissatisfied) to 5 (very satisfied), and sum of item responses represented the global job satisfaction. The alpha was 0.89.

Service quality

Lin and Tsaun (2004) found that there was positive correlation between service behavior of frontline employees and customers' cognition about service quality. Most elders in care institutions were with functional degeneration or Alzheimer's disease, they could not express themselves clearly, so it was hard to make elders express how the service quality they received was. As a result, this research studied the service behavior of care attendants as the dimension of service quality. In this study measured by Prosaically Service Behaviors was of Lance & Stephen (1997). The form consisted of 15 items- helped customers with problems beyond expected or required, performed all tasks that are required, and helped other employees with heavy workloads. The scale used in present study was measured on 7- point Liker scale from 1 (strongly disagree) to 7 (strongly agree). The alpha was 0.92.

Ethical climate (EC)

The measure of ethical climate (EC) in this study, based on work by Charles and Schwepker (2001), consisted 7 items and five-point Liker-type statements 1(strongly disagree) to 5 (strongly agree). Items were as follows, institution enforces ethical codes strictly, and good management of a company to let employees know unethical behaviors would not be tolerated. The Scale had satisfactory reliability with coefficient alpha 0.90.

Data analysis

The returned data from questionnaires were analyzed by SPSS 15.0. The variables were examined by descriptive statistics- Frequency, Percentage, Standard Deviation, job satisfaction, service quality and ethical climate were assessed by Pearson correlation coefficient, difference between intrinsic and extrinsic satisfaction was tested by t-test, and related factors of job satisfaction were examined by the linear regression analysis.

Results

There were 60 male care attendants, 21%, and the average age was 45.5; female objects were 225, 78.9%, the average age was 42.7(the oldest was 68; while the youngest was 20). Their education levels were: elementary schools, 9.1%; junior high schools, 37.5%; senior high schools, 42.8%; vocational schools, 8.8%, universities or colleges, 1.4%. 32.6% of current elderly care institutions was public, 40.0% was private, and 27.4% was juridical persons. In the institutions, 72.6% was formal attendants, 1.4% was temporary attendants, 9.1% was contracted attendants, and 16.8% was from human resources companies. The seniority of care attendants were not limited with the current institutions, and the average was 5.6 years (the longest was 30 years; the shortest was 3 months). Care attendants who had certifications were 96.8%.

Table I presented all the descriptive statistics, correlation coefficient and reliability of all variables. The result showed that Intrinsic Satisfactory ($Mean = 3.80, SD = .53$) was slightly higher than Extrinsic Satisfactory ($Mean = 3.62, SD=.66$). Job satisfaction had a notable positive correlation with service quality ($r = .48, p<.000$); while it had a high positive correlation with ethical climate ($r = .43, p<.000$); the service quality showed a high positive correlation with ethical climate ($r = .35, p<.000$).

Table I Average, standard deviation and correlation coefficient in research (N=285)

Variables	Average	SD	1	2	3	4	5
Job satisfaction	3.71	.52	(.89)				
Intrinsic Satisfaction	3.80	.53	.92***	(.81)			
Extrinsic Satisfaction	3.62	.66	.88***	.61***	(.86)		
Service Quality	5.31	.74	.48***	.50***	.33***	(.92)	
Ethical climate	3.86	.52	.43***	.33***	.45***	.35***	(.90)

Note: *** $p<.0001$, ** $p<.01$, * $p<.05$, diagonal is reliability

In table II this research based on hierarchical regression analysis to assess the first hypothesis, to study the major effect of job satisfaction and service quality. There was a positive correlation between job satisfaction and service quality ($\beta = .48, p<.000$). That was, the higher job satisfaction of care attendants was, the better service quality of elders was. Therefore, first hypothesis (H1) was supported. Secondly, intrinsic and extrinsic satisfactions were also notable, the results were .50 and .33 distinctively, so hypotheses 2a and 2b were proved. The score of intrinsic satisfaction was higher than the extrinsic satisfaction's, so they were assessed by t test and had remarkable difference.

On the aspect of ethical interaction, the original chief effect of job satisfaction was notable ($\beta = .48, p<.000$); while adding interference, the standardized regression coefficient of interaction between independent variable and dependent variable ($\beta = .17, p > .05$) was decreased which was not notable. There was a notable correlation between job satisfaction and ethical climate ($\beta = .36, p<.000$). Furthermore, this research carried a multicollinearity diagnostics in all regression models. The VIF, Variance Inflation Factor, used to prediction variables was between 1.0 and 3.0 and displayed that multicollinearity problem did not have much influence on this research result. To learn more about the interactive state between job satisfaction of care attendants and ethical climate, the high and low score groups were decided by the 25% of the highest and lowest ethical climate scores of valid questionnaires. Put the values of high and low ethical climate into regression, and then made an interaction figure (figure I).

In figure I, we could get the idea that the interaction between high ethical climate and job satisfaction could enhance the positive correlation of service quality; the interaction between low ethical climate and job satisfaction did not have notable effect on the

correlation of service quality. This result agreed with third research hypothesis, so H3 was supported.

Table II The hierarchical regression analysis of influence of job satisfaction and service quality on service quality

Predicted variables	Service quality		
	β	R ²	ΔR^2
Step1 : main effect			
Job satisfaction	.48***	.22	.23
Intrinsic Satisfaction	.50***	.25	.25
Extrinsic Satisfaction	.33***	.11	.11
Step2 : moderate effect			
Job satisfaction	.17	.22	.23
Job satisfaction * Ethical climate	.36***	.26	.04

Note: Regression coefficient in table 2 was standardization β coefficient ;

*** $p < .001$, ** $p < .01$, * $p < .05$

Figure I. the connection of interaction between job satisfaction and ethical climate with service quality

Conclusion and discussion

This research discussed the correlation of job satisfaction and service quality. The research result found that care attendants with high satisfaction could have higher service quality, and it corresponded with theory of reasoned action (Fishbein & Ajzen, 1975). In other words, care attendants with high satisfaction, such as, receiving respect in a group, playing their abilities fully, having good working environment, would initiatively upgrade their

service quality, such as, doing regular service extraordinarily, fulfilling extra requirements, helping elders voluntarily and desperately. Tzeng and Ketefian (2002) found that there were correlations among the working environment of health care attendants, caring process, job satisfaction and fillings of patients. Karatepe, Avci and Arasli (2004) studied the sample of frontline employees, and it indicated that not only job standardization would have influence on job satisfaction and service quality, but job satisfaction would affect service quality. Although this research used care attendants as the sample, the research result was the same as others' - the correlation between job satisfaction and service quality would not be changed by different subjects.

In addition, this research found there was a notable statistical difference that intrinsic satisfaction was slightly higher than extrinsic satisfaction. According to abroad and domestic researches, care attendants occupied 70% of health human resources, but they had to offer direct service to 90% of the elderly (Castle, 2007; Zweig & Lawhorne, 2001). The primary factors which affected extrinsic satisfaction of care attendants were considerable workload, limited promotion, long working hours, poor treatment (Helmer, Olson & Heim, 1993 ; Castle, 2007). On the other hand, factors of intrinsic satisfaction was the obviously different background of care attendants, such as, education background, seniority, working experience, and which made them face working challenges and distinct self-requirement. Many researches already pointed out the importance of vocational education (Aberdeen, 2004) which could both enhance professional knowledge of care attendants and increase satisfaction of care attendants(Lin et al., 2003; Yeh et al., 2004).

On the aspect of interaction between job satisfaction of care attendants and ethical climate, this research brought that in the interaction of job satisfaction and ethical climate the service quality would be improved. It represented that if care attendants could follow the norms of ethical climate in the situation of interacting with elders, it would help the elders accept the responsibility and reliability of care attendants and strengthen the relationship. Moreover, supervisors' value had quite effect on cultivating ethical climate in work place (Cohen, 1993). By changing the ethical climate in an organization, they could prevent employees from having behaviors against ethics, for instance, mistreatment, fake positive attitude. Anti-ethic behavior would cause serious mischief to both elders and organizations (Wimbush & Shepard, 1994), so a feasible way to make employees have positive power was to change the ethical climate of an organization (Sinclair, 1993). Creating ethical climate could provide organizations benefits like higher job satisfaction, stronger organizational commitment, and lower intention to change a job (Schwepker, 2001).

Ethical climate might not be so important in manufacture industry, but it was in elderly industry. No matter what the relation of job nature was, engaging in elderly care industry needed sympathy and patience. Therefore, the care attendants were required not only basic skills but also moderate personal affection to show their concern. Tsai and Huang (2008) studied the relationship among types of ethical climate, job satisfaction and commitment of organization. The research supported that the commitment of hospitals would affect by ethical climate.

Limitations and future research

The best way to understand the service quality was to interview with elders, but most of them were unable to express or could not convey meanings clearly. Consequently, this research could only replace it with assessment of care attendants' behavior. To suggest future research, it might be feasible to arrange observers on the spot and apply longitudinal research. That is because the research design of this study was crossing scale, the job satisfaction and service quality were also measured at the same time, and the research result could not carry out cause and effect inference.

About the research limitations, the problem was common method variance. There might be problem of common variables and overestimate the correlation among variables (Podsakoff & Organ, 1986) because the independent variable, dependent variable, and moderate variable were all collected from the same subject.

Implication for practice

On the basis of conclusion above, this research raised two connotations of management. First, job satisfaction had positive effect on service quality. Wright and Beasley (2004) said that motivation could make job satisfaction better and reach the goal of organizational perpetual management. From related researches on raising job satisfaction, it showed that if employees were satisfied with their job, the sense of safety would be inspired, and they would enjoy working more. Wright and Beasley (2004) pointed that the intrinsic and extrinsic encouragement were the primary elements. Intrinsic encouragement included factors of job itself, and most of them were about job satisfaction: achievement, job itself (liberty, promotion), praise, learning development, workload, and so on. Extrinsic encouragement referred to factors of working environment, and most of them were about job dissatisfaction: interpersonal relationship, leadership, salary, working environment and safety, and so forth. It was important to raise job satisfaction by adopting encouraging methods which were correspond with requirement and agreement of employee to enhance the employee's centripetal force and loyalty to the organization (Deloach & Monroe, 2004). Farther, supervisors could alter job satisfaction of care attendants by socialization. Investiture tactics were associated with not only reduced role conflict, greater job satisfaction but also lower behavioral intentions to quit (King et al., 2005).

Under the interaction between high job satisfaction and high positive ethical climate, employees would increase their service quality. Creating and Maintaining Ethical Work Climates Strategies: Reducing organizational anomie, inconsistency and unreliability of institutional leadership are key factors through changing and developing aspects of organizational culture. Scholars agreed that top management values and practices were critical in setting the ethical climate of an organization (Winbush & Shapard, 1994). Institutional policy has a strong impact on the level of ethical and law-abiding conduct must be implemented (Andrews, 1989). Incentive system was particularly critical in most ethical climates. Managers could take concrete steps to modify a goal-driven reward system and strictly punish violations of expected ethical conduct, even if such actions result in achieving desirable economic objectives (Cohen, 1993).

Key words: TQM, Accountants, Service, quality, High School, Taiwan

Introduction

People frequently criticize the service of the accountants in Taiwan high school owing to the fact that the official accounting department has been an independence administration system with no exception in Taiwan high schools. Besides, accounting department is an independent institution different from the others. However, based on the laws of accounting, accounting department controls the budgets which are the expenditure of other departments. So, the accountants encountered conflicts with the staff of other institutions that was due to different positions and perspectives on laws such as accountants control audits standard, mechanism and so on. Therefore, how to upgrade service quality of accountants has become an important issue to the government (Holzer et al., 2009). For instance, the government of Mauritius perceived that the government had efforts to promote service quality for the public department in order to increase its productivity and efficiency in 2006 (Prabha et al., 2010). Thus, measuring the quality of service in higher education has been increasingly important (Abdullah, 2006), especially in accounting department. Moreover, the implementation of promoting service quality of accountants is a diverse strategy, the total quality management (TQM).

As Kiernan (1993) proposed, TQM is a strategy implementation, that is to say a way of quality management. Chase (1998) commented that TQM is a management practice in general. Dale et al. (2010) tried to build a TQM theory, but only developed the variables of TQM finally. Further, some other researchers also claimed that TQM is a strategy model and a general practice serving as an effective method in public serving quality (Holzer et al., 2009; Kim, 2009). However, In Taiwan, TQM is only implemented in other public sectors for administration evolution since 1980s. Accordingly, this study applied TQM to service quality of accountants in Taiwan high schools. There are three main purposes in this study. The first purpose is to provide better understanding on the importance of the serving quality in accountants and TQM. Secondly, the research investigated the essential factors on service quality of accountants in Taiwan high school. The last and above all purpose is

to offer a substantial amount of data and suggestions regarding how to upgrade service quality of accountants in Taiwan high school.

For above the purposes, due to few studies deeply aiming at relationship between TQM and service quality, the paper deeply explore relationship between TQM and service quality of accountants. Besides, the idea of serving quality was rarely applied to accountants; this study tried to apply serving quality in accountants, and how to upgrade serving quality of the accountants in high school. Consequently, by conducting this study, hopefully, the findings might contribute to fulfill three gaps. The first contribution in this study is to propose a model to investigate relationship between TQM and service quality of accountants. The second one is to explore the main factors within TQM to the serving quality of the accountants in practice. Finally, which factor is the most important on service quality of the accountants?

Literature Review and Hypotheses

Service Quality

Service quality is a mark how works of the person. From previous studies, service quality as an overall evaluation of service (Taylor & Baker, 1994), whereas others view it as a multidimensional construct formed from an evaluation of several servicing attributes (Parasuraman et al., 1988, 1991, 1994). Service quality is as an overall judgment similar to attitude towards the service and generally accepted as an antecedent of overall satisfaction to serving object (Parasuraman et al., 1988; Zeithaml & Bitner, 1996, 2000). In addition, service quality in all service encounters is thus intrinsically affected by the perspectives of both the service provider and the service receiver. Similarly, Czepiel (1990) concluded that research on service quality must always include the perspectives of both the provider and the receiver. Perceived serving quality results from comparisons by serving objection of expectations with their perceptions of serving delivered by the service providers (Zeithaml et al., 1990, 1988). According to the aforementioned, the provider and the receiver of service quality understand information each other. Therefore, the information process theory is a key theory that it process information between the provider and receiver each other.

In addition, the influencing factors of the serving quality, Zeithaml et al. (1990) suggested four influencing factors: word-of-mouth communications; personal needs; past experience; and external communications. Thus, the serving quality of accountants how to measuring the quality of service in higher education is increasingly important (Abdullah, 2006). Moreover, Parasuraman et al. (1985, 1988, 1994) have made use of qualitative and quantitative research following generally accepted psychometric procedures. This resulted in the development of the original 44-item (expect and reality spilt half) SERVQUAL instrument that represents one of the most widely used practice of serving quality. The SERVQUAL has provided researchers with the possibility of measuring the reality-expectations five gaps (tangibles, reliability, responsiveness, assurance, and empathy) ostensibly composed of five determinants that this study adapts.

According to the above statement, the accountants would like to do the better serving quality that they have to focus on the perspectives of information both the provider and the receiver to consist. By accountants provided accurate information to staff who they received the whole accurate information. That not only can decrease the conflict between provider and receiver each other, but can upgrade the serving quality of accountants (Martin et al., 2010; Miller et al., 1997). However, serving quality provided on this process of which has an operating mechanization, and so-call strategy's implement. Besides, how accountants improve their serving quality that is an important lesson. This idea is often applying service quality of the public. This study focuses on the serving quality of accountants in Taiwan high school. Therefore, the staffs were produced a gap between expectation and reality for service quality of accountants. We inference to as following:

Hypothesis 1. The significant relationship between expectation and reality is for service quality of accountants.

Hypothesis 2. There will be ranking among fifth dimensions for service quality of accountants.

Total Quality Management (TQM)

Armand Feigenbaum firstly presented the TQM in 1961 that this conception is from Deming's 14 points management principles (Feigenbaum, 1961). The literature from late 1980s suggests interest, in the higher education sector, in The TQM model, as alternative methodology or philosophy for governance. Thus, TQM is for long-term relationships have been developed with service objects, so we can say TQM is a strategy for service quality. Kiernan (1993) produced TQM is a means for strategy implementation. Soltani et al. (2008) argued TQM is concerned with the problem of defining quality as well as examining a universal set of precepts to safeguard it as a management philosophy. However, this viewpoint was argued that the lack of a clear definition of TQM is problematic at two levels. First, at the surface level, the existence of a vast topics and approaches in quality management will obstruct theory development associated with TQM (Flynes, 1999). Secondly, at a deeper level, unclear definition makes it difficult to associate the bottom line at the commencement of TQM (Reeves & Bednar, 1994). For this problem, we try to apply TQM on service quality of accountants by the information process theory.

In addition, Wilkinson et al. (1998) analysis of TQM literature identified two important issues: the first stems from 'the difficulty in doing so'; and the second is the existence of a 'wide variety of activities and practices under TQM umbrella'. Oakland (1998) suggested TQM can be improving the effectiveness and flexibility of business as a whole, meeting serving object requirements both external and internal the organization. Dale (2003) pointed out TQM approach that ensures mutual co-operation of everyone in an organization and associated the managing processes between products and services. Soltani (2008) generated TQM practices indicates that the evidence a bounds with the definitions of both hard and soft of quality management. In the words, the practice of TQM is linking managing processes about quality management.

Besides, TQM components, in term of Oakland (1998) show five distinct components including: (1) management commitment, (2) customer-supplier chain, (3) quality systems,

(4) statistical process control tools, and (5) teamwork. Anderson et al. (1994) stated TQM have seven components such as leadership, continuous improvement, internal and external cooperation, customer focus, learning, employee fulfillment, and process management. Grandzol et al. (1998) conducted leadership, continuous improvement; employee fulfillment, learning, process management, internal and external cooperation, and customer focus (indicated the staff focus in this study) (Fuentes, 2010). However, accounting department has been an independence administration system different from the others in Taiwan. Therefore, this study adopts Grandzol et al. opinion in 1998.

Judging from the above, TQM is a strategy of which it might upgrade service quality method. This study applied to the serving quality of accountants in high school that aimed to upgrade it to the better serving quality of accountants. And, in term of Grandzol et al. (1998) measured tool by seven components of service quality. Thus, we propose the followings:

Hypothesis 3. The significant relationship among seven dimensions is a strategy for TQM.

Hypothesis 4. There will be ranking among seven dimensions for TQM.

Effect of TQM and Service Quality

Good serving quality based on input-output of bi-direction information (Galbraith, 1974). Daft & Weick (1984) pointed out the information processing that coping with the information between the deliver and the receiver. Similarly, Surprenant and Solomon (1987) stated that service encounters are human interactions. Therefore, base on this viewpoint of the information process also apply the serving quality in accountants. Previous empirical studied the relationship between TQM and organizational performance as well as service quality have shown a significant results (Flynn et al.,1994; Ahire et al.,1996; Terziovski & Samson,1999). Brah et al. (2000) studied TQM and business performance in Singapore service sector that the result showed TQM implementation relationship service quality. Antony et al. (2002) studied the successful TQM implementation will give benefits in improving quality (Samat et al., 2006). According to the above statement, TQM had the better service quality that it can through the information processing to coping with the information between the deliver and the receiver. Therefore, we propose the followings:

Hypothesis 5. Leadership, continuous improvement, employee fulfillment, learning, process management, cooperation, and customer focus have positive impacts on service quality.

Hypothesis 6. The compares between TQM and the expectation service quality, TQM and the reality service quality have significant respectively.

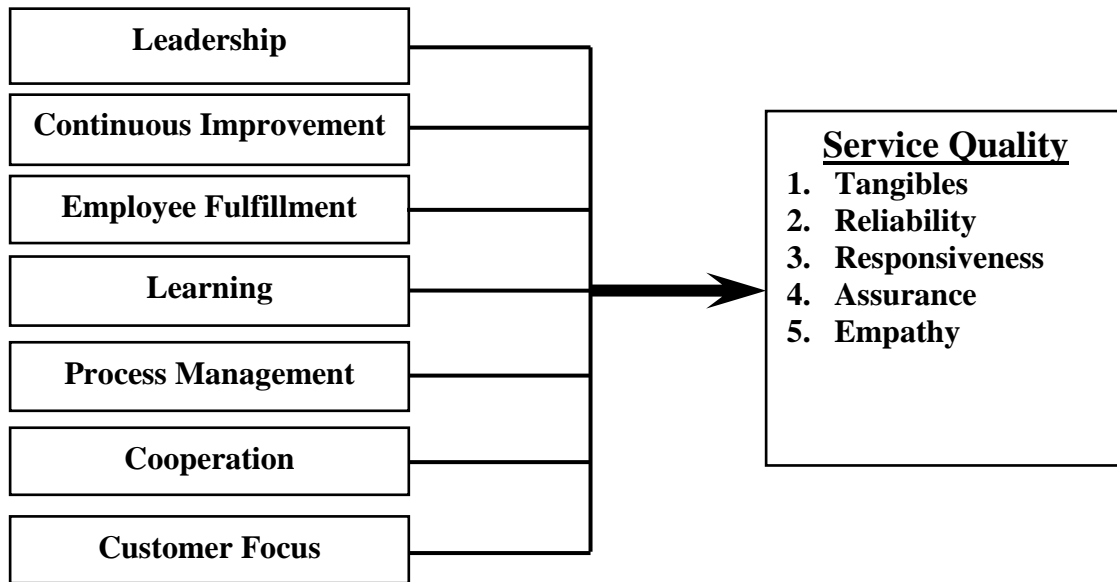

Methodology

Research Framework

This study attempts explore the factors and relationship between TQM and service quality in Taiwan high school. One we tried to find the gaps of service quality between expectation

and reality. The other, we tried to look for the main factors of effect service quality in Taiwan high school. Along with research framework, can be seen in Figure 1.

FIGURE 1
Research Framework

Sample and Procedures

The initial sample consisted of 360 staff from 18 high schools widely spreading in northern, central, and southern Taiwan. Each area comprised 6 schools which were distributed equally among three different sizes of high schools based on the numbers of the school classes. The sizes varied from under 40 classes, 41-50 classes, and over 51 classes. Each school consisted five style staffs including principle, administrating teacher, non-administrating teacher, staff, and accountants that samples were distributed 18, 144, 126, 54, 18. These data were collected from all the public high schools governed by the Ministry of Education in Taiwan. A total of 360 questionnaires were sent to the above samples. The overall response rate on our surveys was 84.72 percent. Of the respondents, 58 percent were women and 42 percent were men; the average age was 43 years (range 29–64 years); the job tenure was five years above (average tenure:16.8); and the most education level was above college. No payment was provided to participants.

Measures and Processes

For this study reliability and validity, the items of two questionnaires were translation Chinese by a university professor and two high school teachers. Then, the translate items checked by two accountants director in the public and they teaching part time a account course in university, two professors about quality management in university, and participants in this study. Unless otherwise indicated, all the variables were measured by the participant responses to questions on a seven-point Likert-type scale. The participants were asked to rate each item using the following scale: 7-“strongly agree”, 6-“very agree”, 5-“agree”, 4-“uncertain”, 3-“disagree”, 2-“very disagree”, 1-“strongly disagree”. We used two scales in this work. One the scale of service quality was measured by forty-four items from PZB

SERVQUAL scale of Parasuraman et al. (1988) and the items categorical from Parasuraman et al. (1991) to fill the bill for this study. Authors of the scale above had agreed with us to translate it into Chinese for the purpose of this study. Other total quality management was measured by 39 items for seven dimensions of TQM scale from Grandzol and Gershon (1998) and they had agreed with us to translate it into Chinese for the purpose of this study.

Measuring process, firstly, we carried out a confirmatory factor analysis (CFA) on these items. CFA for dependent variable tested by SPSS the Amos18. We conducted CFA for further validate our measures. The hypothesized dependent variable and independent variables items measuring model was tested by submitting raw data to Amos 18. Next, we used pair sample t test the gaps between expectation and reality of serving quality, and used a mean method and pair sample t test to expectation and reality dimensions ranking respectively. In addition, we conducted a factor analysis relationship among the seven dimensions of TQM. Then, we compared important ranking among the seven dimensions of TQM. Finally, the main effect of the relationship between TQM and service quality was measured from regression analysis. Besides, one we were tested effect the seven dimensions of TQM to five dimensions of service quality. The other we were tested relationship between TQM and expectation service quality, TQM and reality service quality respectively.

Control Variables

We hoped to be the best significant results and increased reliability and validity in this study. Thus, we reduced the possibility that other factors might effect service quality, so we was control variables two partial for this study. One we included control variables such as age, education, job tenure, and gender, was examined, but they were not included in the final analyses because they did not affect the results (Doucet, 2004). The other respondents' affective states are often assumed to cause common method variance (Burke et al., 1993; Liao, 2007), so themselves-esteem had cause common method variance in this study. Therefore, this study accounted for the possibility that "agree" individuals provided more positive evaluations regardless of the level of service quality and TQM. And we controlled for respondents' affectivity and assessed with a 7-point Likert-type scale (1-strongly disagree, 7-strongly agree) on the respondents specified which the best describes how they typically feel.

Result

Confirmatory Factor Analysis

In generation, we formally tested the hypotheses by a series of structural models in which all of the relationship between TQM and service quality. This study assessed the fit of the data to measurement model prior to assaying essential relationships. The first, testing non-observance estimation, all items standard coefficient were TQM range from 0.110 to 0.482 and service quality range from 0.683 to 0.953, not close 1 or over. Standard errors were TQM range from 0.072 to 0.081 and service quality range from 0.126 to 0.946 that was not much. The variance of testing errors were TQM range from 0.002 to 0.886 and service

quality range from 0.314 to 2.707, they belonged to the positive completely. Therefore, this model was not violating question to estimate. Secondly, measure of parsimonious fit PNFI (TQM: 0.696, SQ: 0.589) and PGFI (TQM: 0.658, SQ: 0.603) were greater than 0.5. Thus, the extra-quality was a good model. Thirdly, all items standard regression coefficient range TQM 0.110 to 0.482 and service quality from 0.683 to 0.953, t-values were greater than 1.96 and showed significant. Next, the sub-dimension construct validity were TQM from 1.242 to 1.287 and service quality from 0.635 to 1.214 to be greater than 0.5. Therefore, they were in compliance with the requirements of convergent validity, and it was excellent model for internal quality. The finally, the minimum of average variance extracted TQM: 0.6368 and SQ: 1.173 were greater than TQM: $(0.482)^2$ and SQ: $(0.953)^2$ that was the square of the maximum correlation coefficient in sub-dimensions. Therefore, the theoretical was in compliance with the requirement of discriminated validity, and proved a good model of the inherent quality again.

Service Quality

Table I presented the results of pair sample t testing hypotheses. We main tested Hypothesis 1: the significant relationship between expectation and reality was for service quality of accountants. The results absolute value t from 3.494 to 9.096, p-value from 0.000 to 0.001 reached significant in whole. Therefore, Hypothesis 1 was supported. In addition, there was the average absolute of difference between the expectation and reality of service quality, assurances (0.601) the maximum, and to empathy (0.203) the minimum. This result implied the important opinion that the assurance was a major factor to upgrade service quality of accountants. Moreover, Table II presented the result for Hypothesis 2 that was ranking among fifth dimensions for expectation and reality service quality respectively. The expectation services ranked important according to priority assurances, reliability, responsiveness, tangibles and empathy. Equally, the reality services ranked in turn priority reliability, assurances, responsiveness, tangibles and empathy. Therefore, the most staff believed the expectation or reality of service quality that the key factors are on reliability, assurances and responsiveness.

TABLE I

Difference between Expectation (E) and Reality (R) of Accountants Service Quality

brief description of the item	R-E	mean	t	p
Tangibles were from item 1 to item 4 that the contents belonged to appearance of accountants and hardware facilities.	Tangibles R-E	- .32049	-9.096	.000***
Reliabilities were from item 5 to item 9 that the contents finished work for service credibility and accuracy of accountants.	Reliability R-E	- .34230	-7.283	.000***
Responsiveness were from item 10 to	Responsiveness	-	-5.848	.000***

item 13 that belonged to negative question about activity and efficiency of accountants in the service.	R-E	.37967		
Assurances were from item 14 to item 17 about trust, safe, politeness and support to accountants in the service.	Assurances R-E	-.60109	-3.494	.001***
Empathy were from item 18 to item 22 belonged to negative question as first taking all staffs.	Empathy R-E	-.20393	-3.636	.000***

Total Quality Management

Hypothesis 3 and 4 showed table III that presented the descriptive statistics and correlation matrix for the analysis data set. The result showed correlation among dimensions for TQM, and them ranking. We used mean method and pair sample t test for ranking of TQM, and understood important factors within TQM to improve service quality of accountants. In order to the means in dimension of TQM was range from 4.753 to 5.255. By this statistics, the ranking were in order priority cooperation, customer focus, continuous improvement, process management, learning, employee fulfillment and leadership, that the method ranked the same as pair sample t test. This hypothesis 3 was supported. Furthermore, the dimensions of TQM correlations were significant all, and correlations coefficient was range from 0.445 to 0.799. Similarly, hypothesis 4 was supported.

TABLE III
Variable ranking (R), Means (M), Standard Deviations (S.D), and Correlations

N	Variable	R	M	S.D	1	2	3	4	5	6	7
1	Leadership	7	4.753	1.038	1

Effect of SQ and TQM

The finally, hypothesis 5 showed Table IV. Hypothesis 6 presented Table V. At first, we used both the line regression analysis and stepwise regression analysis to predict effect TQM to service quality of accountants. Both analyses presented the coefficient of determination (R^2) to 0.633 and 0.631, the statistics showed. Accordingly, one this result had a high explanatory power and a good regression effect by TQM to predict service quality of accountants. The other was Beta contribution (β) that it showed influential for the seven dimensions of TQM to service quality. In line regression analysis, the most influential dimensions within TQM were continuous improvement, cooperation, following by leadership, and the least impact is customer focus. Another the stepwise analysis, model 1 only contained continuous improvement; model 2 contained the two dimensions of continuous improvement and employee fulfillment; model 3 contained the three dimensions of continuous improvement, employee fulfillment, and cooperation; model 4 contained the fourth dimensions of continuous improvement, employee fulfillment, cooperation, and leadership; model 5 contained the fifth dimensions of continuous improvement, employee fulfillment, cooperation, leadership, and learning. Table 4 showed the most influential as the continuous improvement, and the process management and customer focus less

influential. Second and last, Table 5 showed correlation between TQM dimensions and expectation of service quality, TQM dimensions and reality of service quality respectively. The correlation was low between TQM dimensions and expectation of service quality, and high between TQM and reality of service quality. According to the aforementioned, hypothesis 5 and 6 were supports.

TABLE IV
Regression Analyses for Reality Service Quality

N	Line Regression		Stepwise Regression

Discussion and conclusion

In this study, we examined firstly the gap between expectation and reality value of service quality in accountants, ranking for expectation and reality value of service quality in high school. In addition, we tested correlations among seven dimensions within TQM, and ranked them. Last but not least, we measured effect TQM to service quality of accountants. Moreover, we measured correlation between TQM and expectation value of service quality, and TQM and reality value of service quality respectively. The results have supported our hypotheses in whole. We found that the effect of the assurances is the largest and that of empathy is the minimum in service quality of accountants. There is a small between ranking of expectation and that of reality of service quality, but their top three is consistence with reliability, responsiveness, and assurances. Besides, the correlations among seven dimensions within TQM showed significant, and cooperation is the top in the ranking. Furthermore, this good constructive model has high explanatory power. Finally, the relationship between TQM and service quality of accountants reached significant.

Implications and Contributions

In this study, the findings match with the hypotheses totally. To begin, the top three in the ranking in the expectation and reality of service quality are elements of reliability, responsiveness, and assurances. These three dimensions obviously imply the criteria of service quality in accountants. The leader of accountants should take three primary directions to improve service quality. Further, reliability and assurances would be applicable not only to the products but also to the services. In addition, the difference has been significant between expectation and reality of service quality. This shows a true that service quality of accountants is lower. Besides, if accountants tend to fill out the gap that the accountants must disclosure about accounting laws and affairs information to the staffs, so that the staffs can understand accounting laws and affairs. Therefore, it is that appropriate this article applied the information process theory on service quality.

Next, ranking the seven dimensions within TQM were three top orders of cooperation, customer focus, and continuous improvement. For this reason, maybe the accountants should take into consideration to cooperation with the staffs; also they can create high service quality. The work of accountants focused on process management of service quality in Taiwan high school, but it ranked at forth in this study. That mean the process management is still important, but it is not so important. Therefore, if accountants tend to do their works well, they must change their managerial style into the walk-around management and they must coordinate cooperation with the staff in public institution to finish their work together. Therefore, the coordinate cooperation is main criterion to enhance service quality of accountants. In addition, the leadership is ranking the last in this paper which implies the importance of leadership is easily neglected. It maybe because accountants other department belong to the same an independence administration system in Taiwan public. There is no flexible space to change that the public servants must implement their work on the basis of the laws. The leaders of the public are too. Therefore, the leader of the accountants in the public sector isn't the same as a sector in private units who has the power to control the finance and the strict audit. The leader of the public department in Taiwan has not possession of the power above.

In the end, the result shows enough explanatory power effect TQM to service quality of accountants. So, the leader of accounting department can adopt TQM to make improvement strategy of service quality. In addition, the continuous improvement and cooperation are the most influential of all factors. Accountants might strengthen both continuous improvement and cooperation to improve service quality. Besides, the result shows both the expectation and reality of service quality are related to TQM. The expectation of service quality is low, and the reality of service quality is high. The staffs have completely understood the conception of quality management in high school; therefore, they expect not so high to service quality of accountants. However, the fact is that, the staffs desire as well to promote high service quality in accountants. In a word, this is the reason why the expectation is lower and the reality is higher.

Finally, this article offered several contributions to the theory and practice view. To start with, we firstly applied the information process theory to TQM and service quality of accountants to explain the relationship between phenomenon and model. Second, accountants are through the information process to make staffs understand accounting laws and affairs, and staffs are through the information process to understand accounting affairs and endorsed accounting opinion. Therefore, both accountants and staffs will promote their work as well. Third, the result shows cooperation, customer focus, and continuous improvements are important for service quality of accountants. So the leader has to enhance collaboration work among departments. Fourth and last, we understand the important result of this study that TQM is an effective strategy in service quality.

Limitations and Future

This study had two limits as follows: To start with limitation can able to produced common method variance from survey at the same. We adopt the following three ways to deal with this question. At first, the sample consisted of the different area from northern, central, and southern high school in Taiwan. The next, sampling six schools every area and the sizes varied from under 40 classes, 41-50 classes, and over 51 classes that every range sampling two schools. At last, sampling twenty staff every high school, exception one accountants also included principle, administrating teacher, non-administrating teacher, and staff. The second and last limitation was sampling. Owing to the questionnaire was by the school accountant to the responders. The accountants gave the questionnaire of survey to the good interact or know well staff possibilities that it was inevitable. Therefore, this study also surveyed with five categories staff as the above. We were by larger number of the responders as far as possible to decreases this impact. In addition, questionnaire by anonymous and requested the accountants to send back the stamped envelopes, and responders kept neutral attitude and judgment to answer the items content in order to minimize the error.

We proposed several directions for future research in this study. At first, this study used also the information process theory in explanation of the issue of service quality of accountants and the result supported. In future researches, if the researchers consider using other theory to service quality in accountants to explain this affect our results. The next, this study object was the accountants in Taiwan high school, because we observed common

low quality service of accountants in public. Future research might measure the object by other industry or department such as personal department, telecommunication industry, or bank industry. The third, the atmosphere between TQM scale and service quality is seemed close. We put in the both together in the study, and they produced well the result. In the future, maybe some people consider the reverse thought to explain this affect. So any study the future researcher could design about the total difference atmosphere between independent and dependent variable are accepted. The forth, our study deeply explored the relationship between independent and dependent variables without moderate or mediator measures to do test. However, the researcher could be according to themselves study require to add moderate or mediator variable to further examine the effects. The fifth and last, the questionnaire of this study answered by five categories staff, including principle one of them. The future study are could do cross-lever study on those responder.

Conclusion

This study explored the strategies of TQM and serving quality of accountants in Taiwan high schools. The result shows a significant relationship between TQM and the serving quality of accountants. Besides, this study makes an important contribution to studying theory and practice TQM and service quality. In the theory contribution, the information process implicated TQM and service quality of accountants. The hypothesis results of this study were significant. The findings in the present study also proved that information processing theory applying to service quality of accountants and TQM is reasonable. Moreover, the accountants can help the staffs understand the affairs of accounting department and laws by using the information process theory. In the practice contribution, the leader of accountants might adopt the cooperation approach to promote the collaboration between the accountants and the staff in other departments. If the leader is good at the information process theory on the practice work, and be great at a strategy of TQM on service quality of accountants, such as promote interaction, respect staff, continuous improvement, and process management, the leader might enhance service quality in accountants. In conclusion, we can know that TQM is an effective strategy in service quality from the results.

Introduction

In order to respond the highly competitive external environment and the customers' expectations, enterprises have to look for effective approaches to enhance their management capabilities, such as Total Quality Management (TQM), Business Process Reengineering (BPR), Enterprise Resource Planning (ERP), Organizational Change Management (OCM) and Business Excellence (BE), etc. Among them, BE is one of the most popular approaches being used in the past two decades. The definition by Wikipedia (2011) stated that BE is the systematic use of quality management principles and tools in business management, with the goal of improving performance based on the principles of customer focus, stakeholder value, and process management. Key practices in business excellence applied across functional areas in an enterprise include continuous and breakthrough improvement, preventative management and management by facts. Some of the tools used are the balanced scorecard, Lean, the Six Sigma statistical tools, process management, and project management. Based on the definition, we acknowledge that BE is able to trace its root to TQM, however comparing to the principle concepts of TQM, BE is more holistic in nature than TQM. As described by the European Foundation for Quality Management (EFQM), BE refers to outstanding practices in managing the organization and achieving results in terms of a set of eight fundamental concepts. These concepts are 'results orientation, customer focus, leadership and constancy of purpose, management by processes and facts, people development and involvement, continuous learning, innovation & improvement; partnership development, and public responsibility.'

Besides, business excellence models (BEMs) have been generally developed by national bodies as a basis for award programs. For most of these bodies, the awards themselves are secondary in importance to the widespread adoption of the concepts of business excellence, which ultimately leads to improved national economic performance. By far the majority of organizations that use these models do so for self-assessment, through which they may identify improvement opportunities, areas of strength, and ideas for future organizational development. Users of the EQA Excellence Model, for instance, do so for the following purposes: self-assessment, strategy formulation, visioning, project management, supplier management, and mergers. The most popular and influential model in the western world is the Malcolm Baldrige National Quality Award Model (also known as MBNQA model, the MBNQA Criteria, or the Criteria for Performance Excellence), launched by the US

government. More than 60 national and state/regional awards base their frameworks upon the Baldrige criteria.

Due to BEMs have been widely implemented in the industries over two decades, a ton of experiences and evidences are accumulated. Researches were conducted to investigate their effectiveness which includes the benefits and the deficiencies. Some researches indicated that organizations obtained significant benefits. The benefits include the financial profit (Hendricks & Singhal, 2000; Pannirselvam & Ferguson, 2001) and the non-financial outcomes (Hendricks & Singhal, 1996; Ford & Evans, 2000; Wilson & Collier, 2000; Pannirselvam & Ferguson, 2001; Douglas & Judge, 2001). However, it has been noted that not all the messages are positive. On the one hand, some research findings pointed out that an excellence approach is not a guarantee of success (Powell, 1995; Terziovski & Samson, 1999; Fisher *et al.*, 2001). Also, although there is compelling evidence that business excellence delivers benefit to the organization, it is clear that it does not work for everyone (Jennigs & Beaver, 1997; Stephens *et al.*, 2005). On the other hand, practitioners usually complain that they encounter difficulties in implementing BEM which include sophisticated assessment criteria, lack of infrastructure, quality bureaucracy, excessive paperwork, cumbersome procedures, time consuming, and lack of focus (Miller, 1993; Goh & Ridgway, 1994; McTeer & Dale, 1994; Wilkes & Dale, 1998; Lee *et al.*, 2006).

Why the research findings are inconsistent? Why the practitioners meet difficulties? To answer these questions is not an easy task. It's a complicated issue in nature, which involves many contingency factors in the implementation of BEMs, such as size, industrial sector, organizational structure & system infrastructure, culture, and the degree of quality maturity, etc. The present authors argue that the most crucial thing is how BEMs are perceived by the adopters, because the perception of BEMs will guide their behaviors of using the management tool. In the way of dichotomy, BEMs can be perceived either prescriptive or descriptive. The prescriptive aspect indicates that the adopters treat BEM as a 'must' to achieve business excellence. Generally speaking, two groups of people adopt this aspect. One of the two groups is either the quality award examiners or self-assessment assessors. They are requested to follow the criteria provided by the award organization to conduct their examination. And the other group of adopters chooses BEM as the major management approach in the outset and keeps sticking on it. They often feel disappointed in the period of implementation due to the perception of 'must' aspect will keep them away from looking for another effective management approach except BEMs. On the other hand, the descriptive aspect indicates that the adopters treat BEM as a 'reference' to examine how the business excellence of the enterprise is. This group of adopters usually aims at winning the award. The use of BEM is mainly for the purposes of confirming if they have already fulfilled the requirement of the quality award.

The present authors hold that the BEM should be prescriptive-based for the purpose of providing a 'total solution' to every aspect of organizational management. However, the past literature indicated that it is still under debating for whether the existing BEMs (such as MBNQA, EQA, etc) are prescriptive or not. Based on the reasons stated above, to develop a rather comprehensive BEM which is able to help an organization in pursuit of business excellence becomes necessary. More specifically, in this paper, the present authors intend to achieve the following research objectives: (1) to give an introduction to the

existing BEMs and self-assessment, (2) to summarize the deficiencies of the existing models, (3) to raise the fundamental premises for a comprehensive business excellence model, and finally (4) to propose a comprehensive model to meet the fundamental premises.

Literature Review

A review of the past research related to BEMs is described in this section. It includes the introductions to BEMs & self-assessment, the extension models for the implementation of BEMs, and the deficiencies of the existing models. Each of these is presented in the following.

BEMs and Self-assessment

BEMs

The research done by Miguel (2004) indicated that over 80 nations have currently administered a national-level BEM which includes about 50 MBNQA-based and about 25 EQA-based. The remaining few are tailored to suit the particular the specific cultural context of the nations. The two major quality awards are thus introduced in this paper, Malcolm Baldrige National Quality Award (MBNQA) in USA and European Quality Award (EQA) in Europe. The features and attributes of the two major quality awards are briefly described. They are presented in terms of the following aspects: core values & concepts, criteria & scoring system, evaluation dimensions, and award application procedures (see Table I).

Malcolm Baldrige National Quality Award

In an effort to improve quality management practices and the competitiveness of U.S. firms, President Ronald Reagan signed the Malcolm Baldrige National Quality Improvement Act in 1987. The MBNQA was named in remembrance of Malcolm Baldrige, Secretary of Commerce, for his great contribution to US quality excellence movement. This award was created to promote quality awareness, identify the requirements for quality excellence and share information about successful quality strategies and benefits. The National Institute of Standards and Technology (NIST) currently administrate this award with assistance by American Society for Quality (ASQ) for the application review process, preparation of award documents and other administrative duties.

Table I. Summary of MBNQA & EQA features and attributes

Name (year)	MBNQA (1987)	EQA (1991)
Country	USA	European
Responsible organization	NIST	EFQM

Core values and concepts	1. Visionary leadership	1. Results orientation
	2. Customer-driven excellence	2. Customer focus
	3. Organizational & personal learning	3. Leadership & constancy of purpose
	4. Valuing workforce members and partners	4. Management by process & fact
	5. Agility	5. People development & involvement
	6. Focus on the future	6. Continuous learning, innovation & improvement
	7. Managing for innovation	7. Partnership development
	8. Management by fact	8. Corporate social responsibility
	9. Societal responsibility	
	10. Focus on results & creating value	
	11. Systems perspective	
Criteria and scoring system	1. Leadership (120)	1. Leadership (100)
	2. Strategic planning (85)	2. Strategic (80)
	3. Customer focus (85)	3. People (90)
	4. Measurement analysis & knowledge management (90)	4. Partnership & resources (90)
	5. Workforce focus (85)	5. Process & product/ service (140)
	6. Process management (85)	6. People results (200)
	7. Results (450)	7. Customer results (90)
Evaluation dimensions	Process: Approach, Deployment, Learning, Integration (ADLI)	Result, Approach, Deployment, Assessment, Review (RADAR)
	Result: Level, Trends, Comparisons, Integration (LeTCI)	
Award procedures	1. Applicants submit the 75-page application materials	1. Applicants submit the 75-page application materials
	2. Independent review conducted by at least five examiners	2. Individual assessments are conducted by at least six assessors
	3. Consensus review conducted on outstanding applicants	3. Team of assessors meets and determiners consensus score for applicants. Next, those short-listed receive site visits
	4. Site visits are conducted on short-listed finalists	4. The assessment teams prepare the site visit reports
	5. Judge reviews the on-site evaluation report and recommends the award winners to director of NIST	5. The panel of judges reviews the site visit reports, determines the winners and the role model

The process to legislate this award led to the development of a bill stated that it would help to improve quality and productivity by ‘establishing guidelines and criteria that could be used by business, industrial, governmental and other enterprises in evaluating their own quality improvement efforts’ (DeCarlo & Strett, 1990). The MBNQA criteria, used to assess an organizational performance, are divided into seven categories and provide the strategic direction for the entire organization. The seven categories are leadership, strategic planning, customer focus, measurement analysis & knowledge management, workforce focus, process management and results. These categories are built on a set of 11 interrelated core values and concepts (see Table I). The MBNQA model includes a leadership triad (leadership, strategic planning, and customer focus categories), a results triad (workforce focus, process management and results categories), and measurement analysis & knowledge management serves as the information provider to support the two triads. The way in which organizations evaluate each criterion stated above in terms of a two-dimensional system which included ‘process’ and ‘results’. The process is comprised of four sub-dimensions, ‘ADLI’ which indicates ‘approach’, ‘deployment’, ‘learning’ and ‘integration’. The result is also comprised of four sub-dimensions, ‘LeTCI’ which indicates ‘levels’, ‘trends’, ‘comparisons’ and ‘integration’.

One of the major objectives of MBNQA is to provide the recognition to the organizations that show understanding and improving their quality by continuous improvement in terms of MBNQA approach. The award procedures include: (i) applicants submit the 75-page application materials, (ii) each application is reviewed independently by at least five examiners, (iii) consensus review conducted on the outstanding applicants, (iv) site visits are conducted on short-listed finalists, (v) the full panels of judges review the on-site evaluation reports and recommend the award winners to director of NIST.

European Quality Award

14 major European companies formed the European Foundation for Quality Management (EFQM) in 1988 with the endorsement of the European Commission in response to recognize the importance of quality performance. In 1991, European Quality Award (EQA) was developed by EFQM to honor outstanding European businesses.

EQA is similar to MBNQA but has its own fundamental concepts, criteria and evaluation dimensions (see Table I). The nine criteria are comprised of quality improvement enablers and results. The quality improvement enablers include leadership, strategic, people, partnership & resources, process & product/service. Effective implementation of the enablers influences the results. The result criterion includes people results, customer results, society results and key results (see Table I). The evaluation of each criterion includes a five-dimensional system, ‘RADAR’ which indicates the abbreviation of ‘result’, ‘approach’, ‘deployment’, ‘assessment’ and ‘review’. EQA improves its own quality model by continually analyzing applicant feedback and making necessary adjustments.

The EQA procedures include: (i) applicants submit the 75-page application materials, (ii) individual assessments are conducted by at least six assessors, (iii) team of assessors meets and determiners consensus score for applicants. Next, those short-listed receive sit visits,

(iv) the assessment teams prepare the site visit reports, (v) the panel of judges reviews the site visit reports, determines the winners and the role model.

Self-assessment

BEMs illustrated in the previous section are not only designed to present the criteria and procedures to compete award winner; its purpose is to become an effective self-assessment tool for those who are interested in quality and allocate resources to serve as a guidance for improving their organizations. That is to say, the model is geared not only to the organizations in a position to successfully compete for the award but also to those who wish to take up the challenge of pursuing competitiveness and business excellence. Porter & Tanner (2004, p287-312) proposed an eight-step common processes for an organization to conduct a self-assessment (see Figure 1). It starts from choosing the framework and ends up with eliciting the action plans for those that are necessary to be corrected or improved.

Figure 1 Common processes of a self-assessment

Step 1-Choosing the framework

The purpose of the step is to choose a BEM being used in the self-assessment project. The issues to be addressed include choosing between the various frameworks, for example, MBNQA or EQA. There is no ‘best’ framework, only the appropriate framework. Several factors dictate the choice of the actual framework, including length of experience with assessment and geographical location. At the detailed level within the frameworks, many organizations tailor the framework and terminologies to improve its usability. Except that, the management issues which related to this self-assessment project have to be identified by the in-charge manager in this step. They include the details of each main activity, timescales and resource requirements.

Step 2-Forming the assessment team

Due to the criteria address a wide range of areas, including human resource management/organizational behavior (leadership, people management and results), business analysis (all the results’ criteria), and process management. No single person is likely to have an in-depth knowledge in all these areas. Thus, the implementation of BEM self-assessment is a team-based activity. It involves forming a team that has the responsibility for preparing the submission. It is essential that the submission team members are drawn from a broad cross section of the organization, have the necessary insights and the authority to access the information required. Also, the process of assessing business or organizational excellence relies on people being able to make an objective assessment of excellence. People’s perception of excellence differs, and the team-based approach makes the whole process robust to those differing views and experiences.

Step 3-Collecting the information

Self-assessment is an organizational health check that is best based on facts and not subjective opinions. However, there are various ways of establishing the facts. This step is governed by two factors, the objectivity required and the resources available. Generally speaking, greater objectivity requires more resources. A range of data collection approaches is available for different stage of quality maturity. The approaches include questionnaire survey, matrix, pro-forma, and award-type processes. Generally speaking, the organization with the less quality maturity chooses the rather basic data collection approaches, such as questionnaire survey. It allows the assessments project to be made without too much resource consumed. On the other hand, the organization with the more quality maturity chooses the more advanced data collection approaches, such as award-type processes.

Step 4-Assessment and scoring

The first task of the assessment team is to carry out an individual assessment and score the submission in this step. Assessors review the entire submission document to identify the strengths, areas for improvement, and clarification issues in the site visit. This information is recorded in a scorebook in terms of a multidimensional evaluation scoring system, such as 'result', 'approach', 'deployment', 'assessment' and 'review' in EQA. The multidimensional evaluation scoring system has many advantages, it is important to separate approach/deployment/assessment/review from results/scope.

Step 5-Consensus

Following the individual assessment and scoring, members of the assessment team come together to share their views on the submission and to reach consensus on the strengths, areas for improvement, scores and clarification issues in the site visit. Consensus is a learning opportunity for each assessor, and provides the opportunity for the team to take an overview of the total information available from each individual assessment, reassess the evidence and reach consensus. The senior assessor plays a key role in the process and is responsible for organizing and running the consensus meeting.

Step 6-The site visit process – clarification and verification

It is almost impossible to capture the true position of an organization in the submission document. During the assessment process, many areas require further clarification. It is also necessary to make the verification to the validity of the submission document. These tasks can be carried out during site visits to the organization. Individual assessment, consensus and site visit are the key sub-processes to a self-assessment project.

Step 7-Feedback

The feedback report is the major output from the self-assessment process. It is the final analysis of the organization and contains the accumulated knowledge acquired by the assessor team. A good report is tactful and constructive and is based on fact not on subjective opinion. It should encourage the organization to take improvement opportunities forward and ensure that the best practice is deployed across the organization.

Step 8-Action planning

Any self-assessment cycle should be concluded with a post completion review to identify what went well with the process, what could be improved, and what benefits have been or are likely to be achieved. The culmination of the whole process is to take the feedback from the assessment and to develop action plans that deliver increased levels of satisfaction for the stakeholders – namely customers, employees, society at large and the shareholders to the other financial stakeholders.

The extension models

Despite BEMs presented above are designed to serve as a total solution of business management, it is still experienced by practitioners the necessity of further guidance in the implementation. That means organizations usually encounter problems in applying the models because the complex process, such as assessment criteria and scoring system are to generally defined, especially with inexperienced assessors (Siow *et al.*, 2001; Yang *et al.*, 2001; Porter & Tanner, 2004, p287-312). The extension models are then developed to remedy the problems. Some of the models are self-assessment roadmap (Porter & Tanner, 2004, p287-312), self-assessment methodology (Ahmed *et. al.*, 2003), self-assessment decision model (Li & Yang, 2003) and 4P quality strategy model (Dahlgaard & Dahlgaard-Park, 2004), etc.

Among them, it is interesting to find that each model was proposed to respond certain specific deficiencies respectively. For example, ‘self-assessment roadmap’ which was proposed by Porter & Tanner in 2004 is in response of the general defined assessment criteria. This extension model is a contingency-based, which the roadmap is divided into three phases: ‘entry’, ‘user’ and ‘world-class’ in terms of the experience of practicing self-assessment. The three phases were given the names to capture the emphasis of the phase. The entry phase indicates the start to implement self-assessment as a vehicle for improving its performance. The awareness of self-assessment is the essential in this phase. The user phase is entered when the benefits of self-assessment have been recognized and understood. The world-class is reached when continuous improvement becomes embedded into the learning organization. Porter & Tanner suggested that the specific action plan and situation have to be in place for each phase before a self-assessment project being launched. The specific action plan and situation include typical score, time from start, issues to address, leadership, self-assessment approach, organizational elements, support mechanisms, benefits/deliverables, etc.

On the other hand, ‘self-assessment methodology’ and ‘self-assessment decision model’ are proposed to respond the criticism on measurement system. The authors utilized multiple criteria decision making (MCDM) and evidential reasoning (ER) approaches in the self-assessment process. The proposed methodology provide by authors is an eight-level structured framework for self-assessment, which starts from level zero to level seven. Level zero represents the initial decision relating to the appropriateness of applying for the EQA. Level one illustrates the ingredients required for the assessment process. Level two indicates the understanding stage with reference to the EQA criteria. Level three identifies which of the sub-criteria requires a focus on planning, corrective action, measuring, or

improving. Level four concentrates on classifying organizations into seven categories and specifying the characteristics associated with each category. Level five focuses on RADAR logic, and level six provides a comprehensive guideline for assessing each element of the EQA criteria. Level seven is designed to weigh the final scores of the self-assessment process. The authors argued that the intelligent decision system being developed can be used to improve how the self-assessment process is carried out and provide accurate and fast scoring tasks.

'4P quality strategy model' was proposed by Dahlgaard & Dahlgaard-Park in the early 90s. The '4P' definition is based on the argument that the first priority of any quality or excellence strategy should be to build quality into 'people' as the essential foundation and catalyst for improving 'partnerships', 'process' and 'products'. This model starts from conducting a 7-point Likert scale questionnaire of self-assessment. The questionnaire uses a double-scale to measure the degree of importance and agreement in each aspect of excellence. The aim of quantitative self-assessment process is to involve everyone in improving enablers as well as results. The 'vital few' improvement areas are then identified by choosing the biggest differences between the two measures. The organizations finally establish cross-functional improvement team to come up with action plans by using quality map. This model was adopted firstly by the Post Denmark in 1990 and used by several Scandinavian companies after that time. In the opinion of the authors, this model is applicable in almost any organization to ensure a successful start up in TQM, or excellence building process.

The benefits and the deficiencies

A review of the previous researches in this area, it is found that some of the research findings are positive and supportive, while the others are negative and questioning. They are respectively illustrated in the following.

First of all, the positive and supportive research can be summarized into two categories. One of the two categories is to directly investigate the business results for those BEM adopters. The business results include the financial indicators, such as the researches done by Hendricks & Singhal (2000) and Pannirselvam & Ferguson (2001); and the non-financial indicators, such as the researches done by Hendricks & Singhal (1996), Ford & Evans (2000), Wilson & Collier (2000) and Douglas & Judge (2001). The non-financial indicators include the enhanced innovation & idea generation, customer satisfaction, organizational growth, employee satisfaction & involvement and effectiveness & productivity. The other category is to investigate the cause-effect linkages among the enablers and the business results. The researches done by Wilson & Collier (2000), Meyer & Collier (2001), Su *et al.* (2003) and Sauders & Mann (2005) are belonged to this category.

Despite the use of BEMs can produce both financial and non-financial benefits to an organization, it is found that receiving NQA is not a guarantee of long term success and could be failed for those who do not show the continuous improvements in accordance with external environment change (ex., Wisner & Eakins, 1994; Powell, 1995; Melnyk & Denzler, 1996; Terziovski & Samson, 1999; Fisher *et al.*, 2001). For example, the poor

performances of past winners Cadillac, Federal Express, Wallace and Motorola have led pundits to question the value of these awards.

The other researches point out the deficiencies which are related to the operations of self-assessment or award application (Miller, 1993; Goh & Ridgway, 1994; McTeer & Dale, 1994; Wilkes & Dale, 1998; Lee *et al.*, 2006). The operational deficiencies include excessive paperwork, cumbersome procedures, time consuming and quality bureaucracy, etc. To meet the award's requirements it is necessary to collect vast amounts of internal and external information, analysis the data and expend substantial amounts of managerial effort. For example, Corning devoted over 14,000 man hours towards its award submission in 1989. King Division in Westinghouse's Thermo was estimated to have spent almost USD 500,000 on internal labor and as much on outside technical assistance in putting its application together. Florida Power & Light, the first winner of the Deming Prize for Overseas Companies, spent USD 850,000 on fees to Japanese consultants to help it improve its quality systems and the point at which it could meet the Prize's standards. Also, several complaints are come from the adopters that both the Deming Prize and MBNQA represent a creeping bureaucracy of the quality infrastructure (Main, 1991).

Arguments in response to the deficiencies

Now, let's go back to the questions raised in the introduction: Why the research findings are inconsistent? Why the practitioners meet difficulties? Based upon the past literature reviewed in this section, the present authors postulate the following five arguments in response to the deficiencies which were found in the existing models.

The first argument is that the existing models are rarely made adjustments in accordance with the scientific empirical evidences. It would result in the models deviating from the practical arena and the user-friendly perspective. Although two major BEMs follow a different strategy in the model adjustment, they both went through several major and minor changes since they were announced. For instance, the MBNQA made the first major adjustment in 1988 transform the criteria system from a quality framework to a business framework. It was further transformed to a performance framework in 1997. Besides, the number of criteria was made adjustments of more and less, and the form of criteria was also changed as well. Similarly, EQA has undergone several adjustments. One of them was taken place in 1995 for the 'result' criteria being split down into two sub-criteria, leading measures and lagging measures. The other was taken place in 1999 for introducing the RADAR logic and changing the criteria. It is believed that the ideas of the adjustments were mostly derived from the subjective experiences of either the experts in the award-in-charge organization or the external consultant/academician. The present authors argued that lack of scientific empirical evidences will result in the adjustments become too emphasis on the prescriptive perspective which implies the ignorance of users' needs.

The second argument is that the existing models, except self-assessment roadmap and MBNQA, do not include the contingency factors which are particularly important to the organization with different size, industry sectors and experience in practicing self-assessment. For example, small and medium enterprises (SMEs) show their interesting to BEMs, but thus far the models are not widely utilized in this area. Wilkes & Dale (1998)

suggest that the development of a simplified model which is suitable for SMEs is necessary. The simplifications include number and format of the criteria, application processes and guidelines. On the other hand, Svensson & Klefsjö (2006) warned that it probably wastes resources to conduct a self-assessment if the organization has not reached the necessary quality maturity level. Karapetrovic & Willborn (2001) suggested to link the choice of the approaches with the quality maturity level of an organization and the intensity of effort invested in the self-assessment. Less complicated approaches (ex., questionnaire survey) are suggested to the less mature organization, while the more complicated approaches (ex., award simulation) is suitable for the more mature organizations.

The third argument is that the existing models, except 4P quality strategy, are essentially attributed to a sort of assessment tools only instead of serving as a 'total solution' management tool. A total solution indicates that the tool has to be usable in each phase of Deming PDCA management cycle. As we know, both self-assessment and award review processes serve as the function of 'check' in the PDCA cycle. It is necessary to utilize other management tools or techniques to perform the rest of three in the cycle. That means the management tools or techniques except BEMs have to be employed after the areas for improvement being identified. The management tools or techniques are not specified in the existing models in spite of it is always claimed that any management tools and techniques can be integrated into BEMs.

The fourth argument is that the existing models have not had enough persuasiveness to convince 'total employee involvement' which is 'the must' in self-assessment. The researchers in this area indicated that the cooperation and teamwork are necessary ingredients for a self-assessment success (ex., Taylor & Hill, 1992; van der Wiele *et al.*, 1996; Chapman, 2000; Jackson, 2001). Also, Conti (1997) suggested that self-assessment team should be the main mechanism for gaining employee involvement. It is generally that the complexity of most processes places them beyond the control of anyone individual and thus the only efficient way to tackle process improvement is through teamwork. This has to rely on the premise that people are willing to support any effort in which they are asked to take part in (Oakland, 1999). However, the operational deficiencies stated above always keep the employee staying away from involvement in the self-assessment project.

The fifth argument is that the existing models are lack of integration in the operational level in spite of they do have the holistic view in conceptual level. For instance, the double triads of leadership and results are used to conceptualize the principal elements of management in the MBNQA. While, the original philosophy of EQA is that the superior performance is achieved by involving people in improving their processes. Based on the philosophical concepts, they are then further developed the models by decomposing BE into 7-9 criteria and 20-30 sub-criteria. The decomposition breaks down the organizational management into fragmentation that would result in the self-assessment being lack of integration and focus. Although the approaches (such as, the extension models mentioned above), the mechanism (such as, consensus meeting) and the regulations are established to assist the integration, it still does not work well in the practical arena (Munro-Faure & Munro-Faure, 1994, p254; van der Wiele *et al.*, 1996). Lewis (1999) found that most of departments in Southwark Council had experienced the difficulty in embedding the assessment processes into planning and review activity. Also, the researchers suggest that self-assessment and the

subsequent improvement planning should be integrated into the company planning cycle. And strategic planning as the implementation of the identified areas for improvements might need the strategic allocation of resources (Conti, 1997; Henderson *et al.*, 1999; Chin & Pun, 2002).

Fundamental Premises for a comprehensive bem

Having the review of the deficiencies in relation to the existing models, we turn out the way to postulate four fundamental premises (FPs) which are, on the one hand, in response of the arguments raised in the pervious section and, on the other hand, to highlight the required principles for the new model that will be proposed in the next section.

FP 1: It should be a prescriptive-based model but make adjustments in accordance with the empirical evidences which are descriptively derived from the scientific research.

Quality is commonly measured by two dominant factors, ‘functions’ and ‘cost’. It can be mapped to a good quality management tool which is measured by ‘usefulness’ and ‘easy-of-use’. It is apparent that a good quality BEM should be embedded the two dominant factors. ‘Usefulness’ means that adopters choose this management tool in the beginning, and the excellent outcomes are finally achieved through following the guidance of the management tool. ‘Easy-of-use’ means that the management tool is designed by fitting the propensity of humankind, and less mental effort or attention is necessary to pay on it.

Having the illustrations of the two dominant factors, two questions are raised here: What the order of the two factors is? How they are embedded into BEMs? The answers are: ‘Easy-of-use’ is generally the premise of ‘usefulness’. According to the structure of scientific logic, a scientific research often starts from the descriptive approach to empirically look for the possible influential factors in terms of the observed effects. The prescriptive approach is then employed to test the hypotheses which are derived from the previous descriptive research. Both approaches come together to make the progress of science. In other words, science benefits human being by first examining the possible causes from the effects (descriptive approach), and then observing the effects from the experiments of the possible causes (prescriptive approach). The present authors hold that a good quality BEM should follow this structure of scientific logic. That is, on the one hand, the process of following the guideline of the management tool which indicates ‘usefulness’ is the prescriptive approach. And also it can be referred to the terminologies of left-to-right method or cause-to-effect logic which were invented by Conti (2002, 2007). On the other hand, the process of fitting the propensity of humankind which indicates ‘easy-of-use’ is the descriptive approach. It can be referred to the terminologies of right-to-left method or the effect-to-cause logic, the same by Conti (2002, 2007).

FP 2: It should work well not only as a measurement model but also as an organizational improvement model in the self-assessment or the quality award competition.

As we know, BEMs are designed not only to provide the criteria and procedures for the competition of quality award but also the main purpose is to become an effective self-assessment tool for those who are interested in quality management and generate the action plans to improve their organizations. However, the empirical experiences show that both functions often do not exist in the same platform or an organization. Conti (2002, 2007) had proposed these two functions should be separated into two different models as it is used in an organization: 'quality measurement model' and 'organizational improvement model'. He said 'the award and self-assessment with the same model and process. One cannot want to have one's cake and eat it. One cannot manage a model as a recognized standard for measuring (or better, estimating) organizational quality and at the same time promoting it as an organizational improvement model, where flexibility and customization are the name of the game'.

From the philosophical perspective, 'the state of art' indicates certain behavior comes together with rationality and sensibility on the one hand, and the universality is also shown as well on the other hand. 'The state of art' is always the ultimate goal to be pursued. Sometimes, certain management approach or action is called as 'reach the state of art' due to the three attributes, rationality & sensibility & universality, being embedded at the same time. To develop a total solution type of BEM which can work well in both functions (that is, quality measurement and organizational improvement) is challenging. It implies both functions work well not only being used independently but also coming together in one model as well. It deserves the people in this professional society to make effort on it. Thus, the success of this challenging task can be referred as 'reach the state of art'.

FP 3: It should be not only seamlessly merged into the existing system in an organization but also totally accepted by employee.

It is no doubt that the BEM initiatives are utilized for the assistance of an organization in achieving business excellence and organizational sustainability. To accomplish the objective, it is no way without the total acceptance and getting BEM into a habit of daily operation by employee. In practice, integration of the BEM into the existing system can be achieved through a combination of multiple management activities in the organization, including using it as part of the strategic planning process, aligning with other organizational systems, linking with performance management and involving staff in it through teamwork. However, it is found that a number of issues and problems are associated with the implementation, such as excessive paperwork, cumbersome procedures, time consuming and quality bureaucracy, etc., which were mentioned above. These operational deficiencies always keep practitioners away for this management tool. In our opinions, it is resulted from too little focusing on understanding the human factor.

As the suggestion by Oakland (1999), the key is to align the employee with the core processes of the organization. More specifically, if the BEMs can be aligned with activities, which are already taking place within an organization, then it is more likely to become integrated into the organization and thus aid effective implementation. Dale *et al.* (1998) also recommended that the need to integrate the use of the BEMs into other management activities. The example of BE implementation at the University of Bradford Management Center done by Oakland in 2000 showed that it was seen as essential to fully integrate any

BE initiatives into the management systems of Management Center. Nonetheless, Jackson (2001) offers an interesting perspective on integrating BE tools into organizations. She emphasizes the positive effect of the tool facilitating activities that are already in place. As a result people are more comfortable with this situation than they would be in which the existing processes were completely discarded for new ones.

FP 4: It should provide a ready-to-use guidance to incorporate with the other management tools/techniques.

In subsequence of the argumentation in FP2, the existing BEMs are recognized as a good tool in conducting the assessment but it is still deficient in facilitating the organizational improvement. To be a total solution, it is necessary to incorporate the other management approaches into BEMs to remedy this deficiency. The literature told us this truth. Some of the suggested approaches include the balanced scorecard, Lean, the Six Sigma statistical tools, process management, and project management. In addition, many quality specialists (gurus, experts and consultants) have proposed their own approaches. For instance, Ho (1999) proposed a sequence of adoption starting from 5S, BPR, QCC, ISO, TPM and TQM. Krasachol (2000) proposed a five-stage of BE implementation associated with quality techniques starting from no tools in the unaware stage, to Kaizen, 5S and QC tools in the basic stage, ISO 9001, SPC, TPM and TQM tools in the developing stage, BEMs in the mature stage and a complete set of tools for the sustaining stage.

Some of others hold the open aspect, such as Voss (2005) argued that there is no such thing as ‘best’ practice. Practices evolve; they need tailoring to the context and time. He suggests that the right thing to do depends on a complex variety of critical environment and internal contingencies. Hayes *et al.* (2004) also argued that there is no ‘one best way’ and a company must make appropriate decisions to fit the context within which the organization operates. The present authors hold that a systematic and organized approach to be readily incorporated into BEM is encouraged. The models found in literature, such as Ho’s sequence model, are independent of BEMs. It is suggested to be considered a step further to incorporate them into BEMs.

Development of a comprehensive bem fact

In the previous section, four FPs highlight the directions of a new BEM. They manifest the specifications of the new model. How it will be developed in terms of the drawn specifications? In fact, it is a challenging work. Both of ‘the reductionism’ and ‘the holism’ from the existing BEMs are the two philosophical perspectives adopted by the present authors in this work. In light of the experiences in NQA examination and the development of self-assessment system in their own country, the present authors firstly consider the holism perspective to propose the conceptual model in this section. And the reductionism perspective is then considered to implicate the proposed model in the next section.

The proposed model is a three-dimensional design which is called ‘FACT’. ‘FACT’ indicates the abbreviation of ‘Framework of BE’, ‘Add’, ‘organizational Culture/Characteristics’ and ‘management Tools/Techniques’ (see Figure 2). It means that a comprehensive BEM should integrate with not only using BE framework to be guidance

and to make assessment of an organization, but also choosing the appropriate management tools/techniques and cultivating the right organizational culture/characteristics towards BE.

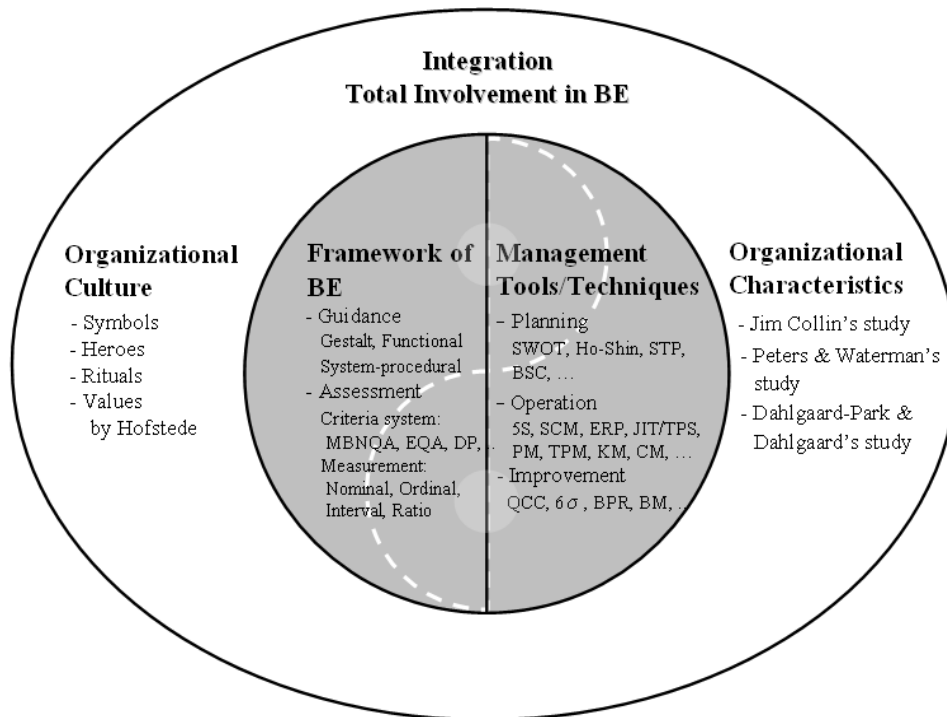

Figure 2 Conceptual model of FACT

Figure 2 presents the conceptual model of FACT. The two dimensions, framework of BE and management tools/techniques, are placed in the left and the right hand sides of the inner circle, respectively. It indicates, on the one hand, they ought to serve as the two independent functions in an organization: ‘BE assessment’ and ‘quality improvement’ which were mentioned by Conti (2002, 2007). And on the other hand, the two functions also ought to come together as one in a circle. The dotline in the circle means that two functions not only coming together as one in a circle but also a step further of fusing each other as a ‘Chinese Tai Chi’. It metaphors that the framework of BE should be further institutionalized into an organization to become an overall guidance to BE and in the meantime, all of the management tools/techniques should be implemented for the purpose of pursuing BE. The third dimension, organizational culture/characteristics, placed in the outer circle indicates that integration and total employee involvement ought to be cultivated in an organization in order to be successful in the journey of BE. It is coined the philosophy of EQA that the superior performance is achieved by involving people in improving their processes, and the 4P quality strategy proposed by Dahlgaard & Dahlgaard-Park (2004) as well. Each of the three dimensions of FACT is illustrated in the following.

Framework of BE

First of all, the use of BE framework is for two purposes: guiding the organization towards BE and conducting assessment of the performance. Guiding towards BE is the primary purpose for the intension of pursuing organizational sustainability. And, conducting

assessment is the secondary purpose which can be either self-assessment to diagnose the strength/weakness of an organization or award examination to select the winners.

For the primary purpose of using BE framework to guide an organization, it is important to set an orientation in the earlier stage of BE journey and to keep sticking on it hereafter. What kind of orientations can be chosen for this purpose? As we know, MBNQA, EQA and Deming Prize are the three most well-known BEMs in the world. Deming Prize is the originator which was launched in 1951. The western countries then followed the Deming Prize in recognizing quality and excellence, as a result MBNQA and EQA were established in 90s. So far as over hundred countries of national and regional BEMs are usually based on either MBNQA or EQA. Despite most of these models are recognized to have a high degree of commonality, the present authors found that they have significant different orientation in the design of each criteria system. For instance, MBNQA consists of seven criteria (see Table I) which represent most of the principle functions of an organizational management. It can be treated as a *functional-oriented* model. While, the nine criteria in EQA (see Table I) adopt the idea for giving the precedence to build people and partnership, then to establish the operation system and to achieve the outcomes hereafter. It can be treated as a *system-procedural-oriented* model. The ten viewpoints in Deming Prize (Porter & Tanner, 2004, p188-204) intend to examine an organization from various aspects as a whole. They include leadership & vision & strategies in top management, TQM framework, TQM concepts & values, scientific methods, quality assurance system, human resources development, effective utilization of information, organization power, management system for business elements and contribution to realization of corporate objectives. Instead of the mutual exclusive criteria design, such as MBNQA and EQA, the ten viewpoints are quite a sense of looking at an organization from different angle. It can be treated as a *Gestalt-oriented* model. Based on the three orientations stated above, adopters are allowed to choose one of them in terms of their preference or the purpose of use in guiding the organization towards BE.

Rather, conducting an assessment is the secondary purpose of using BE framework. For this purpose, the eight-step common processes proposed by Porter & Tanner (2004, p287-312) and the quality award procedures proposed by the award-in-charge organization are some of the good examples for reference. In FACT model, a BE criteria system and its measurement scale have to be chosen in the beginning. As suggested by Porter & Tanner, the choice of a BE criteria system can be one of the following: MBNQA, EQA, Deming Prize, etc. Each of BE criteria system provides a framework of standardized items that an organization can examine its performance. In addition, the choice of appropriate measurement scale suggested by FACT allows the comparisons to be made theoretical correctly among different timelines, organizations and assessors. The measurement scale can be chosen among nominal, ordinal, interval and ratio. In terms of the examinations of written report and on-site visit, the score is ordinal if it is measured by Likert scale in data collection without weighting, while it is interval as the score is derived with weighting. The 1000 point score system is ratio.

Management tools/techniques

The use of management tools/techniques is one of the three major dimensions in FACT. Three types of management tools/characteristics are categorized in this study: planning, operation and improvement. Each category has its specific function. The tools used for the function of planning include SWOT, Ho-Shin strategic management, Balance Score Card (BSC), Segmentation-Targeting-Positioning (STP), etc. The tools used for the function of operation include 5S, Supply Chain Management (SCM), Enterprise Resource Planning (ERP), Just-in-Time (JIT)/Toyota Production System (TPS), Project Management (PM), Total Preventive Maintenance (TPM), Knowledge Management (KM), etc. And the tools used for the function of improvement include Quality Control Circle (QCC), 6 σ , Business Process Reengineering (BPR), Benchmarking Management (BM), Change Management (CM), etc.

In light of BE framework serving as one side of a coin, the use of management tools/techniques is the other side of a coin in FACT. In the opinion of Conti (2002, 2007), a BEM is requested to serve as a recognized standard for measuring organizational quality and at the same time promoting it as an organizational improvement. The functions of both sides in FACT are somewhat broader than the idea proposed by Conti. As mentioned above, the use of BE framework in FACT is for the purpose of not only measuring organization quality but also guiding the organization towards BE. It is the same that the use of management tools/techniques is for the purpose of not only the organization improvement but also for the organization planning and operation. The use of BE framework indicate the functions of 'Check' and part of 'Plan' in a PDCA management cycle. While, the use of management tools/techniques indicates the rest of three functions, part of 'Plan', 'Do' and 'Action' in the cycle. Both sides come up with a coin, which means a complete PDCA management cycle.

Besides, based on the original idea in developing BEM, it is initially used as a tool for the organizational self-diagnosis. The management tools/techniques are then employed for the function of improvement. Afterward, it is extended to be used as for the application of quality award. It indicates that the use of BEM is requested to follow a sequence of self-assessment, improvement and award competition. But the use of BE framework and management tools/techniques in FACT are unnecessary to follow the sequence. In other word, on the one hand, the management tools/techniques can be employed either before or after the assessment. For instance, TPS is able to be employed in any time which is before or after the BE self-assessment being conducted. On the other hand, BE framework can be always used as a guidance to direct the organization towards BE no matter when any specific management tool/technique is employed. Here, 'Chinese Tai Chi' is used to metaphor the process of fusion of the two dimensions in FACT. In terms of Wikipedia (2011) description, the common English translations of 'Tai Chi' are 'Supreme Ultimate', 'Supreme Polarity' or 'Great Absolute'. Chinese philosophers explained the ontological necessity of 'Ta Chi' as any philosophy that asserts two elements, such as yin-yang of Chinese philosophy or positive-negative, will also look for a term to reconcile the two, to ensure that both belong to the same sphere of discourse.

Organizational culture/characteristics

Cultivating the right organizational culture/characteristics for an organization towards BE is the third major dimension in FACT. It is placed in the outer circle to surround the other two dimensions. It implies that it is impossible to have a successful BE without the right organizational culture/characteristics. Two issues are raised here: one is what the right organizational culture/characteristics is, and the other is how it can be cultivated.

In response of the first issue, the present authors postulate that ‘integration’ and ‘total involvement in BE’ are the two most important culture/characteristics in FACT which ought to be cultivated in an organization. There are the similar argumentations raised by the quality specialists. For instance, Dahlgaard & Dahlgaard-Park (2006) argued that to change corporate cultures from a passive and defensive culture to a proactive and open culture among the total employee is the basic principle in order to increase customer satisfaction and continuous improvement. Also, Caudron (1993) and Schein (1993) stated that a supportive organizational culture is essential in promoting a learning organization. Advocating challenging work, open communication, trust, innovation, and cohesion among employees are essential attributes in defining a supportive culture.

Besides, several fabulous empirical studies, which are not often mentioned in the BEM literature, have been done to investigate the characteristic in relation to organizations change themselves from mediocre to excellence. Such as, the study done by Collins & his colleagues (2001) come up with seven organizational characteristics after the conduction of intensive survey to 11 good-to-great enterprises over the period of 15 years (1985 to 2000). The seven organizational characteristics include level 5 leadership, get the right people on the bus, confront the brutal facts, hedgehog concept, rinse the cottage cheese, technology accelerators and flywheel process. The first two indicate the disciplined people. The third and the fourth indicate the disciplined thought. The fifth and the sixth indicate the disciplined action. The last one indicates the combination of the front six characteristics. The other fabulous empirical study done by Peters & Waterman (1982) elicited eight organizational characteristics through the conduction of intensive interviews with more than 14 companies which were leading in the records of long-term profitability and continuing innovation in 1980s. The eight organizational characteristics include a bias for action, close to the customer, autonomy & entrepreneurship, productivity through people, hands-on & value-driven, stick to the knitting, simple form & lean staff and simultaneous loose-tight properties. Each of the eight characteristics can be further attributed to one of the following three aspects: people & structure, customer and action. Except the BE organizational characteristics derived from above empirical studies, Dahlgaard-Park & Dahlgaard (2007) also gave an illustration to the understanding of what is excellence. It is said that ‘Excellence can be attained if you: Care more than others think is voice; Risk more than others think is safe; Dream more than other think is practical; Expect more than others think is possible’.

In response of the second issue, how the organizational culture/characteristics can be cultivated in an organization, the present authors suggested the theory proposed by Hofstede *et al.* (1990). Hofstede *et al.* classified manifestations of culture into four categories which are ‘symbols’, ‘heroes’, ‘rituals’ and ‘values’. The four categories are taken the example of peeling off the successive skins of an onion from shallow (symbols) to deep (values). Symbols are word, gestures, pictures, or objects that carry a particular

meaning within a culture. Heroes are persons who possess characteristics highly prized in the culture and who thus serve as models for behavior. Rituals are collective activities that are technically superfluous but are socially essential within a culture. The three categories are subsumed under the term 'practices', because they are visible to an observer although their cultural meaning lies in the way they are perceived by insiders. The core of culture is formed by values, in the sense of the feelings of good and evil, beautiful and ugly, normal and abnormal, rational and irrational. The feelings that are often unconscious and rarely discussable that cannot be observed as such but are manifested in alternatives of behavior. 'Integration' and 'total involvement in BE', the two most important organizational culture/characteristics in FACT, can be cultivated by using the onion theory and the instrument which are developed for the practitioners.

Implications and Conclusions

Implications of FACT

Having the development of FACT in the previous section, the implications of the model are further illustrated in the following. Instead of using 'Chinese Ta Chi' as the metaphor of the fusion between both dimensions of BE framework and Management tools/techniques in an organizational management, the trinity is used to implicate the three dimensions of FACT as a whole. Figure 3 and Figure 4 present the illustrations of the trinity of the model.

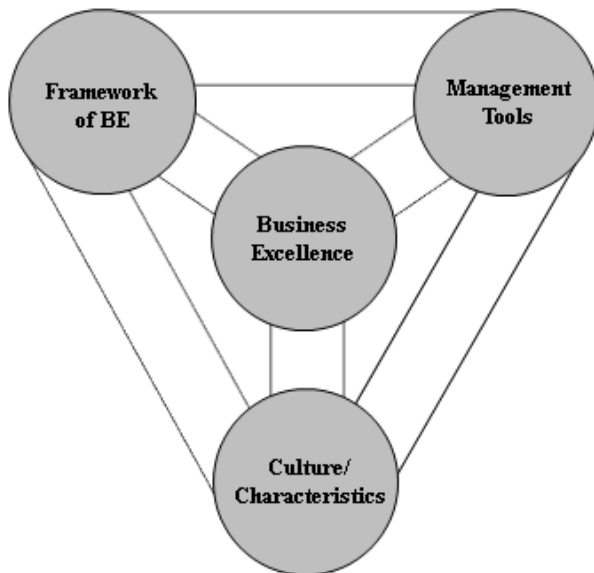

Figure 3 Illustration (I) of the trinity of FACT

The idea of using the trinity as the implications of FACT is derived from the Christian doctrine. This term has been stated in Christian theology since the beginning of the third century. The word of trinity in etymology is derived from Latin 'trinitas' which means 'the number three, a triad'. The corresponding word in Greek, 'τριάς', means 'a set of three'. In this paper, the correspondence with the trinity in etymology of Latin and Greek can be referred to the three dimensions in FACT come together as one goal towards BE. It indicates that not only the fusion of BE framework and management tools/techniques are

the two ‘must’ in the implementation of BEM but also the cultivation of right organizational culture/characteristics is necessary of the third ‘must’ as well (see Figure 3).

Besides, as shown in Figure 4, the trinity in FACT is presented in terms of the three elements of a person. Framework of BE indicates the skeleton. Management tools/techniques indicate the flesh and blood. And organization culture/characteristics indicate the spirit. All of the three elements are not only necessary to sustain one’s life but also should be entirely balanced one another as a whole. It implicates that ‘excellence’ generally represents a talent or quality which is unusually good and so surpasses ordinary standards. The word of ‘excellence’ in Greek is ‘arete’ which means ‘the act of living up to one’s full potential’, ‘something closer to being the best you can be’, or ‘reaching your highest human potential’. It is the most articulated value/virtue in Greek culture. In some sense of this term, it also indicates the happiness which resulted from a life well-lived, being prosperous and fulfilled. Studies have shown that the most important way to achieve excellent performance in fields such as sport, music, profession and academy is to practice, as commonly said, ‘Practice make perfect’.

Figure 4 Illustration (II) of the trinity of FACT

Mappings of deficiency arguments, fundamental premises and FACT

Figure 5 presents the mappings of deficiency arguments, fundamental premises and FACT. The purpose of the mappings is to examine if the new model proposed in this paper does respond all deficiencies found in the existing BEMs. The mappings are individually illustrated in the following. The first two arguments are criticized in regard to the lacks of scientific evidences and contingency factors in the existing model designs. The present authors argue that a new model should be prescriptive-based in order to be not only the guidance of users but also the measurement standard in an organization. This is the point to be postulated in FP1 and the dimension of ‘BE framework’ in FACT model. The third argument is criticized in regard to BEM is basically recognized as a measurement tool instead of the provision of a total solution. The present authors hold that a new model should be functioned as not only the measurement but also the planning/operation/improvement in an organization. This is the point to be postulated in FP2 and the necessity of ‘add’ more dimensions in the new model. The fourth and the fifth

arguments are criticized in regard to the lacks of persuasiveness for total involvement and integration in the operational level. The present authors hold that a new model should be easily integrated with not only the systems that have been existed but also the management tools that are appropriate in an organization. These are the points to be postulated in FP3, FP4 and the dimensions of ‘organizational culture/characteristics’ & ‘management tools/techniques’ in FACT model.

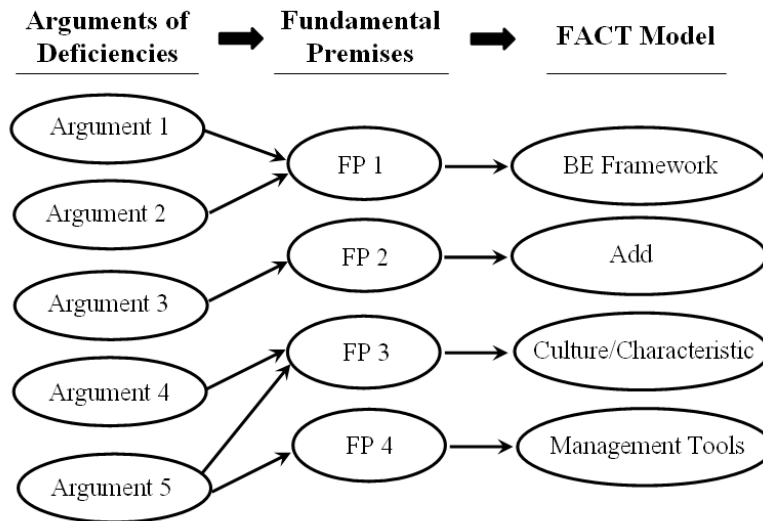

Figure 5 Mappings of deficiency arguments, fundamental premises and FACT

The possible future research

The development of a comprehensive BEM is set for the objective in the beginning of this research. A three-dimensional BEM is finally proposed which is called ‘FACT’. The contribution of this paper is significant, however it is the first study of this proposed model, some issues are planned for the further research. The empirical case studies will be first conducted to investigate, in term of FACT model, what the journey of a BE enterprise had been through. This is for the purpose of developing the roadmap of BE. Here, different forms of organizations can be included as the subjects of the empirical case studies, such as independent enterprise, enterprise group, enterprise supply-chain system or even industrial sector. Upon enough number of the empirical case studies being accumulated, the research objective will be focus on the improvement of national economic performance which is to investigate the benefits of BEMs from the macro viewpoint.

Acknowledgments

The appreciations are extended to Professor Jens Jorn Dahlgaard and Professor Su Mi Dahlgaard-Park, the distinguished visiting professors of Yuan Ze University, for their constructive comments to this research.

Combining Technical and Social Aspects to Conduct a Successful BPR Project

**Chi-Kuang Chen. Professor, Department of Industrial Engineering & Management,

Taiwan**

Key words: Business Process Reengineering, Social Factors, Technical Factors, Conceptual Framework.

Introduction

The business environment of the present day has become so complex that organizations are necessarily to be alert to respond to the new challenges and opportunities. This involves a continuous process of managing the change. Change compels either innovation or improvement or both. Many organizations tend to focus their attention on identifying innovations rather than improvement. Recently, the concept of Business Process Reengineering (BPR) has emerged as a conspicuous tool for restructuring the organization.

BPR has been defined as the fundamental rethinking and radical redesign of business process to achieve dramatic improvements in critical and contemporary measures of performance, such as cost, quality, services and speed (Hammer, 1990). BPR is an effective tool for organizations striving to operate as effectively and efficiently as possible, because reengineering processes must be made simple in order to meet demands for quality service, flexibility and low cost. But Process Reengineering is not reorganizing, restructuring, downsizing, automation or cost cutting. All of these, may be a result of a well thought out, well planned and well-executed reengineering project. Process Reengineering radically changes the work environment. Individual processes are combined to gain efficiencies and productivity. Workers are allowed to make decisions on the spot to eliminate process roadblocks and increase speed to market. Not only is this beneficial for overall business performance, it can also increase employee satisfaction and loyalty. Employees can expand their skill and knowledge into other areas, and have the ability to make decisions that affect their individual performance.

There are many BPR methodologies and models available, and most of them pursue a similar path and exhibit commonalities in key areas such as planning, monitoring and implementation (Butler, 1994). Today, an increasing number of methodologies, models and tools taken from other disciplines are available in the market, claiming that they are suitable for BPR initiatives. The major drawback of all the existing BPR methodologies studied and researched for this paper is that they have shown that the human and organizational issues were not incorporated successfully. It can be said that they don't combine the technical and the social aspects. The reason why this study is necessary is because it will focus on how to combine the technical and social aspects to conduct a successful BPR project. More

specifically, the authors proposed a framework that determines the most important technical and social factors that should be taken into account when conducting a BPR project. This framework will guide BPR top executives to identify the characteristics that the leader and his employees should possess in order to conduct a successful BPR project, as well as the relationship between them. More specifically, in this study, the present authors intend to achieve the following research objectives: (1) build up an effective framework that combines the social and technical aspects to conduct a successful BPR project, (2) develop a tool that will help an organization to evaluate the degree of success of a BPR project according to the factors proposed in the framework.

Literature Review

A review of the past research related to BPR is described in this section. It includes a general introduction to the history of BPR, as well as its technical and social aspects. For purpose of this study, technical factors will be defined as the steps or the methodology used throughout the project.

The History of BPR

BPR became very popular in the early 1990s with the publication of two articles, one in the Sloan Management Review by Thomas Davenport and the other one in the Harvard Business Review by Michael Hammer, both articles discussed the growing wave of process innovation and radical business process change. However, the methodology and approach was not fully understood nor appreciated by that time. Many times, improvement projects labeled with the title "BPR" were poorly planned and executed. Employees and organizations cringed at the thought of another "BPR" experience. The term itself is being used less, or is being altered so that these types of initiatives are not associated with the "BPR" of the past. Despite this abuse of the practice, the practice of redesigning business processes and the associated technology and organizational structure is more popular today than ever. Companies continue to reexamine and fundamentally change the way they do business. Competitive pressures and a sluggish economy provide the impetus for continued efforts to "deliver more with less." Reengineering remains an effective tool for organizations striving to operate as effectively and efficiently as possible, because reengineering processes must be made simple in order to meet demands for quality service, flexibility and low cost.

On the other hand, in the late 90s, more than half of the reengineering projects failed to be completed or did not achieve dramatic improvement results. Benchmark studies with more than 150 companies identified three success factors that this companies lack of (Prosci's 1998-1999 Reengineering Best Practices Study). The top three success factors in a process reengineering project are: first, it is imperative to have executive management support. Second, it is important to have willing participation of all associates involved in the redesign. The associates involved in the change must see value in the need for change and buy into the project. Last but not least, is the ability of the project team to discern what processes are value-added and customer-focused and which are not. It is easy to get side-tracked on processes that do not serve the customer at the end of the day. In process reengineering, a very important word should always be considered. That word is Gemba,

which means 'actual place' in Japanese. The Gemba is where the value is created. Value is created when people, information, materials, equipment, and processes come together to serve the customer (Gemba Research, 2003). In a process reengineering effort, it is important to figure out what processes support the Gemba and what processes do not. The processes that support the Gemba should be at the forefront of any reengineering project.

Technical Aspects of BPR

Methodologies represent the highest level of abstraction for conceptualizing problem-solving methods. In this study, methodology is defined as a collection of problem-solving methods governed by a set of principles and a common philosophy for solving targeted problems (Checkland 1981). Due to the rapid growth of interest in BPR, a large number of existing methodologies have been individually upgraded or combined in order to fall under the BPR umbrella. Some redesigners resist methodologies and consider them as a constraint especially in the case of fundamental/radical change. Their belief is that change management should be the focus from the beginning to the end of the BPR exercise. Others argue that the use of methodologies allow people to avoid mistakes and the use of their modeling techniques can be used as a medium for raising fundamental questions. Several methodologies have been proposed by different BPR's researchers. Table 1 presents the summary of the existing methodologies.

Table 1 Summary of the existing BPR methodologies

Methodology/ Stages	Davenport And Short	Evans	Peter Keeble	Fitzgerald And Murphy	Motwani et al.	Muthu et al.
1	Develop business vision and process objectives	To Be	Initiate Reengineering Programme	Select process to be reengineered	Understanding	Prepare for BPR
2	Identify the processes to be redesigned	As Is	Scope Programme	Establish process team	Initiating	Map and analyze As- Is processes
3	Understand and measure the exiting processes	The Plan	Redesign Process, systems and organizational structure	Understand current process	Programming	Design To- Be processes
4	Identify IT levers	The Crossing	Implement Culture Change Programme	Develop a vision of improved process	Transforming	Implement reengineered processes
5	Design and built a prototype		Sustain Commitment	Identify actions needed to move to new process	Implementing	Improve continuously

	of the new process					
6			Integrate Process and Organization	Negotiate/execute plan to accomplish actions	Evaluating	
7			Implementation and Monitor			
8						

It can be observed in Table 1 that the existing methodologies show commonalities in key steps such as planning, monitoring and control, but only the last two methodologies include the continuous improvement step which is fundamental in BPR because the organization as a whole will never stop competing in a continuously changing environment which leads to the continuous need for improved organizational processes and functions.

After reviewing each methodology, the authors identify the most important steps and the ones that should be included in every BPR project. These are the followings: First, a *vision* should be created. Based on the clear vision, the management should *select the business processes* that are needed to be redesigned. Then, *define clear and measurable objectives* for redesigning the reinvented processes. The new processes need to be *designed* and after all the employees understand the new processes, these ones are *implemented*. The *control and improvement* of the new processes should be done periodically.

Social Aspects of BPR

As the BPR concept has become mature and organizations have gained experience, the literature has emphasized the social and cultural aspects of the reengineering process, a concept known as *Change Management* (Towers, 1996; Cooper and Markus, 1995; Hammer and Stanton, 1995; Bashein *et al.*, 1994; Carr and Johanson, 1995; Bruss and Roos, 1993; Janson, 1992; Kennedy, 1994; Arendt *et al.*, 1995). Harvey's (1995) study found that change management is the biggest challenge in BPR implementation. Towers (1996) and Hammer and Stanton (1995) argued that managing change and people together is a major contributing factor to the success of BPR-related organizational change. In a discussion of the causes of reengineering failure, Cooper and Markus (1995) referred to the inadequate treatment of the human aspect when implementing BPR-related change. Kennedy (1994) discussed some elements of human change management which he described as 'the more difficult challenge', and explained how BPR represents a danger to people when it introduces new job structures and definitions, and forces employees to change their work style.

Change management involves several social processes such as commitment, leadership, empowerment of employees, communication, and process-based team formation (Arendt *et al.*, 1995). Each social process is described as follows.

Commitment. Commitment is the force that drives the relationship forward, toward a mutually desirable goal that usually points to growth and success. Research shows commitment has a positive effect on productivity, turnover and employees willingness to help co-workers (Bishop, J. and Scott K., 1997). Top management commitment is important to ensure the initiative is maintained and focused. But the commitment should be from the entire organization involved in the BPR project. In order to achieve a successful project, the top management, the project managers and the employees should be committed to the project. Commitment is demonstrated by a combination of two actions. The first action is called **supporting**. Genuine support develops a commitment in the minds and hearts of others. This is accomplished by focusing on what is important and leading by example. Supporting means concentrating on what adds value, spotlighting what's working, and rewarding others who are focusing on what is important and leading by example. The second action underlying commitment is called **improving**. Improving stretches our commitment to an even higher level. Commitment means a willingness to look for a better way and learn from the process. It focuses on eliminating complacency, confronting what is not working, and providing incentives for improvement. The spirit of improving is rooted in challenging current expectation and ultimately taking the risk to make changes. It is the combination of both *supporting and improving behaviors* that makes up the practice of commitment. Separately neither action is capable of sustaining commitment. Commitment to change and sufficient authority over all aspects of the change process are both important in dealing with the cultural and political problems in the form of organizational resistance which often stand in the way of BPR implementation.

Leadership. Throughout history, people have tried to say what makes a good leader. Some of the most often quoted historical authors include Plato, Machiavelli, Hobbes, and Confucius. They all tempted to distinguish between emotional and managerial functions (Turner, J. and Müller, R., 2005). Over the last seventy years, there have been six main schools of leadership theory: *The Trait School*, the idea behind this school is that effective leaders share common traits. It effectively assumes that leaders are born, not made. Attempts to identify the traits of effective leaders have focused on three main areas: abilities, personality and physical appearance; *The Behavioral or Style School*, it assumes, in effect, that effective leaders can be made. Most of the best-known theories characterize managers or leaders against one or two parameters, and place them on a one-dimensional continuum or two-dimensional matrix. The parameters include: People, Production, Authority, Decision-making, and Decision-taking; *The Contingency School*, one contingency theory that has proven popular is path-goal theory. The idea is the leader must help the team find the path to their goals and help them in that process. Path-goal theory identifies four leadership behaviors: Directive leaders, Supportive leaders, Participative leaders, Achievement-oriented leaders; *The Visionary or Charismatic School*, two types of leadership were identified: Transactional (task-oriented) and Transformational (people-oriented). In reality, a combination of the two styles will be appropriate in different circumstances. In project management context, researchers predict that a project manager's leadership style needs to be more transformational than transactional, but found no

significant link. The Emotional Intelligence School, for dimensions of emotional intelligence were identified and, from there, six leadership styles: Visionary, Coaching, Affiliative, Democratic, Pacesetter, and Commanding; and the *Competency School*, The emphasis has been to identify the competencies of effective leaders. Competencies can be learned, so leaders can be made, not just born. Different combinations of competencies can lead to different styles of leadership, appropriate in different circumstances, producing transactional leaders in situation of low complexity and transformational leaders in situations of high complexity (Turner, J. and Müller, R., 2005).

Hammer and Stanton (1995), Cooper and Markus (1995) and Arendt *et al.* (1995) consider leadership to play a vital part in directing BPR efforts toward success. The importance of leadership stems from its role in providing a clear vision of the future, communicating this vision, being able to involve widely other people in the BPR efforts, and being prepared to provide sufficient commitment to the BPR efforts (Hammer and Stanton, 1995).

Employee Empowerment. Employee empowerment is an effective factor leading to the success of BPR implementation, since it promotes self-management and collaborative teamwork principles (CSC Index, 1994; Mumford, 1995; Rohm, 1992/93). Empowerment allows the key operations of the upper levels of hierarchy, such as responsibility, accountability and decision making, to be released and implemented further down the hierarchy. Empowerment is proposed as inevitable by the protagonists of reengineering:

- “Redistribution of power and authority among functions and levels and even among suppliers and customers is an inevitable outcome of process innovation” (Davenport 1993).
- “People working in a reengineered process are, of necessity, empowered. As process team workers they are both permitted and required to think, interact, use judgment, and make decisions” (Hammer and Champy 1993).
- “Empowering employees will move decision making, communications, and control down to the level where the work is being done. This will make dramatic improvements in process time and efficiency” (Manganelli and Klein 1994).

Communication. Communication is another essential change management tool perceived as very important in facilitating BPR (Davenport, 1993a; Hammer and Stanton, 1995; Carr and Johansson, 1995; Rohm, 1992/93; Arendt *et al.*, 1995). However, it is also considered by organizations to be the most difficult aspect of BPR (CSC Index, 1994). Davenport (1993) emphasizes the need for communication throughout the change process at all levels and for all individuals, and stresses that communication should occur regularly between those in charge of the change initiatives and those affected by them. Early communication and explanation of the urgency of the reengineering projects and their specific objectives are essential to achieve a culture change in the organization. The top executives and other senior management must play an active role in communicating the commitment of the organization to the reengineering project. Effective communication between stakeholders inside and outside the organization is necessary to market a BPR project (Talwar, 1993), to ensure patience and understanding of the structural and cultural changes needed (Berrington, C. and Oblich, R., 1995) as well as the organization’s competitive situation (Cooper and Markus, 1995). Communication should take place frequently (Davenport,

1993, Carr, 1993; Janson, 1992) and in both directions between those in charge of the change initiatives and those affected by them (Davenport, 1993; Talwar, 1993). Communication should be open, honest, and clear (Davenport, 1993; Janson, 1992).

Teamwork. Teamwork creates a learning environment in which team members are encouraged to share knowledge and expertise (Rohm, 1992/93). With empowered team members, teamwork enhances quality of work (Davenport and Nohria, 1994; Davenport, 1993a), and reduces resistance to change, and allows for different perspectives to change (Carr and Johansson, 1995). Successful BPR implementation is highly affected by the way team members are selected and managed (CSC Index, 1994). Johansson *et al.* (1993) view teamwork as the most important value of BPR. Davenport (1993a) assigns three main functions to the BPR team: managing work by making group decisions and coordinating activities; managing relationships by promoting trust, openness, and resolving conflicts; and finally, managing exteriors such as customers, suppliers and market partners. The literature mentions several advantages of teamwork, such as facilitating interactions between functions and speeding up the redesign process (Davenport and Nohria, 1994).

Davenport (1993) and Harrison & Pratt (1993) believe that external consultants should be included in BPR teams since they provide a business-wide view, encourage unity between members, and are usually neutral. External consultants, if employed, help to facilitate and support BPR efforts. Shabana (1996) believes they bring specialized skills, experience and required know-how to organizations, and he suggests a number of reasons for their success and failure in BPR projects. Success can be attributed to consultants' experience of implementing similar projects in other organizations and their ability to direct the reengineering efforts to areas of substantial benefit to the organization. Failure, on the other hand, can be attributed to their limited knowledge of the existing business processes, and that delays are caused by the time they spend familiarizing themselves with these processes.

Deficiencies of the Past Research

It is apparent that there is a consistent need to understand how to conduct BPR and to apply a type of methodology that can guarantee success. This demand is understandable and does make sense. However, process reengineering is very complex. It is difficult, if not impossible, to produce standard "recipes" of success applicable to every business sector. The majority of the methodologies proposed by various academics and practitioners are general guidelines attempting to cover the needs of all or as many as possible organizations. Despite some common principles like planning, monitoring or implementation, it seems that each sector has its own needs and some unique features. What is good for one company may be totally unacceptable for another, as many issues, including cultural differences, management style, and staff relationships, all impact on the adopted method (Parfett, 1994).

Another important observation that constitutes a problem is that most of the methodologies stop at the implementation phase, and consequently seem to be quite static. The exclusion of evaluation and the notion of continuous improvement seem to be inconsistent with the increasing pressures of an ever-changing world and from a highly competitive environment. On the other hand, it is also important to note that, while some of these methodologies or models include some 'soft' elements in their approach (recognizing the importance of

organizational culture, human relationships and resistance to change), many of the currently available tools focus on the harder and more quantifiable elements of the organization (Ruessmann et al., 1994). As a result, there are many tools and methods available in order to model, map and redesign the organizational processes but there are not many methods or tools aimed at identifying human and organizational factors that affect the change process. Many papers and best practices recognize the importance of the human element and of the organizational functions. However, the latter are often not addressed in the proposed solutions and methodologies, and are, therefore, not recognized as being an integral part of the organizational change. Consequently, most of the existing methodologies do not include stages related to human and organizational requirements, although they do recognize their importance.

As it is expressed in the literature, more than 60% of the BPR projects fail due to the reason that people do not want to adapt to the new changes in the organization. The mistake many organizations make is assuming that changing people's habits will be an easy task, but it is not. Getting people inside the company to get used to the new processes to improve the ways they do their jobs is by far a hard challenge. If the company is resistant to change, the BPR project is more likely to fail.

For all the above mentioned reasons, this study attempts to combine the social and the technical aspect of a BPR project to assurance its successful implementation. A framework that will serve as a guideline to BPR project's managers and employees to conduct a successful project will be proposed in the following section.

Conceptual Framework

As it was exposed before, many authors addressed the technical aspect but just a few of them addressed the social part of BPR. After an exhausted research it was determined that little research has been done to combine both aspects; and this may be the cause that most of the BPR projects fail. To fill this gap in BPR and to contribute to an effective project development, taking into account all the resources involved in the process, is that this study proposes a framework to guide all the people involved in the reengineering project.

The Framework

The aim of this study is to build up an effective framework that combines the social and technical aspects to conduct a successful BPR project. Figure 1 presents the conceptual model. It takes into account the two aspects involved in all BPR projects: (i) social and (ii) technical aspects. The social aspect is divided into three categories. First, *the executive management team*, it is fundamental that the top managers support and understand the project. Second, *the managers*, they have to control the project and motivate the employees. That's why they need to have a positive perception of the project and a leadership attitude in order to empower their employees. Third, *the employees* itself, they have to be motivated and committed to the project in order to give their best and to adapt to the new situation. They have to work in teams to share knowledge and to speed up the reengineering process. The last, but one of the most essential factors is the communication. The communication among project managers and employees should be fluent with the aim of assuring the

understanding of the existing processes, the need of change and the function of the new, redesigned processes.

On the other hand, the technical aspect includes six steps in the methodology used to conduct the project. First a *vision* should be created. As exposed above, the communication should be fluent among the people involved in the project, that's why everyone should know the vision and what they want to achieve with the reengineer project as well as where they want to be after the project is done. Afterwards, based on the clear vision, the managers along with the experiences and opinions of the personnel should *select the business processes* that are needed to be redesigned. Then, it is necessary to *define clear and measurable objectives* for redesigning the reinvented processes. The objectives should be determined by all the people involved in the reengineer project. Next, employees need to work in teams to share and propose ideas to *design more accurate processes*. After all the employees understand the new processes, these ones are *implemented*. The *control and improvement* of the new processes should be done periodically, according to experiences and needs of the people involved in the process.

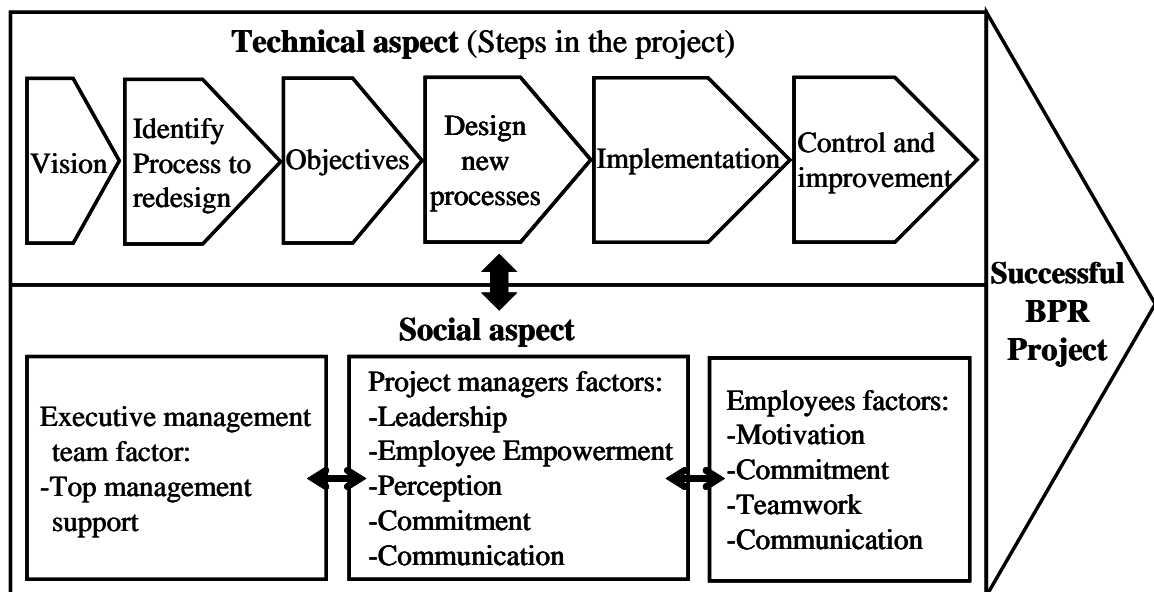

Figure 1 Conceptual framework

Social Aspect

According to past literature, lack of leadership and not motivated employees are frequently causes for the high failure rate of business process reengineering projects. BPR implementation requires top management understanding and support of the project as well as a top-down, directive leadership style. Yet, it also requires the management of motivated, skilled, independent-thinking people doing non-programmable tasks for which a non-directive leadership style is most suited. It can be noticed that the social aspect of BPR involves three categories that are described as follows:

The Executive Management Team: The role of the top executives is fundamental and is the basis for a BPR project to succeed. According to Prosci Research (1998-1999), an industry

leader in business process reengineering, the most critical success factor in this type of project is solid and visible executive support. Strong executive support is essential to keep the project moving forward. They have to understand the need of change in order to support it. They help project managers understand and achieve the project objectives. Top executives usually control a project manager's access to resources which are supervised by functional managers. The level of support provided by the functional manager is usually determined by the level of support from top executives. If the project is part of the functional department, then the availability of resources is not usually an obstacle, because the functional manager is usually also the project manager. (Bellasi and Tukel, 1996).

The Project Manager: A project manager, also known as a project champion is typically someone in management who proposes the business process reengineering initiative. The champion often sees a timely opportunity for the company to increase its competitiveness and performance, or fend off a major crisis in a way that calls for the complete transformation of people, processes and technology. Project Managers are strong advocates for the project with a vested interest in the outcome and use their influence to assure project success. Many factors related to the skills and characteristics of project managers are proposed in the previous framework for the successful completion of BPR projects. In their study, Pinto and Slevin (1989) demonstrated the importance of selecting project managers who possess the necessary technical and administrative skills for successful project termination. They showed that the project manager's commitment and leadership style are the most critical factors during the planning and implementation stages. They should have certain attitudes toward the project, because attitude influence individual behavior. They also need to recognize that their employees react to perceptions, not reality. They need to pay close attention to how employees perceive both their jobs and management practices (Robbins, 1994). Another important characteristic of the project managers is their ability to delegate; this means that they need to empower their employees trusting their decisions. Communication Skills is the most important skill that a Project Manager should have. These deals with keeping all the employees well informed of the project data and update the top executives.

The Employees: The employees are the body of the BPR project, as expressed above the lack of motivation of employees is one of the most frequent causes of the failure of BPR projects. The motivation of the employees usually depends how committed and how motivated is the project manager and how well he can transfer this motivation to his employees. In order to be fully committed they have to understand the existing processes and the need for change. To obtain employee commitment for a major reengineering effort, executives must convey a clear vision characterized by three points. First, they must clearly articulate why such a sweeping change is crucial to the company's overall success. Next, they must convincingly describe what the future looks like when the project is done. Finally, they must provide sufficient detail to enable employees to visualize how they fit into the new organization once it emerges. They should be encouraged to be more aware of how they contribute to the organization. They should also be actively encouraged to develop new ideas and help solve problems within the organization. Teamwork is a key element for the success of the reengineering project. Employees usually work in teams in order to share knowledge and speed up the reengineering process. The competence and

commitment of the team members is also found to be critical factors during the implementation stage, but is important throughout the project duration time.

On the other hand, well established communication channels between the project manager, the organization and the employees are necessary for the success implementation of the BPR project. It is crucial to communicate the necessity for change, the principles of reengineering, and the objectives of the reengineering project to the entire organization, not just those who will ultimately be directly involved. Everyone impacted by the proposed changes must be on board and actively involved throughout the project. Difficulties encountered should not be hidden but should be communicated together with an action plan for their resolution. It is also important that the content of all communications regarding the program is consistent. Inconsistency will undoubtedly undermine the credibility of the project. Communication must also be two-way. Not only must employees be aware of the project, its problems, its progress, and the commitment of management, they must also be part of it.

Technical Aspect

As explained above, project characteristics have long been overlooked in the literature as being critical success factors whereas they constitute one of the essential dimensions of project performance. Among some few studies, BPR researchers identified the creation of the vision and the establishment of measurable objectives as critical factors. Many projects, however, fail due to several other factors inherent in BPR projects, in most of BPR methodologies the control and improvement stage is omitted. For purpose of this study, technical aspect will be defined as the steps or the methodology used throughout the project. Many structure-based methodologies have been proposed for BPR implementation and they were summarized in section 2.2. However, most of them have common elements and view BPR efforts as a top-down implementation project. For purposes of this study, the most common and important steps in existing BPR methodologies were extracted to create a hybrid methodology that combined with the previously explained social factors, will lead to a successful implementation of BPR projects. The inputs for this model were generated from the review of literature. In the proposed framework, six stages or steps are recommended:

Step 1: Develop a business vision: BPR is driven by a business vision that answers the question “Where do we want to go?” Where does the organization as a whole or where do the department undergoing the reengineering project want to go with this change. All the personnel involved in the project should know and understand the business vision, in order to guide the organization toward the same direction.

Step 2: Identify the processes to be redesigned: Not many firms use an exhaustive approach that attempts to identify all the processes within an organization and then prioritize them in order of redesign urgency. As explained in chapter 2, the Japanese word “Gemba” which means “actual place” and is where the value is created, can be used to identify the processes to be redesigned. It is important to identify what processes support the Gemba and what processes do not. The processes that support the Gemba should be at the forefront of any reengineering project.

Step 3: Define objectives: Based on the clear vision and the selected process to redesign, clear and measurable objectives for redesigning the reinvented processes should be defined. These measurable objectives are the specific measures that the company uses to determine whether or not they are successful in achieving the reengineering goal.

Step 4: Design new processes: The actual design should not be viewed as the end of the BPR process (Davenport and Short, 1990). Rather, it should be viewed as a prototype, with successive iterations. Prototypes help produce quick delivery of results when projects are implemented, improving performance and customer satisfaction. On the other hand, employees and customers involved in the previous process should be questioned what are the flaws of the existing process, in order to improve them.

Step 5: Implementation: In order to avoid difficulties, the implementation of new processes had to be carefully planned by the people involved in the reengineering process. Many aspects of the new organization should be monitored after implementation including the performance of the new processes, the organizational culture, and the external environment. A changing or unsatisfactory situation in any of these areas may well indicate a requirement for further reengineering.

Step 6: Control and Improvement: BPR is a successive and ongoing process. BPR should be regarded as an improvement strategy that enables companies to make the move from a traditional functional orientation to one that aligns with strategic business processes (Vakola, M. and Rezgui, Y., 2000). A reengineered process may reach a satisfactory state of efficiency but the organization as a whole will never stop competing in a continuously changing environment which leads to the transformation of business strategy and vision, and as a result to the continuous need for improved organizational processes and functions, this is why this step is so important.

Combining Social and Technical Factors

The BPR project that makes use of the framework proposed in Figure 1 starts with the recognition of the need of change. Usually, the project manager is the one who proposes the business process reengineering initiative. Project Managers transfer their proposition to top executives. The top executives must recognize the need for change; develop a complete understanding of what is BPR, and how they plan to achieve it. The top executives support is essential in this first phase and throughout the whole project. Once the project manager has the support of the top executives, he communicates the idea of the reengineering project to his employees. In this phase, that can be called planning phase, the leadership style of the project manager is very important because he needs to motivate his employees and all of them need to see the value in the need for change and buy into the project. Once the understanding and commitment of the top executives, project manager and employees is guaranteed, the reengineering project starts by creating a vision.

Based on the clear vision, the project manager along with the employees' ideas and suggestions should select business processes that need to be redesigned, define clear and measurable objectives for redesigning the current processes, and form the reengineering

project teams. The literature suggests executives and key staff members from the primary organizational units involved in the processes, as well as from the information systems department, should be included in the teams. Once the teamwork are formed, the project team evaluates and documents current processes, uncovers bottlenecks, and establishes baselines and benchmarks for measuring future improvements. During this phase, the efforts of the project team are focused on identifying breakthrough opportunities and designing new work steps or processes that will create significant gains and competitive advantage.

After gathering all the necessary information and sharing ideas and knowledge among all the personnel involved, the new process are designed led by the project manager. After the design of the new processes is successfully undertaken, they are fully implemented and successfully integrated into the organization. Changes made during this phase may cause resistance or resentment that must be addressed through continual communication among top executives, the project team, and employees. The final phase, involves evaluating the success of the reengineering efforts against the performance objectives previously established. For example, if the reengineering efforts have not achieved all its goals, the processes should be redesigned and modified accordingly. This phase is important as it is one of continuous commitment to the process of reengineering. In this phase, the control of the new processes is necessary in order to determine the existing flaws in the new processes. Communication among the involved parties is also necessary to share new ideas in order to improve the flaws and weaknesses identified in the evaluating phase.

Development of the tool

This section addresses the second objective of this study, in which a tool is developed. The aim of the proposed tool is to recognize the importance of the factors proposed in the framework depicted in Figure 1 and to determine the chance of success of the BPR project. This tool will be conducted among people involved in the project. The tool consists of a list of items, which are measured in a three scenario scale: from the best scenario to the worst. The items are divided into 4 different sections. Each section is related to the different factors described in the previous framework: (i) Factors related to the executive management team (ii) Factors related to project managers (iii) Factors related to employees and (iv) Steps in the project.

Item Development

A list of 30 items was developed as a tool to help the personnel involved in the BPR project determine the chance of success of the project according to the factors existing in it or what will cause the failure according to the elements the project lack of. The tool consists of four sections that should be answered in an honest way to obtain more accurate results. The main idea of each section is exposed as follows:

- (i) *Factors related to the Executive Management Team:* In this section, items about the support of the top management are asked in order to determine how committed they are with the project. From previous literature it was defined that the more committed the top management is with the project, the greater the chance of success.

- (ii) *Factors related to the Project Manager:* In this section, items concerning the project manager's leadership style, motivation and capacity of empowering other are addressed. This section analyzes the fact exposed by various BPR researchers that states that the lack of leadership is frequently a cause for the high failure rate of business process reengineering projects. This section will also determine if empowerment fosters innovation, creativity, motivation and instills shared values to promote and atmosphere for learning and accomplishment in the company.
- (iii) *Factors related to the Employees:* In this section, items related to the motivation and commitment of the employees are asked. This will determine if the project is on the right path to success, because the more motivated and committed the employees are, the more chances of success will be presented. Question regarding the teamwork are also addressed, in order to determine how they share knowledge and ideas. Finally, questions regarding how fluent is the communication between top executives, project managers and employees are also asked. This will help define how committed is each of the parties involved in the project.
- (iv) *Steps in the Project:* This section addressed the methodology used in the project. It guides, step by step, the people involved in the reengineering project in order to assure that all the elements, such as vision, measurable objectives, understanding of existing processes, among other are presented in the project.

Table 2 describes the section and the factor addressed in each item and shows the relationship between the factor and the list of items.

Table 2 Relationship between factor and items

Section	Factor	Item no.
Executive Management Team	Top Management Support	1, 2, 3
Project Manager	Leadership	4, 5, 6
	Employee Empowerment	11, 12
	Perception	9
	Commitment	7, 8
	Communication	10, 19, 20
Employees	Motivation	13
	Commitment	13, 14
	Teamwork	15, 16, 17
	Communication	18, 19, 20
Steps in the Project	Vision	21
	Identify process to redesign	24, 25
	Objectives	22, 23
	Design new processes	26
	Implementation	27, 28

	Control Improvement	and	29, 30
--	------------------------	-----	--------

Measurement Scale Development

Scaling is used in ordering a series of items along a sort of continuum. They are methods of turning a series of qualitative facts into a quantitative series. In order to measure the degree and chance of success of a BPR project, a three scenario measurement scale was added to the items developed and explained in section 4.1. The main idea of the measurement scale is to propose three scenarios (best to worst) and see which of these describe the situation of the company regarding the BPR project. The three proposed scenarios were extracted from the literature review. What the BPR researchers and practitioners recommend for the organization was exposed as the best scenario and what make companies fail a BPR project was proposed as the worst scenario.

Each item developed in the previous section has three possible answers, which are denoted by the letters: a, b and c. Letter “a” corresponds to the best scenario, in other words the idealistic situation of a company regarding the BPR project. Letter “b” corresponds to a scenario that is not the best for the company but can still lead to a successful but long project. Last, letter “c” corresponds to the worst scenario that will lead the company to a fail BPR project. Needless to say, the more numbers of “a” answer will lead the company to the execution of a successful BPR project. The respondent can choose only one answer per question.

An example of the proposed tool is exposed as follows. For the full version on the tool, see appendix A of this paper:

Who decided which processes need to be redesign?

- a. All the people involved in the project, share ideas to determine which processes need to be redesign
- b. The project manager decides which processes need to be redesign.
- c. The top executives decide which processes need to be redesign.

Validity of The Tool

In an effort to ensure the validity of the proposed tool, a *face* and *content validity*, also known as *logical validity*, will be conduct for this study. Face validity is a property of a test intended to measure something. It is the [validity](#) of a test at [face value](#). In other words, a test can be said to have face validity if it "looks like" it is going to measure what it is supposed to measure. On the other hand, [content validity](#) is a non-statistical type of validity that involves "the systematic examination of the test content to determine whether it covers a representative sample of the behavior domain to be measured" (Anastasi and Urbina, 1997). Content validity is most often addressed in academic and vocational testing, where test items need to reflect the knowledge actually required for a given topic area.

One widely used method of measuring validity was developed by C. H. Lawshe. It is essentially a method for gauging agreement among raters or judges regarding how essential a particular item is. Lawshe (1975) proposed that each of the subject matter expert raters (SMEs) on the judging panel respond to the following question for each item: "Is the skill or knowledge measured by this item 'essential,' 'useful, but not essential,' or 'not necessary' to the performance of the construct?" According to Lawshe, if more than half the panelists indicate that an item is essential, that item has at least some content validity.

In order to validate the proposed tool, a face validity and content validity was conducted among five invited subjects. According to their knowledge on BPR, the invited subjects had to choose if they considered that each item in the tool was "essential", "useful but not essential" or "not necessary" to determine if the company is in the right path to a successful BPR project. A content validity was conducted at the end of the questionnaire, in which the judges have to express if they considered that the tool, as a whole, is 'essential', 'useful but not essential' or 'not necessary.' The results derived from the face validity are exposed in Table 3. The content validity of the tool resulted in a ratio of 1.00, since five of five panelist agreed that the 30 items in the tool are "essential" to determine whether the company is in the right path to success or not.

The use of the tool

The tool was designed to be used by any company who is currently carrying out a BPR project. It can be used in the early stages of the project to analyze its current situation and to forecast, based on the existing factors, the outcome of the project. It can also be used at the beginning of the project and it will serve as a check list to assure that the project has all

the elements necessary to succeed. It is recommended to use this tool along with the previously proposed framework for better results.

It is recommended that the tool is filled out by outside consultants hired by the companies who are undergoing a BPR project. The consultants are impartial persons who look at the companies from abroad and therefore they are able to give a more objective opinion of the situation in which the company is positioned regarding the project. Outside consultants bring specialized skills, experience and required know-how to organizations, and a number of reasons for their success and failure in BPR projects exists. Success can be attributed to consultants' experience of implementing similar projects in other organizations and their ability to direct the reengineering efforts to areas of substantial benefit to the organization. Failure, on the other hand, can be attributed to their limited knowledge of the existing business processes, and that delays are caused by the time they spend familiarizing themselves with these processes.

Table 3 Validity Ratio

Section	Factor	Validity Ratio
Executive Management Team	Top Management Support	0.87
Project Manager	Leadership	0.74
	Employee Empowerment	1.00
	Perception	1.00
	Commitment	1.00
	Communication	1.00
Employees	Motivation	0.60
	Commitment	0.80
	Teamwork	0.74
	Communication	1.00
Steps in the Project	Vision	0.60
	Identify process to redesign	0.80
	Objectives	0.80
	Design new processes	0.60
	Implementation	1.00
	Control and Improvement	1.00

In case the company have not hired outside consultants, it is recommended that the tool is completed by the top management, the project manager and employee. The project manager will fill out section 1, 3, 4 corresponding to factors related to the top management,

employees and steps in the project, respectively. The top management or employee will fill out section 2 corresponding to the factors related to the project manager.

In order to determine the degree of success of the project, three possible scenarios were exposed for each question of the tool. As explained above, each scenario was assigned with a letter; from (a) best scenario to (c) worst scenario. Points are also assigned to each scenario in the following way: (a) 3 points, (b) 2 points and (c) 1 point. The maximum score will be 90 points and the minimum will be 30 points.

After completing the questionnaire, the total amounts of points are counted. According to the score, the project may set into one of the following three categories:

80 to 90 points: The company is leading toward a successful BPR project. Even though the 90 points is an idealistic scenario, if the company has over 80 points, they will end up with a successful project. This means the company have taken into account all the success factors for a BPR project and its employees, project manager and top executives are committed, motivated and working hard to reach the common goal.

50 to 79 points: This is an uncertain scenario. The company may be taken into account some successful factors but ignoring another crucial ones. In this case, the questionnaire should be revised and determine which factors are being ignored. Once the factors are identified, they should be incorporated at the earliest opportunity to ensure project success.

30 to 49 points: The company is leading toward a failed BPR project. In this scenario, the project is not given its real importance. The project manager, employees and top executives are not committed or motivated with the project. The first thing to do in this case is to recognize the need of change. After everyone have recognized the need for a change and are committed to the project, the success factors should be identified to guide the project in the path to success.

The possible future research

Davenport (1994) described his vision of BPR's future. He stated that the concepts and practices of BPR are likely to evolve across the following directions to respond to the rapidly changing and diverse world of business: (1) Scope: a shift is likely to be towards changes in the business network for an organization rather than towards internal business processes. (2) Development: efforts may be directed to speeding-up the cycle time for BPR by focusing on rapid implementation of improvements in the context of longer-term and more radical process change. (3) Application: process management is likely to be institutionalized in other management domains like measurement, information systems, and organizational structure. Knowledge work processes such as systems and new product development will also be another rich application area, particularly when ethnographical approaches are used to understand in depth the nature and context of the process under analysis. (4) Integration: BPR may be combined with incremental process changes within the same initiatives or integrated into process management by pulling tools from a variety of process change approaches to build hybrid process design and implementation techniques. It may also become embedded in more conventional strategic planning of departments and approaches.

Some of these concepts and practices have already been applied in BPR, but some of them aren't. This means that BPR hasn't reached its peak yet and there is more to do and explore in this subject. The fear of failure of many companies has made this topic not so popular nowadays, but as more tools are available that help them guide to a successful implementation of the project, companies will feel confident in executing it. This is one of the mayor attempts of this study.

This paper has provided a comprehensive review of literature, bringing together different schools of thought on various BPR-related themes. The overall discussion aimed to propose a framework that, based on past literature, identifies the success factors of a BPR project. It is important to emphasize that the proposed conceptual framework is an idealistic model, that's why a tool was proposed to determine the chance of success of the BPR project if one of the success factor is not present in the project. It can be said that the two proposed instruments complement each other.

Today more and more project managers consider quality to be the most important objective. Quality can be assured by identifying and eliminating the factors that cause poor project performance. Thus, project managers need better understanding of critical success/failure factors and how to measure them. This paper emphasizes the importance of understanding the factors and interactions between them. The present authors expect to see additional future research concentrating on the cause-effect relationship between critical factors and on measurement techniques. Future work may also include assessing the criticality of these factors in BPR implementation based on a global survey of organizations. The last but not least, will be to validate the proposed methodology, which includes the validation of the tool, the items and the score system proposed in this study.

APPENDIX A

Instructions: Please answer the following questions according to your experience in the BPR project you are currently executing.

PART I: FACTORS RELATED TO THE EXECUTIVE MANAGEMENT TEAM

1. Do you consider that the top management of your company entirely supports the BPR project? If yes, in what degree are they supporting the reengineering effort?
 - a. The top executives support the BPR project and are actively involved in it.
 - b. The top executives support the BPR project but do not get involved in it.
 - c. The top executives don't support the BPR project.
2. What departments of the organization are involved in the reengineering program?
 - a. The BPR project is interdepartmental
 - b. The BPR project occurs in one department
 - c. The BPR project occurs in each department separately
3. Do the top executives have preference for one department over the others?

- a. Top executives support all departments equally.
- b. The tops executives support some departments more than the others.
- c. The top executives do not support any department.

PART II: FACTORS RELATED TO THE PROJECT MANAGER

- 4. Who proposed the BPR initiative?
 - a. The Project Manager proposed the BPR initiative.
 - b. The Top Executives proposed the BPR initiative.
 - c. The employees proposed the BPR initiative.
- 5. Which type of leader is the Project Manager?
 - a. The Project Manager has a combination of transformational and transactional leadership type.
 - b. The Project Manager has a transformational leadership type focusing on people
 - c. The Project Manager has a transactional leadership type focusing on task.
- 6. Which type of style has the Project Manager?
 - a. The Project Manager has a directive leadership style.
 - b. The Project Manager has a non-directive leadership style.
 - c. The Project Manager has an interactive leadership style.
- 7. Do you believe the Project Manager is committed and motivated about the BPR project?
 - a. The project manager is committed and motivated with the project.
 - b. The project manager is committed but not motivated with the project.
 - c. The project manager is motivated but not committed to the project.
- 8. Commitment includes two main actions: supporting and improving. Is the project manager:
 - a. Committed by supporting and improving the project.
 - b. Committed by improving the project.
 - c. Committed by supporting the project.
- 9. What does the project manager do when employees are not motivated or committed?
 - a. The project manager persuades them until they are committed and motivated.
 - b. The project manager forces them to be involved in the project.
 - c. The project manager ignores them.
- 10. How would you describe the communication among top executives and project managers?
 - a. The communication between the top executives and the project manager is fluent.
 - b. The communication between the top executives and the project manager is regular.
 - c. The communication between the top executives and the project manager is null.
- 11. Are employees in the project being empower by the project manager?
 - a. All employees have been empowered.
 - b. Some employees have been empowered.
 - c. None of the employees have been empowered.
- 12. Does the Project Manager fully or partially empowers his employees?
 - a. Employees are fully empowered.
 - b. Employees are partially empowered.
 - c. Employees are not being empowered.

PART III: FACTORS RELATED TO THE EMPLOYEES

13. Do you believe the employees are committed and motivated about the BPR project?
 - a. The employees are committed and motivated with the project.
 - b. The employees are committed but not motivated with the project.
 - c. The employees are motivated but not committed to the project.
14. Are employees committed to the project by supporting it, improving it or both?
 - a. The employees are committed by supporting and improving the project.
 - b. The employees are committed by improving the project.
 - c. The employees are committed by supporting the project.
15. Are employees involved in the project working in team? Are the members of the teamwork from the same department or are they interdepartmental?
 - a. Employees work in interdepartmental teams.
 - b. Employees work in teams by departments.
 - c. Employees do not work in teams.
16. If employees are working in teams, how was the team leader selected?
 - a. The team leader was selected by the team members.
 - b. The team leader was selected by the project manager.
 - c. There is no team leader.
17. Does the team leader delegates and empowers other members of the team?
 - a. The team leader delegates and empowers other team members.
 - b. The team leader gives orders to the other team members.
 - c. There is no team leader.
18. How would you describe the communication among employees and project managers?
 - a. The communication between the employees and the project manager is fluent.
 - b. The communication between the employees and the project manager is regular.
 - c. The communication between the employees and the project manager is null.
19. How is the communication between the three parties involved in the project (top executives, project manager and employees)?
 - a. Communication is hierarchically from top executives to project managers and from project managers to employees.
 - b. Communication is fluent and non-hierarchically between the three parties.
 - c. There is no communication between the three parties.
20. Throughout the execution of a BPR project many conflicts are presented. How do you solve them in your company?
 - a. Conflicts presented throughout the execution of the BPR project are solved by sharing ideas between the employees and the project manager.
 - b. The conflicts presented throughout the execution of the BPR project are solved by the project manager.
 - c. The conflicts presented throughout the execution of the BPR project are ignored.

PART IV: STEPS IN THE PROJECT

21. Was a vision statement created in the first stage of the project? If a vision statement was created, who created it?
 - a. The vision statement was created by all the people involved in the BPR project.
 - b. The vision statement was established by the project manager.

- c. No vision statement was created for the BPR project.
- 22. Were objectives established in the first stage of the project? If the objectives were established, are these measurable?
 - a. Measurable objectives were established for the BPR project.
 - b. The objectives were established for the BPR project but they are not measurable.
 - c. No objectives were established for the BPR project.
- 23. Who participated in the definition of the objectives?
 - a. The objectives were defined by all the people involved in the BPR project.
 - b. The objectives were defined by the project manager.
 - c. The objectives were defined by the top executives.
- 24. How does the project manager assure that all the people involved in the BPR project understand all the existing processes in the organization?
 - a. Before the implementation phase starts, the project manager assures the top executives and all the employees understand the existing processes by analyzing the current processes and identify its flaws.
 - b. Before the implementation phase starts, the project manager assures the top executives and all the employees understand the existing processes by making a quick scan through all the processes.
 - c. The project manager does not assure that people involved in the BPR project understand the existing processes.
- 25. Who decided which processes need to be redesign?
 - a. All the people involved in the project, share ideas to determine which processes need to be redesign
 - b. The project manager decides which processes need to be redesign.
 - c. The top executives decide which processes need to be redesign.
- 26. Who was involved in the design of the new processes?
 - a. All the people involved in the project, share ideas to design the new processes.
 - b. The project manager designs the new processes.
 - c. The top executives design the new processes.
- 27. Most researchers stated that the implementation stage is where reengineering efforts meet the most resistance and hence it is by far the most difficult one. Knowing this, who was or will be involved in the implementation stage?
 - a. Since the implementation phase is where reengineering efforts meet the most resistance and hence it is by far the most difficult one, everyone is involved in this phase.
 - b. Since the implementation phase is where reengineering efforts meet the most resistance and hence it is by far the most difficult one, the project manager is the only one involved in this phase.
 - c. Since the implementation phase is where reengineering efforts meet the most resistance and hence it is by far the most difficult one, the top executives are the only ones involved in this phase.
- 28. What is your next step after the implementation phase?
 - a. After the implementation phase is done, we control and monitor the new processes to identify flaws that will help us to continuously improve our processes.
 - b. After the implementation phase is done, we control the new processes.
 - c. Our BPR project ends in the implementation phase.

29. If you are continuously improving your BPR project, who help overcome the identified flaws?
 - a. The identified flaws are overcome by communication and sharing ideas of all the people involved in the process.
 - b. The identified flaws are overcome by the project manager.
 - c. Our BPR project does not include the continuously improvement phase.
30. From whom do you receive feedback in order to determine if the new processes fulfill all the requirements?
 - a. We receive feedback of the performance of the new processes from our employees and customers.
 - b. We receive feedback of the performance of the new processes from our employees.
 - c. We don't receive feedback of the performance of our new processes.

HRM practices-organisational performance relationship framework refined: a circular model representation

**Alexandra-Paraskevi L. Chytiri. PhD student. Athens University of Economics and Business (AUEB). Department of Marketing and Communication, Governmental Scholarship holder. Greece
chytiri_alexandra@yahoo.com**

Key words: Human Resource Management (HRM), Human Resource (HR) Practices, High Organisational Performance, Causality, Reverse Causation

Category: Literature Review Paper

Introduction

Increasing competition and the continuously changing internal and external environment in the business world, particularly in the service sector, force organizations to implement strategies and take actions aiming at more effective and wise utilization of all production factors. Employees are considered to be an imperative in order to survive and to increase their performance (Armstrong, 2006; Davis et al., 2001; Connolly and McGing, 2007; Yang, 2006; Vlachos, 2009).

Empirical findings during the last few decades, suggest that there is a positive link between Human Resources Management (HRM) practices and Organizational Performance (OP), although it is not clear which particular HRM practices affect and to what extent the organizational performance and why this link exists (Guest, 1997; Pfeffer, 1998; Becker and Gerhard 1996; Vlachos 2009). Moreover, it is not clear if the HRM practices are actually the impact factor in the relationship. Results only show the positive association, but do not prove the actual direction of causation in the relationship. On the contrary, there are studies which claim for the reverse causation in the relationship (OP having an impact on HRM practices) or a bilateral one (Guest, 2001; Katou and Budhwar, 2010).

In the following section the reasons why companies adopt and implement HRM practices are identified, so as to form the basis for the presentation of a brief literature review on the HRM practices and OP relationship. Previous studies suggesting or implying the reverse causation in the relationship will be examined as well. A short discussion of the literature will follow and based on the previous studies in the field a revised model of the HRM practices-OP link will be proposed as a conclusion.

Human Resource Management practices – why is there a need for them?

In a continuously changing global environment of a firm, the need to focus on enhancing firm's competitive advantage emerges. In order to confront any change in their external environment and remain successful firms need to adopt the critical success factors. Ability to embrace change stands as the first one among the three, followed by creativity (combining ideas in a unique or unusual way) and innovation (the ability to diffusing creativity in positive outcomes) and becoming a world-class organisation, namely becoming an organisation which constantly acquires knowledge and uses it in forming its

strategic decisions and planning its actions so as to be the best in the world in its area (Coutler, 2005). Any external change might lead to an organisational change and any successful embracement of this change might lead to an effective performance. Therefore, firms need to identify their competitive advantage as well as the processes and mechanisms by which this advantage leads the firms to higher organisational performance.

According to resource based view (RBV), firm's resources can stand as a sustainable competitive advantage if they are unique. That is firm's resources should accumulate the following characteristics, a) be rare, b) be hard to imitate them, c) add value and d) organisations have the ability to exploit them (Coutler, 2005). In a knowledge economy, employees and in a broader sense, human and intellectual capital of the organisation, emerge as a source of competitive advantage as it concentrates all of the above characteristics (Boxall and Purcell, 2003; Kinnie et al., 2006). Thus, people management should form the main focus area of an organisation which seeks to remain successful.

Policies, practices and organisational or departmental structures concerning employee management constitute the Human Resource Management (HRM) concept (Boxall and Purcell, 2003). A more strategic approach of HRM implies that HRM is comprised of a set of practices applied in an effort to improve organisational performance and effectiveness (Boselie et al., 2005). Therefore, the adoption and implementation of HRM practices is not only necessary for the good management of the company; it is closely linked with the enhancement of employee and organisational performance, either as individual practices or as a bundle of practices (Huselid, 1995; Mondy et al. 2002; Jeffrey and Donald 2003). This more strategic view of HRM in association with the need of a sustainable competitive advantage for the organisation might form the reason why the study of the link between Strategic Human Resource Management (SHRM) and organisational performance has been considered as the "Holy Grail" of the HRM field (Boselie et al., 2005, Purcell and Kinnie, 2007).

Literature Review-The HRM practices-OP relationship

The past few decades, a great number of studies have been conducted in the HRM practices-OP link subject area, both theoretical and empirical ones; most of them supporting the existence of a positive link between HRM and performance. Several comprehensive research reviews have been conducted as well in the field, which are presented afterwards so as to solid basis of previous studies in the field and their results (Becker and Huselid, 2006 Boxall and Purcell, 2008; Combes et al., 2006; Purcell et al., 2008).

Early research in 1980s and 1990s on the linkage of HRM practices and organizational performance has been conducted, in which the HRM practices of selection, training, appraisal and compensation are shown to have an impact on financial performance (Russel et al., 1985, Terpstra and Rozell, 1993, Borman, 1991, Milkovich, 1992, Huselid, 1995, MacDuffie, 1995). The impact of a set/bundle of HR practices on financial performance and market outcomes, and on productivity and quality was emphasized in 1995 by Huselid and MacDuffie as well.

A summary of few previous literature review studies would be helpful so as to identify the trends in the field in more detail. Starting with that of, Purcell (1999), Purcell attempts a literature review in the HRM-performance field focusing particularly on the studies of best practice model. (The best practice approach suggests that specific best practices that have a universal positive impact on organizational performance and are applied in all organizations, across all employees (Kohan and Osterman, 1994; Pfeffer 1994)). He considers high commitment management as the most common and acceptable element in the HRM-performance relationship, but questions the fact that the HR practices form the HR bundle that lead to higher performance as well as the proper diffusion of HRM in companies. It should be mentioned at this point that with the term HR bundle it is meant a set of HR practices which when they are combined together have a positive effect on organizational performance (Subramony, 2009). Several scholars have claimed it exists a specific bundle of HR practices which when adopted by the firm lead always to higher performance. Scholars when adopting this approach deny to consider in their models any impact from the external environment and focus only in the internal environment of the firm and embrace only the internal fit approach. Thus, they support that there is only one and best bundle and ignore any other approach (set of HR practices) which might have positive effects on performance. Based on these two major issues, HR bundle and HRM diffusion, Purcell (1999) raises questions regarding problems of measurement, link to strategy and response to change.

According to Purcell, previous researches are based on single respondents' answers and include a limited number of employees. Moreover, he refers to the Hawthorne effect occurring in several studies. The Hawthorne effect refers to cases in which the behaviour of an individual is changed positively and temporally by observation (Mayo, 1933). The Hawthorne effect only captures the moment and do not allow for the universal applicability of the research results. Flexibility should be considered as the solution to that problem. Having this as a starting point, Purcell implies that the phenomenon of the reverse causality in HRM-performance link might be the case.

Richard and Thompson (1999) conducted a work project-study for the Institute of Personnel and Development (IPD) in the general area of HRM-performance link. They reviewed both the theoretical and empirical literature up to that date. They concluded that 30 empirical studies are pioneering in the field, with the data being collected mainly in USA and with a lower rate in UK. They showed that most of the previous study results are based largely in statistical tests outcomes and that they are not theoretically supported neither they embrace practitioners' view. Their review stands as a start point for both theoretical and empirical developments in the field as it highlights a number of inadequacies in previous studies and needs for future studies.

Firstly, by taking a closer view of the HRM-performance relationship they show that even though a massive number of HR practices have been included in different related studies, it exists no study showing which HR practices (individually or as a bundle) cause exactly which outcomes, behavioural or at a latest stage performance ones. This implies that no satisfactory theoretical basis exists for the classification of HR practices regarding their outcomes. Moreover, previous studies provide no description on the process of how HR strategies are developed and on how they impact on performance. They merely use

different HR practices and policies and test their impact statistically with limited if no control variables.

Based on this finding, it can be concluded that the omission of the process description and other policy areas, apart from HR area, might lead to an overestimation of the contribution of the HR function in organisational performance. Thus, a broader view of the HRM-performance relationship is needed, so as to extend the number of variables used and to consequently to achieve more reliable results. All these omissions in combination with the proliferation of paradigms tested statistically in the field, shows that no solid theoretical framework exists on which empirical work can be based. The fact that many theories have been borrowed from other fields, even from other disciplines to support empirical research for HRM-performance link, indicates that even after so many years of research in the field and with the field being already at its growth stage, theory development for it remains still at an introductory stage.

According to Richard and Thompson (1999), it becomes apparent that a great many HR practices have been used with almost no overlap among the studies. Different HR practices individually or as bundles have been claimed to contribute positively into organisational performance. Moreover, several HR and performance measures have been used with usually no coherence among the two, which have created consequently problems in results' interpretation. The positivistic research designs (which only examined the positive correlations between HR practices and performance) used, hinder any questions about failure of HR practices to produce increased performance. In addition, the different level of analysis as well as the mostly cross-sectional surveys add nothing to the "how" question; namely, how HR practices and polices influence performance, by which mechanisms and though which intervening variables if any. They add no clarity to the question of causality as well. They simply support the hypothesised direction of causation from HR practices to performance, as it is depicted in positivistic designs. Thus, reverse causality (performance outcomes influencing HR adoption and implementation) might also be a possibility in the relationship and should not be excluded by the research design.

Once more, from their empirical research overview, it becomes apparent that purely quantitative studies (conducted up to now), which present and test afterwards positive hypothesis for the linkage are not a lot helpful for practitioners so as to understand the linkage and its successful implementation in the real business environment. For this reason, a more longitudinal approach to studies might be useful, to help researchers take into account the variable of time in their study designs so as to have more valid results. However, despite the fact that Richard and Thompson (1999) are having a critical eye on previous studies in the field, they also hold firm the belief that the better the employees are managed, the better the organisational performance outcomes.

Boselie et al. (2005) in a more recent literature review, examined empirical studies in the field between 1994 and 2003. They concluded that a great number of commonalities among the studies exist, which stand as a hindrance in the adaption of new approaches in future studies. They conclude that most studies are conducted in a quantitative way, using single respondents' answers as data and focusing on organisational, establishment or individual level, ignoring usually the industry level. According to them, most of the studies adopt a

macro approach as they set their theoretical background with one of the, so called, three “big theories” (p: 82), RBV, contingency approach and AMO theory (Abilities, Motivation, Opportunity). A micro theoretical approach, which will embrace organisational behaviour (OB) theories, might provide a more comprehensive view of employees’ experience. In addition, a study of the methodologies used in these studies shows that no specific HR practices and processes are assigned for increase in performance and that there is preference for the use of financial and organisational outcomes. A shift in employing HR outcomes (such as employee commitment and satisfaction) can reveal employee attitudes and behaviours which might form missing variables of the “black box” of HRM-performance linkage. Even though, several studies admit the existence of the “black box” few are the studies which search inside it. In that search, Boselie et al. (2005) suggest strategy and climate as moderator factors that should be considered in future analysis of the “causal distance” (p: 75). Moreover, they propose the testing of the reverse causality based mainly on the fact that positive HR attitudes can be created by successful organisational performance.

Another literature review, conducted the same year by Wall and Wood (2005), show that even though studies assume a positive impact of HRM on performance, the existing empirical evidence are not strong enough to support this universally or at least to support the positive impact when particular contingencies exist. According to Wall and Wood (2005), the most possible reason for this is the methodological approach adopted in previous studies, whereas HRM practices are inadequately measured and in several cases measured with financial performance measures only. Moreover, the absence of longitudinal studies (retrospective or prospective ones) results in no causal conclusions. Previous studies are missing an adequate research design with competitive hypotheses, large response base and independent assessment of HRM practices.

To sum up the literature review studies referred above, regarding the link between HRM and performance four issues/problems have been pointed out (Stiles and Kulvisaechana, 2003): 1) the reverse causation-Does (increased) performance leads to changes in HR practices? If it is so, then there is a need to identify such a direction of this linkage in order for researchers to focus on it and practitioners to take related actions to improve organizational performance. 2) The strategy-firm framework suggests the alignment of HR practices to organizational strategy. But this alignment is questionable in practice where firm-specific context affects the choice and implementation of HR practices. That means that the impact of intervention of context factors might be much more affecting than is the impact of HR practices. 3) Since there are successful organizations that do not adopt and do not apply best HR practices, how then is the HRM-OP linkage verified? That question means that there is much more to be researched as to what individual or bundle of HR practices affect performance. 4) The lack of common measures of HR and organizational performance, the different research methods used (i.e. single/multi-industry, single/multi-respondent, quantitative/qualitative) result in the lack of a coherent theory of the link between HR practices and performance (Becker and Gerhart 1996, Guest, 1997).

From these comprehensive reviews it becomes apparent, what Guest et al. (2003, p: 294) stated: “a large majority of studies find an association between HR practices and firm performance, regardless of whether they are cross-sectional or longitudinal, whether

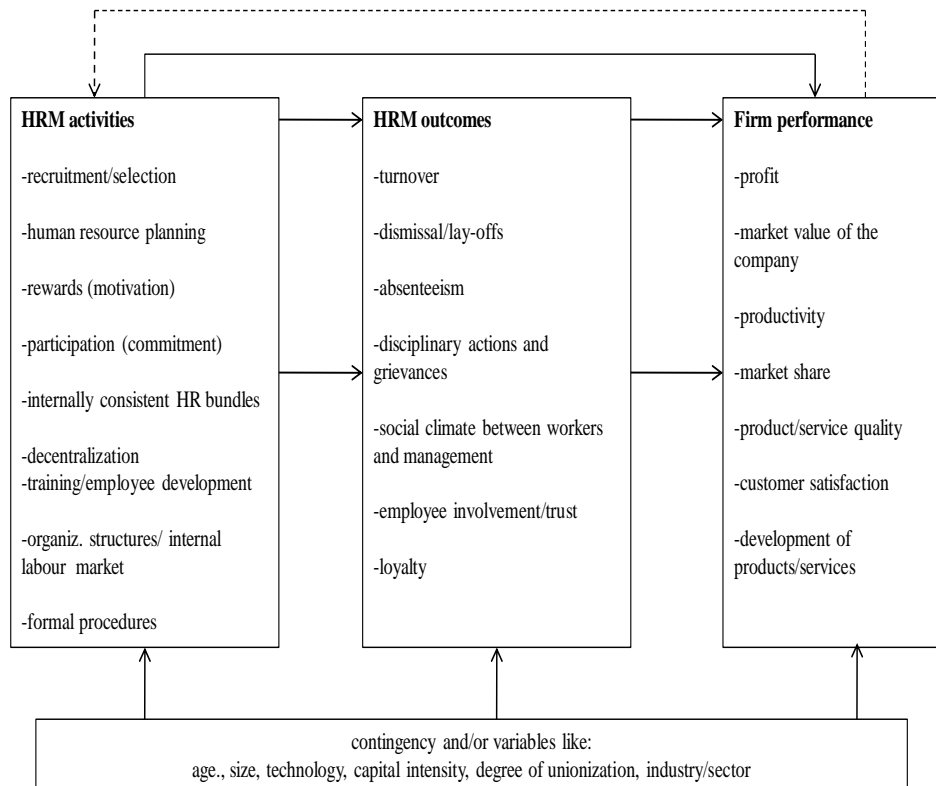

conducted at establishment or company level, whether based on strong performance data or subjective estimates, whatever sector they are based on, whatever operational definition of HR is used and wherever they are conducted”. The study design and the methodology used in previous studies appear as the reasons for this commonly assumed positive association between HR practices and organisational performance. But, no causal order is identified between the HRM practices and performance. In most of them it is assumed that the impact is from HRM practices to firm performance. However, regardless all the different approaches adopted in these studies, a confusion and lack of clarity still exists concerning the causal order of the relationship and the mediating variables influencing it (Gerhart, 2005; Katou, 2008; Wright et al., 2005). It still remains unclear “what causes what”, namely the causal order of variables involved in what is called by several authors the “black box” of the HRM-firm performance relationship (Gerhart, 2005; Katou and Budhwar, 2010; Purcell et al., 2003; Wright and Gardner, 2000; Wright et al., 2003). Hence, it stills remains to be clarified if the high performance and effectiveness of successful and competitive firms stands as the return on investment on managing firm’s human capital or if forms the source for this investment.

Reverse causality studies in HRM-organisational performance field

As stated above, it is not clear if a “forward causality” from HRM policies and practices to organisational performance is the case or a reverse one or even a bilateral one (Guest, 2001; Katou and Budhwar, 2010). Few are the studies which have tested for the opposite causal order, namely when organisational performance influences HRM (Wright and Haggerty, 2005; Wright et al., 2005). But quiet many are those highlighting the importance of reverse or reciprocal causation studies.

More precisely, Paauwe and Richardson (1997) presented a framework, adapted by Hegenzieker and Paauwe (1996), which is based on a sum of empirical studies in the field until that period (Figure 1). In this framework HRM activities are proved to have either a direct or indirect impact on firm performance. A number of control variables are tested as well. In addition, the problem of reverse causation emerges and is depicted in their framework, implying that business performance might cause changes to HRM practices.

Figure 1: A synthesis of empirically based research in the area of HRM and performance

Source: Paauwe and Richardson, 1997, p: 260 (adapted by Hegenzieker and Paauwe, 1996)

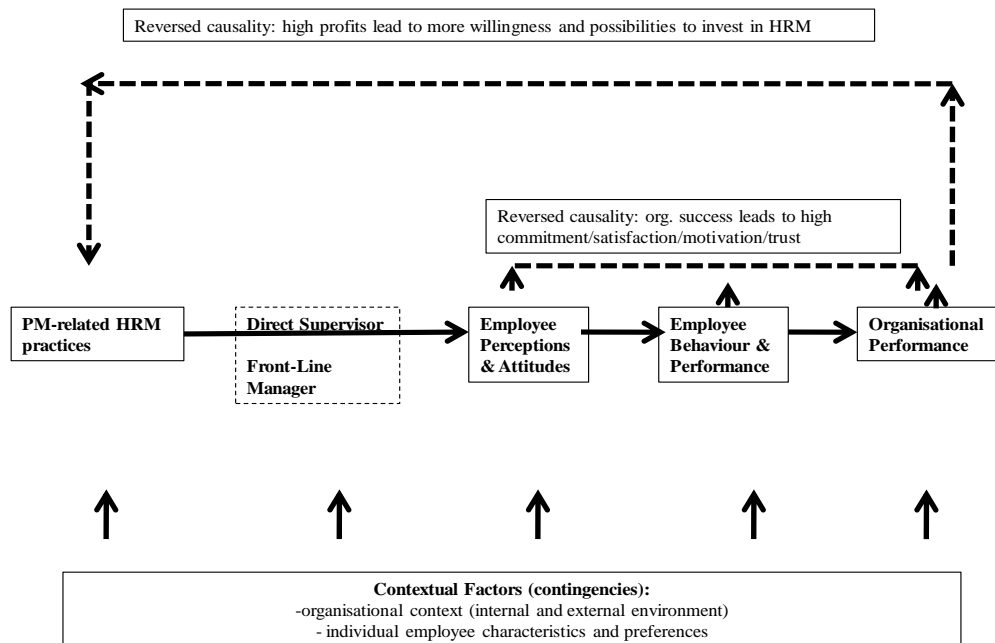

Based on the logical assumption that successful firms invest more in HR practices either to improve performance or to minimise risk or even to fairly distribute earnings, Wright and Gardner (2000) raise the topic of reverse causation and highlight once more, the need of an in depth analysis of the “black box” of HRM-performance relationship to reveal both the process of linkage and the direction of it.

Schneider et al. (2003) in their study focused on the relationship between employee attitudes and organisational financial and market performance. In their research they tested two models, one with a forward impact of employee attitudes on performance and a second one with the reverse impact. The results show that financial and market performance can cause employee attitudes. Their study proves that the belief that high-performance work practices influence employee attitudes and as a result employee and organisational performance, cannot stand any more as the norm in the field (Wright and Gardner, 2000). In addition, their study conducted in the organisational level and based on longitudinal data demonstrates that similar studies based on a single period data might result in misleading findings concerning the causal order of the employee attitudes-performance relationship.

A study based on longitudinal data is that of Guest et al. (2003) which focused on UK companies and examines the association of HRM with both objective and subjective measures of performance measures in a cross-sectional level. The study shows a positive association between HR practices and performance but fails to prove that HR practices lead to enhanced organisational performance. Even though the assumption that prior performance might result to the adoption of specific HR practices, is made, no significant results are reached to confirm the assumption as no evidence concerning the introduction time of HR practices are included in the study (Guest et al., 2003). Thus, future studies should test for the relationship between HRM and performance by examining the results of the implementation of certain HR practices on performance, for a definite time period. It should be also mentioned that Guest et al. (2003) research shows support of the fact that profitability leads to more investment in HRM rather than the opposite.

Den Hartog et al. (2004) propose a more detailed model of HR practices-performance linkage, by including employee attitudes, individual performance and supervisor's role (Figure 2). One of the main of the main assumptions of their model is that of reversed causality, which they examine under a double angle. Firstly, they assume as Wright and Gardner (2000) that successful firms invest more in HRM. Secondly, they presume that high performance leads to increased employee commitment, trust and motivation which impact directly on employee behaviour and productivity (Locke and Latham, 2002).

Figure 2: A model of the HRM and performance relationship from a performance management (PM) perspective

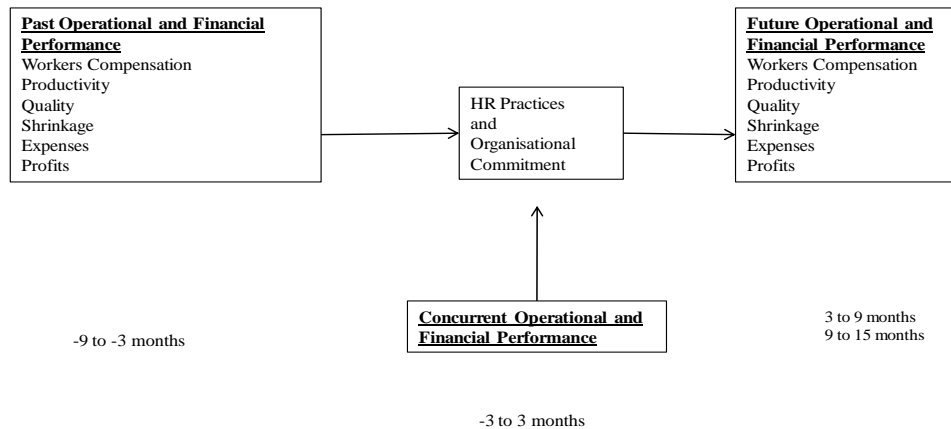

Source: den Hartog et al. (2004), p: 562

Paauwe and Boselie (2005) in their recent review of the literature in the field state the need for multilevel studies, as performance forms a multidimensional concept. Wright and Haggerty (2005), on the other hand, consider cause as one of the missing variables in the relationship. Based mainly on the HRM-economic performance link they imply that since successful firms invest their earnings in the HR department (by distributing bonuses or by investing in HR training and development) reverse causality might be the rule. More specifically, HR practices, such as percentage of total pay and number of training hours are strongly influenced by current and past performance. This in association with the fact that under performing firms decrease their investment in HR department gives support to the reverse causality effect. The development of more complex models, that will include more variables affecting performance, both in the internal and the external environment of the firm, might help revealing the actual direction of the causation of the relationship.

Wright et al. (2005) based on previous studies examined for causal links in the relationship of HR practices and past, current and future performance. They concluded that the majority of the studies in the area are post-predicted, namely examining HR practices after the performance period. Therefore, these studies suggest that HR practices predict past performance. However, even these studies do not examine for the opposite direction of the relationship between HRM and firm performance. According to Wright et al. (2005) only few scholars have attempted to test for the opposite relationship/causation, who measured firm's financial performance, objective and subjective productivity and profitability (Fulmer et al., 2003; Guest et al., 2003; Huselid and Becker, 1997; Watson Wyatt, 2002). These studies indicate once more that there is a level of uncertainty in the field concerning the causal direction of the relationship and also concerning the nature of the relationship, whether it is one way or dual one (Wright et al., 2005). Wright et al. (2005) attempt to clarify the confusion by proposing a model where past and current financial and operational performance cause HR practices and organisational commitment which in turn causes future performance (Figure 3). However, because of the short time period examined in their study they do not conclude in any specific causal direction. Reverse causation is as likely to exist as the forward causation as results show only that HR practices are strongly related with both future and past performance without implying any direction of the link. Furthermore, they observed that many of the studies in the field do not examine for the full set of HRM practices-variables which impact on performance and thus valid results for the direction of causation cannot be inferred (Wright et al., 2005). Previous studies highly ignore external environmental factors and their effect on the HRM-performance link which when considered usually supports the reverse causation. Thus, a need for more in depth research and analysis arises to identify the direction of this relationship and if there is a third variable which causes the direction of relationship of HRM practices and firm performance (Huang, 2000; Subramony, 2009; Subramony et al., 2008; Wright et al., 2005). Indeed, as Harter et al. (2002) propose, evidence for causality is possible only after numerous studies and not after few of them.

Figure 3: The study design

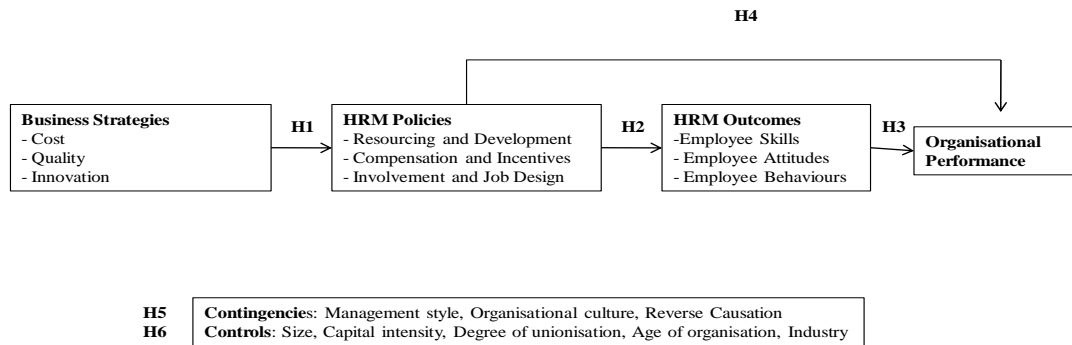

Source: Wright et al. (2005), p: 422

One year later Kinnie et al. (2006) address again the issue of the direction of the causation in HRM-performance relationship as a main methodological problem. They claim that the adoption of specific successful HR practices may be the case only in high-performing firms which have the sources to fund them. In addition, they suggest that the implementation of successful HR practices may only be the result of employee perceptions in successful firms and not the actual case. Finally, they refer to the problem of many factors causing increase in organisational performance apart from HR practices, which should also be examined or controlled.

In a very recent study Katou and Budhwar (2010) proposed a revised operational model of HRM-performance relationship (Figure 4). In this model they included reverse causation as a contingency factor and they tested for it by asking respondents whether they agree or not with the statement that high performing firms' earning causes changes to HRM department and not the opposite. The results show that organisational performance may have a positive impact on HRM. Thus, studies based on more objectives and longitudinal data should be conducted to answer the question of reverse causality as the norm or not.

Figure 4: The operational model for the HRM-performance relationship

Source: Katou and Budhwar (2010), p: 27

From the analysis above it seems, once more, that the direction of the causality in the HRM-performance linkage remains still unclear. More specifically, as it is implied, from the studies examined in this section, it is equally possible to have a reverse causation as the actual causation in the HRM practices-OP relationship. Although, several attempts have taken place to establish the direction of causation, the absence of longitudinal and objective data as well as overlooking external factors or other mediating variables that might impact on HRM-performance linkage and actually cause the linkage, render the question of causation unanswered.

The revised HRM practices-OP relationship model

As it arises from the literature review above, the majority if not all the studies in the field present the link between HRM practices and OP as a linear one. Either they assume a positive forward linear association (Guest, 1997) between the two variables or they claim for the possible existence of a reverse linear association (OP having an impact on HRM practices) (Katou and Budhwar, 2010) or a bilateral one (Wright et al., 2005).

However, taking into consideration results in previous studies, such as a) in the study of Wright and Gardner (2000), in which it is shown that successful firms invest more on HRM practices and as in the study of Pfeffer (1998), in which it is pointed out that several set/bundles of high performing work practices (HPWP) are used by successful organizations and as they have a positive impact on organizational performance irrespective of size, country or sector. These results if examined closely imply that HRM practices adopted and implemented at a different time point (before or after the observation of high

performance rates) indicate a rather different impact/direction of causation in the HRM practices-OP link. Based on this a circular model could be proposed as the one representing the relationship (Figure 5).

Figure 5: A **circular model representation of the HRM-OP relationship**

HRM practices might have been introduced before the measurement of organisational performance and thus be one or the only cause for any change in organisational performance. Or else, HRM practices might have been adopted and implemented after the measurement of organisational performance, which means that they have been carefully selected regarding the organisational performance and the probably new firm goals. This means that reverse causation stands now as a part of the actual model and not just as a contingency factor, as in previous studies (Katou and Budhwar, 2010).

This model stands as a development based also on the findings of the Guest et al. (2003) study, in which he concludes by stating that even though in past studies, the assumption that prior performance might result to the adoption of specific HRM practices, is made, no significant results are reached to confirm the assumption as no evidence concerning the introduction time of HR practices are included in the study (Guest et al., 2003). Furthermore, we should not still exclude the possibility that third factors might have an impact on the relationship or cause the relationship itself. Thus, we should also test the influence of several control factors on the linkage.

Conclusions

From the short and comprehensive literature review in the field, it becomes apparent that previous studies have focused in analyzing the HRM-performance link under several contexts. However, no conclusions about the causality of the relationship and its direction

have been reached. No pure study exists on the reverse causation (from organisational performance on HRM practices). No specific theory has been developed for the link.

As an answer to all the confusion in the field this paper proposes a revised circular model of the HRM practices-OP relationship which includes both directions of causality assumed in past studies. Future research in the field according to this study should focus on examining the impact on firm performance of the implementation of HRM practices in different time periods. Such a development offers a new basis for more theoretical and empirical research in the field and probably a basis for answering what causes what, when, and why.

Introduction

Technological strategy of a firm is integrated in success of a firm and its competitiveness in the market (Tidd, et al 2005). The firm's technology development can be done by making (doing R&D) or buying of technology (technology transfer) or integration of both of them (Zhao, et al, 2005, Granstrand, et al.,1992, McIvor et al, 1997).

Pharmaceutical industry in Iran like most of other developing countries uses the strategy of imitation for technology development with main focus on producing the generic drug (Cheraghali, 2006). In order to fulfill their technological gap for producing the required drugs, they try to transfer the proper technology from foreign countries or the companies which have the technology and adopt it in the firm (Zuniga et al, 2007). For having a good adaptation of technology in the firm and also indigenizing it, existence of internal capability is an important factor (Kamien and Zang, 2000; Katrak, 1997). Internal capability will increase the absorptive capacity of that to acquire the technology properly (Cohen and Levinthal, 1990) and organizational support to innovation (innovation capability) will create the proper environment for the employees and the firm to develop the technology and increase their product innovativeness as well as their performance (Mone, McKinley & Barker, 1998; Cho & Pucik, 2005, Renko, et al, 2009).

Most of innovations in developing countries are related to the imitative innovations in which the products are new to the firm but they are not new to the market (Garcia and Calantone, 2002) and have the low technological and market innovativeness. The internal ability and innovation capability of a company is important to develop new products after establishment of a new technology platform for producing a family of product which serves a variety of markets (product platform) (Ulrich and Eppinger, 2008).

In this study, a conceptual and analytical model for examining relationship of innovation capability of a firm with product platform development as well as performance of Iranian Active pharmaceutical ingredient (API) producers is developed and tested by using data from TAPIC subsidiaries as the largest conglomerate in production, provision and

distribution of API in Iran. The objective of this study is to gain a better understanding the effect of innovation capability on product platform development and performance. In order to accomplish this objective the research questions are developed, research methods are presented and findings analyzed and discussed.

In the following the theoretical background is discussed.

Theoretical Background

Innovation

In the new era, the competitive advantage of a firm come from the knowledge, technological capabilities and experience by which firm create new products in the market (Tidd, et al, 2005). In the increasing international competition environment, there is special attention to innovation in the firms. Although the R&D is aligned with high risk and high cost, but it is important for the survival of the firm (Veugelers and Cassiman, 1999) and the ability to make new product or doing things better than the others is the powerful source of advantage.

Based on Tidd, et al (2005), the majority of failures in innovation are due to the weakness in the management of innovation process. Innovation should be managed in an integrated way to get the best result, then only managing and developing capabilities of the firm in some areas is not enough.

In the fast technological change, innovation becomes important for the firm to be in front of their competitors, and the technological and managerial innovative capabilities are necessary to success of firm and industry and at last the nation (Soares, et. al.1997).

Based on Ramirez and Wallin (cited in Blois and Ramirez, 2006) capabilities are “repeatable patterns of action in the use of assets to create, produce, and deliver offerings” and they can be defined as a distinctive competencies when their imitation by the competitors are difficult (Blos and Ramirez, 2006).

Innovativeness of a firm is related to capability to employ in innovation (Hult, Hurley & Knight 2004) and is the firm’s tendency to support new ideas, creative processes and novelty Innovativeness relates to a firm’s capability to engage in innovation (Lumpkin & Dess 1996).

Guan and Ma (2003) and Yama, et al, (2004) categorized innovation capabilities into seven dimensions which are learning capability, R&D capability, manufacturing capability, marketing capability, organizational capability, resource exploiting, strategic capability

Chiesa, et al (1996) proposed a model for auditing the innovation capability of a firm based on a process model of technical innovation.

Based on Tidd (2005) successful innovation is:

1. Strategy based (Strategy)
2. Dependent on effective internal and external linkage (Linkage)

3. Dependent on effective mechanism for making changes happen (Process)
4. Happened in a supporting organizational context (Organizational structure)

These four specifications of successful innovation are considered in the context of learning organization.

He used the above mentioned factors for auditing the innovation management of the firm.

Product and Technology Platform Development

Technology is embodied in all activities of a company including primary and supportive activities. Based on Porter's (1995) value chain model, a firm has lots of activities in which at least there is a technology in it. Each technology can have impact on competition of the firm, but there are some technologies which create competitive advantage for the company and these technologies will impact more on competition.

Technological change is a key factor in economic growth, industrial change and international competitiveness. It is the major component responsible for increasing output and income in most industrialized countries (Saad, 2000) and based on Dodgson (2000) technological development is the key source of competitive advantage and the companies should have a strategic approach to their investment in technology.

Each firm's technology strategy is based on funds, structures, and the R&D activities whose mission is to create new pathways for technology (Burgelman R. A. and Rosenbloom R. S. 1989 cited in Dorf, R. C., ed. 2000).

Based on many researchers (Zhao, et al, 2005, Granstrand, et al., 1992, McIvor et al, 1997) for achieving a technology development there are two general strategies

- Internal technology Sourcing strategy (making technology)
- External technology sourcing strategy (buying technology)

Roberts & Berry (1995), Tidd and Trehwella (1997), Roberts (2001), Edler, et. al. (2002), Granstrand et al. (1992) found internal R&D as the most common way for technology acquisition. Ruchala (1997) states internal R&D is an important factor for making core competency and is suitable for growing technology (Welch, et. al. 1992), but it needs strong technical experts and also financial investment (Khalil, 2000).

Technology outsourcing will reduce time to market (Tidd, 2005), reduce the R&D costs (Jonash, 1996) and fulfill the lack of internal capability (Cutler, 1991) and based on McIvor and Humphreys (2000), although the cost saving and more profit is important for short term in external sourcing but the loss of core competencies of the firm should be considered for the long term which is the source of competitive advantage for the company

To get a competitive advantage, firm should improve its technological capabilities by internal R&D or external technology sourcing or both of them. As a matter of fact, each of them will have some advantage and disadvantage for the firm in which firm should regard.

Technology sourcing in the technology based companies will be a critical management issue (Zhao, et al., 2005).

Because the gain of knowledge and experience takes lots of time for a firm and the acquired knowledge and experience is its intangible asset, the firm that commences an industrial field based on a platform technology, gains the technological skills to branch out it into new application and new products. A product platform is a group of related products which satisfy a variety of customers and markets and is manufactured by available and preexisting technological subsystems (a technology platform) (Ulrich and Eppinger, 2008). For developing the technology platform lots of investment and effort has been spent and lots of attempts made to use it for production of different products. “A product platform is a collection of the common elements, especially the underlying core technology, implemented across a range of products” (McGrath 1995).

Meyer and Selinger (1998) described a technological platform as a set of subsystems which function as a structure to produce a stream of derivative products. Based on Wonglimpiyarat (2004) technological platform is a cluster of capabilities or competencies which make firm capable to create competitive advantage in terms of later innovations.

In our view a technological platform is an integrated system of capabilities, physical assets and know-how which is used in order to develop a category of derivative products and the product platform is a variety of products which are produced in the same technology platform but with new application.

Certain technologies have expansive market and technological opportunities and gaining knowledge and experience on these technologies serves as a platform for expansion. In the platform, experience of the firm increases the probability of diversification when the market is favorable (Kim and Kogut, 1996).

A product platform has two modes for derivative product development (Ulrich and Eppinger, 2008). As it has been shown derivative products can be involved in the initial efforts for platform development, it means in the establishment of the platform all of its products are introduced and there is no opportunity to produce the new derivative product on the established platform (see platform A, fig 1). In the other mode, there is opportunity for the firm to develop the other derivative products in the established platform which can be gained within time lapse (platform B, fig 1).

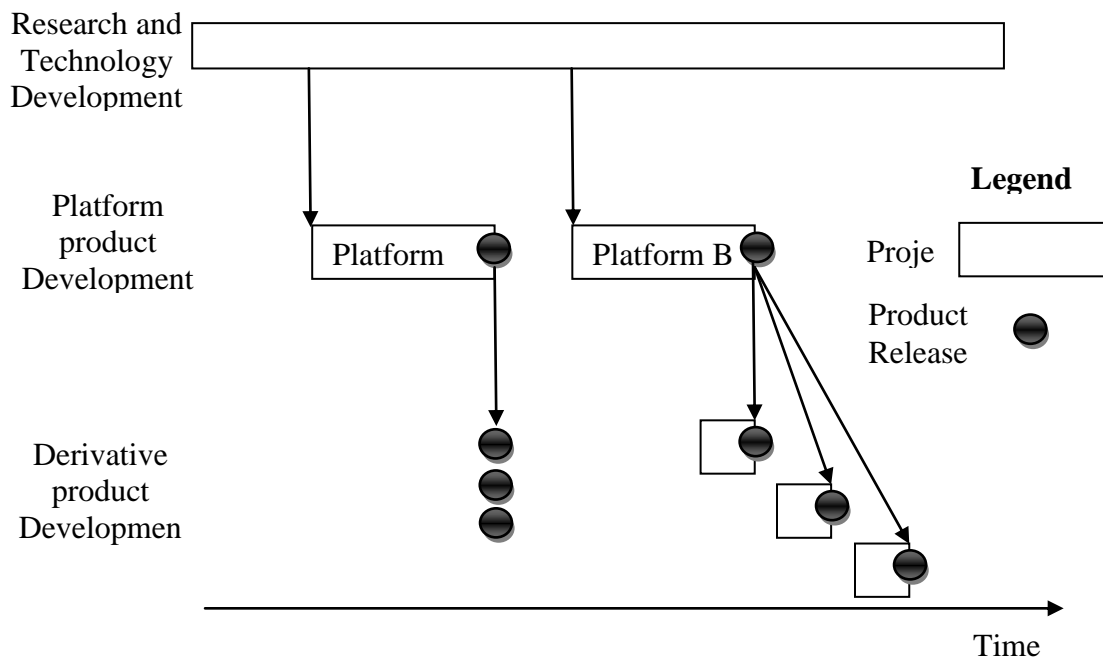

Figure1. A platform development project creates the architecture of a family of products. Derivative products may be included in the initial platform development effort (Platform A) or derivative products may follow thereafter (Platform B).

Source: Ulrich and Eppinger, 2008, p.41

Technology Development in Developing Countries

In most Developing countries, the primary source of technological change comes from industrialized countries through the process of technology transfer. This process can include the application of new technology to a new use for gaining economical profit (Rodrigues, 1985).

Based on Zuniga et al, (2007) in developing countries due to low level of investment in R&D, insufficient human resources, lack of resources and facilities, and weak technological capability, companies don't rely only on their in house R&D, they try to import technologies from foreign companies, then they will use an acquisition technology strategy which fit well with their business strategies. Pharmaceutical industry in majority of developing countries uses the strategy of imitation instead of innovation. For this reason there is a technological gap among the developing countries and developed ones, therefore for filling this gap, firms try to use technology outsourcing besides in house R&D. Using in-house R&D and technology acquisition can be a complementary for each other, e.g. using the capability of R&D can help the firm to choose the appropriate technology, and facilitate the adaptation of the technology in the firm (Kamien and Zang, 2000; Katrak, 1997) and on the other hand, the technology acquisition helps the company to improve its technological capability and optimize the R&D efforts which will lead to internal innovation (Kaiser, 2002; Kamien & Zang, 2000). But there is a dangerous case if the

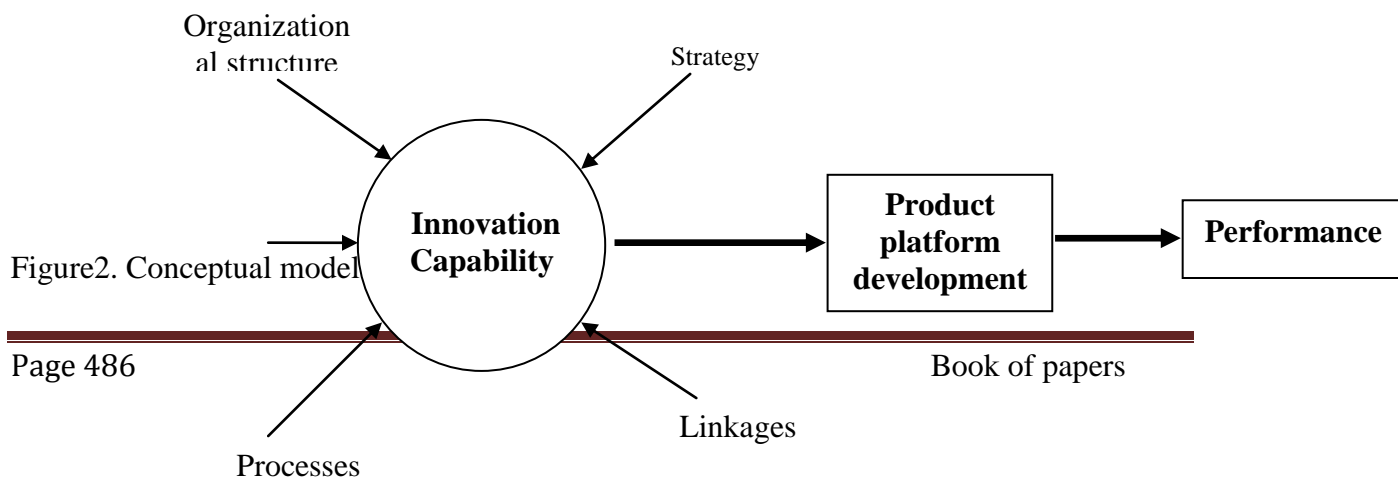

company tries to outsource all of its technological needs instead of using in-house R&D, which causes to be technological dependence and also decrease company innovativeness.

Mytelka (1987) and Pillai (1979) (cited in Katrak, H., 1997) stated the import of technology in developing countries will increase their dependency to import, and in an opposing view Blumenthal (1976), Desai (1989) and Lall (1989), (cited in Katrak, H., 1997) considered technology import as a building block for technology development and increasing internal capabilities.

The Conceptual model and Research questions

One of the important issues which play an important role in the product innovativeness, technological development and performance of the companies is the organizational support to innovation (innovation capability) (Mone, McKinley & Barker, 1998; Cho & Pucik, 2005, Renko et al, 2009). Many researchers found capabilities as the source of performance (Carmeli and Tishler, 2004; Shang and Marlow, 2005). On the other hand, based on Damanpour and Evan (1984) there is positive relationship between organizational innovation and performance and also Subramanian and Nilakanta (1996) found the positive relationship between organizational performance (ROI) and innovativeness of the company. Kleinschmidt and Cooper (1991) investigate impact of product innovativeness on profitability at the firm level.

A firm can get its technological development by the internal or external technology acquisition and many scholars reviewed technology sourcing criteria as well (McIvor and Humphreys, 2000, Granstrand, et al., 1992, Atuaheme-Gima and Patterson, 1993, McIvor et al, 1997). Although the internal R&D is the most common way for technology development (Roberts & Berry,1995; Tidd and Trehwella, 1997; Roberts, 2001; Edler, et al, 2002; Granstrand, et. al, 1992), but in the developing countries, companies acquire their technology by external sourcing from foreign countries (Zuniga et al, 2007) in order to fulfill their technological gap for producing new products. Based on many scholars (Kamien and Zang, 2000, Katrak, 1997, Kaiser, 2002) using technology acquisition and in house R&D can be complementary for each other and technology acquisition helps the company to improve its technological capability to optimize R&D efforts which will lead to internal innovation. But when the companies try to outsource all technological needs from other companies or countries, there is a probability to dependency of the companies to the source of technology which should be considered as a factor to decrease the innovativeness and performance of the companies.

As illustrated in figure 2, the model consists of the following components:

Innovation capability of a company which is a determinant factor is innovativeness of the firm. Innovative organization is not limited to a structure, and it is an integrated set of components in order to create a constructive environment which makes innovation happen. The successful innovation is strategy based which mean how the company develops its policies, plans and strategies to achieve its mission and vision. The mission and vision should be well communicated and people know the influence of innovation on performance and growth of the company. For having a successful innovation, the processes should be facilitated from idea to implementation. Also the organizational structure should support creativity and occurrence of technological change. The internal and external linkage is important to have opportunity to learn from the customers, suppliers and competitors (Tidd et al, 2005). Finally, having a learning organization beside these enablers is also important. Training of employees and increasing their knowledge level, sharing of experience, are good for increasing the learning process.

- Product platform development which is the ability of the company to extend an existing product platform with some new products to address familiar market by using its internal capability of the firm.
- Performance of the firm which is related to the financial ratio of the firm (ROI).

Research method

Study Questions:

The purpose of study can be broken down to the following research questions:

1. What are the common Product and technology platform developments in the TAPIC subsidiaries?
2. What is the difference of successful and unsuccessful companies in the product platform development and innovation capabilities?
3. What is the impact of innovation capabilities on the product platform development?

Research method

Based on purpose, our research type is explanatory. Based on result, our research type is an applied research. Based on kind of data, our study categorized in quantitative research methods, also we applied survey strategy in this research.

Population and Sampling

Population consists of all real or supposed members that we interest to generalize our finding to them.

In this study the questionnaires distributed among the people who are involved in innovation in different departments in eight subsidiaries of Tamin Active Ingredients Investment Company.

The researcher attended in the firm with prior coordination, and then the questionnaires distributed and then gathered. The studied subsidiaries of TAPIC are presented in the table 1.

No.	Name
1	Antibiotic Sazi Iran Company (ASICO)
2	Temad Active Pharmaceutical Ingredients Company
3	Atra Pharmaceutical Complex
4	Darou Pakhsh Pharmaceutical Chemistry Company(DPPC)
5	ChlorPars Company
6	Daana Pharmaceutical Company
7	Rahavard Tamin Chemical Company (RTCC)
8	Tofigh Darou Research and Engineering Company (TODA)

Table1. List of studied subsidiaries

Data Collection

In order to collect data, questionnaire related to innovative capabilities of companies is selected as the main tools to collect data (primary data).

At first by collaboration of TAPIC (the mother company), the researcher is introduced to the eight studied companies, and then the researcher arranged a meeting with the managing directors of each company. After attaining in the meeting and interviewing about product platform development, managing directors are requested to distribute the printed questionnaires among managers and experts in the departments of marketing, R&D, manufacturing, quality control and quality assurance. 200 questionnaires were distributed in the eight companies and 168 filled questionnaires are gathered.

This questionnaire is a valid questionnaire for auditing the firm's innovativeness and is used for identifying their barriers to be innovative. Its variables include:

- 1.Strategy
- 2.Processes
- 3.Linkage
- 4.Organizational structure
- 5.Learning

Scale used in this study is nominal, ordinal, scale and relative. The Likert spectrum for assessing opinions of individuals was used in the questionnaire.

In order to gather data about the product platform development of the companies, the archival documents in TAPIC are studied and also in order to validate the accuracy of data, interview with the managing directors, R&D and manufacturing managers are designed.

For finding the performance of the companies, the financial data sheets in the TAPIC are used to extract the net profit and also their investment in order to find the ROI of companies during 2007, 2008 and 2009.

Results

By using Kolmogorov-Smirnov Test the observed cumulative distribution function for variables with a specified theoretical distribution are compared. The distribution was normal and parametric tests are used in order to study the questions.

First Question: what is the common technology platform development in TAPIC subsidiaries?

Studying the companies in order to find technology platform development, showed that most of companies are using buying strategy for establishment of their basic technologies. In these companies, the main source of new technology platform is outsourcing from foreign countries and two platforms among the existed platforms are internally established by using in-house R&D.

The companies are studied in order to find out how they use the acquired technology to develop their product platform which the results showed that companies try to develop their product platform internally after the establishment of technology platform on their firm.

Generally Iranian pharmaceutical companies use technology transfer from foreign countries in order to fulfill their technology gap as the same as other developing countries (Zuniga et al, 2007) and by transferring the technology, they establish their product platform. But for developing their product platform, they use their internal R&D for developing new product family from their platform which is the complementary use of acquired technology and internal R&D (Kamien and Zang, 2000, Katrak, 1997, Kaiser, 2002).

Second Question: What is the difference of successful and unsuccessful companies in the product platform development and innovation capabilities?

At first the difference of successful and unsuccessful companies in innovation capabilities and then on technology development strategy will be studied.

Difference of successful and unsuccessful companies in innovation capabilities:

For defining the difference innovative capability between successful and unsuccessful companies based on their financial performance, the compare means test is used. This test is used for comparing the means of two groups of high and low performance companies. The first output of compare mean shows the means and differences between means of two groups (low and high performance companies in their innovative capability variables), and

in the second output because significance level is upper than 0.05, the assumption of equal variable is considered to compare which shows in Iranian pharmaceutical companies, high and low performance companies have difference in their innovative capability and its variables (table 2).

Independent Samples Test

		Levene's Test for Equality of Variances		t-test for Equality of Means							Conclusion
		F	Sig.	T	Df	Sig. (2-tailed)	Mean Difference	Std. Error	95% Confidence Interval of the Difference		
									Lower	Upper	
Strategy	Equal variances assumed	1.359	0.245	-7.107	166	0.000	-0.5673	0.07983	-0.72495	-0.40972	Accepted
	Equal variances not assumed			-6.930	131.074	0.000	-0.5673	0.08186	-0.72928	-0.40539	
Processes	Equal variances assumed	0.455	0.501	-7.348	166	0.000	-0.6251	0.08507	-0.79304	-0.45712	Accepted
	Equal variances not assumed			-7.534	155.570	0.000	-0.6251	0.08297	-0.78896	-0.46119	
Organization	Equal variances assumed	0.083	0.774	-5.031	166	0.000	-0.4128	0.08206	-0.57482	-0.25079	Accepted
	Equal variances not assumed			-5.019	142.855	0.000	-0.4128	0.08225	-0.57539	-0.25022	
Learning	Equal variances assumed	1.527	0.218	-6.073	166	0.000	-0.4436	0.07304	-0.58776	-0.29936	Accepted
	Equal variances not assumed			-6.203	153.964	0.000	-0.4436	0.07151	-0.58482	-0.30230	
Linkage	Equal variances assumed	0.141	0.707	-8.279	166	0.000	-0.6337	0.07655	-0.78485	-0.48259	Accepted
	Equal variances not assumed			-8.161	136.711	0.000	-0.6337	0.07765	-0.78727	-0.48017	
Innovation Capability	Equal variances assumed	0.276	0.600	-8.373	166	0.000	-0.5356	0.06397	-0.66192	-0.40932	Accepted
	Equal variances not assumed			-8.357	143.096	0.000	-0.5356	0.06409	-0.66230	-0.40893	

Table 2. Independent sample test

By using the Chi-square test (χ^2), the relationship between performance and innovation capability are studied. The results confirm existence of relationship between the performance and innovative capability variables because the Asymp. Sig. (2-tailed) for all variables are lower than 0.05.

Variables		Pearson Chi-Square	Likelihood Ratio	Linear-by-Linear Association	N of Valid Cases
Strategy	Value	74.1	93.6	38.9	168
	Df	25	25	1	
	Asymp. Sig. (2-tailed)	0.000	0.000	0.000	
Process	Value	63.1	75.8	40.9	168
	Df	23	23	1	
	Asymp. Sig. (2-tailed)	0.000	0.000	0.000	
Organization	Value	38.3	47.4	22.1	168
	Df	23	23	1	
	Asymp. Sig. (2-tailed)	0.024	0.002	0.000	
Learning	Value	62.3	73.9	30.4	168
	Df	21	21	1	
	Asymp. Sig. (2-tailed)	0.000	0.000	0.000	
Linkage	Value	68.1	79.9	48.8	168
	Df	20	20	1	
	Asymp. Sig. (2-tailed)	0.000	0.000	0.000	
Innovation Capability	Value	150.8	203.0	49.6	168
	Df	87	87	1	
	Asymp. Sig. (2-tailed)	0.000	0.000	0.000	

Table 3. Chi-Square Tests

Difference of successful and unsuccessful companies in product platform technology development

For studying the difference of technology platform development of high and low performance companies the cross tabulation table between strategy and performance of companies are done which shows the companies with low performance use buying

strategy and companies with high performance use both of buying and making strategies.

		Technology platform sourcing	
		buying technology platform	making technology platform
Performance	Low		-
	High		

Table 4. Cross tabulation of performance and sourcing strategy

In studying the difference of product platform technology development between high and low performance companies the cross tabulation table (table 5) between the performance of companies and the question " how many products are developed internally in the product platform? " is done which shows most of high performance companies have developed the acquired technology to more products than the low performance companies.

Company	Performance	Number of developed products internally on the acquired technology platform	
		First technology platform	Second technology platform
C	Low	1	-
A	Low	1	0
G	Low	2	-
D	Low	0	-
B	High	5	5
H	High	5	6
F	High	3	4
E	High	0	-

Table 5.18 Cross tabulation of performance and number of internally developed products

Although E company is a high performance company but does not have any internally developed product. The reason to this exception is that the type of product platform in the E company does not have any opportunity to develop new derivative product on it, and all of the derivative products are developed in the initial establishment of product platform.

Finally we can

1. There is positive relationship between innovation capability and the performance of Iranian API producer companies and the Iranian high and low performance API producer companies have difference on innovation capabilities with each others, and high performance companies are better than the low performance in the innovation capability and its variables. The innovation capability of the firms are the determinant factor in performance of the companies (Cho & Pucik, 2005, Renko et al, 2009) and there is positive relationship between organizational innovation capability and performance of them.
2. It has been shown that like the other researcher (Kleinschmidt and Cooper,1991; Cho & Pucik, 2005; Lages, et al, 2009) the product innovativeness of the firms is an effective factor on the performance of the companies and there is a positive relationship among them. In here although, technology sourcing strategies by both of them are almost the same but the high performance companies use the acquired technology and also acquired capabilities in an efficient way which causes to develop more new product from the technology platform. And their innovativeness in their product platform development can cause to have a better performance than the companies which are weak on it.

The firms which are good in their innovation capability in which they have well communicated vision and mission, clear organizational purpose, long term commitment to the main projects, effective mechanisms to implement the innovation, systematic problem solving, proper organizational context, proper working structure, reward system, effective internal and external organizational systems, close relationship with customers, supplier and partners, commitment to training and development have the great probability to develop their product platform better as well as their organizational performance than those companies which do not have proper organizational innovation capability.

Third Question: The impact of innovation capabilities on the product platform development

In order to answer to this research question we choose the companies in which their product platform have the opportunity to develop derivative products. Because there was a company in which all the product are developed by its initial establishment of the platform and it does not have any opportunity to develop new product in it and for new product they should establish a new platform. But the other seven companies have the opportunity to develop new derivative products on the existing platform and for the analysis of this question, we considered these seven companies.

Because the number of the developed product in each company differs, then we used ANOVA Test to compare the several independent groups. The One Way ANOVA is used when the means from several independent groups have difference. In the following table the output of One Way ANOVA between the innovation capability variable and the number of developed products are presented.

		Sum Squares	of Df	Mean Square	F	Sig.
Strategy	Between Groups	13.296	4	3.324	14.474	0.000
	Within Groups	31.691	138	0.230		
	Total	44.986	142			
Processes	Between Groups	20.136	4	5.034	24.452	0.000
	Within Groups	28.411	138	0.206		
	Total	48.546	142			
Organization	Between Groups	8.788	4	2.197	8.523	0.000
	Within Groups	35.573	138	0.258		
	Total	44.361	142			
Learning	Between Groups	9.388	4	2.347	12.490	0.000
	Within Groups	25.932	138	0.188		
	Total	35.321	142			
Linkage	Between Groups	15.378	4	3.845	16.962	0.000
	Within Groups	31.279	138	0.227		
	Total	46.657	142			
Innovation	Between Groups	11.703	4	2.926	19.884	0.000

Capability	Within Groups	20.306	138	0.147		
	Total	32.009	142			

Table 6. The One Way ANOVA output

The results of analysis showed that there is significant effect between the innovation capability variables and the number of developed products. If the significance level is lower than 0.05, it means that there can be relationship between number of developed products and each of variables. As it has been shown in the table, the calculated amount of significance level for all variables is less than 0.05, and then there is relationship between innovative capabilities and number of developed products for companies.

The innovative capability of the firms can have a positive effect on the product quality and innovativeness (Cho and Pucik, 2005; Lages, et al, 2009) and As the results showed there is positive relationship between innovation capability of the companies and their product platform development in which the companies with better innovation capabilities could use better from the opportunities to develop more products in the existing product platform.

Discussion:

Findings for researchers will be mentioned in the following:

1. Most of Iranian API companies buy the required technology in order to establish a new product platform in which the successful and unsuccessful companies are almost the same in this action same as most of developing countries (Zuniga et al, 2007), but their difference is in using the acquired technology in order to develop derivative products internally, The successful API producers (high performance) because of having better innovation capability are prone to use the opportunities to develop the new product derivatives, which can increase the sale and also the profit of company as well as its performance.
2. There is a positive relationship between the organizational innovation capability and product platform development of the companies, and the firms which are better in innovation capability are prone to develop more products (derivatives) in the existing product platform when there is opportunity to develop new products and also there is a positive relationship between the

performance of the companies and their innovation capabilities too, In which the firms which have the better innovation capabilities, have the better performance.

3. The firms which are good in their innovation capability in which they have well communicated vision and mission, clear organizational purpose, long term commitment to the main projects, effective mechanisms to implement the innovation, systematic problem solving, proper organizational context, proper working structure, reward system, effective internal and external organizational systems, close relationship with customers, supplier and partners, commitment to training and development have the great probability to develop their product platform as well as their organizational performance than those companies which do not have proper organizational innovation capability as it has been mentioned by Antoncic et al, 2007; Cho and Pucik, 2005; Lages, et al, 2009

Recommendation:

Most of Iranian API producers are sourcing the basic technology for establishment of new product platform from foreign countries and in order to use effectively the acquired technology and indigenize the technology and external capability in the company, it is important that the companies improve their innovativeness environment, innovation capability and also their internal capability. It is better for these companies to use external technological capabilities as complementary for the internal one.

There is positive relationship between innovation capabilities, product platform development and performance; API producer companies in order to increase innovativeness should improve their innovative capabilities. The most effective factors in high performance companies are strategy, learning capacity and processes (based on Friedman test) in which the low performance companies are weak on it. Therefore, the low performance companies should increase their capabilities in these categories. In order to have an innovative management, the companies should well communicate the company's vision about innovation, the threats and opportunities should be detected and proper action be done, top management should have commitment on innovation, commitment to training and improving employees capabilities and share experiences in order to learn from the mistakes.

By having a learning organization, the internal capacity to acquire the external technological capabilities will increase and capability to get transfer of technology completely and developing that will be increased.

Based on Zuniga, et al, (2007) in developing countries companies for filling the technological gap with developed countries try to transfer technology from them and in order to prevent dependency to external sources of technology, it is important that Iranian API producer companies manifest their internal capabilities, and use technological outsourcing as complementary for their internal capability and in-house R&D.

Factors Affecting the Sustainability of Quality Management Practices: An Agenda for Future Research

Mehran Doulatabadi. Department of Management, University of Technology
Malaysia, Malaysia. dmehran2@live.utm.my

Key words: Quality management, quality award model, key success factors, sustainability.

Introduction

Quality management is broadly recognized around the world as a very important competitive priority for the long-term success of an organization over several decades. However, the recognition of the successes through using the quality management approach historically has been made by obtain national quality or excellence awards (Laszlo, 1996). The national quality or excellence awards programs are the next major quality management event following TQM (Vora, 2002; McAdam et al., 1998). Therefore, for many organizations participating in national quality or excellence award program is a way to support their TQM practices towards achieving world-class statue (Yusof & Aspinwall, 2000) Puay et al,1998, Adebajo, 2001, Grigg & Mann, 2008a).However, to get significant benefit and the best result, organizations must maintaining the practices with the awards principles for the long-term on the competitive path and made it a part of their organizational culture. Studies by Coulambidou & Dale (1995) and Angell & Corbett (2009) support this view.

Today, the national quality/excellence frameworks and their criteria have been commonly accepted by many organizations as a powerful tool for assessing an organization along the quality and excellence path (Meers & Samson, 2003). Therefore, given today's business climate, it would be hard to find an organization to ignore the practice on quality management approaches. However, achieving excellence is hard enough at the best of times; sustaining it in today's world of increasing global competition, rapid technological innovation, changing processes and frequent movement in economic, social and customer environments, is even harder.

Literature Review

After the successful of quality management practices in Japan several countries established national quality/excellence award programs to pursue excellence in an effective way and to recognize which organizations employed the best quality

management practices. All awards principles are strongly grouped based on the core of key principles and major constitutes of TQM (Ghobadian & Woo, 1994, Ghobadian & Galliar, 1997, Thompson & Simmons, 1997, Hendricks & Singhal, 1999, Zairi, 2001, Tan et al. 2003). Therefore, getting a national quality/excellence award is a confirmation for TQM implementation successfully (Hendricks & Singhal ,1996); Ghobadian & Galliar ,2001; and Eriksson ,2004). Improvements as assessed against the quality/excellence framework will lead to long-term business success. As a result, there has been a trend in organizations to use quality-based initiatives as a source of competitive advantage.

The literature suggests that the success of an organization by using the quality-based initiatives does not depend on individual quality tools and techniques, but it much depends on a range of general management practices, including: top management commitment and support, establishment of trust and communication, employee empowerment and motivation, common metrics across the organization, a stepwise problem solving approach, and standardised analysis using quality tools (Choo et al., 2007; Easton & Jarrell, 1999; Ehigie & McAndrew, 2005; Hodgetts et al.,1999; Powell, 1995; Soltani et al., 2005; Venkateswarlu & Nilakant, 2005). Business excellence or organizational excellence and all round growth have been the spicy subject of discussion among management academics at the recent years. The first major study on the concept of ‘business excellence’ as a topic of academic research was undertaken by Peters and Waterman (1982) in the famous book, *In Search of Excellence—Lessons from America’s Best-run Companies*. This investigation, designed to understand what some leading US organizations were doing to succeed in the face of the Japanese-led quality revolution. They provide many suggestions for success criteria behind business excellence concept for ‘excellent organisations’.

TQM versus Business Excellence

TQM as the fourth level of quality management (Van der Wiele et al., 1997) has been one of the major intuitive for improved productivity for almost over three decades ago. Although TQM is much older than that, the ‘total quality movement’ really picked up steam in the late 1970s and early 1980s when several large American corporations adopted the techniques that enabled the Japanese to be so successful. There is clear evidence that many organizations view TQM as the basis for excellence (Adebanjo, 2005). Business excellence is the goal of every modern organization and can be defined as the next step after TQM, for the success of enterprise on the competitive path (Vora, 2002; McAdam et al., 1998).The use of excellence models is popular for the same

reasons that TQM became unpopular. (Adebanjo, 2005).The term of Organizational Excellence or Business Excellence is generally associated with the European Fundamental for Quality Management (EFQM) excellence model. EFQM to provide a model that ideally represents the business excellence philosophy that can be applied in practice to all organizations irrespective of country, size, sector or stage along their journey to excellence (Dommartin, 2000).

Table 1 shows a review of the philosophy, principles, process , performance, and problem indicators of both reveals that business excellence was and still is fundamentally based on the quality management concept and practices. On the other hand, the business excellence model provides a clear road sign for organizations to follow towards excellence, we may also note that both TQM and business excellence stress primarily the importance of continuous improvement.

Table 1: TQM versus Business Excellence

Concepts(5 Ps)	Total Quality Management (TQM)	Business Excellence (EFQM Model)
Philosophy	To combine people and quality techniques to achieve continuous improvement in the quality of the product and hence in all aspects of the operation (Harriss, 1995).	To assist organization to participate in improvement activities leading ultimately to excellence results and driving force for sustainable excellence (EFQM 2010).
Principles	Customer focused, leadership, involvement people, process approaches, continual improvement, and supplier relationship.	Result orientation, Customer focus, leadership and constancy of purpose, management by process and facts, people development and involvement, continuous learning, innovation and improvement, partnership development, and public responsibility.
Process	SPC Statistical Process Control) P-D-S-A (Plan, Do, Study, Act)	RADAR (Results, Approach, Deployment, Assessment, and Review).
performance	Continuous improvement of the organization, Customer satisfaction, and employee development.	Customer results, people results, and society results. Key performance results.
Problem	TQM is conceptual and philosophical. Its strong Ideological and culture perspective cannot be easily developed in companies (Salengun & Fazel, 2000)	Business excellence needs to avoid evolving into a purely scoring, short-term oriented mechanism, losing the fundamentals of the quality focus.

The Dubai Quality Award (DQA)

Dubai Quality Award Secretariat adopted the excellence model based on European Foundation for Quality Management (EFQM) excellence model. The latter has been successfully applied in European private and public sector organizations since 1992. This model provides a holistic framework for organizational excellence. All nine criteria work as one complete system, such that any deficiency in one area will affect the score in other areas. Applicant of the DQA must demonstrate sustained continual improvement. They should focus on the improvement process and not only on winning the award trophy.

DQA is not a process of generating winners and losers; it is a process of recognizing role model organizations (DQA, 2010). It is also a process for providing organizations with a ‘roadmap to achieve excellence through the adoption of good practices and soundly-based approaches that are deployed systematically and are continuously measured and improved. That is because the journey for excellence and improvement activities will be much more valuable for organizations than winning a trophy.

From the award secretariats perspective, recipient of the award represent role model organizations in the sectors they operate in. Therefore, in order to maintain the credibility and high standing of the award, it is important for the organizations to demonstrate sustained improvement activities with the results reflecting favorable trends over three to five consecutive years.

Keeping in view local environment and organizational set up, three award categories were developed as Gold, Dubai Quality Award (DQA) and Dubai Quality Appreciation program (DQAP) category. Since then, this award is conferred to winner organizations from various organizational sectors including Construction, Finance, Health Care, Manufacturing, Professional, Real Estate, Service, Tourism and Trade. Dubai Quality Award is open to private, public and government authorities. Figure 1 presents overview of the DQA categories and its score.

Key Common Success Factors of BX

This section presents a review of the key common success factors or constructs of organizational excellence developed and utilized by researchers in previous studies. Because of limited resources, it is always not feasible for organizations to devote their efforts to concurrently address all the success factors. Key common success factors or contributing variables or critical factors or enablers, in this study can be viewed as those things that must go right in order to ensure the successful implementation of quality management concepts such as Business Excellence (BX). In this paper, we tried to investigate key common success factors for BX based on extant literature review. The investigation of the key common success factors for successful the practices of BX are presented in Table 2.

Various studies have been carried out for the identification of those factors of successful BX practices, from three different areas: contributions from quality gurus, formal evaluation BX models and empirical research. Out of the 38 different critical factors developed by the researchers, 11 were found to be the most popular critical factors for TQM, meanwhile 7 were found to be the most popular critical factors for BX. They are all critical factors for TQM and BX, ranked from the highest to the lowest level of popularity:

1. Top management commitment/support.
2. Product/service design.
3. Supplier quality management (some researchers used different terms such as vendor quality management; supplier chain management; supplier quality assurance; cooperative supplier relations; supplier management).
4. Process management (includes process knowledge, process control and improvement, process analysis and improvement, process focus).
5. Human resource management (includes employee relations, employee empowerment, employee involvement, employee participation, employee management, providing assurance to employees, human resource development, employment continuity, work force commitment).
6. Use of tool and technique.
7. Work environment and culture.
8. Continuous improvement.
9. Customer focus (customer driven processes, customer orientation, customer satisfaction/involvement).
10. Leadership.
11. Training and education.

From the review, it can be summarized that critical factors for successful TQM implementation can be classified into three groups of researchers: Group researchers I: 'soft' factors and 'hard' factors (Ahire et al. 1996; Thiagaragan et al. 2001; Lau & Idris, 2002; Tari & Sabater, 2004; Rahman & Bullock, 2005; Vouzas & Psychogios, 2007; Fotopoulos & Psomas, 2009); Group researchers II: TQM factors can be divided into strategic factors, tactical factors, and operational factors (Salaheldin, 2009); and Group researchers III comprises the TQM framework into organizing, systems and techniques, measurement and feedback, and culture and people (Chin et al. 2002).

The most important factors in the successful implementation of TQM are full management support and commitment and giving the correct training to the right people at the right time (McQuater et al. 1995; Bunney & Dale, 1997). Managers must understand the importance of their commitment in order to spread the use of these tools and techniques and to improve the TQM level & TQM results (Tari & Sabater, 2004). However, tools alone cannot provide results by themselves. They must be developed to reflect the companies' culture and management vision (Govers, 2001). Tools and techniques also can be used to reinforce recommendations made to managers (McQuater et al. 1995). The key to improvement is to focus on the improvement objectives and recommendations, and use tools and techniques as an aid for that purpose.

Table 2: Key Success Factors of Business Excellence Practices Developed and Utilized by Researchers

No .	Key Common Success Factors	Business Excellence Sustainability (BES)											freq	
		I	II	III	IV	V	VI	VII	VIII	IX	X	XI		
1	Top management commitment/support	+	+	+	+		+	+	+	+	+	+	+	11
2	People management	+		+	+	+		+	+	+	+		+	9
3	Middle management involvement	+	+	+	+	+		+	+		+	+		9
4	Training and education	+	+	+		+			+		+		+	7
5	Reward and recognition	+	+		+		+	+			+		+	7
6	Teamwork and cooperation		+	+	+		+	+	+		+	+	+	9
7	Quality policy and strategic planning	+		+	+		+		+		+		+	7
8	Communicating for quality relationship	+			+			+			+		+	5
9	Supplier management	+		+		+		+						4
10	Accredited quality management systems		+			+			+			+		4
11	Organizing for quality		+		+			+					+	4
12	Managing by process	+		+				+		+				4
13	Benchmarking	+				+					+			3
14	Self-assessment		+						+				+	3
15	Cost of quality		+									+		2
16	Quality control techniques	+		+	+			+			+	+		7
17	Measuring customer wants and satisfaction	+		+		+	+		+		+	+		7

The most important factors in the successful implementation of BX are full management support and commitment and giving the correct training to the right people at the right time (McQuater et al. 1995; Bunney & Dale, 1997). Managers must understand the importance of their commitment in order to spread the use of these tools

and techniques and to improve the TQM level and TQM results (Tari & Sabater, 2004). However, tools alone cannot provide results by themselves. They must be developed to reflect the companies' culture and management vision (Govers, 2001). Tools and techniques also can be used to reinforce recommendations made to managers (McQuater et al. 1995). The key to improvement is to focus on the improvement objectives and recommendations, and use tools and techniques as an aid for that purpose.

As can be seen from the review, the CSFs for BX sustainability are very similar to the CSFs for TQM implementation due to its close. The proposed critical factors for effective implementation of BX sustainability are summarized in Table 3.

Table 3: the proposed key factors for effective BES

Key factors (criteria)	Sub-factors (sub-criteria)
Management responsibility	Strategic quality planning/quality policy; the role of divisional top management; top management commitment/support; internal stakeholders' involvement (middle management involvement)
Resource management	Technology-and production related resources; financial-related resources; information and communication-related resources
People management	Employee involvement/empowerment; education; and training; teamwork and cooperation; work environment culture
Quality in design and process	Process management/operating procedures; role of quality department; product design; process analysis and improvement; applied quality tools and techniques
Measurement, analysis & feedback	Quality measurement, feedback and benchmarking; continuous improvement; performance measurement: external and internal; quality data and reporting; communication to improve quality; recognition and rewards; quality systems
Supplier management	Supplier quality management/supplier chain management; contact with supplier and professional associates
Customer focus	Customer involvement/satisfaction/orientation; customer driven processes

Discussions and Future Research

A review of the literature shows that, TQM is rather than a mere set of factors, a network of interdependent components, a management system consisting of critical factors, techniques and tools (Hellsten & Klefsjo, 2000).

These techniques and tools are vital to support and develop the quality improvement process (Bunney & Dale, 1997; Hellsten & Klefsjo, 2000; Curry & Kadasah, 2002; Tari, 2005). BX in general and its principles and criteria in particular are, alongside critical factors, another important component of TQM, which emphasizes their importance for the improvement of quality of business and results. Tari and Sabater (2004) suggested that firms must develop both the hard and the soft parts of TQM in order to succeed. With the passage of time and with changing customer's needs and expectations the word of 'quality' has been replaced by 'excellence'. As part of this quality progress, business or organizational excellence has become a recent goal of quality management movement (Fang Zhao, 2004). Therefore, business excellence practice can be named as the fifth level of quality management and next step after TQM, for the success of an organization (McAdam et al., 1998; Vora, 2002; TH-05, 2001) in this never-ending journey. However, there has been a lack of empirical and published research and any comprehensive studies reported in the literature focusing on and revealing factors affecting implementation of BX principles at management level of winner organizations.

Category: Research Paper

Shortcomings of methods of education used today

When we talk about why it is necessary to improve the system of higher education in Serbia, one of the main often stated reasons is the inefficiency of this system. The proof of this claim lies in the fact that the average duration of the study is almost two times longer than it should be (Ministry of Education, 2005). In addition, about two-thirds of the students give up entirely on the studies: each year, on average, 33,000 students are enrolled, and only 12,000 graduates (Ministry of Education, 2003).

The roots of inefficiency in the system of education are very complex, and there is a significant, although unexplored, the impact of various "external" factors: socioeconomic status of students, the general state of society (in economic and social terms), the problems carried over from previous education (mainly secondary) and so on. However, the inefficiency of higher education is partly determined also by the "internal" factors, related to the organization of studies, the regime of the studies, insufficient compliance of curriculums with the exam criteria, the number and volume of study subjects, the mutual compatibility of study subjects within the same study program, number of students and their readiness to follow the lessons, the number of teachers and their qualifications for teaching, and so on.

Part of these problems should have been solved by adequate implementation of the Law on Higher Education, which entered into force in September 2005, since it envisaged the change of the regime of studies, introduction of the ECTS credits, as well as the definition of the learning outcomes, which was supposed to change the very essence of the current system of education.

Misunderstanding of the essence of the educational process is reflected in the following:

- The teaching methods, within which the *ex cathedra* method is predominant;
- The focus is on the activity of teachers and not on the activity of students;
- The pressure both on teachers and on students is primarily to formally cover the study materials and not to "learn something";
- Often mismatch between what is taught in class and what is asked on the exam;
- Exams are performed in a limited number of ways – periodic tests, written or oral exams conducted through testing, resolving of assignments or oral / written reply to a combination of pre-designed questions - and therefore testing only a limited set of acquired competencies¹⁵

It is significant to note that, during their education, better part of the students will not acquire, among other things, required practical experience (i.e. how to apply the acquired knowledge in practice). There are only few cases in which the needs of the labor market and consultations with employers are considered during the creation of study programs. In addition, only few of the higher education institutions keep records of employment of its graduates.

Considerable uniformity in terms of teaching methods can also be detected. On most of the study programs, (i.e. in the vast majority of the classes), the only teaching method is *ex cathedra*. Too little room is left for discussion with students, and in the number of cases even for the students' questions related to clarifying the content of lectures. If the goal of higher education is merely for students to develop the ability for sitting and listening, with the eventual development of the ability to keep the notes, then the *ex cathedra* method is the right solution. However, it is impossible for students to develop various skills and abilities by using only one teaching method.

¹⁵ In accordance with the EU methodology, during 2005 and 2006 the Center for Education Policy AAEN carried out the regional Tuning project related to social and humanistic sciences, entitled "Regional alignment of curriculums - towards the European area of Higher Education."

Learning outcomes are the essential element of the curriculum, but their formulation in practice is often reduced to mere satisfaction of forms prescribed by the Bologna Process or by the Law on Higher Education (Article 28). However, learning outcomes harbor the potential for a fundamental change in the educational process. Such potential of the learning outcomes stems primarily from a new philosophy of education, which involves changing the focus of education from the process of lecturing / classes to the learning process.

If we agree with the fact that the student and the learning process (rather than the process of teaching) are in the focus of education and curriculum development, the first step in the development of a new kind of curriculum is a departure from the final outcome, i.e. from defining the competencies that a student should possess upon completion of the study program. And here we encounter a problem related to the very notion of competence. The term competencies usually include knowledge, skills and abilities that a person acquires or develops, and which are enabling that person to do something. Educational system in which the focus is on the student *inter alia* aims to provide that students are competent at the end of the educational process, i.e. that students will have certain knowledge, skills and abilities. Competencies in this sense represent a dynamic combination of knowledge and its application, attitudes and responsibilities that reflect the results of educational program.

There are different divisions of competencies. Below are divisions emerged within the Tuning project, with this division primarily dividing the competencies on general (or generic) and professional:

- Generic competencies should be obtained by ones who finish a certain level of education regardless of science or industry you are dealing with (such as foreign language skills, knowledge application in practice, computer literacy)
- Subject specific competencies are identified for each subject or field of study and they are more specific.

The Tuning project defines three groups of generic competencies - instrumental, interpersonal and systemic. Instrumental competences, among others, include the ability to analyze and synthesize¹⁶.

If, for example, the transitional nature of society and recent history of the region are taken into account, the competencies such as social responsibility and critical thinking

¹⁶ Julia Gonzales, Robert Wagenaar (editors), Tuning Educational Structures in Europe II: Universities' Contribution to the Bologna Process, University of Deusto, University of Groningen, 2005.

and reading (developed through the debate as a teaching method) can also be considered as important.

A particular challenge in this regard is the change in attitude and mindset. This change is often considered as “mission impossible”, because the existing attitudes and mindsets are being developed over the long period of time, during which the system of higher education did not change in response to changes in the environment, or did change in a way that it was more isolated from the same environment. What is important to emphasize here is that a change in mindset and approach to higher education as such (as by the academic community and by the students, employers and society as a whole) can come only through broader change in the understanding of the role of education in general. In this context, it is a debate that allows the change in thinking and attitude towards all processes in the society – educational, political, social, economic and other.

Challenges facing education today

Information age has reshaped our society, changed the way we acquire information and changed the labour market in the span of a decade. The workplaces we are preparing our students to fill come with a broadband connection, and data has become the realm of hard drives, not humans. Workers are no longer asked to know everything, but to know how to find out quickly. These changes came about through couple of trends brought by the information age, we will examine a few.

Information overload. It is said that more information can be found on the pages of the NY Times than what was available to an average 19th century person during their whole lifetime. The amount of data available on the web is increasing exponentially. As with every information explosion, problems of managing all the new data arise. This means two things:

1. Workers are more productive if they know how to find good information quickly, then if you specialize them they will find out all the information on their own.
2. Once a worker is delegated to find out certain information, it is lucrative for him/her to know how to filter, organize and present that information to others.

The job of University professors is to prepare their students to be as productive and valuable as possible, hence the need to include education in developing these skills.

Persuasion science has advanced to the point where we are bombarded with messages trying to influence us into doing something. Marketing agencies try to sell us their products, paid experts try to convince us into their points of view, trained negotiators try to bully us into concessions at the negotiating table. This trend calls for several things:

1. Critical thinking is beneficial in the workplace. Critical thinkers will represent the company's interests better against competing interests.
2. Persuasion methods are beneficial once the tables turn, as the worker is able to acquire more concessions than the others can.
3. In every day life, students versed in persuasion skills will be able to see through companies and people trying to influence them, and to preserve their own interests better.

Globalization has brought companies and workers on different continents under the influence of the same forces. The sub-prime mortgage loans bubble in America, and the global economic crisis that followed it in 2008 are proof of this. This trend brings into light more qualities as beneficial to a today's worker:

1. Knowledge of the world problems, which provides opportunity to foresee those problems spreading locally, and then act accordingly, and
2. Communicating with members of drastically different cultures in a super-cultural context, which enables workers to understand and be understood when cooperating with companies from other cultural frameworks.

New media is quickly replacing the old as the provider of the information. Google, blogs, websites and wikis become the go-to places where people find information. However, most of this new media is agenda driven, not accountable. The trend has become so prevalent that some old media, such as television channels and some newspapers, are abandoning the mantra of objectivity and fact checking, for agenda pushing. Agenda driven media can continue to exist as long as there is no objective confrontation of conflicting agendas to the viewer. As that never happens, it is left to the viewer to cut through the agenda driven propaganda into the core of the issue, weather it is a citizen trying to vote, or an investor trying to find a suitable investment. [1]

How does debating as a teaching method rise to the challenges of today's education?

Participation in academic debating creates numerous benefits for the students. Some of them we will outline here, as they respond to the exact requirements posed by the previous chapter.

Data analysis is an essential debating tool. Debaters must learn how to find the relevant information on the topic when they're researching possible motions for a tournament, analyze and save or remember their results. After debating for some time, debaters collect a lot of information, but they will always encounter new topics, where they will have to quickly utilize the data they know in a new problem.

Presentation of knowledge is required from debaters in a limited time frame. Debaters learn how to present vast amounts of knowledge briefly, effectively and to the point.

Critical thinking is forced onto debaters, and debaters quickly adopt it. Sides are randomly assigned in a debate, therefore debaters must know how to argue, analyze and assess opposing sides of any argument.

Knowledge of the world problems is necessary in the international debating scene, as the topics must be drawn from a pool of issues which are equally important to all the countries which are participating.

Finding the right information is important because facts count in debate. Most global debates have competing schools of thought, often with competing information. Debaters need to know how to weigh authorities, how to compare sources and spot when information is biased.

Intercultural communication is developed and trained in debate, as judges come from different cultural backgrounds, as well as the opposition teams. That means debaters train to be understood, as well as to understand.

Persuasion is a peripheral skill for debaters. In theory debates should be judged by completely objective judges. As this cannot be the case, advance debating classes cover persuasion methods as a manner of gaining that last bit of competitive edge. [1]

Outcomes of teaching through debating as a teaching method in universities

International research

After properly defining the outcomes of learning, it is necessary to approach the development of methods of teaching and grading that will enable the fulfillment of those outcomes. Achieving well defined outcomes of learning involves students understanding the teaching as a process in which they question their understanding of concepts and processes and/or create new concepts and understand connections between them. To make this possible, it is necessary for the lecturer's goal to be more than going over matter, but to accomplish "interactive" teaching, through debating to the topic which is planned to be taught by the curriculum. This chapter highlights the results of research that confirms the importance of introducing debate as a teaching method.

Heads of Urban Debating League in Minnesota found that students who have practiced debate had 36% better results in reading tests than before they had debate training, in addition to showing faster progress than the control group. All the debaters showed increased interest in the curriculum. 87 % of debaters analyzed information better than the control group. Positive influence of debate training on academic performance was confirmed by Barfield (1989) who found significant increases in cumulative GPAs with students who had debate training. Debaters will also be favoured in certain professions, as proved for jobs in civil service by Pollock (1982), in the legal field by Church (1975), and educational administrators by Schroeder and Schroeder (1995). Colbert and Biggers conclude that debate experience is highly valued in the business world and they find unequivocally that debate training will help students get a job.

Debate training requires application of knowledge from a wide array of social sciences, and this is why Robinson (1956) describes debate as "introduction into social sciences". In addition to this, Semlak and Shields (1997) determined that debaters are significantly better at analysis, delivery and organization of content.

One of the best researched benefits correlated to debate training is critical thinking. Students with debate training are significantly ahead of control group in regards to critical thinking scores (Brembeck, 1949). Colbert and Barfield confirm these conclusions in 1987. These studies were disputed on several grounds, so Allan et al. started a study to remedy the shortcomings. In 1995 they proved that students with debate participation were ahead of the group who listened to lectures on argumentation. A meta-analysis of studies in 1999 proved further the link between communication skills and critical thinking.

People with good communication skills are rated more highly by their peers, as was proved by Pollock (1982). Pollock also makes the connection of forensic activities with

developing communication skills, as do Colbert and Biggers (1985) who conclude that debate training improves communication skills, as well as the skill of public speech. High verbal skills are correlated with decrease in physical aggression (Boone and Montare 1976.).

Once someone feels capable of responding verbally they feel less inclined to resort to physical force. On top of that debaters learn to respect the opposite side, because of protocol and because they might be in their spot in the next tournament. Debate training increases argumentativeness without increasing verbal aggression (Colbert, 1993, 1994).

Best learning happens when students are asked to organize information and think of alternatives (Newmann and Wehlage), which is exactly what debating is about. In order to learn, students need to be immersed into an interactive experience that must be rich and real, there must be a personally relevant challenge, and there must be intense analysis in order to present the student with other options and approaches (Caine and Caine, 1991). Recommendations of Caine and Caine correlate to debate perfectly: interactive experience is provided through competition with fellow students, even if the grading system doesn't provide a challenge to the student, personal motivation to compete with peers does, and judge's feedback provides exactly the kind of analysis Caine and Caine call for.

In summation we can conclude that debating as a teaching method is supported by scholars who have researched effects of debating training on students, and the scholars who have researched the process of teaching recommend actions that debating fulfills.
[2]

Research at the Faculty of Organizational Sciences

Students of the third year of the Faculty of organizational sciences, majoring Informational Technologies, can choose debating as an activity at their course of Legal Basis for Informational systems. They are introduced to debating for the first time ever in their schooling. They undergo a week of training by the debaters in the faculty's debate club. The topic is given in advance, and they are prepared for that particular topic.

The goal of the research was to determine whether this method of teaching was successful. In order to measure successfulness certain criteria was set, some of which were how much knowledge of facts in regards to the topic the students attained, how do students cope with opposing opinions, how do they rate their knowledge of the topic, in

which degree they felt interested in the topic, how skillful were they in arguing their positions, and whether they supported this method of teaching.

Legal Basis for informational Systems is taken by some 180 students and they were the sample of the research. These were divided into three groups: **participants** in the debate, **audience** of the debate, and those who **did not attend** the debate. The research set out to determine differences in the quality of the way the topic in question was conveyed to students, through the criteria mentioned above.

Students were distributed a 12 question anonymous questionnaire on the classes that followed the debate. 120 students attended those classes, 60% of which did not attend, 36% were the audience and 4% were the participants in the debate. Debate in question was nationalization of the national telecommunication company.

Students supported debate as a teaching method. 80% of those who participated stated they gained something through debating, of which 60% could explain what it was they thought they gained. The remaining 20% did not have an attitude towards this question. Among the audience only 8% felt they've lost something, and among those were the ones who claimed they lost their time. No students felt disadvantaged because the topic wasn't covered in the traditional teaching method, and 68% claimed they gained something in debate. Those who could explain what they gained mostly claimed it was information on the topic. Majority of those who did not attend did not have a stance, but slightly more (6%) of them said they lamented the fact they did not attend the debate.

Students were asked to say whether they are for or against the sale of the company which was the topic of the debate, and then asked to explain why. Later in the text, the same mechanism was used again with a different issue that was discussed in the debate. Participants did significantly better than the other two groups, on average some 2 points out of 12 ahead of the other groups. The audience and those who did not attend were on par, differentiating only by a couple of tenths of a point per question. This signaled the need to introduce ways of including the audience into a more active role in the debates.

Even though the audience was no better than those who did not attend at explaining their stances, it did not stop them from rating their competence in the issue 0.7 points out of 12 higher on average than those who did not attend. Participants in the debate were even more self confident, on average rating themselves as a whole 4 points out of 12 more competent in the issue than the audience. This signified that debating as a

method seemed understandable to students, even though, as we concluded previously they did not engage enough to actually advance their knowledge as audience.

We've discussed that one of proven benefits of debating is learning how to deal with opposing opinions. This research suggests that this trait needs to be nurtured over time, as the participants did not do better than the other group when it comes to displaying aggression towards people with different attitudes. Key group we identified as the problematic in this research were those students who, when asked what they think of those with different stances on the issue, and why might they think differently, replied in an insulting, derogatory manner, and attributed malicious attributes to the people who have opposing stances, not being able to imagine that someone might have a good reason to think differently than them. This group was 15% of those who did not attend, 9% of the audience, and 20% of the participants. The group was reshaped the most over the three categories of students was the group that said they had no interest in people who thought differently, non-existent in the participants, but larger in the audience than those who did not attend. It seems that, once confronted with people who advocate a view opposed to theirs large portion of those who otherwise would not reply to this question skipped into stating "they don't care about those people category", however this cannot be proven by this research. What we can conclude is that there is no immediate benefit of debating when it comes to confronting people who think opposite to one self.

Future goals

If there is one thing people who are involved in academic debate love, whether they're judges, debaters, or professors, it's to talk about how transformative experience debate is. Sharing enthusiasm among friends is not enough, and we must seek scientific proof in order to gain backing to introduce institutionalize debate in universities. Research on the Faculty of Organizational Sciences has shown that there are some benefits from introducing even a week of debate training into students curriculum. Further research needs to prove that constant debate training yields even greater benefits and mandates introduction of debate, either across the curriculum, or as an elective.

No research to date suggests what would be the optimal time frame for developing debating skills in an academic setting. It is suggested that debating should be an overarching method for the entire curriculum, others suggest electives. These two should be rivaled. Comparisons with other methods of teaching should be made. Long term development of students who start debating in earlier years of studies should be

researched in comparison to students of same faculties who don't pick up debate. There is no scientific evidence on how well debaters do once they begin their professional carriers, except for anecdotal evidence. The more information we obtain on these issues, the more compelling the case for introduction of debate into universities becomes.

Category: Research paper

Introduction

Production rate is a well-known construct among today's manufacturing companies. The construct is also regarded as something positive among employees since it brings forth an optimized and evened up workflow that does not result in an unreasonable individual pressure. It all started at Toyota as a part of the Toyota Production System to produce and deliver exactly what the customers want at the time they want it by avoiding over production and minimizing repositories [0].

In service and development processes this way of thinking is more unusual even though it becomes more and more common in development processes to work with visual plans instead of using software support such as Microsoft project. In the product development concept Lean Product Development for example one of the core principles deals with application of Visual Planning in the project planning [0, 0, 0, 0]. These processes though include process flows that are not as visible as is the case in production processes when the flow composes of a physical product that processes through a manufacturing process. On the other hand application in service processes is not that different than manufacturing processes regarding classification of activities even though it is about realizing activities in document or answering on telephone calls or E-mail. The difficulty with development processes is rather the fact that this kind of process normally includes creativity and innovation activities which are really hard to predict regarding size and time consumption.

The fundamental attitude in this article is therefore that a rated visual plan is useful in development projects even though it is harder to find the optimal balance between freedom and structure in complex and creative development projects. The focus in this article is the author's research program at the Royal Institute of Technology regarding

product development. Since a research program is about developing new research results it turns out to be extremely similar to a development project regarding structure, organization and challenges. The purpose with the article is therefor to apply the advocated method in the authors' research field product development and especially in Lean Product Development, namely Visual Planning (VP). Visual planning is initially an important part of Scrum, a popular approach in development projects which in turn is built up on Lean and the Agile manifesto [0]. Visual planning is applied on the research projects to try out the method and exemplify the application in a development environment. In this article also self-experienced advantages and disadvantages with the method are presented.

The article is structured as follows. First the used method is described follow by fundamental theories about Scrum. The presentation of the actual Scrum application on the research program is divided into three sessions: description of the actual state of the Scrum application, presentation of implemented improvements of the application and description of planned future improvements. Finally an experience discussion is performed including a summary of positive and negative experiences as well as challenges with applying the method. The paper then end with conclusions.

Method

Based on the Scrum theories an adjusted application of the method have been developed and applied on the authors' research program. Also to simplify the realization of the method firstly Scrum is applied in a visual way inspired also by visual planning and secondly this application includes reservation of activities to individuals. The research is conducted in accordance to the action research method since the researchers themselves are actually performing the application of the method and supremely parts of the process [0, **Error! Reference source not found.**].

The visualization of research projects by using Scrum thinking with a visual planning perspective has been realized as an action research project since one year. During this time the policies around the method have became more and clearly structured. Also there is an ongoing work with continuous improvement in the proeject and the methods of the application is updated and improved in connection to every renewal of another four weeks sprint.

Theories about Scrum

Scrum is an incremental project management framework frequently occurring within agile software development. Initially it is used to reveal new ways of developing software with focus on: individual and interactions, working software customer collaboration and responding to change. The physical solutions of processes and tools, comprehensive documentation, contract negotiation and the following of a plan are subordinated [0].

According to Sebestyén [0] visualization is important when working with production, product development as well as with any other part of the organization. Looking away from the traditional application of visual planning (VP) in production, the realization in product development organizations is rather commonly advocated by [0, 0, 0, 0] and then performed from a perspective to front pull results by ordering results to move on the project. Instead of working with requirement specifications, product- and effect goals are applied to make the organization knowledge oriented and to create a common apprehension of what to reach and how to reach it [0].

This could be straightforward when performing one project at a time but in service or development organizations multi project management is common. Traditional multi project management is about operating several parallel projects that affect each other [0]. Such project characterizes of continuity and links between projects since it endeavors for reuse between projects due to the concept's descent from Japanese automotive industry [0].

In pushing production system the check points related to gates and milestones are not commonly restrictive and projects often continue without waiting for a gate decision. In Lean Product Development with the support of a visual pulse board promotes a pulling production system. On the pulse board it can be seen which results are missing and information about actual problems that need to be solved before the project can process. Thus the pulse board also is about minimizing waiting time. Having internal stocks increases the lead time and bring forth costs for reproduction and accumulation of capital but these semi active projects also thieves energy from the organization [0]. When organizations become over stressed cycle time is multiplied, the focus of personnel is disrupted, lead time increases and quality of the products decrease which brings them into a vicious circle [0]. Driving two projects in parallel fosters that happening. By driving two projects serial instead would result in both of them reaching the market faster but also a bigger flexibility since the decision of the final content of the second project is postponed [0].

Description of the actual state of the Scrum application

The actual realization of visualizing research projects is performed in 4 week session sprints inspired by the Scrum method described in [0]. The difference compared with Scrum is the dedication of activities to specific individuals already during the sprint planning event. This is performed twofold purpose, to secure the best knowledge realizing an activity and to be able to distribute learning tasks to individuals within activities. Planning and visualization of the implementation of planned activities is actualized by a pulse board proposed by [0] as can be seen in Figure 28.

The pulse board is physically located on one of the walls in the corridor of the department. This placement is chosen to make it visible both for the participating Ph.D. students and its supervisors but also for other colleagues at the department. In Figure 28 the realization of the pulse board can be seen. The board summarizes all the participating Ph.D. students' ongoing activities for the moment. Each research project has its own row, and there is one row for Ph.D. courses seminars etc. and one for other institutional administrative activities such as master thesis supervision, teaching etc.

Figure 28 – Visualizing board of research projects

As can be seen in Figure 28, the pulse board at first glance looks rather complex. Basically it is built of different rows in yellow and green, one for each project. The white column to the left provides information about each project regarding: name of the project, project participants, the project manager responsibility, project deadline and target publication forum.

The planning is conducted in four week sessions and each week includes one pair of a red and a blue square on top of the wall. These squares refer to planned activities (red) of the week and finished activities (blue). Finally the red column to the right is used to collect upcoming ideas and unscheduled activities that are realized need to be performed later.

Individual coloured post-it notes are used for each Ph.D. student to facilitate distinction of one's individual activities from one others. Information about estimated time of how many hours the realization of each activity would take is also provided on the post-its. When an activity is done the actual required time for that activity is summarized on that activity's post-it note. There are also a code system to indicate activities that result in physical absence from the office, delayed activities or activities that are difficult to estimate their time consumption. Such activities are coloured marked with fluorescent pen frames to indicate prioritization of delayed activities or the "scope creeper" effect of an literature search activity that might result in several articles to read. Internal deadlines during a sprint are marked using large yellow post-IT notes. On these notes the deadline and its planned deliverable is stated.

A Scrum sprint

The planning of a scrum sprint is conducted in a group meeting with all participating PhD students but not necessarily the supervisor in front of the board every 4th week. All meetings and activities that are known throughout the forthcoming timeperiod is planned first. After that external and internal deadlines are applied and activities are prioritized in according to them. If it is unclear how to prioritize the supervisor, comparable with an R&D manager, is involved to discuss possible solutions and potential outcomes. During this process also each activity's required time of human effort is estimated. The target is not to schedule more than 32 hours each week since unplanned activities such as mail management and unforeseen events always appear. In joint projects between several of the visual planning participants, activities can be moved between the participants to even out work efforts.

Practically, the work day for the participants start with a morning meeting in front of the pulse board. During this meeting the activities of the day is defined. The activities corresponding post-it notes are moved to the white column which symbolize that these activities should be performed at that current day. Gradually activities are finished and then moved back to the blue column of the current week. As finishing an activity the real operating time is registered on the post-it note beside the planned operating time.

Every Monday a following up activity of the previous week is realized in front of the pulse board. This meeting composes the reporting to the supercisor about how the work and general and each project in particullar is performing. To this meeting each participant prepares a sumary of its individual outcome of work load compared to plan of the previous week. This information is also summarized in a diagram, see Figure 29.

Figure 29 – Follow up of planned time for activities versus outcome and unfinished activities

Concretely the meeting consist of a short summary for the supervisor of how each project is going, what was done in each project and what is left compared to plan. Also, possible faced problems, the outcome of time estimations of activities and what should be done the actual week are disputed. If there is a need to move activites, for instance if there is an unfinished activity, replanning of the forthcoming weeks is performed during the meeting. The supervisor provides its opinion about prioritization of project and/or activities and can also questioning the amount of scheduled time for the participants

during a week or involvement in a specific project. During this following up meeting potential future process improvements of the pulse board can be discussed even though this discussion preferably are performed in conjunction with the planning of a new sprint.

Long-term goals

Research programs as well as product development projects are long-term activities with normal average project times of some years. It is common that a product development project last at least two years and a research program is normally defined in between three and five years. Thus the pulse board with short Scrum sprints have to be supported by long-term goals. Such a solution for one of the participating Ph.D. students in this research project can be seen in Figure 30. Here are the knowledge goals for the student's research project categorized and specified depending on to which extent the Ph.D. student is expected to control each subject. The long term goal composes a great support for the Ph.D. student as well as for the supervisor when it come to prioritizing of the participation in projects.

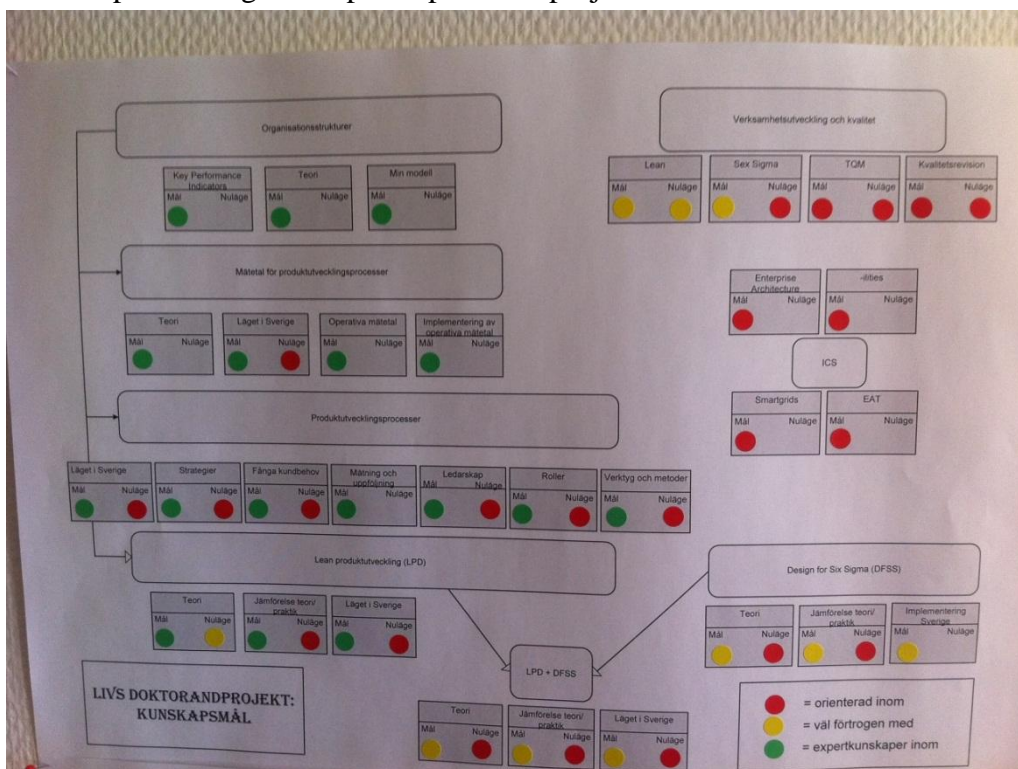

Figure 30 – Long-term goals of a research project

Implemented improvements to the Scrum application

Since the project with scrum pulse board started a lot of improvements of the method have been realized. These are of course included in the description of the actual state

above but to illustrate the development of the method the most important improvements are presented below.

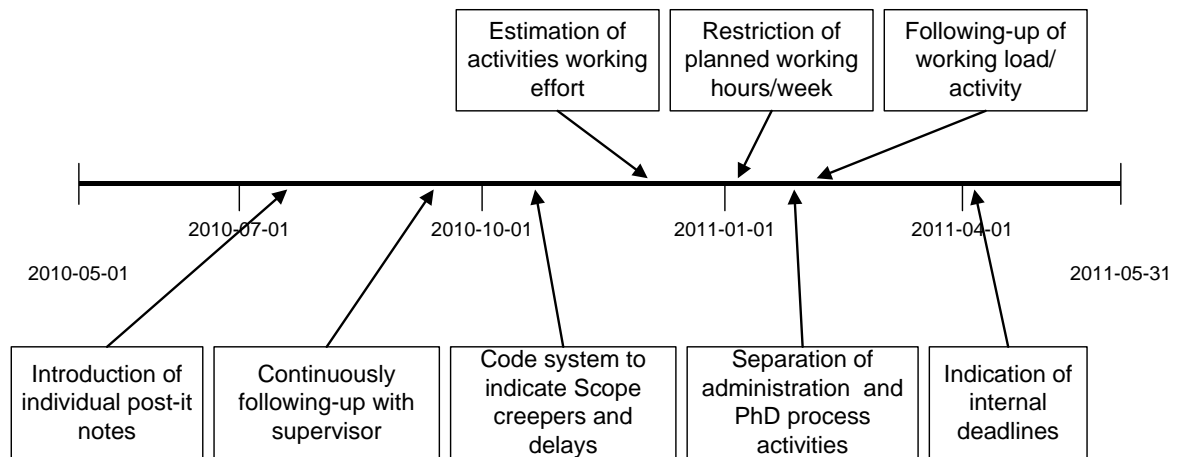

Figure 31 – Process of carried out improvement of the scrum pulse board

As can be seen in Figure 31 two different kinds of improvement have been performed. The activities compiled above the time-line deals with measurement and follow-up of the outcome whilst the activities below the line treat physical adjustment of the realization of the method.

A natural development of the work with continuous improvement is initiating physical adjustments which probably will be a continuous work as long as the method is applied. This improvement primarily deal with technical solution as a new coding system, for activities, dadlines etc. On the other hand it do also include the improvement to initiate structured and regular follow-up activities together with the supervisor in front of the visual board.

The other part of improvements, dealing with measurement and follow-up is an essential experienced after some sprints. The activity of initiating competely new parts to the method is only done once. However, the concrete realization of it still needs further development and one experience so far is that the optimal amount of measurment and follow-up is extremely individual which need procedures to control.

Experience Discussion

There are several advantages with the Scrum board. To be aware of which activities that consumes working hours and which projects that are on track in which process step is learnable. Still several challenges remain. To secure the focus on the long-term goals

and the overall process whether it is development or research it is important to restrict the amount of parallel project. Even though there is no physical adjustment times in development or research projects the human brain requires extra energy for adjustments. Also, since it always appear new urgent fires that need to be solved it is necessary to have energy left to convert for solving these problems.

When it comes to finishing projects, project management literature propose the importance of kick-out as on the same relevance as kicking of in the beginning of a project. However, this is much more difficult to realize when participats already are in to new projects when it is time to refine the pulse board with another print and take away the finished activity. To be able to perform the kick-off of finished projects but also th reduce waste within the visual planning method it is necessary to use the long term goals and to reserve time for the next planning session within the actual sprint.

Early in the specific application of a visual Scrum board as described in this article the need for some measurement follow-up appeared. As described above actual required time is measured and compared with working hours and planned consumption. This acting is based on participants estimating their expected human effort for each activity, which at least in the beginning is really difficult. Of course it becomes easier after some applications but there is a tight balance in this acting. How to be honest to yourself without planning to short time or too much time for performing an activity? Depending on personal properties you have easier to fall in one or the other trench. Thus it is important to evaluate the deviation relative plan when following up these measurements. It is very easy to foster an overloaded schedule by always encourage a fast acting which often bring about less quality on the outcome.

Thus, measurement and follow-up on the visual scrum method described in this article is necessary but it is not obvious how to conduct that in a strengthening way that stimulate both effective and lazy personalities rather than burn-out the participants. More concrete the pro's and con's with the method is summarized in Table 13 below.

Applying Scrum visualized in a research environment	
Positive effects	Negative effects
Helps structuring the working days.	Stressing with a lot of remaining activities at the end of the week.
Visualize "time thieves".	Fully planned weeks foster cheat-working without defining activities on the pulse board
Creates awareness of timescales in the process and its activities.	Easy to over load the weeks with activities.
Provides immediate feedback by clarifying	Fires during a sprint are killed without re-

what the working time is used to.	planning the sprint and eliminating some activities.
Enables rating between projects.	Difficult to concretize activities and make them all on the same detail level.
Visualize work distribution between projects.	Over-loaded plans foster a stressed realization of activities.
Smoothing of time between participants in and between projects	
Foster increased structure since reflection of internal process between activities is necessary.	

Table 13 – Experiences of applying a Scrum inspired visual board in a research environment

Individual experiences from a supervisor perspective

This approach is appreciated from a sponsor perspective. After the implementation of visual pulse board the quality of discussions at the weekly follow-up meetings have solidly increased compared to before when they were realized in an office. It is easy to see when the participants have a problem and reserve a separate meeting discussing that problem. The disadvantage is that it is easy for the participants to schedule too much activities, but they learn through the continuous process improvements. It is also very obvious when one participant is faster than the others. It is tempting to praise such a behavior, but thoroughness, time to think, originality and quality can not be forgotten as well as the health of the Ph.D. students. As a sponsor you need to be aware of who is doing more than they should, and that someone does not feel bad because others seem more productive. One advantage is that it is easy to keep track of the participants, and to discuss the relevance of different projects they are spending time on.

Conclusions

It is obvious that research processes and product development processes are rather similar. Both businesses differ from production processes with a standardized and well-tried product portfolio since part of these businesses' "production processes" is about developing new and creative solutions. Creativity and innovation activities are subjective and many times dependent on the personal feeling and however more difficult to rate. Nevertheless the method of visual scrum sprints turns out to be useful in the described environment within this article. There are though some necessary success factors that has to be considered:

- The method requires training.

- It causes big positive effects after a while, thus the investments will pay off after some time but requires patience.
- Requires honest and open-mindedness to both oneself and the project team. On the other hand the method contributes to creation of such a project climate.
- A strong, committed and accessible sponsor is necessary.
- Individual adaptation of the method is required.

Key words: Innovation, EFQM Excellence Model, Human Resources Practice

Introduction

Total Quality Management (TQM) and particularly the adoption of the EFQM Excellence Model have turned into a competitive advantage for organisations in changing and complex environments. Those organisations have succeeded because they are flexible and efficient at the same time. As present environments can be defined as turbulent (they are complex, dynamic and uncertain) firms must be adaptable and able to give quick responses (Andersen, 2000 and 2004; Bueno and Ordoñez, 2004; Brews and Hunt, 1999; Hendry, 2000; Mintzberg and Lampel, 1999; Rico, 2000). The EFQM Excellence Model encourages firms to be excellent and flexible, promoting the use of a participative management, oriented to customer service and excellence. This work tries to analyse the use of some Human Resources Practices (HRP) as empowerment,

autonomy and participation that are encouraged by the EFQM Excellence Model, and if the use of those practices has any influence on innovation.

The capacity of generating innovations becomes the basis for competitiveness, and a key factor for surviving in actual environment (Baumol 2004; Danneels 2002). And HRP can help to promote the innovation process in the firm. Literature shows different innovation models that reveal the need of specific HRP to develop abilities, knowledge and behaviour oriented to innovation (Tang 1998). Specific HRP as participation, rewarding systems or performance assessment can affect employees' creativity, giving as a result an increase of product and process innovation and, consequently, an improvement of organisational results (Beugelsdijk, 2008). And, as we have pointed out, the application of the EFQM Excellence Model facilitates the adoption of those HRP.

Taking all these considerations as an starting point, the objective of our work is to analyse if HRP encouraged by the EFQM Excellence Model have an influence on the innovation process. With this objective in mind, the work has been structured in different sections: firstly, we have developed the literature review related with the different concepts analysed, namely, EFQM Model, HRP and innovation. We propose two hypotheses and a research question, and explain the methodology used. After, we describe the results of the empirical analysis and present some conclusions, limitations and future research lines.

Theoretical Framework

TQM, the use of EFQM excellence model and human resource practices (KRP)

TQM has represented a real innovation in management practices in the two last decades in Europe, and Spanish organisations are not an exception. The application of TQM, or the use of the EFQM Excellence Model, was initially considered as “fashionable”; but this approach has turned strategic from a managerial point of view, and has been accepted and recognised as a useful and effective management practice by European firms.

An effective implementation of a quality management system requires that every employee (from top managers to the lower levels of the organisation) develops his commitment to the organisation as a fundamental part of his work (Soltani, 2005). As a consequence, it's absolutely necessary to develop a quality culture in the firm (Dale *et*

al., 1997). Although TQM and the use of the EFQM model have been recognised as useful strategic frameworks with positive effects on performance (Sousa and Voss, 2002), other authors try to show opposite evidence (Hill and Wilkinson, 1995; Wilkinson *et al.*, 1998; Yong and Wilkinson, 1999). Particularly, they state that TQM has been understood as mainly focused on the production process and on achieving conformity and zero defects, what implies a more bureaucratic approach, more concentrated on following some internal procedures than developing high quality goods and services (Seddon, 2004).

TQM is based on customer orientation, continuous improvement and people development (Dean and Bowen, 1994; Perdomo et al, 2009). And, consequently, the adoption of a TQM approach has several implications for human resources in the firm. But, literature on TQM approaches this phenomenon with a very restrictive perspective. Quality literature argues that HRP have relevant implications for reinforcing the implementation of a TQM approach. Prescriptive literature on TQM considers commitment as a relevant topic, but doesn't say many things about how to achieve commitment or which problems organisations may have when trying to increase the degree of commitment of the employees (CIP, 1996; Snape et al., 1995; Wilkinson et al., 1998). The most frequent argument of TQM literature is that commitment and involvement of the employees (from bottom-line workers to supervisors and managers) must be increased through the leadership style, training processes and recognition (Oakland, 1993). In the framework of the TQM approach, excellence models (as the EFQM or the Malcolm Baldrige) show in their criteria the relevance of people assessment, rewarding and participation to promote learning, teamwork and motivation (Sousa and Voss, 2002; Perdomo et al, 2009). Consequently, it would be very interesting to analyse to which extent participation, improvement suggestions, and rewarding and recognition systems have an influence on organisational results.

Excellence models are considered strategic tools in the framework of a TQM approach. Excellence models are normally associated to quality awards and also can be used as important tools for managers. Specifically, the EFQM Excellence Model is used in the framework of the European Excellence Award. This model proposes a framework that is not prescriptive and it is based on nine criteria that can be employed to assess the progress of an organisation to Excellence. Criteria are grouped into two different categories: Enablers and Results. The former analyse how the organisation is managed; the latter are focused on the consequences of the managerial actions. In the *enablers* criteria we can found the "People" criterion, which is referred to human resource

policies coherent with a TQM approach; these policies can drive an improvement on organisational results (EFQM, 2010).

In particular, the “People” criterion makes reference, among other topics: to the need of the firm to assess and reward its employees in order to facilitate the alignment of individual goals with organisational objectives (and, as a consequence, maintaining the level of involvement of employees), using interactive tools to obtain information from people; to put the emphasis on knowledge creation and development, focusing on the need of achieving abilities and competence that help people to achieve the strategic objectives of the organisation; to the need of people to be committed, involved and empowered, creating a culture that encourages talent, creativity and innovation to promote changes in the different parts of the organisation; to encouraging people to share information, and to create active communication flows, in both bottom-up and top-down directions (EFQM, 2010: 15).

Advancing one step further and from a contingent perspective, we want to analyse the relationship between HRP (autonomy, participation and rewarding) in the framework of the EFQM Excellence Model and product innovation. In this respect, Beugelsdijk (2008) showed the existence of a positive relationship between these practices and results in terms of product innovation. So, in the following section we will analyse the concept of innovation and its relationship with HRP.

Human Resources Practices (HRP) and innovation

Van de Ven (1986) defines innovation as a process that includes the generation, development and implementation of new ideas and behaviour. Literature distinguishes among different types of innovation. Product innovation means important changes in products or in service capabilities. It includes both totally new goods and services and important improvements of the existing products. Process innovation implies significant changes in the production methods and delivery systems (Oslo, 2005). We focus on both types of innovation, process and product.

Strategic management literature has thought explicitly about the relationship between human resource management and innovation and the positive effect that a particular way of managing human resources can have on innovation (Laursen, 2002; Laursen and Foss 2003; Terrien and Léonard de 2003; Lau and NGO de 2004; Pini and Santangelo 2005). Innovation has been related to the learning processes that can take place in organizations (Shipton 2005, 2006 a & b). Some HRP can help to the development of

skills and knowledge that fosters innovation (Perdomo et al, 2009; Tang, 1998). Beugelsdijk (2008) also analysed the relationship between some HRP (training, job autonomy, work timetable flexibility and reward systems) and product innovation, obtaining as a result a positive relationship among training, autonomy and rewards systems on innovation. Other works, as Ortín and Santamaría (2009) have concentrated on analysing HRP in the R&D departments. Data showed that certain practices as recruiting or the organization of the work must be adapted to the characteristics of the people working in that department. Weia et al. (2011) have analysed the relationship between human resource management system and product innovation, obtaining a positive relationship that increases with an organizational culture oriented to development.

Taking all those arguments into account, our objective is to analyse the way in which the EFQM Excellence Model facilitates specific HRP (autonomy, participation and reward systems oriented to participation) that have a positive relationship to process and product innovation.

According to this objective, and to the arguments developed in the theoretical framework of this paper, we formulate the following hypothesis:

***H.1.-** HHRR practices developed in the framework of the EFQM Excellence Model (autonomy, participation and reward systems) are positively related to innovation results (product)*

***H.2.-** HHRR practices developed in the framework of the EFQM Excellence Model (autonomy, participation and reward systems) are positively related to innovation results (processes)*

As a research questions, we have also considered:

***RQ.1.-** ¿To wich extent can the proposed relationships change with more experience in the use of the EFQM Excellence Model?*

Research methodology

We have used a quantitative methodology in order to analyse the hypotheses and research questions formulated. The population of the study was formed by Spanish firms included in the EFQM web, because those firms had participated in a process of recognition (531 organizations). The data come initially from a broad project financed by the Local Government of Valencia. The process of gathering data was developed in

2009; we obtained 104 valid questionnaires where a 75% of the organizations belong to the services sector.

Variables measurement

The analysed variables in this study are autonomy, participation and reward systems as independent variables; and innovation results as dependent variables.

We analysed the reliability of the scales measuring autonomy, participation and reward systems. Reliability was measured through the analysis of Cronbach's alpha to evaluate the internal consistency of the scale (Nunnally, 1978). The interviewed organisations should indicate their degree of agreement with different sentences that made reference to the degree of autonomy, participation and reward systems in the framework of the application of the EFQM Excellence Model. We used a five-point Likert scale. The questionnaire items were based on the EFQM Model criteria (EFQM, 2003) following other works (Bou Llusar et al, 2005).

The construct *autonomy* includes items related to autonomy and decisions on strategic subjects, and on the employee's degree of autonomy over the development of his/her activity and their degree of self-management. The Cronbach's alpha of this construct is 0,733. The construct *participation* refers to the process of generation of initiatives on the part of the employee, analysing if they participate in the decisions over their own work and on specific decisions over firm's strategy; Cronbach's alpha for this construct is 0,874. Finally, the construct reward system has a Cronbach's alpha of 0,894.

Table I.- Reliability analysis

Construct	Cronbach's Alpha
Autonomy	0,733
Participation	0,874
Reward systems	0,894

With respect to the *innovation processes*, they are measured in terms of participation on improvement suggestions; on improvement processes; and on knowledge generation processes. And *product innovation* was measured analysing the degree of introduction of new products in the market.

Results

To contrast the hypotheses we developed a correlation analysis among the different variables that make reference to the constructs: autonomy, participation and reward systems and innovation. The results of the correlation analysis are showed in the following table (See Table II):

Analysing results we can conclude that, in general, some of the HHRR practices encouraged by the EFQM Excellence Model affect positively the innovation products and processes what sustain partially our hypotheses. Particularly, and as Table II shows, we observe a positive and significant correlation between the variables that make reference to participation and those that measure process innovation (H2) (degree of generation of suggestions or the involvement of people in improvement actions for the organization).

On the other hand, we observe how the reward and recognition systems give support to process improvement, showing also a positive and significant relationship with the new product launch. These results support partially (as autonomy in a EFQM context does not show a relevant influence on innovation) the formulated hypotheses. With respect to Hypothesis 1 we must point out that only the variable “reward systems that encourage participation” supports this Hypothesis.

Table II: Correlation analysis between HHRR practices encouraged by the EFQM Excellence Model and Innovation

CORRELATIONS N=101	Improvement suggestions developed by employees	Degree of involvement in improvement actions	Degree of involvement in actions for knowledge generation	Evolution of the degree of new product launch
Autonomy and decision making capacity on strategy	0,130	0,149	0,098	0,124
Autonomy and decision making capacity on work organisation	0,042	0,168	0,083	0,145
Involvement and self-management of the work	0,132	0,092	0,144	0,161
Participation and initiative with respect to the organisation of the work	0,179†	0,249*	0,183†	0,029
Participation and initiative at a strategic level	0,214*	0,173	0,128	0,164
Employees can make suggestions and their opinion is considered with respect to the work	0,166	0,136	0,035	0,137
Employees can make suggestions and their opinion is considered with respect to future strategy	0,216*	0,281**	0,171	0,101
Reward systems and recognition that support participation in the organisation of the work	0,125	0,171†	0,153	0,215†
Reward systems and recognition that support participation in the strategy	0,201†	0,102	0,037	0,161

† p < 0,10 correlation is significant at a level 0,1; * p < 0,05 correlation is significant at a level 0,05; ** p < 0,01 correlation is significant at a level 0,01.

To answer the Research Question (RQ1) we analyse the existence of positive correlations depending on the level of experience that the firm shows with respect to the use of the EFQM Excellence Model.

We considered a low degree of experience if the Model has been used 2 years or less, and high degree of experience if it has been used more than two years. results are summarised in table 3.

Table III: Correlations among the variables autonomy, participation and reward systems with product and process innovation in firms with low experience in the use of the EFQM Excellence Model

Low experience in EFQM N=18	Improvement suggestions developed by employees	Degree of involment in improvement actions	Degree of involvement in actions for knowledge generation	Evolution of the degree of new product launch
Autonomy and decision making capacity on strategy	0,167	-0,181	-0,074	0,285
Autonomy and decision making capacity on work organisation	-0,093	0,162	-0,447†	-0,223
Involvement and self-management of the work	0,190	-0,061	0,105	0,493*
Participation and initiative with respect to the organisation of the work	0,035	0,175	0,431†	-0,026
Participation and initiative at a strategic level	-0,087	0,044	0,241	0,226
Employees can make suggestions and their opinion is considered with respect to the work	0,41	0,213	0,432†	0,152
Employees can make suggestions and their opinion is considered with respect to future strategy	0,424†	0,186	0,323	0,098
Reward systems and	0,140	0,141	-0,109	0,209

recognition that support participation in the organisation of the work				
Reward systems and recognition that support participation in the strategy	0,271	0,026	-0,096	0,128

† p< 0,10 correlation is significant at a level 0,1; * p<0,05 correlation is significant at a level 0,05; ** p<0,01 correlation is significant at a level 0,01.

Results show the existence of a positive relationship between participation in the definition of future strategy and improvement suggestions, and also between participation in the decisions that affect the workplace and the degree of involvement in actions oriented to knowledge creation, what will facilitate process innovation.

We observe also a positive and significant relationship between self-management of the work and the degree of new products launch (product innovation). However, results show a negative correlation among the variable *autonomy and decision making capacity on work organisation* and knowledge creation for firms with lower experience in the use of the Model. We could understand that this limited degree of autonomy can inhibit the knowledge creation process. This negative relationship is not observed in the case of firms with higher levels of experience in the use of the Model (Table IV), perhaps because relatively the levels of autonomy are higher, although referred to the workplace only.

Table IV shows the same relationships for higher levels of experience in the use of the European Excellence Model. This table shows again positive and significant relationships among the variables related to participation and the ones that measure process innovation. The table shows also a positive influence of the reward and recognition practices that sustain participation in the organization of the work on process innovation (suggestions). Additionally, results show a positive relationship between work autonomy and the degree of generation of new products.

Table IV: Correlations among the variables autonomy, participation and reward systems with product and process innovation in firms with high experience in the use of the EFQM Excellence Model

High experience in EFQM N=80	Improvement suggestions developed by employees	Degree of involment in improvement actions	Degree of involvement in actions for knowledge generation	Evolution of the degree of new product launch
Autonomy and decision making capacity on strategy	0,126	0,184	0,113	0,093
Autonomy and decision making capacity on work organisation	0,079	0,158	0,181	0,216†

In both tables (Table III and Table IV) autonomy shows a positive relationship with product innovation. On the other hand, we can say that the higher the level of experience in the use of the Model, the higher the effects of the HHRR practices on suggestions and participation of improvement plans (that measure process innovation).

As a result, we can say that the relationships among the variables that measure HRRR practices and innovation results have changed when introducing Experience in EFQM, so Experience is a relevant variable in this study.

If we compare the initial results (Table II) with the results obtained when we introduce the variable “experience in the use of the EFQM Model” (Tables 3 & 4) we observe that the variable “autonomy” turns significant with respect to product innovation in the group of firms with experience in the use of the Model. Experience in the use of the Model gives the employees more training and capabilities; consequently, autonomy can generate in this situation the expected effect on innovation.

Involvement and self-management show also significant results on innovation in the sample that has less experience in the use of EFQM Excellence Model; probably these employees are more motivated to generate ideas that lead to product innovation. Anyway, the consideration of the variable “Experience in the use of the EFQM Excellence Model” reveals the importance of the variable “autonomy” that was no relevant in the initial analysis.

Conclusions

The contribution of this work basically lies in the fact that analyses the relationship between several motivational HRP and the generation of innovation in the particular context of those firms that apply the EFQM Excellence Model with a strategic perspective.

This Model, employed under the TQM framework, is a tool that allows the firm to search for the continuous improvement of the business through product and processes improvement and giving, as a result, an increase of organisational performance. As we commented in the theoretical framework, there is literature that shows a positive relationship among autonomy, participation, performance-based rewarding systems and product innovation processes (Beugeiskijk, 2008). Also, we have seen that a context or culture facilitating participation and HRP contributes to generate innovation (Weia et al., 2011).

Our results support these arguments and show how some HRP such as participation or rewarding systems oriented to reinforce participation are positively related to innovation, both in the form of processes improvement as well as the creation and launch of new products. It is noteworthy to say that autonomy and self-management

variables play a relevant role if we consider the experience in the application of the EFQM Excellence Model. Such as the specialist literature pinpoints, the application of this model generates a positive context and a culture based on commitment that contributes to reinforce the effect of HRP on innovation results.

Thus, from a managerial perspective we argue that the use of the EFQM model facilitates and reinforces the relationships between participation and autonomy and innovation results and processes. However, rewarding systems become more motivational when the variable *experience* is not considered, perhaps because the continuous employment of rewarding and recognition systems makes them decrease their effectiveness.

This study is a preliminary approach to our object of analysis, namely, the relationship between HRP and creativity and innovation concepts. As a future research line, we intend to develop a theoretical model which allows us to analyse causal relationships among the different constructs, also including other business performance measures (profitability, sales growth, market share) as well as society results in terms of positioning and image. To do so, we have the intention of making bigger our database and, as a consequence, we will be able to carry out a rigorous quantitative analysis. Also, another future research line has to do with the study in greater depth of the relationship between creativity and innovation, trying to separate empirically both concepts (this question is not clearly studied by the specialist literature). Due to the complexity of the concepts to be analysed, this study could be initially carried out through the application of a qualitative methodology.

Key words: Postgraduates, Higher education, student satisfaction, Malaysia

Paper type: Research paper

Introduction:

Customer satisfaction has become a requirement for all successful firms and organizations to remain competitive (Dawkins and Reichheld, 1990). Many researchers have emphasized the importance of capturing customer satisfaction initiatives which have resulted in improving firm performance, and behavioral intentions like customer retention (Abratt et al. 2008, Powers and Valentine, 2008). Given that higher education is a service section which students see themselves as consumers, it has become an increasingly competitive market (Angell *et al.*, 2008). It is becoming increasingly difficult for universities, as the core of higher educational institutions, to manage their students' satisfaction. In the literature there is much emphasis on the importance of managing student satisfaction in educational institutions (Franklin, and Shemwell, 1995, Douglas et al., 2007).

The main aim should be to aspire to maximize students' satisfaction with their experience even as they are at university in order to preserve students. Next aim should be to improve the institutions' performance by providing a number of league tables, and so aid recruitment. In this line, the development of a statistical model and its application within higher education (HE) highlights the critical drivers of satisfaction with international student experience and this has been created out of this study. Deployment of a successfully validated model could improve the quality of both

teaching and learning and various supplementary services by providing a guidance framework that would allow a focusing of limited resources and improvement efforts towards those areas that will impact most on student satisfaction, i.e. to increase satisfaction.

Literature Review:

A recent study by IDP Australia forecasts that the global demand for international higher education (i.e. international mobility of students) will increase from a base of 2.173 million in 2005 to 3.720 million by 2025 – an increase of more than 1.5 million students seeking higher education overseas by 2025 (International Development Programs (IDP), 2007). In this market, most universities that offer services in international level try to gain competitive advantage by increasing their student satisfaction level.

An interesting paradigm that investigates student satisfaction considers the student as a consumer (Chadwick and Ward, 1987; Christensen and Philbrick, 1993; Franklin and Shemwell, 1995). From the perspective of theories of this school of thought, higher education can be considered as a business. This attitude focuses to make the case for examining the student as a consumer and the ways that institutions can assess their service in an age where quality, measurement and accountability are usual and very important (Brown, 1979; Glenn, 1997; Rawls, 1998). From this perspective, students should receive positive service to satisfy their college experiences as valued consumers. Otherwise, they will easily transfer to another college (Casto, 1995; Edwards, 1993; Stalnaker, 1994).

On the other hand, behavioral consequences of satisfaction are crucial. Enrolling often is mentioned as a consequence of satisfaction (Chadwick and Ward, 1987; Cooper and Bradshaw, 1984; Liu and Jung, 1980; Wince and Borden, 1995). Students may appeal to an institution because of good word from satisfied students. The more students testify to satisfaction with higher education institutions, the more likely they are to continue. Satisfied students are more likely to return for more education and more inclined to recommend the institution to others. In marketing literature, student satisfaction is accompanied by another important notion, i.e. service quality. This relation has been discussed in next section.

Customer satisfaction and service quality are usually adherent in higher education marketing literature. There are two approaches used for measuring quality of education:

mechanistic and humanistic (Li, 2005). Research assessment exercise or Quality assurance assessment is a tool of the mechanistic approach performed by the experts and agencies. The humanistic approach focuses on students' perspectives, most researchers in this approach use SERVQUAL (Sunanto, 2007). This research utilizes last approach for measuring service quality.

Satisfaction and Quality:

Satisfaction and quality are usually used by non-academic staff interchangeably; nevertheless they have distinct definitions in marketing literature. It is basically accepted that the two concepts are fundamentally different in terms of their underlying causes and outcomes. Satisfaction can be considered an extensive concept while service quality measurement focuses specifically on dimensions of services (Harris, 2002). In addition, Bolton and Drew (1991) uncovered both perceptions and disconfirmation to have a straight effect on overall service quality. After distinguishing between these two concepts, researchers encountered another question: What is the order of their occurrence in the customer's mind?

First, most researchers had proposed that customer satisfaction with a given service experience would lead to an overall evaluation/attitude about service quality eventually (Bitner, 1990; Bitner *et al.*, 1990; Brady *et al.*, 2002; Hernon *et al.*, 1999; Oliver, 1981; Parasuraman *et al.*, 1988). After that, Dabholker (1995) maintained that the relationship is situation specific and depends on the context of the service encounter. He suggested customers who think cognitively about the encounter, service quality precedes satisfaction. If the customer approaches the encounter emotionally, satisfaction is the antecedent of service quality. Several researchers such as Anderson and Sullivan (1993), Oliver (1993), and Spreng and Mackoy (1996) have found empirical support for this model, wherein customer satisfaction is a consequence of service quality. With consideration to the above, the following framework is adopted for doing the research, i.e. satisfaction is a consequence of service quality.

In addition, Dabholkar *et al.* (2000) mentions the importance of measuring customer satisfaction separately from service quality when the aim is to determine customer evaluations of service. In their article they concluded that customer satisfaction is a much better forecaster of behavioral intentions. They found constructs of service quality and satisfaction is distinct, even if highly correlated (Dabholkar *et al.*, 2000). In their article, Ruyter *et al.* (1997) described a number of differences between service satisfaction and service quality:

-Satisfaction is directly influenced by the intervening variable of disconfirmation;

-In order to achieve satisfaction customers must have experienced a service;

-Satisfaction expectations are predictive, service quality expectations are based on an ideal standard;

-Satisfaction can result from a large variety of dimensions, service quality dimensions are specific; and

-Satisfaction is influenced by cognitive and affective processes, service quality is influenced solely by forms of communication.

Methodology:

Parasuraman *et al.* (1985, 1988) argued that in order to measure service quality, customers' expectations compared to perceived service quality levels should be evaluated. To gain a better understanding of service quality in an educational situation, this study seeks to examine international students' expectations and perceptions of educational services rendered by five Malaysian universities. Using stratified sampling based on gender and level of study, 522 international postgraduate students were selected to participate in this study.

A modified SERVQUAL questionnaire comprising 35 items was used as the survey instrument to collect data. The items were found to be consistent with findings from studies by Boulding *et al.* (1993), Ham (2003), Hampton (1993), and Harris (2002). Subsequently, a panel of four professors in the faculties of education and management in Universiti Teknologi Malaysia conducted content validity on the instrument. The panel recommended several amendments which were incorporated into the finalized questionnaire. The instrument was administered to 30 postgraduate international students enrolled in Universiti Teknologi Malaysia to test the instrument for face validity.

The finalized instrument consists of an introduction and three sections. The cover letter provides information on the research. The second section consists of 35 items with two separate sub-sections to assess the respondents' expectations and perceptions. Each of the items in the first section is anchored on a five-point Likert scale to measure the respondent's agreement to the item posed. The third section contains demographic questions.

According to Buttle (1995), SERVQUAL gap can be determined based on three methods: (a) item-by-item analysis (e.g., P1 – E1, P2 – E2,P35– E35); (b)

construct-by-construct analysis (e.g., $(P1 + P2 + P3 + P4)/4 - (E1 + E2 + E3 + E4)/4$), where P1 to P4, and E1 to E4 represent the four perception and expectation statements relating to a particular construct); and (c) computation of an overall single measure of service quality $[(P1 + P2 + P3 + \dots + P35)/35] - (E1 + E2 + E3 + \dots + E35)/35$). For purpose of this study, all the three methods to determine the gaps were used. The means of perceptions and expectations were calculated for all 35 items, 5 constructs, and the overall service quality. Furthermore main hypothesis for this research is as followed:

Ho₁ : Satisfaction can be predicted by SQ dimensions, i.e. professionalism, reliability, hospitality, tangibles, and commitment.

Findings:

Factor analyses

To verify the dimensionality of the education service quality construct in the SERVQUAL, a factor analysis, using the principal components extraction technique, was performed on students' gap scores, calculated by perception-minus-expectation mean scores. Because we used only one source (the student), who provided his or her assessment of the dependent and independent variables, we acknowledge the possibility of common method bias (CMB). We applied counter mechanisms suggested by Podsakoff (2003) by ensuring respondent anonymity in order to reduce evaluate apprehension as well as counterbalancing question order in the instrument. The analysis made use of the Varimax factor rotation procedure in line with the approach used by Parasuraman *et al.* (1988) in their initial SERVQUAL study.

The results of the factor analysis in terms of factor name, rotated factor loading matrices, the variance explained by each factor, and the results of reliability test coefficient alphas can be seen in another paper by authors of this article (Shekarchizadeh, et. al. 2011). In the current study, the five factors were defined as:

- (1) professionalism (items 22-35)
- (2) reliability (items 4 and 9-13)
- (3) hospitality (14-21)
- (4) tangibles (items 1-3); and
- (5) commitment (items 5-8)

Here, the tangibles in the higher education context means the quality of university facilities i.e. classrooms, computer labs, and the campus library. This is in line with

suggested definition of tangibles in a higher education context by Franklin and Shemwell (1995). Reliability is the consistency of performance and dependability. Professionalism is possessing the required skills and knowledge to perform the service. Commitment is the apparent commitment of employees to their work. Hospitality is warmth and personal approachability, cheerful attitude. These findings confirm with findings by Douglas et al. (2007). All the factors and their related items has been exhibited in the Appendix table.

The relationship between education service quality and on a separate measure of the overall satisfaction of students was examined. Regression analyses were administered using mean of satisfaction items as the dependent variable and the five perception-expectation factors resulted from factor analyses as the predictors. There are four assumptions for using regression: Linearity, independence, normality and equal variance. In cross-sectional data, as this study, the assumption of independence is not relevant since the observations are not made in any meaningful sequence (Carver and Nash, 2009).

The stepwise regression with stepping method criteria was performed between satisfaction as the dependent variable and professionalism, commitment, hospitality, reliability and tangibles as independent variables. Stepwise regression approach attempts to find the best regression model without examining all possible models. For this study, probability of F to entry a variable was selected at 0.05 and for removal variable was selected at 0.10 levels.

Table 1 shows the means of all IVs and DV, the standard deviations, and the inter-correlations among the variables. Inter-correlations among variables were performed at 0.01 significant level (two tailed).

As Table 2 depicts, there are two models. Multiple correlation coefficient (R), can be interpreted as the simple correlation between observed satisfaction level and satisfaction level predicted with the regression equation. Furthermore, coefficient of determination, R^2 indicates proportion of the variance of the dependent variable is explained by the independent variables. Also, in the table, adjusted R^2 based on the number of independent variables and the number of cases, is shown, respectively 0.211. As Table 2 demonstrates, model 2 is the best based on the biggest R^2 earlier.

Table 3 contains the results of the analysis of variance. In this analysis, the null hypothesis, states that all regression coefficients, with the exception of the intercept,

equal zero. The alternative hypothesis H_1 states that at least one regression coefficient differs from zero. As Table 3 presents, the significance level is 0.000. Applying $p < 0.05$ criterion, leads to rejection of the null hypothesis. In other words, at least one regression coefficient, and the R^2 as well, significantly differs from zero.

As Table 3 depicts, only two of the Independent Variables (IVs) contributed significantly to prediction of satisfaction level of students. Based on the following table, the regression equation representing model 2 is

$$\text{Satisfaction} = 3.047 + 0.289 \text{ Professionalism} + 0.207 \text{ Reliability}$$

One important problem in the application of multiple regression analysis involves the possible collinearity of the independent variables. According to Snee (1973), if the maximum VIF exceeds 5, alternatives to least-squares regression are recommended.

As Table 5 depicts, all the VIF values are less than 5.0, implying the absence of multicollinearity among the Professionalism and Reliability. Alternatively, Table 4.25 represents standardized coefficients, Beta, to facilitate comparisons among the regression coefficients. As reflected in the Table, professionalism has 40 percent more importance than reliability dimension. Besides, Table 4.25 presents results of T-test for coefficients. In this test, the null hypothesis H_0 states that a regression coefficient is zero. The alternative hypothesis H_1 states that a regression coefficient differs from zero. The last column of the table 4.25 contains the two-tailed significance level for the computed T-value. Applying a critical α of 0.05, we reject the null hypothesis that the regression coefficient equals zero, for independent variables and the intercept.

Discussion:

The findings of this study, suggest that professionalism is the most important in assessing service quality and student satisfaction in Malaysian universities. Interestingly, this finding is comparable with finding by Yang (2008), who reported commitment and professionalism are significant predictors of overall satisfaction. Interestingly, there are two common items in professionalism dimension that was found by Yang (2008) in a higher education field in East culture and professionalism that was found in current study. These common items are:

Item 22: Members of my faculty are well dressed

Item 32: My faculty has the knowledge to answer students' questions

It is noteworthy from a managerial perspective, in the current study that the strongest predictor of overall satisfaction, the professional dimension, also tended to show a significant negative gap scores regarding student perceptions. All of the items scores for the professionalism construct were not poor. However, the students' ratings of perceptions of performance were considerably lower than their expectations. This reveals the problem managers may have with performance-only evaluations (Yang, 2008).

Conclusion:

As attention to improving quality in higher education is increasing, there needs to be a correspondent increase in the use of its assessment tools. This research began with the basic SERVQUAL survey instrument. A main purpose of the survey was to provide information for predicting student satisfaction in a Malaysian context.

The results from such a survey can be used to identify areas of priority. The use of stepwise regression provides an analysis in identifying the significance of individual attributes to overall student satisfaction. The above analyses provide information useful for university administrators in decision making. The focus of this research had been on both the acculturated survey as well as the derived methodology.

Rz.chitsaz@yahoo.com

Key words: Environmental management system, integrated management system, occupational health and safety management system, quality management system.

Introduction:

Developing and implementing a management system is a continuous improvement process that involves several key steps. Quality, Environmental, Occupational Health and safety (OH&S) and.... management systems play an important role in today's organizations. They include planning, implementing, monitoring and measuring, and revising-or quite simply “plan, do, measure, and revise”. The public sectors can also include the concepts of quality, best management practices, and continuous improvement in their planning efforts.

Also, increasing accountability for product (service) quality, tighter environmental controls and tough safety requirements, mean companies cannot afford to be complacent in these areas. Management systems provide a framework to ensure companies minimise potential risks to their customers, employees and environment.

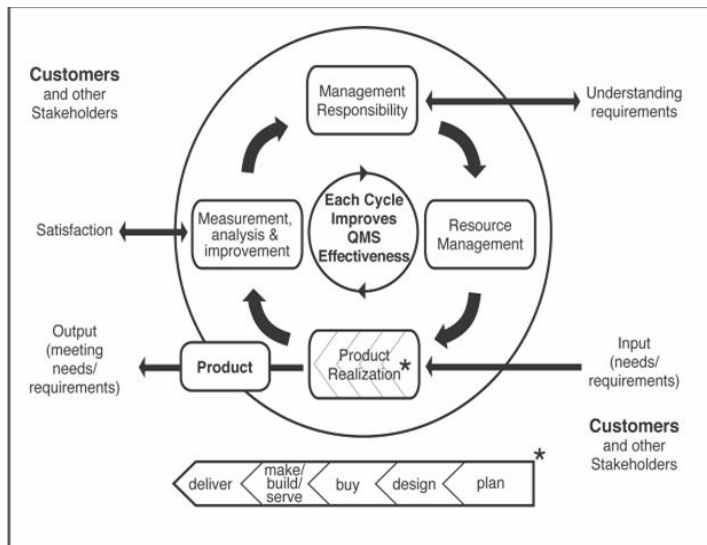

An organization's performance can be greatly enhanced by increased employee involvement and commitment. But while this aspect is critical, it is also imperative that managers commit to any new system and properly implement its initiatives. When management systems are understood and implemented correctly, they produce better job processes, eliminate unnecessary steps, reduce errors, and create an overall work environment that is truly motivational.

A management system consists of four essential parts:

1. Policy and objectives to guide the organization
2. Responsibilities defined so that people know what is expected

3. Defined processes linking people to business objectives
4. Data shared and analyzed to improve the performance of the company

(1). The System Model

Every organization is unique, so while every company has a management system that consists of these four elements, no two management systems are alike. That is why:

1. Every company must develop their own system so it can be used and improved.
2. Management systems cannot be bought, downloaded or created by consultants every company must do it for themselves “of course, sometimes with the help of a consultant!”.

Nowadays, organizations use of different kinds of systems. In addition there is now a move toward “integrating” management systems, especially when seeking combined certification against more than one external standard, based on an external assessment of a single system description. But the word “integrated”, which suggests you take discrete systems and some how combine them, can obscure the fundamental principles involved in running a business. How ever a management system that integrates all of your systems and processes into one complete frame work, enabling you to work as a single unit with unified objectives.

Therefore implementing a management system gives you the opportunity to focus on optimising the most important areas for you and your stakeholders.

This paper:

- Explains briefly management systems and their advantages
- Illustrates the benefits associated with integrating management systems
- Presents one example of the development and implementation of an integrated management system at health care organization “Imam Khomeini Hospital” and its outcomes

Concepts & definitions:

Management system

A management system is a proven framework for managing and continually improving an organization's policies, procedures and processes. Also, a system is for managing a particular activity or a specific type of asset. It means to manage all relevant areas of operation, often in relation to a specific aspect for example: quality, environment, information security...

Considerable management system advantages

Taking a systematic approach to management makes managing your business both easier and more effective. You work out the best way to handle each key activity and make sure that everyone uses the same approach every time.

The advantages of a management system include: increased employee enthusiasm and motivation toward doing a job well. Incorporating pride in public service, ownership in the job, and quality into the job processes adds value without costing additional labour. The results are quality projects completed on time and within budget and highly satisfied clients.

Quality management system

An ongoing effort to provide services that meet or exceed customer expectations through a structured, systematic process for creating organizational participation in planning and implementing quality improvements. (Goonan, 1995), (Gitlow, 2001)

Implementing an effective quality management system can help you to:

- Increased efficiency
- Increased revenue

- Employee morale
- International recognition
- Factual approach to decision making
- Supplier Relationships
- Consistency
- Customer satisfaction
- Improvement processes (Gitlow, 2001), (www.iso.org, 2004)

Environmental Management System (EMS)

Part of management system of an organization used to develop and implement its environmental policy and manage its environmental aspects. An Environmental Management System “EMS” is a set of cohesive elements that an organization may use to minimize its impact on the environment and also a continuous cycle of planning, implementing, reviewing and improving the actions that an organization takes to meet its environmental obligations. (Federal Facilities Council, 1999)

The benefits of having an EMS are numerous:

- Helps staff track environmental compliance requirements.
- Increases environmental awareness on grounds.
- Requires designation roles and responsibilities so the proper people can be notified in case of a problem or emergency.
- Requires training to ensure that everyone knows about the EMS and their individual role.
- Requires training to ensure that everyone who performs a task related to a significant aspect is properly trained so as to minimize any potential impacts associated with that activity.
- Provides a means by which employees and staff can offer suggestions on ways to improve the Organization.
- Ensures Organization facilities are closely examining their operations and looking for ways to minimize their impact on the environment thus promoting sustainability within our community.
- May result in a cost savings as wasteful practices are replaced.
- Is a key part of the Organization's overall sustainability commitment. (Federal Facilities Council, 1999), (www.iso.org, 2004)

OH&S Management system

Part of management system of an organization used to develop and implement its OH&S policy and manage its OH&S risks. OH&S management is a management tool which ensures focus on all major aspects of the working environment. (Reese, 2003)

OH&S Management system benefits

A consistent approach like this reduces the number of mistakes and the cost of correcting problems. It also reduces the level of risk and ensures that you comply with legislation. This can positively influence your business:

- Improved health and safety performance by your business will reduce the costs associated with accidents and incidents.
- Improved awareness of regulatory requirements reduces the chance that you will commit any offences. The Health & Safety Executive will generally regulate your business with a lighter touch if it is well managed.
- If employees see that you are actively looking after their health and safety, relations and morale will improve.
- Improving the efficiency of your business reduces your costs.
- You can demonstrate to your insurers that you are controlling risk effectively. This may help lower your insurance premiums.
- Banks and investors will be more willing to finance your business if you can show that it is well managed.
- Business partners have more confidence in your business. Larger companies and government agencies may only buy from businesses that can show effective management systems. (Reese, 2003), ([www.OHSAS](http://www.OHSAS.com). 18001, 2007)

Integrated Management system

An integrated management system is a management system which integrates all components of a business into one coherent system so as to enable the achievement of its purpose and mission. (Smith, 2001)

With an integrated system, your organization becomes a unified whole, with each function aligned behind a single goal: improving the performance of the entire organisation. Instead of “silos” you have a genuinely co-ordinated system: one that is greater than the sum of its parts, and can achieve more than ever before. An integrated

system provides a clear, holistic picture of all aspects of your organization, how they affect each other, and their associated risks. There is less duplication, and it becomes easier to adopt new systems in future.

An integrated management system allows a management team to create one structure that can help to effectively and efficiently deliver objectives of an organization. (Sadeghi Fard, Namazi, 2008)

From managing employees' needs, to monitoring competitors' activities, from encouraging best practice to minimizing risks and maximizing resources, an integrated approach can help an organization achieve their objectives. (Smith, 2001), (Sadeghi Fard, Namazi, 2008)

Key advantages of Integrated Management System

- Encourages risk management
 - Gives you a competitive edge
 - Attracts investment
 - Improves and protects brand reputation
 - Raises stakeholder perception and satisfaction
- So with an integrated management system:
- There is less duplication of efforts
 - Lower operation cost than supporting overlapping or redundant systems
 - There is a simpler documentation system with one quality manual and one set of standard procedures
 - There is a more complete compliance to the multiple standards (Smith, 2001), (Xiaojiang, 2007)

In this section, we focus on healthcare system

Today's healthcare system has evolved as a complex and tightly coupled system.

The challenge ahead

One of the fastest growing industries in the service sector is health care and also this rapid growth has been accompanied by dramatic changes in environment. These forces of changes include that growing demand for health care, rising costs, constrained resources, competitive pressure and monitoring by public and private groups and a

markedly better informed client have begun to exert extra pressure on health care managers to reassess their strategies. (Lighter, Fair, 2004)

Introduce Imam Khomeini Hospital as one example implementation of such systems

Imam Khomeini Hospital “I.KH.H” affiliated with social security organization and was located in Arak– Iran. It is a 160 bed, general Medical Surgical hospital.

The strategy of this hospital is to excel at quality development by constantly orientating towards and taking actions to fulfil the needs and expectations of its patients

The hospital systems has been designed individually and I.KH.H achieved independent certification for each system ⁽¹⁷⁾ under relevant ISO from IMQ Management service “the Italian company”. Then, I.KH.H opted to integrate, to the extent possible, its systems for quality, environmental and occupational health and safety.

Management systems in Imam Khomeini Hospital:

Management systems provide the important framework to ensure hospital manage the quality of its health care services, the safety of its employees and the impact to the surrounding environment. Management systems are fundamentally concerned with what this hospital needs to do to manage the processes involved with health care quality, environment and safety. (Lighter, Fair, 2004)

Whilst different management systems have several unique elements, they also have many common ones such as policy development, documentation and reporting, auditing, emergency and awareness, operational procedures and process control and training and awareness. For these reasons, I.KH.H decided to integrated 3 its systems.

Background of Imam Khomeini Hospital

There were apparent gaps in this hospital and its management before implementing management systems. Some of important gaps included:

- Poor hospital management system

¹⁷- Hospital systems include : 1) ISO 9001 : 2008

2) ISO 14001 : 2004

3) OHSAS 18001 : 2007

- Poor strategic and operational planning
- Lack of teamwork approach
- Poor communication and information systems
- Budgetary constraints and inappropriate utilization of resources
- Fragmented health information and medical record system

Besides, this hospital did not think it needed to integrate these systems after implementing them. “We are a good hospital”, top management asserted. “We like the way we do things, so we will just add the requirements to our standard operation procedures.” So, along with regular meeting, top management had to conduct three additional management reviews with the organisation's quality, environmental and occupational health and Safety management system leaders. Each of these reviews required long presentations and separate action plans.

Thus, to run the situation around, the hospital integrated the requirements of ISO 9001, ISO 14001 and OHSAS 18001 into the business reviews already conducted by top management. All the requirements were not examined during every monthly review, but they were covered at a rate that seemed more reasonable to management. In this way (after implementing and integrating of management systems), three meeting were integrated into one business review meeting and resulted in one action plan. This created less confusion and cost less to implement and maintain. Rather than problem solving for three standards as well as normal operational concern, top management could focus on the most effective solutions for the integrated issues discussed at the one meeting.

KH.H systems consist:

Quality management system

In this hospital, health care quality management is tried to continuously improve the quality of health care services by:

- ✓ Establishing the system more responsive to patient needs.
- ✓ Providing cost effective health care solutions.
- ✓ Supporting the health care service performs correctly and dependably at the first time.
- ✓ Increasing the patients satisfaction by emphasizing the patients needs and expectations.

Imam Khomeini Hospital has adopted the ISO 9001: 2008 standard as a key tool in its commitment to continuously improving health care quality and patient satisfaction.

The hospital has identified the key processes necessary to ensure patient satisfaction and continuous improvement of the IMS. Also the hospital has established a set of corporate objectives which are supported by the following quality objectives:

- | |
|---|
| <ul style="list-style-type: none">- Reduce the cost of quality “health care quality”- Maintain and grow the Integrated Management system <p>This system with input from patients, employees and suppliers using a structured problem solving methodology</p> |
|---|

- ✓- Developing and deploying basic quality training for all employees
- ✓- Reducing waiting time at the emergency ward
- ✓- Reducing waiting time for admitting & discharging
- ✓- Reducing unnecessary cancellations of general operations
- ✓- Lowering the rate of caesarean sections
- ✓- Decreasing mortality and morbidity in the health care processes

Environmental management system

I.KH.H takes its obligation to responsibly manage its environmental impacts⁽¹⁸⁾ seriously and it has adopted the ISO 14001:2004 standard as the foundation of its Environmental care system.

The requirements of the IMS for Environmental care apply to all hospital wards and administrative departments and to all operations conducted within the physical bounds of those wards & departments. This hospital is dedicated to the protection through the implementation of responsible environmental practices. Continuous improvement, waste minimization, pollution prevention, as well as commitment of its employees are the basis for implementation of this system. Therefore they perform:

- | |
|--|
| <ul style="list-style-type: none">- Maintain compliance with all applicable regulatory requirements. |
|--|

¹⁸- Environmental impact: Any change to the environment, whether adverse or beneficial, wholly or partially resulting from activities of an organization, products, or services.

- Determine those activities that can have a significant impact on the environment and identify ways to improve them.
- Exercise care in how they use materials and energy and minimize waste.

The structure of EMS in this hospital is based on Plan-Do-Check-Act “PDCA” cycle:

- ✓- Identifying hospital activities impacts on the environment & providing and developing a list of Environmental aspects ⁽¹⁹⁾ by every hospital ward
- ✓- Identifying risks of every activities in hospital
- ✓- Identifying applicable legal requirements
- ✓- Defining objectives and targets “such as: reduction in energy consumption”
- ✓- Setting up control plans to achieve the objectives and targets include: establishing of some procedures for controlling of significant aspects
- ✓- Preparing emergency response plan
- ✓- Verifying achievement of objectives and targets
- ✓- Continuously improve control plans, objectives and targets

Adherence of this system to ISO 14001 will definitely help to sustain their long-term competitiveness, as discerning patients around the country are becoming more environmentally conscious.

Occupational health and Safety management system

This hospital has adopted the OHSAS 18001: 2007 standard with the benefits, such as:

- Fewer accidents and fewer interruptions of services through better control of workplace related hazards.
- Reduced likelihood of occupational disease and better working conditions.
- Consideration of employee needs creates a stable and motivated workforce.
- Ensure legal compliance with minimum of administrative effort.
- Support of sustainable hospital development by reducing costs caused by accidents and emergencies.

I.KH.H developed, established and implemented OH&S Objectives. This objectives concluded:

¹⁹- Environmental aspect: An element of an organization 's activities, products, or services that can interact with the environment.

- ✓-Reducing number of patients and employees “Doctors, nurses,” injuries
- ✓-Decreasing costs due to personnel injury
- ✓-Reducing personnel compensation insurance costs
- ✓-Minimizing resource constraints from personnel injuries
- ✓- Increasing employee safety awareness and improving employee motivation
- ✓-Identifying and accessing the legal and compliance requirements of OH&S
- ✓-Identifying of hazards and safety risks in every ward of hospital

Management systems outcomes in Imam Khomeini Hospital:

For management systems to function effectively they need to be utilised by all employees “such as: doctors, nurses, ...”. The management framework that each system subscribes to need to be incorporated into daily activities of all employees. These systems will fail to protect hospital from quality, environmental and safety nonconformist unless adopted by all employees and all requirements of the individual system are adhered to.

Significant results of these efforts are: maturity of system and implement of hospital management system and hospital information system, responsive to patient needs with special attention, identify areas requiring immediate improvements and use of teamwork approach.

On the other hand, the first hurdle was that adopting and certifying three individual management system was not only a timely and costly exercise, it might also required employees to undertake similar tasks for the separate management systems.

These tasks, especially where duplicated between systems could seem unnecessary and wasteful of employee resources, to avoid this problem, this hospital applied to IMS.

Integration of the quality, environmental and OH&S management systems has been a way the hospital has reduced of inappropriate work of three individual systems. The integration of management systems allowed the common elements of the systems to be identify and merge as one, whilst still recognized individual requirements that each system would have.

Other recognised associated with management systems include:

I. CONSIDERABLE IMS OUTCOMES

1	- Managing social, environmental and financial risks
2	- Improving operational effectiveness
3	- Reduction costs
4	- Increasing patient and stakeholder satisfaction
5	- Promoting innovation
6	- Improved hospital performance.

Conclusion:

Hospitals have a great responsibility in our community to provide and offer health care and medical services with high quality, to meet all environmental requirements and to ensure the safety of their patients and employees. It is these responsibilities that have led most hospitals to implement quality, environmental and OH&S management systems into their daily operations.

Today, companies regardless of size, face ever increasing demands for profitability, quality, and technology that contributes to sustainable development. As a manager looking to turn these pressures into a competitive advantage, you need to develop an efficient management system tailored to your business processes and use it systematically to maintain and constantly improve your company's overall performance.

Thus a well-developed management system is the tool all in the organization use to communicate the interdependency of people, processes and the system and make informed decisions affecting profitability.

Also integration of management systems is a logical step for every organization such as: hospital, that have or are or seeking to implement one or more certifiable systems.

The successful integration of management systems depends on a variety of factors. However the most important is acceptance and willingness to use by all members of staff.

Therefore it is essential for the integrated system to be easy to use, whilst still satisfying all requirements of each management system. Of course, implementing an integrated management system for quality, environment, health and safety is not a simple task.

Implemented carefully it can yield a rapid return in investment in conjunction with a better grip on operation.

With an ongoing continual improvement to the integrated management system framework the use of IMS will have enormous benefits in the way organizations are able to manage their quality, environmental and OH&S responsibilities.

Quality Control and Capability Improvement for Advance CDSEM Measurement

Kelly Feng

P.Y Lee

Thomas Tseng

H.F. Huang

Jacky Wei ^a

Taiwan Semiconductor Manufacturing Company, Taiwan, R.O.C.

Key words: CD-SEM, SPC, EWMA, Carry over, QC monitor, Capability, GR&R

Introduction

Minimizing tool induced metrology errors becomes more and more critical as processes evolve to 40 nm and beyond. According to the National Technology Roadmap for semiconductor, the use of CD-SEM requires special attention with respect to the precise, tight, and accurate monitoring associated with advanced process quality control. And, small CD measurement bias contributes to significant device shift (ex, from 40nm process, 3A mis-matched bias causes device performance shift ~1%). How to monitor CD and assure CD-SEM capability (Precision, Accuracy, Stability and Matching) is the most important research. Monitoring CDSEM capability and quality control in many fabs today relies on X-bar and S chart for daily pitch QC monitor. However, though it ensures stable scan calibration, pitch monitor is not sensitive in beam quality. This is because repeated e-beam measurement on the same location induces carbon build-up which is often called carryover, physically deposits carbon atoms where e-beam strikes the surface, and changes CD line. This carryover makes it impossible to set a tight spec to assure CDSEM capability for effective CD line QC monitor. Further, if more tools are to be matched, the same places will also have to be strike many times. It is difficult to know the true bias between tools. Minimizing carryover and the bias evaluation of different tool types are also important for matching, in addition to its usefulness in CD line monitor. The paper describes the usefulness and feasibility of the approach

determined using technical and statistical methodologies to reduce carry over effect and monitor CD line effectively.

In addition, CD-SEM still needs improvement in many areas of performance to keep pace with the technology roadmap. The specification addresses each area for improvement in a separate section. The critical areas addressed, are, GR&R, precision, stability and tool performance matching. Goals of this specification are to outline needed capabilities of CDSEM, and to set forth methods and KPI (key performance index) for evaluation these capabilities. This paper presents the complete solution that would enable CD-SEM quality control and capability

Methodology

In order to fulfill the rigorous requirements of advanced process control and increasingly tighter device, this paper interprets and discusses new approaches to investigate three factors, including carryover reduction, QC monitor methodology and CD-SEM capability CIP (continuous improvement plan). The following semiconductor technical and statistical methodologies were chosen for consideration.

Carryover Reduction Methodology

The CD line QC monitor methods, including GRR, accuracy and stability are repeated measurement induces charging due to carryover effect when tool variation is dominated by QC wafer noise. Carryover effect is a complex phenomenon occurring in the course of the interaction of the electron beam with the sample to be measured. It is usually linked to carbonization, contamination, heating and charging. A typical manifestation of the carryover effect is the charge in the critical dimension measured. A very well known but not widely studied phenomenon, related to the sample damage, which directly affects the capability and quality control of CD-SEM measurement. We investigate the carryover in an attempt to reduce the effect of sample degradation by repeated measurement and improve measurement precision

Short-term repeatability- Regression Model GR&R

We compare to typical GR&R by sigma. Typical %R&R is larger than 30% will fail GR&R to total variation in advance process poly line CD measurement is dominated from QC wafer noise.

Regression model GR&R application is based on the linear regression mode and hypothesis linear mode with p-value <0.05. The assumed linear model to predict the daily target, \hat{y}_i denoted as $\hat{y}_i = \hat{\beta}_0 + \hat{\beta}_1 t_i$, and where $\hat{\beta}_0$ is the initial value of control wafer, $\hat{\beta}_1$ is the rate of growth per one measurement and $t_i = i$, $i = 1, 2, \dots, a$ is the frequency of measurements. The regressed target is estimated by means of daily iterating the historical line measurement data, where the solid diamond line represents the original measurement data and vacant square line is regressed target. The bias value that equal to the delta of measurement data and regressed target can be generated simultaneously, therefore can be converted the bias data to bias control chart.

The linear regression model is diagnosed by p-value and RSQ to ensure the estimated bias data at 95% or better confidence level. In general, if RSQ is close to 1 and P-value less than 0.05, then the linear slope ($\hat{\beta}_1$) is considered “Significant”. In other words, if p-value less than 0.05, bias values are meaningful in statistics. It means CD line measurement is fitted very well by the linear regression model. RSQ and P-value formula can be expressed as (Eq.1), (Eq.2)

$$R - \text{square} = \frac{\sum_i^a (\hat{y}_i - \bar{y})^2}{\sum_i^a (y_i - \bar{y})^2} \quad (\text{Eq.1})$$

$$p - \text{value} = FDIST\left(\frac{\sum_i^a (\hat{y}_i - \bar{y})^2}{\sum_i^a (y_i - \hat{y}_i)^2 / (a - 2)}, 1, (a - 2)\right) \quad (\text{Eq.2})$$

We got the result is regression model %R&R is <10% passed GR&R to total variation.

	Typical Model	Regression Model
EV	19.22%	3.44%
PV	6.94%	18.44%
%R&R	49.08%	8.59%

Table 1: Regression Model and Typical Model GR&R

Long-term repeatability - Advanced EWMA and Range chart

Figure 1 is an example of CDSEM daily CD line monitor trend chart in the same reference wafer. The carryover induces by carbon build-up could be approximated by a gradual linear model with the frequency of measurements as the independent variable.

Figure 1: Poly raw line CD daily monitor trend chart

Exponentially Weighted Moving Average (EWMA) control chart was employed, to detect the measurement small shifts (generally shifts less than 1.5σ) of the measurement process. The series was generated that derived from $(Bias)_i$ to be as (Eq.3)

$$EWMA((Bias)_i) = \lambda \times (Bias)_i + (1 - \lambda) \times EWMA((Bias)_{i-1}), \quad i = 1, 2, \dots, a. \quad (Eq. 3)$$

and $EWMA((Bias)_0) = 0$ is the target of measurement process. and where λ is the so-called smoothing parameter, ranging $[0,1]$.

Figure2 shows QC CD line monitor data from four CDSEM tools can be collected and evaluated through applications Advanced EWMA. With the stability quantified and carryover trend compensated, it is now straight forward to quantify all CDSEM line CD measurement performance in-line. The chart is within the control limit as reset the linear regression model.

Figure 2: Daily $EWMA((Bias)_i)$ chart control for multiple CDSEM tools

Figure3 shows range from CDSEM tools, with it, we can further ensure that all CDSEM tools are tied together well for tool performance matching to meet device tight requirements.

Figure3: Daily Range chart control for multiple CDSEM tools

In observing Fig.1, Fig.2 and Fig.3, it indicated APCD10 had a k-shift from tools that cause the out of control limit event in EWMA control chart and range chart.

New design for QC Standard wafer :

Not only with above good statistic methodologies to simulate it but also using process methods to solve it and find a good QC standard wafer to monitor daily life and real life.

New process flow was used on the low charging wafer to reduce the e-beam carryover effect. The substrate with poly is no any dielectric interface and no dielectric on poly top either, then the heavy doping play the important role for the wafer preparation also.

Beside low charging wafer preparation as figure 4, wafer clean process is another key for daily QC monitor. The optimized wafer clean process can reduce wafer charging effect and prolong the wafer lifetime. Figure 5 shows the significant effect and improvement.

Figure 4: the pattern of CD SEM low charging wafer

Figure 5: the Clean flow comparison to the low charging wafer

QC Monitor Methodology

After using a new design QC STD, we also need a good methodology for QC monitor, measurement location qualification and decision.

Application Systemic Sampling Method:

For CD line QC monitor of multiple CDSEM tools, the charging caused by the repeated measurements from multiple tools is a key problem in CD-SEM CD line metrology. The idea of these measurements is test to what a sample plan to be performed on all multiple tools. Investigate Systemic Sampling Method on a QC wafer is to split groupings for multiple CDSEM tools, and use statistic analysis to test the average CD line measurement per grouping and carryover risk estimation for each CDSEM tool.

Grouping A for CDSEM No.A
Grouping B for CDSEM No.B

Figure 6: A grouping idea of Systemic Sampling Method for CDSEM tools

Therefore, the measurement per grouping is collected and tested as below:

Step1: Repeat to measure full map 5 times.

Step2: Calculate the average and standard variation each chip

$$\bar{s}_i < \bar{s}_i - 3 \times S_{s_i} \text{ or } \bar{s}_i > \bar{s}_i + 3 \times S_{s_i} \text{ and } \bar{x}_i < \bar{x}_i - 3 \times S_{x_i} \text{ or } \bar{x}_i > \bar{x}_i + 3 \times S_{x_i}$$

Step3: Delete outliers and ranking:

Step4: Select >10 chips be a grouping for a CDSEM tool

$$H_0 : \bar{x}_{group1} = \dots = \bar{x}_{group_i} \quad H_1 : \text{at least one } \bar{x}_{group1} \neq \bar{x}_{group_i}$$

Step5: Establish the following hypothesis:

Step6: Grouping resolution is the 10 to 1 rule is being interpreted to mean that the measuring equipment is able to discriminate to at least one-tenth of the process variation.

The application systemic sampling method can reduce carryover risk made and the tool performance is similar in day 1 in order to well CD line QC monitor.

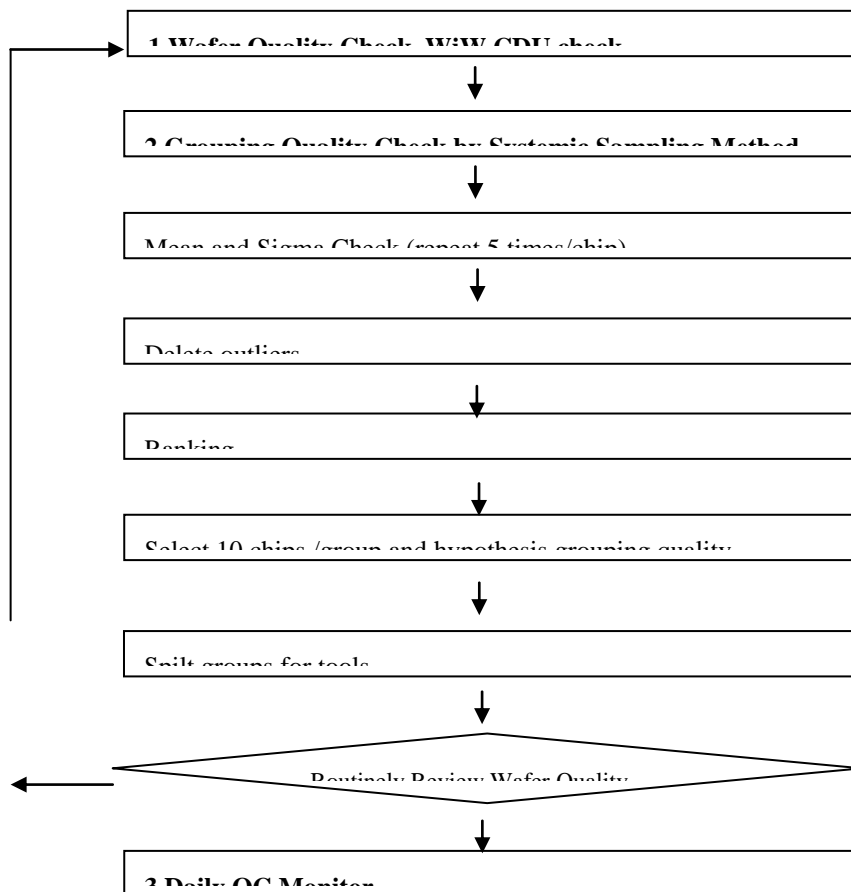

QC Wafer Quality Control

Of principal concern here is QC wafer quality, sufficient to capture the target for proper CD line measurement. According to simulation based on measurement error <5% to CDSEM CD line, getting wafer in wafer uniformity (WiW CDU) around 1nm causes systemic sampling method worse and approaches to the end of QC wafer lifetime. Both cannot capture the proper CD line measurement.

Wafer in	Wafer uniformity	Grouping Range	Measurement Error
	0.6	0.024	4.06%
	0.7	0.026	4.39%
	0.9	0.029	4.83%
	1	0.033	5.42%
	1.5	0.043	7.13%
	2	0.053	8.83%
	2.25	0.058	9.69%
	2.5	0.063	10.54%

Table 2: A Simulation for the measurement error of wafer in wafer uniformity

It is worth noting that, from 2-2-1 & 2-2-2 content, for each feature, a standard and completed procedure is below.

Based on the standard flow, we can improve a grouping bias from 0.793nm to 0.057nm, and the measurement error is less than 5%. It is important to have a good QC wafer quality control for QC monitor

3 CD-SEM Capability Improvement: Indeed, well CD line QC monitor can be extracted from useful carryover reduction and QC monitor methodology. We still face CD-SEM matching difficulties, different offset and capability questions.

The ultimate goal of the CD-SEM specification is to improve CDSEM capability, including accuracy, precision for tool performance matching to meet device tight requirements, and even triple capacity in CD monitor stages owing to free of restriction in some mis-matched CDSEM tools.

Accuracy means closeness to a reference value. Applying a bias is difference between the reference value and the observed average of measurements to meet tsmc request the bias performance matching from multiple tools

Precision is a multiple of reproducibility and is typically used for comparison to process tolerances, as in the commonly use Precision/Tolerance (P/T) ratio. A P/T ratio greater than 0.2 has an adverse effect on common production metrics such as Cpk. Applying a 20% P/T ratio to the 10% CD budget yields the necessary tool precision need from the CD metrology tool suppliers to meet these ITRS outline.

Moreover, there is a big challenge to CDSEM tool limitation. Then we surveyed and implement AAA (Auto-Axis-Alignment) and an offset evaluation to improve it.

Precision Improvement: (Auto-Axis-Alignment)

Image maintenance CIP, AAA(Auto Axis Alignment) fully auto instead of manual, frequency to 1 day from 4 days, fine tune time to 3 min from 25 min, the methodology including,

1. Alignment (beam perpendicular and current calibration) :
2. Stigma (beam X,Y direction sharpness calibration) :
3. SEM monitor mask: tsmc developed a mask as below for AAA function application.

We found the image is adjusted and clear as figure 7 obviously and sigma improve around 50% from table 3 and daily QC monitor chart as figure 8.

Figure 7: Image performance from AAA mode and Manual Model

800V CD-SEM tool	Tool 1	Tool 2
3 Sigma (Manual)	1.5	0.36
3 Sigma (AAA)	0.3	0.3

Table 3: Sigma performance between AAA mode and Manual Model

Figure 8: Tool 1 Daily QC Monitor Chart

Accuracy Improvement:

The paper implicates the most difficulties are the different tool type matching which would has a gap of image shape to cause CD measurement bias. The paper summarizes and innovates the steps for different tool type bias evaluation as follows:

Step1: AB map matching or ABBA matching (short term)-Assume offset $AX+B$

- a. AB map matching for ADI: PR film has significant charge effect then choose AB map to get the CD line measurement

- b. ABBA matching for AEI: Measure $A1 \rightarrow B1 \rightarrow B2 \rightarrow A2$ to average be the CD line measurement.

ABBA Matching

$$\frac{A_1 + A_2}{2},$$

$$\frac{B_1 + B_2}{2}$$

Step2: Image Matching - Confirm to image bias

Step3: Numerical Method - Finalizes to hypothesize A value

Step3: Inline production matching (long term) - Finalize to define B value.

In conclusion, the hypothesis testing, short-term and long-term data verification conducted in the paper demonstrates that A and B value across generations in the empirical case presented here.

A case study about N40 ADI CD line shows the result of the innovation such as below
AX+B evaluation is offset assumes CG4000 poly line measurement =0.8nm+S9380
poly line measurement based on table 4, table 5, figure 9 and figure 10.

ABBA	S9380	CG4000
Part I	48.8	48.2
Part II	49.6	49
Part III	50.8	50.4

Table 4: AB Map Matching Data (short-term)

Method to define A=1

Table 5: Inline Production Data (long-term) to define B=0.8nm

Conclusion

We found statistic methodologies including regression model GRR and EWMA to be a potential standard and evidence that wafer design, clean method which reduced the carry over effect in order to monitor long-term and short-term precision of line CD for multiple CD SEM.

We also have presented a data and strategy that was successfully implement at tsmc to monitor and match multiple CD-SEM. Then, those innovations and accomplishments

bring great benefits and values to tsmc. That is not only to minimize CD measurement error from 1nm to 0.3nm (70% improvement), and fulfill tight device requirements shift <1% (69% improvement) and 20% P/T ratio based on ITSR outline, but also triple capacity in CD monitor stages owing to free of restriction in some mis-matched tools.

Diffusion of Innovations

Introduction

Learning and change in health care

Traditional views on the spread and diffusion of knowledge and learning in health care have been criticized as being overly linear, simplified and rational, leading to an often plodding progress of clinical praxis (Ferlie, Fitzgerald, Wood & Hawkins, 2005, and Bhattacharyya, Reeves & Zwarenstein, 2009). Rationalistic perspectives on implementation interventions seem unable to adequately portray the complexity of changing the behaviour of a professionalized organization. There is a great deal of confusion regarding the essential components of practice change and also to what extent health care providers can borrow new practices developed in contexts different to their own.

The scope of implementation science is broad and related questions can therefore be formulated from various perspectives. Based on a systematic literature review Greenhalgh et al. (2004) summarize empirical research studies from across several traditions on different aspects of diffusion of innovations in service organizations. Their results include a conceptual model for considering the determinants of diffusion, dissemination and implementation of innovations in health care organizations. Among the findings are significant aspects of the innovation, the adopter, assimilation, diffusion and dissemination, system antecedents and readiness for innovation, inter organizational networks and collaboration, and the process of implementation. Greenhalgh et al. (2004) state that “a striking finding of this extensive review was the tiny proportion of empirical studies that acknowledged, let alone explicitly set out to study, the complexities of spreading and sustaining innovation in service organizations”.

In a review of literature on organizational learning and knowledge with relevance to public service organizations, Rashman, Withers & Hartley (2009) found that public organizations which operate in a complex policy and political environment constitute an important, distinctive context for the study of learning and knowledge. The primary drivers for learning and innovation in public service organizations are not financially related but derive from demands and expectations by a wide range of stakeholders. Haynes (2005) states that in order for inter-organizational learning to occur in the public sector, a partnership approach is needed between managers, professionals and users. Increasing competition among public service providers might hamper this approach. Rashman et al. (2009) conclude that there continues to be an over-reliance on the private sector as the principal source of understanding and research, and that the concepts of organizational learning and knowledge are under-researched in relation to the public sector.

Change strategies vary and change agents can design their approach taking the context more or less into account. In a very simplistic way change initiatives may be seen as a) top-down, i.e. emerging from a high hierarchical level or central position of the system or organization and from there spreading towards its bottom or periphery, or b) bottom-up, i.e. emerging from some peripheral or lower hierarchy position of the system or organization and from there spreading horizontally and/or upwards in the hierarchy. Initiatives could also use combinations of a) and b), leading to a mixed strategy, which might as well vary over time. The chosen change strategy for a project is assumed to have a high impact on how successful the change initiative will be.

The present study will address some of the challenges discussed above, focusing on how to implement large changes in a dynamic and complex health care environment where several change attempts, initiators and strategies for change coincide. The aim of the study is to describe initial strategies and results when concurrently commencing a regionally initiated but system-wide organizational learning intervention program called the Dynamic and Viable Organization (DVO) in a Swedish county's specialised hospital care with a coinciding national initiative on stopping health care-associated infections (SHAI). The initiatives main focus and goals differed but they shared the aim of achieving organizational learning by increasing staff competence regarding systematic work procedures for improvement, see Figure 1. The questions addressed were if DVO used SHAI to achieve its goals and vice versa and how change agents of DVO and the SHAI improvement teams viewed the situation.

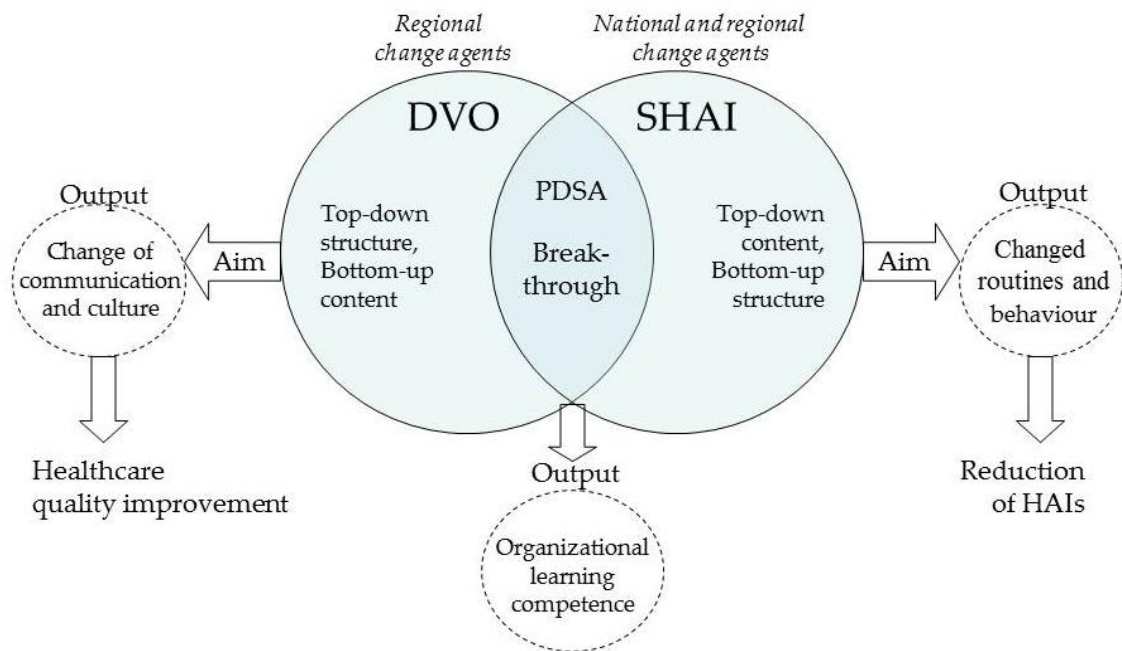

Figure 1 A basic model of the dominant initial strategy, aims, outputs and outcomes of the two studied interventions.

The study is interdisciplinary and forms a part of a Vinnvård financed research program aimed at examining organizational learning and development processes in health care. The research program's intention is to broaden our understanding of when, how and why interventions get implemented, spread and sustained, including the relations between content, context, process and outcome of the change effort.

Method

The present case study of two complex and large interventions implemented in a heterogenic context used triangulation of mainly qualitative data from interviews, questionnaires and documents. Our ambition has been to enable theoretical rather than empirical generalization (Walshe, 2007).

Empirical Setting

The studied Swedish county council serves about 250 000 citizens and has about 10 000 employees. The county council has since 1998 a development unit as a support organization, the process facilitating agency, with coordinators, trainers and mentors focusing on quality related knowledge management and process facilitation for departments and clinics within the county council. At the time of the study PFA had 10

employees and had developed into an improvement resource for the whole county council, focusing on several organisational levels.

The Dynamic and Viable Organisation (DVO)

In 2004 a developmental venture was initiated by top managers and the development unit of the county council. This initiative was named Dynamic and Viable Organization (DVO), a new meso structure intended to be rooted on a middle management level with development groups and with procedural assistance by assigned facilitators from the council's internal support organization and a strategic group of higher management and strategic actors. The new communication and work process structure was launched in 2008, including groupings on different levels (strategic development group, unit development group and improvement teams) as well as communication arenas (Figure 2). It was also decided to make use of a PDSA-based improvement approach with the aim to increase the organisation's ability to transfer knowledge into practice and transform limited subsystems views to a holistic system view by a change process based on learning. The goals included building a learning culture, increasing competence in systematic ways to work with improvement (PDSA), competence for several management levels in motivating, setting goals, coordinating, supporting, and following-up improvement work of teams.

The design of the change process for implementing DVO had been inspired by models and theories developed at the Institute for Healthcare Improvement (IHI) and by Idealized Design of Clinical Practice (Moen, 2002) with the aim to enhance system wide change.

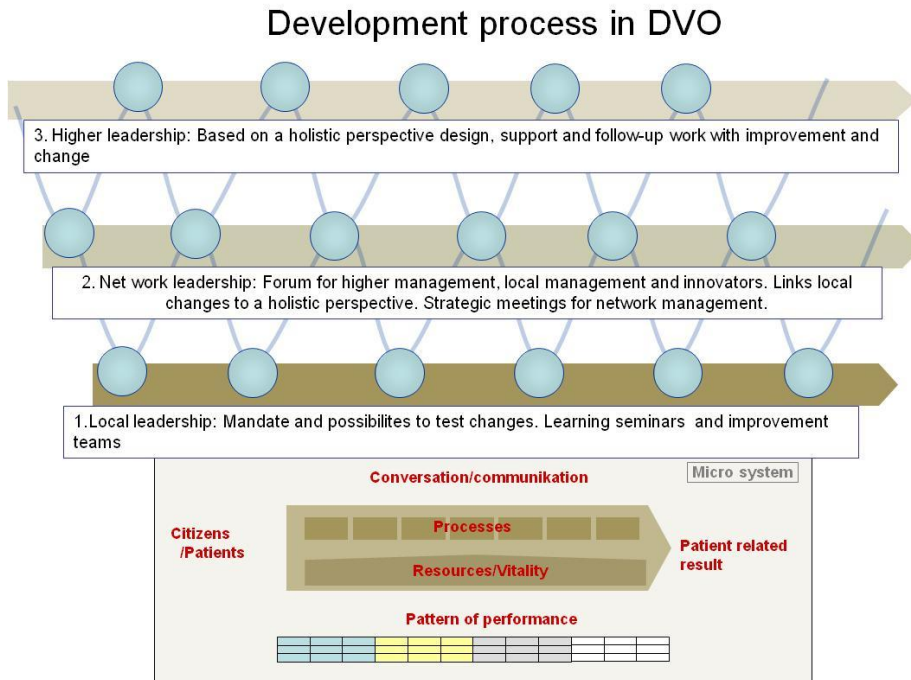

Figure 2 The structure and process of the Dynamic and Viable Organization

Thus, the original approach of PFA, which focused on local initiatives based on willingness to participate in development, was enlarged to incorporate additional managerial levels and a strategic group which included actors responsible for medical care, economy and staff. Forums dedicated to dialogue and the spread of good experiences were planned at micro, meso and macro system levels. The intention was to facilitate a two way communication between the parts and the whole of the system and thereby increase understanding and learning.

DVO and the IHI Breakthrough model

The Breakthrough model implies that ideas and new approaches are tested on a small scale and then evaluated and either abandoned or made permanent and disseminated, depending on the results. By doing so, theory and knowledge are put into practice. The goals should be clear, challenging and possible to measure. Coaches and support should be available, but the work is supposed to add a great deal of responsibility on the participating teams and organizations to learn by doing things themselves.

The model of improvement used by the teams and supported by the process facilitators consists of three central questions and the PDSA-circle for small-step testing of changes, see Figure 3. The innovation process is intended to provoke new ideas,

stimulate participants of the improvement teams to test their ideas and then also share their experiences of the experimentation.

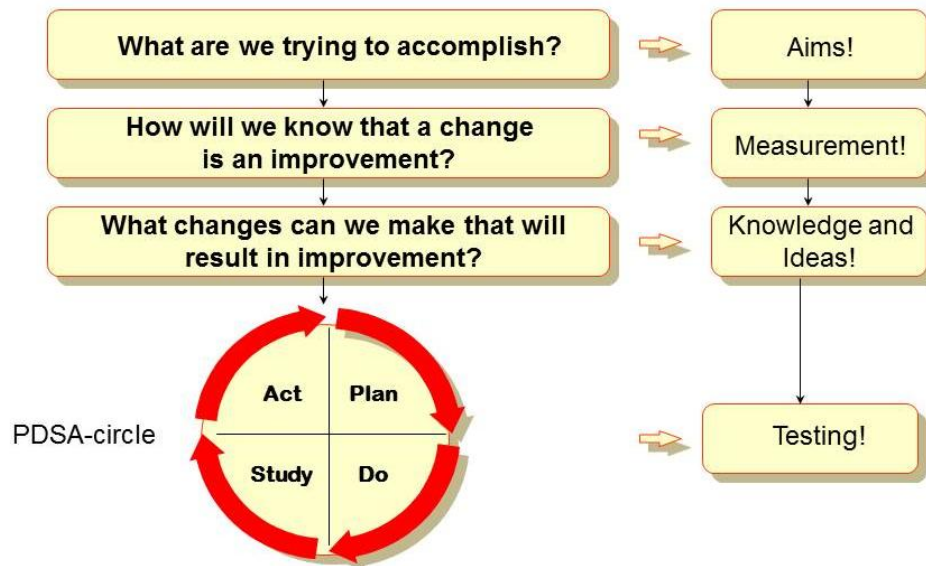

Figure 3 Model of improvement, derived by PFA from Deming (1986) and Langley GL, Nolan KM, Nolan TW, Norman CL, Provost LP. *The Improvement Guide: A Practical Approach to Enhancing Organizational Performance* (1996).

National initiatives to stop health care-associated infections (SHAI)

Health care-associated infections (HAIs) are a major problem worldwide, leading to increased mortality and morbidity for patients and higher cost of care (Centers for Disease Control and Prevention, 2002; Burke, 2003). Improving hygiene among health care workers is an essential intervention in preventing HAIs. However, despite the very well-known positive effect of good hygiene, compliance among healthcare professionals remains low (Larson, Albrecht, & O’Keefe, 2005; Whitby, McLaws, and Ross, 2006) and interventions to improve hygiene have only small or temporary effect on actual behaviour (Beggs et al., 2006; Sacar et al., 2006).

In 2004 the first SHAI-program was initiated in Sweden, which lasted for about one year. In total 21 multi professional improvement teams from different parts of the country participated, representing many specialities. Before the start an expert group was invited to describe state of the art in terms of HAIs reduction and to suggest the

best strategy to get there. In 2005 the second round of SHAI was launched, with the National Board of Health and Welfare as one of the arrangers (Wallin, 2007). Also this time 21 teams were involved. In order to participate the health care organizations were required to form a cross professional team including a physician, and to have active support from their unit managers. Unlike the first round municipalities were now represented among the participants.

SHAI and the IHI Breakthrough model

All SHAI programs were performed using a similar structure, in both cases consisting of three learning seminars for the improvement teams with work periods in between where changes were tested and spread, finishing with a conference. The teams had access to their own web based work places where they could also report and locally read about each other's results. During these projects the Swedish Association of Local Authorities and Regions (SALAR) offered help and support, for instance regarding guidance on the use of different methods.

The purpose of using the Breakthrough model in SHAI, was pointed out by SALAR as twofold: First, the participating teams and organizations should reach their HAI-related project goals by applying the method. Second, they should learn and internalize the method so that they – and the organization – after the project / learning period, may apply it to new and other areas.

SHAI – Local intervention and process of implementation

In the spring of 2008 all clinics in the studied County council were supposed to participate in a national wide measure of HAI prevalence. Those who wanted could also participate in a SHAI intervention, using the Breakthrough model. In the studied organisation twelve clinics chose to participate in the intervention using the Breakthrough model. The projects lasted for a year and were conducted in collaboration with SALAR, the County council's units for infection control and patient safety and PFA, i.e. the support organization. As in previous national SHAI initiatives, the primary focus was on eliminating incidence of healthcare associated infections. A specific goal identified was to halve the number of HAI. Each team had to write monthly reports and also a final report at the end of the project.

Data collection and analyses

Several different sources of data have been used as a basis for the analysis regarding progress and results, see Table 1.

Table 1 Data sources used in the analysis

		2007	2008	2009
Survey	Improvement teams		x	x
Observations	Learning seminars	x	x	
	Process facilitator meetings	x	x	x
	DVO forum	x	x	x
Archival data	Agendas, documents, presentations, team reports	x	x	x
Interviews	Process facilitators	x	x	x
Process diaries	Process facilitators	x	x	x

Data analyses of team reports

In the autumn of 2009 a review was made of all final reports and parts of the monthly reports from the studied SHAI projects. Preliminary categories for classification of material were created and a tentative summary of final reports from participating clinics was presented and thoroughly discussed within the research team. On the basis of this discussion the following categories of analysis were used:

Number of team members	Factors hindering the change of work procedures
Number of represented professions	Factors facilitating change of work procedures
Managers involved	Previous experience of Breakthrough models
Compliance to hygiene routines	Reflections
Compliance to clothing routines	Type of source
Patient related measurements	Goal fulfilment

Data was processed and analysed with the purpose of finding themes and patterns. Results were then compared and variation and deviation were noted. Finally, a report summary was made.

Data analyses of process diaries and interviews

To gain an overall conceptualization of process facilitators' main focus, strategic considerations, perceived challenges to manage etc. during the period (late 2007-mid

2009), interviews and process diaries from the process facilitators have been screened and main content areas has been identified.

Descriptions of essential/crucial elements, conditions, activities, events (i.e. determinants) and to these, linked strategic plans or actions, when launching DVO and simultaneously taking on the mission to support top-down initiated SHAI has been sorted out, analysed and interpreted as a whole – i.e. render in an overall description of the main reasoning of process facilitators during the period. Through this content screening and analysis, we also aimed to reveal the existence, or nonexistence, of indications on strategies being used to incorporate aspects of the SHAI initiative into the DVO-intervention, or vice versa.

Based on content, frequency of statements and comments on crucial elements, activities, events, conditions and strategic changes when launching DVO and/or managing SHAI where sorted as:

- *Strong indication:* frequently repeated, given by more than 75% of the respondents and originating from more than one data source
- *Medium indication:* often occurring statements/units mentioned by at least 50% of the respondents
- *Weak indication:* occasional, sporadic or implicit statements.

Data analyses of improvement team questionnaires

Based on a literature review of organizational change, learning and quality improvement together with a study of six successful organizational case studies Nyström (2009) has developed a model called CAOLD (Characteristics Associated with Organizational Learning and Development). This model formed the base for the closed questions posted in the questionnaires as well as the base for analyses.

The original CAOLD model covered 20 characteristics divided into three main areas: A) Organisational system, B) Key actors and C) Change management processes. In this study focus were on five of these characteristics, see Table 2. The total questionnaire consisted of 35 statements related to these areas and characteristics, to be judged on a scale from 0 (do not at all apply to the current situation) to 5 (fits the current situation very well). The five characteristics of primary interest in this study, where captured in 11 of the closed questions in the questionnaires.

Table 2 Studied characteristics of the CAOLD model

Staff motivation and commitment
Staff cooperation and team work
Encourage experimentation and quick pilot tests of ideas
Systematically use a Plan-Do-Check-Act (PDCA) cycle ^{12,33} or equivalent
Enhance sustainability by incorporating successful changes into organizational structures and processes

The two identical surveys were intended to explore changes over time in staff response to the selected aspects/characteristics of the CAOLD model.

Results

Structure, strategy and content

The regionally developed DVO had initially a clearly stated bottom-up and emergent design regarding what issues the different development groups and improvement teams were about to work with (Figure 1). On the other hand, the organizational structure and strategy of DVO was defined before the program was launched and thereafter described and disseminated during several so called strategic forums.

The nationally initiated SHAI had a clearly stated agenda regarding what issues the teams were intended to work with (Figure 1). These issues were introduced during learning seminars, where also the IHI Breakthrough approach was initiated and used, i.e. the strategy was very well defined from the start. The SHAI concept included guidelines and templates for minutes, data presentation and reports but was not as specific with regard to the organizational structure supposed to carry out the intervention.

Prior to the study the process facilitators had been primarily focusing on a micro system perspective when working with change teams at specific units and clinics.

The focus of process facilitators during the initial implementation of DVO

There were *strong indications* that the group of process facilitators focused on the core thoughts and strategies within DVO (the left side of figure 1). The most urgent achievement and central area of concern seemed to be:

- Helping clinics define their own areas of improvement, i.e. define clinic specific needs
 - Participants view themselves as owners of their improvement processes
- A structure for communication, policy deployment and reporting is established, centred around a design group, multi professional development groups and improvement teams at each clinic
- Participation in learning seminars and strategic forums for dissemination, spreading ideas, sharing information and providing motivation and inspiration
- Structuring the micro level improvement work according to the PDCA-cycle (with small scale testing etc.).

There were *medium indications* that the mission of process facilitators was perceived as un-clear. Expectations on what ought to be supported and done were not explicitly defined (neither from a management level nor within the group of process facilitators).

When top down SHAI arise, the process facilitators (to varying degrees) supported their clinics in creating the improvement team (for SHAI), getting the picture of present status at the clinic (regarding HAI), defining adequate goals and related measurements and in other ways help the clinics in gaining structure and systematic improvement work. They also supported the clinics in the process to systematically report on progress and results on the established website, that all clinics had access to and were supposed to retrieve information and inspiration from. Participation in learning seminars (SHAI) is spoken of as high as all teams were represented in all learning seminars.

Potential strategies on how to handle and combine DVO and SHAI did receive far less attention. Even though the issue with staff perceiving DVO as a project “owned” by others but themselves how to design the mission accordingly to each clinics’ specific needs were discussed, a strategic plan for these aspects were not discussed, and thus seemed to be missing. The issue of how to use the DVO-approach when working with “top-down” initiatives in general did arise and was briefly discussed.

However, there were *medium to strong indications* that the group of process facilitators used the SHAI initiative to help clinics structure their improvement work according to the thoughts in DVO (structuring the micro level improvement work according to the PDCA-cycle). The gap between the initial idea with DVO, that areas for improvement and development should be identified by the involved staff themselves, and the top-down initiated SHAI initiative was not discussed strategically or explicitly managed.

Nor were there any indications that a strategic discussion on how to make use of the SHAI initiative to achieve goal effectiveness in DVO (or vice versa) took place.

There were some indications that the group of process facilitators noted a potential setback for the DVO-progress when taking on the SHAI initiative. There were weak indications that members of the group even saw the SHAI initiative as a reason to “put DVO on hold”.

Effects on improvements teams’ competence in working with systematic improvement procedures based on questionnaires

The effects on the improvement teams’ competence in working with systematic improvement procedures were captured by use of eleven of the closed questions of the repeated CAOLD model questionnaire regarding the five model factors outlined above.

Results from the questionnaire indicated that the clinics’ capacity to work systematically with improvements had increased during the period regarding small scale testing and working according to the PDSA-cycle. The questionnaires also indicated positive changes in how well the clinics managed to enhance sustainability by incorporating successful changes into organizational structures and processes and that staff motivation and learning style had changed. There seemed to be no changes when it came to the clinics capacities to work in teams.

Effects related to knowledge and learning based on team reports

Many respondents stated explicitly that the measurements conducted as a result of their involvement in SHAI projects had been contributing significantly to a reduction of so called hidden statistics. Previous tacit knowledge had become explicit, aided by graphs and tables providing clear descriptions of the situation within the clinic. Respondents claimed that the systematic measurements performed centred attention to problematic areas and areas with high improvement potential, lead to increased awareness, development of new knowledge and a greater focus on problem solving at staff level.

When it came to the studied teams’ reflections regarding the Breakthrough-approach as a method, there were also recurring themes. The Breakthrough approach was described as contributing to an increased degree of reflection and discussion. It was also thought to encourage networking, both when it came to collaboration across professional

boundaries and in the sense that it included knowledge sharing and the exchange of experiences with colleagues in other clinics.

The learning seminars that had been arranged were found to provide new energy and also incentives to keep on working within the project. Many teams reported that they were surprised by the results of the measurements performed, for instance by discovering that HAI occurred more frequently than they had thought previously.

Effects related to behaviour and HAI based on team reports

In many teams, compliance to routines regarding clothing and hygiene had increased slightly over time. However, in some of the teams initial gains had started to deteriorate at the end of the measuring period. Physicians were clearly overrepresented in the group of professionals that are described as having difficulties following health regulations.

In many cases the patient related results presented in the teams' final reports did not show clear trends of improvement. The improvements that may be discerned in some of the graphs in the reports were in many cases over-stated by the teams.

Problems and hindrances identified based on team reports and questionnaires

A large majority of the respondents stated that too little time was provided for the completion of the SHAI projects. The projects had been more time consuming than the respondents had imagined and expected from the start. Working with preventing HAI was reported as having a low priority and in some cases the respondents stated that it had been difficult to get their managers support for the implementation of the SHAI initiative.

There were several similar and parallel activities going on at the same time as SHAI within the county and the respondents reported that it had been difficult to find energy and engagement in relation to all the on-going activities. A common reflection among the respondents was that it had been unfortunate and ill-timed to launch the SHAI projects just before vacations had started, when the level of inspiration and motivation might be lower than usual.

Several respondents expressed a feeling of having been forced to engage in the SHAI projects, and with short notice. It was argued that too few did participate from each clinic, making it more difficult to disseminate the results and make an impact among all

employees. Some had experienced problems due to the fact that some measurements and goals had not been developed or agreed upon within the clinic.

Lack of computer experience was stated as a big problem in many clinics. The approach involved extensive documentation, which was also perceived as problematic. Lack of writing skills was mentioned by several teams as a problem. Negative or ignorant attitudes among physicians were pointed out as a concern in some cases.

In terms of the common organizational learning processes described by Rashman et al. (2009) the SHAI projects were characterized by shared understandings and perspectives at a group level through communication and interaction. Diffusion via organizational routines was also present but the individual perspective and embedding of learning was much less apparent.

Discussion

During the first year of the DVO implementation, there were no clear indications that the two initiatives of DVO and SHAI were strategically combined in order to let any of them benefit from each other. The core idea of DVO – the bottom-up approach regarding the selection of areas for improvement – was being put on hold, or was being breached, when the top-down SHAI initiative arise. The process facilitator group was obligated, and tried to support the work of the clinics within the SHAI initiative, but DVO and SHAI continued to be viewed upon as two separate and somewhat incompatible efforts. Working strategically with the progress of DVO, in terms of changing the culture and individual and unit based learning styles was temporarily put on hold, since its essential elements were based on a bottom-up approach. Some progress was reached during the period when it came to the goal shared by both initiatives; improving staff competence in working systematically according to the Breakthrough model including the PDSA cycle.

Thus, our in-depth analysis of the data indicates that in the early stage comprehensive management strategies to utilize the national SHAI initiative and its resources were partially lacking. Instead the initiative was regarded by many of the respondents as a strictly top-down project with little room for contextual adaptation regarding its content or strategy. The newly developed structure of DVO was used when implementing SHAI.

In terms of organizational learning the SHAI projects were characterized by shared understandings at a group level and dissemination of innovations via organizational routines. In hindsight it was argued that the national initiative could have benefited from a stronger incorporation with DVO, especially for reducing content focus and overriding of process knowledge building, thereby increasing adopter motivation and managerial support for solutions and insights. Process facilitators played a key role in enabling this organizational learning, and at the following stages the building of improvement competence on different organizational levels, the sense-making activities provided and the national support structures available for measurement and feedback were used to pursue DVO related goals of reducing fragmentation and enhancing capability to handle complexity.

It is important to realize that the data collection was performed during the early stages of the DVO implementation (the main part gathered during 2008 and 2009) and SHAI was the first national initiative for the DVO approach to handle. Since then the DVO initiative in the county has been enlarged and also incorporated and used several national Break through initiatives in order to enhance the DVO approach. The organization has also scored high or medium high on many of the factors related to a learning organization in the CAOLD model.

Taking initiatives to change the way organisations work are well known to be difficult endeavours. A general conclusion of our study is the need to recognize intermediate phases when moving from knowledge to practice and when designing studies evaluating effects of change initiatives in health care. Our contention is that if treating these processes as “black boxes” then potentially important information might be lost. Instead it is important to acknowledge the relations between evidence based knowledge, innovative/creative processes of producing and selecting interventions, interventions design, the choice of implementation process and its effects on sustainability, the learning-in-context by professionals and its connection to sustainability, the cognitive processes involved in learning and behavioural change and effects on health.

Acknowledgement

We are grateful to the participants for sharing their time and experience and also to the Vinnvård Research Program (www.vinnvard.se) for the financial support enabling this study to be performed.

Key words: Entrepreneurship, education, multidisciplinary, innovation, teaching methodology

Category: Research paper

Introduction

Since Myles Mace taught the first entrepreneurship course at Harvard Business School in 1947 (Katz, 2003) the number of education programs designed to instill entrepreneurial spirit and ultimately boost new firm creation has continued to grow, leading one author to claim that “the younger generation of the 21st century is becoming the most entrepreneurial generation since the Industrial Revolution” (Kuratko, 2005, p. 578).

This proliferation of entrepreneurship education programs is a consequence of the positive effects that entrepreneurship has in terms of economic growth and job creation (Audretsch, 2002) as well as the recognition that entrepreneurship education has now reached full maturity (Katz, 2008) and is close to gaining full legitimacy (Kuratko, 2005) as a scientific and academic discipline.

On the other hand, the profound changes affecting the economy, the technological revolution, and the social and environmental crisis, among other aspects, are generating greater levels of uncertainty and even ‘unknowability’. Thus educators need to profoundly rethink the methods and approaches they use in the University (Neck & Greene, 2011; Bechard & Gregorie, 2005; Fiet, 2001). In the same line, “entrepreneurship within a formal education structure requires a new approach based on action and practice” (Neck & Greene, 2011, p. 68).

But despite this huge growth in entrepreneurship education, particularly in the universities, researchers have shown relatively little interest in identifying the benefits that students gain from participating in these programs (Peterman & Kennedy, 2003; Athayde, 2009).

In this context, a group of professors at the University of La Laguna (Spain) conducted a project to test an innovative methodology for teaching entrepreneurship. The project involved the drawing up of business plans by multidisciplinary teams of students studying for degrees in chemical engineering, industrial engineering, computer engineering and business management. In the current work, the authors present the methodology they followed and the main results from the evaluation of the impact of participating in the project among the students. They offer their main conclusions from the experiment and suggest possible improvements for the future. The authors first contextualize the initiative by offering a diagnosis of the current state of entrepreneurship education and the role universities play in it.

Entrepreneurship education and the university’s role

The importance of the entrepreneur and entrepreneurship in the real world are increasingly difficult to ignore (Wennekers & Thurik, 1999), which can be explained on the basis of an “emerging economic environment created by the confluence of changes in the corporate world, new technology, and emerging world markets” (Fiet, 2001, p. 102).

Nevertheless, entrepreneurship is more than the mere creation of a business, and although that is certainly an important facet it is not the whole picture. The characteristics of seeking opportunities, taking risks beyond security, and having the tenacity to push an idea through to reality combine into a special perspective that permeates entrepreneurs (Kuratko, 2005). Entrepreneurship can be defined as “the

pursuit of opportunity beyond the resources you currently control (Stevenson, 1983, 1985; Stevenson & Jarillo, 1990; World Economic Forum, 2009).

According to this perspective, entrepreneurs are shaped by their experiences, during which they try to make the right choices. Thus entrepreneurship can be understood as a process of learning, and a theory of entrepreneurship requires a theory of learning (Minniti & Bygrave, 2001). Clearly, what is learned may be false: entrepreneurs may fail. But entrepreneurs, like all individuals, also learn from their failures and the key question about entrepreneurship is not who the entrepreneur is, but what he/she does (DeTienne & Chandler, 2004; Gartner, 1988). Entrepreneurship can even be understood as “a method of human action, comparable to social forces such democracy and the scientific method” (Wiklund et al. 2011; Sarasvathy & Venkataraman, 2011).

Just as entrepreneurship can be learned, “most of the empirical studies surveyed indicated that entrepreneurship can be taught, or at least encouraged, by entrepreneurship education” (Gorman, Hanlon, & King, 1997, p. 63). The possibility of learning entrepreneurship is clear not only in the later, more technical, stages of the entrepreneurial process—such as the elaboration of the business plan—but even in the initial stages when the innovative ideas are generated (DeTienne & Chandler, 2004). Considerable debate exists about the most appropriate pedagogical models for teaching entrepreneurship (Neck & Greene, 2011; Honig, 2004).

The conviction that entrepreneurship can be taught has driven the growth in the number of colleges and universities offering courses teaching some aspects of entrepreneurship from a handful in the 1970s to 1,600 at the dawn of the new millennium (Katz, 2003). A fierce competition has grown up among these institutions, and a number of researchers have compared the content and quality of their courses (Vesper & Gartner, 1997; Gartner & Vesper, 1994). More importantly, the academic legitimacy of the field of entrepreneurship has now almost been consolidated (Kuratko, 2005). In parallel, the conviction exists that “entrepreneurship education is essential for developing the human capital necessary for the society of the future. It is not enough to add entrepreneurship on the perimeter – it needs to be central to the way education operates” (World Economic Forum, 2009, p. 15).

According to Kuratko (2005), the question is not whether entrepreneurship can be taught, but what should be taught and how it should be taught (Honig, 2004; Fiet, 2001). Thus educational institutions at all levels (primary, secondary and higher education) should adopt 21st century methods and tools to develop the appropriate learning

environment for encouraging creativity, innovation and the ability to “think out of the box” to solve problems (World Economic Forum, 2009).

Thus educational systems need a fundamental rethinking to bring their contents closer to real life. Theory should always be applicable, and “[i]f we fail to teach our students how to apply it in surprising ways, it is we who are at fault, not the theory” (Fiet, 2001, p. 101). Thus in recent decades, with experiments in entrepreneurship education accumulating, came the realization that one of the basic lines of development needs to be research into the teaching methods commonly used in entrepreneurship programs (Kuratko, 2005; Zeithaml & Rice, 1987).

Researchers have observed the benefits of participating in programs to promote entrepreneurial spirit among university students in terms of their level of entrepreneurial vocation (Athayde, 2009; Harris & Gibson, 2008; Peterman & Kennedy, 2003). According to Rodrigues et al. (2010), entrepreneurship education is the most important factor explaining propensity for business creation, over and above aspects such as personal, family and demographic attributes.

The above is particularly important in the context of higher education in Europe, given the conclusions of a study from The Commission of The European Communities (2008) among 664 higher-education institutions:

- Less than half of university students have access to some type of initiative related to the development of entrepreneurial spirit.
- European universities are trailing far behind US and Canadian universities in this area.
- Very little cooperation takes place between institutions to exchange good practices.
- Most institutions allocate less than €50 per student per year to promoting entrepreneurial spirit.
- It is necessary to agree on a more inclusive definition of what is understood by entrepreneurial education.

In this context, it is essential to promote entrepreneurship education. Educational institutions in general, and universities in particular, have to play a key role in this as fundamental elements in the configuration of the “entrepreneurial ecosystem”, since they contribute to “shaping young people’s attitudes, skills and behaviors” (World Economic Forum, 2009, p. 15). The aim should therefore be to consolidate the tendency to include entrepreneurship in the curriculum in higher education that started at the end

of the last century (Katz, 2003), and to evaluate and learn from the many initiatives that have taken place (see e.g., Dévora, 2010).

A Practical initiative: multidisciplinary teams of university students

A group of professors at the University of La Laguna (Spain) who teach four courses from four different degree programs in business management and the engineering sciences carried out a project to test an innovative methodology for teaching entrepreneurship and inculcating entrepreneurial spirit among the students. The project involved setting up multidisciplinary teams of students to draw up business projects on the basis of an idea. The starting point for the project was the following ideas about the role and potential of entrepreneurship education in the University:

- Entrepreneurship education could offer a broad, integrative, pragmatic, and rational approach to business, avoiding the problem of the continued increasing fragmentation of business education into narrow specializations (Kuratko, 2005; Zeithaml & Rice, 1987).
- On the other hand, teaching entrepreneurship requires a multidimensional and cross-disciplinary approach with an emphasis on dynamic processes (Fayolle, 2007). In this respect, Kuratko (2005, p. 584) notes the trend in “new interdisciplinary programs that use faculty teams to develop programs for the nonbusiness students”. For this, universities need to change their structures with regard to their entrepreneurship classes, because they only offer these classes to students from one or sometimes two disciplines (Fayolle, 2007).

Description and objectives of project

The project consisted of the drawing up and subsequent presentation and defense of business plans by interdisciplinary groups of final-year students on various degree courses at the University of La Laguna. The business plans were based on business opportunities detected in the environment. The objectives of this project were as follows:

- To teach entrepreneurship and promote entrepreneurial spirit among the university students.
- To show the students the utility of the knowledge they had gained during their courses and help provide them with an eminently practical focus adapted to solving real needs.

- To promote initiatives and attitudes among the students focused on problem solving, providing them a channel through which to develop their knowledge and ideas in a business environment.
- To promote cooperative team-work and the exchange of ideas and experiences among students studying different degrees, encouraging an interdisciplinary approach to problem solving.
- To facilitate interrelation between professors and the creation of interdisciplinary teams of professors, as well as the exchange of perspectives on teaching methodologies.

The professors formed multidisciplinary teams consisting of two distinct sets of students: first, students studying one, and not more than one, of either computer, chemical or industrial engineering; and second, business management students. The idea was that they work together to develop a business idea and draw up a business plan. The students coming from the scientific-technical areas would conceivably contribute a more technical and operational perspective to the project, while the business management students would offer the vision and conceptualization of the business, support in the market research, and above all the economic-financial analysis. The business management students would be acting as “business consultants”, advising the scientific-technical students in the development of the business plan.

The four professors teaching the courses participated in the project. Of the 217 students registered on the four courses, a little over half (109) were studying one of the engineering degrees and the rest were studying business management. A total of 12 interdisciplinary teams of students were established. The teams ranged in size from 11 to 20 members, with a mean of 16.

After four months the results of the project were evaluated. For this, the professors drew up a questionnaire to measure participating students’ satisfaction with and evaluation of the project. The next section describes this evaluation process and the main results obtained.

Methodology of evaluation

For the evaluation process a questionnaire was drawn up. The questionnaire had its basis, on the one hand, on the dimensions for assessing the quality of a project for testing an innovative teaching methodology for entrepreneurship, and on the other, on

the attributes defining entrepreneurial activity according to the Annual Report of the GEM Spain project (De la Vega et al, 2009).

With regard to the quality of the project, and following Mauri, Coll and Onrubia (2007), the questionnaire considered four dimensions: implementation of the project; results of learning; fundamental elements of the innovative methodology; and degree of satisfaction. The next step involved establishing a set of indicators to define each dimension of the construct. These variables made up the questionnaire sent to the students participating in the project. Table I presents the items grouped into the four main dimensions.

Table I. Quality of project to test innovative teaching methodology

Implementation of project
I1 The professor informed us at the beginning of the course how the project was going to proceed (objectives, content, methodology, evaluation, duration...)
I2 The initially established deadlines for the project were met
I3 The professor resolved any doubts we had during the project clearly and quickly
Results of learning
I4 Participating in the project has helped improve my understanding of the contents of this course
I5 After participating in this project I now understand the business environment better
I6 Participating in this project has allowed me to apply what I have learnt in this course to the business reality, orienting my knowledge to the solution of real problems
I7 After participating in this project I am more likely to start a business at some time in the future
I8 This project has enabled cooperation with students from other degrees, which has given me a new perspective in the solving of real problems
Fundamental elements of innovative methodology
I9 The structure of the project was clear, logical and organized
I10 The professor gave a clear explanation of the concepts involved in the implementation of the project
I11 Working on the project has provided us with motivation and interest in the course
I12 The teamwork with classmates from my degree was fruitful and stimulating
I13 The teamwork with classmates from other degrees was fruitful and stimulating
I14 The material recommended (bibliography, documentation, transparencies, etc.) helped us carry out the work and was easily accessible
I15 The virtual classroom and the information and communication technologies were adequate and useful in doing the work
I16 I think the evaluation criteria and the weight of the project in the total grade for the course are about right
Degree of satisfaction
I17 In general, I am satisfied with how the practical work went

I18 In general, I am satisfied with the professor's support of the practical work
I19 I think I learnt a lot from doing this work and it will be useful for my education
I20 Doing this work meant that this course required more effort than the other courses

The population object of study consisted of all students officially registered, in January 2011, on one of the following courses as part of their degrees: Management Accounting (MA); Computer Systems Management (CSM); Business Administration and Organization of Production (BAOP); or Economics and Industrial Organization (EIO). According to data from the Office for Analysis and Planning at the University of La Laguna the total number of students officially registered on these courses at that time was 217.

For the data collection the professors of these courses uploaded the questionnaire onto the corresponding Virtual Classroom at the end of the first four-month term of the academic year 2010-2011, after the students took their exams but before they learned their grades in order to encourage greater homogeneity and objectivity in the responses. The professors received 126 validly completed questionnaires, which represents a response rate of 63%. Table II shows the response rate in each course.

Table II. Composition of population and sample size

COURSE	Degree	No. students registered	No. questionnaires	Response rate
Management Accounting (MA)	Business Management	104	48	46%
Computer Systems Management (CSM)	Computer Engineering	30	15	50%
Business Administration and Organization of Production (BAOP)	Industrial Engineering	62	46	74%
Economics and Industrial Organization (EIO)	Chemical Engineering	21	17	81%
Total		217	126	63%

The information collected was codified and stored in a database for subsequent treatment (preliminary analysis of data quality and replacement of absent data by the mean of the series using the statistics program SPSS 19.0). The statistical analysis of the data followed, and the following subsections look at the results.

The SPSS 19.0 program was used to analyze the validity and reliability of the measurement scale used to measure the quality of the project to test the innovative methodology in entrepreneurship education. After confirming the normality and linearity, the Cronbach alpha coefficient was calculated to evaluate the internal

consistency of the indicators of each latent variable. The results show that each set of observed variables is representative of its corresponding factor, since values close to or exceeding 0.6 are considered acceptable in exploratory analyses (Hair et al., 1999). Thus for Implementation of project and Degree of satisfaction this statistic is lower than 0.6 but remains acceptable because it exceeds the minimum of 0.5 (0.504 and 0.545, respectively). For the other two dimensions—Results of learning and Fundamental elements of innovative methodology—the statistic gives higher values (0.654 and 0.756, respectively). The Cronbach alpha for the whole scale is 0.858, which means that the questionnaire is reliable as a whole. Finally, with regard to the discriminant validity, for a 95% confidence interval the correlation between each pair of latent variables does not contain the value 1. The variables are not perfectly correlated, so they each represent a distinct concept.

Results

The authors now look at the main results. They first analyze the four dimensions defining the quality of the teaching innovation in entrepreneurship, using the questionnaire described and validated previously. They then evaluate the predisposition to engage in entrepreneurship among the students participating in the project in comparison to the population in general according to data from GEM.

Implementation of project

The results in Table III show that the students thought highly about the aspects relating to the implementation of the project. More than 90% select the most favorable responses (agree or strongly agree) in the case of items I1 (The professor informed us at the beginning of the course how the project was going to proceed) and I3 (The professor resolved any doubts we had during the project clearly and quickly). The students are less positive about item I2 (The initially established deadlines for the project were met): 27% opt for the least favorable responses (strongly disagree or disagree). Looking at the results by degree, these students are studying the courses MA and BAOP, their work teams have the most members and they provide the most questionnaires (see Table II).

With regard to this latter item, the authors should note that the limitations due to the time available and the number of participating students were an enormous obstacle to the organization of the work groups, so that in some cases (MA and BAOP) the professors had to establish big groups (average of 16 students per group). This led to

some loss of control on the part of the professors and a reduced capacity of interaction or feedback between professors and students and between students.

Table III. Evaluation of Implementation of project (%)

Implementation of project	Strongly disagree	Disagree	Neither disagree/nor agree	Agree	Strongly agree
I1. The professor informed us at the beginning of the course how the project was going to proceed (objectives, content, methodology, evaluation, duration...)	-	2.4	2.4	50.4	44.8
I2. The initially established deadlines for the project were met	5.6	21.8	12.1	41.9	18.5
I3. The professor resolved any doubts we had during the project clearly and quickly	-	3.2	6.4	40.8	49.6

Results of learning

Table IV shows the proportion of students selecting each of the five options in the questionnaire from strongly disagree to strongly agree. In general, the students participating in the project have a very positive opinion about the results of their learning. This is particularly the case in the aspects to do with understanding of contents (I4), knowledge of the business environment (I5), and application of learning to solving real business problems (I6). At the same time, with regard to the promotion of entrepreneurial spirit (I7), 44% of the students manifest a clear predisposition toward entrepreneurship in the future, with 28.8% and 15.2% responding agree and strongly agree, respectively.

In contrast, it is striking to see that 23.8% of the students have a very unfavorable opinion about the interdisciplinary nature of the project (item I8: This project has enabled cooperation with students from other degrees, which has given me a new perspective in the solving of real problems). The large group sizes and the separation between education centers (the students participating in the project came from two different university campuses) put enormous difficulties in the way of the normal development of the work. The authors consider that they are the main reasons for this result.

Table IV. Evaluation of Results of learning (%)

Results of learning	Strongly disagree	Disagree	Neither disagree/ nor agree	Agree	Strongly agree
I4. Participating in the project has helped improve my understanding of the contents of this course	0.8	3.2	9.6	55.2	31.2
I5. After participating in this project I now understand the business environment better	0.8	3.2	12.0	56.0	28.0
I6. Participating in this project has allowed me to apply what I have learnt in this course to the business reality, orienting my knowledge to the solution of real problems	-	4.8	20.0	51.2	24.0
I7. After participating in this project I am more likely to start a business at some time in the future	5.6	12.8	37.6	28.8	15.2
I8. This project has enabled cooperation with students from other degrees, which has given me a new perspective in the solving of real problems	23.8	12.7	24.6	30.2	8.7

Fundamental elements of innovative methodology

This dimension consists of aspects to do with: the organization and methodology of the work; the team work; the teaching materials; the use of ICT; and the evaluation of the learning. In general, the respondents have a very favorable opinion about the elements of the innovative methodology. Table V shows that nearly 80% respond agree or strongly agree in all but two cases. The respondents have a slightly less favorable opinion about item I14 (The material recommended helped us carry out the work and was easily accessible).

Table V. Evaluation of Fundamental elements of innovative methodology (%)

Fundamental elements of innovative methodology	Strongly disagree	Disagree	Neither disagree/ nor agree	Agree	Strongly agree
I9. The structure of the project was clear, logical and organized	0.8	6.4	14.4	61.6	16.8
I10. The professor gave a clear explanation of the concepts involved in the development of	-	6.5	13	56.9	23.6

the project					
I11. Working on the project has provided us with motivation and interest in the course	1.6	2.5	13.1	64.8	18
I12. The teamwork with classmates from my degree was fruitful and stimulating	1.6	5.6	12.9	44.4	35.5
I13. The teamwork with classmates from other degrees was fruitful and stimulating	32.8	19.7	30.3	13.9	3.3
I14. The material recommended (bibliography, documentation, transparencies, etc.) helped us carry out the work and was easily accessible	1.6	8.0	24.0	52.0	14.4
I15. The virtual classroom and the information and communication technologies were adequate and useful in doing the work	0.8	2.4	9.6	52.8	34.4
I16. I think the evaluation criteria and the weight of the project in the total grade for the course are about right	1.6	8.9	12.2	53.7	23.6

In addition, 32.8% of the students have a very unfavorable opinion about item I13 (The teamwork with classmates from other degrees was fruitful and stimulating). Looking at this result, a connection exists with that of item I8 (This project has enabled cooperation with students from other degrees, which has given me a new perspective in the solving of real problems). These two results point to potential improvements to the project in future years.

Degree of satisfaction

The students participating in the project are very satisfied with the development of the business plan (I17), the support of the professor (I18), and the utility of the knowledge acquired (I19). This in spite of the fact that the majority consider that carrying out the project meant that the course demanded more effort than the rest of the courses (I20). Table VI shows the main results for the degree of satisfaction.

Table VI. Evaluation of Degree of satisfaction (%)

Degree of satisfaction	Strongly disagree	Disagree	Neither disagree/nor agree	Agree	Strongly agree
I17. In general, I am satisfied with how the practical work went	-	3.2	11.2	61.6	24
I18. In general, I am satisfied with the professor's support of the practical work	0.8	2.4	4	56.5	36.3
I19. I think I learnt a lot from doing this work and it will be useful for my education	1.7	1.7	14.9	62.0	19.8
I20. Doing this work meant that this course required more effort than the other courses	2.4	4.8	30.4	33.6	28.8

Aspect to improve

The questionnaire included an open question asking the participants for their opinion about how the project had gone and for their suggestions for improvement. A large majority express a very positive opinion about their participation in this project, mainly because it has provided them with a new perspective on the course, and brought the academic content closer to the professional reality. But at the same time they mention a number of difficulties and offer some suggestions for improvement:

- a) Interaction between group members. The students stress that the excessive group size made the teamwork more difficult; some students did not get particularly involved because they did not consider the course to be fundamental; different learning rhythms in the four courses involved; incompatibility of class times between group members based in centers on different university campuses.
- b) Duration of project. The students argue that they had barely enough time to do the work considering the objectives.
- c) Weight of project. Students stress the need to increase the weight of the project in the total grade for the course, given its importance.

Participants' attitudes toward entrepreneurship after finishing project

The authors evaluated the students' attitude and pre-disposition toward entrepreneurship and compared the results with data from the Annual Report of the GEM on entrepreneurial activity in Spain in 2009 (De la Vega et al., 2009). They considered two fundamental dimensions: the entrepreneurial activity and dynamic; and the motivation and capacity to engage in entrepreneurial activity.

According to De la Vega et al. (2009), 5.7% of the Spanish adult population is considering starting a new business in the next three years, compared to 24% of the university students participating in this project. In addition, 5.1% of the Spanish active population have started or tried to start a new business in the past 3.5 years, compared to 9% of the students in this study. Consequently, the intention and the attitude toward entrepreneurship is significantly superior among the university students participating in this study than in the active Spanish population in general.

On the other hand, 51% of the Spanish adult population say that they have the knowledge, skills and experience necessary to start a new business venture, compared to 50% of the students. But almost 17% of the general population perceive opportunities to start a business, compared to only 6% of the students.

Conclusions

The current work has described the methodology and the main results of a project to test an innovative methodology for teaching entrepreneurship. The methodology involves the elaboration of business plans by multidisciplinary teams of students studying for scientific-technical or business management degrees at the University of La Laguna (Spain).

The authors can conclude from the results that the interdisciplinary elaboration of business plans is an excellent pedagogical tool in economics/business and scientific-technical degrees in response to some of the challenges higher education is currently facing in the international context in general and in Europe in particular. The authors would stress the potential of such projects to promote entrepreneurial spirit among students—a key element in the University's progress toward fulfilling its “third mission” on top of its traditional teaching and research roles. In this respect, after participating in the project the students manifest a greater long-term intention to start a business than the general Spanish population.

At the same time, the methodology described seems to be offering the students learning closer to the real world, a closer contact with the business reality, and a greater involvement in the solution of real problems.

To exploit the potential of this interdisciplinary approach it is essential to give the students the most individualized attention possible. The size of each group and the

number of groups that the professors must coordinate are key variables. The process of forming the interdisciplinary work teams must be done carefully, and the students of the different degrees must be offered efficient tools, spaces and methods of contact, coordination and communication. Otherwise much of the potential of the interdisciplinary work process may be lost.

It would be very interesting to deepen the analysis of the impacts among the students of entrepreneurship teaching methodologies via the creation of interdisciplinary teams, like the one described in the current work, and compare them with more classical teaching methodologies.

Key words: quality, total quality management, service gap model, Empathy, Assurance, Servqual

Introduction

Quality is one of the most expected by customer's aspect of almost all service products. High and unique quality is a way to win customers and make them loyal for a long time. Management literature proposes many concepts and approaches concerning how to deal with service quality. There are also many different concepts how the notion “service quality” should be understood (Urban, 2009). The perception of service quality has been extensively studied during the past three decades. Owing to the intangible, heterogeneous and inseparable nature of services, service quality has been defined as “the consumer’s judgment about a product’s overall excellence or superiority, or “the consumer’s overall impression of the relative inferiority/superiority of the organization and its services’. Many models have been developed to measure customer perceptions of service quality (Martinez & Martinez, 2010).

The general philosophy and attitude which is based on marketing principles in insurance industry are "since no one buys the products, rather they should be sold". Therefore insurance organizations by using appropriate measures such as ideal service, quality and policies of encouragement should motivate the public to buy the products. But today this problem in order to put forward the private sector contribution in Iran's insurance industry is serious and is becoming increasingly more serious. So it is easy to understand that one of the successful factors in insurance companies is the use of management theories especially total quality management because the main centre of total quality management is attending to customers needs and continual improvement of all products, services and processes. The great problem, however, in performing total

quality management is that this kind of attitude in every organization according to its goals and conditions would face with its difficulties and it wouldn't be performed as a framework in any organization. Hence, the present study will investigate TQM approach with emphasis on these five principles in insurance industry so that it recognizes how the performance of TQM principles can affect on service quality improvement and what is an optimal model of service quality improvement in Iran's Insurance Industry?

Literature review

The Emergence & Concept TQM

Global competition and economic liberalization are creating opportunities for organizations. They use “quality” to compete with other organizations to improve their market share. TQM is one of the important quality improvement techniques, which many firms are using to achieve success. TQM has been widely implemented throughout the world across different industries and sectors. The implementation of TQM has given them positive results (Bhat and Rajashekhar, 2009). TQM has been described as a new way of thinking about the management of organizations, a comprehensive way to improve total organizational performance and quality, an alternative to “management by control” and ultimately, as a paradigm shift. (Fotopoulos and Psomas, 2010). Although originally applied to manufacturing operations, but In the late 1980s, corporations such as American Express finally began abstracting and applying TQM to the service sector. (Kumar et al, 2011)

The purpose of TQM is to provide a quality product or service to customers, which will, in turn increase productivity as well as customer satisfaction and decrease the cost With a higher quality product/service and lower price, competitive position and customer satisfaction in the marketplace will be enhanced. TQM is a way of managing the industries to improve product as well as service quality and the overall efficiency of production and other operations (Kumar et al, 2011). TQM is a management philosophy that is based on a set of theoretical principles that seek to mobilize organizational resources to increase stakeholders’ satisfaction. (Das et al, 2011) and that is a compilation of various processes, systems, committed people, transparent communication and culture for customer satisfaction. (Kumar et al, 2011)

Service quality concept

The emergence of quality as a top priority in many corporate entities is primarily due to the globalization of world trade and the competitive pressure brought about by the escalating demands of consumers, who want better products and services. According to Feigenbaum (1999), the key is transforming quality from the past emphasis upon the reduction of things gone wrong for the customer, to emphasize upon the increase in things gone right for the customer, with the consequent improvement in sales and revenue growth. Creating better planning, better external and internal focus, better design, strengthening weak processes and protecting strong areas, which give organizations an edge over their competitors, is being achieved through total quality management (TQM). It ensures that the voice of the customer is always matched by the voice of the processes (Fotopoulos and Psomas, 2010). Since the service quality is very important in surviving and profit making of an organization, it affects in customer's satisfaction and motivation after shopping positively and customer's satisfaction also affects in tendency toward shopping positively. (kuo et al. 2009). Quality has been generally defined as “fitness for use” and “those product features which meet customer needs and thereby provide customer satisfaction” These basic definitions are commonly accepted and can also be applied in service management.(Juga et al, 2010). Service quality can have many different meanings in different contexts. For example, Bitner and Hubbert (1994) defined service quality as “the consumer’s overall impression of the relative inferiority or superiority of the organization and its services”. Parasuraman, Zeithaml, and Berry (1985) defined perceived service quality as “a global judgment, or attitude relating to the superiority of a service” and noted that the judgment on service quality is a reflection of the degree and direction of discrepancy between consumers’ perceptions and expectations.(Rajasekhar et al, 2009)

Service quality has been conceptualized as an overall assessment of service by the customers. It is a key decision criterion in service evaluation by the customers. Perceived service quality is believed to be resulting from comparison between customers’ prior expectations about the service and their perceptions after actual experience. Besides service outcomes, service quality perceptions also involve evaluation of the service delivery process. Hence, conceptualization of service quality ought to include both the process as well as the service outcomes. A firm’s ability to serve the customer needs as well as to maintain its competitive advantage also affects the customer perception of service quality (Ganguli and Roy, 2010).

SERVQUAL Model

The conceptualization and measurement of service quality has been dominated by the use of the expectancy-disconfirmation paradigm and the related service quality model and SERVQUAL instrument. According to this model, service quality is based on a comparison of customer's expectations with perceptions of the service actually received. (Juga et al, 2010). The authors developed SERVQUAL, a five-dimension scale which represent Tangibles, Reliability, Responsiveness, Assurance, and Empathy (see Table I). This framework and scale have been widely used in various industry segments (Zeithaml et al., 2006).

Zeithaml, Parasuraman, and Berry (1990) emphasized four basic characteristics of services: intangibility, perishability, heterogeneity, and simultaneity. More specifically, intangibility suggests that services are performances only experienced by the customer. Perishability indicates that a service cannot be produced and stored for future use. Heterogeneity reflects that the performance of the producer and customer's perception are often different from producer to producer, customer to customer, and from day to day. Thus, services are inherently variable and lack consistency. Lastly, simultaneity means the production of the services occur at the same time as consumption. Thus, a customer cannot judge the quality of the product Prior to using it. (Lee et al,2010)

Table I. Five dimensions of service quality

Dimension	Explanation
Tangibles personnel	Physical facilities, equipment, and appearance of
Reliability	Ability to perform the promised service dependably and accurately
Responsiveness	Willingness to help customers and provide prompt service.
Assurance ability to inspire	Knowledge and courtesy of employees and their trust and confidence
Empathy customers	Caring, individualized attention the firm provides its

Note. From Parasuraman et al. (1988): p. 23.

However, Cronin and Taylor (1992) criticized SERVQUAL and proposed an alternative scale called SERVPERF. It includes all the SERVQUAL scale dimensions, but uses

only service performance (perception) as a measure of customer perceived service quality instead of the gap (between expectation and perception) approach of SERVQUAL(Wong et al, 2010).

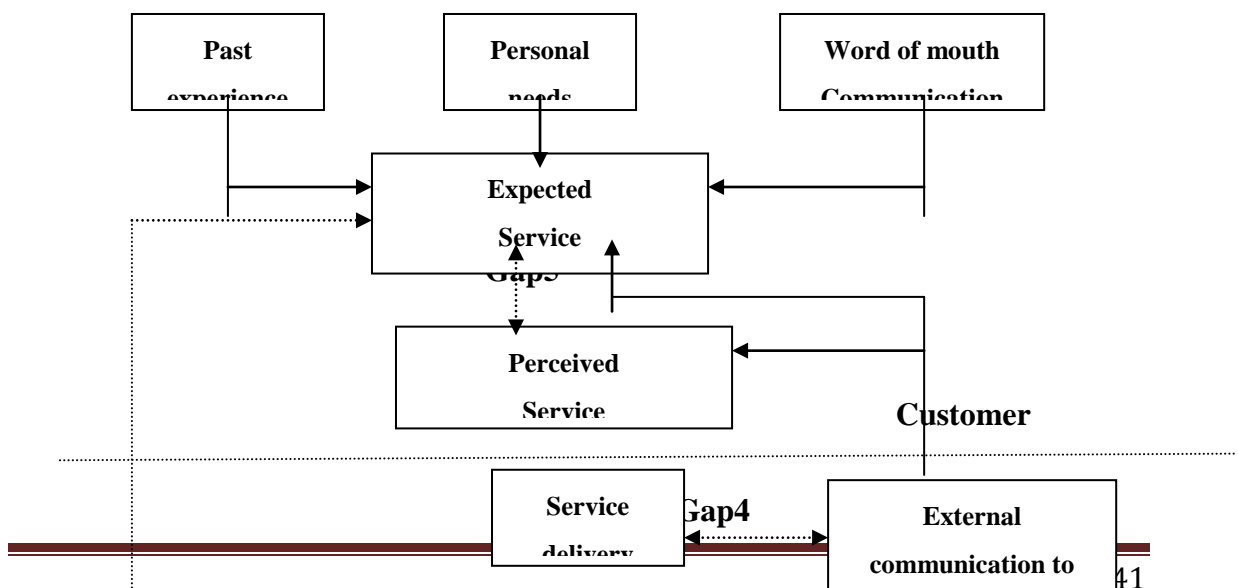

Service Quality Gap Model

Among many concepts of service quality, the service quality gaps model plays an unquestionably significant role in the service management literature. Gaps approach proposes precious propositions on how the notion “service quality” might be understood and how the service quality emerges across a service organization. (Urban, 2009)

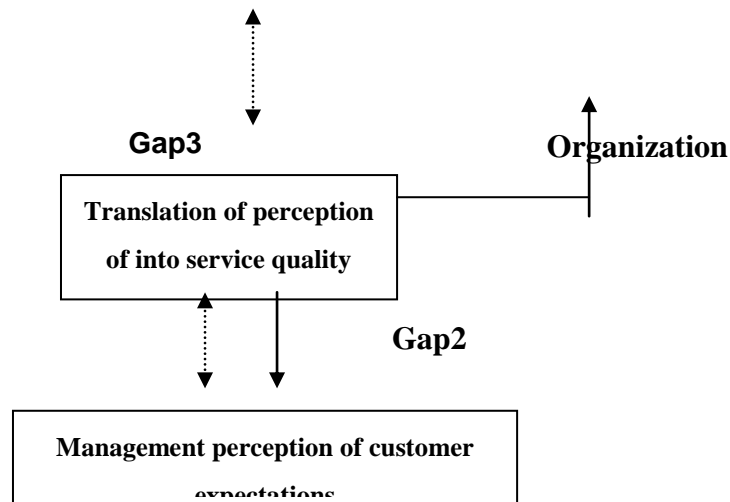

Parasuraman et al. (1985) thinks that the cognition level of service quality is evaluated by The difference between pre-sell service expectation and after-sell service perceptions. Therefore, the bank, credit card, security agent and product maintenance, etc industries were processed using exploration study to further establish service quality model. The model is mainly to explain the reason that the service quality of the service industry cannot meet the customer demands, and considers that in order to meet the customer demands, it is necessary to break through the five service quality gaps in the model. These five gaps respectively are:(Figure 1).

- (1) The difference between customer expectation and manager cognition.
- (2) The difference between manager cognition and service quality standard.
- (3) The difference between service quality standard and provided service.
- (4) The difference between provided service and external communication.
- (5) The difference between customer cognition service and expected service.

Figure1: Model of service quality gaps

Gap1

Parasuraman et al. (1985) thinks that Gap 5 is the function of Gap 1 to Gap 4, which is $Gap\ 5 = f(Gap\ 1, Gap\ 2, Gap\ 3, Gap\ 4)$, among which Gap 1, Gap 2, Gap 3, and Gap 4 are from the service provider, which originated from the internal organization, and Gap 5 is decided by the customer, which originated from the difference between customer expectation and actual perceptions. In order to satisfy the customer, the difference of Gap 5 needs to be shortened, therefore, directly considering the customer expected service standard and actual perceptions service standard will be allow the evaluation of the overall service quality result, which is the value of Gap 5.(YuanHu et al ,2010).

Parasuraman et al (1988) used ten service dimensions as the foundation to develop 97 questions and adopted the concept of service quality is originated from the difference between customer expected service and cognition service, which is $Q(\text{service quality}) = P(\text{Perceptions}) - E(\text{Expectations})$, to process questionnaire investigation and analysis, using the factor analysis method to find the service quality scale with good reliability and validity. This scale is formed using five dimensions and 22 service quality questions. The scale is called "SERVQUAL", and the five dimensions of the scale respectively are Tangibles, Reliability, Responsiveness, Assurance and Empathy.(YuanHu et al, 2010).

Research hypothesis and aims

The aim of the present study is to determine the status quo of service quality and a survey of total quality management's implementation focusing on five main principles such as customer's satisfaction, sustainable improvement, staff cooperation, attention to task processes and systematic viewpoint in insurance companies. That is to present an ideal model finally and determine the effective way of TQM principles on service

quality improvement. Therefore in this regard there are two main research hypotheses. In the first hypothesis there is significant relation between the principles of total quality management and the components of service quality gaps. In the second hypothesis there is a significant relation between the principles of total quality management and the components of Servqual model.

Research Methodology

The research method was applied and Survey –Correlation and The statistic population includes the all managers, staff and customers of Iran's three insurance companies of Alborz, Iran and Dana. By using Morgan table the sample volume for managers is 203, employees 312 and customers 385 people that has been selected by simple random and clustering sampling. The data collected tools are six questionnaires related with the five fold gaps of service quality and TQM principles whose validity by content method and reliability by Cronbach method have been confirmed and for the first through fifth gaps are respectively 0.877, 0.758, 0.944, 0.878 and (two questionnaires 0.916 and 0.959) also TQM principles questionnaire 0.988. In order to analyze the data, there have been used Spearman correlation, Wilcoxon tests, Mann-Whitney assessment and ANOVA methods.

Research Findings

The condition of service quality determines on the basis of service gap model by considering the fifth gap that is the difference between customers' expectations and believes from received services. This gap is the result of the first four fold gaps. The fifth gaps' measurement is done on the basis of Servqual model. The results of Servqual model show that the range of customers' satisfaction from the presented service quality is %52.2. By considering the range of customers satisfaction %90.44 and the range of their understanding from service quality %52.2, there is a gap of %38.24. Furthermore in order to measure the service quality condition, there is a survey the service five fold gaps in which the received results are shown in Table II.

Table II. The rate of service quality gaps

Gap5	Gap4	Gap3	Gap2	Gap1
-1.6	-0.2	-2.5	2.7	-2.5

As you see in Table II, there are gaps in all five status so that the rate of the gaps is all negative and the rate of the second gap is only positive because insurance industry managers have misconception about customers' expectations. The service quality characteristics in second gap have been based on such a misconception. Therefore although the gap extent is a positive number, it accounts for misconception of customers' expectations by insurance companies' managers and this leads to the practical standards selection to offer services. This subject approves the effect of the rate in second gap in low service quality.

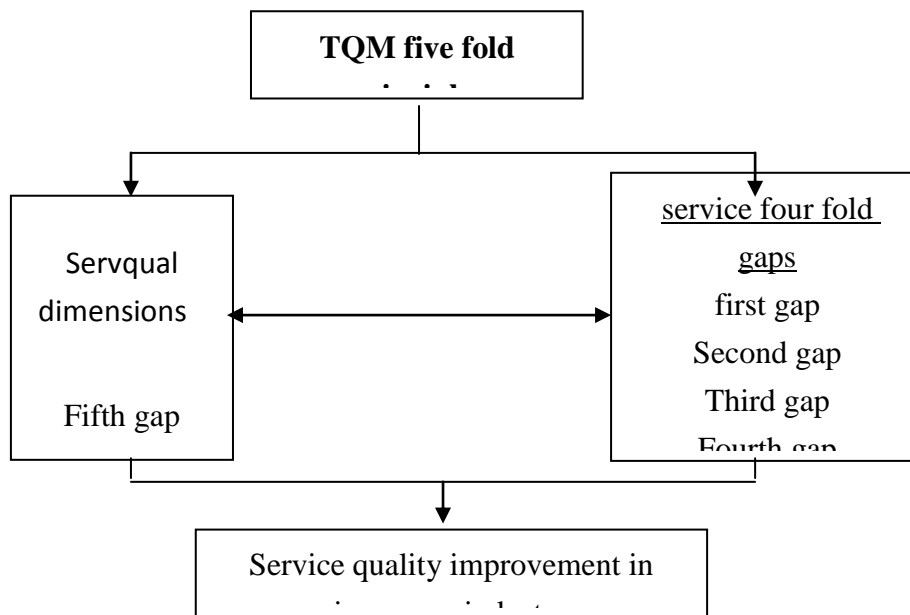

In order to survey the first hypothesis, first of all by considering the method components of service quality gap and TQM principles, the relation between the components of each principles of total quality management has been surveyed in order to separate and make fit the components with each five fold principles of total quality management. Hence through content and conceptual study and survey of theoretical discussion about TQM principles and service gaps components, the results shown in Table III .

Table III. The relation between TQM principles & service quality gaps components

TQM Principles	Service Quality Gaps Criteria
1- customers' satisfaction	1-scientific research and studies 2-fitness of occupation & employee 3-fidelity
2- continual improvement	1-control system of management 2-role ambiguity 3-performing control system 4-role contradiction
3- Involvement of people	1-group work 2-horizontal communication 3-bilateral communication
4- process approach	1- duties standardize 2-management levels 3-fitness of occupation & technology
5-systematic approach	1-outstanding management commitment 2-attention to aims 3-understanding feasibility

Now by considering Table II the research theoretical framework about the first hypothesis is that since the service quality gaps exist in insurance industry, TQM five fold principles should be used to leave out these gaps and improve the service quality at the end. That is if five fold principles of total quality management perform in Iran's insurance industry, it leads to leave out the service gaps which are shown in Figure 2.

Figure 2. How TQM five fold principles affect on service quality improvement

Therefore, there is a reverse relation between total quality management and service quality four fold gaps consequently. The gap of service quality lower by using and performing total quality management principles and that is the reason of reverse meaningful relation between TQM principles and service quality gaps. The results of Spearman assessment show that there are reverse relation between customers' satisfaction, sustainable improvement, staff cooperation, attention to task processes systematic viewpoint principles and related components of service gaps with quotients of -0.745, -0.833, -0.747, -0.790, -0.895 respectively. And Wilcoxon assessment results also approve the research first hypothesis. That is there is a meaningful reverse relation between TQM principles and service quality gaps which the service quality gaps decrease by performing TQM principle.

But, the theoretical framework in representing the second hypothesis is that since the condition of service quality according to Servqual model in insurance industry is low in order to improve it there should be a struggle in leaving out the fifth gap. Hence there is a belief that by applying total quality management principles and Servqual components by improvement in Servqual components this gap leaves out and a direct relation between TQM principles and Servqual components takes place. In order to survey this hypothesis, there is a survey of the rate and kind of correlation between TQM principles and Servqual components by using Spearman and Pearson correlation test. The results were 0.825, 0.875, respectively. It means that by performing TQM principles, there is

an improvement in physical dimension, reliability, responsibility, assurance and empathy which leads to lowering the fifth gap.

Table III. Mann-Whitney test results between TQM principles and Servqual scales

	TQM
Mann-Whitney U	9275.500
Wilcoxon W	72821.500
Z	-18.687
Asymp. Sig. (2-tailed)	.000

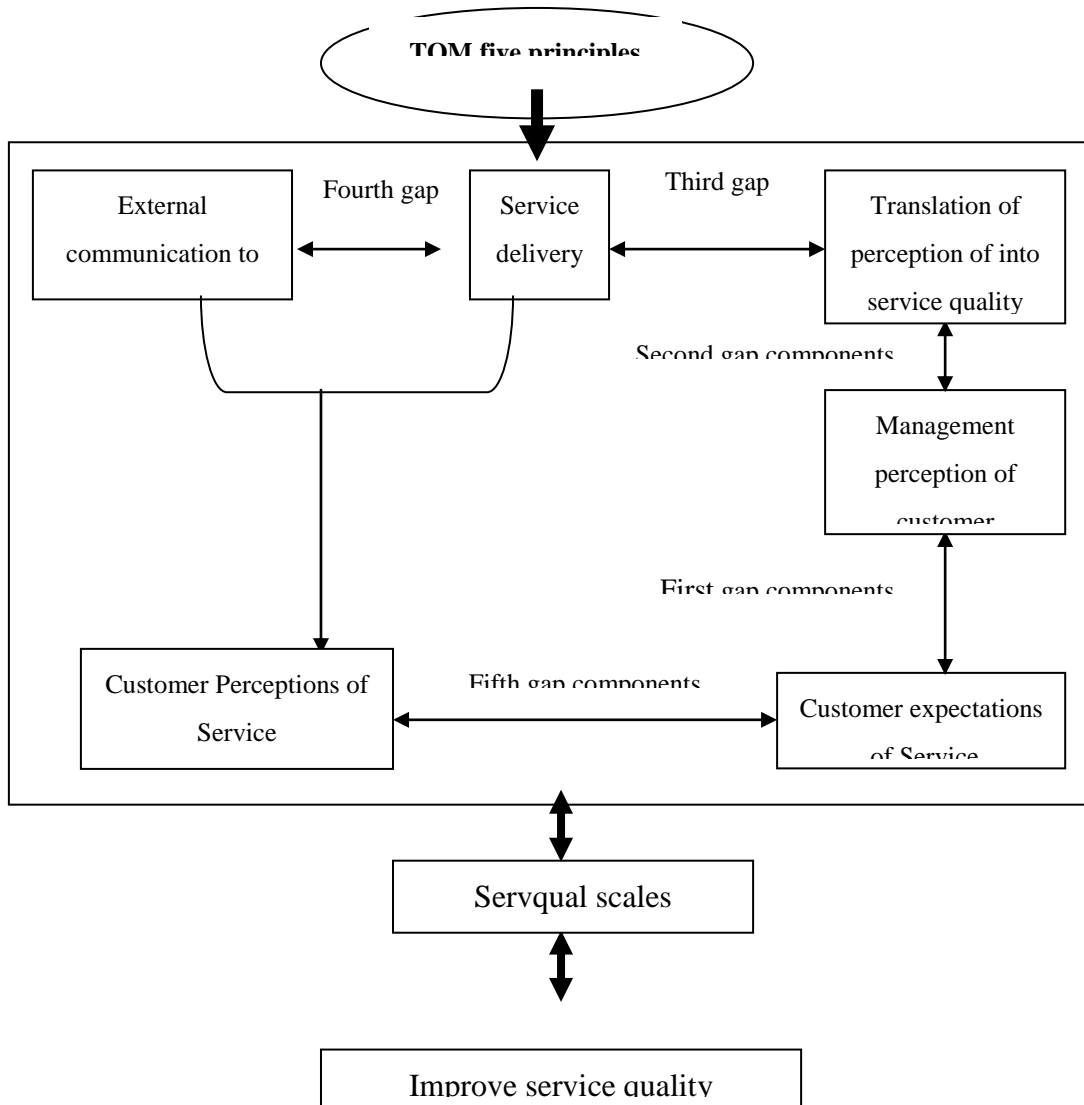

Table V. ANOVA test results between TQM principles and Servqual scales

	Sum of Squares	df	Mean Square	F	Sig.
Between Groups	203984.300	1	203984.300	587.808	.000
Within Groups	231118.970	666	347.025		
Total	435103.269	667			

Also, according to the results derived (Tables III & V) of the Mann-Whitney and ANOVA tests we can conclude that approve the research second hypothesis. Totality by approving the research hypothesis the conclusion is reached that if the service quality according to Servqual model components in an organization decreases, the fifth gap happens, so we should leave out the fifth gap to improve service quality and it is possible by leaving out the quality's four fold gaps. It can be done by applying and performing the five principles of total quality management. It means that by applying TQM principles we can affect on service gaps components in insurance industry and leave out them which affects on Servqual model components indirectly and leads to leaving out the fifth gap and improve the service quality in insurance industry finally. In order to determine the effective rate of total quality management principles, we surveyed the correlation rate of TQM principles and the related components of service quality gaps. The results are in the followings respectively: % 86 systematic approaches, %85 continual improvement, %80 processes approaches, %78 customers' satisfaction, %76 Involvement of people. It shows that systematic and staff cooperation have the most and the least effect on service quality respectively.

lastly considering what we went before we illustrate the proposed model in figure3, According to the proposed model, in order to improve the service quality we can affect the components of quality four fold gaps by implementation TQM five principles and emphasis on characteristics and tools which apply in total quality management separately and leave out the service quality gaps. Therefore by leaving out four fold gaps, five fold gaps also leaves out and lastly an improvement in service quality.

Figure 3. The suggested mode

Conclusions

The purpose of the current paper is to determine the status quo service quality condition and survey the implementation of total quality management in insurance companies, So that we will have an optimal model and determine the effective way of TQM principles in service quality improvement. The results on the basis of Servqual model shown to determine service quality condition. The rate of customers' satisfaction by receiving services are %52.2, and according to the rate of customers expectations (%90.44) and the rate of their perceptions of service quality (%52.2), it shows the gap of %38.24. Also the five fold were recognized according to service gap method. The results derived

from hypothesis tests by using Spearman test show that there is a reverse relation between customers' satisfaction, continual improvement, Involvement of people, processes approach, systematic approach principles and components related to service gaps with quotients -0.748, -0.833, -0.747, -0.790, -0.895 respectively. The results of Wilcoxon test also approved research first hypothesis. It means that there is a meaningful reverse relation between service quality gaps and TQM principles. It represents that the service quality gaps decrease by performing TQM principles and there is an improvement in service quality finally. Furthermore these principles of systematic approach, continual improvement, processes approach, customers' satisfaction and Involvement of people with quotients of %86, %85, %80, %78 and %76 respectively affect in lowering the quality's five fold gaps. The research second hypothesis was approved by using Spearman, Pearson correlation test and with quotients %825 and %878 respectively. It means that the implementation principles of total quality management in insurance industry will strengthen and improve Servqual model scales as well as service quality improvement. Therefore, we can conclude that by applying five principles of total quality management, the components based on service gap method make four and finally five gaps and then were left out. They improve service quality under positive and direct effects on Servqual scales. And according to the findings at the end the proposed model was planned.

By considering the research results and suggested model there are recommended in the followings:

1-Insurance companies' managers should collect and process defined criteria and components of service quality firstly as indices of organization performance quality management. Secondly they should run advanced learning levels for introduction, importance and effects of total quality management approach to improve the service quality. Because performing a successful TQM, calls for an outstanding management commitment.

2-Managers in performing these principles simultaneously and the rate of TQM principles on service quality emphasize their order and effectiveness priority.

3-It could be possible to prepare healthy and constructive competition ground in insurance industry by using various promotion ways such as introducing a top service quality company after selecting service quality standards in order to apply total quality management in insurance companies.

4-It should be noticed when performing total quality management is effective that it leads to a change in an organization's culture. Since it makes time and there is also staff stability against changes, therefore building it up take patience and immediate result is not reasonable.

Introduction

The complex needs of today's markets and societies frequently require service solutions that reach far beyond a single organizations' inherent capacity, and sometimes even beyond its control. The nature of value-creation, as defined and perceived by the customer in-context, does not necessarily follow organizational boundaries (Vargo and Lusch, 2004; 2008a; 2008). Working together within organizational networks provides one popular way of facing the challenge of providing these boundary-spanning services. Working together with external actors has according to last decade's research become an important part of a company's success and possibilities to compete and create growth (e.g. Kogut, 1991; Ahuja, 2000; Rothaermel and Boeker, 2008). In a traditional business-to-business setting, the development of a network could be seen as an investment process in which the parties freely select their counterpart and gradually develop trust and commit resources to each other, in order to receive benefits in the future (Ford *et al.*, 1996; Turnbull *et al.*, 1996). The relationships and the cooperation between the actors in the network will continue to exist only if the parties involved yield returns that exceed the costs of the relationship. If not, the relationship is dissolved or at least transformed in the long-term (Dwyer *et al.*, 1987). In order to create value for the parties involved and create a foundation for long-term business success, developing and/or improving the offering under deliverance is one important ingredients in virtually all organisations (deBrentani, 1989; Cooper, 1996; Johne and Storey, 1998; Cooper and Edgett, 1999; Menor *et al.*, 2002; Smith *et al.*, 2007). The willingness to develop the customer offering is in most cases driven by commercial incentives, since it is important to satisfy the customers' needs and wants in order to increase the organizations earnings in the long run.

In other contexts the partners does sometimes not have commercial incentive or by other means feels obligated to show commitment by engaging in different forms of development tasks or projects. This is for example the case in the public sector where the selection of partners often is accomplished through various forms of public tendering or complete procurement (Swedish Code of Statutes 2007:1091 and 2007:1092). The relationships that are developed under these contextual circumstances could be described as forced or elementary relationships (Laing and Lian, 2005). An elementary relationship is characterized by being a relationship at arm's length, with low trust, a short time-orientation, and with a low degree of socialization, formal communication and substantial unilateral dictation of the content of the relationship. In this elementary relationship context, resulting from public tendering described above,

the operators does sometimes not have these kinds of commercial incentive to develop the offerings agreed on in the contract between the parties, since the contract regulating the roles and obligations between the parties is written in fixed terms without higher earnings for increased sales or improved service offerings. Since the commercial operators often have several comparable contracts with other organizations within their portfolio of contractual relationships, they must prioritize and adjust the resources committed to each relationship in order to optimize the return on their entire portfolio. One consequence of these commercial realities is that the operator seldom appears to be doing anything outside the negotiated contract, leaving the other party with the responsibility for developing and improving the service.

The discussion above describes a situation that is somewhat different from a more traditional commercial setting, since the development of new service offering with a view to increasing the earnings for the involved actors are not necessarily the primary imperative of the organisation in the contractual dyad. This situation creates somewhat specific conditions for why and how the long-term development of the offering under deliverance in the contractual dyad is created and handled. In the recent year there has also been a shift in focus of public tendering or procurements role from to a large extent being a tool to reduce costs and streamline operations, to a situation where the focus of the procurement process besides the cost reduction part also is about how to create basis for long-term business development and how to create value for the parties involved. This shift in focus from cost reduction to value creation has made the procurements a highly strategic question in the involved organizations.

Based on the discussion above, the aim of this paper is to increase the understanding of how the long-term development of the service offering can be reconciled within the context of more competitive based and priced oriented logic induced by a public tendering process or competitive bidding, where you initially do not have a close and co-operative partnering relationship with the one you provide the service offering together with. To do so we have chosen to make use of case studies to exemplify and discuss how long-term service developments are maintained within the frames of a public procurement setting. The three selected cases from the public transport sector shows three different way to handle the restraint resulting from the procurement setting, where you not can anticipate or rely on a partner to develop the service offering together with. The examples will each show three different ways; the market way by regulating with contracts, the hierarchical way by doing it in house and the intermediary form by using a network approach.

Theory – markets, hierarchies and intermediary forms

Market and hierarchy are two of the classical ways to organize coordinated action (Coase 1937; Williamson 1975). The basic idea of procuring parts of the own operation is based on the idea that competition spurs efficiency and development in a way that is difficult to achieve within a traditional organization. The model that the market looks at has an inherent dynamic that organizations through procurement hope to take a part of. An important part of the market concept is the classic so-called "invisible hand" that tends to match the supply with demand so that the right activities are carried out by using the right resources at the right price. What is "right" in the actual case is stated in the formal contract where the object of the transaction and the commitment of each party are stated (Coase, 1937; Callon, 1998).

While the invisible hand in theory is a very efficient way to organize activities, does the market solution in many cases not work as good in practice as it does in theory. Proof of this is the existence of businesses and public organizations where coordination efforts are done within the company with the help of an organizational hierarchy that arose as a result of a market not always functioning optimally. The reasons for this can often be traced to various forms of misinformation that sometimes makes it hard to predefine what is to be achieved and to verify that the actual transaction has been completed as agreed upon (Coase 1937; Williamson 1975). It is difficult to establish a sufficient comprehensive contract, and a problem increases the more complex the actual activity in question is. Expressed in economic terms this proposes that the cost to implement the market transaction will rise as the contract becomes more complicated to design and follow up.

Organizations can simply be seen as a way to solve problems by replacing the invisible hand and the regulations of the contracts with "visible" administration. Within the organization there are set rules on how various activities are to be implemented, who should decide and do what and when it should be done and what benefits should be eliminated. There are set procedures for what happens if someone violates the mutual agreements. All together the activities can be coordinated without having every little detail needed to be clarified and agreed upon in advance. The organization also develops a more fundamental approach and informal rules and procedures on how to act in different situations. Such culture related coordination mechanisms are particularly important when dealing with complex, non-routine situations, situations which are unsuitable for the market or the strategies that the formal organization is based on. According to Williamson, the market and the hierarchy are two separate alternatives for

how to organize coordinated action. Each form is supported by clear contractual agreements (fundamental agreements). Transactions carried out in the market are underpinned by the classic formal formation of contracts, where transactions take place within an arm-length distance and any eventual conflicts are resolved in a formal way. Companies with hierarchical structures are based on consensus and collaboration in which the hierarchy itself manages and resolves conflicts within the organization. These different forms of organizations mean different incentive and control opportunities (Williamson, 1991). Williamson argues “.....*not only do the alternative modes of governance differ in kind, but each generic mode of governance is defined by an internally consistent syndrome of attributes- which is to say that each mode of governance possesses distinctive strengths and weaknesses*” (Williamson, 2002:6)

The reasoning is a variant of the so-called Coase theorem (Coase, 1937) under which it is always possible to find contractual solutions to market exchanges, given the preconditions for a functioning market is satisfied (especially with respect to full information, clear property rights and independent operators). Callon (1998) extends the argument to the cases where these conditions are not met (which they, as also Coase points out, in practice rarely are), and highlights the work and investment that is needed for a contract to be established and a market exchange to come about. Further, the existence of various intermediate forms of transaction solutions have made Williamson describe the market-hierarchy as a continuum, rather than a dichotomy where many transactions are made through various collaborations in a so-called hybrid- or network organizations. Contract management can be seen as one such intermediate form, to control the market and the governance contained in a business (Bryntse, 2000). Contract management is characterized as an interaction between elements of opposite nature. Among other things, combining formal communication with informal cooperation, short term contracts can be combined with long term relationships. The benefits drawn from this can have connecting resource use, changes in norms and technological development. Disadvantages may be related to coordination and specific quality aspects to name a few.

According to representatives of the so-called school of networks, that has its roots partially in the industrial market research (and which is of particular interest to the discussion on how procurement works) are saying that important factors that influence the organizational operations are lost in the simplified classic theory. In a similar manner Adler (2001), criticizes the classic division between market and hierarchy to be ineffective in dealing with transactions of different types and resources, especially the knowledge- intensive ones. According to Zenger and Hesterly (1997, in Adler 2001),

we have an increasing number of transactions that has neither been organized according to the market nor in hierarchies (organizations), instead there is an increase of alternate shapes of organizational structures where we find a mix of market structures in the tools that are available on the markets in hierarchies, and in various control- and monitoring mechanisms within the market. Adler (2001) argues that the focus on the different intermediate forms does not fully resolve or explain the difficulties in completing effective operations. He argues that besides the two forms of market and hierarchy (who build on the price mechanism or authority) and the intermediate of hybrid forms there is also a form that he calls 'community', which is based on the existence of 'trust' between the involved actors (Adler, 2001).

Method

This study uses a case study approach (Yin, 1994) with the aim of increase the understanding of how the ideal of long-term development of a service offering can be reconciled within the context of more competitive based and priced oriented logic induced by a public tendering process or competitive bidding which is the case in the public transport sector. A case study approach was adopted since service development is a fairly new area, in which rich qualitative data from case studies are considered more appropriate for theory building than theory testing (Eisenhardt, 1989; Merriam, 1994; Daymon and Holloway, 2002) The present study is empirically based on three cases from the Swedish public transport sector which each are working very actively to provide transport solutions in accordance with contractual requirements and to develop the public transport services. However, the transport solutions required by each cases were different, because of differences in populations, geography and traffic types. Selection of the three cases was made by means of intentional sampling of information-rich cases (Patton, 1990).

The public transport in Sweden – a short background

The responsibility for regional public transport in Sweden is assumed by the Public Transport Authority (hereafter labelled PTA), which are commissioned by Cities and County Councils to manage the delivery of public transport within their geographical area (SLTF 2002). The PTAs are responsible for developing and delivering public transport and meeting the demands of different groups. The PTAs do not operate services themselves. The actual services are instead produced within a network of interacting actors, each responsible for different parts of what the customer perceives to be "public transport". Operators are selected by means of a public tendering process

pursuant to the Public Procurement Act (Swedish Code of Statutes 2007:1091 and 2007:1092).

Data collection and analysis

To build up the cases we have used two sources of data (i) interviews and (ii) internal and external documents. Interviews were done with executives/managers from each of the three public transport authorities and their operators in Sweden, who had personal experience in and/or knowledge about the development and delivery of public-transport services including the business relationship and the contracting processes. Each of the interviews, which took place at the offices of the respondents, lasted between 30 minutes and 150 minutes. The interviews were all recorded and transcribed verbatim. In some instances, the data recorded in these interviews were supplemented by data from follow-up interviews or clarifying questions by e-mail correspondence. A semi-structured interview guide was used to provide some degree of uniformity to the interviews, while allowing the interviewees to speak as freely as possible. The interviews focused on: (i) service development process (ii) working relationships between PTAs and their operators; and (iii) contractual issues (including the content of the contracts and the contracting process, and evaluation of the content of the contract).

We have also gathered data from three types documents (i) laws and regulations governing the public transport sector in Sweden; (ii) government reports and statements regarding the guidelines and regulations for the sector; and (iii) internal and external documents from the PTAs and the operators as well as information from the Swedish Public Transport Association, which is the trade organisation of the local and regional public transport in Sweden.

Empirical descriptions and findings

In this section the three cases and the findings from the cases are presented. The analysis of the cases indicates that there are three different ways to handle the development of the delivered offering under the restraints of public tendering contractual relationship settings.

Case A – Contract Development

Case A represents a traditional contextual solution in the Public Transport area focusing on a relationship between the Public Transport Authority and operator formed by a public tendering. In this traditional dyad the partners sees themselves as the central actors that should in between them should create the long-term development of the public transport service they are responsible for. In order to create this long term perspective both parties are aware of the need for having a trustful and committed relationship, since they will work together for a long period of time during which they should deliver a service of high quality. Although both the PTA and the operator wished to develop a trusting and cooperative relationship, it was apparent that representatives of the operator were placing more emphasis on the written requirements in the contract. The fact that the operator had adopted this attitude toward the relationship made the PTA play safe and write as much into the contract as possible in order to safeguard a certain level of quality and development. Because of this, it has become important to have a detailed specification of the services being purchased and how these should be provided in order to guarantee the quality of service. A consequence of this is that the relationship is managed to a greater degree through the contract.

Discussion – Case A

The first case above showed a traditional relation based on a public tendering setting, resulting in a market based approach to handling the activities in the relationship. In Case A the contract was used to a high extend to control the counterparty and guaranteeing a certain level of contribution to the exchange in general. The contract used in this relationship could be labeled a transactional contract (Macneil, 1978) in which formal rules and measurability are prioritized issues (see also Sjöstrand 1985; Lindvall, 2001). These kinds of contracts are often written, impersonal in nature, and have a preventive purpose since the sanctions applicable when not fulfilling the contract are clearly stated in them. A transactional contract is also characterized by having a clear start and finish, and by the content of the contract being measurable and quantifiable. By using a regulative style of writing, the contract could be used to control the counterparty to a greater extent and thus the need to trust the other party decreases. Laing and Lian (2005) labels this types of relationships resulting from formal public tendering processes as forced or elementary relationships with arm's length interactions, low trust, a short time-orientation, and a low degree of socialization, high degree of formal communication and unilateral dictation of the content of the relationship. One problem of using formal contracts as the dominant management tool is that they cannot

address all the issues existing or developing during a long-term relationship, since formal contracts, especially explicit ones (Hart and Holmström, 1987), mainly focus on governing the short-term and foreseeable aspects of an exchange. This creates some restrictions concerning the long-term development of the relationship and what is created during this since a strict formal contract that to a high degree governs the interplay between the parties and gives very little room for creative business solutions. In our case described above, these problems were fairly obvious since the operator showed no willingness to contribute to developing the service besides the parts agreed upon in the contract, or if they receive extra payment. In many cases the operators have a number of similar contractual dyads and have to distribute their resources in a way that makes them earn the most money in respect to the resources they invest in the relationship. This resulted in a formalized contractual situation where the tendering organization made sharp demands in the contract to make certain that they receive actions within the area, which only enhance the situation by making the operator even more following the writings in the contracts when they make the bid.

Case B – In-house Development

Instead of working together with operators some of the larger PTA's choose to handle all long-term development within their own organization since they believe this gives a higher degree of control of the long-term process and they also have the control (Owner-right) of what has been developed, which makes it possible to apply on other contractual dyads, i.e. what has been developed in one area could be transferred and used in the relationship with another operator.

One such example is case B that is about the long-term (5–8 years) development and implementation of a new ticketing and information system by a single public transport authority in one large Swedish city. The development process was conducted jointly with a technical consultancy firm that was responsible for developing the hardware and software for the project. At the beginning, the project was run by a project group, but it subsequently involved 8–10 subgroups that became responsible for developing and integrating various aspects of the system. A major challenge was ensuring that the system suited the needs of different groups of operating staff.

Discussion – Case B

One way to handle the coordination problems is to solve these difficulties is to single-handedly take care of the development task. This is done in the second case where the

tendering organization, instead of relying on a market solution, they decided to take care of the development process themselves and use a more hierarchical solution by doing most of the work in-house. Doing the work inside the own organization facilitates the process as the organization controls what is happening. Within the organization there are established rules for how various activities are to be implemented, who should decide and do what and when it should be done. All together the activities can be coordinated without having every little detail clarified and agreed upon in advance. The organization also develops informal rules and procedures on how to act in different situations. Such culture related coordination mechanisms are particularly important when dealing with complex, non-routine situations, like for example service development projects. Organizations can simply be seen as a way to solve problems by replacing the regulations of the contracts with “visible” administration. One problem with in-house solutions is that in today’s society organizations have though difficulties to have sufficient technical competence as well as other resources that are needed within the organizations.

Case C- Networked Development

Instead of doing the development work at one PTA, sometimes a number of PTAs work together to create solutions for the long-term perspective that could be applied to their own business as well as the other actors. Case C illustrates such an example describing a study of the long-term (6–8 years) development of a new ticketing and information system involving collaboration between six Swedish Public Transport Authorities. The collaboration involved: (i) a formal project group of four members with the overall responsibility for the project; (ii) an advisory and board of managers of public transport authorities; (iii) large project groups of approximately 25–30 participants representing different areas of expertise within the Swedish public transport sector; and (iv) smaller workgroups tasked with working on technical solutions to specific problems. In addition, an external technical consultancy firm was also hired to build the actual ticketing system. The ticketing and information system was based on a joint standard created by an industrial organisation for the Swedish public transport sector.

The main reason for working together was, according to the interviewees, mostly practical. The PTAs in themselves are rather small, and they lack the manpower to have expertises for all different parts of an integrated ticket and information system. By working together, the participating actors could combine the existing knowledge that was dispersed between the different PTAs and jointly create the knowledge base required to develop the system. As it was 10-15 years ago since the last time a new

system had been developed, the level of experience was very low among the PTAs. This lack of knowledge is very obvious due to the fact that a new ticketing and information system is nowadays a high-tech-product, requiring specific knowledge vis-à-vis both practical requirements and technological ones. Another reason facilitating the decision to work together was the fact that a number of PTAs had experienced previous cooperation positively.

Discussion – Case C

Working together within organizational networks like in Case C provides one popular way of facing the challenge of providing boundary-spanning services and to help out the problem that the companies have difficulties to have sufficient technical competence as well as other resources that are needed within the organizations to do in-house (hierarchical solutions). The interactive and networked nature of value-creation (Vargo and Lusch, 2004; 2008, 2008a), as defined and perceived by the customer in-context, does not necessarily abide by organizational boundaries. Instead, service is often provided via complex combinations of physical goods, information, and institutions. Service is co-created and value is experienced contextually by various customer groups interacting with these combinations, rather than with individual organizations (cf. Vargo and Lusch, 2008).

Within the framework of these relationship networks there are a set of activities and exchanges done to access the resources needed to create value in an efficient manner. Companies interact and develop relationships with each other in order to exploit and develop their resources for the mutual benefit of each other (Turnbull and Wilson, 1989). This is the kind of value creation, or rather expected value creation that drives the interaction and development of relationships and networks. Different resources such as physical, human, scientific, financial, are combined and transformed through activities into goods and services. Networks of relationships are developed whereby the parties continuously exchange resources and activities (Morgan and Hunt 1994); or, as some recent thinkers would have it, whereby ‘service’ is exchanged for ‘service’ (Vargo and Lusch 2004). The result is a long-term form of governance which transcends the classical market-hierarchy dichotomy (Williamsson, 1975; 1981) and which relies on mutual understanding, commitment, and trust (Morgan and Hunt, 1994).

The Business-to-Business research highlights that a company’s operations cannot be understood in isolation from a context, but the company is in one way or another dependent on various internal and external stakeholders. Business is done in a complex

interaction process between stakeholders, both internal and external (see e.g. Turnbull *et al.*, 1996; Ford *et al.*, 1996) The businesses often have close, complex and long term relationships who are created during intense, changing and complex contract patterns that involve and engage the stakeholders at different levels within each organization (Håkansson and Snethota, 1995; Turnbull *et al.*, 1996).

Conclusions and managerial implications

In this paper we have provided three examples of how long-term service offering could be handled by using different way to organize coordinated action;

The first of the three examples shows the classical market solution, where the contract is used to state by using sharp demands, detailed terms and conditioned in the contract terms and conditions about what and how the offerings should be developed. This puts a lot pressure on the formulating of the contract, and the forming of the contract becomes a vital part of the service development process, done in beforehand of the relationship. Based on this, the formal contract established between the parties play a key role, since it specify, to a great extent, the short-term as well as the long-term obligations and duties of the parties including what types of development that should be undertaken during the contract period. Moreover, all requirements regarding the service have to be stated before the bidding process is initiated, which results in restricted creative and spontaneous service development. These findings suggest that the formulation of the terms of the contract represents an especially important aspect of the service-development process. Indeed, the formulation of the contract could actually be seen as service development in itself, given that the contract provides the guidelines for how the service is to be developed during the coming years. Based on this it is important for managers to recognize that a large proportion of service-development planning is actually undertaken before the contract period begins; indeed, this is often done unilaterally by the purchaser, who decides (without consultation) what service output it wishes to achieve during the contractual period. One conclusion to drawn from this is that it is difficult to establish a sufficient comprehensive contract, and a problem increases the more complex the actual activity in question is. Expressed in economic terms this proposes that the cost to implement the market transaction will rise as the contract becomes more complicated to design and follow up.

The second example shows the hierarchical way by taking care of the development in the own organization. In this case the tendering organization disregards the tendered partner and take care of the long-term development within the own organization. In this

one of the main problems is that in today's society organizations have difficulties to have sufficient technical competence as well as other resources that are needed within the organizations.

The third case shows an example of a mix of market and hierarchical structures - by using network actors outside the dyad delivering the offering to create the long-term aspects and then implement it in the offering. The notions of exchanges, interactions, and relationships provide a rich source for understanding various aspects of inter-organizational cooperation. However, the concepts do not offer much analytical guidance when it comes to what actually happens in the network, i.e. what should actually be done, and by whom. The question of how coordination is achieved between the actors thus remains. One way of remedying this is to elaborate on the systemic nature of inter-organizational networks and to consider what holds them together on a more fundamental level.

Customer satisfaction to implement benchmarking in the public sector

**Guglielmetti Roberta. Roberta Guglielmetti, Researcher, University of Roma Tre,
Faculty of Economics, Via Silvio D'Amico, 77 Roma, Italy**
rguglielmetti@uniroma3.it.

Key words: CS ProMod Model, citizen satisfaction, improvement, benchmarking, multi-channelness, Health Agency.

Type of paper: Research paper

Introduction

CS ProMod is a standard measure model of the Customer Satisfaction (CS) regarding to public services provided online, offline and in multichannel way. CS ProMod model has the aim to give the administrations, information about the service quality provided to citizens. The model proposes a new conceptual measuring method of the CS based on the connection between the citizen perception and the providing service process also considering the providing service channel (Cappelli et al., 2011). Specifically, the CS ProMod model reflects the recent use - in the public sector – of new methods of proving multichannel service.

Multi-channel service is a way to simplify the service use and to make public administrations more flexible and reachable from the citizen. However, increasing multichannel service can lead to collect fragmented data: this suggests the use of CS collecting and analyzing methods which permit to maintain an overall vision. This is possible only throughout the use of standard measuring tools which allow collecting homogeneous and integrated information (Eipa, 2008). CS ProMod model bases on the connection between the client satisfaction and the providing service process, which integrates the quality of a provided service throughout different channels; this connection is inserted in the submitted survey. The survey contains standard aspects and a personalized dimension, “Capacity of Response”, coming from the determination of satisfaction items directly connected to the back office service process. A part of the survey is dedicated to the dimensions, coherently with the idea that it's not only important to determine the citizen satisfaction but also his consideration about a specific or more aspects, this in order to direct the improving actions in the right way, focusing on those elements which can impact the satisfaction (Cappelli et al., 2010). The logic is that the importance of the citizens perception represents the driver for the priorities

fixation (Martilla, 1977). The model fosters improving actions and an internal benchmarking process, starting from the CS results, first step for developing a less referential action of external benchmarking (Camp, 1989; Zairi, 1995).

Any organization that pursues a continuous improvement has the aim to search in a systematic way, within the company, the performance and its own organization optimization. The risk and the limit of this approach is the self-referentiality that can cause the missing of new improvement opportunities formation. Benchmarking, throughout managerial solution research and methodology coming from external environment, allows to revitalize the continuous improvement process. Companies that implement/adopt benchmarking have consciousness of the applicable improvements at their contest learning by the best practices. Benchmarking can be defined as a improvement systematic process fit for/suitable for determining standard performance, compare themselves with the standard performance and identify the procedures that allow to get/reach the new standard reference. Its definitions and classifications vary according to the time and criteria they focus on. For example, Kulmala (1999) suggests that benchmarking refers basically to the process of evaluating and applying best practices that provides possibilities to improve the quality. According to Bhutta and Huq (1999) benchmarking is first and foremost a tool for improvement, achieved through comparison with other organisations recognised as the best within the area. On the other hand, Ahmed and Rafiq (1998) argue that the central essence of benchmarking is the learning how to improve activities, processes and management. It means “challenge themselves” analyzing their managerial procedures and their relative performance in order to identify strong and weak points. Determining the performance gaps they can also define new target and action plans in order to improve all the organization’s levels.

Recently, it has also extended its scope from large firms to small businesses and public as well as semi-public sectors (Kulmala, 1999). Benchmarking developed in a typical private setting and it is a management tool with the aim to improve the performance and competitive positioning compared to the competitors. Can benchmarking be applied to the public field/sector? The answer is positive though the different purposes respect the private sector; in fact they must be led to the supplied services’ quality and to the performance efficiency in order to improve the society/company. Benchmarking can be adopted/applied both in those companies that are going to introduce for the first time in their organization TQM logic and tools and in those “advanced” administrations that have already introduced them and want improve. This comparison can be made between “advanced” and “less advanced” administrations basing on remarkable performance

indicators, so that the “less advanced” administrations have external reference points as strategic objectives in order to improve their efficacy and efficiency. In the public sector benchmarking can be led through a realization of a network based on a sharing and improvement of the common practices. It’s easier to start a comparison process if there are measurement standard methodologies both in the organization and in the others. It’s really fundamental opening up to those organizations that have the same activity so that the involved companies/organizations could use the same measurement methodologies. The first step to launch an organized benchmarking process is to evaluate if in the internal organization there are some opportunities to learn effective methodologies from their own excellence cases (best practice). The consciousness of their internal strong and weak points allows to the organization to start up a continuous improvement, getting over the self-referentiality and analyzing the external organizations’ behavior that have better performance.

Methodological approach

The aim of this paper is to verify the following research questions:

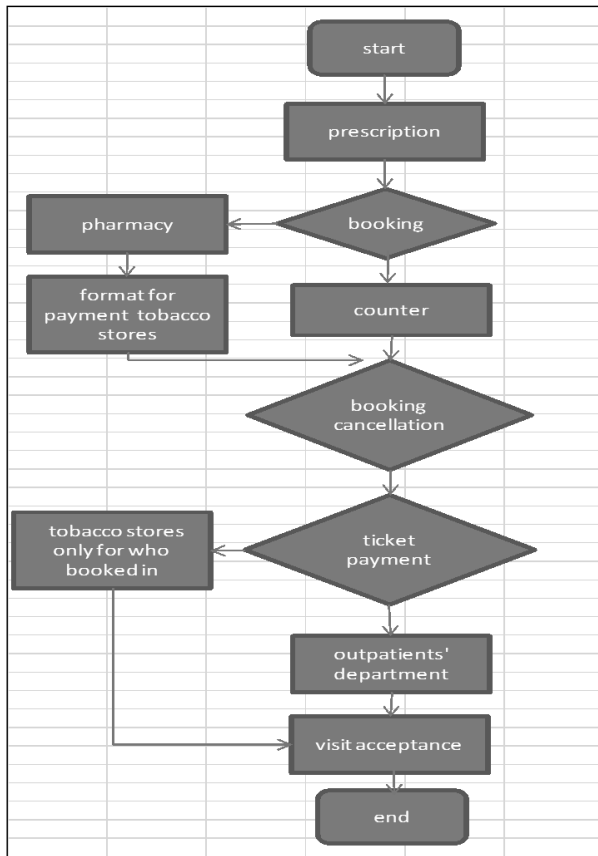

1. Can the CS ProMod model provide cues in order to improve the quality service throughout the determination of characteristics which have a significant impact on the citizen satisfaction?
2. Has the CS ProMod Model the capacity to provide integrated information and to start (up) a benchmarking process?

The research hypotheses are verified throughout the model experimentation in an Health Agency concerning the “Booking health centre” provides by the counter and by pharmacy channels. We highlight that this kind of service is provided in all the Health Agency and that the survey results could be analyzed in the entire nation; however, this research is limited to the study case here mentioned and it doesn’t regard other realities. The survey research verifies the research hypothesis highlighting specificities and common aspects related to multichannel service (Cappelli et al. 2010).

“Booking health benefits centre” is a centralized and computerized system to reserve and to cancel health service and it is usually provided over the counter or by phone. The well-known problem of this service is the rising demand respect the health service supply, with limited available resources, factors which convince the citizen that the long waiting list a great inefficiency.

The Health Agency here analyzed, coherently with the Ministry of Health Guidelines (2009), has started up a new way to book/cancel a health service in order to simplify its access: it enabled the city pharmacies to accept the health service reservations and cancellations and the tobacco stores of the area to receive their payments. This innovative channel guarantees a best territorial expansion of the system and reservation quality, less hardships caused by the distance and drastic reduction of the queue counter and/or by phone. It's important to underline that this survey doesn't analyze the telephone channel but it focuses on counter and pharmacies channels. The aim of the survey is to measure the satisfaction of those citizens who made use of the booking health centre service over the traditional counter and throughout the pharmacies in order to evaluate the users' satisfaction level between the two channels. Specifically, we want to test the impact of the new and innovative service delivery channel (Kano, 1984) on the citizens and to realize if there are significant differences in the satisfaction between the two channels. Within the guidelines for a specific delivery offline service (Cappelli et al. 2010) we have realized two specific questionnaires, one for the counter and the other for the pharmacies, whose structure considers all the transversal and common aspects of the two channels in the service delivery. The questionnaire, within the standard structure of the CS ProMod model, is structured in four sections: one dedicated to the "profiling", a six dimensions set and 20 satisfaction items, a section dedicated to the importance and another to the suggestions. Moreover there were two questions overall, the first one at the beginning of the questionnaire in order to test the citizen instinctive opinion and the other at the end in order to have a reasonable opinion. As indicated in the model, the Likert scale was used with anchor 1-6 (1= totally disagree; 6=totally agree). The stream analyze of the back-office process has allowed to define the customized items to insert in the Response capacity.

Figure 1. Flow chart to determine the items to insert in the Response Capacity

The analyze of the citizen steps to benefit of the service together with the opportunities offered by the Health Agency, has permitted to determine the customized items: particularly, we have determined one common item “Rightness of time to get a medical examination” (CR.3) and two specific items for the pharmacy channel “Advantage of reservation throughout pharmacies” and “Information clarity about the payment at the tobacco’s stores”.

Questionnaires were distributed, throughout a face-to-face interview, at the “Booking health benefits centre” counters (counters 1, 2 and 3) and in 25 pharmacies operating within the health national service. According to the data provided by the Agency and considering a 15 days period, the operation number effected over the counter num. 1 was 97, over the counter num. 2 was 610 and over the counter num. 3 was 1095, total 1802 operation. Regarding to the 25 pharmacies involved in the survey, in the same 15 days period, the operation number was 734 (just one datum). The sampling plan was elaborated considering the specific target of the delivery channels.

In order to determine an appropriate number of interviewees, it must be calculated the sample number basing on some strategic considerations. Generally, do not knowing the value of the proportion in the population, we assume $p = 0.5$. Moreover we suppose that

political-management valuations could lead to fix the maximum acceptable error limit value in the sample calculation equal to 5%. It's moreover necessary to fix the probability that the error doesn't exceed the 5% limit and therefore considering this probability equal to 95% (therefore $1 - \alpha = 0,95$).

The value of the Normal standard distribution in point 2 = 0,025. For this value, the

Normal standard distribution, $\frac{z_{\alpha}}{2}$ takes the value 1,96.

In the "Booking health benefits centre" Pharmacy survey case, it was effected a casual sample on limited population, getting the following sample number:

$$n = \frac{1,96^2 \cdot 734 \cdot 0,5(1-0,5)}{0,05^2(734-1) + 1,96^2 \cdot 0,5(1-0,5)} = 252$$

Regarding to the counter it was instead effected a proportional sample on "not limited population", getting the following sample number:

$$n = \frac{1,96^2 \cdot 0,5(1-0,5)}{0,05^2} = 385$$

In the "Booking medical visit centre" counter case the suggested sample number limit was exceeded and 484 questionnaires were collected: 26 from counter num. 1, 162 from counter num. 2 and 292 from counter num. 3, in line with the turnout proportion at the three different counters. Concerning the pharmacy, instead, 252 questionnaires were collected. The data collection had place in 2010.

Survey results

The data analysis was effected on three different statistical techniques of different complexity: the descriptive analysis, the multiple regression and the hypothesis test, which permitted to verify the research hypothesis (Cappelli et al. 2010). The sample is distributed in the following way: 35% at the counter are males, 40% are females, 2% didn't answer. The most presented age range in both surveys was between 45-60 years old. It's interesting to notice how the citizen is not sensitized of the reservation cancellation, aspect inserted in the profiling questions: in fact, 97% of the subjects went to the pharmacy to reserve a medical examination and only 3% to cancel it; in the same way, 99% of the interviewees went to the counter to reserve a medical examination and only 1% to cancel it. In order to analyze the data, the opinion scale was unified in three classes: 1-2 negative opinion; 3-4 sufficient opinion; 5-6 positive opinion (Cappelli et al. 2010). Here following the analyses of the medium opinion of the common items presented in both questionnaires, comparing the medium satisfaction for the two

channels (Fig. 2). As shown in the graphic, the pharmacy channel presents a medium opinion quite high (5-6) and homogeneous respect the counter channel which has a not homogeneous course and it sets himself in the intermediate range (3-4). Specifically, the items which present a greatest variance are: the overall beginning satisfaction opinion (SCI) and the last one (SCF); the item “Waiting time rapidity to get to the service” (A.5); the two items related to the “courtesy” (P.1) and staff “professionalism” (P.2). We notice that the item “Rightness of time to get a medical examination” (CR.3) doesn’t present a significant gap, but it will be deeply analyzed because it presents a low peak caused by the satisfaction opinion for both channels.

Figure 2. Common items gap analyses of the two surveys.

Here follows the percentage distribution on the total satisfaction, put at the beginning and at the end of the survey (Fig. 3). Comparing the two channels, we can see that the distributions are similar. The values of the initial satisfaction result been moved to the high opinion part (5-6) for the pharmacy, whereas for the counter there is an homogeneous percentage distribution on all the vote ranges, that shows that the citizens, who benefit of the counter service, have a different opinion about the service quality.

The percentage distribution confirms that the pharmacy users are more satisfied respect the counter’s users. Both regarding the pharmacies and the counter the opinion is essentially unchanged considering the beginning and the final satisfaction.

Figure 3. Beginning and final overall satisfaction analyses on between pharmacy and counter.

Here following the comparison between counter and pharmacies concerning the items regarding to the employees, P.1 and P.2 (Fig. 4). You can point out that in this case there is a quite big difference for both the items in the two surveys. The satisfaction of the employees is greatest for those users who benefit the service in the pharmacy. It can depend to the chemists' approach, that is the most similar to the private one, and therefore they distinguish themselves from the public employees because they are more trained and oriented to the client respect the counter employees.

Figure 4. Analysis of the courtesy/helpfulness and competence/professionalism of pharmacy and counter employees

It's also interesting to analyze the items regarding the waiting time: specifically, concerning the time to get to the reservation, it's possible to assert that to reserve throughout the pharmacy is faster than over the counter. Regarding to the CR.3 item "Rightness of time before to get a medical examination", common element to both surveys, you can see a dissatisfaction for both channels with a homogeneous opinion (Fig.5). However, if you pay attention to the highest opinion, it's possible to notice the twice the interviewees for the pharmacy is on 5-6 range.

You can therefore suppose that the citizen, more satisfied by the new pharmacy service of booking, has a less negative perception of the waiting time that elapses between reservation and medical service, even if the time is the same one.

Figure 5. Waiting time analyses to book (a) and make (b) a medical exam for pharmacy and counter

(a)

(b)

Throughout the descriptive analyses is possible to highlight that the CS ProMod model allows noticing the users' satisfaction level and giving comparing information which can support the benchmarking process. This hypothesis can be also analyzed throughout statistical analyses as a hypothesis test on independent sample (Fig. 6), which allows verifying the quality of a hypothesis, watching a specific phenomenon. The hypothesis test was calculated using the *Minitab* software. The *p value* analyses results 0 and therefore less respect the α level, fixed equal to 0,05; therefore, we can refuse the null hypothesis and therefore to assume that the medium of CR.3 is indeed less in the counter survey case. The same result is verified also for the hypothesis regarding the beginning and final overall satisfaction (Fig. 7 and Fig. 8) and also if we consider the courtesy and competence of the employees (Fig. 9 and Fig. 10).

 T-Test of difference = 0 (vs <): T-Value = -19,63 P-Value = 0,000 DF = 684

Figure 10. Independent sample hypothesis test on common item to pharmacy and counter “Competence and professionalism of the employees” (item P.2).

$H_0: \mu$ satisfaction “Competence and professionalism of the employees” counter = satisfaction “Competence and professionalism of the employees” pharmacy

$H_1: \mu$ satisfaction “Competence and professionalism of the employees” counter < satisfaction “Competence and professionalism of the employees” pharmacy

	N	Mean	StDev	SE	Mean
P.2_S	473	4,19	1,55	0,071	
P.2_F	249	5,723	0,588	0,037	

Difference = μ (P.2_S) - μ (P.2_F)
 Estimate for difference: -1,5284
 95% upper bound for difference: -1,3961
 T-Test of difference = 0 (vs <): T-Value = -19,03 P-Value = 0,000 DF = 670

Therefore, it is possible to consider satisfied the second research hypothesis concerning the CS ProMod model capacity to provide integrated information and to start up a benchmarking process. Another element to add and which supports the obtained results is the classification of the open questions, which underlines the main criticality of the item CR.3. It’s interesting underline that 398 observations have been collected respect the 484 interviewees (80% ca.) for the counter and a total of 30 observations respect the 252 interviewees (12% ca.) for the pharmacy. In both cases, the most common category is the decrease of the waiting time to get a medical examination, then the second category, for the counter, is “the operators’ number” (it means a decrease of the reservation waiting time) and, for the pharmacy category, is the information clarity to reserve in the tobacco’s stores, item quite critical studying the same percentage distribution. You can assume that the open questions analyses let emerge aspects not considered among the survey’s questions (f.e. counter operators’ number or development of the telephone service).

The CS ProMod model provides the elaboration of the connection between the average of the dimension Importance and the average of the Satisfaction item (average I/average S), so as to rank in order of priority the items from a quantitative point of view. A priority item is an item which has a high importance level even having a low satisfaction level. Determining this kind of item allows to the manager to find out the main improving areas, directing the possible actions to the most important - and at the same time the most critical - dimensions (Cappelli et al. 2010). Therefore, also in this case, throughout the calculation of the index I/S (Tab.1) is possible to estimate the priority action for both channels. This analysis confirms that item CR.3 “Rightness of time to get a medical examination” is the most critical item for both the providing channels. Another critical item for the pharmacies is that related to the “Information clarity about the payment at the tobacco’s stores” (CR.2), whereas for the counter is priority the “Facility to make a complaint” (U.1) and to fast the counter reservation time.

Table I. Determination of the priority actions throughout I/S rate.

I.3	Adequacy of information- The provided information are complete	5,61	5,60	1	A.4	Accessibility- It is easy to identify the employees the provide the service	4,70	5,51	1,17
A.5	Accessibility - Rapidity in the waiting time for the booking at the pharmacy	5,52	5,48	0,99	AT.3	Tangible aspects- The environment is functional	4,67	5,40	1,16
I.2	Adequacy of information- The information are provided with a simple language	5,66	5,60	0,99	I.2	Adequacy of information- The information are provided with a simple language	4,87	5,58	1,15
P.2	Personnel- Courtesy/helpfulness of the employees	5,72	5,56	0,97	I.5	Tangible aspects- It is easy to identify the counters	4,88	5,58	1,15
P.1	Personnel - Competence/professionalism of the employees	5,73	5,56	0,97	I.4	Adequacy of information- The steps that I must do to book a medical visit in the counter is clear	5,12	5,58	1,09
A.1	Accessibility - The open time of the pharmacy is appropriate	5,66	5,48	0,97	A.1	Accessibility - The open time of the office is appropriate	5,10	5,51	1,08
AT.3	Tangible aspects- The environment is functional	5,55	5,33	0,96	A.2	Accessibility- It is simple to reach this office	5,52	5,51	1,00
					A.3	Accessibilit�- This pharmacy has not architectural barrier	5,76	5,51	0,96

The collected data have been represented throughout the priority map, where every point has coordinates equal to the medium of satisfaction (X coordinate) and to the medium of importance (Y coordinate). This tool is really effective because it allows to understand how the items are set on a Cartesian axis (Martilla, 1977). The priority map (Fig. 11) represents at once the priority items and allows to individuate them: particularly, for pharmacies are CR.3, because even if they have an high importance opinion they also have a low satisfaction level and CR.2, that has an higher importance level but at the same time a lower satisfaction level; also in the counter case, CR.3 is the most critical item, because even if it has an high importance level it presents a low satisfaction level, as item U.1 (user contact – It’s easy to make a complaint/suggestion) that has a lower satisfaction level but at the same time an higher importance level.

Figure 11. Priority map for counter and pharmacy

From the data analyses comes out that the model, throughout the priority map and the I/S index, allows to managers to determine the action priorities in order to take effective and efficient actions, basing on the citizens opinions, concerning not only the dissatisfaction but also the importance of every aspect. In order to answer to the research question about the informative capacity of the CS ProMod model to generate an improvement in the service quality, it's necessary to investigate the characteristics that have a positive impact on the citizen total satisfaction. In this specific case it's possible to analyze this impact on two different opinions about the satisfaction overall, the first one at the survey beginning and the second one at the end (where the answer must be judicious).

In Fig. 12 – here following - it's also possible to compare the multiple regressions occurred for both surveys considering the initial and final satisfaction (De Luca, 2002). The regression factors analyses allows to determine the most impact variables on the satisfaction. Specifically, for the counter, the variables which can clear the initial satisfaction are: “Rapidity in the waiting time for the booking” (A.5); “Comfort in the waiting halls” (AT.1) and “Rightness of the waiting time to get a medical examination” (CR.3). In the case of final satisfaction the item with more impact on the satisfaction is the CR.3. In the case of pharmacy the factors which can explain the initial satisfaction are connected to aspects regarding the employees and they are “Language simplicity used by the employees” (I.2) and “Employees professionalism and experience” (P.2). In the case of the final satisfaction the items with more impact on the satisfaction are “Employees courtesy and helpfulness” (P.1), “Language simplicity used by the employees” (I.2) and “Rightness of the waiting time for the booking” (A.5).

I.537						I.3	0,13068	0,05593	2,34	0,020	2,227
AT.3	0,15655	0,04677	3,35	0,001	1,266	AT.3	0,09802	0,03894	2,52	0,012	1,244
P.1	0,08570	0,04976	1,72	0,086	1,630	P.1	0,13236	0,04171	3,17	0,002	1,645
CR.3	0,13878	0,04175	3,32	0,001	1,154	CR.3	0,22984	0,03514	6,54	0,000	1,169
S = 1,23922 R-Sq = 44,6% R-Sq(adj) = 43,6%						S = 1,04397 R-Sq = 49,8% R-Sq(adj) = 48,8%					

In both the factor $R-Sq(adj)$ explains the 45% of the variance, whereas acceptable values for a good regression model are around the 70% (De Luca 2002): this shows that the survey must be considered as a still optimize and improving tool. It's interesting to see as the main factors - which present the greatest impact on the satisfaction - are the same in the final satisfaction case, but different in the case of the pharmacy and counter. This information is useful to decide the improving actions on which to invest in order to increase the citizen total satisfaction. Specifically, in the pharmacy case the items have impact on the employees and on the used language simplicity, that have high satisfaction values and this simply suggests to maintain the satisfaction level on these aspects whereas, to improve the counter users perception, is necessary acting on the waiting time. The results have allowed determining the priorities' actions for the Agency in order to improve their service. Among these items, in order to decrease the waiting time to get a medical examination, a free toll number to cancel the reservation

has been activated and a sensitive campaign regarding the cancellation has been started up, whereas to implement the pharmacy channel a communication campaign has been effected.

Conclusions

The results of the survey made in the Health Agency on the “Booking health benefits centre” service allow giving a positive answer respect the research questions put on the CS ProMod model that, throughout the use of statistic techniques of different complexity, can give useful information on the strength, critically and priority points of intervention regarding both channels and the providing process. It’s interesting to see that throughout simply descriptive statistics and more complex techniques, the model allows to study the citizen perception, giving the possibility to have a comparison among common measures and those intervention priorities on which the manager should act in order to improve the satisfaction level. It has been possible to verify that the CS ProMod CS provides useful information for the improvement and can be the starting of an internal benchmarking process, dedicated to increase the value of the good procedure. Specifically, the model allowed to evaluate the satisfaction impact introducing a new providing service tool and to classify it as internal best practice. However, this can be the first step to implement the process to other administrations that provide the same service. However, it is possible to presume that the model presents anyway optimization margins in effectiveness and it’s necessary to proceed with other efforts to validate it and make it more rigorous and trustworthy.

Identification of customer needs in healthcare – translating patient needs into critical-to-quality characteristics

Susanne Gustavsson . PhD student at the division of Quality Sciences, CHI-Centre for Healthcare Improvements, Department of Technology Management and Economics, Chalmers University of Technology, 412 96 Gothenburg Sweden. Chief Nursing Officer at Skaraborg Hospital Group, 541 85 Skövde, Sweden.

Key words: Patient, Customer, Kano model, Critical-to-customer, Critical-to-quality characteristics, Healthcare

Category: Case study

Introduction

According to patients, there has been a recent increase in interest in how the customer concept could be used in healthcare (Lengnick-Hall, 1995, 2000; Mazur, 2003). Previously, patients were thankful if they could visit a doctor or a nurse. Healthcare was given on sufferance and the patient's natural role was one of servility. However, modern patients have a completely different position in society and expect to be treated differently. Nevertheless, the old strict hierarchical mentality still prevails within some hospital walls (Kettunen, Poskiparta and Gerlander, 2002). Healthcare staff use their knowledge and resources in a way that they assume is best for the patient. Consequently, the patient is seen as an object and is handed from one specialist function to another; this way of working builds barriers in the processes of care (Bohmer, 2009). According to Mazur (2003), organisations obtain better results if there is a focus on improving the experiences of the customer process from the customer's point of view, rather than simply improving work processes. However, it seems somewhat far-fetched to expect the patient to be seen as a subject and where the care processes flow smoothly, thus creating value for the customers (that is, the patients).

There is reason to believe that knowledge about the customer concept and how to visualise the needs of the customer could be translated from operations management knowledge into healthcare knowledge domains (Batalden and Stolz, 1993; Bergman and Klefsjö, 2001; Berwick, 2008).

Although the healthcare system trying to satisfy the needs of its customers could be seen as a complex situation, healthcare staff must find strategies to cope with this

situation (Glouberman and Mintzberg, 2001). Lengnick-Hall (1995) suggested four dimensions of the patient as a customer that could support the customer concept in healthcare. According to Lengnick-Hall (ibid), healthcare providers adapt a number of tools and techniques that are used in other settings to systematically incorporate patient information into their planning and service delivery activities. It is necessary to develop a systematic approach in order to find out the real requirement of patients, as this requirement leads to greater customer satisfaction and ultimately makes the hospitals more successful (Yeh, 2010).

This paper describes how the management team at a Swedish hospital applied the customer concept from a patient perspective, using the Kano model in the identification of patient needs to support the translation of needs to critical-to-quality characteristics when designing the care process.

The paper will first provide a background to the patient concept and the patient as a customer, and then continue with a description of the Kano model. This is followed by a description of the methods used in the study. Finally, the case study is described, followed by a discussion and concluding thoughts.

Background

The patient as a customer

As early as 1988, Grönroos and Montheleie used the word “customer” to describe a consumer of public services, including healthcare (Grönroos and Montheleie, 1988). The introduction of market- and service-management discourses in healthcare has paved the way for a situation in which the patient has become a customer. The word “patient” comes from the Latin word *patior*, which means “the suffering” or “those who patiently endure suffering” (Eriksson, 2001). According to Nordgren (2008), the word “patient” could be emotionally charged; on the other hand, the word may have no importance and it may be the meaning of the concept that determines the consequences of actions and behaviours.

The relationship between healthcare professionals and patients is built on the fact that the healthcare professionals have medical knowledge that the patient needs. This relationship creates an unequal power balance and means that one of the parts is more dependent on the other (Eriksson, 2001). The relation between healthcare providers and receivers is in focus for development and change. The customer concept involves

overturning the medical hierarchy and shifting the power to the patient (Nordgren, 2008; Eriksson, 2001).

According to Lengnick-Hall (1995), the relationship between healthcare systems and their patients is complex, and a traditional perspective on quality development and familiar views of customer satisfaction is inadequate for managing this relationship. Lengnick-Hall proposed four different roles for the patient in a healthcare system: a supplier, a product, a participant, and a recipient (Lengnick-Hall, 1995). The key differences between healthcare processes and other service delivery firms are that “the product” that healthcare produces is human change. Healthcare deals with experiences, rather than with objects. The production and delivery are inseparable (Zeithaml, Parasuraman, and Berry, 1990). Moreover, the product is assumed to be improved over time, rather than worn out. The in-house service production processes are often as important to the patient as the final result.

Visualise the needs of the customer

The 1980s saw the presentation of Kano’s model of attractive quality (see Figure 1) (Kano, 1984; Mikulic and Prebezac, 2011). According to Walden (1993), use of the Kano model requires a deep understanding of customer requirements. Customer ideas about quality are often confused and difficult to see clearly, but they must be made clear. Expected requirements are essential to the customer but, in most cases, are not mentioned. However, if these requirements are not met, the customer will be very disappointed. Hence, Gremyr et al. (2009) argued that the explicit voice of the customer is sometimes not enough as a main input. Instead, the voice of the process and the voice of compliance may take centre stage in particular settings. The focused voice of the customer is difficult to handle in a healthcare application because patients have limited insights into the medical aspects of the healthcare process. According to the Kano model, these medical characteristics are *must-be quality* criteria in the process (Figure 1). Other requirements are indifferent and provide the customer with a neutral feeling. One-dimensional requirements are the spoken needs of the customer and affect satisfaction to the extent that they are present or absent. Exciting requirements are difficult to find and are connected to the attractive perspective of quality. The customer will not notice if they are absent but will be very pleased if they are present. The horizontal axis of the Kano diagram indicates how some aspects of the service are fully functional. The vertical axis indicates the customer’s degree of satisfaction (Walden, 1993). However, Kano’s theory also includes a third class of requirements, which

behaves as if the positive and negative axes were continuous and one-dimensional factors.

Figure 1. *The Kano model of customer satisfaction (based on Walden et al. 1993).*

According to Yeh (2010), a patient’s consciousness regarding health will increase, which is why hospitals need to pay more attention to satisfying patient demands. Examples of must-be quality presented include: hospital washrooms being properly cleaned, skilful techniques of nursing staff, and convenient hospital parking. When it comes to attractive quality, the patients mentioned the doctors’ ability to explain the disease and its treatment in detail. One-dimensional qualities include empathy from doctors and the degree to which the hospital guarantees the confidentiality of the patient’s personal information (Yeh, 2011).

Analysis of complaints and compliments may be one reason for applying the Kano technique (Friman and Edvardsson, 2003; Mikulic and Prebazac, 2011). The quality attributes may be categorised by comparing how frequently customers mention an attribute in a positive context or a negative context. Kano’s analysis aids in an understanding of the relationship between the fulfillment of a requirement and the satisfaction experienced by the customer. According to Walden (1993), the Kano analysis seems to increase the credibility and confidence of the team with respect to the care process design, perhaps due to increased traceability. The model verifies that the team has accurately understood the voice of the customer and translated it into an appropriate requirement statement. A graphical representation may often convey more information simultaneous information than a non-graphical approach (Walden, 1993). Mikulic and Prebazac (2011) argued that the Kano model provides managers with valuable information that can be used to design new products/services or to improve existing processes. The Kano model is particularly useful in the design stage because it

helps categorize existing and non-existing attributes according to their potential to elicit satisfaction/delight and dissatisfaction/frustration from a customer perspective.

Care for mothers and their newborns

Care for newborns and their mothers is one aspect of healthcare that can be improved to better satisfy patients' needs (Ellberg, 2008; Erlandsson, 2007; Sandin-Bojö, Kvist, Berg and Wilde-Larsson, 2009). The most important need for these patients is that the family is able to stay together. Being together is important for achieving a positive family relationship, which leads to better breastfeeding initiation, better bonding between mothers and their children and earlier discharge from the hospital (Aagaard and Hall, 2008). However, these requirements not only create demands pertaining to the design of the facilities, but also demands pertaining to the organisation of the actual care process. Children in need of neonatal care must have their mothers and fathers at their side as much as possible (Aagaard and Hall, 2008). This requires new forms of cooperation between women's healthcare and paediatrics.

The hospital under study, Skaraborg Hospital (SkaS), is situated in the Western region of Sweden and handles approximately 2500 births each year, about 10 percent of whom need neonatal care. The delivery ward, the maternity ward and the neonatal care unit are located far from each other in the hospital building. This means that large distances must be covered when transporting patients between the wards. The "patient process" is defined as the patients' journey from prenatal diagnosis through antenatal care, the birth and on to maternity care and, perhaps, neonatal care for the baby (Figure 2).

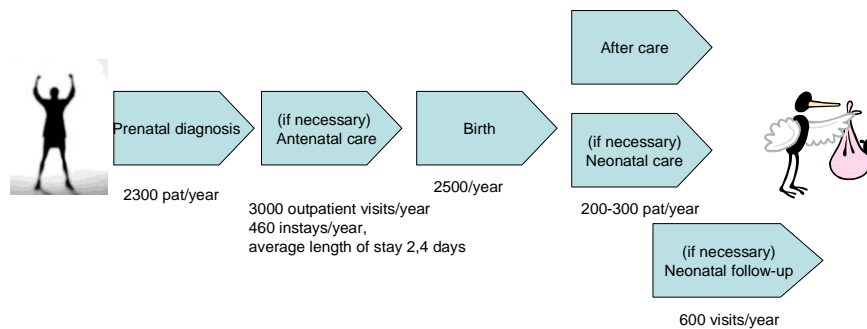

Figure 2. The patient process.

Method

The research is empirical and focuses primarily on contextually rich data from real-world settings to explore the application of customer orientation in healthcare. This is in line with Barratt, Choi and Li's (2011) definition of qualitative case studies. This case was chosen because it was included in a longitudinal action research study at this division, with the researcher as an insider. This meant that the method could be regarded as action scientists conducting research within their own organisation, which Coghlan and Brannick (2008) described as "insiders". The advantage of being an insider is that the researcher may have access to the local practices but also the credibility of the organisation, knowing the people and the culture. The disadvantage is that the researcher's pre-understanding of the problem and context can make it difficult to take a step back to analyse, reflect, and sometimes criticise the research role. Coghlan and Brannick (2008) argued that if the researcher is aware of this disadvantage, it can be turned to his or her advantage and pre-understanding will be of great use in the research.

The empirical material was collected over a two-month period and consisted of observations (attendance at meetings by the insider researcher), documents (meeting notes and reflexive diary), and reflecting dialogues with the management team. Subsequently, seven interviews were conducted with staff members (doctors, nurses and a secretary). The collection of empirical material was carried out in a systematic manner

(Benzabat et al., 1987; Mintzberg, 1979). The insider researcher collected the data, which was then analysed qualitatively and inductively and reflected on with the management team. In a single-case study, the depth of the observations enables the researcher to capture more details of the context about the phenomenon under study (Barratt, Choi and Li, 2011).

The use of multiple data sources and multiple investigators could be considered triangulation of data from different sources to strengthen the analysis and the results of the study. There was an overlap between data collection and data analysis, which, according to Meredith (1993) and Coghlan and Brannick (2008), allows the researcher to capture the reality from which the data was collected. The purpose of the analysis was to gain a deeper understanding of the case related to the broader body of knowledge expressed in the scientific literature. Action Research, with a focus on innovations in a healthcare environment, requires each situation to be regarded as unique. The research will not create knowledge on a predictable “truth”. Instead, the result should be seen as descriptive insights of using the customer concept in a healthcare context, which could therefore be regarded as a tentative framework for other practical implications. Generalisability is analytical rather than statistical and the result is presented as a narrative supported by quotations from key informants (Yin, 1994).

The Case

In the spring of 2009, a major project begun in the area of Children’s and Women’s Healthcare. The aim of the project was to plan for a new building that could harbour, support and enhance the efficiency of some of the division’s critical care processes. The present study has focused particularly on the “perinatal centre” part of the project. The main purpose of the project was to create a patient process that was attractive, accessible, effective and safe for patients. The new centre was to be designed according to the patient process, without taking into account existing organisational structures or existing buildings. The care for the patient was planned to be more patient-oriented and patients were not supposed to be able to notice any differences between the functions of care.

Patients as customers

The management team consisted of the divisional manager, the manager of the obstetrics clinic and the manager of the pediatric clinic (including neonatal care). An accountant and an improvement facilitator were also represented in the team (the latter

being the internal researcher in this project). The managers were educated in improvement knowledge and became familiar with the customer concept as a guiding principle for intensive quality improvements at the hospital, according to the “corner stones” described by Bergman and Klefsjö (2001). At the start of the project, the most important issue was to create and organise a common picture of the management team’s responsibilities. The team had representatives from two organisations, in the form of managers from the obstetric and neonatal care departments. The two managers had to develop a common picture of the project that they could convey to their own staff. The team dialogue contained several reflections about difficulties getting the other staff in the clinics to share the vision. Comments included: “We must give those new ideas time”, and “The staff may feel threatened when the old organisation is changed”. A thorough plan for communication was seen to be essential. The managers decided to go and tell the rest of the staff together. Initially, there was an unstructured brainstorming session regarding what the project should elaborate on. There were several discussions about processes and patient flows, and even more discussions about “manageable parts” and “concepts”. Questions included, “What do we actually mean by antenatal care?” and “What do we actually mean by neonatal care?”

The team conducted a stakeholder analysis and identified the patient and his or her family as key stakeholders. The managers clearly stated and agreed that the project should primarily focus on patients’ needs. As one of the managers mentioned, “It is important for the patients to keep their autonomy during their stay at hospital”. All individuals in the management team were enthusiastic and had many ideas, which they wanted to share. Two of the managers had written down their thoughts from a patient perspective, how it would look if everything was perfect. Notably, several of the things they had written coincided: “To feel seen and welcomed”, “Everything felt calm”, “I got all the information that I needed” and “It felt safe”.

The team was then introduced to the Kano model and the process of translating patient needs to requirements, requirements to functions, and functions to solutions. The team members found it interesting and wanted to use this process for their work. Later, they also wanted patients to be more involved in the work. Everyone in the management team agreed that the patient perspective could be translated to a customer perspective. During a brainstorming session, the team translated the customers and their main needs as corresponding primarily to the patient, his/her relatives and then the staff

The focus of the project was to improve the experience for patients, their relatives and the hospital staff. Thus, the first task was to find out about the patients’ experiences of

the existing care. All patients in the organisation had the opportunity to be involved in a survey of after-care services (called the “Quick Search” survey). The survey contained information on patient’s experiences that could be available to the team. Results from focus group interviews with parents from the neonatal care unit were used as an additional basis for understanding patient experiences. Drawing from this data, the management team decided that the new patient process should be based on patient needs and not on the current situation at the clinics. The team decided to come up with a shared vision in order to work towards stronger collaboration between the current functions.

The voice of the customer

The experiences of the patients were important to the management team. The team analysed the patient experiences found in the “Quick Search” survey result for the preceding year and the result of the focus groups. Some examples of quotations from the patients are provided below (translated from Swedish):

“Pure luck that the father had the chance for an overnight stay. He was thrown out during the second night. It should be obvious that the father wants to be with his new family as long as necessary. Where has all the nagging about equality gone regarding fathers’ rights? Construction of the single rooms *promptly* where the father may stay in an extra bed!”

“I was an inpatient for a very long time before the birth and it was boring to just watch television. Unfortunately, we were not allowed to bring a laptop with us to watch movies and listen to music.”

“Why don’t you try to cooperate better with the children’s department? Sometimes you had the feeling that it was ‘us against them’. I would feel better if after-care and the children’s department could work together better, but that’s a typical women’s characteristic to say that one is better than the other.”

“Having to change rooms due to lack of space was not so good.”

The team then analysed the experiences and translated them into customer needs. The team made a subjective judgement about the most important needs. These needs were then categorised using the Kano model (Figure 3) from both a subjective and qualitative perspective.

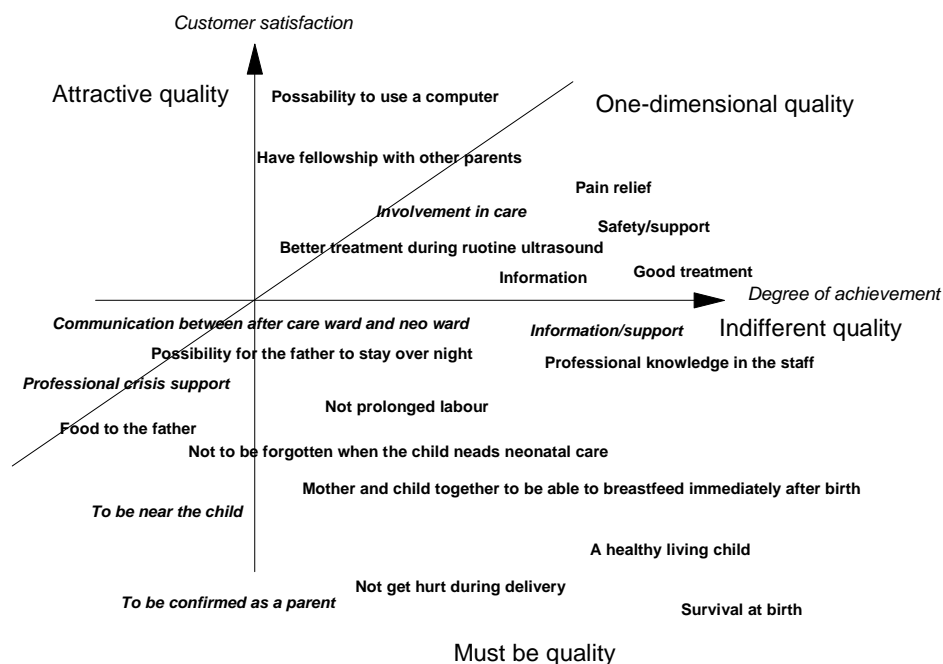

Figure 3. The Kano model

Some of the basic needs were not mentioned by the patients and the management team identified these needs based on their professional knowledge; for example, “not to be killed during childbirth”. The needs in italics (Figure 3) come from patient experiences that were mentioned in the focus groups at the neonatal unit. The rest of the needs were extracted from the survey results at the maternity ward. When the number of negative experiences exceeded the number of positive experiences, the attribute was categorised as a “one-dimensional” quality. When the number of positive experiences exceeded the negative experiences, the attribute was categorised as an “attractive quality”. Needs that were not mentioned by the patients but were experienced by the professional team were categorised as “must-be” quality. This model was presented to patients and their partners later on in the project, and they accepted the model created by the management team. According to the management team, placing patient needs into the Kano model provided a rich picture of the wholeness of the care that the patients needed. After the Kano model workshop, the management team thought about how to explain the results within a few sentences that could be included in the assignment for the project group.

Translating patient needs to critical-for-quality characteristics

The management team translated the patient needs into critical-to-quality characteristics using collaborative reflecting dialogues, with a focus on how patient needs are fulfilled

currently and how they could be better fulfilled in the future. The whiteboard was used frequently to share thoughts during the dialogues and the whiteboard pen was in constant demand. There were sometimes difficulties getting others to listen. Everyone wanted to talk, but all team members eventually had their voices heard and had the chance to share their thoughts. The process involved a great deal of enthusiasm. The team arrived at a shared vision about the new centre that could be conveyed to the project groups, to the architect, to the building company and, later, to all employees at the clinics. The premises in the “Perinatal centre” were intended to provide an opportunity for healthcare professionals to pursue treatment based on patient needs, while also offering a good working environment for employees. The critical-to-quality characteristics based on patient needs can be summarised into nine important requirements guiding the planning of the new centre. The premises should allow families to:

- Receive safe health care
- Feel supported and safe
- Obtain their autonomy
- Feel noticed and welcomed
- Experience a quiet and calm unit
- Have simple access to the centre
- Feel informed
- Feel that the premises are flexible
- Not experience unnecessary waiting

These requirements illustrate what the project should focus on in order to bring forward a patient-oriented design of the new care process. The requirements were delivered to the project group, which then had to translate them into functions and, later, to solutions. In the interviews, the project group members responded that the requirements felt very natural and provided a good framework for their future work. Comments included: “You have to be constantly reminded that the patient should be in focus”, “It is important to get a common picture”, and the requirements were described as a “light in the dark”.

Results – Comments to the case

The goal for the management team was to transform the care process from the present to the future, as shown in Figure 4 below.

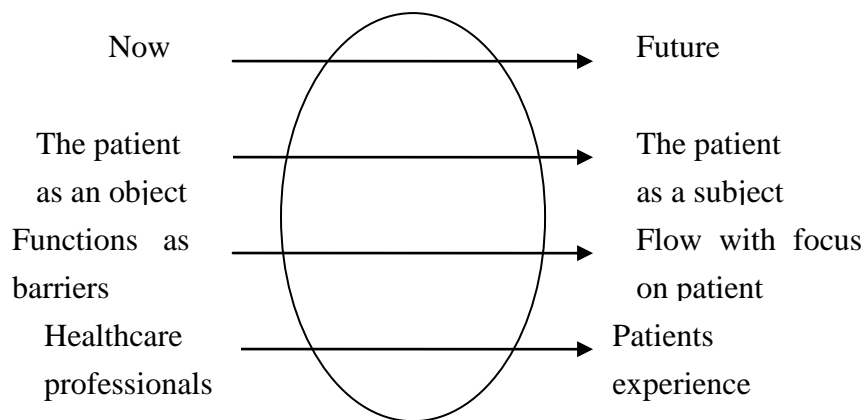

Figure. 4. Model of transformation from present to future.

In the presented case, the management team recognised the need for a difference from existing care to achieve higher quality in the future; the patient became an important central subject in the design of healthcare. The main steps the management team took were to *identify* the experiences of the patient and *translate* them to needs that were then *visualised* in a Kano model and *communicated* to the rest of the organisation. The management team *learned* through reflective dialogue and *defined* critical-to-quality characteristics in their design process to *achieve higher quality* in the patient process. Focusing on the experiences from a patient perspective instead of drawing from existing functions gave the team clear insights into the patient pathway. As one of the interviews with a member from the project group noted:

“It is obvious that, from the start, there is a vision to keep the patient in the centre, but in a while there will be other things in focus instead of the patient. I think that is what is happening in all healthcare situations. You have to be reminded of the patient focus. They are our customers. Now we have to think differently in the process, you could see beyond the situation today; that is what I learned”.

Patients’ experiences were important for the design of the new building, as well as for organising the care processes. Thus, the new patient process has been developed from a patient perspective, acknowledging critical-to-quality characteristics that are important to the patient. The graphical presentation (Kano model) of patient needs did verify that

healthcare staff understood and examined the voice of the customer and conveyed the purpose of the model to healthcare staff. One of the members of the management team said: “We have different pictures of how it could be in the future. It feels good to have a supporting picture with emphasis that shows the direction.” One of the members in the project group stated: “I have learned to focus on the assignment and it feels like we are developing a new way of thinking. It is exciting.” The Kano model and the list of requirements increased the credibility and confidence of the management team with respect to the patient process.

Discussion

From a healthcare perspective, it sometimes seems difficult to replace the patient concept with the customer concept. A reasonable approach would be to adapt the customer concept to a healthcare context. Nordgren (2008) argued that if a certain discourse is legitimised and comes into use in a society or a part of the society, it will, depending on its fulfilment, become powerful enough to influence the everyday speech, writing, thoughts and actions of that part of the society. This change implies that a gradual transformation in the view of the person seeking care has occurred, from someone waiting patiently to a customer who is obliged to be active when seeking care, asking questions and collaborating in the care process (Nordgren, 2008). In this case, there were no doubts when patients were identified as customers. The power of healthcare staff, vis à vis patients, was not discussed in a negative way; it was seen more as a positive move to translate the customer to the patient perspective. The patient’s role became more and more empowered and important throughout the project. According to Eriksson (2001), healthcare professionals have more knowledge, which gives them extra power towards the patient. Accordingly, the patient may be the one with more power than the staff because of the influence that the patient has on the process from the different dimensions mentioned by Lengnick-Hall (1995).

One possible reason why the patient perspective as a customer became obvious in this case could be that the knowledge of the management team was not only based on the domains of medicine, nursing and economic knowledge, but also on improvement knowledge. This meant that there were existing guiding principles in the hospital to put the patient in focus. These guiding principles were probably a success factor. The management team carried out an understanding of the importance of the patients as a customer in developing high-quality care. However, members of the project group mentioned that they had to be reminded of the patient as the central part when working with the design of the new patient process. It could be that the knowledge of quality improvement is strengthening the customer concept from a patient perspective.

The analysis of complaints and compliments in the “Quick Search” survey provided the management team with valuable information during the design phase. Consequently, the management team had to use its medical and nursing knowledge to identify the basic needs of the patients. Gremyr et al. (2009) argued that the explicit voice of the customer is sometimes insufficient as a main input; rather the voice of the process and the voice of compliance may take centre stage. As Miculic and Prebezac (2011) suggested, the Kano model was capable of classifying patient needs in the design phase and was shown to be a practical model to use when visualising and communicating patient needs in the organisation. Not only are there the customer needs in different dimensions, but it is also a picture of the current state and the degree to which the needs are fulfilled. The Kano model provided a systematic way of defining patient needs. Miculic and Prebezac (2011) also argued that managers receive valuable information when they use the Kano model; information that could be used when designing service. This was clearly what happened in this case.

According to Ellberg (2008), the care of mothers and newborns must be improved in order to satisfy the patients and the most important thing is to bring the family together. In the case of SkaS, this has been a major task. SkaS will probably become the first hospital in Sweden to integrate and collaborate its obstetric and neonatal care in the same patient process adapted building.

In an industrial context, the healthcare sector has seen a great influence of total quality management. These techniques are sometimes linear and there is an assumption that the healthcare context is more complex than the production process in a factory. Experiences from the patient are then crucial when carrying out high-quality services (Bergman & Klefsjö, 2001). Lengnick-Hall (1995) suggested that healthcare organisations that systematically incorporate patient preferences and requirements in their service design will achieve and sustain higher quality service accomplishments and reputations than those that disregard this relationship.

In the present case, as a development of using the customer concept from a patient perspective, the management team decided to involve the patients in the project in different ways later on. These included putting up boards where the patients could come up with ideas to make the new building better than today’s facilities, and inviting patients to work with improvements together with health care staff.

During this case, managers described the design process as “Fun”, “Feels contemporary”, and “We have thrown ourselves into something exciting and unknown, no one has done this before us”. The managers felt proud and visionary when talking about their project.

The management team managed to theoretically transform its organisation into a future system where the patient concept was highlighted and the patient was seen as a subject, experiencing events that are important for managers when making decisions regarding the design of new healthcare processes.

Conclusion

The result could be considered to be descriptive insights when using the customer concept in healthcare processes, and could also provide a framework for other practical implications. The study contributes to the current understanding of how patient processes in healthcare may be designed based on the patient as a customer. The study also suggests that the Kano model may be useful in a healthcare setting, visualising and communicating the fulfillment of customer needs. The importance of improvement knowledge, in addition to the professional knowledge in healthcare professionals, has an impact on the possibility to apply the *customer* concept from a patient perspective. The next proposed level is to involve the patient in the design of patient processes.

Acknowledgements

The author is grateful to the management team at the women and children’s department at Skaraborg Hospital Group, Sweden for their contribution of empirical material and their reflective discussions during the project, as well as their willingness to improve the care for newborns and their mothers (and partners).

Key words: quality costs account, management, control, continuous process improvement

Category: research paper

Introduction

The quality cost account should be an important tool to assess the effectiveness of production processes. In theory, there are many models, structures and different ways of quality cost accounting. Many authors in the literature convince of the undoubted benefits of the application of financial measures to evaluate the quality management system. Unfortunately, the quality cost accounting in practice often does not work, as it may be demonstrated by the examples of some Polish companies. In other words, there is a gap between the cost account, presented in the literature, and its perception in practice. The aim of this paper is to present considerations about the strengths and weaknesses of the quality cost accounting. Indication of the most common weaknesses in cost accounting practice should enable analysis of the improvement solutions.

In publications, such as (Ciechan-Kujawa, 2003) (Balon 2006) (Szczepańska, 2009) (Szymonik, 2002) (Skrzypek, 2000), numerous models and cost structure of quality are presented, and aims of quality cost accounting are described. These are usually a diagnosis of the current state or transformation of classics' ideas, of Juran, Crosby, Deming, Bank. Some questions have been raised if such general information and reports are applicable in practice. In order to verify the sources of literature on the quality cost accounting, a research among Polish entrepreneurs was conducted. One applied a survey questionnaire, consisting of six questions relating to:

1. the elements of quality cost account (identification, records, planning, accounting, analysis) used in manufacturing enterprises,

2. causes of not-using of quality cost accounting in manufacturing companies,
3. departments which realize tasks related to running of quality cost account,
4. tools used for the analysis of quality cost accounting,
5. areas in which decisions are based on the quality cost accounting,
6. problems connected with running of quality cost accounting.

The questionnaire survey was filled in by forty-three Polish entrepreneurs (Table I). The dominant industry was the production of the ready metal products for machineries and equipment (17 companies). The questionnaire was mostly filled in by medium-sized enterprises (24 questionnaires). Only one company had not implemented a standardized management system, 19 had implemented the management system but had not certified it, the remaining 23 companies had both implemented and certified the management system. The respondents could indicate more than one answer in the case of questions of the quality cost accounting.

Table I. Analysis of the responses, provided by 43 companies, in a questionnaire survey concerning application of on the quality cost accounting.

21% of companies do not apply quality cost account		1 company with no implemented management system	The main reason for non-applying quality cost account is the lack of formal structures and guidelines, identifying costs of quality - 8 indications	
		8 companies have implemented and / or has certified management systems	Other causes: ignorance of a tool (1 indication), a lack of faith in the cost account (3 indications) high expenditures associated with its conduct (2 indications);	
79% companies apply elements of quality cost account	56% apply quality cost accounting in the departments of management and / or quality control and in the manufacturing department	63% of enterprises apply up to three elements of quality cost accounting		71% have problems with the use of quality cost accounting. Among the problems are: the reluctance of workers, lack of techniques to

	each of 16% in the Controlling Department and the departments of accounting and finance	37% companies apply more than four elements of quality cost accounting	all of them have been implemented and / or certified management system for more than 1 year	conduct quality cost and analysis of the structure of quality cost, high expenditures connected with distinguishing quality costs
			57 % use 3 or more tools for the analysis of quality cost accounting	
12% in all areas of the enterprise		75% have problems with the use of quality costing		

source: own work

In the further part of the elaboration, a focus was set on the selected issues, resulting from the analysis of surveys:

- I. why as many as 21% of the surveyed enterprises do not apply the quality cost accounting, and the others use only some of the elements?
- II. where does the problem of the lack of formal structures and guidelines of identifying quality costs come from - if there are so many models and interpretations of quality cost accounting?
- III. what is the problem connected with the available tools, used for the analysis of quality cost structure?
- IV. where does the reluctance of workers for applying this tool come from?

The problem of non-applying or applying only the elements of quality cost account.

To answer the first of the raised questions, a management theory was combined with the concept of quality management, according to ISO 9001:2008.

Advantages resulting from the implementation and certification of the quality management system, according to ISO 9001:2008, can be described in accordance with the eight principles of TQM. The company is focused on customer needs, whose requirements are realized by the committed staff led by a leader, top management maintains good relations with suppliers and takes decisions based on reliable data, which ensures continuous improvement, the organization is seen as a system, which

consists of related processes . Such a picture of the organization, seen through the prism of quality management principles, should convince for implementation of standardized management system. However, practice shows that what convinces management to the effort for implementing the system and incurring expenditures, related with the issue, are requirements of the market or the prospect of financial benefits. Economic effects associated with the quality management system may result from, for example:

- elimination of waste, what results from ordering of the internal processes (identification of processes),
- conscious and consistent designing, manufacturing, supplying and proper disposal of products (identification of the product, product design),
- manufacturing of products compatible with customer’s requirements,
- focusing on the quality of products - minimizing losses resulting from internal defects and any complaints,
- making objective decisions based on facts.

In order to make the benefits associated with the implementation of the QMS convincing, they ought to be expressed in specific values - indicating incomes or expenses. Revenue growth may occur due to many actions: research of the customer's requirements - greater demand for products adjusted to the needs of customers, the possibility of selling at higher prices – thanks to the improvement of product quality. To illustrate the evolution of costs before, during and after the implementation of QMS, it is reasonable to apply quality cost account. So the use of elements of quality cost accounting, as the analysis of literature and conducted research show, it is usually associated with the implementation and / or certification of the standardized quality management system. Quality Management System (QMS), understood as the enterprise management subsystem consists of some related and mutually interacting elements. Activities in the frame of QMS, realized in accordance with ISO 9001, can be referred to the function of management: planning, organizing, motivating, controlling [Table II].

Table II. Comparison of Quality Management System according to ISO 9001:2008 with the management functions

Management function	Theory of mangement	Points of the ISO 9001:2008 Standards

improvement – as a function of the quality management		8.5 - Continuous improvement, including corrective and preventive actions

source: (Hamrol, 2005) (Kozmiński 1997) (Norma ISO 9001:2008)

QMS assumptions are consistent with the theory and management functions: planning, organizing, motivating. Some differences in the activities are noticeable at the stage of control [Table1].

In the case of management at the control stage, there is the emphasis on assessment of efficiency. Efficiency is the relationship between the achieved results and the used resources (ISO 9000:2000). Therefore, we must not ignore metrics and indicators based on financial data. This makes communication of universal language of money easier and allows to compare the results.

In the quality management, stage called in theory of management “controlling”, should be called here “evaluation”. Activities within the scope of this stage are measurements, analysis and the resulting from it improvement. Monitoring, measurement and analysis are to ensure compliance of a product with requirements, efficiency of QMS and continuous improvement of effectiveness. Effectiveness is defined as the degree of activity realization and achievement of planned results (ISO 9000:2000). Thus, in the ISO 9001:2008 there is no monitoring requirement of activity effectiveness what distinguishes the subsystem of quality management from management.

Comparing the conclusions from the above analysis with of the responses from the questionnaire survey, one can conclude that the full quality cost accounting is not applied in companies since nobody requires it. Since the ISO 9001 standard does not directly demand the efficiency assessment, the quality management system is evaluated through the prism of the effectiveness or with the application of financial measures, indirectly or partially related to the quality management system.

The problem of lack of formal structures and guidelines to identify the cost of quality, since there are so many models and interpretations of the quality cost accounting?

The concept of quality costs is not precisely defined in the literature. For specialists in the field of quality management, quality cost is an element isolated from the total costs connected with manufacturing of products. For the economist, the costs of quality include the amount of costs incurred for the manufacturing of products of a specific quality, fulfilling requirements of customers.

The literature presents different views on the definition and classification of quality costs, such as:

- taking as a basis the extracted costs in the process of product manufacturing (narrow approach),
- taking into account all the costs incurred by the organization,
- relating to costs to be borne by the user,
- relating to costs that are incurred throughout the whole life cycle of products by all users (broad approach) (Balon, 2006)

The interest of quality costs in the enterprise often results from improvements of implemented quality management system in accordance with ISO 9001. The ISO 9001 does not refer directly to the issue of quality costs, the requirement for the assessment of the system leaves flexibility as to the methods used. International Standards

Organization developed the Technical Report ISO / TR 10014 for the management of economics of quality. In paragraph 7 of the report it was estimated that there are many approaches to the classification of costs, some examples include:

- PAF model in which costs are divided into groups: prevention, assessment, incompatibility (Prevention, Appraisal, Failure);
- process model in which costs are divided into groups: the compatibility and incompatibility;
- life cycle model in which the quality costs are divided into groups depending on the phase in the life cycle;
- a model that involves identification and measurement of the loss of value added, the so-called loss of quality model (ISO 10014:2006). model PAF, w którym dzieli się koszty na grupy: zapobieganie, oceny, niezgodności (Prevention, Appraisal, Failure);

In the traditional system costs (PAF): prevention, assessment, failures, represented also in the American model of ASQC (Zymonik, 2002), the costs of prevention and evaluation should be associated with expenditures related to achieving the expected level of quality, while the costs referring to the errors should be equated with the losses. The concept of cost, by definition, involves its purposefulness, therefore it is advisable to apply the concept of losses in relation to defects generated in connection with the activities of the company (internal and external).

Prevention costs are related to activities that are not allowed to generate errors, as well as identifying and eliminating causes of errors. Evaluation costs include expenditures designed to verify compliance with quality requirements. Losses resulting from errors or failure of the product quality requirements should be identified both inside the organization and in its vicinity (Table III) (Zymonik, 2002).

Table III. Sample costs of quality according to ASQC model

Prevention costs			Evaluation costs
Product production design of training employees in quality control	Quality quality measurement methods	Planning control methods	control of input materials control of products ancillary works associated with attempts maintenance of test and measurement equipment assessment of the quality of materials in warehouses
Internal losses			External losses

irreparable alterations identifying re-inspection service - transformation of the lower classes of quality	and causes of defects and tests sorting of discards	gaps repairs	customer after-sales processing of repair of replacement of technical errors associated with the installation of products	complaints service of returned products under warranty errors of the installation of products
---	--	---------------------	---	---

Source: Own elaboration based on (Zymonik, 2002)

Process model of quality costs results from the approach presented in code 9001 and assumes analysis of individual processes, in terms of occurring in them compatibilities and incompatibilities. Compatibility costs include expenditures to meet the actual and potential customer needs, with appropriate process progress: incompatibility costs are caused by improper conduct of the process. Both compatibilities and incompatibilities are treated as a source of savings (Balon, 2006).

Costs in the life cycle model can be attributed to the individual stages of product development and extract the generated costs associated with both the producer and the client side. The manufacturer shall bear the costs related to the design, development of a product, manufacturing, and sale, the customer bears the operating and often decommissioning costs (Sobańska, 2003).

Quality loss model based on Taguchi approach, namely the assumption that the customer requires improving the quality of the product offered and is willing to pay for improvements. Any failure to meet customer requirements is a loss for the manufacturer. Manufacturer's loss can be divided into tangible and intangible. Tangible loss result from the incompatibilities, hidden inside and outside the organization, whereas intangible one is associated with customer's dissatisfaction, lost opportunities, loss of customers, etc. (Balon 2006).

The classification of costs is based on division of the total expenditure into different groups and assignment of them into specific objects or processes. The effect of the classification of costs is the picture of their structure and forms the basis for the construction of quality cost account (Balon, 2006). The above presented cost classification models are not mutually exclusive, but can and even should be modified so that they would present quality cost in system that might be useful for analysis, monitoring, and decision-making in the enterprise.

In the further part of the paper, as a model of quality cost system – one adopts combination of the cost of a product life cycle [Fig. 1] with the PAF model. One has

given up here both the process model quality loss model. Process model is hard to generalize because it is closely linked to specific companies, with a unique network of internal processes. In the model of quality loss too much emphasis is put on the intangible costs, which may only be estimated.

In the life cycle, product takes on different forms and figures [Fig 1].

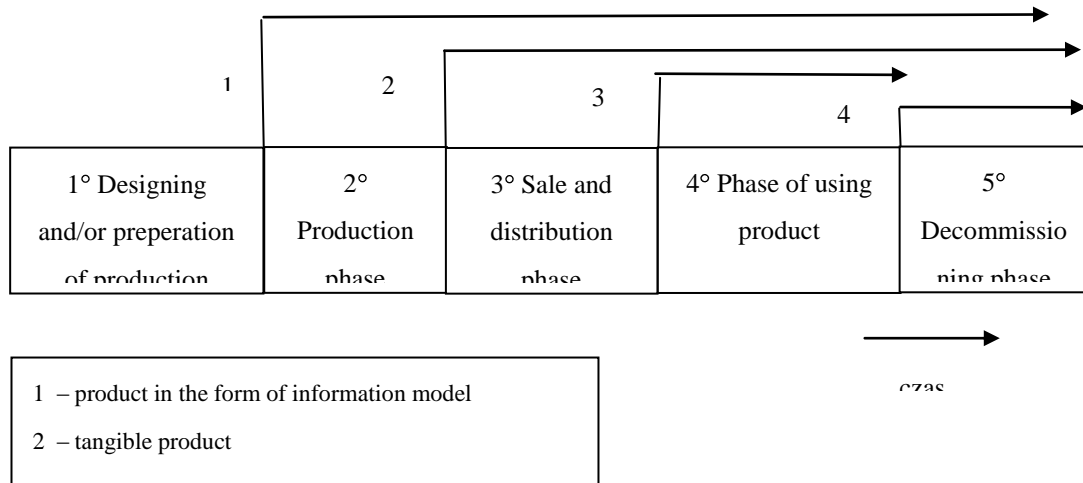

Figure 1. Structure of product existence, source (Mantura, 2000)

In the first phase, products occur as an informational or conceptual model. Then the preparation of the product realization processes take place. If the goods or services are new to a particular enterprise or innovative on a global scale, an important step in the design and construction phase. In the second phase, the product gains material form and is passed to the client, who realizes useful functions of the purchase. During decommissioning phase, the product has a material form but modified: recyclables and / or waste. With giving and modification of individual forms of the product - cost bearing is indispensable part. The costs are borne not only by the manufacturer, but also a customer, and even those not directly related to the use of the product (it mainly concern the decommissioning phase). Interpreting the cost of quality in broad terms, so the costs incurred throughout the whole life cycle of the product by all users, one can associate them with the PAF model [Tab. III]. So the costs may be grouped as: assessment, prevention, internal and external loss [Fig 2].

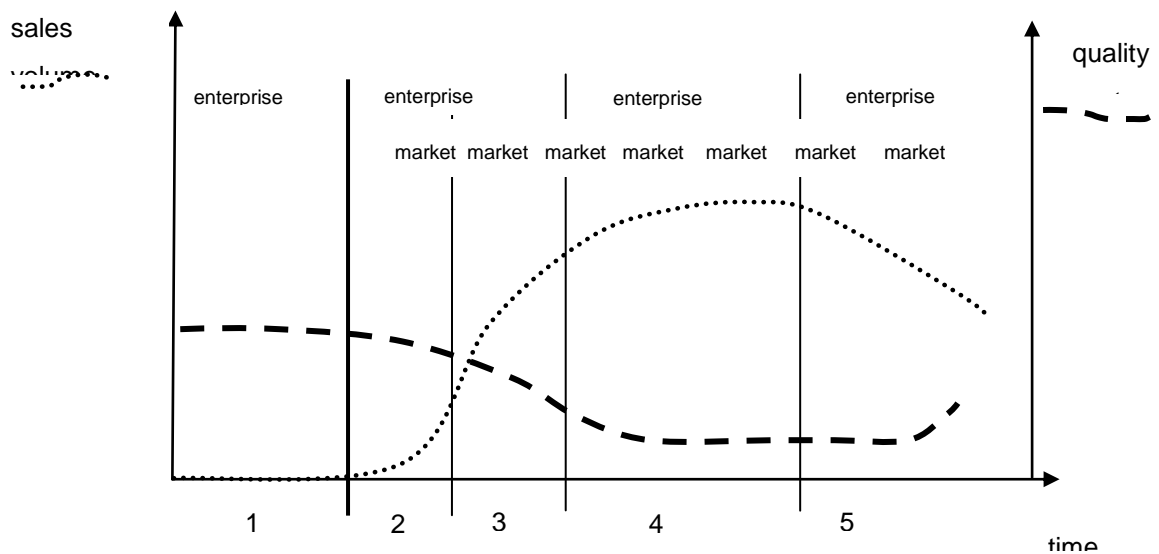

Figure 2. Costs of quality in the product life cycle [own work]

At every stage of life cycle, costs may be divided according to different criteria: those borne by the customer and the manufacturer, the external and internal in the case of the manufacturer, the costs of assessment prevention, external and internal losses [Fig 2] [Tab. IV].

Tab. IV classification of quality costs according to various criteria.

Phase in the product life cycle	Who bears the costs?	Costs of the enterprise	Costs according to PAF model
Conceptional	producer	external and internal	prevention
Production preparation	producer	external and internal if outsourcing	prevention
Manufacturing	producer	external and internal if outsourcing	prevention, assessment, internal losses
Sale and distribution	producer	external	external losses, prevention
Usage	client, producer	external and internal	external losses
Decommissioning	client, producer	external	external losses

Source: own work

Since both the ISO 10014:2008 "Guidelines for the realization of financial and economic benefits", as well as in the literature, various types of quality costs are given, it might lead entrepreneurs to the conclusion that there are no formal structures and rules. Information noise makes it difficult to choose the proper method of cost accounting. The lack of pattern makes verification of the developed approach to quality cost account, in a given enterprise, difficult. Thus, one should adopt and promote the most universal approach, which should ought to be built on the achievements of classics

of quality management, but at the same time adjusted to contemporary realities. Development of the concept of quality costs dates back to the 50th years of the twentieth century, so then developed ideas may not fit today's production methods, technologies, management methods.

The problem of the available tools for the evaluation of quality cost structure?

The entrepreneurs who took part in the research declared that they used tools to analyze the cost of quality, for example: comparison of results of different periods, the reference to other business metrics, comparison with the plan. At the same time, there were answers that one of the problems of accounting quality costs is the lack of tools to analyze the costs of quality.

An analysis of the literature suggests (Szczepańska, 2009) (ISO 10014:2006), that for the management of quality it is often proposed to apply the tools of quality management and others enabling processing and ordering of data, detecting waste, etc.

In publications concerning the quality cost accounting, authors usually focus on the purposes of running accounts and benefits of implementation of quality cost account. There is no answer, however, how to do it. For example, (Skrzypek, 2000) only goals of quality cost account are given, including:

- controlling,
- finding a basis for comparison in order to carry out awareness on how to shape the cost of quality in comparison with those of other undertakings in the same industry, an instrument is benchmarking,
- study on the costs to create the impetus to improve the rationality of actions
- possibility of quality planning, including costs
- possibility of better understanding of economics of quality requirements
- optimal planning of quality control, in terms of costs
- disclosure of excessive costs.

The question remains how to implement these goals? Most of them assume possibility of comparison of costs in a given enterprise with the results from previous periods, and even with the costs generated in other companies (benchmarking). Cost data as well as know-how companies are usually secured, so it is difficult to compare oneself to other

companies. Due to similar reasons, it is difficult to assess whether the planned and / or reached a value of cost or structure of quality costs is optimal.

The quality cost account is sometimes defined as a collection of costs, on the proper balance and off balance accounts, related to quality of production, occurring in all phases of product realization together with the analysis of development of these costs (Skrzypek, 2000) (Łańcucki, 1995) (Szczepańska, 2009) . An account of quality costs consists of: identification, documentation, planning, accounting and cost analysis. Definition and elements of cost accounting quality are consistent with the definition of cost accounting in the enterprise. Therefore, we refer the account to the overall cost of quality standards relating to the evaluation enterprise. In financial accounting and managerial function indicators to assess the condition of the company in many respects. For these indicators are assigned specific values or ranges of values that enable the interpretation. It could be postulated that after the adoption of a uniform, universal model of quality costs, could be valuable to define indicators to assess the cost structure to verify the quality or value of the various cost groups. This objective requires the pooling of cost data from various companies and generalization of these data.

The reluctance of workers

The reluctance of workers, which evoke the entrepreneurs as a problem in conducting quality cost account, probably stems from the above-described gaps in the concept. If the quality cost account is not a formal requirement, it can be treated as overtime, extra duty. Moreover, the multiplicity of models and structures, differences in the interpretation of the concepts create information noise. The weakness of the tools and the lack of tools dedicated to the quality cost account may cause the impression of uselessness of identifying quality costs.

Conclusion

Identification and analysis of weaknesses of quality cost accounting indicates what action should be taken to encourage entrepreneurs to apply it. It should also mobilize them to use the results of quality cost analysis as a measure of efficiency in the continuous improvement of production processes and improvement of the quality management system.

Possibility of changing the aspect, concerning the ISO 9001 standard, that is no requirement to assess the effectiveness of the system, are for obvious reasons, beyond

the reach of authors of the study. Thus, the quality cost accounting remains one of the tools that can be used for the realization of requirement to test the effectiveness or for the implementation of the rule of making decisions that are based on facts. Attention should be paid to other problems, indicated by entrepreneurs: unification and generalization of the structure of quality costs and propose tools that will affect its usefulness. The proposed in the paper structure of quality costs, based on the product life cycle and a PAF model, and inspired by the concept of Activity Base Costing, contemporizes cost interpretation. The next step will be to develop indicators to assess the structure of quality costs, assigned to homogeneous groups of companies. Identification and interpretation of the values of these indicators will enable benchmarking, which will not require high expenditure and collection of information outside the company, but will facilitate decision making concerning the location of funds at different stages of life of the product.

Introduction to KitVes

The Project “KitVes - Airfoil-based solution for vessel on-board energy production destined to traction and auxiliary services” is funded under the Seventh Framework Programme of the European Union and started in October 2008, with a duration of 36 months. Within the project, ten partners from seven countries work jointly in the development of a technical solution for harvesting high-altitude winds in the troposphere with the aim to generate energy for the auxiliary systems on vessels.

In comparison to near-ground winds, the wind in heights from 200 to 1000 meters has a higher velocity and is more constant. To use this advantage, the KitVes project aims to develop a wind-powered generator for the conversion of high altitude wind into electric energy. In detail, the generator is connected to a kite, which is equipped with sensors for the identification of the kite’s position, orientation and acceleration. This data will then be submitted to the vessel-based control unit and will be used to control the kite flight for an optimized energy generation. This control is carried out by the generator, which is equipped with double effect drives, and thus poses as a motor as well. In fact, the solution comprises two generators, one for each line. Therefore, the lines can be controlled separately.

To make the operating mode of KitVes fully comprehensible, it is further explained and shown in the following paragraphs and pictures:

Figure 32 shows a possibility how KitVes could be integrated on a ship, in this case on a cruise ship. Also, this picture shows the basic structure of the KitVes solution.

Figure 32: Possible appearance of KitVes on a vessel (project internal illustration)

Directly on the vessel is the Kite Steering Unit (KSU), which consists, among others, of the two generators mentioned above. The generators are each connected to one drum, on which the lines are reeled in. Attached to the KSU is the stem, which damps the lines movement.

During the ascent of the kite, the control makes it flying in ellipses, as shown in Figure 33. Thus, the amount of generated energy is maximised. The ascending kite pulls out the lines, what in turn causes the drums to rotate, so that energy can be generated. The project aims at 100 kW of average nominal power of the demonstrator.

Figure 33: Schematic Representation of the Elliptic Ascent of the Kite

When the kite has reached the maximum height at approximately 1000 meters, it is pulled in. For this, the so called side slip manoeuvre is used, as shown in Figure 34.

Within this manoeuvre, the lines are pulled in with a short delay between the first and the second line. By this manoeuvre, the wing area exposed to the wind is minimized, and thus the kite can be pulled in with a minimal effort, using a minimal amount of energy.

Figure 34: Schematic Representation of the Side Slip Manoeuvre

The Research Group "Product Safety and Quality Engineering" (ProQ) takes part in this project, mainly in supporting the system analysis and the risk assessment. During these tasks, three major problems have emerged:

- The complexity of the KitVes system makes a proper risk assessment that includes all necessary aspects rather difficult.
- Different reliability and quality methods have to be applied to the system, e.g. FMECA (Failure Modes, Effects and Criticality Analysis), RBD (Reliability Block Diagram) and FTA (Fault Tree Analysis).

- Due to the linguistic and professional diversity within the project, with partners from seven different countries, the conceptual understanding of the system and its elements widely differs.

These problems can be faced with a methodical approach towards the system. The approach used for KitVes will be presented in this paper.

Introduction to DeCoDe as Methodical Tool in Product Development

To handle the increasing complexity in the development of technical systems, the Demand Compliant Design (DeCoDe), a method for product development and systems engineering, divides the system in question into four different views on the system : requirements, functions, components and processes (cf. e.g. Sitte et al. 2005, Hartmann et al. 2011). By the identification of these elements and of the interrelations in between, DeCoDe supports the systematic description and modelling of technical systems, thus building a well-founded groundwork for the further analysis of the system. Furthermore, the early detection of potential conflicts and failures within the system is supported.

DeCoDe as a method supports a product development that is suitable to the requirements already in the early phases of the development. It features a well-founded basis for the analysis and the modelling of technical systems and of the interrelations within these systems. As mentioned above, this takes place by dividing the system into the four basic views. These views facilitate a structured collection of the system's elements, and thus a holistic assessment of the system and its borders to the environment (Müller et al. 2010).

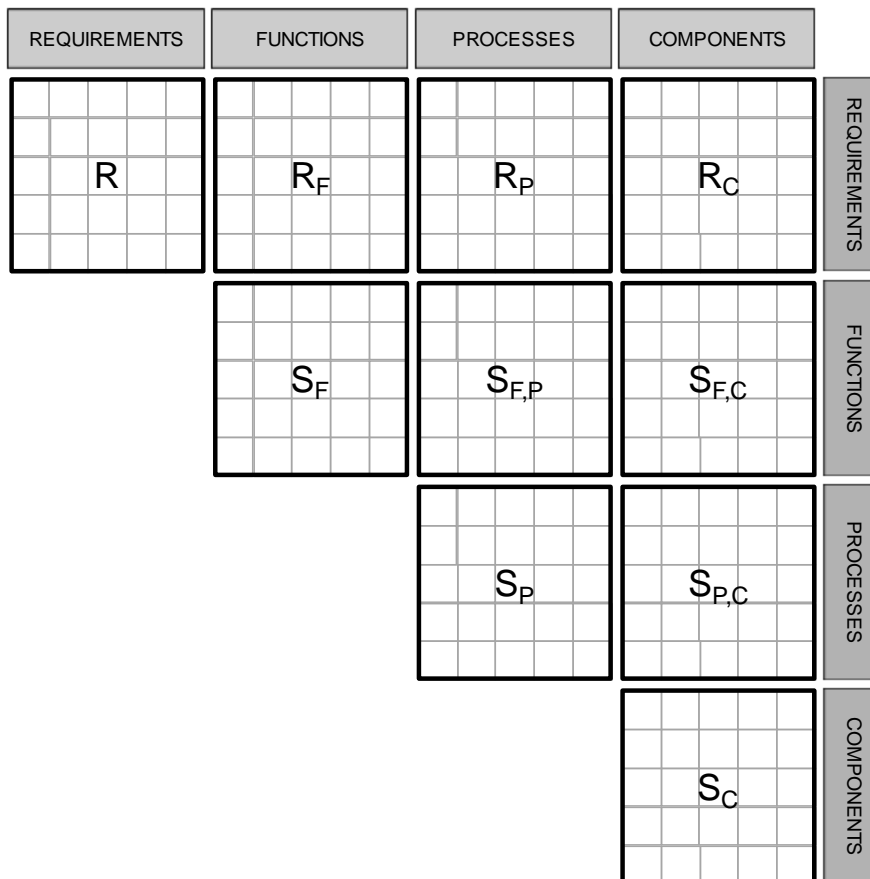

Figure 35: Concept of the DeCoDe model (according to Riekhof et al. 2010)

After the elements of the views have been collected or deduced, the next step is to observe the interrelations between and within the views with the help of tools, mostly matrices or graphs. As shown in figure, the single elements of the views are collected, arranged, structured and then connected among themselves. This connection takes place with the help of requirement (A_X) and system (S_X) matrices (Müller et al. 2010).

By the connection of the views with matrices, one can deduce potential conflicts - like conflicts of goals between requirements - and mutual interrelations like the influence on the function of one component by another, and those can be deduced quite early within the product life cycle. DeCoDe thus qualifies itself as a development-accompanying description tool with an iterative modelling approach, by successively completing the system's elements and their relations (Müller et al. 2010).

If a product or at least a very detailed idea for the product already exists, the product design team does not deal with a strict product development, but with reverse engineering, that is "the process of analyzing a subject system to identify the system's

components and their interrelationships and create representations of the system in another form or at a higher level of abstraction." (Chikofsky et al. 1990). Therefore, if dealing with reverse engineering, DeCoDe needs to be adapted accordingly. First of all, the main focus will be put onto the collection and definition of the components. Contrary to the product development from scratch, the demands are not the main focus. Instead, the functions and processes will be deduced by a thorough observation and analysis of the underlying system.

Furthermore, DeCoDe can be combined with established methods of quality engineering, reliability and simulation (e.g. Ishikawa, FMEA (Ott et al. 2007), RBD), by using conjoint definitions and defined interfaces (cf. e.g. (Rosendahl et al. 2009)). This approach, as it supports the application of different methods, is called DeCoDe+X. Using DeCoDe+X, a defined subsystem can be examined more detailed for a specified problem, and can be regarded beyond the four basic views (Müller et al. 2010).

The interlinking of the different methods with DeCoDe+X is carried out bidirectional. On the one hand, a system model mapped in DeCoDe delivers the input needed for the method execution, and on the other hand, the method's results are integrated back into DeCoDe and thus lead to an actualisation of the system model (Riekhof et al. 2010).

Use of DeCoDe within KitVes

As mentioned above, a thorough system analysis and risk assessment are necessary within KitVes. To support these tasks, the DeCoDe method has been chosen. The realization of DeCoDe within KitVes will be explained in the furthering. As the project is not yet finished, not all details can be presented here. Nevertheless, the methodical approach will be explained, stating advantages as well as problems that occurred during the use of DeCoDe within the KitVes project.

As a rough idea for the system already existed at the beginning of the project, the main focus was not laid onto the requirements, but onto the discussion and definition of the system's components. Thus, common ground was found for further cooperation during the development of the KitVes system. Based on this, DeCoDe was used as a supporting method throughout the developing process of the KitVes system.

Collection and Definition of the KitVes Elements

As mentioned above, the demands for the project have not been formulated beforehand. Instead, the first focus was laid onto the components. For this, several workshops were performed with some of the partners - chosen accordingly to their responsibilities in the project - in order to collect and define the KitVes components. Using mind maps as a tool in this stage, we chose a hierarchical top down approach, starting with a modular structure of only seven main components, as shown in

Figure 36. From here on, the components catalogue was subdivided further within several steps, resulting at last in a catalogue with up to seven hierarchical levels (depending on the “complexity” of the specific main component) and with the elements in the component view onto the KitVes system.

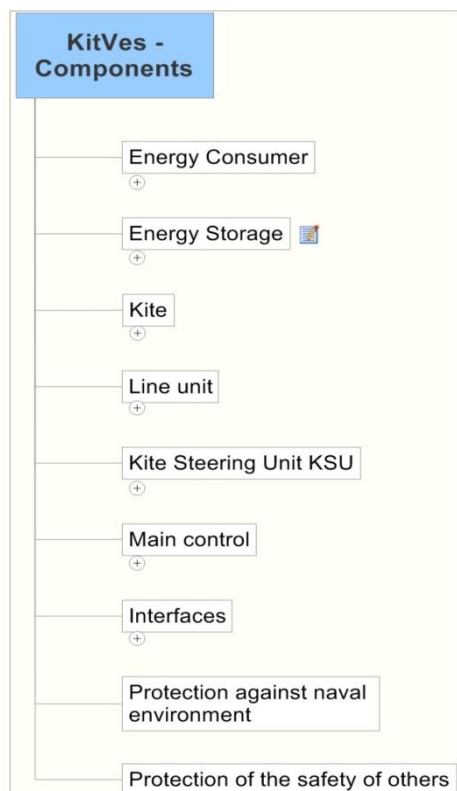

Figure 36 : Top Level of the Components Structure (Mindmap, project internal illustration)

At this point, we derived a component list from this component catalogue: Whereas the catalogue, which is presented in the form of a mind map or tree structure, containing a hierarchical, modular structure as mentioned above, the components list only contains

the “smallest” components on the lowest level; that means the component level which was not split into further subcomponents. This is due to the fact that this list will be used as input for the DeCoDe matrices. A non-hierarchical list can be handled much easier in the following, as there is no need to focus on the inheritance of attributes or interrelations between different levels of detail. This differentiation will be used for the process view and the function view as well.

In the next steps, several workshops for the collection and definition of the processes and the functions have been performed; the approach was nearly the same as for the components. These workshops lead to the following results:

- Components catalogue and list
- Processes catalogue and list
- Functions catalogue and list.

As a first output of the DeCoDe method, the catalogues were distributed to all project partners. As not all partners participated in all workshops due to the different responsibilities within the project, the catalogues served as a data base for the project-wide understanding of the KitVes system.

Furthermore, the lists serve as the first input for the collection and definition of the interdependencies between the elements both within one view as well as in between views. For this purpose, we use matrices as tools (cf. Figure 35). As a software tool for the next steps, LOOMEO (© 2011 Teseon GmbH, cf. <http://www.teseon.de/>) has been used.

Interrelations of the KitVes Elements

Within LOOMEO, the elements can either be connected within matrices or within graphs. For a systematic approach with as high a number of elements as in KitVes, the matrix view is to be preferred, as within a graph with a high number of elements, track can easily be lost.

As the analysis was started with the components, the first matrix to be filled and analyzed is the Components-Components-Matrix (S_C). The main question to be asked while filling this matrix is “Which component is physically depending on which component?”. In this first matrix, the direction of analysis is not important. Therefore, for each connection two cells have to be chosen accordingly, in the upper and in the lower half matrix. A section of the resulting matrix is shown in

Figure 37. There, the symmetric half matrices can well be seen.

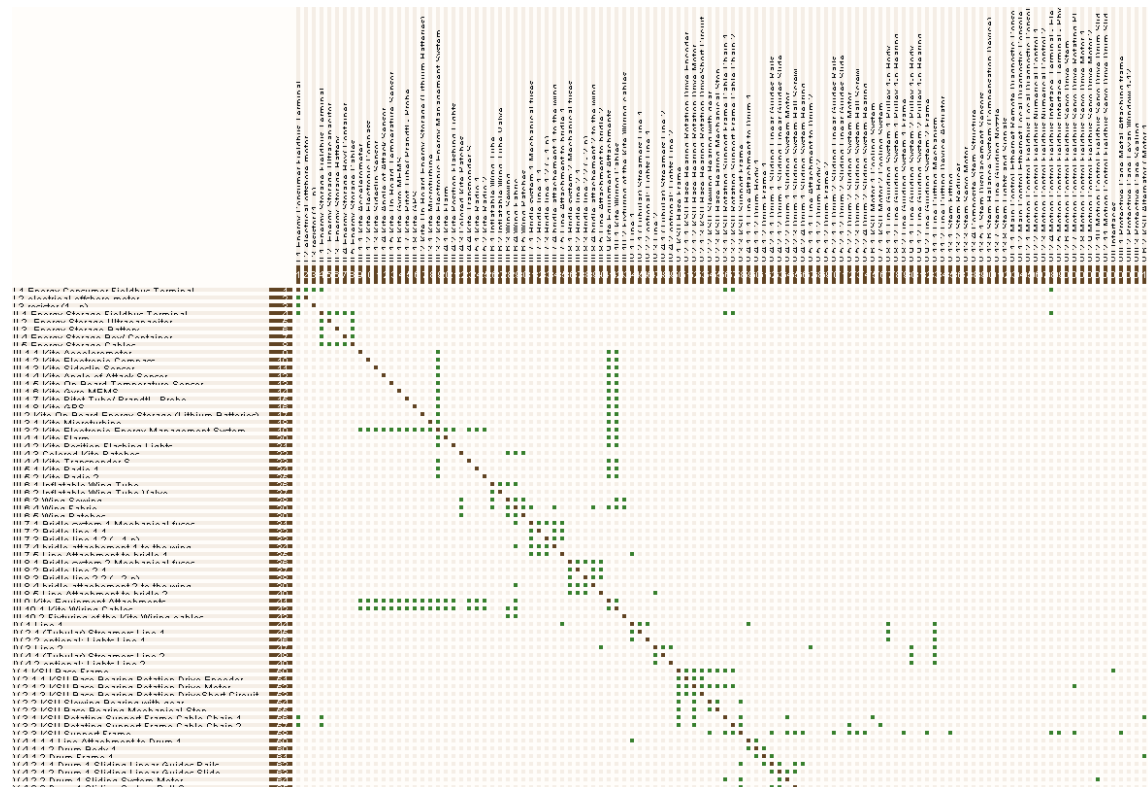

Figure 37: Part of S_C (Components-Components-Matrix)

During the process of filling the S_C -Matrix, the partners were forced to have a very detailed look into the physical interrelations of the KitVes system, as they had to point out clearly the contact points of each component to the surrounding components. Already at this point, DeCoDe helped to improve the system, as for example at the beginning it was not yet clear how the electronic equipment aboard of the kite would be fixed – and therefore how they would have physical contact. As the kite and the electronic equipment were to be developed by different partners, they were not aware of this problem before. They only noticed this gap during the discussion over the S_C -Matrix, and were then able to implement a solution for this by including a sort of equipment pocket. Furthermore, if single components have to be switched during the development, it can easily be determined which further components are influenced by these changes.

Having finished the S_C -Matrix, the S_{FC} -Matrix followed, which represents the dependencies of components and functions. To be more specific, the question that needs

to be asked while filling this matrix was “Which component realizes which function?”. Part of the resulting matrix is shown in Figure 38.

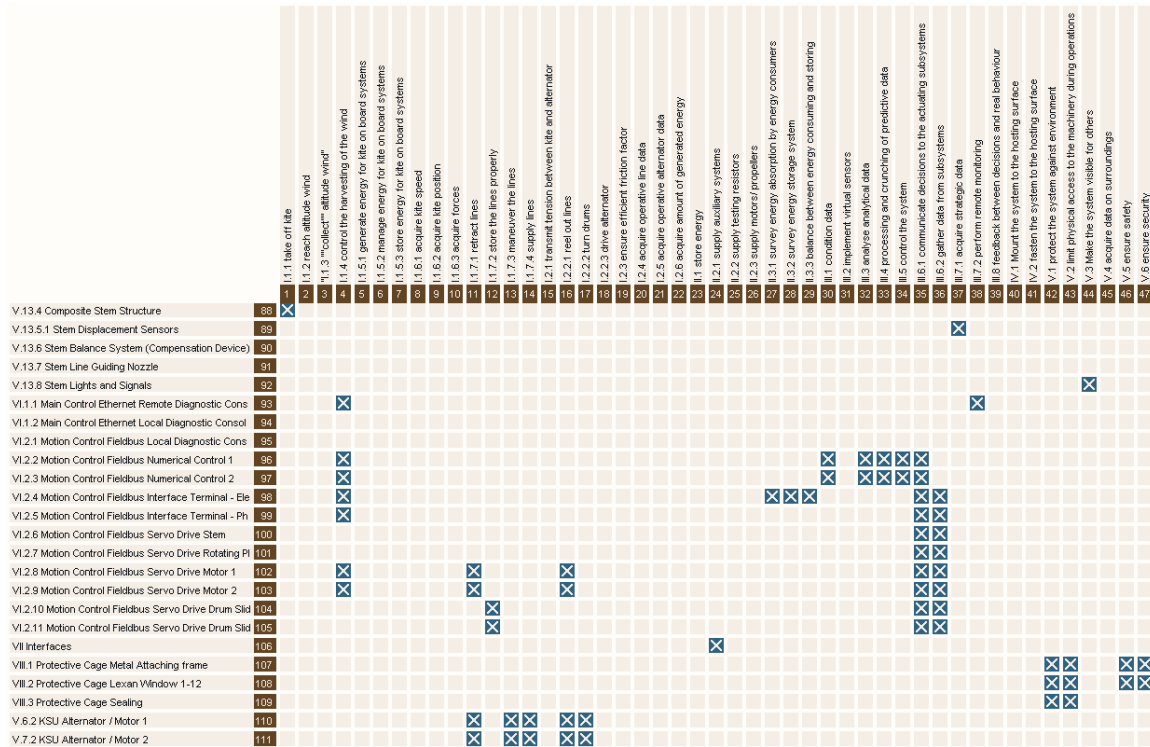

Figure 38: Part of $S_{F,C}$ (Components-Functions-Matrix)

Similar to the $S_{F,C}$ -Matrix, the $S_{C,P}$ -Matrix has been filled, whereas here the underlying question was “Which process uses which component?”.

Using the $S_{F,C}$ -Matrix and the $S_{C,P}$ -Matrix, a first draft of the $S_{P,F}$ -Matrix can be derived, showing the interdependencies of functions and processes, answering the question “Which process realizes which function?”. This derived matrix has then to be analyzed thoroughly, using the chance of detecting faulty or illogical interrelations as well as to add further dependencies, drawing conclusions for the underlying matrices as well.

Following this procedure, further matrices can be filled or derived, and in the furthering be analyzed. Besides those matrices, we can as well derive a full system graph, showing the interdependencies between all the KitVes elements. This graph is shown in Figure 39. It contains the elements for the components, functions and processes views and their interrelations.

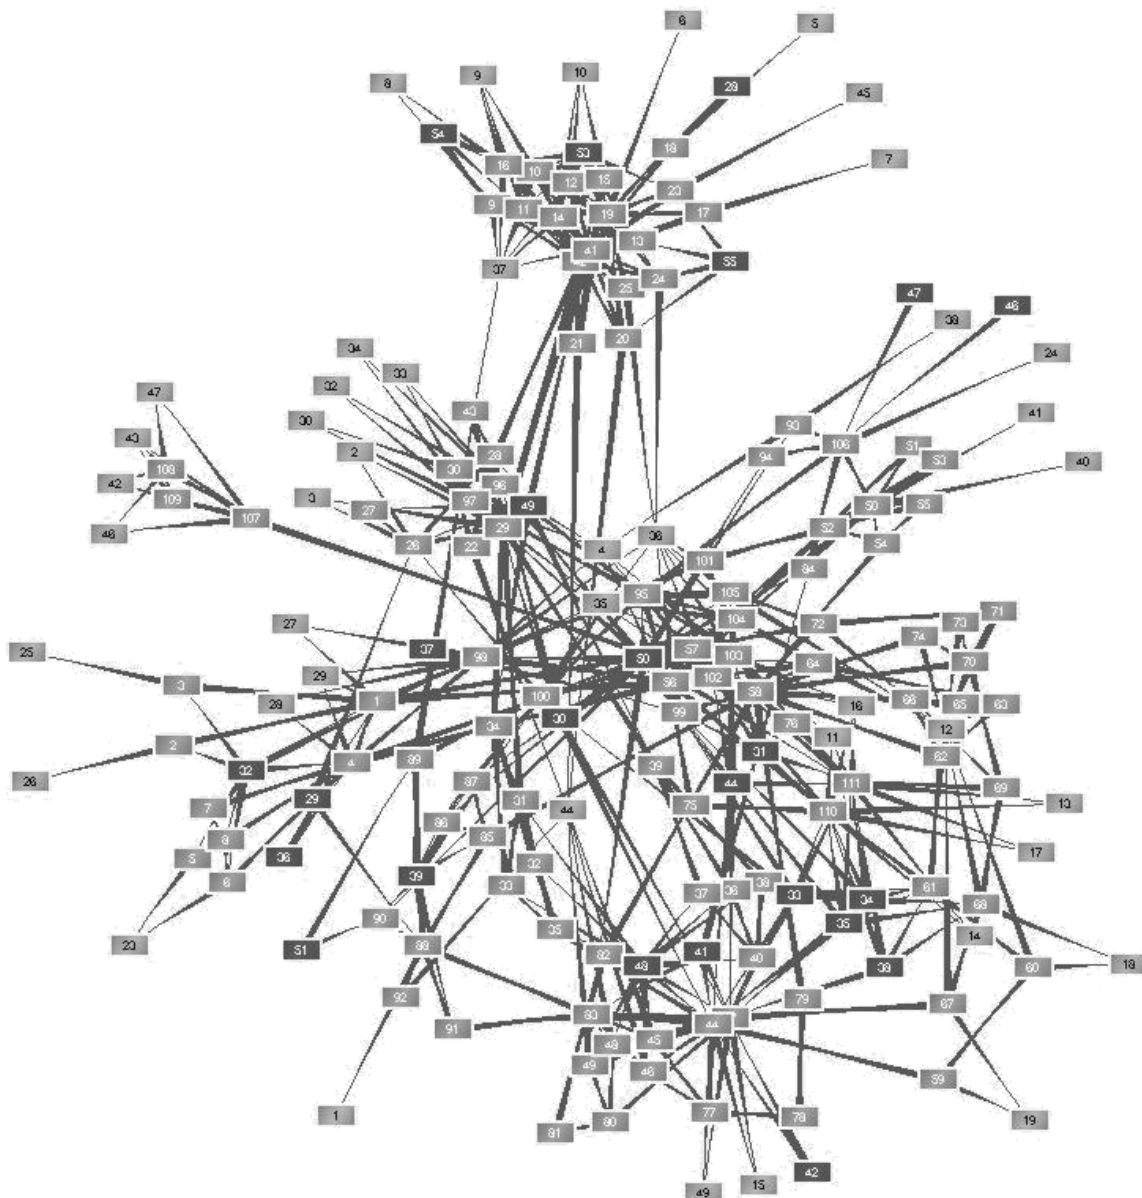

Figure 39: Interdependencies Graph

In the furthering, we can use the matrices respectively graphs to find peculiar elements and interrelations for the further analysis. This analysis, enabled by the combination of DeCoDe with several methods of quality engineering and reliability, is explained in the next chapter.

DeCoDe+X in KitVes

As mentioned before, ProQ had to perform several quality and reliability methods within the KitVes project, e.g. RBD (Reliability Block Diagram), FTA (Fault Tree Analysis) and FMECA (Failure Mode, Effects and Criticality Analysis). The methods will be presented briefly in the following, referring to exemplary literature sources.

- The FMEA (Failure Mode and Effects Analysis) is a systematic analytical tool to show possible failures of a product in the early stages of the development, aiming at the early identification of failures, their causes, their results and the possibilities of detection. By evaluating the probability of occurrence and detection as well as the severity of the failure, the risk priority number (RPN) can be calculated, enabling the comparison and prioritisation of failures (IEC60812 2006).

In addition to the FMEA, the FMECA (Failure Mode, Effects and Criticality Analysis) includes the criticality of a failure as the effect of redundant components within the calculation of the RPN. Here, the quantitative and the qualitative FMECA are differentiated (IEC60812 2006, Head 2006). The quantitative FMECA takes into account the failure rate of the components, thus is used if precise data already exists. If only imprecise or no data at all exists, the qualitative FMECA is used.

- The RBD (Reliability Block Diagram) shows the interconnection of the components based on the functioning of a technical system, in which the individual components are represented by rectangles. The central question of the RBD is: "What components must function so that the system works?" From the RBD, a Fault Tree can be derived (see below) (Biolini 2010). The RBD is composed of two basic system structures: serial and parallel structures. In a serial structure, all components need to work in order to ensure a working system. In a parallel structure only one of the components has to be intact, so that the system still works.
- The Fault Tree Analysis (FTA) aims to identify and investigate the factors that may lead to a specified main event (failure). This is shown graphically in a fault tree, basing on standard symbols of the Boolean algebra (c.f. IEC61025 2007).

DeCoDe+FMECA

In the context of the FMECA, DeCoDe supports the implementation of the methods through the component, process and functional structure as well as the matrices that include the components. Since it is not possible to perform a FMECA in complex

systems for all components - because of the large number of different components – the DeCoDe matrices can be used to identify critical elements, which are mainly components. Thus, for example, from the product of active sum and passive sum of components, i.e. the number of directed links from and to other elements, the criticality of a component can be derived by trend. Due to this possibility to prioritize, the effort for the determination of relevant components can be minimized. Moreover, the matrices support the implementation of the FMECA by providing information on further components and processes that are affected by occurring failures, using the component-component matrix and the component-process matrix and thus what functions are no longer feasible (components-function matrix).

The RPN and possible changes of components or processes (such as preventive maintenance or additional detection processes) are results of the FMECA. These results – the FMECA output – are then integrated within the system model. Within DeCoDe, the changed elements are labelled <Element'>.

Within KitVes, the FMECA is used for the identification of potential failures as well as for the deduction of suitable counter measures. For example, with the help of the FMECA, one simple and cost-efficient measure (amongst others) could be identified to screen the gradual dismantling of the connection between kite and line: The parallel line endings will both be marked at the same point, and these markings will be compared ahead of every start. A solution based on measurement technique would not have been suitable for the prototype, due to high costs and development effort.

DeCoDe+RBD/FTA

Due to their relation to Boolean algebra, RBD and FTA are considered together, since they regard the system once positive and once in negative logic. The representation of components for the realization of functions is supported by DeCoDe. Due to the complexity of the system and the existence of critical and risky processes, partial system processes are considered for the RBD and the FTA. For example, the process "Usage" is seen as critical to the success of KitVes system, as in critical conditions or in case of failures it is likely to result in far-reaching consequences that go beyond a temporary dysfunction of the system. To this end, various scenarios have been created in DeCoDe. To go through these processes successfully, functions are implemented by embedded components.

The components that are needed for the processes relevant for a scenario are used as input for RBD and FTA. Thus, DeCoDe supports and comprehensibly documents the selection of components by the component-process matrix and the component function matrix (Müller 2009). The implementation of the method then generates the attribution of components and processes, indicating the importance of individual components due to their structural arrangement in the system or because of their failure behaviour. Thus, they enable an additional attribution of components and interrelations, and point to fail-related vulnerabilities of the system. At the same time, processes can be assessed for their feasibility in context with the component assembly. The combination of RBD and FTA data with DeCoDe is part of current research. In principle, for different scenarios - such as the landing of the kite in normal and in emergency processes – the integrated components are to be pointed out and analyzed by FTA or RBD. In this way, lessons can be learned about whether the system can react to faults or failures by bringing the whole system to a safe condition, which excludes any risk.

Conclusion

During the implementation of DeCoDe within KitVes, it became clear that the success of the method strongly depends on the quality of the data that is maintained into the model.

Furthermore, the applied methods of technical reliability and risk reduction can be significantly improved in their efficiency and effectiveness when they exchange information through the DeCoDe+X approach as a system model, serving to systematize the methods and the optimization of the system description.

Within the KitVes project, these approaches are currently being tested. The aim must be to relieve the developer, to generate valid data and to document the system modeling in a comprehensible way.

By combining the methods of technical reliability by DeCoDe+X, a systematic, interdisciplinary description of the system is made possible, which in turn provides the desired structured, standardized input and output for the methods. Thus, a linkage of methods is made possible, and the effectiveness of the methods used increases, so that the system is not described again and again. This way, the change of the system can be made traceable. The completion of this approach is subject of current and future projects.

Introduction

Increasingly performance measurement is being seen as an emergent sub-discipline within operations management (Beasley and Thorpe, 2002) with commensurate development of theory (Garengo et al, 2005; Sousa and Voss, 2008) and practice (Johnston and Pongatichat, 2008; Martin-Pena and Diaz-Garrido, 2008). However existing studies are mainly predicated on the assumptions of large manufacturing organisations with a relative paucity of SME based studies (Garengo et al, 2005; McAdam et al, 2008). The literature reflects a paucity of studies on performance measurement in SMEs (Garengo and Bititci, 2007) ; Raymond and Croteau, 2009) and a representation of SMEs as scalar versions of large organisations or “little big organisations” with attendant assumptions. For example some implementation based performance measurement studies in SMEs use the term “Performance Measurement Systems”, which, as indicated by Garengo et al (2005) and Johnston and Pongarichat (2008) fails to recognise the informal and broader approaches to performance measurement practices adopted within SMEs. It is suggested that further research is needed to view an SME as a phenomena in its own right and that the focus should be on what Garengo et al (2005) refers to as “performance measurement practices”.

Within the performance measurement literature there is no dominant or overarching theoretical framework where the diversity of performance measurement practices adopted and applied by organisations has led to the development of the need for contingency based theoretical approaches (Sousa and Voss, 2008; Jusoh and Parnell, 2008), where performance measurement practices are viewed as contingent upon a range of contingency variables. This approach is consistent with configuration-based studies where a configuration is a constellation of conceptually distinct characteristics

that occur together (Nair and Boulton, 2008) The contingency approach is useful in exploring performance measurement practices in SMEs where there tends to be a focus on what works in practice (Verreynne, 2006) and a lack of ideology (Jarzabkowski and Spee, 2009). The mutual shaping of theoretical and practice based representations in contingency based studies of performance measurement practices in SMEs can help in avoiding a uni-dimensional understanding of the phenomena under consideration and allow for a richer and deeper interpretation than that of a single theoretical concept being applied (Johnston and Pongtichat, 2008).

To help in avoiding large organisation assumptions being transferred over to performance measurement studies in SMEs there is a need to move outside the manufacturing sector. The majority of performance measurement studies are based in the large manufacturing sector and there is a problem with the reification of findings and the subsequent application to other sectors and situations without a proper contextual critique (McAdam et al, 2008), which is consistent with Hultman and Shaw's (2003) reference to the lack of research in service based SMEs. It is suggested that studies on service sector SMEs will provide a two fold contribution; namely addressing the paucity of studies on performance measurement in service sector SMEs and also in helping to avoid the dominance of the large manufacturing operating assumptions within performance measurement.. Machuca et al (2006) suggests that there are two approaches to studying operations management issues in service sector companies. First, the service sector is treated as being totally unique, and second, that service sector organisations can be probed using a "service operations management" (SOM) viewpoint. Throughout this paper the service operations viewpoint is adopted where Machuca et al (2006) and Heineke and Davis (2006) suggest that such an approach is consistent with viewing performance measurement as a sub-discipline within operations management and allowing for meaningful comparisons and contrast to be made; whereas the former approach fails to fully recognise the operations nature of performance measurement.

Overall this discussion leads to the aim of the paper which is to explore the development and implementation of performance measurement practices in service based SMEs during a growth phase using a contingency approach. The achievement of this aim will lead to a contribution to theory development for performance measurement in service-based SMEs through the contingency approach, where Machuca et al (2006) suggests there is a need for more research in an operations management context and where SOM suggests less structured and more cross functional activity as is the case in service based SMEs. Moreover SME performance measurement practices can be

appraised in terms of relevance and fit with the organisations's direction and environment. The specification of a growth phase is included based on findings by Garengo and Bititci (2007) in relation to the lifecycle model of growth, which show that a growth phase can lead to increased organisational scrutiny of the relevance of performance management practices within SMEs due to changing strategic intent and the redundancy of existing measures (Johnston and Pongatichat, 2008).

Performance measurement and Contingency theory

Contingency theory has emerged as a lens for viewing and interpreting operations management practices (Sousa and Voss, 2008). These practices, including that of performance measurement practices, have proliferated under the banner of best practices (Raymond and Bergeron, 2008). However ensuing critical perspective literature has emphasised context and questioned the universality of best practice applications (Bititci et al, 2006; Sousa and Voss, 2008). This contextual emphasis, and the lack of an overarching theory within operations management and performance measurement (Raymond and Bergeron, 2008), has led to an evaluation of contingency theory as a means for developing more effective conceptual foundations and evaluation of promising practices for specific contextual application.

Essentially contingency theory, in relation to the development of performance measurement practices implies that a number of contingency factors, as defined by contingency variables (CVs), which can only be changed in the long term and with considerable effort (Sousa and Voss, 2008), and are related to performance measurement practices through a "fit" process (Johnston and Pongatichat, 2008), (Figure 1).

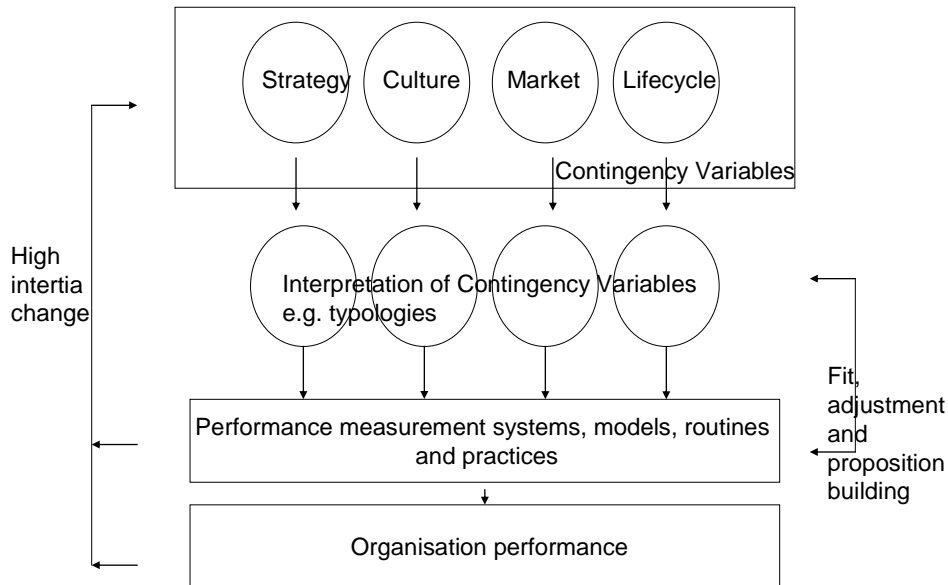

Figure 1 – Contingency framework

A set of contingency factors should be interdisciplinary in nature (Langfield-Smith, 1997) and hence will cover the wide and eclectic range of performance measurement practices (Bititci et al, 2006). Contingency theory implies that changes to the contingency factors for performance measurement due to outside influences leads to the need for realignment of the performance measurement practices through a process of fit or realignment (Figure 1). The underlying assumption is that contingency factors need to be derived for the context under consideration (Johnston and Pongarichat, 2008) and that bundles of operational practices (in this case performance measurement practices) should be dependant on changes in these factors through the fit process (Sousa and Voss, 2008). Hence, the concept of universal best practices, that are considered relatively independent of context, is questioned; rather it is suggested that the development of performance measurement practices, consistent with that of Bititci et al (2006), should be considered contextual and based on changes within the organisation across a range of contingency factors.

The process for applying contingency theory to performance measurement (Figure 1), consistent with that of Langfield-Smith (1997), is to first determine the contingency variables. Second, conceptual representation of each of these contingency variables is defined for determining subsequent influence on performance measurement practices. Third, the process of contingent fit between the contingency variables and the performance measurement practices is examined and represented in a set of loosely

organised propositions which can be further refined in future studies (Raymond and Croteau, 2009).

The generic rules from the literature for selecting contingency variables are that they should be interdisciplinary (Langfield-Smith, 1997), relatively independent and cover the bases of outside influence on performance measurement practices (Sousa and Voss, 2008). They should be exogenous to the manager responsible for the implementation practices (Bititci et al, 2006)) and should only be influenced to a very limited degree (i.e. high inertia) by changes in the implementation practices (Martin-Pena and Diaz-Garrido, 2008) (Figure 1). Overall one should be parsimonious in selecting CVs to avoid overt interdependencies (Martin-Pena and Diaz-Garrido, 2008; Sousa and Voss, 2008). For the current study Bititci et al (2006) and Raymond and Bergeron's (2008) set of contingency variables for performance measurement studies in SMEs were initially adopted. This list of CVs were then modified to reflect the SME service sector context of the current study, including the addition of new CVs to reflect the different context. Table 1 lists and explains the CVs along with supporting literature sources. This list of contingency variables is not exhaustive but is considered sufficient to enable a meaningful exploration of the study aim. Raymond and Bergeron (2008) and Garengo et al (2005, 2007) suggest that this parsimonious approach can help in identifying the affects of the both the CVs identified and in identifying the need for further CVs due to unexplained affects on the performance measurement implementation practices.

Table 1 – Contingency Variables

Contingent Variable	Supporting literature	Explanation
Strategy	Raymond and Bergeron (2008); Sousa and Voss (2008); Heineke and Davis (2006); Machuca et al (2006); Garengo and Bititci (2007); Jung et al (2009); Garengo et al, 2005); Reje (2004); Langfield-Smith (1997);	Strategic direction within the organisation is viewed as a contingent variable which affects the implementation of performance management practices
Culture	Sousa and Voss (2008); Garengo and Bititci (2007); Garengo et al, 2005); Reje (2004); Richie and Brindley (2005); Bititci et al (2004 2006)	Prevailing organisation culture is considered to be a contingent variable which affects the implementation of performance management practices
Customer Focus	Heineke and Davis (2006);	Within service based

	Hultman and Shaw (2003); O'Dwyer et al (2009); Garengo et al, 2005); Silvestro et al (1992); Silvestro (2001)	SMEs customer focus is viewed as a contingent variable which affects the implementation of performance management practices
Lifecycle	Raymond and Bergeron (2008); Garengo et al (2007); McAdam et al (2008)	Organisation lifecycle positioning is considered as a contingent variable which affects the implementation of performance management practices

As shown in Table 1 strategy is identified as a CV for a number of studies in SMEs. A number of existing studies of strategy as a contingency variable in performance measurement studies mainly uses the established Miles and Snow (1978) typology or variants thereof (O'Regan and Ghobadian, 2006; Raymond and Bergeron, 2008; Langfield-Smith, 1997). This typology (Figure 2) helps to represent strategic intent as a starting point for alignment with operational practices consistent with Johnston and Pongatichat (2008).

Raymond and Bergeron's (2008) and Sousa and Voss's (2008) observe that typologies to contextualise contingency variables tend to be borrowed from a range of fields and create a better understanding of strategy and common language for those involved in strategy and performance measurement. The four different categories of the Miles and Snow (1978) typology are: Defender – emphasis on efficiency and cost reduction to maintain existing markets; Analysers - simultaneous focus on maintaining and growing existing markets while seeking out new markets to sustain and increase growth; Prospectors - a focus on new service and market opportunities to drive growth as opposed to the duality of the Analysers; Reactor – no clear strategy with a tendency to react to market changes in a lag manner. Within the typology (Figure 2) there is support for the concept of equifinality within contingency theory; namely that the same outcomes can be achieved in multiple ways with different transformation processes (Jusoh and Parnell, 2008).

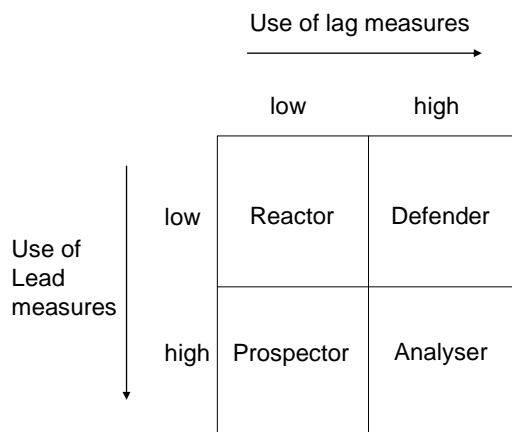

Figure 2 – Strategy Typology (Adapted from Miles and Snow, 1978)

The adoption of the service operations view point (Machuca et al, 2006; Heineke and Davis, 2006) allows for the application of this approach to service based SMEs. However O'Dwyer et al (2009) and Garengo et al (2005) suggest that any expression of strategy in service based SMEs may be formal or informal within SMEs and that informality should not be interpreted as paucity thereof. Verreyne (2006) and Jarzabkowski and Spee (2009) suggest that strategy-as-practice and emergent approaches to strategy, which are often used by SMEs, tend to be more informal. It is therefore suggested that each of the four elements of the Miles and Snow (1978) typology may be expressed on a formal – informal continuum that can be interpreted by managers and affect the subsequent development and implementation of performance measurement practices. Therefore a working proposition for the empirical research is:

Proposition 1: An organisation's approach to strategy as articulated in the typology of Figure 2, and the level of informality or formality by which it is expressed, will affect the development and implementation of performance measurement practices.

Table 1 also shows that organisational lifecycle is used as a CV following McAdam et al's (2008) and Garengo et al's (2007) studies of lifecycle effects on performance measurement. These studies, along that of Nair and Boulton (2008) suggest that using lifecycle, as distinct from organisational size (i.e. number of employees), or organisational age, is more relevant as size and age may mask dynamic lifecycle and

growth effects (Raymond and Bergeron (2008). Reference to the life-cycle models (Greiner, 1972; Churchill and Lewis, 1983, Bessant et al, 2006) provides insights into the relevance of the transformational process and the management challenges to an SME. The lifecycle models typically incorporates five stages. (Greiner, 1972; Churchill and Lewis, 1983). In a review of lifecycle model studies, Beverland and Lockshin (2001) indicates that the lifecycle stage model is a useful and robust representation in terms of being a “roadmap” and “timetable” for small firm development and growth. At each stage the organisation undergoes changes in management practices and style, organisational structure and degree of informality of systems and strategy (Greiner, 1972; Churchill and Lewis, 1983).

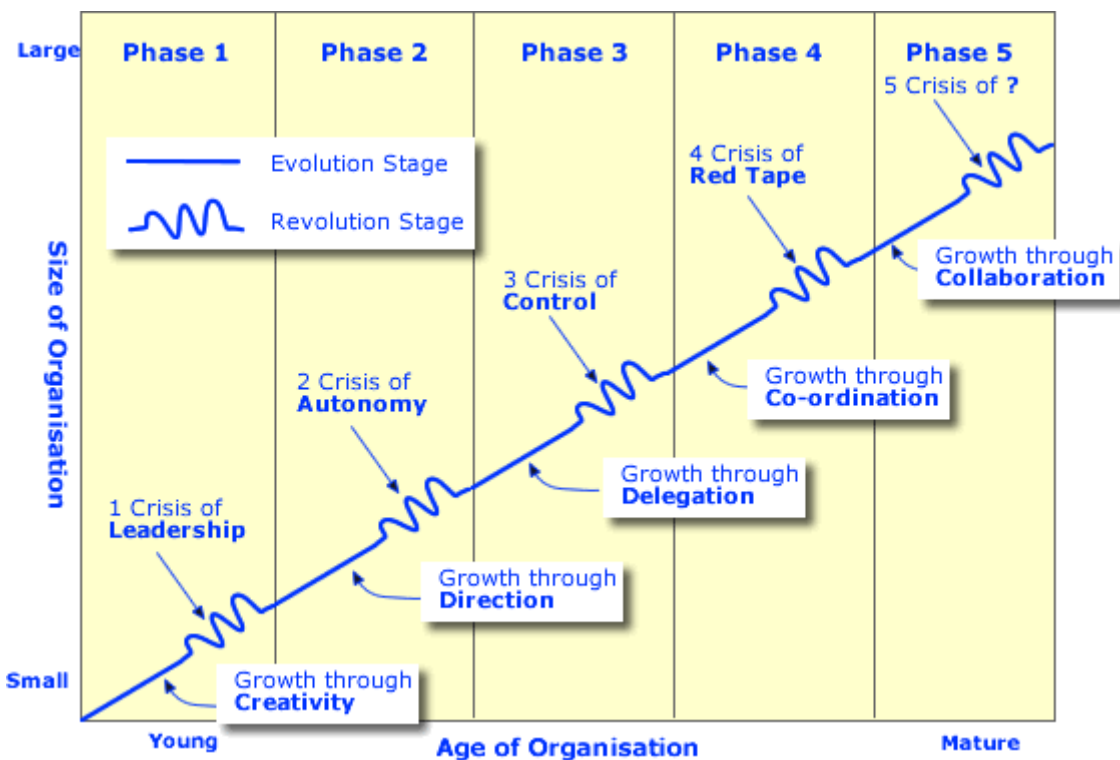

Figure 3 – Greiner lifecycle model (adapted from Greiner, 1972)

The Greiner lifecycle model (Figure 2) was chosen for the current study as critique by Beverland and Lockshin (2001) show that Greiner’s five stages are reflected in most lifecycle models and are sufficiently adaptable to cover a wide range of SME studies with different periods of growth. Greiner (1972) suggests that organizations go through five stages of growth: Phase One - growth through creativity; the founders go through a preparatory search phase of identifying matching resources and opportunities; Phase

Two - growth through direction; systems and procedures now provide direction through a functional structure; Phase Three - growth through delegation; decentralised decision making gives more autonomy; Phase Four - growth through co-ordination and monitoring from the centre of the organisation allows the decision makers to operate freely but the organisation maintains overall control; Phase Five - growth through collaboration means working together in small teams to accomplish tasks and using a wide range on industry networks. This model was also used by Garengo et al (2007) in studies of lifecycle effects on performance measurement in SMEs. The model also reflects an increasing level of formality in an SME's modus operandi as it progresses through the lifecycle stages (Figure 3). Based on these observations the Greiner's (1972) lifecycle model was chosen to interpret the empirical findings using the working proposition:

Proposition 3: An organisation's development and implementation of performance measurement practices will be affected by their respective lifecycle stage as represented by the typology shown in Figure 3.

The inclusion of Customer Focus as a CV (Table 1) reflects the service context of the current study and is consistent with that of Hultman and Shaw (2003) and O'Dwyer et al (2009) in studies of service based SMEs. These studies reflects the customer emphasis within service based SMEs consistent with Heineke and Davis's (2006) statement of the need for customer fit within SOM studies. Customer Focus is omitted from existing contingency studies on manufacturing SMEs where changes in customer requirements may be less direct subsumed within other contingency variables (Silvestro, 2001). Silvestro et al (1992) refer to as the need to appraise performance related activities over time in relation to customer needs and classifications and that performance measurement must be customer derived. supporting the role of customer focus as a contingency variable in the current study. Ng et al (2007) and Silvestro (1992, 2001) suggest a typology for customer focus of three key elements, namely: Professional Services; Service Shops and Mass Services (Figure 4).

Figure 4 - Customer-focus typology

These categories relate to the levels of customer contact and customer numbers. Professional Services have a high degree of customer contact with high elements of customisation and process and front office operations and low numbers or volume of customers. Mass Customisation types have high numbers or volume of customers but low contact time, customisation and an emphasis on back office operations. Service Shops have medium levels of customer contact, customer numbers, and customisation. Silvestro (2001) suggests that all aspects of customer focus in service based organisations must address the performance measurement issues associated with the intangible nature of many service operations. Hultman and Shaw's (2003) study of service SMEs and performance measurement suggest that this issue of tangibility will also emphasise the transactional – relational response to a customer focus typology where transactional orientated actions tend to be used more where there are larger customer numbers and less customer contact time for any given customer. Transactional approaches tend to use traditional 4 P style approaches and relational covers the development of in depth relationships at personal and organisational levels including formal and informal networking (O'Dwyer et al, 2009). It is therefore suggested that the customer focus typology, as shown in Figure 4 should consider both transactional and relational issues in interpreting performance measurement in service based SME, leading to the proposition:

Proposition 4: An organisations approach to customer focus as represented by the typology of Figure 4 will influence its development and implementation of performance measurement practices including transactional and relational approaches.

Sousa and Voss (2008) and Bititci et al's (2004, 2006) studies of organisational culture and performance measurement state that from a contingency perspective organisation culture has an impact on performance measurement. Continuing with the concept of "borrowing" from other fields (Sousa and Voss, 2008), a comparison the Handy (1985), Ritchie and Brindley's (2005) review and Bititci et al's (2006) work on culture and performance it is suggested that Handy's (1985) culture typology has obtained sufficient credibility from these critiques as being sufficient in scope for the current study.

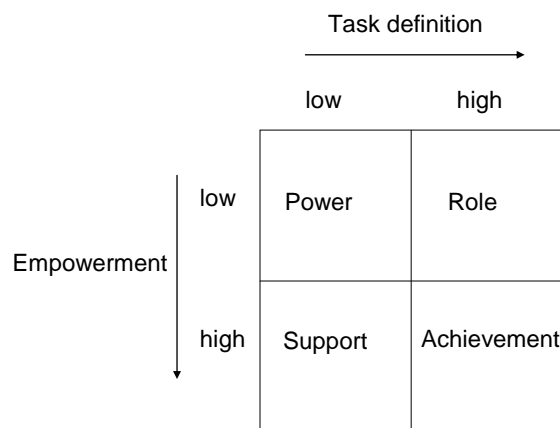

Figure 5 – Culture typology

The typology as shown in Figure 5 has four elements: Role culture: there is a focus on procedure, hierarchy and status; Power culture: dominant and authoritative person in charge with mainly informal or tacit rules; Achievement culture: task and purpose orientated approach with a can-do participatory orientation; Support culture: empowered environment with high levels of intrinsic motivation. As shown by Hultman and Shaw (2003) and O'Dwyer et al (2009) the application of the different elements of this typology is likely to have a differential effect on performance measurement in service based SMEs. The working proposition at this stage is summarised as:

Proposition 5: The prevailing culture within a service based SME as represented by the typology of Figure 5 will influence the implementation of performance measurement practices.

The issue of fit

Fit is based on the deviation between the CVs, as represented in typologies of ideal type, and the relevant practices within the organisation (Johnston and Pongatichat, 2008). It is a dynamic process of alignment as over time the level of fit decreases unless there is an intervention (Raymond and Croteau, 2009; O'Regan and Ghobadian, 2006) which is referred to as "the dynamic process of adjusting to environmental change and uncertainty" (Miles and Snow, 1978, p. 3). Therefore, as stated in Raymond and Bergeron's (2008) study of contingency in SMEs, "alignment cannot be prescribed in a universal fashion". Sousa and Voss's (2008) review refers to the idea of "quasi-fit" to allow for other theoretical considerations such as strategic choice theory and the Resource Based View to explain aspects of fit or miss-fit. Criteria for evaluating the level of fit are manager's degree of recognition of the need for fit; recognition of the affects of misalignment; ability to cope with changes in CVs and the effectiveness of alignment skills within the organisation (O'Regan and Ghobadian, 2006; Johnston and Pongarichat, 2008). As shown by Jung et al (2009), Jusoh and Parnell (2008), Johnston and Pongatichat (2008) and Garengo et al (2007) organisations often use a range of quality or business improvement tools such as the TQM, ISO 9001; BEM, BSC and the Performance Prism to help with the process of fit between CVs and performance measurement practices, where Garengo et al (2005) states that the establishment of a quality culture in SMEs has a significant effect on performance measures and practices. Verreynne (2006) concludes that the use of these approaches by SMEs often lacks sufficient depth and Machuca et al (2006) suggests there is a need for more research within this area in a service context. Moreover, Sousa and Voss (2008) suggest that the selection and role of these approaches needs to be clarified within organisations seeking to improve fit and that studies should thus focus on mature or established practices used by organisations such as those identified by organisations at advanced stages of the "quality journey" (Dale and Lascelles, 1997). By using these criteria and considering the role and application of these tools, the fit between performance measurement practices and each of the CVs can be explored leading to performance measurement practices being placed in Sousa and Voss's (2008) framework. This framework (Figure 6) uses two dimensions in relation to fit for the implementation of performance measurement practices, namely performance and degree of use.

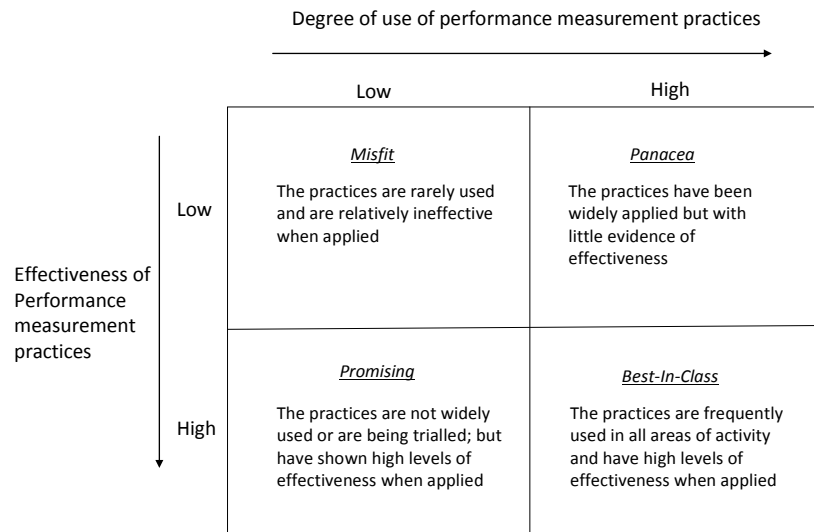

Figure 6 – Classification of performance measures and practices in relation to fit (adapted from Sousa and Voss, 2008).

The four classifications are Misfit: the practices are rarely used and are relatively ineffective when applied; Best-in-Class: the practices are frequently used in all operations and have high levels of effectiveness when applied; Promising: the practices are not widely used or are being trialled, but have shown high levels of effectiveness when used; Panacea: practices that have been widely applied but with little evidence of effectiveness. Although this framework helps to classify fit it does not readily explain the dynamics of fit. It is suggested that legitimacy theory may help where Weber (1947), Suchman (1995) and Johnson (2004) have developed a multi level approach to legitimation theory in organisations for the introduction of new knowledge or methods (i.e. new or modified performance measures and practices in the current context). Key constructs within this approach are normative evaluation and legitimisation. Normative evaluation is an innate resistive force and is based on comparing new knowledge against existing organisational norms, routines and practices (Alvesson and Deetz, 2002). Finnegan (2000) states that manager's and employee's views of organisational values and practices are encouraged to be normative. Suchman (1995) suggests that a cyclical pattern is created where normative evaluation takes place concurrently with attempts at legitimising new knowledge. Legitimation goes beyond evaluation and is formative in nature involving debate, opinion forming and critical reflection relating to the new knowledge (Alvesson and Willmott, 1996). Thus, as suggested by Suchman (1995) attempts to introduce new or modified performance measures and practices can be

viewed from a dynamic perspective as a cyclical process where legitimising forces, or attempts at establishing validity, constantly iterate with normative evaluation resisters (Johnson, 2004; Suchman, 1995).

This discussion gives rise to three interrelated research questions:

RQ1: What is the relationship and level of fit between the contingency variables and the development and implementation of performance measurement practices in service based SMEs?

RQ2: How is Quality Management models, routines and practices used in the implementation of performance measurement practices within service based SMEs?

RQ3: How can the working propositions (1-4) be further refined based on the findings from RQ2?

Research Methodology

Sousa and Voss (2008) suggest the need for theory building methodologies such as case research in contingency studies to build explanations and engage in a sense making process. This view is supported by both Yin (2003) and Eisenhardt (1989, 1991) who suggest the “how” and “what” style of the research questions are suited to this type of interpretative research philosophy to enable in-depth and cumulative theory building inquiry. In this approach multiple sources of data are embraced and analysed in a recursive sense making process in which results and discussion are compared and contrasted as suggested by Yin (2003) until a saturated level of understanding is achieved. This research philosophy capitalises on the rich practitioner based knowledge discourse of contingency studies and performance measurement practices (Garengo et al, 2007; Gunasekaran et al, 2001).

The chosen research methodology was that of multiple Case studies which is suited to the interpretive research approach (Yin, 2003; Eisenhardt, 1991). Heinske and Davis (2006) suggest that the service operations management perspective views each service industry as having unique operations leading to the need for a multiple case approach. Five Case organizations, as shown in Table 2, were selected to provide a wide range of companies and perspectives, as opposed to a single sector study, which created a richness through their inter and intra variation, as suggested Remenyi et al (1998). Each of the organizations chosen (as shown in Table 2) were service based SMEs which were experiencing growth based on the definition of growth at different stages of the lifecycle model. The growth criterion was chosen as SMEs faced with the challenges of growth tend to re-examine the assumptions and practices relating to their performance

measurement practices (Neely, 2005 Hayes et al, 2005, McAdam and Anderson-Gillespie 2008). The Cases selected as suitable were SMEs (EU SME guide (http://ec.europa.eu/enterprise_policy /sme_definition/index_en.htm)), and at least at the middle stages of the “quality journey” of Dale and Lascelles (1997) to address Sousa and Voss’s (2008) suggestion of looking at more mature approaches to get more meaningful results. The research process consisted of two stages.

Stage 1 - Scoping Meetings and identification of Cases

The SMEs were selected as being in a growth phase. Delmar et al, 2003 (cited by Dobbs and Hamilton, 2007) suggest that multiple measures should be used in defining a growth phase in relation to the lifecycle model. The selection of specific cases to meet the growth condition at different stages of the lifecycle model used a screening procedure which consisted of analysing documents and interviewing (n=20) people and stakeholders knowledgeable of potential candidates as suggested by Yin (2003). In particular help was obtained from the Government development and support agencies and The Centre for Competitiveness, (a private sector, not for profit, membership organisation endorsed by the Department of Enterprise, Trade and Investment).

Stage 2 – Interviews, focus groups and methods of analysis

For each case semi-structured interviews (n=9 for each case; 45 for all cases) were held with the Managing Director (or equivalent) and at least two other members of the management team who were most knowledgeable or responsible for each of the contingency variables and related performance measurement practices. The repeat interview technique was used with the interviewer sharing initial structuring for each preceding interview and attempts at proposition building with the interviewee at the next interview. The repeated interviews were supplemented with specific enquiries involving telephone calls, emails and document exchanges and enabled a relationship of trust and mutual exchange to be established (Remenyi et al, 1998). This developmental approach enabled the researchers to obtain reflective practitioner inputs as suggested by Yin (2003). All interviews were taped, transcribed and coded. Following the interviews focus groups (n=5) were held with each of the case organizations comprising on the Managing Director (or equivalent) and the management team where the entire research process and findings were reviewed with particular emphasis on apparently conflicting information, leading to further insights and developments as suggested by Remenyi et al (1998).

Other data sources included a range of organizational documents including each Case's BEM self assessment submission, company reports, Government reports, and minutes of meeting as suggested by Remenyi et al (1999).

Case summary

Case 1 (Hotel and Tourism). Although this business achieved only modest growth from 2007 to 2008, above average returns for industry sector measures have been realised. This business has developed substantially over the last few years ago in all areas of its activities.

Case 2 (Transport). This very profitable transport sector business has changed its business model to include an emergent "green" transport side to the business. The business is continues to grow.

Case 3 (Software development and licensing). This high growth company had a turnover in 2008 which was 183% higher than 2006. As a result of high marketing and research and development expenditure in 2008, profit levels for 2008 were significantly lower than 2007. The company continues to grow.

Case 4 (Construction services). This company has achieved significant growth (29% and 45%) for the last two years as well as increased profit margins due largely due to diversification into sustainable building services.

Case 5 (Business services). The company has achieved high growth over the last two years of 17% and 45% respectively, and has also increased its net profit before tax for the same period. For the first quarter of 2009, while others in the same sector suffered a 20% reduction in turnover, this business has continued to grow.

Table 2 – Case summaries

Case 1 – Hotel and Tourism	2006	2007	2008
Turnover	£2, 448,000	£2,743,000	£2,862,000
Net Profit before Tax	£144,000	£308,000	£270,000
Number of employees	54	54	54
Case 2 - Transport	2005	2006	2007
Turnover	£31,207,000	£34,545,000	£36,109,000
Net Profit before Tax	£11,574,000	£12,538,000	£13,603,000
Number of employees	208	196	197

Case 3 – Software and licensing	2006	2007	2008
Turnover	£1,200,000	£1,900,000	£2,200,000
Net Profit before Tax	Break even	£532,000	£88,000
Number of employees	22	28	35
Case 4 – Construction services	2006	2007	2008
Turnover	£2,700,000	£3,500,000	£5,100,000
Net Profit before Tax	£500,000	£850,000	£1,760,000
Number of employees	27	46	101
Case 5 – Business services	2006	2007	2008
Turnover	£2,800,000	£3,300,000	£4,800,000
Net Profit before Tax	£105,000	£175,000	£350,000
Number of employees	20	20	24

The method of analysis was similar to that used by Radnor and Boaden's (2004) in studying operations management issues using multiple case research data. First topics and categories were constructed from the interview transcripts under each of the four CVs. Second the findings were coded within tables. Third the findings were interpreted using the literature. Fourth the focus group data was used to add more depth to the findings, resolve anomalies, and add new findings.

Results and discussion

The results and discussion are combined, due to the Case-based and exploratory nature and interpretive case based approach to the research, as suggested by Yin (2003) and Simon et al (1996). The structure of this section is based on discussing the fit between the performance measurement practices and each of the CVs in relation to the research questions.

Table 3 – Case typology placings

	Strategy				Culture				Lifecycle				Customer Focus			
	D	P	A	R	Supp	Role	Power	Ach	S2	S3	S4	S5	PS	SS	MS	
Case 1 (Hotel and Tourism)	√					√						√		√		
Case 2 (Transport)			√				√		√					√		
Case 3 (Software and Liscensing)		√					√		√				√			

Case 4 (Construction services)			√		√						√		√			
Case 5 (Business services)		√						√		√				√		

Strategy

From the analysis in Table 3 and Figure 2 it is seen that Case 1 was in the highly competitive economy hotel and tourism sector and was thus focused on competitiveness and cost reductions using standardised operational procedures for room bookings and customer provision (e.g. room bookings and event management practices). To improve efficiency the organisation also had a high level of vertical integration with suppliers such as food materials and specialist event management functions. Potential new entrants were mainly economy based international hotel chains. These characteristics place Case 1 in the Defender category of Miles and Snow's typology (Table 3, Figure 2, 1978). Coupled with this strategic intent Case 1 had a number of performance measurement practices predicated on the use of quality management approaches including the Business Excellence Model, the Balanced Scorecard, Investors in People (IiP) and a service industry sector award model similar to the findings of Jusoh and Parnell (2008) and Garengo et al (2005). The organisation used an integrated version of the performance measurement criteria of the BEM and the Balanced Scorecard in a similar manner to that of McAdam et al (2008). The sector award performance measures were also covered in these criteria where the IiP criteria addressed employee development performance measures. However, even though the BEM results criteria and BSC criteria emphasis the use of lead performance measures in addition to traditional lag or financial performance measures (Jushoh and Parnell, 2008; Kaplan and Norton, 2001), there was a lack of use of lead performance measures in shaping performance measurement practices (such as the development of new service offerings based on market changes or employee training methods for analysing market changes) reflecting the defensive nature of the strategy which is consistent with the Defender strategic approach as shown in O'Regan and Ghobadian's (2006) strategy analysis of SMEs. Benchmarking practices were in-sector (i.e. hospitality) as opposed to innovation or out of sector benchmarking and led to efficiency savings rather than more radical innovation, consistent with Raymond and Bergeron's (2008) study in relation to Defenders. The growth within the organisation was driven by efficiency based practices and measures rather than lead based performance measurement practices. Although

none of the Cases were in the Reactor category O'Regan and Ghobadian (2008) and Langfield-Smith (1997) suggest that this category also tends to focus on lag based measures without a strategic set of practices based on lead performance measures.

Cases 2 and 4 were classified as being Analysers (Table 3, Figure 2) i.e. they had to simultaneously focus on maintaining and growing their existing markets while seeking out new markets to sustain and increase growth similar to that found by Jusoh and Parnell (2008) and Raymond and Croteau (2009) in relation to SME Analysers Case 2 focused on maintaining growth in their traditional transport services (e.g. road haulage) operations while seeking to develop new markets in terms of "green" based alternatives involving transport using green or renewable energy sources. Similarly Case 4 had a traditional focus on construction services such as design and build of traditional building developments but was also moving towards providing services for sustainable developments. This duality or "balance" (Raymond and Bergeron, 2008) was reflected in the performance measures and practices used by these cases. For example Case 2 used finance and process measures and practices which addressed the traditional side of the business such as financial measures (profit, turnover, sales, fixed and recurring costs), delivery time, load planning and scheduling. These measures were used to guide performance measurement practices such as budgeting, schedule planning, and load balancing (return and outward journeys). The development of the "green" market involved using lead measures such as carbon equivalents for operations, costs per alternative energy source and potential payload measures, which were incorporated into practices to scan for new technology, benchmarking emerging practices, and analysis of potential markets. In Case 4 these practices were also evident where they were driven by lead performance measures such as heat retention for new materials, cost saving practices in terms of waste generation and lifetime sustainability measures. Overall Cases 2 and 4 had high levels of flexibility to maintain both sets of markets conditions as found by Raymond and Croteau (2009) in relation to Analysers.

Case 3 and 5 were classified as Prospectors (Table 3; Figure 2) which reflected a focus on new service and market opportunities to drive growth as opposed to the duality of the Analysers (Jusoh and Parnell, 2008; Raymond and Bergeron, 2008). This focus was reflected in the predominance of lead performance measures and associated practices for these cases consistent with O'Regan and Ghobadian's (2006) findings for Prospectors. Case 3 which was based on software development and licensing had to design and offer new services to existing customers while seeking out new markets with these services and offerings. Typical lead performance measures related to innovation, which was mainly based on the Balanced Scorecard rather than the BEM (as found by

Jusoh and Parnell, 2008), were market trends, technology effectiveness, return on investment and training in new methods. These measures were reflected in practices such as out of sector benchmarking (in contrast to Defenders (O'Regan and Ghobadian, 2006), market scanning and investment decision making. Case 5 were similar to Case 3 in that their provision of business services had to seek out new services and markets to drive growth. This direction led to the use of lead performance measures such as numbers of new services developed, lifecycle of existing and anticipated services, which were reflected in similar practices to that found within Case 3 and studies of Prospectors by Raymond and Croteau (2009).

In relation to the dynamics of fit throughout the cases a continual process of change was observed at two levels in relation to fit. First there was a dynamic at an operational level which involved trying new performance measures and practices, developing modifications, and discarding old ones, in relation to strategic intent. Second a range of quality related methods and models were used in a continuously changing manner as the catalyst for the performance measures and practices (e.g. BEM, BSC, IIP, ISO – Jung et al, 2009). It is suggested that these dynamics can be interpreted using the multi level approach to legitimacy theory (legitimation theory of Weber (1947), Suchman (1995) and Johnson (2004)) where changes due to fit considerations need to be legitimised or successfully adopted at all levels. Using the key constructs within this approach of normative evaluation and legitimisation it is suggested that each case when seeking to align their performance measures and practices with the strategic intent of the organisation face innate resistive forces which are based on comparing new measures and practices against existing organisational norms, routines and practices (Alvesson and Deetz, 2002). Finnegan (2000) states that manager's and employee's views of organisational values and practices are encouraged to be normative or to maintain the status quo. This resistance was most noticeable in the Analyser category (Cases 2 and 4). Both of these cases were introducing new aspects to their business ("green" transport in Case 2 and sustainable building practices in Case 4). The forces resisting the development of the new performance measures and practices were twofold. First, employees did not see the need to change due to a lack of understanding of the new strategy where managers did not adequately communicate the change or train employees in the new methods required in a timely manner. Thus, a cyclical pattern is created (Suchman, 1995) where normative evaluation takes place concurrently with attempts at legitimising the performance measurement practices. Similarly, in Cases 2 and 4 belated efforts were made to improve the communication and introduce training based around the quality methods and models to drive lead performance measurement practices. However the previous use of these models had previously been that of

focusing on efficiency measures and practices and now they were being reconceptualised to address a drive towards more innovative approaches. Hence the legitimisation process was multilevel and time consuming (Suchman, 1995). What initially appeared to be a simple switch-over practice became a time consuming process which was formative in nature involving debate, opinion forming and critical reflection relating to the need for the new performance measures and practices (Alvesson and Willmott, 1996). In cases 1, 3 and 5 the respective Defender and Prospector categorisations had a more single focus than the duality of the Analysers as found by O'Regan and Ghobadian (2006). The resultant fit dynamic for these categories was therefore mainly at the operational level with an emphasis on changes to performance measures and practices with the use of the quality models and methods being relatively fixed in either an efficiency mode (Defender) or innovation or lead mode (prospector).

In appraising the classification of fit between the strategic focus and the performance measures and practices of the cases based on Figure 2 (Sousa and Voss, 2008), there was little evidence of Misfits or Panaceas. However as Cases 2 and 4 continue to grow the new side of their businesses there is a potential for old technology, market measures and practices to become redundant through the legitimisation process which ultimately could lead to Sousa and Voss's Panacea definition (widespread application of ineffective processes in relation to strategy). The promising practices category mainly covered practices using lead performance measures and practices, especially within the Prospector cases such as out of sector benchmarking and environmental scanning (Cases 3 and 5). However these practices were limited by their degree of use and also by the limited range of lead performance measures incorporated within these practices. The wider use of these practices depended on the speed of the legitimisation process in overcoming innate resistance (Leseure et al, 2004). For example Case 5 had a relatively limited range of lead based people development measures incorporated within their investment decision process and Case 3 had Case 2 used only a limited set of process innovation measures within their practices for evaluating new and emergent technology. The wider use of these practices depended on the speed of the legitimisation process in overcoming innate resistance (Johnson, 2004). These findings for the strategy contingency variable enable the initial working proposition (P1) to be revised:

Revised P1: A service based SME's approach to strategy as articulated in Figure 2, will tend to have increased use of lead performance measures and practices for the Analyser and Prospector categories in comparison to the Reactor and Defender categories.

Culture

Based on the culture typology of Figure 3 the cases were analysed and situated as shown in Table 3, Case 1 was classified as having a Role culture. This finding reflects the focus on procedure, hierarchy and status within the hotel and hospitality industry where there are clearly defined roles, responsibilities and reporting links. This hierarchy was reflected in the cascade approach to performance measurement and practices where formalised measures were devised by the management team and communicated downwards to all levels and areas of operation. This approach ensured consistency of the performance measures used throughout the organisation, however the lack of empowerment led to sub-optimal performance measures being applied at operational levels as found by Bititci et al (2004) in relation to Role cultures and performance measurement translation in SMEs. The Balanced Scorecard approach was used to aid this process however the same Balanced Scorecard was used at all levels as opposed to operational team developing their own devolved scorecards through strategy mapping practices as suggested by Jushoh and Parnell (2008). At an operational level efforts to improve performance measurement practices such as room turnaround between guests and provision of outside contractors for special events had to rely on imposed measures which were too generic (e.g. overall cycle time, recurrent cost and quality check list measures) when more precise and localised measures of each operational step were needed to lead to continuous improvement at a localised level. This approach was also reflected in Case 1's approach to Benchmarking practices where clearly defined approaches were laid out but the practice was applied to internal and in sector benchmarking using generic performance measurements, similar to that found by Jung et al (2009) and Garengo et al, 2007 (e.g. average service rating - from a sector quality model and the BEM, employee turnover, absenteeism and training needs analysis). There was a corresponding lack of employee development measures and associated performance measurement practices as reflected in this Role culture category (Bititci et al, 2007).

Cases 2 and 3 were analysed as having Power cultures (Figure 3, Table 3). Each of these cases had a strong leader (Managing Director - MD) with a knowledge of, and influence on, all levels and operations within the organisations which, as shown by Ritchie and Brindley (2005) is characteristic of Power cultures. In Case 2 (Transport) the MD had led the company since its inception and continued to have a hands-on role at both strategic and operational levels. However his reliance on his tacit knowledge resulted in a lack of formalised procedures and an informal approach to performance measures and practices. The management team and the operational level employees had a tendency to

“check with the boss” which is a characteristic of Power cultures (Bititci et al, 2004). Similarly in Case 3 (Software and Licensing) the MD was a technical expert in software design and tended to impose an informal performance measurement approach based on his tacit knowledge. The drive for new business compounded this informal and tacit approach where new services were developed without clearly defined and formally applied quality performance measurement practices leading to lack of clarity at operational levels.

The culture typology suggests that Case 4 (Construction Services) has an Achievement culture (Figure 3, Table 3) with a task and purpose orientated approach combined with a can-do participatory attitude. This finding is indicative of Case 4’s employment of professional staff (e.g. Engineers, Surveyors, Architects), each with their own role and purpose and with a professional ethos. The multifunctional nature of the business services projects (such as design and build) suited the participatory approach of the Achievement culture (Bititci et al, 2004; Handy, 1985) The Achievement culture was reinforced by a focus on employee development performance measures for each area of professional staff (manual staff tended to be fixed term or sub contractors) with an employee recognition scheme for exceptional efforts. The performance measurement practices included professional development practices for each of the specialisms within the organisation. The task nature of the achievement culture with Case 4 was also reflected in the use of ISO 9001:2000, ISO 9014 and ISO 18000 Standards and practices. These criteria added resulted in a formalised and procedural driven approach to performance measurement practices in terms of compliance with the Standards which reflects an Achievement culture as shown by Bititci et al (2006) and Ritchie and Brindley (2005).

A Support culture was found within Case 5 (Business Services) with an emphasis on empowerment and high levels of intrinsic motivation (Handy, 1985). This approach reflected the strong emphasis on developing new services for new and existing markets. The empowerment culture encouraged employees at all levels to develop ideas for improving and developing new services as found by Bititci et al (2006). This approach also tended to lead to continuous change in terms of performance measures and practices with a commensurate lack of formalised approaches. For example efforts to apply the BEM and IiP were marginalised due to the ever moving base line measures and the degree of bureaucracy these models were seen as imposing. There was a strong focus on developing employee development measures, consistent with the empowered culture, such as levels of proficiency in new skills training, number of employee recognition awards at different organisational levels and number of suggestions for new

services and service improvements. These measures were incorporated within relatively informal performance measurement practices such as new service development, staff appraisal and training and development needs analysis.

In relation to culture the dynamics of fit process for the culture CV was mainly limited to one level for all of the cases; that of performance measures and practices with minimal influence at the second level of the quality methods and models. This finding reflected the relative rigidity of the Cases within their culture categories. Hence the dynamic of fit from a culture CV perspective was limited to legitimising the degree of alignment with each respective culture category rather than seeking fundamental questioning of the status quo (Johnson, 2004).

In relation to the classification of fit between the prevailing culture and the performance measures and practices of the cases based on Figure 3, there was some evidence of Panaceas where Case 1 adopted and applied the BEM practices across the organisation. However the model had not been sufficiently adapted for service based organisations leading to confusing language which had a manufacturing origin and hence problems with legitimation in lack of change driving forces (Suchman, 1995). The promising practices in relation to culture mainly related to people development. For example in Case 5 practices in line with the Support culture included time allocations for new service development activities and development of multi-skilling. However, these promising practices tended to be somewhat localised due to the informal and tacit nature of their use and needed increased formalisation for legitimation and overcoming normative resistance across all areas of the organisation. Overall the findings for the culture contingency variable enable the initial working proposition (P2) to be revised:

Revised P2: A service based SME's approach to culture as articulated in Figure 5, will tend to have more informal and tacit approaches to the use performance measurement and performance measurement practices for those SMEs in the Power and Support culture categories in comparison to those SMEs in the Role and Achievement categories.

Customer Focus

Table 3 and Figure 4 places Case 1 (Hotel and Tourism) in the Mass Services category of Customer Focus. This analysis is consistent with Case 1's emphasis on increasing their customer numbers with a focus on efficiency and an economic customer offering consistent with the Mass Services type (Ng et al, 2007). There was an emphasis on the

use of models such as IIP, BEM and hospitality sector award models to form performance measures and practices as found by Jusoh and Parnell (2008). The continuous improvement ethos within these models was consistent with the enhancement of services ethos across a large number of customers. However the effective application of the BEM was limited due to its innate large manufacturing organisation language. Typical customer measures tended to be more transactional than relational and included efficiency measures such as room occupancy levels and room turnaround times and practices. This finding reflects Silvestro (2001) and Hultman and Shaw's (2003) findings that Mass Services type focuses more on transactional dealings with customers.

Cases 3 and 5 were located in the Professional Services category where the emphasis is on the unique proposition offered (Ng et al, 2007; Silvestro, 2001), which focuses on their service offerings being complete and relatively distinct within the market place (Design and Build services in Case 3; Integrated Business Services in Case 5). This approach led to an emphasis on relational customer performance measures and practices. For example, Case 3 had a small number of large customers where relational performance measurement practices included practices for partnering with suppliers and customers and other stakeholders (including regulators) in developing licenses.

Case 4 (Construction Services) and Case 2 (Transport) were in the Service Shop category where the emphasis was on the duality of the business, i.e. the traditional business which was mainly transactional in terms of performance measures and practices and the new or emergent part of the business which was more relational in nature. For example in Case 2 transactional measures included cost effectiveness per tonnage delivered while relational measures included networking levels with "green" stakeholders in the travel industry.

In relation to the dynamics and classification of fit between the customer focus category and the performance measures and practices of the cases based on Figure 4, there was little evidence of Misfits or Panaceas or Best-in-Class practices however there were indications of Promising Practises and Best-in-Class practices. For example in Case 1 the new/improved service provision and development and joint development teams between customers and large clients for event management were informed by customer analysis. However their initial application was predicated on the BEM language for large organisations which limited the application of the practices. However there were signs that the switch to the Balanced Scorecard was improving the situation. Thus in terms of legitimation (Suchman, 1995) the drivers for increasing the deployment of the

promising practices were customer needs and awareness of those needs at all levels in the organisation. Normative evaluation and resistance came from the entrenchment of existing processes (Johnson, 2004) and reliance on transactional and efficient based performance measures and practices. Based on the discussion of Customer Focus as a contingency variable Proposition 4 has been revised as follows:

Revised Proposition 4: A service based SME's Customer Focus categorisation as articulated in Figure 4, will tend to result in performance measures and practices being more relational based than transactional for the Service Shop category in contrast to the Mass Services category.

Lifecycle

Case 1 (Hotel and Tourism) was placed on stage 5 of the Lifecycle model (Table 3; Figure 5) where performance measures and practices reflect a fully networked organisation achieving a level of maturity and consistent growth (Greiner, 1972). In Case 1 performance measures and practices were well established and had a level of robustness through clearly defined procedures. A limitation of this engraining process was the lack of agility in relation to responding to innovations in the marketplace (O'Regan and Ghobadian, 2006) where new sets of performance measures and practices are required often leading to redundancies in terms of existing measures.

Toward the other end of the Lifecycle model Cases 2 and 3 were located in Stage 2 where there is an emphasis on growth through direction following the establishment of the firm (Nair and Boulton, 2008) For example, in Case 2 there was a clear emphasis on developing new greener modes of transport services in addition to the existing provision. This approach led to the development of new performance measures and practices which were less established and defined but which addressed the new emerging marketplace which was being targeted (e.g. performance measures such as carbon equivalents and practices such as scanning for new technology). Similarly in Case 3 there was an emphasis on growing new markets using licensing of software services which led to a search for new performance measures and practices which were contextual rather than relying solely on prescriptive measures from quality models.

Cases 4 and 5 were situated in the middle region of the Lifecycle model i.e. Stages 4 and 3 respectively. In Stage 3 the emphasis is on growth through delegation which was consistent with Case 5's approach to developing performance measures and practices to empower employees to develop service and organisational improvements (Greiner,

1972). Stage 4 emphasises growth through increased coordination (Nair and Boulton, 2008). This situation was reflected in Case 4's project based approach to design and build in their traditional markets and their coordination with customers and suppliers in relation to their new renewable markets. Thus their performance measures and practices were not as established as those of Case 1 (Stage 4) however there was more agility within the measures and practices to accommodate innovations in services and markets as found in Raymond and Bergeron's (2008) study.

In relation lifecycle dynamics and classification there was a dynamic at both performance measurement and practice, and quality management method and model levels for all of the Cases. This dynamic resulted from all of the cases being in state of growth (case selection criteria) and thus being in a state of transition either inter or intra lifecycle stage(s). In Case 1 the need to develop performance measures and practices to support increased agility led to normative resistance from well established approaches which addressed plateau states within the business and which did not conceptually identify with an overall pattern of lifecycle growth. A lack of out of sector benchmarking tended to reinforce the status quo with minor changes rather than legitimising the need for increased growth. Similar attempts to reconceptualise the use of quality models such as the BEM into a driver for innovation and agility measures met with similar resistance. Cases 2, 3, 4 and 5 which were located in lower stages i.e. Stages 2-4 where the emphasis was on directed growth (Ritchie and Brindley, 2005) following the establishment of the firm led to the management driving the implementation of more innovation orientated performance measures and practices using the quality management methods and models in a growth mode with more focus on customer measures and involvement of empowered employees to meet customer expectations. This approach created an interesting duality with normative evaluation and resistance emphasising the need for stability to guarantee continues existence while the legitimising forces focused on the need to grow and the fallacy of relying on traditional markets which were being eroded (Johnson, 2004).

In relation to the classification of fit between the Lifecycle model and the performance measures and practices of the cases based on Figure 2, there was little evidence of Panaceas or Best-in-Class. However in the Promising Practices category there was some evidence from the cases that in the earlier stages of the Lifecycle model measures and practices were more fluid and could accommodate change and innovation; however at the latter Stages such as 4 and 5 the relative rigidity of established performance measures and practices could potentially limit opportunities from market and technology innovation ultimately leading to Misfits as the market place continues to

move on and develop. Hence legitimation of new or modified performance measurement practices and overcoming normative resistance may take longer as an organisation progresses through the lifecycle model. Based on the discussion of Lifecycle contingency variable Proposition 5 has been revised as follows:

Revised Proposition 5: A service based SME's Lifecycle categorisation as articulated in Figure 5, will tend to result in increased rigidity of growth based performance measures and practices as the SMEs progress towards the Latter stages of the model.

Conclusions and recommendations

The development and implementation of performance measures and practices in the service-based SME Cases, in relation to RQ1, were found to be dependant of a number of contingency variables. Adopting a services operations management viewpoint for services proved useful and enabled meaningful comparisons to be made with existing studies of non-service based SMEs and helped in analysing the performance measures within the SMEs. The contingency variables of strategy, culture, lifecycle and customer focus, while not exhaustive, enabled performance measures and practices to be explored from a wide range of influences. Each of the contingency variables had been identified in the literature where some were used in single variable studies however the use of multiple contingency variables, as suggested by Sousa and Voss (2008) and Garengo et al (2005), added different perspectives and richness to the study and helped explain the development of the performance measurements and practices within the cases. Interpreting the contingency variables by using established typologies borrowed from the literature, as suggested by Sousa and Voss (2008), helped in understanding the fit or alignment issues for the performance measures and practices.

In relation to RQ2 Quality management methods and models emerged as key approaches within the alignment or fit process for both prompting and aggregating performance measures and practices to a given typology category in a similar manner to that found by Jusoh and Parnell (2008) and Jung et al (2009). In some situations the existing use of such models was challenged and required a change in focus (e.g. from efficiency to innovation).

The typologies enabled a number of what Raymond and Croteau (2009) refer to as loose propositions to be developed in addressing RQ3. In relation to each of the contingency variables and the relationship to the performance measures and practices. These propositions were initially developed from the literature and then refined using the Case

analysis as suggested by (Garengo and Bititci, 2007) and Raymond and Bergeron (2008). In relation to strategy it was concluded that Analyser and Prospector categories tend to have increased use of lead performance measures and practices in comparison to Reactor and Defender categories. The culture analysis revealed that those Cases in the Power and Support categories tend to have more informal and tacit approaches to the use performance measurement and performance measurement practices in comparison to those SMEs in the Role and Achievement categories. The Customer Focus analysis showed that the SMEs in the Professional Service category tended to have performance measures and practices that were more relational based than transactional in comparison to the Service Shop and Mass Services categories. Overall these findings show the need to consider a wide range of organisational issues when attempting to understand the effective design and implementation of performance measures and practices.

The contingency variables led to a range of fit or alignment issues. Sousa and Voss's classification scheme (Figure) proved useful in separating out best in class, panaceas, miss fits and promising practices. However, contingency theory was also helpful in seeking to explain the dynamics of fit (Suchman, 1995; Johnson, 2004) within Sousa and Voss's (2008) framework where legitimising forces for developing and applying new or modified performance measures and practices seek to overcome the normative evaluation and resistance of the status quo (Johnson, 2004). The lack of upward change pressure on the CVs from the performance measurement practices and quality models and methods reflected both the customer demand led nature of service based SMEs (Hultman and Shaw, 2003) and the quasi stability of the CVs (Langfield-Smith, 1997).

It is recommended that the study could be further developed in two respects. First, by using a larger number of Cases from different service classifications leading to new or further refined propositions, and second by developing the propositions into hypothesis as part of a cross sectional theory testing study.

Key words: Tidy environment, Messy environment, Conscientiousness, Human reliability, Human error, Job performance

Category: Research paper

Introduction

The relationship between personality and job performance has been a frequently studied research topic in Management, Organizational Behavior and Psychology in the last decades. A number of studies have identified that individual behavior at work can be significantly influenced by personality traits and several researchers have studied the predictors of job performance (e.g. Barrick and Mount, 1991, Hough et al., 1990, Ones et al., 1993, Tett et al., 1991). In this paper, an important part of individual performance is considered: reliability. This component of performance is analyzed in the relation between personality trait called conscientiousness and the tidy work-environment.

Psychologists have identified literally thousands of personality traits and adjectives that differentiate one person from another. But for some decades, researchers have identified five fundamental factors or dimensions of personality. Each of these factors consists of a group of more specific traits. The five factors are commonly called the “Big Five personality traits”. Thus, the Big Five refers to a type of taxonomy or personality traits classification system used to describe personality dimensions (Goldberg, 1990, John, 1989, Digman, 1990, Costa and McCrae, 1992, Costa et al., 1991). This taxonomy has been systematized and recognized as a reference tool for personality analysis and now is especially relevant to organizations in the last decades. The Big Five dimensions are Extraversion, Agreeableness, Conscientiousness, Neuroticism, and Openness. Costa and McCrae (1995) have suggested that, within each personality dimension, there are facets (essentially first-order factors) that combine to form the entire construct. They described six facets for each domain. The names for each facet are derived from the items that contribute to it. For example, the conscientiousness facets are competence, order, dutifulness, achievement-striving, self-discipline, and deliberation.

From the Big Five personality traits, conscientiousness has been the most consistent personality predictor of job performance across all types of work and occupations (Barrick et al., 2001, Schmidt and Hunter, 1998, Barrick and Mount, 1991, Salgado, 1997, Ones et al., 2007, Mount et al., 1998, Mount et al., 1999, Witt et al., 2002, Witt, 2002, Behling, 1998). Conscientiousness is a broad personality dimension defined as the extent to which a person is able to self-regulate and be purposeful, achievement oriented, responsible, and persistent (Digman, 1990). High conscientiousness people are described as organized, reliable, and ambitious (Costa and McCrae, 1992, John and Srivastava, 2001). Furthermore, they are also skilled planners who maintain impulse control (e.g., act cautiously, delay gratification, and follow rules and norms), which often leads to enhanced task performance (John and Srivastava, 2001). Thus, it is logical that individuals with high conscientiousness have a better performance since they are characterized by a high level of reliability.

Many authors have suggested that some traits of personality may change over time (Mischel and Peake, 1982, Roberts and Caspi, 2001, Helson and Stewart, 1994). The path to finding stability in personality traits requires one to take into account the situation and its impact on an individual; and this may be identified in the stable interactions between traits and circumstances (Mischel, 2004, Cervone, 2004, Furr and Funder, 2004). This would imply that the situation or environment in which the person is working can alter or modify his expression of conscientiousness, as one traits of personality. This implication leads us to consider the effect it could have on the

employee a work environment based on conscientiousness, i.e., a work environment that has the characteristic of to be essentially described with at least one of the facets of the conscientiousness (e.g. tidy work environment). It is interesting to know the effect of this type of work environment on the performance of employees, especially reliability, since this environment is based on a facet of conscientiousness. The present article does not conclude on the dynamic relation between work environment and trait consistency because it does not employ a dynamic methodological framework for observations collected over several time periods. Nevertheless, the cross-sectional model's main results of this article may motivate future researchers to study these dynamic effects in an extended statistical setup, which may evidence changing personality traits in different work environments.

In this article, one of the six facets that compose the conscientiousness, i.e. the order (tidy), is considered. Hence, this work aims to study if there are interactions between work environment based in tidiness and conscientiousness that affect work reliable of the individuals.

To the best of our knowledge, there has been no research on the reliability of employees conditional on both the order trait of work environment and the employees' conscientiousness personality trait. Hence, the contribution of this article is the novelty of having studied the relationships among the following three subjects: work environment based on the trait of order, conscientiousness and reliability of employee.

The remaining part of this article is structured as follows. First, the definitions of order facet are examined to use these concepts as a guide to design a work environment for our experiment. Once the meaning of tidy and messy work environment is defined, it is hypothesized how these environments can mediate in the relation between conscientiousness trait and reliability. Then, an experiment is employed to test these hypotheses and the main empirical results are summarized. Finally, implications of these results and suggestions for future research are discussed.

Defining a work environment based on the order trait

Order facet reflects the tendency to apply structure to one's working environment. According to Costa and McCrae (1992, 1999, 1998), high scores on the order facet are characterized by being neat, tidy, clean and well-organized; keeps things in their proper places. The order as tendency to keep one's environment tidy and well-organized is familiar from several personality inventories (Costa et al., 1991). Low scorers might

therefore be described as dirty, messy, untidy, disorganized, slovenly, and sloppy, “but those terms are so harshly evaluative that many psychologists, especially clinicians, would be reluctant to use them. In feedback to the client it would probably be more politic to say ‘not well organized’ or ‘not excessively neat’” (Costa and McCrae, 1998).

The present research focuses on the work environment based on the order. The above definitions of personality trait of order are used as a guide to design a work environment that is based on this trait. In this sense, the *tidy work environment* would be defined as the environment of work where everything is orderly and organized in the right place. And the *messy work environment* would be defined as the environment of work where everything is untidy and disorganized.

Reliability, work environment and conscientiousness trait

With respect to reliability, an employee that is reliable can be trusted or believed because he/she works or behaves well in the way firm expect. In this sense, reliability is the ability of an employee to perform and maintain his/her expected work in routine circumstances, as well as hostile or unexpected circumstances. The organizations have expectations, which must be concrete and realistic in order that they can assess reliability. Thus, expectations “represent the institutional and role beliefs about how a task is to be performed and typically take the form of rules, regulations, standard operating procedures, organizational goals, and normative standards” (Ramanujam and Goodman, 2003).

Human reliability is related to the field of human performance, which it can be affected by many factors such as age, state of mind, physical health, attitude, emotions, propensity for certain common mistakes, errors, etc. Reliability is the first of the qualities any job performance predictor should possess. Reliability can be measured in a huge number of ways within business. One of these ways is by human error, which it is a cause or contributing factor in wastage and accidents in many types of business. A considerable number of these human errors might be fitted inside what Ramanujam and Goodman (2003) define as *latent errors*. According with these authors the principal characteristics of latent errors are: (1) a set of organizational expectations, (2) deviations from these expectations, and (3) absence of direct consequences. The type of work environment could influence the reliability of the employees, inducing them to work in a defective way or deviations that do not produce direct and immediate adverse consequences.

In summary, we hypothesize that the relationship between conscientious trait of the employees and their reliability are mediated by the influence of the work environment in which they operate, according to if this environment is tidy or messy.

According to the theory that we have seen before in the introduction, individuals with high conscientiousness are more productive and reliable than individuals with low conscientiousness. The question is if these differences in productivity and reliability are maintained in spite of the fact that the work environment is tidy or messy. As a result, we propose the following hypotheses:

Hypothesis 1: In a messy work-environment the employees with high conscientiousness make fewer mistakes than the employees with low conscientiousness.

Hypothesis 2: In a tidy work-environment the employees with high conscientiousness make fewer mistakes than the employees with low conscientiousness.

Besides, one must ask if there are differences in reliability among the individuals with high conscientiousness by the fact of working in a tidy or messy environment. The same question would be for the case of individuals with low conscientiousness. In the past literature, this relationship has not been studied. Therefore, the hypotheses of this article state that these two types of environments could influence the reliability of the individual. It is more intuitive that a messy environment could influence negative in individual reliability because is an environment that would lead to be annoyed or to be not concentrated on the work. Thus, we propose the following hypotheses:

Hypothesis 3: Employees with high conscientiousness make more mistakes in a messy work environment than in a tidy work environment.

Hypothesis 4: Employees with low conscientiousness make more mistakes in a messy work environment than in a tidy work environment.

Figure 1 depicts the reliability relations that arise in these hypotheses.

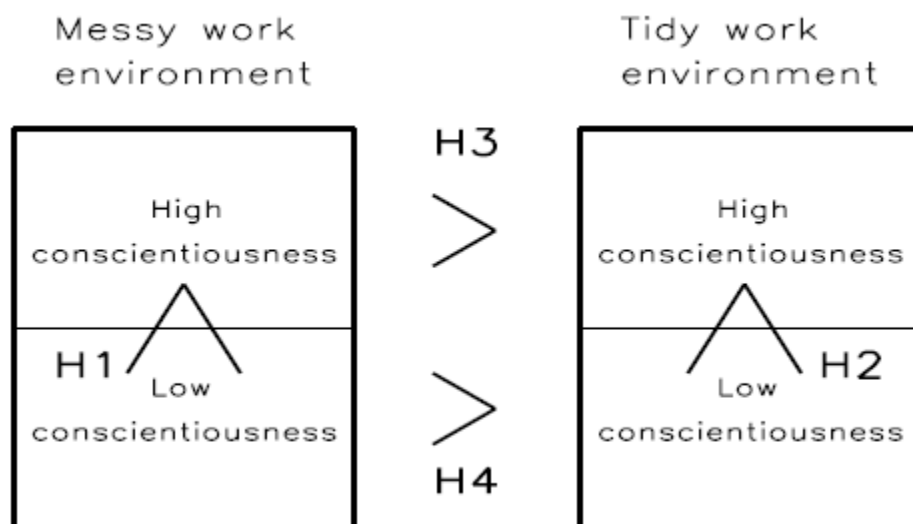

Figure 1. Hypotheses H1-H4 about the average relative errors of individuals in different situations

Note: The signs "less than" (<), "greater than" (>) and "equal" (=) denote in which situation the individuals make less, more or equal mistakes, respectively.

Method

Study design

To test these hypotheses, an experiment is employed. A field experiment is conducted, where subjects performing a simple task in a highly controlled environment are exogenously sorted into two different treatments. The experiment manipulates one independent variable: things in work environment that are evident that are not in its place, i.e. that they are in a messy condition. There are two levels or treatments: a) messy work environment, i.e. an environment of many papers and objects of work scattered on the desk and workplace, where it is evident that these objects were not in its place; b) tidy work environment, i.e. an environment where there is nothing out of place. The focal dependent variable is the reliability level of the individual. Reliability is measured computing the right answers and the relative error of the individual, i.e. number of incorrect answers divided by number of total answers.

Participants

All of our subjects are university students recruited from different schools of the University. The final dataset comprises 80 students of whom 31 are male and 49 are

female. Their median age is 20 years. Fifty four percent of the participants are students of the School of Economics and Business Administration.

Students have been asked in announcements posted on notice boards and Website of University if they would like to do a simple short-term job requiring no previous knowledge. In the announcement, it has been stated that the job is a one-time 2-hour job and it pays € 14 (1 € \approx 1.35 US\$), that it is part of an academic research and also that they would fill out a personality test.

Students have applied by e-mail. After receiving their applications, each participant has been randomly assigned to one of the two treatments and we have informed them of the precise date and location where they are expected to carry out the job. There has been a different date for each treatment. Each participant has come only to one date. A total of 85 subjects have participated in the experiment. Once five clear outliers have been eliminated, there are 39 subjects in the messy work environment treatment and 41 in the tidy work environment treatment. Both treatments have been performed in a computer lab of the University in October 2010.

Procedure and Task

A simple and easy to measure work task is chosen that required no previous knowledge. In this task, students transcribe the results of a survey. A survey through an online program called Encuestafacil.com has been designed (program access is available at: www.encuestafacil.com). The survey simulates a market research about the preferences of recent graduates in the selection of the firms to work. The survey includes multiple choice questions. The answers are chosen by mouse clicks, except the first question in which it is necessary to write the number of the survey.

Before the experiment, we have filled out the survey that we had designed in the online program, in order to create thus the responses of 80 supposedly different individuals. The surveys that we give to the participants are the printed results of the data that we had filled earlier in the online program. Thus, each participant has received a package of 80 surveys that supposedly already had been filled out by 80 different subjects. Each survey has contained 44 answers (inputs) to transcribe (to enter) in the online program. Moreover, each survey has included an identification number and the 80 surveys have been arranged in ascending order according to this number. The objective of the participants has been to transcribe the surveys in the order in which has been given

them. The surveys data, type and model of computer, identification numbers and order of the surveys are the same for all participants.

Upon arrival, subjects are welcomed and informed about their task of transcribing the results of a survey and the procedural details. Thus, participants probably have perceived this task as a "real" work. The participants have not known neither what duration of the two contracted hours is to be spent to work. Moreover, they have not been informed about that their work performance has been measured. They have worked one hour in the transcription of the surveys. Afterwards, they have filled in the NEO PI-R personality test and finally they have filled in a brief questionnaire about their impressions of the physical environment of work in which they have worked. Payment is independent of output and has been paid by electronic transfer. The procedure is exactly the same for both treatments.

In the messy treatment, participants have a work environment with many papers and documents on the desks that are unnecessary; pencils, clips, staples scattered on the desks and floor; many papers and some empty boxes scattered on the floor. It is important to clarify that the location of these things does not interfere with the operating capacity of the participants, i.e. they have had sufficient free space on the desk to maneuver the surveys. In contrast, in the tidy work environment treatment, there have not been untidy or unnecessary things both on the desks and in the floor. Thus, on the desks of the participants there have been only the surveys and the computer.

Measures

Reliability. Reliability is measured computing the relative error of the individual, i.e. number of incorrect inputs divided by number of total inputs. Each survey answer that the participant clicked on is counted as an input. The identification number of each survey that he/she had to transcribe is also counted as an input. An input is considered to be correct when the participant enters an answer that coincides with respective survey received in the beginning of the work task. If a participant omitted or repeated a survey, this was counted as 44 incorrect inputs, i.e. the total number of inputs of the survey. The program of the website Encuestafacil.com has a tool that collects in an Excel sheet all the answers (inputs) filled in by the participants. This allows us to compare the answers of the participants with the answers filled out previously by us.

Conscientiousness. The Revised NEO Personality Inventory (NEO PI-R) (Costa and McCrae, 1992) is used to measure the Conscientiousness factor, which is a 240 item set

of self-statements that assess the five dimensions of personality along with six facet scales for each factor. This is an instrument with well-established reliability and validity (Costa and McCrae, 1992).

Work environment. A short questionnaire has been employed to ask participants about how they have perceived the physical environment of work: tidy-untidy and other physical conditions. The aim of this questionnaire is to confirm if the participants have perceived the environment according to the type of treatment that they have been assigned.

Clustering with respect to conscientiousness

In order to study the hypotheses stated before, individuals with high and low conscientiousness are identified in the sample. Two clusters of high and low conscientiousness individuals are formed for each treatment (tidiness and mess) separately. This clustering procedure yields the next four groups (G) of individuals from the sample:

- (G1) high conscientiousness (*h*) individuals in the treatment of tidiness (*t*),
- (G2) low conscientiousness (*l*) individuals in the treatment of tidiness (*t*),
- (G3) high conscientiousness (*h*) individuals in the treatment of mess (*m*), and
- (G4) low conscientiousness (*l*) individuals in the treatment of mess (*m*).

Each treatment is clustered separately instead of clustering the pooled sample of both treatments because the fact of tidiness or mess may affect the measurement quality of the conscientiousness variable and clustering the two treatments separately can control for this problem and therefore provide more robust results.

The clusters of conscientiousness are created using the Ward's linkage clustering procedure (Ward, 1963) and the Euclidean distance measure is used in the clustering procedure. Ward's linkage clustering method is applied because several past papers, which compare alternative clustering techniques, conclude that Ward's method tends to identify better clusters than other methods. For example, Kuiper and Fisher (1975) in a Monte Carlo comparison of six agglomerative procedures, find Ward's method generally the best, followed closely by the complete linkage method. Moreover, Jain et al. (1986) conclude that the complete linkage and Ward's methods are generally superior to other hierarchical clustering methods.

Comparison of cluster means

After forming two groups for each treatment, the four hypotheses stated previously are tested by comparing the mean relative errors of each two clusters stated in the hypothesis. First, the following notation is introduced for the mean relative error of individuals in each group G1-G4 defined in the previous subsection:

(G1) Let μ_{ht} denote the mean relative error of high conscientiousness individuals in the treatment of tidiness.

(G2) Let μ_{lt} denote the mean relative error of low conscientiousness individuals in the treatment of tidiness.

(G3) Let μ_{hm} denote the mean relative error of high conscientiousness individuals in the treatment of mess.

(G4) Let μ_{lm} denote the mean relative error of low conscientiousness individuals in the treatment of mess.

Using this notation, the four hypotheses presented before can be reformulated as follows:

H1: When there is messy work environment, the mean relative error of low conscientiousness individuals μ_{lm} is greater than to the mean relative error of high conscientiousness individuals μ_{hm} , i.e. $\mu_{lm} > \mu_{hm}$.

H2: When there is tidy work environment, the mean relative error of low conscientiousness individuals, μ_{lt} is greater than to the mean relative error of high conscientiousness individuals μ_{ht} , i.e. $\mu_{lt} > \mu_{ht}$.

H3: The mean relative error of high conscientiousness individuals in a messy work environment μ_{hm} is greater than high conscientiousness individuals in a tidy work environment μ_{ht} , i.e. $\mu_{hm} > \mu_{ht}$.

H4: The mean relative error of low conscientiousness individuals in a messy work environment μ_{lm} is greater than low conscientiousness individuals in a tidy work environment μ_{lt} , i.e. $\mu_{lm} > \mu_{lt}$.

Notice that each hypothesis is about the comparison of mean relative errors between two clusters.

Therefore, the H1-H4 hypotheses can be verified by the following three alternative two-sample mean difference tests (T):

(T1) two-sample mean difference test with equal variance;

(T2) two-sample mean difference test with unequal variance and use Satterthwaite's (1946) approximation formula to evaluate the significance of the test statistic; and

(T3) two-sample mean difference test with unequal variance and use Welch's (1947) approximation formula to evaluate the significance of the test statistic.

The T1 test assumes that the variance of relative errors in both clusters is equal. However, T2 and T3 do not make this restrictive assumption and employ alternative approximation formulas in order to evaluate the significance of the corresponding test statistic. As a consequence, the three alternative test results check for the robustness of the two-sample mean difference tests.

Results

The results of the work environment questionnaire confirm that the participants had perceived the environment according to the type of treatment that they were assigned. The 93% of participants in treatment of mess answered that the room was very messy. The 55% of participants in treatment of tidiness answered that the room was very tidy and 29% that the room was slightly tidy.

Table I summarizes some descriptive statistics of the conscientiousness and relative error variables for the pooled sample of individuals and for various subgroups of the full sample. The pooled sample is divided by two binary variables: the type of treatment (tidiness and mess) and the cluster of the level of conscientiousness (high or low). Table 1 informs about the distribution of individuals in the different groups reporting the number of individuals for each group. Moreover, Table 1 presents the mean and standard deviation of conscientiousness and relative error for the pooled sample and its subgroups.

Table I. Descriptive statistics of data

Conscientiousness				Relative error					
		Messy WE	Tidy WE	Total			Messy WE	Tidy WE	Total
Low	Count	21	34	55	Low	Count	21	34	55
consc.	Mean	34.00	39.21	37.22	consc.	Mean	1.43%	1.56%	1.51%
	SD	3.63	6.53	6.12		SD	1.72%	2.62%	2.30%
High	Count	18	7	25	High	Count	18	7	25
consc.	Mean	46.61	59.43	50.20	consc.	Mean	3.92%	0.68%	3.02%
	SD	3.90	5.03	7.18		SD	4.48%	0.63%	4.07%
Total	Count	39	41	80	Total	Count	39	41	80
	Mean	39.82	42.66	41.28		Mean	2.58%	1.41%	1.98%
	SD	7.37	9.91	8.83		SD	3.48%	2.42%	3.02%

Note: The SD denotes standard deviation. The Messy WE and Tidy WE refer to messy work environment and tidy work environment, respectively.

Table II summarizes the results of the two-sample mean comparison tests. These tests evaluate the four hypotheses H1-H4 of this article. First, tests T1, T2 and T3 reject the H1 hypothesis ($\mu_{lm} > \mu_{hm}$) at the 5 percent level of significance. We evidence that the opposite relation is significant at the 5 percent level of significance: $\mu_{lm} < \mu_{hm}$. Thus, high conscientiousness individuals on average make more relative errors than low conscientiousness individuals when both are in a messy work environment. Second, the T2 and T3 tests accept the H2 hypothesis at the 5 percent level of significance, i.e. $\mu_{lt} > \mu_{ht}$. Thus, low conscientiousness individuals on average make more relative errors than high conscientiousness individuals when they are in a tidy work-environment. Third, the T1, T2 and T3 mean comparison tests evidence that $\mu_{hm} > \mu_{ht}$, i.e. when high conscientiousness individuals are considered, the level of relative errors have committed is higher in treatment of mess than in tidiness treatment. Thus, we accept H3. Fourth, all mean comparison tests reject H4 ($\mu_{lm} > \mu_{lt}$), i.e. we find that $\mu_{lm} = \mu_{lt}$. This means that independently of the tidiness or mess of the working place, low conscientiousness individuals perform the same level of relative errors during their work.

Table II. Two-sample mean comparison test results

H1	H ₀ :	$\mu_{lm} = \mu_{hm}$	$\mu_{lm} = \mu_{hm}$	H2	H ₀ :	$\mu_{lt} = \mu_{ht}$	$\mu_{lt} = \mu_{ht}$
	H _a :	$\mu_{lm} < \mu_{hm}$	$\mu_{lm} > \mu_{hm}$		H _a :	$\mu_{lt} < \mu_{ht}$	$\mu_{lt} > \mu_{ht}$
T1		1.2%	98.8%	T1		80.6%	19.4%
T2		1.8%	98.2%	T2		95.4%	4.6%
T3		1.8%	98.2%	T3		95.4%	4.6%
<hr/>							
H3	H ₀ :	$\mu_{hm} = \mu_{ht}$	$\mu_{hm} = \mu_{ht}$	H4	H ₀ :	$\mu_{tm} = \mu_{lt}$	$\mu_{tm} = \mu_{lt}$
	H _a :	$\mu_{hm} < \mu_{ht}$	$\mu_{hm} > \mu_{ht}$		H _a :	$\mu_{tm} < \mu_{lt}$	$\mu_{tm} > \mu_{lt}$
T1		96.4%	3.6%	T1		42.1%	57.9%
T2		99.6%	0.4%	T2		41.3%	58.7%
T3		99.6%	0.4%	T3		41.3%	58.7%

Note: The table presents the p-values associated to the mean comparison T1, T2 and T3 test statistics. The T1 test assumes that the variance of the variable is equal in the two samples. The T2 and T3 tests assume that the variance of the variable is not equal in the two samples and apply the Satterthwaite (1946) and Welch (1947) approximation formula, respectively, to evaluate the significance of the test statistic. The *l*, *h*, *t* and *m* sub indices of the expected values μ denote low conscientiousness, high conscientiousness, treatment in tidy work-environment and treatment in messy work-environment, respectively. Figures in bold script indicate the acceptance of the alternative hypothesis at 5 percent level of significance.

Figure 2 presents these findings on the relations of relative errors among different groups of the sample studied.

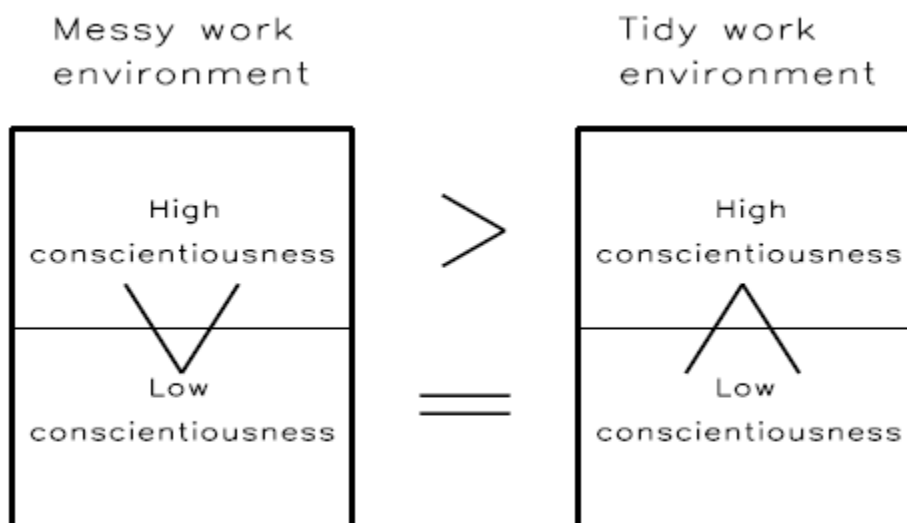

Figure 2. Implications of the two-sample mean comparison test results on group mean relations

Note: Figure shows the results about in which situation the participants make more (>), less (<) or equal (=) mistakes.

In Figure 3, we can see the negative influence that has messy environment in reliability of people with high conscientiousness. Figure shows that the level of relative error is highest in the case of individuals with high conscientiousness that are in a messy environment, i.e. they make even more mistakes than those individuals with low conscientiousness in messy and tidy environments.

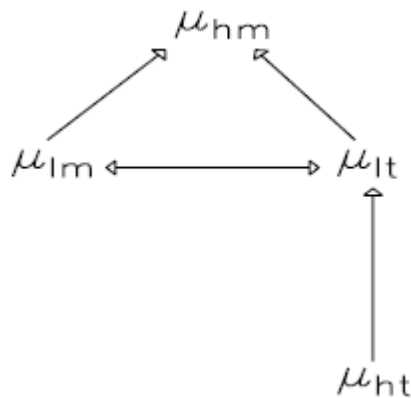

Figure 3. Relative error mean in relation with the other groups

Note: The arrows show decreasing level of relative error. The double arrow shows equal level of relative errors.

Discussion

There are many studies that suggest that people with high conscientiousness tend to have a better performance in his/her work and therefore a better reliability. Nevertheless, the results of this study suggest that a physically messy environment can influence in the reliability degree, doing that the people with high conscientiousness tend to commit more mistakes in the task that they work. Thus, the reliability of these individuals is lower when they are compared with individuals with high conscientiousness in a tidy work environment, as well when they are compared with individuals with low conscientiousness in a messy and tidy work environment, as specified in Figure 3. One way to explain this negative influence could be because conscientious people like the appearance of orderliness and tidiness, i.e. they have

tendency to keep their environment tidy and well organized and being in a messy environment perhaps makes them feel uncomfortable, annoying or to be not concentrated on their work.

On the other hand, when people with high conscientiousness are in a tidy environment then there are fulfilled the predictions of that they are more reliable than people with low conscientiousness. This result indicates that tidiness could promote that those individuals with high conscientiousness feel comfortable to work concentrated on their task and behave with the level of reliability that characterizes their personality trait.

Mess can stop motivation of people with high conscientiousness and prevent them from doing their best. They will not do their work as well as they can, because they are intolerant with mess and therefore a messy environment keeps them from focusing on their work by constantly demanding their attention. Their lack of concentration in this kind of environment could influence their reliability, inducing them to work in a defective way or to make mistakes. This mean a greater expense in the production since it would imply a greater waste in the consumed resources. This fact has even more relevancy for work environments where are bring into play the life of other people, such as operating rooms, pharmaceutical laboratories, air traffic control towers, nuclear power plants, etc. It is important that the physical working environment in these places be tidy, for thus avoid errors that could be fatal.

People with low conscientiousness perform the same level of mistakes in a messy work environment than in a tidy work environment. This result may mean that mess do not influence in their level of concentration on their work, probably because low scores on the conscientiousness scale correlate with people who are unorganized and therefore they are more accustomed to living in an environment like that.

From a practical point of view, when the work environment is tidy, the results provide empirical evidence that conscientiousness trait should be congruent with the performance criterion that it is seeking to predict. Nevertheless, this criterion changes when the environment is mess. On the basis of this result, performance prediction can be improved by accounting the level of tidiness in environment as a potential moderator of relationships between personality and job reliability.

People are fallible, even the best make mistakes. It is human nature to err. Because of their fallibility or innate characteristic of imprecision, human beings are vulnerable to many external conditions that cause them be unreliable. Vulnerability to such conditions

makes people susceptible to error. “Countermeasures are based on the assumption that although we cannot change the human condition, we can change the conditions under which humans work” (Reason, 2000). The messy work-environment possesses the characteristics to be called as *latent error*, in the sense that this mess is a “deviation that does not produce direct and immediate adverse consequences” but it is a “condition that deviates from expectations, and may cause adverse consequences of organizational significance” (Ramanujam and Goodman, 2003). Thus, a distinguishing feature of high-reliability organizations should be their collective preoccupation to improve the conditions of tidiness under which employees work.

Finally, this work has several limitations. First of all, the sample is small with eighty participants. Second, the task was restricted to introduce data in a computer. There are several kinds of tasks where the response of workers to the tidy work environment could be different. It is necessary develop new experiments with other tasks. Another limitation is that only there were seven participants with high conscientiousness in the treatment of tidy environment. Nevertheless, this is the first attempt to quantify the importance of tidy work environment in terms of moderator of relationships between personality and job reliability, and may contributes to reduce wastage and accidents in many types of business.

Conclusions

The most important contribution of this research is the novelty of having studied the relation that exists among these three subjects: work environment based on the tidiness, conscientiousness trait and reliability of employee. The results offer some insight into the process through which a work environment based in tidiness affects reliability of people with high conscientiousness. The finding of differential results for tidy and messy environment suggests not only that people with high conscientiousness commit more mistakes in a messy environment than in a tidy environment but also that they commit more mistakes than people with low conscientiousness when both are in a messy environment.

The main conclusion of this experiment is that there is empirical evidence to support the suggestion that a tidy work environment can influence the reduction of mistakes and improve reliability in workers with high conscientiousness. More generally, our research suggests that it is important that managers ensure that the environment in where employees are working should be usually tidy, instilling in them values and

methods that promote tidiness, achieving by this way a better reliability in the employees.

Introduction

Innovation is the main component in the current economy in private sector as well as in public sector. In the Lisbon strategy, the innovation stimulation is clearly highlighted to be able to tackle globalization and demographic change. In this sense, several reforms have been undertaken in which the innovation is the key lever aiming at improving the quality of public service and at offering new services to citizens.

The objective of our study is to identify the key factors, which lead to the innovation in the public administration through the common assessment framework (CAF) model. Also, an identification of the limits of the model and the lack factors is made. The CAF model is an innovative tool that has known 2 000 applications in Europe (Staes & Thijs, 2010). This tool is based on the excellence principles coming from the European Foundation for Quality Management, which is the principle of continuous improvement and innovation. Since the new version in 2006, this concept was emphasized within the leadership, the strategy and planning and the processes.

The public research centre Henri Tudor has been involved since 2006 in the continuous improvement program whose main objective is to promote, sustain and develop the continuous improvement in public administrations and the innovation in public sector in order to reach a better performance and a service quality concerning citizen's needs. In

this perspective, the article aims at modeling the innovation process based on two main innovative services in a public administration through the CAF.

Next to the literature review of the innovation and the CAF, we present our global approach through the main steps to develop the new innovative services. In the third part, we focus on the specific case study through the innovation process and we draw up this process based on the CAF model. At the end, we discuss on the limits of this study.

The literature review

Innovation is the core activity in the numerous private companies whereas in the public sector, the organizations are less pushed to innovate. Nevertheless, these last few years, this has become an issue. In this sense, we explore the innovation concept before introducing the CAF model that promotes the innovation in public organizations.

The innovation process

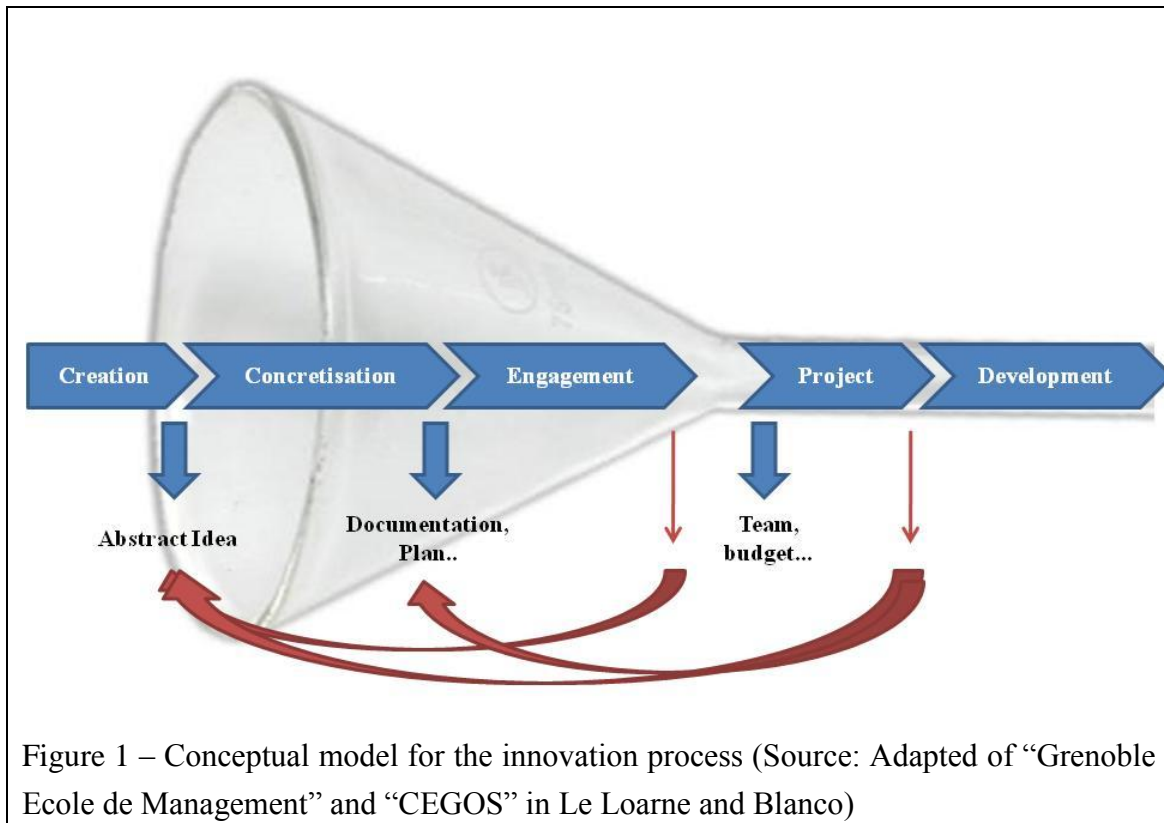

Oslo manual defines innovation as “the implementation of a new and significant improved product (good or service) or process, a new marketing method or a new organizational method in business practices, workplace organization or external relations” (OCDE, 2005, p 46-47). In this definition, four types of innovation are highlighted: product innovation, process innovation, marketing innovation and organizational innovation. The product innovation involves a good or service that is new or significantly improved; the process innovation involves a new or significantly improved production or delivery method; the marketing innovation involves a new marketing method involving significant changes in product design or packaging, product placement, product promotion or pricing; organizational innovation involves introducing a new organizational method in the firm’s business practices, workplace organization or external relations. The innovation must allow to increase the competitiveness and overall profitability. In the framework of our study, we focus on the service innovation in the public organization. Thus, service innovation can be defined as “a new or considerably changed service concept, client interaction channel, service delivery system or technological concept that individually, but most likely in combination, leads to one or more (re)new(ed) service functions that are new to the firm and do change the service/good offered on the market and do require structurally new technological, human or organizational capabilities of the service organization” (Van Ark et al., 2003). According to (Moore and al. 1997, Hartley 2005), “those changes worth recognizing as innovation should be globally (or at least locally) new to the

organization; be large enough, general enough and durable enough to appreciably affect the operations or character of the organization; or be consciously designed or adapted as a response to a perceived problem by some level of the organization”. This definition underlines the fact that the innovation is considered as a success. In the public sector, the innovation allows to improve the performance of the organization; and in this sense, it will increase the quality of services offered to citizens. Innovation may include reinvention or adaptation to another context, location or time period. In the public sector, the diffusion of innovations to other organizations, localities and jurisdictions is particularly important (Rasham and Hartley 2002, Hartley 2005). This is an important difference between public and private sector innovation. Innovation in the private sector is driven by competitive advantage – this tends to restrict the sharing of good practice to strategic partners. By contrast, the drivers in the public sector are to achieve widespread improvements in governance and service performance, including efficiencies, in order to increase public value (Moore, 1995, Hartley, 2005).

Many studies have been conducted on the important elements required to achieve the successful application of a new idea, but in general all relate to three basic steps to be considered (Cumming, 1998, Kenny, B. and Reedy, E.):

- 1) Idea generation (creativity);
- 2) The successful development of that idea into a useable concept;
- 3) The successful application of that concept.

These different steps are highlighted in the innovation process. Indeed, the innovation process is “the development and implementation of new ideas by people who over time engage in transactions with others within an institutional context” (Van de Ven, 1986). The innovation process consists in two main phases: the exploration phase, during which the actors of the organization seek ideas for innovation and the exploitation phase that consists in the development of selected ideas into practical innovations, products, processes or innovative services (Le Loarne and Blanco, 2009). At the beginning, the innovation process includes a key step to generate creative idea based on the specific techniques (Brooke, 2010; De Brabandere, 2005). Creativity is the personal ability to recognize unusual patterns, relations and produce new ideas or things. It is a pre-requisite for innovation (Tang, 1998). To represent the innovation process, numerous models exist; these models represent the different stage that organizations follow in order to promote the innovation from the ideas creation to the innovation implementation. Figure 1 represents an innovation process model in funnel.

To conduct the organizations in the change perspective, the innovation culture seems to be an important factor. An innovation-based organizational culture must possess the following values: client-orientation, commitment towards objectives, challenge and initiative, exemplary behavior, team work and permanent improvement (Canalejo, 1995 in Kenny, B. and Reedy, E.).

In the public sector, many administrations use the CAF model (Staes & Thijs, 2010), a tool that allows to conduct the organizations towards the change and to introduce new innovative services. Thus, the next part presents the model and explains these principles, that allow to consider the CAF as a tool for the innovation.

The “Common Assessment Framework”

To promote the innovation in the public sector, the CAF is a very innovative process tool that encourages administrations to launch it in the continuous improvement process. This tool was defined by the Innovative Public Services Group of the European Public Administration Network in 2000. The CAF is a total quality management tool inspired by the excellence model of the European Foundation for Quality Management and the model of German University of Administrative Science in Speyer. The idea of the CAF model is that excellent results in organizational performance, citizens/customers, people and society can be achieved through leadership driving

strategy and planning, people, partnerships, resources and processes (European Institute of Public Administration, 2006). Figure 2 represents the model through the nine key criteria.

A distinction should be made between the cause-effect relationship between the left part of the model (the enablers-causes) and the right part (the results-effects). This study, which analyses the enablers of the innovation, is focused on the left part.

The two main innovative services, which are identified in the case of the studied administration, are results. The criteria of the results are both the key performance results and citizen/customer oriented results). The issue is to understand the main enablers, which drive to these results innovative services.

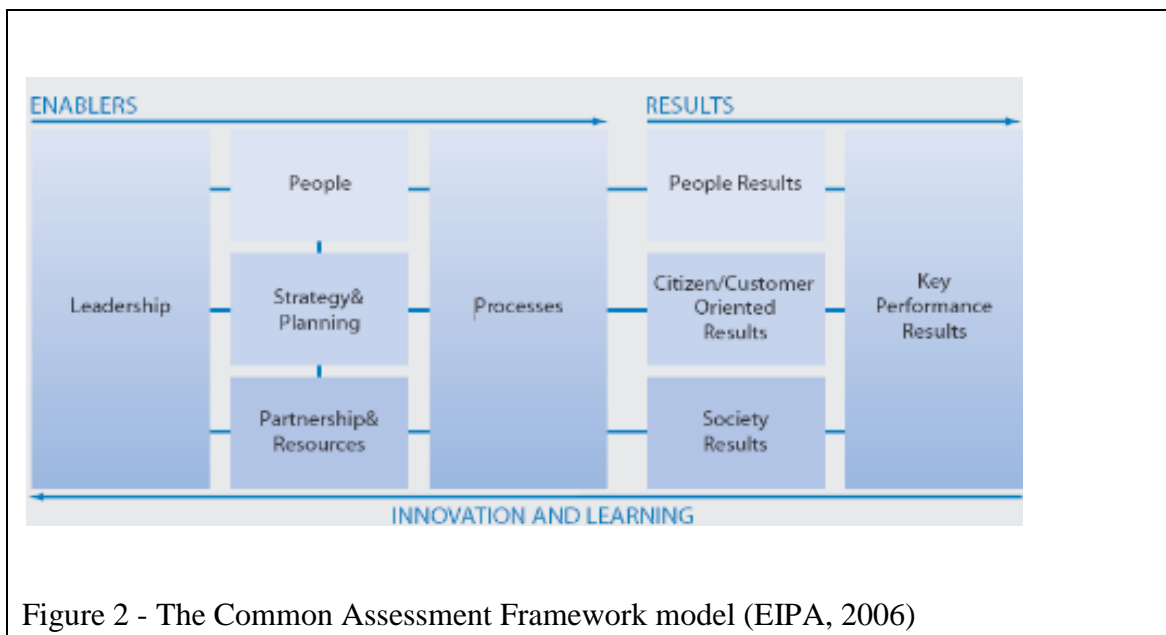

Figure 2 - The Common Assessment Framework model (EIPA, 2006)

As a tool of Total Quality Management, the CAF's criteria make reference to the fundamental principles of excellence as defined by the European Foundation for Quality Management: results orientation, customer focus, leadership and constancy of purpose, management by processes and facts, involvement of people, continuous improvement and innovation, mutually beneficial partnerships and corporate social responsibility. The CAF aims at improving the performance of public organizations on the basis of these principles (EIPA, 2006).

In the light of these criteria, the administration must assess its strengths and weaknesses. This assessment conducts the organization to identify these improvement efforts.

The Caf model is used in a global process of continuous improvement, which is designed and carried out in a number of ways, ten steps to improve organisations with CAF (CAF 2006) :

Phase 1 – The start of the CAF journey

- Step 1 Decide how to organise and plan the self-assessment (SA)
- Step 2 Communicate the self-assessment project

Phase 2 – Self-Assessment Process

- Step 3 Compose one or more self-assessment groups
- Step 4 Organize training
- Step 5 Undertake the self-assessment
- Step 6 Draw up a report describing the results of self-assessment

Phase 3 – Improvement plan/prioritisation

- Step 7 Draft an improvement plan, based on the accepted self-assessment report
- Step 8 Communicate the improvement plan
- Step 9 Implement the improvement Plan
- Step 10 Plan next self-assessment

At this time, the CAF was implemented at the European level in numerous public administrations. Indeed, we currently count more than 2 000 users in Europe and beyond Europe's borders (Staes & Thijs, 2010). In the transfer perspective, different events were organized with the objective of presenting good practices where the use of the CAF has led to improved results (Staes & Thijs, 2010).

Next to the presentation of the CAF model, we present the conducted approach in the framework of our study and we focus on the two main innovative actions that were implemented in the specific administration.

Research Framework

In this paper, we chose to present the case study led in the specific public administration. The case study enables us to justify our findings with concrete data. Indeed, Yin (1994) stipulates that single cases may be used to confirm or challenge a theory, or to represent a unique or extreme case. In this sense, several steps have been conducted in the framework of our work.

During the continuous improvement program, our team of researchers has followed the administration in order to identify the main steps of the process. Between 2007 and 2011, several workshops have been regularly organized with the centre's team and the staff of the administration (project manager, top management). The key data concerning the launch and the progress of the approach have been registered in reports, which include the action, the participants, the date, the delay, the decision, the obstacles and the material resources.

Our team participated in the important events of this process (first meeting with the ministry, training, launch of the self-assessment, report to the management, information session, action plan definition, action plan presentation, follow-up of the plan).

Globally, the team of researchers is composed of 3 persons that have participated in 14 working groups between 2007 and 2011.

After 5 years, an interview was conducted with the administration director in order to discuss the main innovative services of the action plan. This semi-directive interview was based on a questionnaire of 15 questions, which was decomposed in 6 steps:

- Context,
- Motivation, objectives :
 - o what were the triggers of the improvement approach ?
 - o What were your expectations at the beginning?
- Difficulties, obstacles, development:
 - o How was the team of the project chosen?
 - o What was your reaction during the self-assessment?
 - o What was the degree of general satisfaction during the process?
- Main actions
 - o What were the main actions of the actions plan?
- Implemented actions or not,
 - o What is the progress of the implementation of the actions plan?
- Impact of the actions.
 - o What are the results of the actions ?

- Is there a change of the image of the administration?

The interview, which was recorded, was the subject of a transcript for data analysis. In the framework of this interview, the global process was discussed as well as the key performance results get next to the implementation of the two main innovative services.

On the base of this interview and the previous workshops, we selected two main innovations of services (see below) following the features of an innovative services described in the literature.

In this global process, we identified the most important steps of the improvement approach (26 in total), which led to these new services. These steps were classified in the CAF model following the enablers (five first criteria) and its examples (table 1).

In this study, we decided to focus on the actions, which lead to innovation service, that is why the results criteria of the model aren't directly included in the classification.

Nevertheless, we can underline that the two innovative services have had an impact on the different criteria "results" of the model CAF. These main impacts have been significant on the citizen/customer oriented results and on the key performance results.

The CAF experts and the research team validated this classification.

For the classification, we defined some rules:

- The step must be only classified in one sub criteria;
- If certain steps could be classified in different sub criteria, we chose the sub criteria in function of the main representative example;
- In the CAF model we have two kinds of criteria, factors and results. To classify our steps, only the five factors were used. The idea is to see which factors conduct to the innovation of services.
- The examples are only mentioned to justify our classification, other examples could be defined.

Case study

Case study description

The case study concerns the Factory Inspectorate administration in Luxembourg. This public administration has a mission of systematical inspection of the well-being of

workers, on the one hand, the relationship and working conditions, and on the other hand, the health and safety of workers at work.

For example, the Labour Inspectorate and Mines is responsible in particular for:

- Ensuring the implementation of legal, regulatory, administrative and agreements relating to working conditions and protection of employees;
- Providing information and advice to employers and workers;
- Bringing defects or abuses to the attention of the Government;
- Ensuring the implementation of mining legislation;
- Intervening in setting permit conditions for establishments classified as dangerous;
- And ensuring the implementation of legislation on the protection of workers against ionizing radiation and monitoring of facilities.

Before the involvement in the continuous improvement program (see below), there were 2 important external assessments in 2002 and 2003. The first one was a peer review or a benchmarking of the Factory Inspectorate in comparison with other Factory Inspectorate in Europe, the second one was an external audit realized with the International Labor Office.

In 2007, the administration started with the continuous improvement program, which was the first internal approach (bottom up) contrarily to this previous approach.

In the context of the administrative reform, the Ministry of Civil Service and Administrative Reform in Luxembourg launched in 2006 a continuous improvement program (Figure 3) using the self-assessment tool for the public administration.

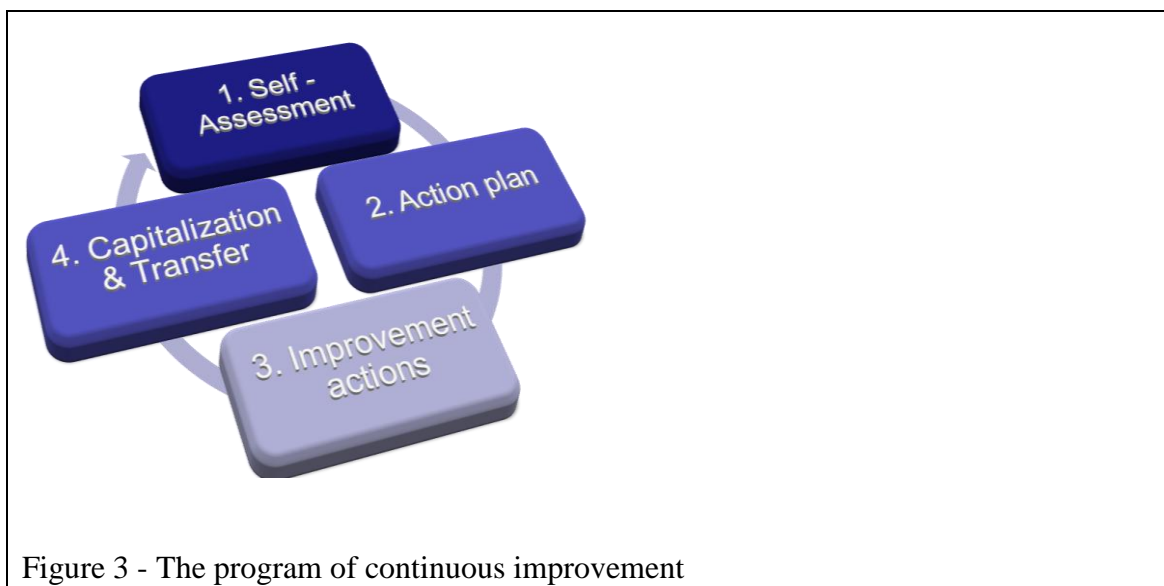

Figure 3 - The program of continuous improvement

The program is implemented by the Ministry in collaboration with the Public Research Centre Henri Tudor. In the first step, a self-assessment is realized in conformity with the excellence model. In the second step, an action plan is defined by the management team in order to improve the organization. The third step is the implementation of the action plan followed by the last step (capitalization and transfer). Until 2011, more the 25 administrations were involved in this process the Factory Inspectorate was one among them.

Innovations studied

During the continuous improvement program, an action plan was defined, 80% of the plan was implemented after 2 years. The global approach produced several results as the creation of a duty holder, a training plan for the staff, a frequently asked question on the website, the definition of key performance indicator, a new organization chart and prevention campaign on TV spot and the helpline service.

This study was focused on the two main innovations in order to analyze the different steps of this global improvement approach. These main innovations, which are the prevention campaign on TV spots and the helpline service, was chosen on the basis of the definition of product innovation in literature. This two services are new in this administration and in general in the public service in Luxembourg, they include the use of new information and communication technology and they have a direct impact on the mission of the factory inspectorate.

Since 2009, the helpline has been implemented with a direct line and with email. The objective is to provide an answer to all the questions related to safety and health at work. With the helpline, the factory inspectorate has had a reduction of 50% of the number of questions in the other services, and they were able to treat the pending requests.

The TV campaign on spots was launched with scenes of 6-8 minutes on several topics (safety, fire, health, law) and TV shows of 20 minutes. This information was in line with the frequently ask questions in order to disseminate information widely. The TV spot are at disposal in podcast on the website on the factory inspectorate.

Process description

The aim of this study is to understand the innovation process, which drives to the innovation services. Based on the continuous improvement program planning and the project follow-up, we introduced the different steps of this process. In a following part, these steps are identified in the criteria and sub criteria of the CAF model.

Steps of this process:

1. In 2003 and 2004, two external assessments with benchmarking and involvement of the stakeholders.
2. Presentation of the continuous improvement program by the Ministry of the administrative reform (Information meeting).
3. Risk identification in the administration environment (re-organization by an external committee).
4. Identification of the continuous improvement program as an opportunity to fight against this risk.
5. Strategic thinking and decision to involve the administration in the continuous improvement program.
6. Team selection (project manager, members).
7. Quality training of the top management.
8. Internal communication at the beginning of the approach (general meeting and email).
9. Call for participation of the employees.
10. Training of the staff and quality awareness.
11. Self-assessments following a quality excellence model with a representative team.
12. Report of the self-assessment presentation of the top management.
13. Constitution of the working group to define the action plan.
- Structured method to define the solutions with external support :
 14. Analysis and selection of the main improvement area, (during workshop).
 15. Collective sense making of the problem and solution.
 16. Innovative solutions finding (during workshop).
 17. Definition of an action plan with the management.
18. General communication with the staff and the ministry (action plan introduction).
19. Following of the implementation of the plan by the duty holders.
- Implementation of the action concerning the helpline and TV campaign :
 20. Helpline procedure definition.
 21. Helpline team selection (job description definition, internal recruitment).
 22. Budget definition for the helpline and the TV campaign.
 23. Infrastructures (room) and materials (Phone, computer) selection.

- 24. Discussion with the TV partner, definition of the final concept.
- 25. Monitoring of the impact of the helpline and TV spot.
- 26. Adjustment of the actions.

Thus, 26 steps were identified in the innovation process to conduct to the two main innovative services in this administration. After this identification, we propose to classify these steps in the different factors and their sub criteria of the CAF model.

Establishment of this process in the CAF model:

In the first part, we classify the 26 steps of the process in the factors and sub criteria of the CAF model. To facilitate and to justify the classification, we indicate the examples of the sub criteria, which are the most representative to the step. Two elements are subject to the discussion. In the CAF model, two steps did not refer to the sub criteria. In the table I, each step is numbered following the chronological order of the process.

Table I: Classification of the innovation process steps in the sub criteria of the CAF model

CAF criteria – sub criteria (enablers)	Steps of the approach of innovation products
1. Leadership	
1.2. Developing and implementing a system for the management of organization, performance and change.	
l. Communicating change initiatives and the reasons for change to employees and relevant stakeholders.	8. Internal communication at the beginning of the approach (general meeting and email). 18. General communication with the staff and the ministry (action plan introduction).
k. Identifying and setting priorities for necessary changes regarding the organisational design and business model.	14. Analysis and selection of the main improvement area, (during workshop).
2. Strategy and planning	
2.1 Gathering information relating to the present and future needs of stakeholders	
b. Systematically gathering and analysing information about stakeholders, their needs and expectations.	12. Report of the self-assessment presentation of the top management.
d. Systematically analysing internal strengths and weaknesses.	1. In 2003 and 2004, two external assessments with benchmarking and involvement of the stakeholders. 11. Self-assessments following a quality

	excellence model.
c. Regularly gathering and analysing information, its source, accuracy and quality. This may include information about important variables such as social, ecological, economic, legal and demographic developments.	2. Presentation of the continuous improvement program by the Ministry of the administrative reform (Information meeting).
2.2. Developing, reviewing and updating strategy and planning taking into account the needs of stakeholders and available resources	
a. Developing and applying methods to monitor, measure and/or evaluate the performance of the organisation at all levels ensuring the monitoring of the strategy's implementation.	25. Monitoring of the impact of the helpline and TV spot.
b. Systematically reviewing risks and opportunities (e.g. SWOT-analysis) and identifying critical success factors by regularly assessing these factors in the organisation's environment (including political changes).	3. Risk identification in the environment of the administration (re-organization by external committee). 4. Identification of the continuous improvement program as an opportunity to fight against this risk.
2.3. Implementing strategy and planning in the whole organization	
c. Translating strategic and operational objectives of the organisation into relevant plans and tasks for departmental units and individuals within the organisation.	17. Definition of an action plan with the management.
e. Assessing the need to reorganise and improve strategies and methods of planning.	26. Adjustment of the actions.
2.4. Planning, implementing and reviewing modernization and innovation	
c. Planning of changes leading towards the process of modernisation and innovation (e.g. applying net services) on the basis of discussions with stakeholders.	5. Strategic thinking and decision to involve the administration in the continuous improvement program. 19. Following of the implementation of the plan by the duty holders.
3. People	
3.1 Planning, managing and improving human resources transparently with regard to strategy and planning	
a. Regularly analysing current and future human resource needs, taking into account the needs and expectations of stakeholders.	6. Team selection (project manager, members).

3.2. Identifying, developing and using competencies of employees, aligning individual and organizational goals	
h. Planning of training activities and developing communication techniques in the areas of risk and conflict of interest management.	7. Quality training of the top management. 10. Training of the staff and quality awareness.
3.3. Involving employees by developing open dialogue and empowerment	
b. Proactively creating an environment for gaining ideas and suggestions from employees and developing appropriate mechanisms (e.g. suggestion schemes, work groups, brainstorming).	9. Call for participation of the employees.
c. Involving employees and their representatives in the development of plans, strategies, goals, the design of processes and in the identification and implementation of improvement activities.	13. Constitution of the working group to define the action plan.
4. Partnerships and resources	
5. Processes	
5.1. Identifying, designing, managing and improving processes on an on going basis	
a. Identifying, describing and documenting key processes on an on going basis.	20. Helpline procedure definition.
b. Allocating resources to processes based on the relative importance of their contribution to the strategic aims of the organization.	21. Helpline team selection (job description definition, internal recruitment). 22. Budget definition for the helpline and the TV campaign. 23. Infrastructures (room) and materials (Phone, computer) selection.
5.3. Innovating processes involving citizens/customers	
b. Involving stakeholders in process innovations e.g. by piloting new services and e-government solutions.	24. Discussion with the TV partner, definition of the final concept.

In the CAF model, two steps are not covered namely:

- 15. Collective sense making of the problems and solutions;
- 16. Innovative solutions finding (during workshop).

These elements will be explained and analyzed in the next part of this communication.

A model through the five factors of CAF model is proposed in the figure 4 in which the 26 steps of the innovation process are identified in a logical chain.

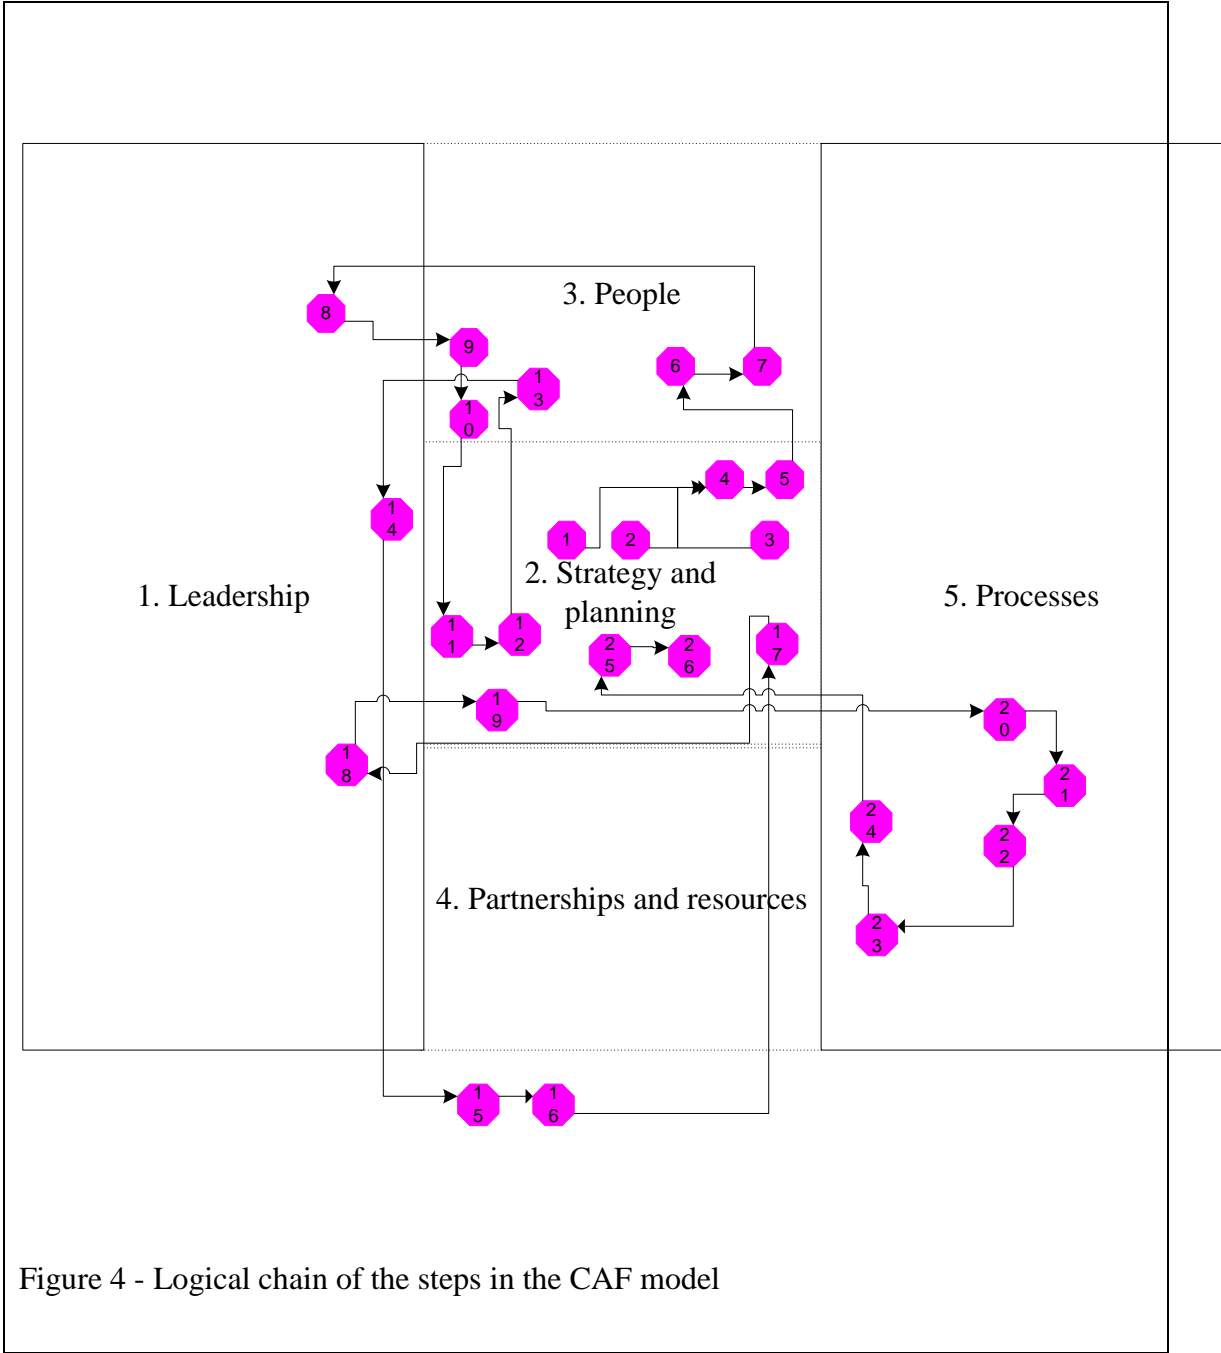

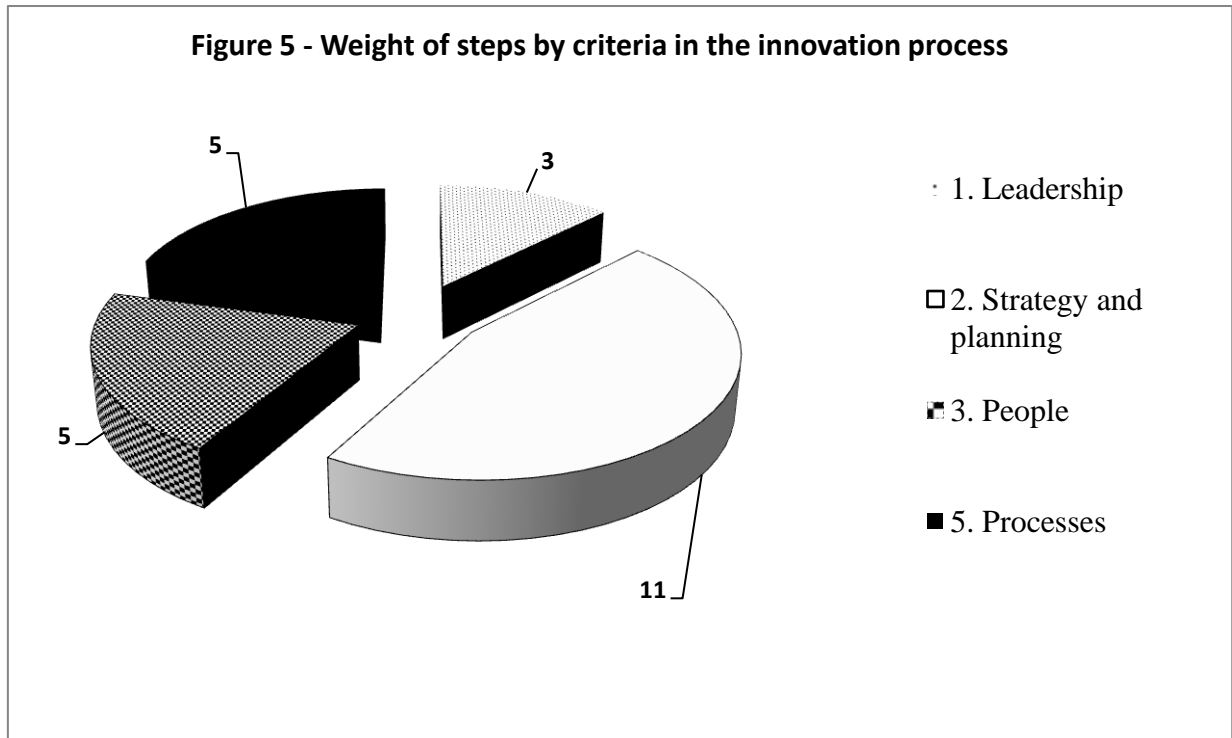

Figure 4 - Logical chain of the steps in the CAF model

Among the 26 steps of the innovation process (Figure 4), which drive to the product innovations, 11 steps come from the second criteria of the CAF model, the strategy and planning. The other steps are shared between the criteria 1, “leadership” (3 steps), the criteria “people” (5 steps) and the criteria 5, “processes” (5 steps).

Discussion

Two main objectives were aimed at in the framework of our study:

- the identification of the key criteria in the model CAF which leads to innovation;
- And the identification of missing elements, which are key for innovation.

Four main criteria have been identified in the model CAF that constitute elements to lead to innovation.

The criterion, “strategy and planning” gathers the majority of steps of the innovation process. In this criterion, the triggers of the process have been identified, the two external assessments in 2002 and 2003. These approaches have created the need to change with the identification of problems and the areas of improvements. More recently, the proposition of a re-organization by an external committee has been perceived like a “treat” by the top management. In this context, the continuous improvement program was perceived like an opportunity to start the internal change, which could limit the risk of external re-organization. A good perception of the

environment is a key element in this situation, both for the risk identification as well as the opportunity detection. All these triggers are in link with the criteria 2, strategy and planning.

This triggers drive to the strategic decision to involve the administration in the continuous improvement program with an objective of modernization and innovation. Thus, the administration defines an action plan, following by the monitoring of the actions progress and the adjustment of actions.

The second main criterion is people, which contains five steps of the innovation process. It demonstrates the crucial importance of involving the employees in a spirit of collaboration. A participative approach seems to be a key factor of success for innovation. In this way, the approach was opened to all the employees through a global communication.

The employees and the management must be trained and must be aware of the quality and continuous process.

The second main criterion at the same level of the “people” criterion (same number of steps) is “processes”. The different steps of this criteria aim at designing the concrete solution and at managing them. The technical material, the infrastructure, the financial and human resources are defined in line with the new processes.

The last main criterion is “leadership”. The top management supports the project with a strong communication during a global information session in the beginning of the approach and after the action plan definition in order to introduce the plan to all the administration and the stakeholders (ministry).

We could see that the criteria “partnerships and resources” is not covered in the innovation process. If another classification and rules is to be defined, some steps could be classified in this criterion and could change this fact. Nevertheless, in this case, the factor “partnerships and resources” is not a key element to the conduction of the innovation.

Two main steps of our innovation process could not be clearly classified in the CAF model:

- “Collective sense making of the problems and solutions”;
- And “innovative solutions finding (during workshops)”.

The “collective sense making of the problems and solutions” is one of missing elements in the CAF model. Weick (1969) refers to sense making as making sense of uncertainties in environments through interaction. He applies this theory to demonstrate how the members of the organizations make choices (or are forced to make choices) when uncertainties arise. Weick (1995) argues that sense making examines the critical issues of organizational behavior and also the meanings that are constructed with/within organizations. Numerous employees intervene in the innovation process that conducts to the interaction between them in order to go in the same direction. In this perspective, the “collective sense making of the problems and solutions” seems crucial to reach the innovation.

Although this element wasn't clearly mentioned in the CAF model, we agree that this element could be classified in a large vision “people” criteria (sub criteria 3.3 for example), but we remark that this element is not clearly included in the model (absence in the sub criteria and in example). This approach of “sense-making” was underlined like a key element by the top management during the interview; it launched a collective action of innovation.

The concept of “ideation” is the step of creativity step “Innovative solutions finding (during workshop)”. In the same way, this element could be classified with a large vision in “strategy and planning” criteria (sub criteria 2.4 for example). For the same reason, the step is not clearly present in the model. The research of innovative solutions is a main step to imagine the new solutions and the future, which drive to implementing innovative solutions. The step of “ideation” is frequently mentioned in the processes of innovation in the literature (Le Loarne and Blanco, 2009; Brooke, 2010; De Brabandere, 2005).

As illustrated in Figure 4, these steps are in a logical chain with frequent “round trip” through the criteria. Nevertheless, there is not a clear sequence between the different criteria or sub criteria. The process begins in the criterion “strategy and planning”, continues in the people “criterion”, goes to the “leadership” criterion, returns into the people criterion, with a loop to the strategy and planning.

If we compare our innovation process to the theoretical innovation process (figure 2), the 26 steps follow the same logical process from the idea creation to the development and implementation of product/service.

Previously we introduced the ten steps of improvement in a public administration described in the guideline for improving organisations in addition to the CAF model. In this guideline, a clear sequence of steps is recommended with the start of CAF, the communication of the project, the self-assessment group composition, the training organisation, the improvement plan design, the implementation of the plan. The guideline contains in itself the main steps of the innovation process.

As a consequence, the innovative services are the result of the combination of the CAF model and of the guideline for improving organisations, which creates the precious sequence of events.

Conclusion

In this paper, the idea was to demonstrate that the CAF model is a tool that supports the administration to innovate. Thus, we identify the main factors and the missing factors of the CAF that enter in the innovation process.

It was interesting in the first time to explain the generic innovation process and the CAF model criteria before identifying the main steps of our innovation process that have been deployed in the specific public administration. The next step of our study consisted in the identification of the main steps of the innovation process defined to conduct the administration to innovate.

Indeed, the innovation is a complicated process of applying new ideas for gainful purpose (Tang H.K., 1998). Thus, rapid innovation requires an effective innovation process. "The process of innovation is a rhythm of search and selection, exploration and synthesis, cycles of divergent thinking followed by convergence" (Leonard D. and Sensiper S., 1998).

After presenting the main steps of our innovation process, we identified the criteria and sub criteria of CAF model that intervene in order to develop new innovative services. These different steps have been modeled in the CAF through the different criteria. In the framework of our case study, two new innovative services that have been developed and implemented in the public administration, allowed to build this study. Four main enablers of the CAF model have been identified in the innovation process :

Strategy and planning: It contains the triggers of the approach with the environment perception (risk and opportunity) and with the strategic decision to start in a improvement program.

People: The involvement of the personal is a key element to create an “open innovation”.

Processes: The different operational steps aim at designing the concrete solution and at managing them

Leadership: The top management supports the approach with a global communication and implication.

Nevertheless, two key steps, which drive to innovation, aren't clearly mentioned in the CAF model: the collective sense making of the problems and solutions, and the creative solutions finding (Ideation).

In the innovation perspective, the administration must, beyond the identification of criteria, define an innovation process. The innovation process is not a random chain; it follows a logical process with the triggers steps namely the decision of involvement, the planning, the design, the follow-up and the adjustment of the actions. In this sense, the organization must manage an innovation process with a coordination of each key criterion. The organization must not focus its efforts on the criteria only; the criteria are only a support in the building of this logical innovation process. A clear sequence is introduced in the guideline for improving organisations in addition of the CAF model in ten steps.

In consequence the innovation is both the results of key points (environment perception, risk and opportunity, strategic decision, staff involvement, leadership implication, collective sense-making creation and creative solutions finding) and the combination of the element in a logical chain. If the model CAF contains the key elements for innovation, with the exception of the collective sense making and the creative solution finding, a logical combination of all these elements in a precise sequence have to be introduced in the guideline for improving organisations.

Limits of this study:

Although the study through the CAF model allowed the identification of the main factors in our innovation process, some obstacles have been encountered such as the classification of the different steps of the innovation process in the CAF model.

In this study, we decided to focus on the actions, which lead to innovation service that is why the results criteria of the model are not included in the classification.

Nevertheless, we can underline that the two innovative services have had an impact on the different criteria “results” of the model CAF. These main impacts have been significant on the citizen/customer oriented results and on the key performance results. Another study could focus on the results that the innovation process through the CAF model produces.

Introduction

Engineering degree courses do not seem to be as attractive as required, neither for men nor for women. The number of engineering students is too small, and the number of female engineering students is obviously underrepresented. In 2003, about 28 percent of the engineering students in Germany were female /destatis 2003/. To underline the necessity of a higher number of engineers the following quotation is given: ‘The lack of engineers threatens our competitive advantage and thereby in the end our prosperity’ Louis Gallois told in an interview /Welt am Sonntag, 19.4.2011/. To intensify this statement the ICB (Institute for Work Market and Education Research, Nürnberg, Germany) expects a ‘substantial lack of engineers if no countermeasures were taken’.

The Institute of the German Economy assumes that in 2020 230,000 engineers will be missing / Welt am Sonntag, 19.4.2011/.

The lack of engineering students leads to two problems: to increase the number of engineering students, especially female engineering students, and to enable these students to create innovation and sustainability.

Supporting and hindering factors concerning female engineering students have been investigated in several studies, especially by the European projects INDECS (2001) and WomEng (2005). The main result is that interdisciplinarity attracts more women. Due to this observation, some of the engineering degree courses involve more non technical subjects into their curricula than traditionally usual.

Mechanical Engineering and Security and Safety Engineering are two degree courses at the Faculty of Engineering at the University of Wuppertal. Both courses show a rather small percentage of female students: Mechanical Engineering about 14% and Security and Safety Engineering about 13%. Within the engineering curricula the students take different modules and in between both degree courses a 'management module' is offered. This management module includes subjects like project management, management methodologies as well as creative methodologies. The module is not structured in the same way for the two engineering degree courses but similar. And both modules combine non technical lectures.

Due to the two hypotheses that interdisciplinary modules attract more (female) students on the one hand and on the other hand that serious games are a holistic methodology to train management and decision making skills as well as soft skills and therefore train innovation and sustainability abilities this module combines two measures to verify a sustainable engineering education.

Application of Serious Games

General Remarks

Serious games are known for many years right now and their advantage is to offer the possibility to learn individually in a holistic context. These games can be used as tools for life-long-learning /Baalsrud Hauge et al. 2009/. The students just have to be enabled to carry out, to play the games. By playing they increase their competences by getting individual skills and knowledge /Piekkola 2004/. Depending on the content of the game

the students are lead towards innovative and sustainable solutions. It turned out that the students, especially the female engineering students liked the risk free environment for active experimentation. They enjoyed the individuality of solving the given tasks, the creativity. Playing enables the students to develop creatively problem solutions and to get a holistic view. At the same time the team competencies as defined by /Haug 1998/ are improved through simulation of various and changing conditions. This course of the games supports the network competencies as well and enables the students to realize a diversity management. Through serious games content and methodologies are trained, the results are students being able to work interdisciplinary and innovative.

Serious games belong to the media ecology of the 21st century doubtlessly and the support and improve unexpected learning processes (Klimt, 2008). Serious games do not have to be digital related educational tools; many non-digital easily applicable serious games exist as well which do not use any digital equipment.

Nevertheless, it is quite unusual to apply serious games within university lessons. When participating in the QMOD Conference 2009 in Verona the authors met a manager of the LEGO Company, who was a keynote speaker at the conference. And he invited all participants of the conference to get involved in a game. We enjoyed playing as everyone did and decided to apply this game in classes. The LEGO Company offered the necessary stuff and descriptions of the game.

Since 2009, we carry out this LEGO Racers Championship with our students in two engineering degree courses: mechanical engineering and safety and security engineering.

In general, the applied game aims at improving management skills just as the ability to take decision, to work in a team, to communicate, to install management structures, to show social responsibility, and methodological knowledge. Its application is within a module including management and creative methodologies.

Situation in class

Within the lectures one actual project is being worked out during the entire lecture of the whole semester like to build up a company to produce bicycles. The students are trained to work in groups, to present results, to work interdisciplinary and to think holistic; the lectures are mostly non-technical.

At the time we apply the game the students knew each other and they knew the lecturers for at least some weeks. Demands of lecturers as well as of students were discussed; the atmosphere is driven by confidence and trust.

When we start the LEGO game we did not discuss any pedagogical issues of the game, and usually the students did not ask for them. This leads to the following general conditions:

- The students did not get any information about the game at all before it starts.
- They may not use any additional equipment just the stuff offered by the lecturers.
- The students may communicate with each other (in between their group) during the whole game.
- They are split into groups of about 10 students playing at the same time at different places.
- The group members are chosen by the lecturers. Due to the fact that we knew the students, we knew about extroverted and introverted students, about their personality, we knew about the female students and about their behaviour in class, so, we always tried to arrange a balanced group. Balanced group for us meant to get one of the male peer students in each group as well as one of the female peer students e. g.
- After building the groups, the students got the instructions and the opportunity to ask and get explanations. But they did not get any information concerning pedagogical sense and aims of the game as already mentioned. Usually they do not ask for any pedagogical goal, just for the superficial game goal itself, how to win the game. We did not discuss the pedagogical aim in advance. The students were interested in playing the obviously offered game, and they do not care about any pedagogical background.

Description of Game

The following description is mainly given by an internet link by LEGO which does not actually work [/http://www.nff.dk/index.php?option=com_content&id=67/](http://www.nff.dk/index.php?option=com_content&id=67/); some variations for the students had been made to simplify the application. Here it is quoted the way it is used in class:

„LEGO Racers Championship

As you may know, the LEGO racing team is the best in the world, but in order for the team to stay that way, they will need your help. The reason why the team is number one is that they have the most stable cars in the world. However, before the next race they will need three new cars and that is where you come in. Because of your expertise, The LEGO racing team has hired you to select the three new cars.

The game is divided into two phases:

- a **preparation phase** and
- an actual **race phase**

Preparation phase: chose the cars and prepare for race

Race phase: you attempt to score as many points as possible

Duration is 20 Minutes, including both phases, for example if you spend 12 minutes on preparation, you have 8 minutes left for the actual race and vice versa.

Preparation Phase

- The **track:** you have to start at the launch area and to reach the bull's eye (scoring the most points)
- The **preparation phase rules:**
 - select *three cars*,
 - you may use the *given materials* –scissors, cardboard, boxes e.g.- to build whatever construction you might like to help the cars hit the bull's eye
 - you are only allowed to *build within the launch area*
 - you may *change the construction at all time* during this exercise
- The team leader: *I will choose the team leader* when I am done explaining the rules.
- Only the team leader can *start* scoring points process by clapping into his/her hands and saying '*Go!*'

The Race

- The **three cars** you have chosen must all be used in the race, and they **must take turns.**
- The amount of points you score depends on where the **front wheels** of the car stop. Both wheels have to be inside the same ring.

- You can **lose points**:
- If the car stops outside the bull's eye you will lose **1,000** points.
- You will lose **5,000** points if you touch a car in motion.
- You will lose **5,000** points if you damage a car.
- You have to administer your time! Total amount of 20 minutes!

Advice

- You can buy an advice from me at any time during the game.
- An advice in the preparation phase will cost you 500 points.
- An advice in the race phase will cost you 5,000 points.”

These instructions are offered to the students via a power point presentation.

Methodological Approaches and Empirical Performance

Field Work

Case studies including focus group discussions and participating observations are carried out at two universities, one settled in Germany and the other one located in Slovakia. The students belonged to engineering degree courses. 12 case studies were carried out.

The instructions as mentioned were offered to the students via power point. The students got the opportunity to question and after clarifying all questions the game started. This procedure was carried out in the same way during all case studies. All lecturers were female.

Due to our hypotheses that serious games enhance the ability of innovation and the ability to create sustainable solutions on the one hand and on the hand those interdisciplinary modules attract (female) engineers we decided about the parameters to investigate on.

Therefore, the observation of the students' behaviour was focused on /Hoeborn and Bredtmann 2011/

- *General attitude* towards the game: Are their gender and cultural differences? Taking personality differences into consideration.

- *Roles of students* (team structure) within the group: Does any gendered or cultured leadership behavior appear?
- *Solution of tasks and decision making process*: Do the students get the pedagogical sense of the game and therefore solve the tasks in an adequate way, and is this recognition driven by gender or culture? What about any decision making process within the game, is it gendered or cultured?

All observations were carried out by at least 2 observers (female lecturers), mostly by 3 or 4. All observations were recorded and after finishing the game the different observers evaluated their results. At the end of the game, the game was discussed with the students, and the results of the observations were offered to and discussed with them as well and as a final step the students were interviewed (as a focus group) about their experiences and feelings concerning the games. Additionally the students were interviewed about their attitude towards interdisciplinary offers and especially towards serious games as teaching and learning methodology and *to investigate on the supporting character of the interdisciplinary module and especially of the serious games to increase the number of female engineering students on the one hand and on the other hand to gather the influence of serious games on innovation and sustainability.*

Two female groups were carried out as control groups as well, even if the situation in class differs a bit for these case studies.

Observation and Description

All students focused on winning this game by getting as many points as possible. They did not reflect possible reasons for the lecturers' choice or think about the pedagogical aims of the game. The lecturers did not explain that the game can only be won by co-operation and team play. It was up to the students to recognize these demands for winning the games. There was always a competition with at least a second group.

- *General attitude* towards the game: Are their gender and cultural differences? Taking personality differences into consideration.

In general, the groups behaved very heterogeneously depending on their national backgrounds (German, Indian, Chinese, and Pakistani) or their gender. In other groups some of the female students seemed on edge, but mostly because they had to play with

their male classmates. Some students were very reserved at the beginning and some started with enthusiasm. The game always turned out as funny and valuable.

In Slovakia it turned out quite different due to extremely different pedagogical ways of teaching. The groups behaved totally reserved, they did not know at all how to react to the given task of playing, and they felt like doing an exam. The students really felt uncomfortable which was not intended. The lecturers explained the games several times taking small language skills of the students into consideration on the one hand and on the other hand –and this was weighted even higher- the students were not used to apply serious games or to carry out group work. When the game was carried out the first time it was a disaster which was not discussed due to students' feelings, the students did not solve the given tasks. After teaching some hours by using creative methodologies and creating an atmosphere of confidence the game was offered a second time. The students started to play and the game turned out as funny and valuable.

- *Roles of students* (team structure) within the group: Does any gendered or cultured leadership behavior appear?

The leadership behaviour being performed varied a lot. The lecturers determined the team leaders as already mentioned before. Performance clusters in between the groups:

Differences in accepting male or female leaders were performed. Groups partly accept the boy as leader even if they did not show any adequate team structure, but there was no competitive or discriminating atmosphere observable. But groups having a female leader- did not react to the leader and her instructions. The boys did it their way even if the leader intervened. In one case one of the male students disturbed any teamwork anytime and behaved as a self-appointed leader and the other team member react to him in the required way. The atmosphere in between the group was competitive and discriminating – intentionally forced by the self appointed leading male student. Concerning all groups the students did not discuss any role distribution.

In Slovakia the male leaders²⁰ distributed roles and all male students behaved as assumed for their roles, but the female students were very shy and introverted, and they took by their own choice and accepted a subordinated role to their male classmates. All male students showed a much bigger extroversion. The group members as well as the

²⁰ We chose male leaders because the male students were more extroversive, and we hoped for a bigger success of the game by their support.

leaders did not try to motivate all members to participate and to solve special tasks having just one exception when they needed the language skills of a female student.

Experienced student groups (master studies) performed co-operation and team work. The leader distributed roles and the students behaved as expected for their roles. But there were obvious differences concerning extroverted behaviour due to different national backgrounds and language skills. But the group members as well as the leader tried to motivate all members to participate more obviously.

Female control group: The students did not discuss any role distribution, but often women turned out to be self-appointed leaders. In general they performed like a team.

- *Solution of tasks and decision making process*

None of the students got the pedagogical sense of the game. They just thought of getting points in the race, the obvious goal.

In general, there exist two ways of performance: The leader's decisions were not transferred and the other students tried to smooth the situation by making additional suggestions to these of the self appointed male leaders or the leaders' decisions were transferred and the groups reacted like a team, they discussed decisions as well.

Even the Slovakian group transferred the leaders' decisions and the group react like a team by having female visitors or female observers (Female classmates who did not get involved). The female students did not demand their participation. The groups react the same way. They lived a male dominated competition for getting the most points. They did not buy any advice.

None of the students in the female control groups made any decision without consultation with the other students. They did not buy any advice.

It was quite astonishing that the students did not buy advices. They were not interested in the advices at all. None ever asked for the number of advices. Three Groups bought two advices (out of eight possible), but they did not continue the way of buying advices and getting support. Buying all advices leads to the solution of the tasks.

Purpose

The purpose is directly related to the two problems: to increase the number of (female) engineering students and to enable the students to create innovation and sustainability. By implementing serious games as a sustainable part of the curricula more (female) engineering students are attracted, and those students are enabled to create innovation and sustainable solutions. Therefore, the implementation of these games is sustainability and sustainable at the same time.

Results

After finishing the game the students were asked about their experiences and feelings concerning the game. Here are the students' comments:

- All students liked the game and really enjoyed playing it.
- And they underlined that they feel comfortable to play in a girl group and that it offers the possibility to generate creativity without being discriminated.(Female control group)
- The students noticed themselves as a team without any role assignment.
- They enjoyed their team work especially due to the fact that they did not know each other.
- They enjoyed it to play in a female group and they expected a more competitive atmosphere when playing with boys. The female students liked to feel free to develop a solution without getting male comments.(Female control group)
- Only 2 groups were aware of the aim of the game and the management tasks even though they did not know the game before. The group was very empathic and noticed the cultured differences of extroversion.
- When discussing most of the groups reflected their behaviour and noticed grievances. Then they recognized the aim of the game and evaluated that they failed. They were just competition driven without taking any soft skills into consideration even if it would support their competitive position.

This positive attitude of the students towards this serious game drives us to apply more serious games and we noticed a sustainable learning effect: All groups were aware thinking about methodologies to solve tasks, discussing creativity, to co-operate e.g.

The hypothesis that non technical lectures as interdisciplinary study offers attract more (female) engineering students was verified through interviews with the students.

We carried out 25 small qualitative interviews. During the interviews we asked the students about their likes or dislikes of the serious games which had been applied (not just about the LEGO Game). All students liked the games, but the female students (18) underlined that they would recommend this module to their classmates because of the application of serious games. Additionally we carried out 12 focus group discussions with our students being involved in the case studies.

The type of personality characterizes the behaviour of people and it likely overlaps gender and cultural influences, but nevertheless a gender and culture relevance of the behaviour towards serious games turned out very obviously:

- Female students behaved in a different way when being in a mixed group, up to getting into subordinated roles to their male classmates.
- Female students rarely perform leadership competencies in mixed groups.
- A cultural background leads to big differences towards using games up to denying them. A special preparation of the students in advance should be taken into consideration.
- Background of the game is the competition of the race which can only be won by co-operation and team play. In general the female students performed more towards co-operation by building teams and taking common decisions than the male students.
- Due to the fact that the game includes the two sides of a coin 'co-operation as well as competition' it offers the possibility to be aware of and to break gender barriers as well as any diversity barrier /Hoeborn and Bredtmann 2011/.

Research Limitations

At this time the number of case studies is limited, and the development of further steps to improve the serious games themselves as well as their implementation has to be improved.

There is still more research work to do to improve interdisciplinary modules in engineering degree courses on the one hand and on the other hand to improve serious games concerning their consideration of gender and culture differences.

Performance-based logistics

A literature review

Martin Holmbom. Ph.D. student. Luleå University of Technology. Quality
Technology
Luleå University of Technology, SE-971 87, Luleå, Sweden
martin.holmbom@ltu.se

Key words: Performance-based logistics, Performance contracting, Product service systems, Servitization

Category: Literature review

Introduction

Recently, many manufacturing firms have moved from selling only products towards selling the outcome of their products, i.e. the product performance. The transformation has mainly been made by suppliers of defense and aerospace equipment, providing large scale, capital-intensive products, known as ‘technical systems’ or, as further referred to in this article, exclusively ‘systems’. These manufacturing firms, hereafter called ‘suppliers’, became performance orientated relatively early and seem now to have the most developed approach for selling performance – often referred to as *performance-based logistics* (PBL) (Hypko et al., 2010).

In PBL, the supplier provides a combined offer of both the system and related support services, such as maintenance, repair and logistics. Moreover, instead of paying for the system, the customer pays according to achieved system performance, e.g. the availability of an aircraft. Consequently, the responsibility for the system performance is shifted from the customer to the supplier, forcing the supplier to concentrate on delivering results rather than delivering resources. An extreme form of PBL would be a case where the supplier keeps the ownership of the system during its entire lifecycle, using the system merely as a means to deliver the required performance, see figure 1. The expectation of PBL is that performance will be produced more efficiently, resulting in advantages for both the supplier and the customer.

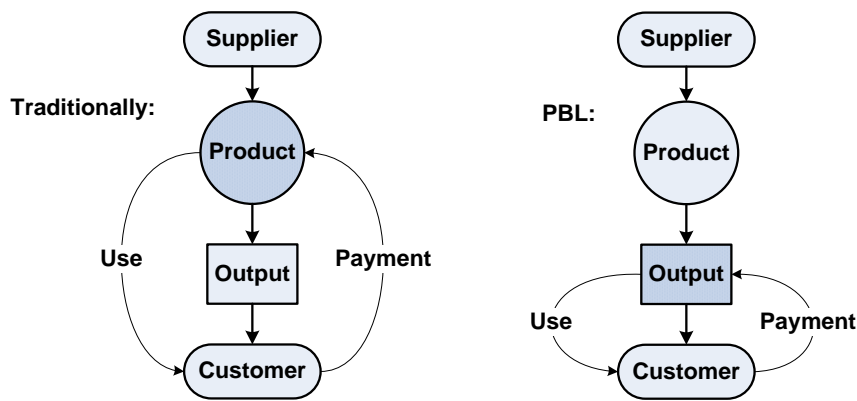

Figure 40: The difference between PBL and the traditional way of making businesses. Adapted from Pawar et al. (2009).

The notion of PBL originated in the United States military in 2001 (Devries, 2004, GAO, 2004, Berkowitz et al., 2005). To date, a limited number of articles on PBL have been published. The limited literature has not yet devoted enough attention to key PBL aspects such as how performance should be measured, what the risks are for the customer and the supplier, and if PBL is profitable?

However, the history of selling and contracting for performance goes back further in time than PBL. Research applicable to PBL can be found under different headings, such as ‘product-service systems’ (PSS) and ‘servitization’.

PSS is described as an integrated product and service offering that delivers value in use (Baines et al., 2007). Similar to PBL, the essence of PSS is selling and buying performance instead of products. PSS originated in industrial ecology as a result of the expectation that reduced consumption of materials could be obtained if the product ownership stayed with the supplier (Tukker, 2004, Baines et al., 2007, Spring and Araujo, 2009). Nonetheless, PSS is also discussed as a means to gain better product performance, and PBL is regarded as a variation of PSS with a large service component, implying that the supplier is relatively free to decide how to produce the performance (Tukker, 2004, Park and Lee, 2009, Neely, 2009, Kuo et al., 2010).

Servitization is the occurrence of adding a service to a product, i.e. moving from selling a product to selling a PSS. Commonly identified as the first article giving attention to servitization is Vandermerwe and Rada (1988), suggesting main motives for servitization and impacts on competitive dynamics. Even so, Schmenner (2009) propose

that the servitization has antecedents going back around 150 years, when some manufacturing companies started bundling goods with services to gain market power.

The interdependence between PBL, PSS and servitization is described in figure 2.

Figure 41: Servitization is the transformation of a product to a PSS by adding a service. Moreover, PBL is a variation of PSS.

In this study PBL is reviewed in the broader context of PSS and servitization, enabling knowledge to be drawn from related research areas. The purpose of this study is to describe how PBL is implemented, explore strengths and weaknesses, and point out areas for future research.

The article begins with a discussion of the methodology used for conducting the literature review. Thereafter the findings are presented, beginning with the benefits of trading performance, followed by considerations when implementing PBL, and the risks for the supplier and the customer. Finally, the conclusions are presented along with a discussion of the findings and suggestions for future research.

Methodology

This article is based on a review of literature concerning PBL, PSS, servitization and performance contracting. The reason for extending the literature review beyond PBL was that few PBL publications had been made, and many of them were conceptual publications containing little empirical evidence. The search was conducted in Web of Science and Scopus. These databases were selected since they usually cover technical and management journals as well as conference proceedings, which is where the research on servitization and related concepts primarily has been published. All articles mentioning “performance-based logistics”, “product-service systems”, “servitization” or “performance contract” in the title, abstract or keywords were initially selected.

A total of 434 articles were identified through the search. I reviewed the abstract of each article and classified the articles as “relevant” or “not relevant” for this study. A relevant article focused on servitization, PSS, PBL, or an aspect closely related, such as contracts in PSS or PBL. When all abstracts had been reviewed, 65 articles were classified as relevant. During the review of these articles, I found some of the references in the articles interesting. These articles were added to this study, which increased the list of articles to 78. All articles are presented in table 1.

Findings

The benefits of selling and buying performance

PBL is commonly regarded as a win-win strategy for the supplier and the customer compared to a more traditional way of buying and supporting capital intensive and complex systems, see e.g. Keating and Huff (2005), Beatum (2007), Sols et al. (2007), Dang et al. (2009) and Hypko et al. (2010). Traditionally, the customer buys a system and is thereafter responsible for all support services. Moreover, the original equipment manufacturer is usually the only actor able to provide support and spare parts to such systems (Keating and Huff, 2005, Nowicki et al., 2010), implying that the customer becomes dependent of the of the system supplier. Meanwhile, there is little motivation for the supplier to improve the reliability of the system, since much of the supplier’s profit comes from selling parts and support services (Sols et al., 2007). However, Nowicki et al. (2010) suggest that even though the traditional way of providing support services seems advantageous for the supplier there are small opportunities to make large profits.

Now follows a discussion on how PBL could address the shortcomings of the traditional model from a supplier, customer and value chain perspective.

The supplier perspective

In PBL, the supplier’s income depends on the performance of the system, e.g. the availability of an aircraft. Consequently, the supplier’s profit is increased if the system and the support processes are improved. Moreover, since the supplier is responsible both for manufacturing and support, the supplier is free to decide how to produce and improve the performance of the product. The supplier could thus e.g. improve the repair processes, logistics processes, and product reliability (Smith, 2004, Kim et al., 2007, Kumar et al., 2007). Such improvements generate profit as the performance increases,

but are also likely to improve the supplier's competitive position as the improvements may lead to enhanced technologies (Baines et al., 2009b, Hypko et al., 2010). Furthermore, PBL is carried out in close cooperation with the customer, which should enable a strong customer relationship and customer loyalty (Hypko et al., 2010). However, despite the possible advantages of PBL it should be recognized that the supplier could be forced to engage in PBL as a consequence of customer demands or fierce competition that increase the need for a differentiated product (Baines et al., 2009b).

The customer perspective

From the customer's perspective, PBL implies a change from working with support services to concentrating on core activities, such as e.g. maintaining a country's defensive ability or defending a country (Martin, 1997). Buying performance also implies that the customer's financial risks are reduced as the customer no longer is responsible for supporting the system (Dang et al., 2009). The customer acquires better system performance and more efficient support if the supplier manages to improve the system and the support services (Fino, 2006). Altogether, PBL strives for providing the customer with better performance to a fixed cost, or similarly, less cost to a fixed performance (Nowicki et al., 2010)

The value chain perspective

In the value chain perspective of PBL, the intention is to create customer value more efficiently. This is supposedly accomplished by: concentrating manufacturing and support services to one actor, opening up for the supplier to improve system performance, strengthening the supplier's motives for improvements, creating better opportunities to earn profit, and reducing the customer's cost (Howard, 2004, Sols et al., 2007, Nowicki et al., 2010, Baines et al., 2010). For PBL to be a win-win strategy in a financial sense, the customer and the supplier must share the gains of a more efficient value chain to increase the profit and reduce the total cost, as illustrated in figure 3.

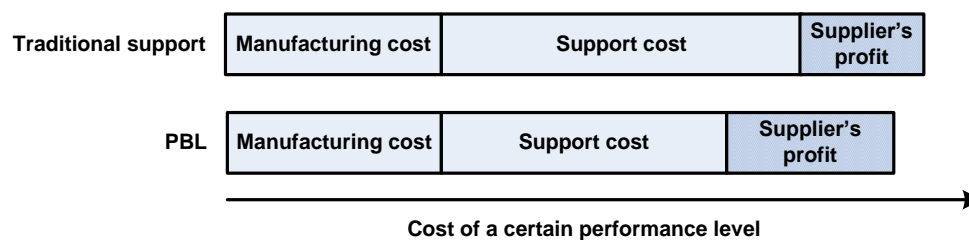

Figure 42: The intention of PBL is to reduce the customer's cost and increase the supplier's profit.

Implementing PBL

This section of the article presents the findings regarding the implementation of PBL. Four topics are discussed: commonly used contracts in PBL, the scope of PBL-contracts

and what PBL-contracts usually include, performance measurements and payment models.

PBL-contracts

PBL-agreements between suppliers and customers are settled in contracts. The literature emphasizes that each PBL-contract has to be highly tailored (Sols et al., 2007, Nowicki et al., 2010), which is perhaps why it seems hard to identify different contract types. In fact, authors do not even agree on how to separate PBL contracts from traditional contracts, see e.g. Kim et al. (2007) and (Nowicki et al., 2010). The same contract type is considered traditional by one author and as a PBL-contract by another. Nevertheless, two contract types are more frequently mentioned in PBL-literature than others: the *firm fixed price* and the *cost plus award fee* (Cunic, 2003, Kim et al., 2007, Sols et al., 2007, Nowicki et al., 2010).

In firm fixed price contracts the supplier agrees to maintain some level of performance (e.g. aircraft availability) based upon some level of use (e.g. the amount of flying hours per month). Moreover, the customer pays the supplier a fixed price according to the level of use, e.g. price per flying hour. An award fee can be added to the price to stimulate performance improvements (Kim et al., 2007, Nowicki et al., 2010). The price of a given service will thus increase if the supplier manages to deliver better performance than the contracted minimum level. The financial risks are concentrated to the suppliers whose incomes are dependent on their abilities of producing performance. The risks are especially high when the supported system is new and future system performance must be predicted with no historical data available (Smith, 2004, Kim et al., 2007, Erkoyuncu et al., 2011, Sols et al., 2008).

In a cost-plus award fee contract, the customer reimburses the supplier's costs for the performed services, adding an award fee to stimulate performance improvements or cost reductions. Here, the financial risks are concentrated to the customer who is forced to pay the supplier regardless of the performance outcome (Cunic, 2003, Sols et al., 2007, Nowicki et al., 2010). Cost-plus award fee contracts are often used in a transition phase when a non-PBL contract is being converted to a firm fixed price with award fee (Kim et al., 2007, Nowicki et al., 2010, Liu et al., 2009).

Scope of PBL-contracts

PBL-contracts can be implemented over complete systems, part of systems, i.e. subsystems and major components, or on certain support services, e.g. providing spare parts (GAO, 2004, Sols et al., 2008, Dang et al., 2009). Moreover, PBL can be applied to a system's whole lifecycle as well as a part of the lifecycle (Sols et al., 2007). A disadvantage of implementing PBL partially, i.e. not to a whole system, may be that opportunities to economies of scale might be lost (Nowicki et al., 2010). Furthermore, performance measurements can be complicated if the supplier only is responsible for the performance of a subsystem, (Fino, 2006).

As any contracts, PBL-contracts vary in length. However, it is commonly suggested that PBL-contracts ought to be long, (Maples et al., 2000, Keating and Huff, 2005) and some authors even suggest that PBL-contracts are long by definition (Berkowitz et al., 2005, Nowicki et al., 2010). There are two main benefits of long term contracting both of them regarding return on investments: First, setting up and implementing PBL is costly and there has to be enough time to harvest the benefits of a PBL-contract to insure that the benefits exceed the costs (Berkowitz et al., 2005) Second, a long contract enables the supplier to get return on large investments in the system that take long time to realize, but might improve system performance significantly. (Nowicki et al., 2010) Such improvements might be mitigating obsolescence and enhancing system reliability (Fino, 2006) that is especially important for systems with long product life cycles (Sols et al., 2007). For these reasons, it is argued that a PBL-contract should extend at least around five years (Sols et al., 2007, Nowicki et al., 2010).

Performance measurements

Performance is a central part of PBL as performance reflects customer value and forms the basis for the supplier's income. Consequently, measuring performance accurately is crucial (Devries, 2004, Sols et al., 2008, Hollick, 2009). The supplier and the customer must agree on: performance variables and metrics, definitions of the variables and metrics, target values and how to perform measurements and analyzes (Forslund, 2009).

The performance variables should be specific, straightforward, measurable and relevant to the customer's requirements (Fino, 2006, Dang et al., 2009). Selecting performance variables that reflect the customer value is challenging, since the customer's needs often are formulated in abstract terms (Tukker, 2004, Spring and Araujo, 2009). Commonly, several performance variables are used in a PBL-contract, for example: availability, reliability, maintainability, supportability, logistics response time, logistic footprint and cost of usage (Fino, 2006, Sols et al., 2007, Dang et al., 2009, Nowicki et al., 2010).

The variables can be used on different system levels and address different aspects. For example, reliability can address a component (component reliability), a system (system reliability) or the system's performance (mission reliability) (Dang et al., 2009). Furthermore, a performance variable must not be an objective variable but can also be subjective, e.g. customer satisfaction (Dang et al., 2009).

Availability of e.g. an aircraft is a highly aggregated performance variable, dependent on many less aggregated variables. It is difficult to track improvements or problems by only observing the aircraft availability. Performance variables at a lower level are therefore required (Fino, 2006, Sols et al., 2008, Hollick, 2009). Moreover, if the supplier is responsible for the availability of some components, the supplier can not be held responsible for the availability on an aggregated level, as the supplier is unable to control all factors affecting the availability (Hollick, 2009). However, it should be noted that achieving performance goals on a lower level does not guarantee good system performance (Hollick, 2009).

Defining performance variables and corresponding metrics can be challenging, e.g. if the definition must respect a certain equipment requirement. For example, if a military aircraft will be considered available or not might depend on what kind of missions it is available for. Such availability is commonly referred to as operational availability or operational readiness (Dang et al., 2009, Hollick, 2009). Agreeing a definition of a metric could also be complicated. For example, the mean time between failures (MTBF) is commonly used to measure reliability, but MTBF requires a definition of a failure and determination of how many failures that are required to get statistical significance (Richardson and Jacopino, 2006).

Performance target values must represent the customer's needs while at the same time constitute a realistic challenge for the supplier. A baseline constituting the "normal" performance of the system must thus be identified to set a target. If the system have been used, the baseline could be drawn from historical performance (Sols et al., 2008). However, identifying a baseline through historical values might be difficult e.g. if the way measurements have been conducted is not in line with the adopted definition of the metric, or if the system have been used differently in the past (Sols et al., 2008). For new systems the baseline must be built on predictions of future performance exclusively (Kim et al., 2007), which is even harder.

Payment models

When performance variables and metrics are set, a payment model must be established to translate achieved performance into payment for the supplier. A good payment model creates incentives for the supplier to produce high performance (Dang et al., 2009), whereas a poor model could impose unwanted supplier actions (Nowicki et al., 2008).

Payment models must often consider many performance variables and this makes them complex (Sols et al., 2007). A conflict appears when the system is over-performing with regard to one variable and under-performing with regard to another. Consequently, the payment model must be designed as a kind of balanced scorecard, with the function to translate several performance variables to a payment (Sols et al., 2008).

Nowicki et al. (2008) propose a payment model consisting of a minimum performance limit, a penalty zone, a dead zone and a reward zone, as showed in figure 4. The minimum performance limit determines the performance that the supplier must reach to receive any compensation. If the supplier delivers performance just above this limit, the supplier enters the penalty zone, receiving payment according to the achieved performance. However, in the penalty zone the payment is smaller than the cost of delivering the performance. If the performance is within the limits of the dead zone, which is around normal system performance (Sols et al., 2007), the payment is comparable to the cost for delivering the performance, i.e. the supplier earns marginal or no profit. If the system performance is above the dead zone, the supplier enters the reward zone and receives payment exceeding the production cost (Nowicki et al., 2008).

Figure 43: Payment model. The supplier's payment depends on system performance.

Also the frequency of measurements and performance review is discussed in the literature. Sols et al. (2007) suggest that performance should be assessed over relatively short periods, with relatively long periods over which the payments are calculated, to allow some of the small payments to be balanced by some of the large payments earned by the supplier.

Risks and uncertainties

The supplier's risks

PBL moves the responsibility for system performance from the customer to the supplier and the supplier is therefore confronted with higher financial risks as a consequence of bad system performance (Jacopino, 2007, Hypko et al., 2010). Moreover, the risk that delivering system performance will cost more than expected is also shifted from the customer to the supplier (Kim et al., 2007, Nowicki et al., 2010). In the bidding stage of a PBL-contract, the supplier's risk is depending on the supplier's ability to predict costs and performance (Tukker, 2004, Erkoyuncu et al., 2011). Such predictions are difficult to make because the complexity of the systems generates significant costs and performance uncertainties and PBL-contracts often are long term (Smith, 2004).

Furthermore, the supplier faces organizational risks, as going from providing products towards providing performance requires extensive organizational changes, investments in infrastructure and new skills (Baines et al., 2009b, Kuo et al., 2010). The supplier also faces new challenges in understanding customer value, managing close interaction with the customer and long term partnerships (Baines et al., 2009c, Martinez et al., 2010).

The customer's risks

The customer's risks when moving to PBL are also increased in some aspects. One risk is that the supplier will deliver bad performance (Hypko et al., 2010) and the customer is locked to the supplier for the duration of the contract (Nowicki et al., 2010), while being unable to enhance the system performance (Jacopino, 2007). Moreover, if the supplier breaks the contract, the customer will have difficulties to introduce a new supplier to support the system, since the customer could have little access of the technical data of the system (Kim et al., 2007, Dang et al., 2009).

Risks in military PBL-contracts

Applying PBL to military systems introduce operational risks for the civilian supplier which might be forced to support the system in war at unsafe locations (Doerr et al., 2004). Apart from the challenging task of the delivering performance in war, the supplier also risks losing the employees' lives (Gansler and Lucyshyn, 2006). From the customer's perspective, having the supplier responsible for the support services might limit the oversight of military operations (Tegtmeier, 2010).

Conclusions and discussions

The purpose of the literature review has been to describe how PBL is implemented, explore the strengths and weaknesses of PBL and identify future research challenges. PBL is a business concept mainly applied to complex and capital-intensive technical systems in military and aerospace industries. In PBL, the supplier of a system delivers not only the system, but is also responsible for the performance of the system. Consequently, PBL transfers the responsibility for providing support services from the customer to the supplier. The intention of PBL is to enhance the efficiency of the value chain, i.e. reducing the total costs for delivering a certain performance level. The cost reduction aims to increase the supplier's profit while reducing the customer's costs for the system, and thus creating a win-win situation for the supplier and the customer. However, the transfer of responsibilities is not without risk, requiring the customer and supplier to put efforts on designing contracts, conducting performance measurements and structure conditions for payments. Moreover, PBL introduces financial risks for the supplier that require long term predictions of future costs and performance.

An unanswered question is whether the costs for mitigating the risks in PBL and rearrange organizations, equipments and mindsets from a traditional support structure are lower than the cost reductions that PBL might result in. Certainly, there are numerous of reports of successful implementations that have resulted in reduced costs, see for example Phillips (2005), Keating and Huff (2005), Gansler and Lucyshyn (2006), Mahon (2007) and Ott (2008), but these reports do not account for how measurements have been conducted and thus give little empirical evidence of the profitability of PBL. However, there are some profound studies regarding profitability. In two extensive investigations of PBL-contracts in the U.S military, the U.S. Government Accountability Office (GAO) concludes that some PBL-contracts seem to reduce the customer's total costs for the system, while other PBL-contracts seem to increase the costs, see (GAO, 2005) and (GAO, 2008). Moreover, investigating

financial data for more than 10 000 companies, Neely (2009) concludes that large manufacturing firms generates less net profit if they move towards providing PSS, while the opposite holds for small manufacturing firms. These three studies provide some results in the profitability of PSS, but more empirical research is needed for other or specific contexts.

In the bidding stage of a PBL-contract the supplier's risk is depending on the supplier's ability to predict costs and performance. Moreover, as PBL transfers the responsibility for the performance of the system to the supplier, the supplier must assure the performance of the supported system. Even so, the literature gives little advice to how the supplier should make predictions as well as enhance the system's performance. Block (2009) give some suggestions, addressing an aircraft supplier's need for a simulation tool to predict the availability of an aircraft fleet. However, there is a need for more research into the specific challenges of predicting performance and enhancing system's performance that suppliers' must be able to handle under PBL-contracts.
