

A MULTI-PHYSICS MODELLING TOOL FOR REVERSE ELECTRODIALYSIS

L. Gurreri, F. Santoro, A. Cipollina^{*}, A. Tamburini, M. Ciofalo, G. Micale Dipartimento di Ingegneria Chimica, Gestionale, Informatica, Meccanica, Università degli Studi di Palermo

Introduction

electrodialysis (RED) Reverse generates electric power by direct conversion of the chemical potential difference of two saline solutions (salinity gradient power). A RED stack is fed by the two solutions in alternated channels, separated by anion and cation exchange membranes. An electric potential difference, due to the chemical potential difference, is established over each membrane, along with an "oriented" flux of cations and anions from each concentrate channel towards the two adjoining dilute ones. Ionic flux is converted into electric current by means of reversible redox reactions at the electrodic compartments (Figure 1).

Various factors, identifying the stack configuration, affect in a complex way a number of phenomena that interact at various scales and affect the power output and the energy efficiency.

Model calibration and validation

Experimental data measurement: • Lab stack 10x10 cm² • Fujifilm membranes • Pure NaCl solutions

Assumptions and constant parameters

- Pure NaCl solutions
- Linear velocity = 1 cm/s
- Temperature = 20 °C
- Concentrate concentration = 4 M

- Ions diffusion coefficient, D_i
- lons mass mobility, u_{m,l} (... by a β factor)

Theoretical	heoretical driving force Ohmic resistances		resistances	Non-Ohmic resistances		Pumping power		

Aim of the work Developing a multi-physics modelling tool for the Reverse ElectroDialysis process, being able to describe the main phenomena involved and evaluate the process performance.

Modelling

Computational domain

The model was developed in COMSOL Multiphysics[®].

A single 2D cell pair is simulated as periodic unit of the stack (Figure 2). The discretisation was done by multi-block quadrilateral grids with finer discretisation near the walls. A preliminary grid dependence analysis was performed and a 12,200 nodes-per-cell grid was adopted in the end, corresponding to 37 and 24 divisions for channels and membranes thickness, respectively.

- $C_{fix.aem} = 1.28 \text{ meq/g}_{dry}; C_{fix.cem} = 1.45 \text{ meq/g}_{dry}$
- Number of cell pairs = 10
- Blank resistance = 0.94 Ω

Results and discussion

Phenomenological description of the RED process

The governing phenomena were accurately predicted, as confirmed by the fields of the main computed quantities. Some examples (computed with the single-cell approach) are reported here, related to the case of a 10-cells empty-channels stack, fed with 4M–0.5M NaCl solutions.

Computed Na+ and Cl- total fluxes in O.C. conditions

Figure 2. Schematics of a cell pair domain, equations at the interfaces & boundary conditions.

<u>E</u>	quations system
Mass balance	$\vec{\nabla} \cdot \vec{N}_i = 0$
Current balance	$\vec{\nabla} \cdot \vec{j} = 0$
Electroneutrality	$\sum_i z_i C_i = 0$
Mass flux (Nerst-Planck eq.)	$\vec{N}_i = -\mathcal{D}_i \vec{\nabla} C_i - z_i u_{m,i} F C_i \vec{\nabla} \varphi + \vec{v} C_i$
Electric current	$\vec{j} = F \sum_{i} z_{i} (-\mathcal{D}_{i} \vec{\nabla} C_{i} - z_{i} u_{m,i} F C_{i} \vec{\nabla} \varphi)$
Continuity*	$ ho ec abla \cdot ec u = 0$
Momentum*	$\rho \left(\vec{v} \cdot \vec{\nabla} \right) \vec{v} = \vec{\nabla} \cdot \left[-p + \mu (\vec{\nabla} \vec{v} + (\vec{\nabla} \vec{v})^T) \right]$
* solved in the fluid domains only	

The system is completed by the algebraic equations for the cell pair potential, the average current density module, the stack potential and the power density (Figure 3):

Cell pair potential	$E_{cp} = \varphi_1 - \varphi_0$	with $\varphi_0 \neq f(y) \neq \varphi_1$
Avg. current density	$\bar{J}_{cell} = (NE_{cp})/[A(R_{blank} + R$	<i>ext</i>)]
Stack potential	$E_{stack} = NE_{cp} - A\bar{J}_{cell}R_{blank}$	
Power density	$P_d = E_{stack} \bar{J}_{cell} / N$	

Boundary conditions

The boundary conditions are reported in Figure 2. Periodic conditions for concentrations and fluxes were imposed at the terminal boundaries, while continuity of mass fluxes and electric current was imposed at each solution-membrane interface. Finally, the average computed current density was imposed at the terminal boundaries, assuming constant potential along them (this is supported by many other multi-cells simulations).

Computed Na+ fluxes (diffusive, migrative,

convective and total) in O.C. conditions

Computed potential profiles in condition of open circuit, maximum Pd and shortcut (blank resistance neglected).

Computed Na+ fluxes (diffusive, migrative, convective and total) in condition of maximum power density.

Computed Na+ and CI- total fluxes in condition of maximum power density.

Effect of spacers and dilute concentration

RED stacks equipped either with standard non-conductive spacers or with profiled membranes are compared. In this part of the study, the channel length was reduced to 1.2 mm and the number of grid nodes increased to about 30,000 per cell. This allowed to efficiently compare the four scenarios.

Donnan potential generation

The voltage generation at the membrane-solution interfaces was calculated by the Donnan exclusion theory (assuming unitary activity coefficients):

$$\varphi_{Don} = \varphi_m - \varphi_s \cong \frac{RT}{z_i F} \ln \frac{C_i^s}{C_i^m}$$

Interface sorption equilibrium

Partition coefficients were adopted to relate the membrane-side co-ions concentration to the solution-side one:

Figure 3. Equivalent electric circuit.

Profiled conductive membranes (C_{dil} =0.5M).

Profiled conductive membranes (C_{dil} =0.1M).

Profiled conductive membranes (C_{dil} =0.01M).

Current density by-passes pins when leaving a concentrate channel... it converges towards pins when leaving a very dilute one.

Conclusions and future remarks

A multi-physics model for the RED process was developed as a powerful tool for the thorough characterisation of the complex process phenomenology and for the prediction of the stack performance. The behaviour of different spacers and profiled membranes was analysed and compared, highlighting advantages and limitations of each case.

<u>Future developments</u>: (i) 3D simulations for accurate predictions with complex spacers/channels geometry; (ii) structural mechanics analysis to simulate membranes bending and channel geometry deformation; (iii) implementation of an all-embracing model for the process design and optimisation.
